Mr. Sanderson, in reply, said he could not give any information about the alleged elephant worship in Siam, for he knew nothing about it. As to the use of pitfalls, he had intended to make it clear that the Government had prohibited them all over India, and though they were still in use in some of the native territories, yet even from these they had had inquiries as to the more advantageous method of catching elephants, and some of these native States had expressed their desire to abolish this barbarous system. With regard to the length of tusks, he had himself seen a pair from the Garrow hills, in Assam, obtained in 1879, which measured 8 ft. 9 in. in length, and he had no doubt they were still in the possession of Lord Lytton, who was then Governor-General. They weighed 168 lbs. Sir Victor Brooke, in the Mysore, shot an elephant, one of whose tusks was eight feet in length, and weighed 90 lbs. As to discouraging the slaughter of African elephants, he feared that nothing short of giving up the use of ivory would bring it about; for as long as the native traders could sell the ivory they would destroy the elephants. With regard to the sacrifice of human life in elephant hunting, everything was done to prevent it; but it must be remembered that risk of life was unavoidable in fishing, and indeed in almost all industrial pursuits. Unless the elephant was left alone altogether, there must be some danger, but every possible precaution was taken to prevent loss of life. With regard to elephant catching in Africa, Sir Joseph Fayrer communicated with him on the subject some four or five years ago, and submitted a plan to him. He then suggested that it would be well to send a few Indian elephants over first, to see if they would stand the tsetze fly, because some Indian buffaloes which Dr. Livingstone took there were killed within about ten days' march from the coast. Subsequently four elephants were shipped from Bombay, and landed at Zanzibar; they were under the care of Mr. Carter and another gentleman; but unfortunately, after a few days, they quarrelled with the Indian attendants, who left, and he did not know how they got on. There were accounts sent that they were not at all affected by the fly, and did very well for some weeks or months; then one or two of them died, and subsequently the expedition was cut up. Mr. Carter and the other gentlemen were killed, and what became of the elephants he did not know. As regards riding African elephants, he had three about 7 ft. high in the Dacca establishment for two years, with the object of testing them by the side of the Indian elephants, and they were found to be docile, but more stubborn. He had heard the same character of them from the keepers of menageries in England. The men sat upon their shoulders, and put their feet behind the ears; if necessary, a pad could be arranged to be kept behind the elephant's ears, to take off the pressure on the rider's legs. It would be a very good thing if the African elephant could be subjugated, because one would carry as much load as thirty or forty porters, and half the difficulty of African exploration arose from having to take so many, the greater part of whom were carrying goods to be given to themselves and their fellows as wages. Three elephants would be sufficient for any expedition, and this would, no doubt, be the best means of opening up Central Africa. Unless, however, it was decided to settle in the country for some years, he did not see how elephant catching was to be established; the negroes were perfect savages, who regarded an elephant simply as so much meat; and so long as the African slave hunters had more profitable employment in their own line, they would not take to elephant catching. It would, therefore, require a permanent establishment. He had made many experiments on the quantity of food an elephant would consume, having kept as many as ten for a month on a stone platform, where everything they had was carefully weighed. They would eat from 650 to 800 lbs. of green fodder in eighteen hours, and the rest of the time they had been out in the jungle getting it, during which time they got a picking also. With regard to their age, the sign of the ear was much relied on by the natives, but it was not always satisfactory, and required to be taken in conjunction with other things. As to the deciduous teeth, no doubt Sir Joseph Fayrer was perfectly accurate, and he was satisfied that they did not shed their tusks. He believed Mr. Corse originated the idea; whether any elephant ever did so he was not prepared to say, but to test the fact, he had, in a large number of instances, had a file mark put upon the tusk the moment it came through, but although he watched them carefully, and had never known a tusk drop, nor was the idea entertained by anyone in India who was connected with elephants. Mr. Tegetmeier, however, and other naturalists, judging from the skull, asserted that he was wrong, and that elephants had milk teeth. This was no doubt correct, but they were absorbed in the gum.

Miscellaneous.

THE FRENCH VINTAGE OF 1883.

The total production of wine in France, which in 1879 only amounted to 25,000,000 hectolitres (or about 550,000,000 gallons), rose in 1880 to 29,000,000, and in 1881 to 34,000,000, while it fell in 1882 to 30,000,000. Last year, however, it amounted to 36,000,000, an excess of 5,142,830 hectolitres over the previous year, and only 9,023,879 hectolitres less than the average of the last ten years. The *Journal de la Société de Statisque de Paris*, for March, says that the year 1883 was the most prosperous as regards results obtained, that has been experienced in France since the phylloxera commenced its work of destruction. Although the results of the wine harvest cannot be regarded as anything but most satisfactory, yet the favourable and healthy appearance of the vines at the commencement of the season gave a prospect of even a much more abundant yield than was actually obtained. In certain of the eastern districts, notably in the departments of the Doubs, Haute Savoire, and Jura, though the heavy rains and frost, to a great extent, injured the crops, yet the extreme mildness of the early spring was eminently favourable to the development of the vine. In other departments, such as the Dordognes, Landes, Isère, &c., sharp attacks of hail seriously injured the vines and prevented the grapes from ripening. In the departments of Aveyron, Gers, and the Haute-Loire, the extreme heat and absence of rain which was experienced during the months of August and September, burnt up the grapes, and materially affected the quantity if not the quality of the production. The departments which have suffered most from the ravages of the phylloxera are the Aude, the Bouches-du-Rhône, Cher, Pyrenees-Orientales, Rhône, Deux-Sevres, and Herault. It has again made its appearance in the Indre et Loire and the Loiret, and in addition another disease to which the vine is subject has made its appearance in the Gard, the Basses-Pyrénées, Vaucluse, and the arrondissement of Aix; this is the mildew. On the other hand, many vine-growers in several of the districts of the Midi have been most successful in their efforts to reconstitute their vines, the departments where this is particularly noticeable being the Ardèche part of Ariège, the Bouches-du-Rhône, the Herault, the Lozere, the Loire, Drôme, Vienne, Var, and the Gironde. In all these departments the young American plants are to be found flourishing. Taking the whole of the departments, it will be found that in spite of the many adverse atmospheric and other influences to which the vines have been subjected, fifty-nine show an increased yield last year as compared with 1882, and in twenty-nine, the production in 1883 has considerably exceeded the average of the last ten years.

As in previous years, it has been found necessary to have recourse largely to importations to meet the demands of consumers, and the country from which the supplies have been chiefly drawn is Spain, whose exports of wine to France during the first eleven months of last year exceeded 5,501,000 hectolitres, or 121,022,000 gallons. There is another source from which supplies are now largely drawn in France, and to which considerable attention has of late been directed; this is the vine of Algeria. Though a very recent introduction into this colony, and only within the last few years, the vine has proved eminently successful, and has shown increased production each year. Great things are expected from this vine culture in Algeria, and it is confidently anticipated that it will be very largely developed, and become a source of considerable revenue to the mother country. In 1876 there were only 16,700 hectares under vines in Algeria, with an estimated production of 221,000 hectolitres; in 1882 the extent of land under vine cultivation had increased to 37,000 hectares, and the production to 947,153 hectolitres. Many of the vineyard proprietors reside in France, where the Algerian wine is sent to be sold.

THE VICTOR EMANUEL LIBRARY OF ROME.

Her Majesty's Secretary of Legation, at Rome, says the Victor Emanuel Library is one of the richest in Italy, and has been taken over by the Government from the Jesuits, together with a large building known as the Collegio Romano, which contains a celebrated museum of archæological and other treasures, as well as one of the best observatories in the kingdom. The Collegio Romano is four stories high, and cover an area of 13,400 square metres, including 3,772 occupied by the church of St. Ignatius, and a garden of 2,000 square metres. On the ground-floor are the Lyceum Government School, the new Philological Institute, the Scholastic Museum, a portion of the library, and a space for the National Geographical Society. The first and second floors contain the bulk of the ancient library, which has been entirely re-arranged and largely added to under the new administration. The Jesuits formerly divided the collection into the "secret or major library," used only by the priests, and the "minor library," for the use of teachers. The former division contained over 65,000 volumes, and many precious manuscripts, including those of Cardinal Pallavicino, Largomarsini, and others, some of which appear to be now missing. A new hall has been built, capable of containing 2,400 volumes, and suitable arrangements have been made connecting the various departments of the library. The reading-room recently added is capable of holding 200 persons. To the Collegio Romano is now united the celebrated Casanatense, the richest ancient public library in Rome. With this addition the Victor Emanuel Institution has space for a million works. The books collected from forty-eight monasteries, together with those already in the Collegio Romano, amounted to 360,000 volumes. There were 120,000 in the Casanatense. In 1876, the date of its inauguration, about 200,000 scientific works had already been arranged on the shelves of the library, and about the same number of theological books remained to be set in order. In appealing to the Italian Government for the requisite funds to support and develop the institution, it was mentioned that the British Government expends on the British Museum alone an annual sum of £50,000—more than double the amount laid out by Italy on all her libraries, museums, art acquisitions, ancient monuments and excavations put together; while in one year alone, 1872, England spent £34,800 for the purchase of books—more than six times the sum devoted by Italy to the same purpose. The organisation of the new institution is of undoubted value in the preservation of literary works from the gradual destruction which menaced them. Three new collections have been added to the old Kircherian Museum; these are the Prehistoric, Ante-Roman, and the Lapidary Museums. To complete the circle of intellectual bodies comprised under the roof of the Collegio Romano, each institution has its own school and meeting-room. On the 25th November, 1882, a report was issued, showing the progress made since the opening of the library, from which it appears that the assiduous labour of several years will yet be necessary before the desired arrangement can be fully completed. Meanwhile a reading-room has been given to the public, with a supply of 369 magazines and periodicals. During the first ten months of the year this room and the remainder of the library was frequented by 14,770 readers, and it is recorded that not a single book or paper had been found missing throughout the whole year, nor has the least damage been caused to the property of the institution. The main resources of the establishment have been devoted to supplying the want of modern standard works, of which there was found to be the greatest deficiency. Among those purchased may be mentioned the collection of Didot, Hachette, Brockhaus, and the works of Goethe, Voltaire, Darwin, Shakspeare, Milton, Humboldt, Kepler, Laplace, and many other of the most eminent writers of England, France, and Germany. For nearly a whole century the monks appear to have added little or nothing to their collection, and this is quoted as a reason to justify the Government in taking possession of their neglected property. The whole number of periodicals now possessed by the library amounts to 1,127. From November, 1881, to November, 1882, there were purchased 4,594 scientific works (in about 15,000 volumes), while the Government officials sent in 16,186 pamphlets, or other documents; 910 books were deposited for purposes of copyright, and 2,229 works of different kinds were presented as gifts to the institution. Great labour has been expended on the compilation of a new catalogue, which is bound in boards of an ingenious model, invented for the purpose, locked and opened by a special key, and so formed as to afford immediate detection of the removal of any portion of its contents. At present, this catalogue is only arranged alphabetically, but it will, in time, be supplemented with another, arranged according to the classification of the works. Telephonic communication has been laid between the library and the central telephone office, for the convenience of the Ministries and the Houses of Parliament, and several excellent internal arrangements have been made for the accommodation of the public. The library is opened on every working day, from 9 a.m. until 3 p.m., and also, from the 5th November to the 31st May, from 7 to 10 o'clock in the evening. Persons under 18 years of age are not admitted to the reading-rooms.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, eight o'clock :—

March 26.—"Vital Steps in Sanitary Progress." By B. W. Richardson, M.D., F.R.S. Sir Robert Rawlinson, C.B., will preside.

April 2.—"The Dwellings of the Poor of Great Cities." By Elijah Hoole.

After Easter.

May 14.—"Telpherage." By Professor Fleeming Jenkin, F.R.S.

Foreign and Colonial Section.

Tuesday evenings :—

April 1.—"The Rivers Congo and Niger

entrances to Mid-Africa." By ROBERT CAPPER, Major-General Sir FREDERICK JOHN GOLDSMID, K.C.S.I., C.B., will preside.

APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings :—

APRIL 24.—"Economic Applications of Sea-weed." By EDWARD C. STANFORD, F.C.S.

MAY 8.—"Cupro-Ammonium Solution and its Use in Waterproofing Paper and Vegetable Tissues." By C. R. ALDER WRIGHT, F.R.S., D.Sc. Prof. W. J. RUSSELL, Ph.D., F.R S., will preside.

⁂ The date of this meeting has been changed from March 27.

INDIAN SECTION.

Friday evenings :—

MARCH 28.—"Trade Routes in Afghanistan." By GRIFFIN W. VYSE. LORD ABERDARE, F.R.S., will preside.

APRIL 25.—"The Existing Law of Landlord and Tenant in India." By W. G. PEDDER.

CANTOR LECTURES.

The Fourth Course will be on "The Alloys used for Coinage." By Prof. W. CHANDLER ROBERTS, F.R.S., Chemist of the Royal Mint.

LECTURE II. March 24.—Gradual Development of the Processes of Coining. The Composition and "Standards of Fineness" of the Alloys used for Coinage in Ancient and Modern Times.

LECTURE III. March 31.—Methods by which Accuracy of Weight and "Fineness" of the Alloys is ensured.

LECTURE IV. April 7.—Questions connected with the liability to Reduction in Weight and various Coins by Wear during Circulation.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 24...SOCIETY OF ARTS, John-street, Aldelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. W. Chandler Roberts, "The Alloys Used for Coinage." (Lecture II.)
Surveyors, 12, Great George street, S.W., 8 p.m. Mr. W. Fowler, "The Ancient Terms applicable to the Measurement of Land."
Geographical, University of London, Burlington-gardens, W., 8½ p.m. Lieut.-Colonel Sir Charles W. Wilson, "Notes on the Physical and Historical Geography of Asia Minor, made during Journeys from 1879 to 1882."
British Architects, 9, Conduit-street, W., 8 p.m.
Institute of Agriculture, Lecture Theatre, South Kensington Museum, S.W., 8 p.m. Mr. W. Topley, "The Physical Structure of England, and its Influence on Agricultural Practice."
Medical, 11, Chandos-street, W., 8½ p.m.

TUESDAY, MARCH 25...Royal Institution, Albemarle-street, W., 3 p.m. Prof. A. Gamgee, "Animal Heat, its Origin, Distribution, and Regulation." (Lecture IV.)
Medical and Chirurgical, 53, Berners-street, Oxford-street, W., 8½ p.m.
Civil Engineers, 25, Great George-street, Westminster, S.W., 8 p.m. Discussion on Mr. James A. Longridge's Paper, "Wire-gun Construction."
Anthropological, 4, St. Martin's-place, W.C., 8 p.m. 1. The Earl of Wharncliffe, "Exhibition of a Flint Implement from the North Riding of Yorkshire." 2. Mr. F. G. Hilton Price, "Note on some Ancient Egyptian Bronze Implements." 3. Mr. J. G. Garson, "The Frankfurt Craniometrical Code."

WEDNESDAY, MARCH 26...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Dr. B. W. Richardson, "Vital Steps in Sanitary Progress."
Hospitals Association, 11, Chandos-street, Cavendish-square, W., 8 p.m. Mr. William J. Nixon, "Difficulties associated with the administration of the Out-Patient Department, and how best to deal with them."
Royal Botanic, Gardens, Regent's-park, N.W. Exhibition of Spring Flowers.
Royal Society of Literature, 4, St. Martin's-place, W.C., 8 p.m.
College of Physicians, Pall-mall East, S.W., 5 p.m. (Croonian Lectures.) Dr. H. Jackson, "Evolution and Dissolution of the Nervous System." (Lecture III.)
Civil and Mechanical Engineers, 7, Westminster-chambers, S.W., 7 p.m. Mr. Thomas Cole, "Steam Tramways."

THURSDAY, MARCH 27...Royal, Burlington-house, W., 4½ p.m.
Antiquaries, Burlington-house, W., 8½ p.m.
Society for the Encouragement of Fine Arts, 9, Conduit-street, W., 8 p.m. Mr. J. Forbes Robertson, "Some Remarks on International Exhibitions, with Special Reference to the Recent Exhibition at Munich."
Parkes Museum of Hygiene, 74A, Margaret-street, Regent-street, W., 8 p.m. Mr. W. Watson Cheyne, "Practical Demonstration of Bacteria, particularly of the Organisms Occurring in Disease."
Royal Institution, Albemarle-street, W., 3 p.m. Prof. Tyndall, "The Older Electricity, its Phenomena and Investigators." (Lecture V.)
Telegraph-Engineers and Electricians, 25, Great George-street, S.W., 8 p.m. 1. Professor George Forbes, "The Proportion which ought to subsist between the Size of Conductors and the Strength of Currents." 2. Mr. Thomas H. Blakesley, "The Relation which should subsist between a Current of Electricity and the Conductors employed to convey it."

FRIDAY, MARCH 28...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Indian Section.) Mr. Griffin W. Vyse, "Trade Routes in Afghanistan."
United Service Inst., Whitehall-yard, 3 p.m.
Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m. Prof. Osborne Reynolds, "The Two Manners of Motion of Water."
College of Physicians, Pall-mall East, S.W., 5 p.m. (Lumleian Lectures.) Dr. James Andrew, "Ætiology of Phthisis." (Lecture I.)
Quekett Microscopical Club, University College, W.C., 8 p.m.
Clinical, 53, Berners-street, W., 8½ p.m.
Browning, University College, W.C., 8 p.m. Paper by the Rev. Mark Pattison.

SATURDAY, MARCH 29...Geologists' Association, 2½ p.m. Visit to the British Museum under the Direction of Professor Rupert Jones.
Royal Institution, Albemarle-street, W., 3 p.m. Captain Abney, "Photographic Action considered as the Work of Radiation." (Lecture V.)

Journal of the Society of Arts.

No. 1,636. Vol. XXXII.

FRIDAY, MARCH 28, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CONFERENCE ON WATER SUPPLY.

In accordance with an invitation from the Executive Council of the International Health Exhibition, the Council of the Society of Arts have undertaken to organise a Conference on Water Supply, to be held at the Exhibition on some date to be hereafter announced. H.R.H. the Prince of Wales, President of the Society, has graciously intimated his intention to preside on this occasion.

INTERNATIONAL HEALTH EXHIBITION SEASON TICKETS.

The Executive Council of the International Health Exhibition have consented to allow Members of the Society of Arts the privilege of purchasing Season Tickets for the Exhibition at half-price. Each Member will only be allowed the privilege of purchasing a single ticket on these terms, which will be a personal admission, not transferable. Season tickets admit to the opening ceremony on the 8th May. As soon as the tickets are ready, due notice will be given in the *Journal*.

SIEMENS PRIZE.

Lady Siemens has placed at the disposal of the Council a sum of £20, to provide a prize, to be called the Siemens Prize, to be offered for the best application of gas to heating and cooking in dwellings (Class 24 in the International Health Exhibition). The prize will consist of a Gold Medal or £20, and will be awarded under the same conditions as the prizes announced in the *Journal* of the 14th inst.

CANTOR LECTURES.

The second of the course of lectures on the "Alloys used for Coinage," was delivered on Monday evening, the 24th inst., by Professor Chandler Roberts, F.R.S.

It was shown that the word "alloy" is inaccurately used in Mint language, as it is applied to the base metal added to a more precious one, and not, as it should be, to the mass of the mixed metals. Biringuccio, speaking of the gold alloys, had used the word with perfect accuracy in 1540. "I have told you," he said, "that an alloy only signifies an intimate association of one metal with another," and that is what a chemist understands by an alloy at the present day. The history of the more important alloys actually used for coinage in different countries, was then traced and illustrated by references to the results of assays made on ancient coins, several of the results being published for the first time.

It was pointed out that, within certain limits, the selection of a "standard fineness" for the alloy to be used for coinage was not a matter of much importance, as there were many alloys of precious and base metals of which very convenient coins might be struck, while, at the same time, they possessed excellent physical properties, probably the most important being the power of resisting loss of metal by wear.

INTERNATIONAL HEALTH EXHIBITION HAND-BOOKS.

The Executive Council of the International Health Exhibition propose to issue a series of hand-books, dealing with the various subjects included in the Exhibition programme. They propose, at the conclusion of the Exhibition, to present the copyright of these books to the Society of Arts, and the Council of the Society have readily undertaken to continue their publication after the Exhibition has closed.

The following is the list of hand-books for which arrangements have already been made. Others are in contemplation:—

Food. Mr. A. W. Blyth, M.R.C.S.
Principles of Cookery. Mr. Septimus Berdmore.

Food and Cookery for Infants and Invalids. Miss Wood, with preface by R. B. Cheadle.
Drinks, Alcoholic. John L. W. Thudichum, F.R.C.P., M.D.
Drinks, Non-Alcoholic, Aerated. John Attfield, Ph.D.
Fruits of all Countries. Illustrated. Mr. W. T. Thiselton Dyer, M.A., C.M.G.
Condiments, including Salt. Rev. J. J. Manley, M.A.
Dress in Relation to Health and Climate. Illustrated. Mr. E. W. Godwin, F.S.A.
Athletics. Part I. Illustrated. Rev. E. Warre, M.A.
Athletics. Part II. Illustrated. Hon. E. Lyttleton, M.A., and Mr. Gerard F. Cobb, M.A.
Manual of Heating, Lighting, and Ventilation. Illustrated. Captain Douglas Galton, C.B., F.R.S.
Healthy Town Houses and Country Houses. Parts I. and II. Illustrated. Mr. W. Eassie, C.E., and Mr. Rogers Field, C.E.
Healthy Villages. Illustrated. H. W. Acland, C.B., M.D., F.R.S.
Healthy Bedrooms and Nurseries, including the Lying-in-Room. Mrs. Gladstone.
Healthy Furniture and Decoration. Illustrated. Mr. R. W. Edis, F.S.A.
Healthy Schools. Illustrated. Mr. Charles Paget, M.R.C.S.
Health in Workshops. Mr. J. B. Lakeman.
The Ambulance. Illustrated. Surgeon-Major Evatt, M.D., A.M.D.
Legal Obligations in Respect to Dwellings of the Poor. Mr. Harry Duff, M.A., Barrister-at-Law; with preface by Mr. Arthur Cohen, Q.C., M.P.
Moral Obligations of the Householder, including the Sanitary Care of his House. G. V. Poore, M.D.
Laboratory Guide to Public Health Investigations. Illustrated. W. W Cheyne, M.B., and W. H. Corfield, M.D., F.R.C.P., M.A.
Scavengering and other such Work in Large Cities. Mr. Booth Scott.
Fires and Fire Brigades. Illustrated. Captain Eyre M. Shaw, C.B.

MAP OF BORNEO.

A map of Borneo, to illustrate Mr. Cobb's paper (see *ante* p. 400), in which the British possessions are marked red, is issued as a supplement with the present number of the *Journal*. The Society is indebted to the North Borneo Company for the map.

UNION OF INSTITUTIONS.

The following Institution has been received into Union since the last announcement:—

Kentish-town Science Classes, Wilkin-street, N.W.

Proceedings of the Society.

APPLIED CHEMISTRY & PHYSICS SECTION.

Thursday, March 13, 1884, the Right Hon. Sir LYON PLAYFAIR, K.C.B., M.P., F.R S., in the chair.

The paper read was—

THE UPPER THAMES AS A SOURCE OF WATER SUPPLY.

By PERCY F. FRANKLAND, Ph.D., B.Sc., F.I.C., Assoc. R.S.M.

During the past year, the average quantity of water supplied in London amounted to 145,000,000 of gallons per day; of this enormous volume as much as 72,000,000 of gallons, or nearly one-half, were taken from the Thames, whilst of the remainder nearly the whole was derived from the River Lea, and but a comparatively small fraction from deep wells sunk into the chalk.

The Thames water is supplied by five independent companies to the western portion of the metropolis, both north and south of the river. These several companies all abstract their respective supplies from the river between Hampton and Sunbury. Thus the intakes of these water companies, situated as they are a few miles above Teddington Lock, lie almost at the bottom of the Upper Thames basin, by which is understood the area drained by the Thames and its tributaries down to Teddington Lock. By means of this lock the waters of the Upper Thames are shut off from—and rendered independent of—the tidal waters of the Lower Thames, which extend from Teddington to the sea.

Reference to the map on the wall shows that the basin of the Upper Thames is an area of vast extent, covering 3,676 square miles. The waters draining from such a large area might be expected to be of very different chemical composition; owing, however, to the geological formations of which this basin is composed being almost all more or less calcareous, the chemical composition of the waters of the Thames and its tributaries varies within comparatively small limits. Thus the total solid matter in these waters is generally about 30 parts in 100,000, of which about 20 to 25 parts consist of carbonate of lime, or other hardening or soap-destroying ingredients.

The River Wey, which is one of the last tributaries to join the Thames above the intakes, forms a noticeable exception to this rule. Its waters are chiefly derived from the greensand, and exhibit considerably less hardness than the other waters of the Upper Thames basin. (See analytical table, p. 436.)

In addition to these mineral ingredients, there is present also a small quantity of organic matter, partly dissolved and partly suspended, the amount of which varies considerably with the season, being greatest when the river is in flood, and least in dry weather. The presence of this organic matter in the waters of the Thames and its tributaries imparts to the river that particular colour intermediate between green and brown, which, although difficult to describe, is so familiar to all. Although this organic matter is, as regards its mass, one of the least significant, a mere mustard seed indeed among the ingredients of the water, yet, from a sanitary point of view, it is of far greater importance than all the other ingredients put together. It is with this organic ingredient of Thames water that I propose alone to deal this evening.

The questions which naturally suggest themselves in inquiring into the subject of this organic matter are:—

(1). Its origin and nature.

(2.) Possibility of excluding it from the river and its tributaries.

(3.) Its removal before the water is employed for domestic purposes.

On considering the extent and character of the Upper Thames basin, it is at once apparent that the rain falling on this area must, in its passage to the river, come in contact with abundance of organic matter, both vegetable and animal. In so doing, it exerts on this organic matter its solvent action on the one hand, and on the other its mechanical power of carrying matter in suspension. And, consequently, it reaches the river bearing a certain amount of organic matter in solution, and a certain amount of organic matter in suspension. The presence of vegetable organic matter in water, although undoubtedly objectionable if excessive, is yet comparatively of such small importance by the side of animal organic matter that, in our present investigation, it may be altogether disregarded. The animal organic matters gaining access to the waters of the Thames are principally the excrements of man and the lower animals; these animal matters are either discharged directly into the river in the form of town drainage, or they find their way there by soakage from manured land.

Ever since it has been established beyond doubt that the excrements of man may be the means of communicating and distributing enteric disease, the presence in the waters of the Upper Thames of such animal matters has been the cause of uneasiness and inquiry. In the year 1866, this uneasiness in the public mind led to the appointment of a Royal Commission, to inquire into the subject of the Water Supply of the Metropolis. It was before this Commission that those vast schemes of supplying the inhabitants of London with water from Wales, and even from Cumberland, were ventilated and discussed in detail. Among the chemical witnesses, whose evidence was, as usual, highly conflicting, there were not wanting those who unhesitatingly pronounced the Thames water, into which the drainage of every town in the Upper Thames basin possessing a sewerage system was freely discharged, a perfectly wholesome and suitable source of supply; whilst others gave it as their opinion that water which had once been fouled by sewage could not be considered a safe or satisfactory source. These latter gentlemen, moreover, were of opinion that no process of purification with which they were acquainted could render sewage fit for mixing safely with water intended for domestic use. In plain words, it was the moderate and common sense opinion of these gentlemen, that no process of purification known to them could render sewage a fit and safe beverage for man. The Royal Commissioners, after balancing this conflicting evidence, express the following opinion, which I extract from their Report, p. 126:—

> "That, when efficient measures are adopted for excluding the sewage and other pollutions from the Thames and Lee, and their tributaries, and for ensuring perfect filtration, water taken from the present sources will be perfectly wholesome, and of suitable quality for the supply of the metropolis."

Fourteen years have now elapsed since that report was published, and yet no measures for excluding the sewage, not to mention the "other pollutions," have been taken. Indeed, the efficient execution of such measures would involve the expenditure of a sum of money which renders any scheme of the kind practically impossible. Improvements, and these important ones, however, have taken place upon the banks of the Thames, and to a less extent upon those of its tributaries. All these improvements have, however, been in the direction of sewage-purification, and not of sewage exclusion. In order to illustrate how extensive these improvements have been, I may mention that in the year 1874, according to the Sixth Report of the Rivers Pollution Commissioners, there was, in the basins of the Thames and the Lee, only one town, viz., Banbury, where the mitigation of the sewage nuisance was effectively carried out. In order to ascertain the progress which has been made in this respect during the last ten years, I have recently addressed inquiries to all the towns of 5,000 inhabitants and upwards, situated in the basin of the Upper Thames and its tributaries, with regard to the system of drainage carried out, and I must take this opportunity of expressing my thanks to their respective Local Boards of Health, for the courtesy and frankness with which my questions have in most cases been answered. From the accompanying diagram you will see in what a large proportion of these towns, representing a total population of 269,221, it is attempted to purify the sewage before it finds

its way into the Thames or its tributaries. The improvements have in most cases been carried out at great expense to the towns in question; thus the sewage works at Slough, where the drainage of about 5,000 persons is disposed of, were carried out at a cost of about £25,000. Indeed, it appears that in some cases the estimated expense of such works greatly exceeds the whole rateable value of the district, thus rendering the execution of such improvements exceedingly difficult. In several cases it has been admitted to me by local authorities that untreated sewage does enter the Thames and its tributaries, a fact which is sufficiently well-known to all frequenters of the river. Moreover, in the smaller towns and villages comprising the greater portion of the population of the Upper Thames basin, the sewage is generally allowed to collect in cesspits, the overflow from which usually communicates with the nearest stream or watercourse, whilst in other cases the street-drains are utilised for conveying the sewage matters into the nearest running water.

The Thames Conservators, in their report of last year, state that the river is now "practically free from sewage;" but even had they used the expression, "untreated sewage," the statement would have been sufficiently premature, for how frequently do we not read of the Conservancy prosecuting some offending town which has still failed to discontinue the discharge of unpurified sewage into the river? Thus, the following passages were extracted from the daily papers within a week or so of each other, October, 1883—

"Mr. Harrison, C.E., held a Local Government inquiry at Newbury yesterday, upon the application of the Newbury Urban Sanitary Authority, for powers to obtain a loan of £25,000 to carry out a scheme for the drainage of the borough. Dr. Shea, Medical Officer of Health for Reading, appeared for the Reading Corporation, who had lodged a complaint against Newbury for polluting the River Kennet with sewage. The evidence of the engineer, Mr. Anstie, and others having been given, the inquiry terminated."

Again, October 30, 1883—

"The Staines Local Board were summoned before the Spelthorne magistrates yesterday, by the Thames Conservators, for allowing to flow from their drains in Church-street into the River Thames foul and injurious matter. Mr. Payne, who appeared for the Conservators, stated that the Board had been fined three times before for polluting the River Thames, and yet had taken no steps to prevent a recurrence of the nuisance. This case was one of the worst that had ever been taken, and as the inlets of the water companies were within a few miles of the outfall of this sewer, the consequences might be of a very serious nature. Mr. Engall, the clerk of the Staines Local Board, said that the Board were doing all they could to carry out a system of drainage for the town, and were only waiting to receive Mr. Hawksley's report. The Board were in this position—the Conservators threatened them with penalties if the Church-street drain were not closed, and the inhabitants of Church-street threatened to sue them if the drain was cut off. The Bench imposed a fine of twenty guineas. Mr. Payne then applied for a summons against the Board for allowing foul matter to flow into the Thames from their drain in the London-road, and this was granted."

A few days afterwards, it appears Mr. Hawksley's report arrived; it contained, however, but little consolation for the ratepayers of Staines. Thus on November 20, 1883, we read—

"The Staines Local Board were yesterday summoned before the Spelthorne magistrates, for the fifth time, for having failed to comply with the notice served upon them by the Conservators of the River Thames on the 27th of September, 1871, and causing or suffering offensive or injurious matters to flow or pass from their drain near Station passage, Staines, into a water-course communicating with the River Thames. Mr. Engall said the Board had endeavoured to secure a system of drainage, and had consulted several competent engineers. Mr. Hawksley had just reported that Staines was the most peculiar, the most exceptional, the most difficult, and would prove the most expensive place of any he knew to provide with an efficient system, and that to drain the place, with a population of five thousand, would cost £32,000, or thereabouts. The Bench decided that the Local Board were at last taking steps to provide the town with drainage, and imposed a penalty of one guinea only, and five guineas costs."

Judging from the result of a more recent prosecution by the Thames Conservancy, it appears that their laudable crusade against Thames pollution is fraught with insuperable difficulties, even when a clear case of sewage discharge is proved, and even admitted by the defendants. Thus:—

"At the Uxbridge Petty Sessions yesterday, the Uxbridge Local Board of Health were summoned by the Thames Conservancy Board, for having, on the 22nd of November and the 3rd of January last, caused, or suffered to pass into the Colne from their sewage works at Uxbridge-moor, injurious or offensive matter which was likely to enter the Thames and prejudicially affect the river. Mr. F. O. Crump was counsel for the complainants, and Mr. H. S. Greene for the defendants. Great interest was taken in the case from the fact that in February, 1881, the Thames Conservancy were beaten by the defendants under precisely similar circumstances. Mr. Wigner, the analyst to the Conservators, deposed that a sample of water was taken from the mouth of the outfall belonging to the defendants and found offensive and injurious matter, unfit to pass into any tributary of the Thames within a distance of ten miles of that river. Similar evidence was given by Dr. Stephenson, another analyst; but the defence was that even supposing sewage matter of the worst description entered the Colne at Uxbridge-moor, there was not the probability of its injuriously affecting the Thames in any way, it having to run seven and a quarter miles before it reached that river. Evidence on this point was given by Dr. Tidy, who deposed to having found that the polluting matter was entirely destroyed after proceeding half-a-mile. Professor Wanklyn, public analyst for Middlesex, also gave strong evidence for the defence, and, after an inquiry extending over six hours, Colonel Cox, the chairman, announced that the magistrates were unanimously of opinion that the case had not been proved. Mr. Green applied for costs, and the Bench decided to grant the Local Board forty guineas."

I believe it used to be stated by Dr. Letheby, and subsequently by his disciple, Dr. Tidy, that it required ten miles' flow for a river to purify itself; but I suppose that the high-pressure system, which is so characteristic of the present day, has even affected our rivers, which now succeed in performing this wonderful feat in half a mile instead of in ten!

Really, as long as there are magistrates to be found who are so ignorant as to credit such romances as the destruction of sewage matters in half a mile's flow of a river, even the most zealous Board of Conservators can expect but little success.

In connection with the prosecution of the Staines Local Board, the following extracts from a letter to the *Times*, by the Vicar of Staines, is interesting and instructive:—

"Sir,—The parish of Staines has been lately brought unfavourably under public notice, in reference to the pollution caused in it to the water with which some of the water companies are supplied, the Thames Conservancy having frequently summoned our Local Board for the offence.

"It is quite true that impure stuff does run from some of the drains and water-courses of this parish into that part of the Thames which is above the intake of some of the London water companies, and most desirable it is that this should be prevented. But it is not easy to decide which, if any, of the many modern systems of town drainage would be the best for the town of Staines. It is so very flat, and so subject to floods in winter, that it will be difficult so to construct main drains and their house connexions that in time of floods the water shall not force its way into the pipes, and thus carry their contents not only into the river, but into the flooded streets and houses, thus imperiling the health and lives of the inhabitants.

"Staines is one of those places which continue to use the once universal system of cesspools, notwithstanding which, its death-rate will compare favourably with that of most English towns; and until last year its entire water supply has been drawn from wells, for no one here would think of drinking the water of the Thames. If our new water company, which draws its supply from the chalk, can give the town a sufficient supply of water, it may well be doubted whether a continuance of the cesspool system, accompanied by a well-organised plan of periodical cleansing, officially carried out, will not be the best for both the river and the town, as wel as the most economical.

"Our Local Board, of which I am not a member, has been at considerable pains to arrive at a sound conclusion in the matter, and have sought the advice of competent authorities. That there should be considerable hesitation on their part in arriving at a decision will not be wondered at when I state that the system last recommended to them will, from first to last, cost about £40,000, the rateable value of the parish being only £27,000.

"Meantime the Thames Conservancy are frequently summoning our Local Board, and thus parading before the public as the zealous and watchful guardians of the purity of the water for which they charge the water companies of London several thousands a year —a mode of appropriating to special purposes what is public property which I commend to the notice of Mr. Lefevre, in connexion with his recently-announced crusade against encroachment on the public rights of the Thames.

* * * * *

"Any one acquainted with the upper reaches of the Thames knows that thousands of persons bathe in it, and that hundreds of dogs are washed in it almost daily in the season, and that many of the eyots form the camping ground of boating parties. Moreover, every year sees a vast increase in the number of house-boats on the river in this neighbourhood and other places above the intake. These boats are inhabited day and night, sometimes for three or four months at a stretch, by parties, all of whose necessary pollutions go direct into the Thames. The contamination of the water supply of London by these causes can be more easily imagined than described. Do the Conservators of the Thames take any steps to mitigate these pollutions?

"Again, it is well known that accumulations of sewage are used, with other dressings, as manures for the fields which border the river. Every heavy fall of rain drains some of the impurities into the Thames. For this, of course, the Conservancy is not responsible; but when the floods rise and spread over the riparian lands, they in their fall sweep into the water supply of London tons of the offensive matter. . . . . I remember an instance not long since where the floods covered a large grass field which had just been dressed with manure largely composed of night soil, and when, after a few days, the water subsided, there was not a trace of it to be found in the field; it had all gone down to London.

"J. H. Armstrong, Vicar of Staines.

"November 29, 1883."

Even where sewage purification is, under ordinary circumstances, efficiently carried out, it is only in those towns which are provided with what is known as a "separate system," that the cleansing of the sewage can be carried out in times of flood. The separate system consists in having two independent drainages, the one for carrying away the rain water from the streets and housetops, the other for conveying the true household sewage. The street drainage is in such cases discharged directly into the nearest available watercourse, whilst the sewage proper alone is subjected to purification. The advantage of this system is that the sewage purification can take place even in times of flood, as the quantity to be treated is practically independent of the rainfall, and dependent only upon the abundance of the water supply. The disadvantage which the separate system obviously entails is the discharge of street drainage, without any purification, into the river. Now, street drainage, although unquestionably less objectionable than sewage proper, is yet, I take it, an undesirable ingredient of drinking-water.

In those towns where no such separate system exists, the purification of the sewage in times of flood is quite impossible, as the appliances for such purification are proportioned to deal with the average volume of the drainage and not with the excessive quantity occasioned by flood-waters. In all such towns, therefore, untreated sewage must, in times of flood, be freely discharged into the river.

Here it may be well to pause for a moment, and consider what the various processes of sewage treatment in vogue at the present time are; in what they differ from each other, and to which the preference should be given.

The methods of sewage purification may be divided into two classes—

1. Those depending upon filtration through soil.

2. Those depending upon precipitation by means of chemical reagents of one kind or another.

The first of these two classes includes the well-known processes of "broad irrigation" and "intermittent downward filtration." As these terms have become, I may say, household words in sanitary engineering, it is almost unnecessary for me to explain them here. I may, however, briefly state that in broad irrigation the sewage is distributed over the surface of cultivated land, drained either naturally or artificially. In percolating through the soil, the coarser solid particles of the sewage are arrested, an active process of oxidation goes on, resolving more or less of the organic matters of the sewage into inoffensive mineral ones, whilst this process of purification is assisted by the vegetable life with which the land is clothed.

Intermittent downward filtration, on the other hand, may be described as a concentrated form of irrigation; a far larger amount of sewage is applied to a given surface of land, and in order to meet this greater tax put upon the soil, the latter must be drained at a considerably greater depth. As in irrigation the land must not receive the sewage continuously, but must be divided into separate plots, which are worked in succession. During the period of repose which each plot of land enjoys in turn, the soil becomes recharged with oxygen, and when thus revivified is fit for the reception of a fresh quantity of sewage. The accompanying Table

PURIFICATION OF SEWAGE.

Name of Process.	Average per-centage of dissolved organic pollution removed.		Average per-centage of suspended organic pollution removed.
	Organic Carbon.	Organic Nitrogen.	
Chemical Processes.			
Best result	50·1	65·8	100
Worst result	3·4	0	59·6
Average result	28·4	36·6	89·8
Downward Intermittent Filtration.			
Best result	88·5	97·5	100
Worst result	32·8	43·7	100
Average result	72·8	87·6	100
Irrigation.			
Best result	91·8	97·4	100
Worst result	42·7	44·1	84·9
Average result	68·6	81·7	97·7

shows that the degree of purification attained by means of irrigation, and by intermittent downward filtration, is much the same. Both processes, in fact, when carried out with care, yield equally satisfactory results. The choice between the two processes will obviously depend upon circumstances; where land is cheap and a suitable site obtainable, irrigation may be carried out with most success, the expense being more or less defrayed by the crops yielded; where, on the other hand, land is costly, the more compact form of intermittent downward filtration will find most favour with the sanitary engineer.

The various processes, and their name is legion, of sewage purification by means of precipitation, all depend upon the well known property which lime, iron, and alumina possess of entering into mechanical combination with organic matter.

A great number of patents have been taken out for treating sewage by precipitation, but in most cases they have attracted merely passing notice, and have then disappeared into that obscurity from which they ought never to have emerged.

The simplest as well as the most ancient process of precipitation is by means of lime. This process has been tried in more places than any other, and although it fails to purify the sewage, it acts as an efficient clarifier, and doubtless renders the sewage more fit for treatment on land.

As far as I am aware, the only precipitation processes of sewage purification which are at present in operation in the Upper Thames basin, are the so-called "A. B. C. or Native Guano Process," and "Hanson's Process." The former is employed at Aylesbury, and the latter at Aldershot.

The A. B. C. process has attracted an altogether undue measure of popular attention; probably on account of its very plausible and seductive name, which we can imagine may not be without influence upon the ignorant persons who are frequently entrusted with the management of local sanitation.

This process was very thoroughly investigated by the last Rivers Pollution Commission, and the result of their exhaustive examination is embodied in the following words:—

"1. The A. B. C. process removes a large proportion of the suspended impurities from sewage; but on no occasion, when we have seen it in operation, has this removal been so complete as to render the effluent sewage admissible into running water.

"2. The A. B. C. process removes a very small proportion of the soluble polluting matters from sewage. After treatment by this process, the effluent sewage is very little better than that which is obtained by allowing raw sewage to settle in subsidence-tanks."

The most reliable analytical figures, upon which the above opinion is founded, are contained in the following Table:—

Results of Analysis in Parts per 100,000.

Description.	Dissolved Matters.						Suspended Matters.		
	Total Solid Matters.	Organic Carbon.	Organic Nitrogen.	Ammonia.	Total Combined Nitrogen.	Chlorine.	Mineral.	Organic.	Total.
	A. B. C. or Native Guano Process.								
London Sewage	67·3	3·614	1·886	5·418	6·348	10·23	10·30	18·00	28·30
Ditto after treatment	80·5	2·257	1·878	6·086	6·890	10·20	Traces.	Traces.	Traces.
	Hanson's Process.								
Raw Sewage	132·72	7·441	2·234	·90	2·975	5·7	4·96	44·70	49·66
Ditto after treatment	120·16	4·777	1·802	·80	2·461	7·1	2·36	—	—

This then is the only barrier interposed between the raw sewage of Aylesbury and a tributary of the Thames.

"Hanson's process" consists in treating the sewage with lime and alkali waste. The efficiency of this process has, during the past year, been investigated in my laboratory. It is not difficult to form an opinion concerning its value, on reference to the above analytical figures. The sewage of Aldershot thus undergoes but very imperfect purification, before passing into a tributary of the Thames.

If we reflect that these processes of precipitation thus signally fail in removing such organic matter from sewage as is recognisable by chemical analysis, the thought cannot be entertained that they either arrest or destroy those subtle forms of organic life which are capable of communicating zymotic disease.

Indeed, even in the case of sewage purified by the far more efficient processes of irrigation and downward intermittent filtration, there is absolutely no evidence to show that morbific matter, if present, would be removed. But on the contrary, there is very strong reason to believe that these processes of purification offer no sort of guarantee that noxious organised matters present in the sewage may not pass through into the effluent. For the removal of organic matter, by means of either irrigation or intermittent filtration, depends upon the oxidising action which a porous soil exerts upon such matter, and is quite analogous to the purification of water percolating through a few feet of soil into shallow wells. Now, the instances on record of the percolation of sewage into shallow wells becoming the means of infection are so numerous and well authenticated, that it is unnecessary for me to refer to them here. If, therefore, the filtration through in many cases considerable depths of porous strata, does not suffice to exclude such organised matter from shallow wells, what reason is there to believe that the far less favourable filtration which takes place in the purification of sewage should be more successful in attaining this result? As I shall presently demonstrate to you, the effluent from such sewage works is always charged with minute suspended particles which have escaped removal in the process of purification.

At Stuttgart in Germany, and Winterthur in Switzerland, some years ago, epidemics of typhoid fever were proved most conclusively to have been caused by the contamination of the water supply with the effluent from irrigated meadows.

It thus appears that the waters of the Upper Thames are contaminated with:—

(1.) Raw town drainage.

(2.) The effluent from sewage works.

(3.) The drainage from cultivated land, frequently manured with human excrements.

Of these sources of pollution, the first, or that due to raw town drainage, is, thanks to the exertions of the Thames Conservancy, becoming annually diminished. The second, or that due to sewage works, is, for the same reason, increasing; whilst the third cause, viz., drainage from manured land, remains practically stationary. Further, by means of all three polluting causes, noxious organic matters may gain access to the river, although the second and third sources of contamination are in this, as in other respects, less objectionable than the first.

As we have now seen that there is no guarantee whatever that noxious organic matters do not find their way into the Upper Thames, let us consider what kind of assurance there is that such noxious matters, when present in Thames water, are removed before the latter is supplied to the London consumer.

Before proceeding to this investigation, I must allude to the composition of the waters of the Thames in various parts of its course, so that we may understand what the character of the water is with which the London water companies have to deal.

I have recently made a systematic chemical examination of the Thames water between Oxford and London, and the results of my analyses are recorded in the accompanying tables and diagrams.

In order to obtain a knowledge of the general quality of the Thames water in various parts of the river's course, I had samples for analysis collected on the same day at Oxford, Reading, Windsor, Hampton, and other places. A somewhat similar investigation was made by the Royal Commission on Water Supply, in 1868, but in their case, the value of the experiments is greatly reduced by the samples not having been all collected on the same day, nor, indeed, within the same week. I may, however, mention that it was upon the evidence of these some ten or twelve samples of Thames water, collected, as it appears, in the most haphazard and unsystematic manner, that the Royal Commission on Water Supply lent their support to that fallacious doctrine of the self-purification of river water which has probably done more to check and paralyse the prevention of river pollution than anything else. My analyses show that on the day in question—and on this day the river was in a perfectly normal condition—the water above Oxford contained but a very moderate proportion of organic matter, considerably less than is often present in drinking water; the sample taken below Oxford contained somewhat more, the river having received the polluted water of the Cherwell. The sample taken just above Reading exhibited a further increase; that from Windsor more still; whilst the sample collected at Hampton contained a larger proportion than any of those taken higher up the river. A sample taken at Staines, which lies

NOTE.—Those dated 1868 were analysed for the Royal Commission on Water Supply in 1868. All the river waters were filtered through Swedish paper before analysis.

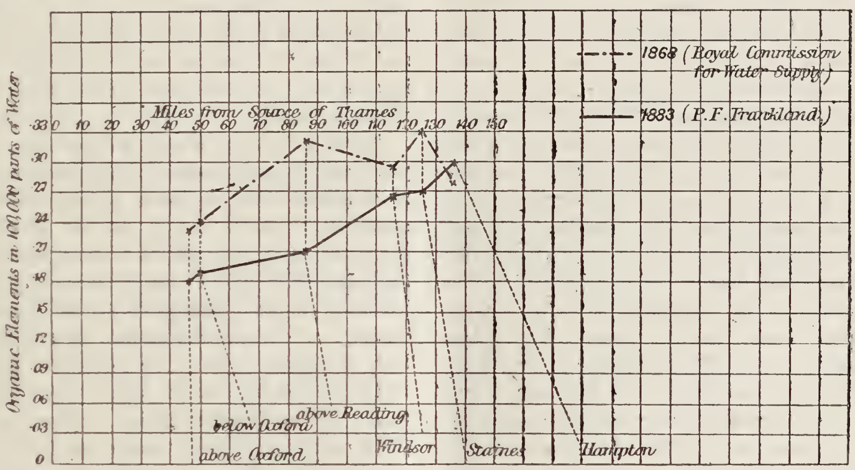
between Windsor and Hampton, although collected about a fortnight after, presented a quantity of organic matter intermediate between that in the Windsor and Hampton samples.

On comparing these analyses with those made for the Commission on Water Supply, in 1868, it will be seen, that with the exception of the Hampton sample, the river was at all the above points in a worse condition in April and May, 1868, than in November of last year. From the superiority of the Hampton sample to those taken higher up the river in 1868, it has been generally supposed since, that the river at Hampton contains less organic matter than at any point above. As this state of things appeared from my analyses to have become reversed, I deemed it worthy of further investigation. I consequently collected weekly samples during January last, at Hampton on the one hand, and at Windsor or Chertsey on the other. The average of these samples show in 100,000 parts of water.

	At Windsor or Chertsey.	Hampton.
Organic carbon	·275	.285
Organic nitrogen	·058	.061
Organic elements....	·333	·346

The difference between the two is not great, but, such as it is, is in favour of the Windsor samples, as indeed *à priori* considerations would lead one to expect. For between Windsor and Hampton, there enter the Thames two tributaries of moderate size, the Colne on the north and the Wey on the south; now both these streams, and especially the Wey, are more highly impregnated with organic matter than the Thames itself at the points of

PROPORTION OF ORGANIC ELEMENTS IN THAMES WATER AT DIFFERENT PLACES IN 1868 AND 1883



junction, as is apparent from the foregoing analytical table. Indeed, all the tributaries of the Thames that I have examined, viz., the Cherwell, the Kennet, the Colne, and the Wey, are, with the exception of the Kennet, richer in organic matter than the Thames at the points where it is joined by these streams. In fact, the Wey is a particularly objectionable tributary of the Thames, and exhibits pollution with very highly nitrogenous organic matter; it receives as we have already noticed, the untreated sewage of both Farnham and Guildford, towns of no inconsiderable magnitude. The sewage of Farnham has only recently been the subject of litigation, on account of the nuisance which it causes to the riparian landowners below, and on this occasion the sewage discharged into the Wey was analysed in my laboratory. From the analytical figures below, it will be seen what an excessively foul liquid was there permitted to enter a tributary of the Thames.

SUSPENDED MATTER.

Mineral.	Organic.	Total.
71·80	139·40	211·2

The treatment which this Thames water undergoes at the hands of the companies who abstract it at Hampton, is twofold. In the first place, the water is stored in large reservoirs, where it remains at rest for many hours or even days. In these storage reservoirs the water deposits a great deal of the coarser matter which it holds in suspension, and thus becomes prepared for the second process of clarification, viz., filtration through a few feet of sand. Now, beyond this, the water receives no further treatment at the hands of the companies, and, during the greater part of the year, this treatment is sufficient to render the water of the Thames clear and transparent to the eye. The manner in which these two operations—storage and filtration—are carried out by the several water companies, has undergone very marked improvement during the past few years. Thus, whereas in 1868, out of 84 samples of river-water examined there were only 48 clear and transparent, in the past year there were out of the same number of samples no less than 73 clear and transparent. Moreover, the 11 turbid samples last year were all only slightly turbid, whilst in 1868, out of 36 turbid samples, 20 were slightly turbid, 9 turbid, and 7 very turbid. It is not without great exertions on the part of the water companies that this amelioration has been accomplished, for most of the companies have expended large sums of money in the extension of their storage reservoirs, and in perfecting their filtering plant. These improvements, although deserving every recognition as highly beneficial to the public, still furnish no guarantee whatever that the waters of the Thames are thereby rendered suitable for human consumption. Neither the process of storage, nor yet that of filtration through a few feet of sand, is able to remove from the water those lower forms of life which may at any time be present, and which are so dangerous to health. Some exceedingly interesting experiments on this point have been recently made by Professor Pumpelly, of Newport, for the National Board of Health of the United States. Professor Pumpelly allowed water to filter through a stratum of fine sand, 100 feet in depth, the bottom of the column being connected with a flask containing a sterilised infusion of beef, and he found that the first water which passed through the sand was sufficient to cause the putrefaction of the infusion. As these experiments were performed with the very greatest care and judgment, they most conclusively prove that filtration through even great depths of sand offers no barrier whatever to the passage of bacteria.

That Thames water, after filtration by the water companies, still contains suspended particles, may be very strikingly shown by passing a beam of light through a flask containing such water. A beam of light, it is well known, is only visible to an observer not placed in its path, when minute particles of matter are present to reflect the light which impinges on them. If a beam of light be passed through a flask with distilled water, its path is practically invisible, owing to the absence of suspended particles; and in this manner the presence of some suspended matter, although exceedingly small in amount, may be demonstrated in the purest water obtained from deep wells in the chalk.

It is thus evident, firstly, that the exclusion of sewage matter from a river like the Thames is practically an impossibility; and, secondly, that such sewage matters may at any time be accompanied by the germs of zymotic disease; and, thirdly, that no process to which the water is subjected can remove these germs should they be present.

These are facts which are becoming every year more clearly understood and more widely recognised, and in those places where the question of water supply is not fettered by the investment of a capital amounting to many millions of pounds in existing works, the River Thames is not employed as the source of supply. The accompanying diagram shows how unpopular are the Thames and its tributaries as sources of water supply in other towns of the Thames basin. Indeed, there is good reason to believe that even some of the metropolitan water companies themselves are new deeply impressed with the necessity of ultimately abandoning the Thames. In many cases a first step in this direction is already being made, by utilising certain subterranean waters that are available on their premises, and by sinking deep wells into the subjacent chalk.

The accompanying diagrams clearly indicate the immense superiority of this water from deep wells in the chalk to the river water. Unlike the latter, it is not liable to those fluctuations in quality, which so frequently render it impossible to furnish even moderately pure water, however perfect the appliances of the water companies may be. Indeed, this deep-well water, which is so abundant in the Thames basin, is, as regards freedom from organic matter, unsurpassed by any water in the kingdom.

There is, perhaps, no test of the purity of water so crucial or searching as its use in the operation of brewing. For successful brewing it is indispensable to have a water almost wholly free from organic matter, as the latter in any but the most minute quantity induces a premature and unhealthy fermentation of the brewer's wort. The brewer, in fact, requires a water free from bacterial life, so that in the process of mashing, the diastatic action of the malt may take place unmolested by the chemical changes which are incidental to the life of bacteria. Now these deep well waters find especial favour with brewers, whilst the river waters supplied in London are only under the most exceptional circumstances employed. The natural filtration which this deep well water has undergone, in passing through the porous strata, is of the most complete and thorough nature, and places almost beyond doubt the impossibility of its containing even any trace of noxious organic matter.

Unfortunately, this source of pure water, which the chalk at present furnishes, is so far wholly unprotected by law, as was shown only a few weeks ago in an action—Ballard *v* Tomlinson—heard in the Court of Chancery, before Mr. Justice Pearson. The plaintiff in this case is the proprietor of a brewery at Brentford, who for the purposes of his trade, has for many years used the water from a deep well sunk through the London clay into the chalk beneath his premises. A similar well sunk into the same stratum exists at 100 yards distance on the premises of the defendant, who has converted this well into the receptacle of the sewage from his printing factory. The sewage matters thus put down the defendant's well find their way into the plaintiff's well, and render the water thereof wholly unfit for brewing purposes. That the wells are intimately connected, was conclusively proved by putting chloride of lithium down the defendant's well, and discovering it, after twenty-four hours' pumping, in the water of the plaintiff's well. The pollution was, indeed, not denied by the defendant, who simply contended that inasmuch as he was admittedly entitled to abstract every drop of water from the chalk, he surely must have an equal right to alter the quality of the water by any act that he might be pleased to perform on his own premises. This ingenious line of reasoning found favour with Mr. Justice Pearson, who dismissed the action with costs. (See p. 455). Thus, according to Mr. Justice Pearson, it is at present lawful for a person to introduce into the water-bearing stratum on his own premises any poisonous matter which he is perfectly well aware will find its way into his neighbour's water supply. If this really is the present state of the law—and there appears to be no reason to doubt that it is—no time should be lost in remedying such a palpable defect, which imperils the safety of the annually increasing numbers who are becoming dependent upon the chalk and similar strata for their water supply.

The feasibility of supplying London with this deep-well water is clearly shown by the Kent Company, who have, since 1866—and even before—continuously supplied this water to a portion of the metropolis, and the magnitude of their supply is now equal to that of the Chelsea Company drawing from the Thames.

I have thus shown :—

1. That the present water supply of London from the Thames is, to say the least of it, an unsatisfactory one; and, moreover, that it is unsatisfactory in spite of important and very expensive improvements that have been made on the banks of the river, and in the appliances of the water companies.

2. That it is impossible to protect a large body of water like the Thames, flowing as it does through a populous district in a high state of cultivation, from contamination with sewage and other objectionable matters.

3. That such matters are at present largely discharged into the river, in spite of the active measures which are taken to prevent such pollution.

4. That water which is polluted with sewage, and even with sewage effluents, may at any time carry with it infection, and that the water of the Thames is not subjected to any process by the water companies which can ensure the removal of such morbific matter, if present.

5. That in nearly all other towns in the Thames basin, the Thames and its tributaries are rejected as sources of water supply, and that these towns are generally supplied with spring or deep-well water, which is especially abundant in the valley of the Thames.

6. That the great obstacle in the way of a similar supply being obtained for the metropolis is the great magnitude of the capital invested in existing works, the interests of which capital are at present allowed to override all other considerations.

DISCUSSION.

The CHAIRMAN said it had been a great pleasure to him to preside on this occasion, Dr. Frankland's eminent father having been a pupil of his in former times, so that he might consider Dr. Percy Frankland as his scientific grandson. When he heard pointed out the pollutions which were sent into the Thames by so many towns on its banks, he was in hopes that Dr. Frankland would have gone on to point out how those evils were to be removed, and he could not help thinking of the words of Macbeth—

> "Come, Sir, despatch; if thou coulds't, doctor, cast
> The water of our land; find its disease,
> And purge it to a sound and pristine health,
> I would applaud thee to the very echo
> That should applaud again."

But, unhappily, Dr. Frankland had not been able to give them the comfort of thinking that the Thames, under any system of purification, could ever be thoroughly purified from that organic matter, which a large experience all over the world showed to be the great source of disease. On the other hand, the water from the chalk promised a source of supply, which was, perhaps, equal to the occasion. He should be glad to believe this, but he had some doubts of it, because the operations of breweries in London showed that the pumping of water for those breweries acted to a large distance from London. The Rev. Mr. Clutterbuck, a good many years ago, when living at Watford, measured the depths of the wells every day, and found there was more water in them on Monday than any other day in the week, the reason being that there was no pumping on Sunday, so that, even at that distance from London, the effect of pumping for the large breweries was something considerable. He hoped it was true that there was abundance of water in the chalk to supply the metropolis. Much had been added to the chalk water supply, and much more might be added, but whether it would supply their whole requirements he should like to hear from those of more experience. As there was a probability of a discussion coming on in the House of Commons that evening, in which he had undertaken to speak, he must ask Sir Frederick Abel to take his place.

Sir Frederick Abel having taken the chair,

Mr. Norman Bazalgette said he must admit it was rather presumptuous in him, as a layman, rising to criticise this paper, but with the indulgence of the audience he wished to offer some remarks upon some points which seemed to call for criticism. In the first place, the author having quoted from the report of the Royal Commissioners of 1869, said fourteen years had elapsed since that was published, "Yet no methods for excluding the sewage, not to mention other pollutions, had been taken." Was the energetic action of the Thames conservators during the last fourteen years to be altogether ignored. But this statement was contradicted by the author himself, for further on in the paper it was stated, "that these sources of pollution, the first, or that due to raw town drainage is, thanks to the exertions of the Thames conservators, becoming annually diminished." What, then, did he mean by saying that no measures had been taken for excluding the sewage during the last fourteen years? Again in another place, he said—"If we reflect that these processes of precipitation thus signally fail in removing such organic matter from sewage as is recognisable by chemical analysis, the thought cannot be entertained that they arrest or destroy those subtle forms of organic life which are capable of communicating zymotic disease." That no doubt referred to the celebrated germ theory advocated by the author's distinguished father; not being an expert, he had not been able to pursue investigations into these matters himself, but it had been over and over again proved that chemical analysis had, at the intakes of the water companies, failed to discover these germs. If, then, they were passed into the rivers, and could not be discovered at the intake, what became of them if they were not destroyed by the agency of oxidation? In another place the author referred to magistrates being ready to believe such romances as the destruction of sewage matters in half a-mile's flow of a river, which evidently meant to intimate that the notion of self-purification in polluted rivers was a fiction of the brain, and that, if it existed at all, it was so slight as to be practically inoperative. If that were so, he might quote two or three authorities who believed in such a romance. He did not know that there was much romance in Dr. Letheby or Dr. Angus Smith. He could not attempt to pose as an authority on this self-purifying power of rivers, but he threw in his lot with those who believed in oxidation. The bulk of the evidence, taken *pro* and *con*, must certainly prove that this self-purifying power was a most important feature. He should not attempt to defend the "A. B. C." process, as there were other gentlemen better qualified to do so; but when he found the statement made that this process removed a very small proportion of soluble polluting matters from sewage, and that after treatment it was very little better than that obtained by letting the raw sewage settle in subsidence tanks, he could not keep silence altogether. The author there was quoting from very ancient history, the report of the Rivers Pollution Committee in 1874. That report being the work of his father, of course was entitled to all respect, but that statement, judging by the light of present experience, required considerable modification. When he first read that report he was much prejudiced against the process, but since then he had been to Aylesbury and looked into the matter himself, and was so far a convert that he believed it was the best of all the precipitating processes. With regard to the germ theory, he would simply refer to an answer given by Dr. Angus Smith before the Royal Commission in 1879, the purport of which was that a sufficient quantity of pure air acted as a barrier to the communication of zymotic diseases through the atmosphere, and a sufficient quantity of pure water would act in the same way. That struck him as an answer which appealed eminently to common sense. A considerable portion of the paper was devoted to analyses made by the author of Thames water, and the discovery of what was called noxious organic matter; but he should be glad to hear from him what was his authority for describing it as noxious. Of course they all knew there was organic matter in the water, but could he show, by reference to health statistics, that it had been productive of any injury to the health of the population which consumed it? Before coming to that meeting, he referred to the report of Messrs. Crookes, Odling, and Tidy, on the London water supply for 1882, which was entitled to some consideration, inasmuch as the opinions there expressed were based on the examination of more than 1,200 samples of water from the mains of the seven London companies drawing their supplies from the Thames and Lea. From that it appeared that the filtered Thames water, as supplied to London, contained a variable, but always minute, proportion of organic matter, ranging from less than $\frac{3}{8}$th of a grain to $\frac{3}{4}$th of a grain per gallon, and that would be of importance only if it could be shown to be an unwholesome constituent of the water; but taking a series of years, and relying solely on the water analyses as supplied to the Registrar-General, it showed with singular perversity that the years in which the rate of mortality was excessively high were those years in which the proportion of organic matter in the water was relatively low, whilst the years in which the mortality was low were those in which the proportion of organic impurity was high, not of course because the organic constituent was any more wholesome than it was prejudicial, but most probably because the climatic conditions of the years which affected the rate of mortality in one way, affected the proportion of organic matters in the opposite way; thus in the successive years, 1869, 1870, and 1871, with a high mortality of over 24 per 1,000, the mean proportion of organic impurity was 912, whilst in the years 1872, 1880, and 1881, in each of which the mortality was exceptionally low, being less than 22 per 1,000, the amount of organic matter reached 1,171. Having regard to these statistics, what became of the argument that, because there was organic matter in the river it was necessarily noxious. A most interesting paper had been compiled by Mr. Baldwin Latham, who compared, as regards the zymotic death-rate, those districts which derived their water supply from the river with those deriving it from the chalk. Taking the death-rate due to diarrhœa, which all would agree was a disease peculiarly attributable to bad water, though, of course, other considerations also affected it, he would select two places as fairly comparable as possible, Lambeth on the one hand, supplied by the Lambeth and Southwark and Vauxhall Companies, with an estimated population of 229,190, in which the deaths from diarrhœa were 1·00, and on the other hand, Greenwich, supplied by the Kent Water Company, with an estimated population of 110,920, and a diarrhœa death-rate of 1·05, so that the advantage was very slightly in favour of the district supplied by river water. There were other statistics in those tables which pointed in the same direction. What was the use of going into chemical analysis, and saying that it showed the organic matter discovered must be prejudicial to health, when by reference to statistics you can gauge its precise effect on the health of the consumer, which was worth ten times as much as theoretical considerations of the possible effect. He would also refer to a diagram prepared by Sir Francis Bolton, upon which were traced lines showing the death-rate in London from 1868 to 1882, the ratio of organic impurity in Thames water during the same years, the same with regard to the Lea water, and the same with regard to the water from the chalk. It was somewhat remarkable that that showed there was absolutely no connection between the death rate and the organic impurity in the Thames and Lea water, but there did appear to be some connection between it and the ratio of impurity in the chalk water. Lastly, with regard to the conclusions drawn by the author, he maintained that the first was not borne out; the second he agreed with, though at the same time sewage was being gradually excluded, and would be totally excluded in a few years, whilst the impurities that did enter were got rid of by oxidation; the third might be admitted. With regard to the fourth, there ought to be some statistics brought forward to show that the morbific matter referred to was present; the fifth simply meant that those towns which had their own supply of well water preferred that to the Thames water, and so would anybody, but it said nothing against the use of Thames water; and with regard to that he might observe that the title of the paper was somewhat misleading, as while it professed to be a paper on the "Upper Thames as a Source of Water Supply," it was really an attack upon the Lower Thames. With regard to the sixth, he submitted that the present supply was eminently satisfactory, and that the investment of capital for the purpose of introducing another substituted or supplemental supply would be a wasteful expenditure of the money of the ratepayers.

Sir FREDERICK NICOLSON said so many allusions had been made to the Conservators of the Thames, that he hoped he might be excused for saying a word or two. He would not go into chemical details, but would bring to the notice of the meeting a few facts showing what had been done for the purification of the River Thames. He, like the previous speaker, had been much struck with the statement made by Dr. Frankland, that for fourteen years nothing whatever had been done. Beginning with the smaller affairs, Aldershot and Farnham, and a great many other places on the diagrams, were beyond the limits of the Conservators' jurisdiction, that embraces, first, the river proper, and originally three miles up the tributaries, which had been subsequently extended to five miles, and was now ten miles in a direct line from the river. Dr. Frankland had skilfully alluded to two or three cases where proceedings had been taken against places on the tributaries where the Conservators had been unsuccessful, thanks to certain eminent chemists, in stopping the pollution of those tributaries. At Uxbridge, the effluent was about seven miles from the Thames, and there was an immense difference of opinion on the part of chemists as to whether seven miles would purify an effluent or not; some said it was purified in half a-mile, whilst others said it was never purified at all. Dr. Frankland seemed to belong to the latter class. Then there was Staines, a very unhappy town with regard to its situation, being at so low a level that, although it had had consulted four engineers to try and doctor the sewage, they hardly knew how to devise a plan to do so. It would cost about £40,000 to keep it out of the river, and the inhabitants were only 4,000. It was only a part of the sewage of which there was any serious complaint, so that, although it was above the intakes of the water companies; this was not a very serious case, but to show that the conservators were not lax in their endeavours to carry out the Acts, he might say, that they had obtained five convictions against that town, which was now in the hands of the Local Government Board, and he hoped that ultimately a satisfactory result would be produced, and that it would become one of the towns whose sewage was entirely diverted. In framing the Act under which the conservators endeavour to purify the tributaries, certain words were introduced with regard to them rendering it necessary to prove that the effluent was "likely to flow into the Thames." Those words were probably put in to help the Conservators, but, on the contrary, the words had proved a stumbling block, and if the Act had been worded as the Rivers Pollution Act is, there would have been no difficulty whatever. They would not then require any expert chemists, because the offence would consist in passing something offensive or injurious into the tributary, and they would not be obliged to prove, as they now had to do, that whatever went in was likely to reach the Thames. Still, it would be some satisfaction to the meeting, after what had been stated, to know that something at any rate had been done. At Oxford, sewage works were completed in 1880, at a cost of £185,810; those at Abingdon were completed in 1877, and although there was little hitch in 1880, they were now satisfactory, at a cost of £23,000. At Wallingford, £19,000 had been spent; at Reading, £205,000; and at Henley, £22,000; there again they were now extending the works to meet a slight impurity. At Marlow, Cookham, and Windsor, the sewage was diverted, £45,000 having been spent at the latter place, and the Castle works, which were separate from the town, had cost £14,000. At Eton and Eton College the sewage was diverted. The total expenditure on all these works has been £513,800—a fair proof that the statement, quoted from the Conservators' annual report by Dr. Frankland, was correct, viz., that the Thames proper is practically free from sewage, all these towns having diverted their sewage from the river. He was aware that some chemists would say that no matter what they did to the sewage the water was not thoroughly pure. Into that question he did not enter, but after all this expenditure by these towns, it was rather too much to say that nothing had been done. As to the details of what the conservators were doing, they maintained a thorough supervision of the river, getting monthly reports from every part above the intakes, and with the exception of occasionally small cases up the tributaries, where eminent chemists said the effluent was so distant from the river that it had no practical effect on the water supply of London, he maintained that the river was practically free from sewage. He should also add they had not always been obliged to institute legal proceedings, but by serving notices, &c., they had obliged all the manufactories, as to which there was formerly great complaint, to keep their effluents and refuse out of the river.

Sir Robert Rawlinson said he knew something of the Thames and its water, and had necessarily paid attention to the question of water supply, but although he had a great admiration for Dr. Frankland, for his able son, and for the able Chairman, he could not adopt the views that chemists took of what water should be, or the effects it had or might have on the human constitution. Three times within the last 30 years he had lived out of London under conditions which he assumed those gentlemen would tell him he ought to live under—that is, in pure water districts, where the water came from the granite, and in each case it had very seriously affected his own health, and that of his family, and he had been uncommonly glad when he got back to London again, and got the hard water. For thirty-five years he had been supplied by the Chelsea Water Company; his cisterns were never any trouble in cleaning, his toilet service was pure and white, and he had not had occasion to find fault more than once or twice with any turbid appearance of the water. If it was absolutely necessary to health that water should be absolutely free from all impurities, he was in despair, because he had not the slightest idea where such water was to be got, or how it was to be preserved. The pure water that fell on the granite mountains of Scotland came into contact with everything growing on the surface, and he apprehended that every particle of growing matter was imbued with ammonia, which would combine with the water, and there was also the chance of other forms of impurity from decaying organic matter. Whether that going into solution in the soft water was the cause of the injurious effects it had on strangers, he did not know; but he knew that, in 1745, when the British army went into the Highlands, Dr. Pringle, the most celebrated army doctor of the period, recorded that the entire British army became disorganised by drinking the water. It seemed to be a question of acclimatisation, and he believed that the changing from one class of water to another might be very injurious. But taking water as it was found on the surface of the earth, he would say that, out of the whole population of the globe, 95 per cent. must be drinking water which, according to chemical tests, ought most seriously to injure their health; and more than 50 per cent. of the water would horrify any person who had the chemical contents explained to him. All through India and China, water was more or less polluted; and on the Continent, wherever wells could be sunk, they were almost invariably sunk in close proximity to the farm middens. Yet those people went on year by year drinking that impure water, no doubt with some injury, but not with all the injury imputed to it. He knew some extraordinary cases with regard to the non-effect, apparently, of water on population. In 1833, 1849, and 1854, cholera prevailed in Staffordshire, and the towns above Birmingham, such as Bilston, were decimated. The whole of the cholera virus was washed down into the streams and tributaries of the Thame, from which Birmingham was supplied. The water was neither strained nor filtered, but was pumped direct from the reservoirs fed by the Thame, but there was not a single case of cholera generated in Birmingham. At North Shields, when cholera prevailed at Newcastle-on-Tyne, there being nearly 2,000 cases with no quarantine, the water of Tynemouth was so bad, that it was sold in canfuls at the street corners, with a flannel bag tied round the nozzle to keep the filth out; there was not a single case of cholera generated in that town. When he was in the Crimea, he saw the Sardinian army come in 16,000 strong, and a finer body of men he never saw. They took up virgin ground, supplied with a magnificent volume of water from the oolitic rocks in a large Russian fountain. One thousand of those men died of cholera the first month. When he came back he heard Dr. Snow explaining the theory that cholera-polluted water was necessary to the production of cholera, and he then said to him that it must be a mistake, because he had seen, on the largest possible scale, that it was not a fact; and whatever might produce cholera, he was satisfied that it could not be imputed, in all cases, solely to impure water. He did not say London should not have the best supply of water which could be given to it; but in his opinion, to sacrifice the present source, and to lay out fresh capital to bring in some imaginary pure supply, would be gross waste of money, and would not accomplish the object intended.

Mr. BRYAN, as a comparative stranger to London, but having read a good many alarmist paragraphs in the London papers, had been somewhat puzzled to understand how it was that London, with the water supply which it had, should be so much healthier than the large towns of the North, with most of which he was well acquainted, as well as their sources of water supply, especially Liverpool, Manchester, Burnley, Preston, Bolton, Halifax, Bradford, Leeds, and Lancaster. He also knew the gathering-grounds for Glasgow. He was responsible for the water supply in one of the largest towns in Lancashire; its gathering-ground was 6,800 acres, and at the intakes of the waterworks there was absolutely not a single source of pollution. Other towns he knew had similar gathering-grounds. Most of those waters were delivered unfiltered, very soft, but not as bright as the London waters, being sometimes tinged with peat. Nearly the whole of these towns were exceedingly well drained, having spent during the last few years large sums in dealing with the sewage, and yet these towns were much more unhealthy than London. Most of them had a death-rate from 6 up to 20, and even 40 per cent. higher than London. He lately read the report by Dr. Tripe, of Hackney, giving the statistics of that borough, from which it appeared that the population being about a quarter of a million, the death-rate for six months was 17, which he thought was the finest testimonial to the two water companies supplying that district he had ever seen. Another peculiar thing occurred in the North of England. Many of the towns were formerly supplied by companies, and at that time there were always complaints, but as soon as the corporation obtained the supply, no complaints were heard, and he had no doubt that when the waterworks of London were acquired by some central authority, they would hear very little of the impurity of the water. With regard to the quantity of water to be obtained from the chalk, he had lately tried some experiments in the valley of the Lea, and he was informed that of all the wells already existing, the level had steadily decreased during the last forty years approximately one foot per annum, depending on the amount pumped. One well which he knew very intimately affected another well three-quarters of a mile away to a very great extent, so that he did not think it certain that chalk was a reliable source to supply a large population requiring about 145,000,000 gallons a day. No doubt the steady increase in the number of houses on the constant supply would do good to the quality of the water, and no doubt also the companies would be very happy to give a constant supply, if the inhabitants would like to take it. He knew a case where the supply was 32 gallons per head per day, and on the constant supply it rose to 100 gallons. Manchester got about 17 gallons per head, Liverpool 17, Nottingham 17, Norwich 17, but in London, on the average, it was over 30.

Mr. HOMERSHAM asked what were the precise wells referred to by the speaker?

Mr. BRYAN said he referred to the wells north of the Thames, in the valley of the Lea. He could not give the names, but his informant was a gentleman who had sunk more wells than anybody else, Mr. Docwra.

The discussion was then adjourned.

ADJOURNED DISCUSSION.

Friday, March 21st, Sir FREDERICK ABEL, C.B., F.R.S., Chairman of the Council, in the chair.

Dr. FRANKLAND said he could not compliment the author of the paper upon having arrived at any original conclusion, as he had followed a long succession of authorities who had substantially expressed the same opinions. First of all, they had Professor Brand's Royal Commission, which sat in 1828, and which emphatically condemned the Thames as a suitable water supply for London; and then they had the General Board of Health sitting in 1850, which arrived at the same conclusion. Another Commission, composed of Professor Graham, Dr. Hofmann, and Professor Miller, of King's College, investigated this subject very carefully in the year 1851, and also arrived at the conclusion that other sources of water would be better for London than the Thames. Next they had the first Rivers Pollution Commission, presided over by Sir R. Rawlinson, which condemned the Thames water as being unfit for the supply of the metropolis; and then came the Duke of Richmond's Commission, which reported in 1869, and which gave a modified derogatory opinion of the Thames as a source of water supply, saying that if the sewage were diverted from the Thames, and if the water were efficiently filtered, it would then be wholesome, and fit for the supply of the metropolis. Next came the second Rivers Pollution Commission, of which he had the honour of being a member, which reported in 1874 much to the same effect, and a similar opinion was also uttered by Sir Lyon Playfair, as chemical adviser to the Board of Health. Why, he would ask, was the Thames water not considered suitable for the supply of the metropolis? This was a very serious question indeed. An enormous amount of capital had been spent in the construction of water works, and he must say that he was one of those who did not think that property of this description ought to be lightly meddled with. He thought the private companies who had had the courage to attack a problem of this kind, and to run great risk in embarking their capital in such a project, ought not be thrown overboard lightly when their project had succeeded in producing a good revenue. That was his candid opinion about the position of the water companies. They had the Vestries and the municipal authorities in the metropolis, and it was owing to the parsimony and cowardice of these bodies that they had not themselves taken up the water supply; they waited until some private company had furnished a supply, and then they wished to take it over when there was no longer any risk; but in such cases the companies ought to be liberally treated, if it was contemplated to purchase them under such circumstances. Now what was it that made Thames water unfit for domestic supply? As everyone knew. it was the influx of sewage into the river. Why should sewage make the Thames water unwholesome and unfit for domestic supply? A very large proportion, indeed, of the inhabitants of this country had been in the constant habit of drinking their own sewage or other people's, and they had very often not been injuriously affected by it; it was not, therefore, merely the discharge of sewage into a river which made it unwholesome, whatever might be said upon the sentimental view of the question, which he would not deal with. From a strictly physiological point of view, the admission of sewage into the water supply of a town did not necessarlly affect the health of the inhabitants drinking the polluted water; but if you have fever epidemics occurring upon the banks of such a river, if you have abnormal or infected sewage discharged into it, then you run a very great risk; you run a risk probably proportionate to the number of infected persons contributing to the sewage. At any rate there could be no doubt that infected sewage was most deadly when it gained admission to a water supply. Moreover it must also be borne in mind that infected sewage could not, by any process with which they were acquainted, be disinfected before it was discharged into a stream. It was true that many processes of sewage purification rendered the liquid clear and palatable, so much so that he knew a physician who put effluent sewage upon his dinner table, so that his guests might drink it, and he then asked their opinion upon it, the effluent being clear, transparent, and palatable. All the experiments which had been made had proved in the strictest way that none of these processes could destroy those living germs which propagate epidemic or zymotic diseases. All the processes were more or less efficient in purifying sewage, but they afforded no guarantee that the water so purified would not communicate the disease with which the contributories of unhealthy sewage had infected it. It had been proved over and over again that the bacterial life, of which zymotic organisms were examples, was exceedingly persistent. The germs of bacteria might be boiled for three or four hours and yet not be destroyed. He had himself seen that they continued to exist in an atmosphere of cyanogen; they got on very well in sulphurous acid, in fact there were very few poisons which would affect them. Now, it must be borne in mind that such polluted river water was the raw material with which the companies supplying London from the Upper Thames at the present moment had to deal. As Sir Frederick Nicolson considered that the Thames Conservators had not been sufficiently recognised in the paper, he would willingly say a word in their behalf, for he thought their efforts had been most successful in excluding from the Thames those obvious pollutions which rendered it offensive to the eye, and offensive generally to the senses, though he did not think that their powers were sufficient to enable them to divert sewage from the Thames, or that there was a possibility of so dealing with the sewage of these places that it should not enter into the water supply. The work had been sewage purification, and not sewage diversion, or sewage exclusion. Statistics were utilised by Mr. Bazalgette on the last occasion, and though he was always suspicious of statistics, as an offset to those of Mr. Bazalgette, he would quote two or three with regard to the prevalence of fever in London, and under that head he would class typhoid and typhus, and remittent or relapsing fevers. Of those three separate kinds of fever, typhoid was by far the most prevalent. Beginning in the year 1851, when all the water supplied to London was derived from highly polluted sources, namely, from the Thames between the bridges, and from the Ravensbourne, which was, perhaps, the more polluted, the deaths in that year from fevers reached 20 per week per million of population, which amounted to about

133 attacks per week per million of population. In the year 1861, when all the water companies had abandoned the Thames between the bridges, and had gone above Teddington-lock, and the Kent Company had abandoned the Ravensbourne, and begun to use their deep well water, the deaths from fever fell to twelve per week per million, and the attacks from 133 to 80. Between 1861 and 1871, the metropolis main drainage scheme had come into nearly complete operation; but, notwithstanding this enormous work, the deaths in the year 1871 from fever were not very greatly reduced; instead of twelve deaths per million per week, they were only ten, and the number of attacks fell to 67. Between 1871 and 1881, the water companies had effected great improvements in purifying the water; they had done all that could be expected of them; they were told by Parliament where to go and obtain their supply, and they had, as a rule, done their duty in purifying the water to the greatest possible extent, so that the only complaint that could be made respecting them, was that they had been rather too slow in going to other sources. Many of them were now actively engaged in substituting other sources for the Thames. In 1881, the death-rate from fever was reduced to six per million per week, and the attacks to 40. In conclusion, he would say that the amount of water available in the Thames basin for supplying London was ample for years to come. It was useless to go into statistics as to the rainfall, and the quantity which evaporated, because they had a most trustworthy source of information, in the quantity which flowed over Teddington-lock, which was 400,000,000 gallons per day in dry weather; that quantity represented the yield of spring water from the chalk oolite and greensand above Teddington, and all they had to do was to intercept a portion of this water, to prevent it from going into the Thames at all, and to convey it in a pure and wholesome condition to London.

Dr. Meymott Tidy said it certainly was not his desire to have taken any part in the discussion, and in doing so he yielded most reluctantly to the wishes of those whose opinions he valued. He did not hear the paper delivered, and having read it only within the last forty-eight hours, he had had but little time to arrange his remarks, and therefore must crave indulgence should any want of order or continuity be apparent in his observations. Further, he must beg Dr. Percy Frankland to bear with him, and to forgive him, for the criticisms he should have to offer; they would be offered in all friendliness, but the occasion was one which demanded that he should speak in no unknown tongue. He was bound to say that he had never read a paper so deluged with extravagant partisanship as that which Dr. Percy Frankland had read before the Society; a paper which would entirely undo the very object it was designed to effect. As he apprehended, the view put forward by the author was this. If a river be once polluted by sewage matter, the water of that river was for ever unfit for dietetic purposes, and that no practical distance of flow would render that river safe. The Sixth Report of the Rivers Pollution Commissioners stated this definitely. And here he should like to mention that in future he should call this report Dr. Frankland's Report. Although it was signed by another gentleman, who was well known, Mr. Chalmers Morton, an excellent editor and agriculturist, still he knew nothing about chemistry, as he had often himself admitted. The report was, for practical purposes, Dr. Frankland's, and Dr. Frankland's only. Dr. Frankland said, "We are led to the inevitable conclusion that the oxidation of the sewage proceeds with extreme slowness, and that it is impossible to say how far such water must flow before the sewage matter is thoroughly oxidised." His own view was directly the opposite, and he would state definitely the conclusions at which he had arrived, viz., that when sewage was discharged into running water, after the run of a few miles—the precise distance depending upon several conditions—the whole of the impurities would be removed; and that whatever might be the cause of certain diseases, the *materies morbi* which found its way into the river was destroyed together with the organic impurities. There were three methods by which this purification was effected, the first being what was called subsidence, the forcible carrying down of impurities; the second was the influence of fish life and of the lower forms of life. The remarkable report of Dr. Sorby had shown beyond all question that a large part of the more objectionable constituents of sewage were removed by the unobjectionable action of minute animals. That view, which was so stated by Dr. Sorby, was adopted by the Royal Commission on the London sewage in their report, in which they stated:—"Besides the purification of the river by oxidation, there is evidence of its purification by means of animal and vegetable life; animals of a low type, notably the *entomostraca*, such as water fleas, feed upon the solid elements of sewage. These animals excrete solid matter, but in a diminished amount; the balance is decidedly in favour of purification." Subsidence was admitted as a purifying process by Dr. Frankland. The influence of the lower forms of life, which had been proved by Dr. Sorby, and accepted by the report of the committee, he might take as fairly well demonstrated. As to the third point he would deal with that only, viz., the influence of dissolved oxygen, and of the oxygen set free by the action of plant life on water purification. He had discussed that over and over again with Dr. Frankland, and he had looked in the paper for a single new fact to support the view which his father had advocated, but had failed to find one. Nothing to his mind was more delicious than the manner in which Dr. Frankland absolutely ignored all arguments used, and all the facts proved upon the other side. He would now proceed to argue the truth of his own propositions, and the inaccuracies of Dr. Frankland's, discussing the subject from three points of view. First, as an ordinary observer; secondly, as a chemist; and thirdly, as a medical man; and he would ask whether, regarding it from any of those points of view, Dr. Frankland's theory did not go to the wall. As an ordinary observer, he did not desire any exaggerated importance to be attached to naked eye changes. He was quite ready to admit that bad water was not necessarily bad looking; but when he saw a river at one spot with a black and a slimy bed, containing water turbid, offensively brown or black in colour, without vegetation, except sewage fungus possibly the higher forms of fish life entirely wanting, and then gradually, within a mile or so, changing its character, the bed becoming clean, the water clear, inoffensive, colourless, and full of fish, with abundant vegetation, surely he was justified in saying that that water had undergone some change. Common sense might suggest that the water had improved. Whereas, at one spot, he would not have tasted it, at another place he could drink it without a shudder. That was no romantic sketch. Look at the Soar, at Leicester black, and at Loughborough clear; look at the Irwell, black at Manchester, at Warrington clear; the Colne, at Uxbridge black, becoming within a mile and a-half clear; the stream at Witney, black, and at a mile distant perfectly clear. What could be said of this. He maintained that the common-sense view of this question was not to be despised, even when regarded by the instruments given to them by nature. Judge Dr. Frankland's theories by common sense, and where were they? He would now deal with the matter as a chemist; and here he would limit himself to oxidation. Did analysis confirm the appearances seen by the naked eye, or the reverse? He had given numberless illustrations to prove that analysis did confirm them. For instance, on the Severn, the Wear, the Shannon, and various other rivers. But all these were passed over by Dr. Frankland. Were they discredited? No. He would give another case, and this time he would quote Dr. Percy Frankland:—"I have examined all the tributaries of the Thames," and he mentions the Colne, which he says is richer in organic matter than the Thames at the point where it is joined by these streams. He (Dr. Tidy) knew the Colne better than most people, for very few persons had had the opportunities of examining it which he had had, and he knew where the Uxbridge sewage went in exceedingly well. Where the sewage went in, the organic matter rose enormously. But he knew also the composition of the river before the Uxbridge sewage went in; it had a given quantity of organic carbon, required a given quantity of oxygen to oxidise the organic matters, and contained a given quantity of free oxygen. The sewage went in, and immediately up went the organic matter; up went the oxygen required to oxidise the organic matter, and down went the free oxygen. Three-quarters of a-mile further on, the whole thing again became normal, and the organic carbon, the oxygen required to oxidise the organic matters, and the free oxygen, were absolutely identical to what they were before the sewage went into the river. Dr. Frankland said that the Colne at its junction was not so pure as the Thames, but that statement he entirely disputed, for taking the average of the Colne at its junction with the Thames, it gave ·160 of organic carbon, ·020 of organic nitrogen; while the Thames above the junction gave ·182 of organic carbon, and ·030 of organic nitrogen; so that, as a matter of fact, the Thames was improved by the junction of the Colne, and the magistrates, in dealing with the case before them, were of that opinion. It should not be forgotten that Dr. Percy Frankland and Dr. Frankland had never given any estimations of free oxygen in water. And no doubt there were reasons for that, which he would discuss directly. He would go a little further, in order to see what facts Dr. Frankland had to support his contentions. According to his report, he had made five experiments on three rivers, the Irwell, the Mersey, and the Darwen. Knowing those rivers exceedingly well, he could say that three rivers more pre-eminently unfitted for determining oxidation in running water it would be impossible to imagine. As Dr. Frankland was rather strong upon this point, he would read what he said about it:—"The rivers upon which the foregoing observations were made are notoriously much polluted by sewage and other refuse organic matters; so intense, indeed, is their pollution, that ordinary life is entirely banished from their waters." To this he would add something else, viz., that they are rivers which along their whole course were perpetually receiving constant supplies of impurities, everything being against their regaining purity. What, however, were the results obtained by Dr. Frankland? In two of his experiments he showed that, after a run of a few miles, a decrease of organic elements occurred, to the extent of, in one case 41 per cent., and in another case of 31 per cent. In the other three cases there was an increase. Dr. Frankland did not like these results, because he said—"We deemed it desirable, in order to complete this part of our investigation, to ascertain the effect of a flow of some miles of the water of a river less polluted, and in which animal and vegetable life still flourished; for this purpose we selected the Thames." The analyses of the Lechlade and Hampton samples, which were collected by Dr. Pole and analysed by Dr. Odling and himself, are given. Did they help him? No. Dr. Frankland was in a kind of despair, and so he very properly wrote, "The Thames is not well adapted for the study of oxidisation by flow in any part of its course, but it lends itself most readily to the support of *ad captandum* arguments about oxidisation." Then Dr. Percy Frankland comes to the rescue, and he selected samples on the same day at Oxford, Reading, Windsor, and Hampton. He says, "My analyses show that on the day in question—and on this day the river was in a perfectly normal condition—the water above Oxford contained but a very moderate proportion of organic matter, considerably less than is often present in drinking water; the sample taken below Oxford contained somewhat more, the river having received the polluted water of the Cherwell. The sample taken just above Reading, exhibited a further increase; that from Windsor, more still; whilst the sample collected at Hampton contained a larger proportion than any of those taken higher up the river." This was a single set of samples, but he (Dr. Tidy), had taken similar samples, off and on, for the last three years, and the conclusion at which he had arrived, based upon a series of experiments extending over a long period, was diametrically opposed to that arrived at by Dr. Frankland from this one sample. The case was this. A large river, free and open, moving with rapidity, occasionally, perhaps, lashed into a foam by mechanical obstacles, constant fresh surfaces being exposed to the air, in parts luxuriant with vegetation, and full of fish. In such a case they had rapid oxidation. "No," said Dr. Frankland in substance, "nothing of the kind. Because, if you put a little sewage mixed with a little water into a little bottle, and shake it up, you get no proof of oxidation." To compare a long river with a little water in a bottle brought into contact with a few bubbles of air was not, he urged, a fair comparison. He should not attempt to criticise these experiments further, because a far more able critic than himself had done so, and he would leave Dr. Frankland to fight this question with Dr. Odling. He would not discuss in detail the experiments which he himself had made on running water in a series of troughs. It might be remembered by some that those experiments were made with an enormous amount of care. The water was allowed to run backwards and forwards in these troughs, and the results obtained incontestibly proved oxidation. He was bound to say that in the matter of these experiments he had received but scant justice from Dr. Frankland. To his mind this scant justice and pooh-poohing stamped the value of the experiments. He knew the labour they had cost, and the care with which they had been made, and Dr. Frankland's treatment of them proved that he knew something also of their value. Although he should be the last person to suggest unfairness, still he could not forget that Dr. Frankland had suggested before the Royal Commission that the apparatus used was not constructed in the manner it was, and further, he had read an extract from his (Dr. Tidy's) paper, in which he scarcely showed his accustomed fairness, by leaving off in the middle of a sentence, as if it was a full stop. Dr. Percy Frankland talked of the romance of oxidation. Dr. Frankland had an opportunity lately of stating his views before a Royal Commission, and he stated them at great length, other chemists having done the same; viz., Dr. Odling, Dr. Dupré, Dr. Voelcker, the Chairman, and himself. Were all these romancing? The Royal Commission heard the evidence, upon that Commission there being one of the most distinguished chemists of the present day, Professor Williamson, and the conclusion at which they arrived was this:—"On the whole, the chemical analyses show that there is a progressively increasing impurity in the river from Teddington down to the outfall; the oxygen dissolved in the water exhibits a corresponding decrease where the impurity enters, and *vice versâ*. This shows, not only the impurity of the water at and near the outfalls, but also that the oxygen does active work in oxidising and thus purifying the sewage impurities of the river. Besides the purification of the river by oxidation, there is evidence of its purification by means of animal and vegetable life. The nett result of these complex processes is pollution by sewage, oxidation of the sewage by minute animals, and re-oxidation of the water of the river by animal and vegetable life, and by renewed absorption of oxygen from the air;" and so on. Was this Commission romancing? Dr. Frankland's theories, judged from a chemical standpoint, had been shattered to atoms. Lastly, dealing with the question as a medical man, he knew that he was on the unpopular side, and that Dr. Percy Frankland was upon the popular side. He was upon the unpopular side, because he was not a sensationalist. He did not believe in the bewildering consciousness of ever-present peril, and that all things around and within them were working together for evil. Although neither Dr. Frankland or his son were medical men, they had ventured within the medical arena, and they must take the consequences. Dr. Percy Frankland said, "That water which is polluted, and even with sewage effluents, may at any time carry with it infection, and the water of the Thames is not subjected to any process by the water companies which can ensure the removal of such morbific matter, if present." Again he said:—"It is thus evident, firstly, that the exclusion of sewage matter from a river like the Thames is practically an impossibility; and, secondly, that such sewage matters may at any time be accompanied by the germs of zymotic disease; and, thirdly, that no process to which the water is subjected can remove these germs should they be present." Now let them listen to what his father had said. The following quotation stood alone, and was not in the least degree altered by anything which came before or after it, and he would be very careful not to read the passage with any unfairness. "The supply of such water" (that is the Kent Company's water), "either softened or unsoftened, to the metropolis generally would be a priceless boon, and would at once confer upon it absolute immunity from epidemics of cholera." That was romancing with a vengeance! Now descend to the hard arena of facts. There was nothing more fallacious, said Dr. Frankland, than statistics. Dr. Frankland did not like statistics when they did not prove his case, though he did not mind them when they did. He would give Dr. Frankland's statistics, quoting from the Registrar-General. He says, "In London the high mortality of the week was due to diarrhœa, which always becomes fatal when the temperature of Thames water rises above 65°. In the last week of June it rose to 65°, then to 67°; the deaths from cholera rose from 78 to 156, and 349 in the corresponding weeks; thus the deaths in the last four weeks were 786 in the district supplied by Thames and Lea waters, whereas the deaths in the district supplied with water drawn by the Kent Company from the chalk were 19—the deaths were in ratio of 3 to 1. Again, in the following week ending July 27th, 1878, the deaths referred to diarrhœa and simple cholera, which in the five preceding weeks also rapidly increased from 23 to 249, again rose to 457, of which 336 were of infants under one year of age, and 99 of children one to five years. During the same period (that is to say, the five weeks) "the annual death-rate from diarrhœa within the area supplied by the Kent Company was 1·7 per 1,000, while in the other parts supplied from the Thames and Lea the diarrhœa death-rate averaged 3·7 per 1,000." So that, as a matter of fact, when statistics answered Dr. Frankland's purpose, he took the statistics of three or four weeks. Such statistics he (Dr. Tidy) admitted were misleading. He would not ask them to take the statistics for a few weeks, but for years. The lowest death-rate recorded since 1868 was in the year 1872, and in 1872 the quantity of organic matter in the Thames was, according to Dr. Frankland, higher than it had ever been; the highest death-rate known was in the year 1870, whilst the year 1870 exhibited the smallest quantity of organic matter that had ever been in the Thames. That was rather awkward, especially when looked at from Dr. Frankland's point of view. But to go to larger statistics, he had taken eighteen towns so supplied by wells, having a gross population of 889,000, and eighteen towns supplied by rivers, having a population of 911,000, and had estimated the average death-rate for 14 years. The well towns gave an average death-rate of 22·81, and the river towns 22·68. So that the death-rate was in favour of towns supplied by rivers over towns supplied from wells. With regard to the view taken by Dr. Frankland, as to the absolute immunity from cholera to result from obtaining water from the chalk, all he could say was, he could not understand why the *materies morbi*—inconceiveably minute cellular structures, Dr. Frankland would tell them—should not get through chalk fissures as readily as through the pores of filters. Now as to the question of the London water supply. London, in spite of Dr. Frankland's chemistry and of Mr. Hogg's microscopy, was the healthiest large city in the world. He challenged Dr. Frankland's results about the turbidity of the filtered water. In 1881, his colleague and himself had examined 2,181 samples; clear 1,993. In 1882, 2,110 samples; absolutely clear 2,059. In 1883, 2,224 samples; perfectly clear 2,187. In the three years, 6,515 samples drawn from the mains of the London water companies had been examined, and 6,239 were found absolutely free from all matters in suspension. In some of them there was a slight turbidity, infinitely too minute to estimate. He knew that Dr. Frankland did not like the conclusions drawn by the Royal Commission presided over by the Duke of Richmond. That committee heard everything Dr. Frankland had to say; and here he might be permitted to remark that their report was the most recent, having a judicial character, because he did not admit that the Report of the 1860 Commission was judicial. This Royal Commission having heard all the evidence, the conclusion they arrived at was that they saw no evidence to lead them to believe that the water supplied by the companies was not generally good and wholesome. He knew that Dr. Percy Frankland did not think much of that, but that was the result of a Commission which was judicial in its character. He unhesitatingly asserted that Dr. Frankland had not proved his point, and that no better supply of water could ever be found for London than the supply which at present was drawn from the Thames and Lea. He was now going to say something he could have wished there was no necessity to say. He would tell Dr. Frankland—and some day he would remind him of what he now said—that a time would come when Government would not want his monthly reports. That time would be when they had acquired the property of the shareholders of the London water companies. Depend upon it, the authorities then would be perfectly satisfied with the present supply, nay, would be enthusiastic in its praise. They would no longer ask for words of warning and condemnation from South Kensington. It was said that history repeats itself, and perhaps they would listen to a story he was going to tell. In the year 1876, a certain water company, which Dr. Frankland knew very well, taking its supply from a certain river, came to Parliament for powers to do certain works, and to take a larger quantity of water from this said river. The local authority fought the the company vehemently, and chiefly upon the quality of the water. Foremost amongst their advocates was Dr. Frankland, who stated in his evidence, "I have no hesitation in saying that water contaminated as this is is entirely unfit for domestic supply." The Committee accepted that view, and the company were compelled to sell their undertaking to the corporation. But what had been the action of the corporation since 1876? No doubt every one would suppose, with Dr. Frankland's warning notes of "contaminated supply," "unsafe water," and "dangerous" (for that was the word he used) ringing in their ears, that they would have altered the state of things when the concern got into their hands. Not a bit of it, for at the present time they continued identically the same supply which the company had in 1876, and so perfectly satisfied were they with it, that they had come to Parliament for power to take an unlimited supply from the same river. A curious question which occurred to him was, "Would they retain, or had they retained, Dr. Frankland in their present case?" He did most earnestly implore Dr. Frankland to prevent his deservedly magnificent position, his great name, his high reputation in the annals of scientific research, from being used as levers to bolster up Parliamentary measures, or for the purpose of making political capital.

Mr. CRESSWELL said that, after the startling speech they had just heard, he felt that anything he had to say would sound stale, flat, and unprofitable. The question before the meeting was one of the most momentous ever raised in that room. If the author were correct, it seemed that no time—not a day—should be lost in urging the Legislature to pass an Act absolutely prohibiting the supply of water from the Thames or the Lea. If, on the other hand, he were incorrect, and his conclusions were open to dispute, he was blameable for having raised an alarm unnecessarily, and probably, if they had a hot summer, for creating a panic. He understood from the paper that there were three causes of pollution so important as to render it imperative that no more water should be taken from the Thames to supply the metropolis. The first was that which all recognised, the flow of sewage water in its crude condition into the river above the intake of the water works; second, the flow of sewage effluents from those works which had been erected for the purpose of modifying or removing that mischief; and thirdly, the continued flow, in times of flood, of more or less organic matter from highly cultivated fields in the Thames valley. As to the first, if the decisions of the Uxbridge magistrates were upheld, he feared that instead of diminishing it would be likely to increase, for he could not conceive a greater dilemma than that in which the unfortunate rural Justices were placed in being called upon by the Conservators of the Thames to decide between two learned doctors like Dr. Frankland and Dr. Tidy in such a question. They must, in construing a penal statute, construe it strictly, and he thought they did their duty in refusing to convict. Unless, therefore, the Conservators were able to obtain a modification in the Act, and remove that great defect to which Sir F. Nicolson referred the other evening, by erasing those ridiculous words, "likely to flow into the Thames," for he did not see how it was possible that any solution going into the river could do otherwise—even at Uxbridge water would not flow backwards—these cases would be likely to increase. The second cause of pollution he would leave for a moment, and turn to the third. He did not see how it was possible to avoid that; so long as water flowed by gravitation, and fields in the neighbourhood of the Thames were highly cultivated, that source of pollution would be inevitable. If there was nothing in oxidation or any other principle which would remedy or modify that portion of the mischief, they must be content to bear it, or at once determine not to take the water supply from the river at all. Now, coming to the most important source of pollution, sewage effluent, the paper of Dr. Percy Frankland almost took his breath away. There were three different systems of sewage disposal and utilisation—irrigation, intermittent filtration, and precipitation. With regard to irrigation, they had been taught to believe that that was an infallible remedy for dealing with the causes of disease and destroying the sources of pollution in sewage. He would leave the champions of irrigation to deal with the author on that point. He said it was the best method of dealing with sewage; but he went on to say that there was no guarantee whatever that it would destroy the sources of disease; that these pestilent morbific germs could not be destroyed by any process of utilisation or disposal. Now if that were so, he could not see the use of any sanitary precaution whatever, or of the Rivers Pollution Act, and even of the Public Health Act, so far as adapted to sewage, if no sanitary expedient were sufficient to destroy the sources of disease. He did not pretend to discuss the chemical question, but he was a lawyer, and was accustomed to sift evidence, and he must say he had never yet seen or heard of any such evidence as would convince a reasonable being of the existence of those marvellous germs which were supposed to be present in every effluent. They were probably the minute undefined cause of disease; but as to their habits and habitat, so far as he could learn from scientific men, they knew nothing, and he apprehended, therefore, for all practical purposes, they might be considered a bugbear. Intermittent filtration was also dealt with by the author in the same curt manner, and he said that it would not produce the desired result, and destroy the germs of morbific disease in sewage, which was essential in order that they might carry out the one simple object of preventing the spread of infection by means of excreta of the human body. If it could not be done by this intermittent filtration, how was it to be done? Now he came to the last point, and here he had to say something which he would fain not have said. When the author came to deal with the question of precipitation, he relinquished that calm, placid, philosophic tone which he had before observed. In speaking of the native guano process, to which of course he was obliged to call attention to (for it was one of only two or three which had survived a long list of 36, and, therefore, even on the Darwinian theory was entitled to some respect), in speaking of it he said, "The A. B. C. process has attracted an altogether undue measure of popular attention; probably on account of its very plausible and seductive name, which we can imagine may not be without influence upon the ignorant persons who are frequently entrusted with the management of local sanitation." Of course ignorant persons were always open to delusion, but when Dr. Frankland came to that room, he was well aware that he was not addressing ignorant persons, and he thought to ridicule a company, because some one had given it a nick-name, was not a fair argument to use in such an assembly. Having given that foretaste of the manner in which he was about to discuss the question, he quoted two extracts from a document to be found in the archaic lore of the Local Government Board, which had probably been pigeon-holed for the last twelve years. But the idea of quoting, in 1884, two passages of such a document as the Rivers Pollution Report of 1870, in order to illustrate what the Native Guano Company could do at the present day, was not worthy of the subject or the man. But not satisfied with that, he gave, as usual on such occasions, a diagram showing the results of analyses. On looking at it, he (Mr. Cresswell) thought the result shown to be obtained by the native guano process was very low, but there was something about it which attracted his eye and seemed familiar to him, and on going home he found to his astonishment that of those analyses put before a London audience in 1884, the one relating to the A. B. C. process was taken by Dr. Frankland in 1870 on London sewage. Was it just to the company, or fair and ingenuous to an audience, to treat them with stale, unprofitable analyses of fourteen years ago, in order to demonstrate the inefficiency of a company at the present moment to deal with a great difficulty, and which had spent thousands of pounds in the endeavour? Was it fair to those who were seeking for the truth to be told that estimations of London sewage treated in 1870 were to be a guide to men groping in the dark still in 1884? Was it fair to take such an analysis at all? It was taken on London sewage; and it must be remembered that London sewage was peculiar—nobody knew why; but the Legislature had said it was not to come within the Rivers Pollution Act, he supposed, because it did not pollute the river. Even if Dr. Percy Frankland himself had not been willing to go a little further in his excursion up the Thames, as far as Aylesbury, to see what was actually being done by this company at the present day, he could have found, even in the archives of the Local Government Board, some better test of the merits of the native guano process than that archæological specimen. In the records of that Board, there was an analysis which bore on the question of the evening, which was—Could you precipitate by chemical means organic matter in solution so as to make the sewage effluent fit to be poured into a river which was a source of water supply to a town? It was said that the organic nitrogen and carbon was the test, and he would assume it to be so. Dr. Angus Smith, in a report published in 1879, at the request of the Local Government Board, on various effluents from various processes of irrigation, filtration, and precipitation, made a report on the native guano process. Instead of a diminution of about 33 per cent., namely, from 3·6 to to 2·2 in organic carbon, he found, taking samples over a period of a month, and at times when he was not expected at the works, and when he had every opportunity of obtaining a fair test, that it was reduced from 6·7 to 0·6, or by 90 per cent. With such analyses of organic carbon lying in the archives of the Local Government Board, certified by Dr. Angus Smith, one of the chief inspectors, why should Dr. Percy Frankland, in order to throw dirt at the much-abused, but very meritorious company, parade this ancient analysis? The same analysis showed that the free ammonia was reduced by 75 per cent., in startling contrast to the result shown on the diagram. The albuminoids were also reduced from ·66 to ·07, or very nearly 90 per cent.; and many were of opinion that albuminoids and ammonia were the best test of the polluted or non-polluted condition of an effluent. In conclusion, he might mention a list of men who were part of the large body of ignorant persons who, as the author intimated, were deluded by the jingling name of the A. B. C. process. He had a list of gentlemen who gave evidence before the Privy Council the other day, to the effect that the A. B. C. process was the best yet invented, and in the absence of other means, was the best available process for sanitary engineers. Amongst these names were Mr. Crookes, Dr. Tidy, Professor Wallace, of Glasgow, Professor Way, Mr. Collingridge, sanitary officer of the Port of London, the late Mr. Keates, Major Flower, Mr. Baldwin Latham, Mr. Hawkesley, and the Mayor of Leeds. Those were the ignorant persons among whom he begged to include himself. On one occasion, when Mr. Norman Bazalgette read a most interesting paper at the Institute of Civil Engineers, an illustrious chemist then present said in effect, "I do not approve of this constant habit of flinging and slinging against these precipitation companies. They have at least done good, and even negative results are of substantial value in the cause and progress of science. They serve to indicate the way we should go. It is ungenerous of us to decry and disparage their efforts. They at least have been content to make sacrifices, and have had the courage of their opinions, and I far one, although I am so well known as an advocate of irrigation, declare that we owe a debt of gratitude to these companies, that, like Curtius at Rome, 'plunged into the gulf to save the State.'" The man who made use of that language came before the Kingston inquiry in 1880, and in cross-examination by him (Mr. Cresswell), said he still adhered to every word of the sentence, both in the spirit and in the letter. That man was Dr. Frankland, and he would recommend the sentiment to his son, as showing the proper spirit in which to approach the discussion of this momentous question. Knowing where it came from, he hoped that he would pay respect both to the authority and to the dictum.

Dr. Jabez Hogg said he was much inclined to come to the conclusion that they had not been discussing the question of the paper, but rather indulging in an attack upon the author. The subject of discussion was Dr. Percy Frankland's paper on the Thames as a source of water supply to London; but instead of discussing this, they had got into various inconsistencies of opinion between chemists, scientific men, and trading companies, who were doing their best to prove that effluent water which passed into the Thames is perfectly pure and wholesome. No one would deny that Dr. Tidy was deeply earnest in this question. It was evident that there were two sides to the water question, and he had been much surprised to hear what had fallen from some of the speakers. Dr. Tidy would excuse him for pointing out that he had been discussing one side of the question whilst the author of the paper had been thinking of another. Dr. Tidy, speaking of his process of oxidation, would lead the meeting to believe that that process would do everything in the way of improving a bad water, forgetting to mention that the oxidation he referred to was the oxidation of dead matter, whereas medical men are thinking of quite another thing; they want a mode of killing living matter, the specific organic germs of disease. Dr. Tidy had also fallen into error in supposing these could not be seen by the miscroscope. The new process of staining in microscopy enabled the observer to see, with a comparatively low power, that which was invisible a few years ago, living organisms in millions in every drop of water. These organisms could now be plainly seen, and they were divisible into various species, if evolutionists would permit him to use the word, distinct species, which were palpable, and which were so far believed to be associated with certain specific forms of disease. For instance, the bacillus of tuberculosis was a distinct organism altogether in shape, character, and life history, from the ordinary bacterium known to microscopists. They had here, at all events, a new organism associated with a disease, which was palpable to the eye of every practical man acquainted with the subject. Another remarkable form was the bacillus of splenic disease; and again, the spirillum of fever which affects large tracts of country in India; this was a thing altogether different in character from the bacillus of tuberculosis. It is a spiral form of vegetable cell, and which, when stained violet, could be seen with a very low power of some 250 diameters. It is these living organisms which medical men desire to kill, and which Dr. Tidy, with all his acuteness, has never seen killed by any process of oxidation in a running river. A considerable run would not kill these organisms; he need only refer to the remarkable instance which occurred at Caterham Waterworks, where by the merest accident of one workman suffering from typhoid fever, who went down into the well and worked there a few hours, and defiled the well, thus contaminating hundreds of millions of gallons of water which were pumped out, and distributed to the townspeople round about. Four hundred cases of typhoid followed the next week, and seventy or eighty deaths occurred in consequence. Such cases proved that neither dilution nor oxidation would make bad water good. He readily admitted that oxidation did something for water, but what was stated in the paper was that, if water was infected with typhoid fever germs, it might run any number of miles, and be diluted to any extent, and yet you would have the fever appear in a person predisposed to fever who drank the water. He did not say that every person would take it, but where there was a predisposition, any person drinking infected water would take it. Again, take the improvement of water by *entomostraca*; granted these crustaceans did purify the water to some extent, though not to an equal extent as living vegetable matter. But taking that, they were most active scavengers, what followed? They were found in enormous numbers, and that certainly was a measure of the gross impurity of the water, as without abundant supply of food they would not have multiplied. In Boston, America, on one occasion, these *entomostraca* were so rapidly productive, that a particular form of disease, choleraic diarrhœa, became prevalent throughout the town, and numbers of persons died through drinking these noxious creatures with their water. In fact, many other animals, as frogs, and fish, denizens of the water, were also affected, and died in large numbers. A similar instance occurred in Sweden. There were ample illustrations of the danger to health from drinking contaminated water. With regard to the statistics of visitations of disease, he would confine his remarks to London. Dr. Tidy had referred to a table on the wall which showed that there was a great diminution of disease in a given year; but he had kept out of sight a fact that in London there had not only been watchful care with regard to water, but great attention had been given to every circumstance of a hygienic nature, and the diminution of disease depended more on general sanitation. Typhoid fever, or, as Mr. Simon had called it, dirt fever, was brought into the house through bad drains, neglected drains, or want of proper drainage. It might be propagated by the air as well as by the water; perhaps the greater number of fever cases were due to foul air. Outbreaks of cholera have, however, been most clearly traced to the water supply. Take, for instance, the principal outbreaks in the years 1832, 1849, 1854, and 1866. The mortality in 1832 was very great, the number of deaths reported being 5,275. The population then amounted to only 1,681,641, so that the deaths were at the rate of 31·4 per 10,000. In 1849, the deaths from cholera were 14,137, out of a population of 2,286,800, or 61·8 per 10,000. In 1854, the number of deaths was 10,738, and the population 2,504,198, or 42·9 per 10,000. This was just at the period when the water companies were changing their intake going higher up the river, to improve the quality of the water. In year 1866, when the estimated population was 3,037,991, the cholera slew 5,596 persons or 18·4 per 10,000. The water companies at this time had removed their intake to the Upper Thames, and the water was much less contaminated. The remarkable circumstance connected with the outbreak of 1866 was, that it was much confined to the East-end of London, where it originated, and was indisputably traced to the East London Waterwork Company, then drawing a supply from a very contaminated point in the River Lea. These striking statistics show that in every epidemic visitation of cholera, mortality varied in intensity according to the excremental pollution of the water which Londoners were compelled to drink. The more detailed facts published in the Rivers Pollution Commission must convince the most sceptical of the close connection existing between cholera mortality and the excremental pollution of the water drawn from the Thames. With regard to typhoid fever, too, there were numbers of instances showing that oxidation did not greatly effect the purification of contaminated water, as Dr. Tidy supposed. At Lausanne, a village much resorted to for the purpose of health, having a population of about 800 or 900, there was a remarkable outbreak of typhoid fever. The water supply was obtained from the opposite side of the mountain, and came to the village from two streams. The head of one portion of the stream flowed past six farmyards where typhoid fever prevailed, and joining the other portion of the stream before entering the mountain, and filtering through a rock, principally of oolitic formation, on its way to Lausanne. In doing so, it travelled several miles, so that oxidation had the fullest possible opportunity of improving the water, nevertheless, it came about that 130 people who drank freely of this water contaminated by typhoid fever excrement were attacked, and many died, whilst six other houses in the village provided with shallow wells, and which consequently did not use this water, were not attacked. That showed how difficult it was to deprive polluted water of its power for mischief. Of course in the case of typhoid fever, fewer persons died in proportion to the number attacked than in cholera. The difficulty, however, lay in ascertaining when water was sufficiently oxidised to render it pure enough to drink. They knew very well, with regard to the Thames and the Lea, that in spite of all the efforts of the Conservators they could not keep out sewage polluted water. With regard to the Thames, it had been sufficiently well shown that it was not a safe water supply. He did not say Thames water was always dangerous to drink, but if an outbreak of fever were to take place in the Upper Thames, above the intake of the water companies, it would most certainly infect the whole of the river. The purport of Dr. Frankland's paper was to show that river water was always, more or less, attended with danger to the public health, and that as London paid the best price, it ought to have the best water it could possibly get for its money. He apprehended the real object of the meeting was to enable them to form some clear common-sense notion as to the best mode of improving the London water supply.

The discussion was then further adjourned, to a day to be fixed by the Council after Easter.

The following is an extract from the Judgment of Mr. Justice Pearson, in the case of Ballard *v.* Tomlinson, February 13, 1884, referred to in the paper at p. 440:—

"It is plain as far as regards quantity, one person cannot have, as against his neighbour, the same right to water which a riparian owner has; the right of the lower riparian owner as against the upper riparian owner being that the lower riparian owner is entitled to have the stream sent down to him in the same quantity and of the same quality as the upper proprietor has it at his premises.

"If, then, quantity is taken away, does quality remain? The argument before me has been that it is impossible for the defendant, although he might abstract all the water, to alter the quality of the water in any respect. I must say that I have the most absolute difficulty in following such an argument. If the defendant is at liberty to take away all the water and to deprive the plaintiff of it, I am at a loss to conceive how you can separate the quality from the quantity, and to say that whilst he may deprive him of all the quantity he, nevertheless, must leave the quality as he found it originally; and I come therefore to the conclusion that the plaintiff has no right in the quality of the water any more than he has in the quantity of the water. If I had to determine the exact point as to whether or not an upper proprietor of land, under which at the depth of 300 feet or more there is found to be subterranean water, had a right to deal with that water as he pleased as regards the quality of it, and to have no action brought against him by the lower proprietor with regard to that subterranean water, and change its quality, I think I should without much hesitation decide that in the affirmative, and say that when the Courts have decided that the upper proprietor has the complete control over the water in his premises, that it is impossible to split that control between quantity and quality, and say that he has the control as regards quantity, and he has no control as regards quality."

SIXTEENTH ORDINARY MEETING.

Wednesday, March 26, 1884; Sir ROBERT RAWLINSON, C.B., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Cosedge, Hiram, 16, Clifford's-inn, E.C.
Crickmay, Thomas, 17, Parliament-street, S.W.
Esson, William B., European Telegraph Works, Dalston, E.
Glyn, Hon. and Rev. Edward Carr, M.A., the Vicarage, Kensington, W.
Hughes, Richard Deeton, 12, Bedford-row, W.C.
James, Edward, 22, Westbourne-terrace-road, W.

Kirkpatrick, Robert, 1, Queen-square, Strathbungo, Glasgow.
Lovett, Phillips Cosby, J.P., Liscombe-park, Leighton Buzzard.
Murphy, Shirley F., 158, Camden-road, N.W.

The following candidates were balloted for and duly elected members of the Society :—

Bratby, William, Sandford-street, Manchester.
Byrne, Charles Pitt, B.A., 52, Bedford-gardens, Campden-hill, W.
Fletcher, Thomas, United Telephone Company, Oxford-court, Cannon-street, E.C.
Francis, E. G., 59, Fulham Palace-road, S.W.
Griffith, R. W. S., Eyeworth-lodge, Lyndhurst, Hants.
Johnson, George Stillingfleet, 11, Savile-row, W.
Johnson, Samuel H., West Ham-hall, Forest-gate, E.
Lethbridge, Roper, C.I.E., 19, Clanricarde-gardens, W.
Nightingale, E. W., 139, Denmark-road, Camberwell, S.E.
Rawes, Francis Bristow, Bowbridge Works, Newark-on-Trent, and 13, Brunswick-ter., Newark-on-Trent.
Smith, Surgeon-Major Samuel, Wyndham-house, Kingsdown Parade, Bristol.

The paper read was—

VITAL STEPS IN SANITARY PROGRESS.

By Benjamin Ward Richardson, M.D., F.R.S.

The work suggested to me for this paper, and which I have undertaken at the request of some of the most trusted and respected members of the Society, is to indicate what, in the future, are the lines which the Society should follow for promoting the progress of sanitation.

I propose, therefore, to speak to-night on four vital steps or advancements for the improvement of the national health, including under the term those steps which relate to the life of the people—indirectly of course to their comfort and happiness—but directly to their life—the reduction of their mortality.

These steps are—

1. The physical purification of the people.

2. The radical suppression of those diseases which kill by communication of the affected with the unaffected.

3. The promotion of a better knowledge, and of thrift, and provision of food and drink for the masses.

4. The encouragement of organisation and unity in sanitary administration.

I might introduce many more topics. I consider these sufficient. If we could for, say, four years, concentrate on these four subjects, physical purification, suppression of the devastating diseases, provision of proper food, and organisation of the sanitary work that has been, by accidental progress, carried out, we should be true sanitarians, trenching neither on the medical nor the social scholars.

Fortunately, our Society is able, on all these subjects, to influence public opinion most favourably. Neutral in politics, it has on its Council men of all callings; politicians, lawyers, engineers, architects, statisticians, meteorologists, historians, men of letters, men of business. It has, in a word, every requirement for the study of sanitary discovery, application, administration; and, asking the attention of the Society to-night to the subjects named, and inviting the discussion on them, I shall state plainly my own views, not merely because they are my own honest convictions, but in order that, by plainness of speech, I may draw forth the views of others, either for or against what is said, without reserve.

Physical Purification.

In speaking, a few months ago, on one of the departments of physical purification, I seem to have startled the proprieties of many of the people by the assertion that absolute cleanliness—cleanliness of the body and mind, and all that belongs to them—is the beginning and the end of the sanitary design, and that such perfect cleanliness would wipe off all the diseases which cause at this time the leading mortalities. I do not withdraw from that statement a syllable, and I again place this subject of national purification first on the paper.

Into all the varied studies connected with this argument it were impossible to enter. It will be fittest to take two of the Augean stables which have to be cleansed.

Underground Purification.

The complete removal from our communities, day by day, of all their organic excreta, is still an unsolved difficulty which, remaining unsolved, is a block to every step of perfect purification.

We are are yet distracted with the debate ever going on between the advocates of the combined and the separate system of drainage. Shall all our organic excreta go with the storm-water into the river and sea, or shall the water go to the river and sea, the sewage to the land? Unlike our neighbours on the other side of the Channel, we have agreed to give up the cesspool, and to divide on two questions which they have not, seemingly, admitted, and one of which, that of disposal in running streams, they have long legally prohibited. But, in giving up the cesspools, have we greatly advanced, so long as we pollute the running stream and lose the natural fertiliser of the land? Looking back on all the controversy for the last thirty years, and reading back still further, I feel we have not advanced. I do not think it would be wise to return to the most scientific system of cesspoolage, but I cannot conceive any next worst plan than the plan of passing the sewage with storm-water, even on the most scientific system, into running streams, and of robbing the land of its greatest requirement for its fruitfulness.

I submit, therefore, as a point to be argued out, that this Society can never be soundly assisting sanitation until it assists none other mode for removal of excreta than the separate system.

In saying so much for the separate system I do not, however, wish to contend for the introduction of that system in the hard and unchanging line which some would fight for. I know quite well, from the inspections I have had to make, officially, of different towns and districts, that there are centres of population in which the separate plan, in its rigid application, is not suitable. A town may have no river into which its storm-water can run. A town may have a river, but no land near to it which can be cultivated. These conditions may affect details, while they need not affect the principle. For storm water for which there is no natural outlet, there is always the good resource at hand of storing it for domestic use. For sewage that cannot be utilised on land near to the community which yields it, there is always land not far away which is waiting for it. In these days there need never be necessity for any difficulty in the removal of sewage day by day from the largest centres of population, presuming always that it is not mixed and increased in volume by storm-water. Closed sewage tanks moveable by night train, closed sewage tanks moveable by steam-power on sewage canals and rivers, closed tanks moveable by steam-power on the sea, could convey away all this product for fertilisation, and deposit it where it could administer its full benefits to the earth. Barren portions of our sea-coasts could, by these modifications of the separate system, be made the most fertile and beautiful of all our tracts of vegetation.

To the engineer, when once a system were decided on and declared, these modes of transit, and many improvements on them, would occur. With the engineers it is not our special province to interfere. They exist to carry out what has been determined on, and when they know what the people want, they will do what is wanted, as surely as they will lay down, after the country has said they must, a new railway or a telegraph. We have but to declare the principle, and get it fixed, that every town in England must be cleansed of its organic excreta out and out, day by day, as certainly as it is supplied with the food that is brought into it, and the thing will be done.

Toward such perfection any powerful society, steadily and resolutely devoting itself, would soon be backed up by the common sense of people who require but a competent instructing authority in order to understand the subject accurately. The utter failure of the combined system as a permanent solution of the drainage difficulty, and as a mere transition from the cesspool to the method of removal day by day, combined with immediate and fruitful utilisation, is of itself becoming apparent with such swift conviction, that it will come whether assisted or not by our will and deed. But it were wise to hasten it, and it is one of those pressing practical things which we could hasten effectively, if, irrespective of all interests but true ones, we laid ourselves out for the duty.

At the instance of Mr. Edwin Chadwick—whose name as a sanitarian is a name of the century—we did, some time ago, commence an inquiry here bearing upon the vital point now under consideration. We opened—or, more correctly speaking, we re-opened—the sewage question, and we discerned all at once, although our inquiries were entirely confined to limited areas of London, so much evil, that we rather abruptly closed the evil up again, as if we were frightened at it. It is all in vain, for sewage, like murder, will out, and we must once more proceed. What we did discover was in truth so serious, that the wonder we labour under is how London can be so healthy as it is. We found that London is still honeycombed with what are in fact, if not in name, cesspools, a fact we all practically recognise by the second-hand measures we take to meet the primary blunder.

From the window at which these remarks are written, I see that one of my neighbours, the owner of a large house in our square, has carried out of his house, from the basement, a three-inch tube to above the level of the parapet, in order to deliver into the air any gases that may accumulate in main drain of the residence.

It is not good for the air which I and many others have to live upon, that it should receive the foul air which rises from the decomposition of my neighbour's organic excreta; and if everybody's neighbours did it, it would be detected in some weathers, so that the process must be stopped, as it was in a former day on a recommendation of the Royal College of Physicians. I do not, however, blame my neighbour for what he has done, because I have done it myself. It is a natural species of self-protection amongst those who know best how to protect themselves. My contention is, that the necessity for any such a method is proof demonstrative of the rottenness of the primary system which causes the necessity, and which keeping us foul beneath our houses, makes the air, at its best, foul also above them. My contention is that the decomposition which gives origin to the gases that are let out by thousands upon thousands of channels, by tubes from houses, by soil-pipes within houses, by accidental openings and pores in all directions, by gullies in streets, by great outlets of sewers from accumulations of sewage, ought never to have been generated at all, but that the sewage, removed clean away, hour by hour, many miles from the community, without having decomposed either above or below the living place, should never infect the place nor have any destination except the land which is calling for it, and which dies if its demands be not naturally supplied.

The moment we can, by the skill of our engineers, get our in and out going drainage system as good as our railway system, as true in its working, as continuous and automatic, the most important of all the basic sanitary reforms will have been introduced. Without any stretch of the imagination, volumes might be written on the affirmative side of this proposition. I must be content to put the negative side. I must declare on all heads of experience and observation, that until the basic reform is carried, there can be no sound sanitation at all. I have asked many times, sought many times, for so much as one instance in which the combined system—apart altogether from its loss and extravagance, which might be tolerated if its results were good—has proved a sanitary success. I cannot find one instance of the kind.

The towns which depend on storm-water to flush and inundate their sewers, are like the old mariners who depended on favourable weather for a favourable voyage. The day has passed for that, as it has for a system of sewerage which at all costs must be swept away.

Overhead Purification.

The plan for completest removal of the fluid and solid organic excreta, basic as it is, would not be perfect unless it were attended with the purification of the air above as well as of the earth beneath. Just now the public mind is full of this topic, and Mr. Westgarth's munificent donation to this Society of prizes for plans of reconstruction, will rival handsomely the Health Exhibition itself in the interest it will excite. A clear sky in a place like London; clearer and cleaner streets; the emancipation in close places of one person from the empoisoned breath and emanation of another; room to breathe; these are the blessings which the people are looking to their sanitary deliverers to give them.

We shall have in this Society sufficient work for some months to come in adjudging on the schemes proposed for these intents; we shall be overwhelmed with details; we shall have before us every plan and every model which human ingenuity can devise, to compromise interests, and make necessity the mother of invention. I will not presume to anticipate the judicial labours of the Society for the awards that will have to be made, nor suggest for it any new labours at present in this direction in addition to these, which will, probably, be sufficiently onerous.

I may, however, tell the Society, that if I were going to be one of the competitors for the purification of London through the reconstruction of it, I should propose such a reconstruction as would be, in an architectural sense, perfect revolutionary. I should propose to go up stairs to the top of the houses to do it, and should indicate the construction of another London over head—London-super-Aër.

To convey what I mean, let us move to the best constructed, as well as the most beautiful street of this metropolis, if not of the world—Regent-street—in the part called the Quadrant. That is laid out for such a design as if it had been prepared for the experiment. All the houses are of the same height, and the height throughout is just right for a city like ours. It is sufficient to be handsome and commodious without being overwhelming and without excluding the light from the streets. The roofs of Regent-street, at this part, are flat in comparison with other roofs. They are utilised here and there by photographers' studios, which, although temporary structures, stand firmly and well, in ready communication with the houses on which they are placed. The studio, where it exists, seems naturally to form and become a part of the house. When we glance along the line of roofs, as on a level terrace, the idea of reconstruction of all roofs, and of the re-adaptation of them, becomes most distinct and suggestive. The width of most London houses averages, as near as I can estimate, about 25 ft. from front to rear. Here, then, is good space for a terrace for foot-passage. Imagine along two lines of long streets a terrace of this kind, with handsome railing on each side, and perfectly level floor surface of wood; and, at intervals, light bridges spanning from one terrace to another, and you have an upper-dayLondon which might almost relieve all the pressure from foot traffic in the streets below. Each house would have its own exit, or door, at the upper as well as at the lower parts; and, at convenient spaces, each terrace would be accessible from the street as the Holborn-viaduct is at the present time.

It suggests, at first, a revolution of ideas to conceive such a change. It suggests much out of which a humorist can for a moment make capital. I know all this very well. But there is, in point of fact, nothing more in it than in the first idea of making a tunnel under the streets or under a river. When the suggestion is looked at bit by bit, without prejudice, it offers more of sanitary advantage for the purification of the atmosphere, the protection of property, the comfort of the people in transit, the lodging of the people, the exercise of the young, and the beautifying of the whole city, than could be entertained on a mere general statement of the proposition.

In the first place, for every house in connection with an upper terrace, there would be the most perfect through and through ventilation of air. The staircase would no longer be a closed cupola for holding and storing all the emanations from the basement upwards.

In the second place, the fact of having terraces on the upper surface of London would lead to immediate arrangements for the purification of the air from smoke. So soon as the roofage was accessible as a terrace, from the plan which Mr. (now Sir) Spencer Wells projected for the removal of smoke from every house, by laying down horizontal conducting tubes with central exits and smoke consuming furnaces, would be easily practicable, presuming always that some smokeless fire be not invented, or that coal gas does not become the fuel of the people. These terraces would then be the healthiest parts of London; charged with flowers and trailing evergreens, they would be the empyrean gardens of the great city.

The terraces, with their light intercommunicating cross-bridges in the long thoroughfares, would be more than pleasant foot-ways and shady lanes for the foot travellers, or travellers in light noiseless vehicles, like tricycles; they would be most useful for other purposes. Along them the electric lines would pass and enter the houses direct; and from them the letter carriers would most easily deliver their letters.

These terraces, while relieving the traffic in the streets below, would remove all necessity for the fire-engine, and would make London practically safe from fire. From them water would be supplied readily, a trained police for this upper London being ready at every moment to go down and extinguish fire in every domicile, carrying his hose with him, or plying it from above.

I think that no one who reflects will fail to see that all these changes would be advancements of great value for the health of a city like ours. They are, however, not the chiefest advantages. If anyone will take the trouble to go observingly through the busy parts of London, where there are long miles of roadway—along Whitechapel and Mile-end, for example—he will see the most jagged, hideous lines of roofage. Here a row of houses two stories high; there a row of three or four stories; then a single house five or six stories; and so on, over and over again, like a set of bad teeth. If the plan here suggested were carried out, all this would be rectified. A street like Regent-street expanded into a straight line, would extend from the Marble-arch to the City, and from the City to the extreme East-end. The line of terrace pitched at five stories would necessitate the building up to the same level all the houses in that line, by which at least one-fourth more housage would be supplied, with arrangements for giving comfortable and healthy homes, beyond what now exists, to a fourth of the present population. The suspension cross-bridges would not be without their compound service. They would be bearers of electric lines along their side-ways, and would probably soon be utilised as centres from which electric beacons would be suspended to light the streets beneath.

Imagine the metropolis turned into a fairy land by this adventure of science into the domain of art, and art reciprocating the idea with all her rich resources, and we see in our mind's eye what our children, when we are all of us gone, may really see, and, perhaps, thank us for proposing for their benefit.

Objections will be made about mechanical and architectural difficulties. I heard them all made when the Holborn-viaduct was projected; I saw them all melt away as Colonel Haywood's practical mind came into work, and his unthanked skill and industry and responsibility and genius carried all before him.

It will be objected that flat-roofed houses are not weather-tight. In the year 1825, the then Parisian Asphalte Company roofed two houses with asphalte in Hinde - street, Manchester-square. I lived in one of those houses for twenty-eight years, and a better roof I never knew; but for the London smoke, it would have been made into a garden. Men working upon it, walking over it, communicated no sound whatever into the rooms immediately below.

It will be objected that houses will not bear the weight of super-imposed suspended terraces for foot-walks. If they will not, they ought. In no direction would the sanitary improvement for the purification of a great city be more useful, as a side improvement, than in so reconstructing defective houses as to make them capable of bearing an equalised weight which, carried by many, would, as we know from the bearing of ice, be comparatively light and practicable.

Of the many plans which have been suggested for giving space to crowded cities such as terraces in the streets opposite to first floor windows, and tunnels subterranean—none seem to me to be half so practical, half so likely, to secure the purification of atmosphere as this, which I have now for the first time, after some years' hesitation, ventured to sketch out, not as expecting ever to see such a project realized in my own time, but foreseeing as even a necessity and practicability in the times to come.

Isolation of the Infectious Sick.

The vital step in sanitation to which I have referred as the isolation of the infectious sick, is one which demands all our care, all our encouragement. No earnest sanitarian can be satisfied with the slowness of the progress of arresting these formidable plagues which, so late as 1880, killed in England and Wales in the one year 106,205 out of the 528,624 who died from all the causes of death. By comparing the mortality of the year 1847 with that of 1880, for a table of my book, "The Field of Disease," I find a small difference in favour of the later period, but it is ridiculously small—3·17 per cent.—considering the long labour that has been expended in the study of prevention.

Great noise has been made about the causes of these plagues; much aside speculation of natural history has been bestowed upon them, and some additions to natural history has been gathered, which, no doubt, will be curious as well as interesting in a future day. But of work of practical prevention, work that is of specific, reliable, and rapid application, little has been effected. Yet without any reference to hypotheses of causation, these diseases are most manageable under a proper system of isolation. Dr. Blackburne, writing in 1803, says:—

> "Mature reflection upon the nature and origin of one contagious disease, and the laws and modes by which it is communicated, naturally drew my attention towards the sources of all acute infections. It appeared from this investigation that so strong an analogy pervaded the whole class, respecting their generation and the methods by which they were multiplied or diminished, that a plan for extinguishing the whole race seemed as obvious and practicable as their partial destruction."

The plan proposed by Blackburne was that of isolation of the sick before they became sources of infection. His plan was not original. Twenty-four years previously, viz., in 1779, the renowned Dr. Haygarth had related how, in the school of the Rev. Mr. Vanburgh, at Chester, scarlet fever, contracted by one of the scholars, had been prevented from spreading in a house holding thirty-seven persons, the majority susceptible to the disease, by one act, that of instant isolation of the one imported case.

These facts have been from then till now well known. They have been lessons which medical men, generally, have adopted. In my career in medicine, extending now from 1845, I have profited by such lessons so advantageously, that I can say I have never known a contagious disease spread in any house into which it has been imported, when the means were at my command to completely isolate the first case. Three times in my own house, since I have been in housekeeping, the accident of importation of contagion has unfortunately occurred; it has never spread. There is not one of the common diseases of the contagious class which has not many times come under my observation in single examples, and been checked at once by perfect isolation, when none but the person affected had been exposed to the contagion.

Yet, with such facts before us, we hesitate to follow Blackburne's advice, to stop the whole race of the contagious plagues as we would one of them; to apply whole measures as we do part. The means of suppression are in our hands, and I earnestly urge on this Society to encourage every effort for the complete organisation and support of these simple means. The secret of the success lies in isolating the sick from the healthy at once, by having stations, under the direction of the Medical Officers of Health, for the reception of every case that cannot be safely treated at home.

In putting forward this view, I should propose :—

1. That there should be no aggregation of infectious cases in large central institutions.

2. That every parish should bear its own burthens, and accept its own responsibilities for the retention and management of the infectious cases occurring within its own boundaries.

3. That the sanitary committee or authority in every parish should have all the special centres of infection in each of its districts thoroughly mapped out, and that it should know, on a calculation of cases occurring in quinquennial periods, what is the permanent accommodation required for its infectious sick.

4. That the required accommodation being known, the local authorities should keep ready, at all times, within the parish, such necessary accommodation, by means of small hospitals situated in different parts of the parish or locality.

5. That each hospital should not be larger than is sufficient to receive twenty-four persons at one time, on the separate system; should be constructed of iron, that it may at any time be absolutely purified by fire throughout all its structure; should be placed on the upper story of a building, forming, in fact, the top storey of one or more houses, that it may be lighted and ventilated directly from its roof, all the air that passes out of the hospital when it is occupied by infectious persons, passing through fire; and that each patient should be carried into the hospital by a valved lift, which should pass through a shaft, so as to draw up air during its ascent, and when required, be effective for flushing the hospital with pure air.

6. That the general supervision should be in the hands of the Medical Officer of Health, and that the nursing, also under the supervision of the Medical Officer of Health, should be carried out by trained nurses, who might be educated to their work in the Union Infirmaries.

7. Lastly, that the medical attendance should be conducted by a special staff of duly qualified medical men, acting under the Medical Officer of Health, and responsible to the local authority, by whom they should be approved and remunerated.

Were these vital steps for the management of the contagious diseases carried out for a few years, irrespective of all hypotheses as to origin, the diseases, in another 33 years, instead of dropping 3·17 per cent., might be remembrances of a past and less happy age; remembrances like the sweating sickness and black death, of interest to the scholar and the historian, unknown to the work-a-day world.

In the neighbourhood of great schools for poor children—Board schools — these fever stations are peculiarly wanted. When in Brighton, two years ago, a lamentable rise in mortality scared the public so seriously, the cause of the scare was largely this want. One infectious case, for which there was no ready receiving station, lighted up an outbreak which, in one school alone, gave eighteen deaths within a few days of each other. Three forms of epidemic, scarlet fever, measles, whooping cough, then followed each other, spreading, always from an imported case, through these child communities until there was almost a panic.

Instant isolation would have prevented this catastrophe; would prevent other such; for which reason I place isolation as a vital step in sanitation, in the absence of which there can be no certain check to the devastations of the great zymotic family of disease.

Supplies of Food and Water.

I need not stay to urge this Society to encourage every reform in supplies of food and water. But there are some reforms which are more pressing than others, and these should have our more careful attention.

I urge once again, with all the power I can, the scientific application of the Jewish system of inspection of all our animal food. The broad fact that in the markets of Deptford and Whitechapel alone, the Jewish inspectors, as Mr. Daniel Tallerman has shown, in the year 1880, rejected as unfit for human food—6,143 oxen out of 13,116; 634 calves out of 1,964; 5,535 sheep out of 19,743; and that the rejected carcases were eaten by our people who are not Jewish, is sufficient to indicate that this subject can hardly be over-expressed, or the practice of inspection it suggests over-emphasised.

The inspection of food ought not to be confined to animal food only. It should extend to the vegetable market also. An immense amount of disease, affecting children especially, is produced by unclean and unwholesome fruit. The summer cholera, as it is called, from fruits, is constantly due to this cause, and, as we know, it largely increases the mortality.

There is another subject relating to food for the people which the Society should watch with the object of giving encouragement on every proper opportunity when true advancements are made. I mean vegetable feeding as a cheap, wholesome, and simple system. I am not a vegetarian, and, therefore, I speak without any bias in favour of the system. But as a fair observer I am bound to say that, within these last three or four years, I have witnessed results which, *a priori*, I should not have expected. That a man, by keeping close to vegetarianism, can live well on sixpence a day, and, with sound health of body and mind, go through regular hard work both of body and mind, I have seen demonstrated by an experiment of the kind which has been brought directly under my observation in the most convincing manner.

Such truths, bearing directly on sanitary progress, we, of this Society, cannot ignore. It is our duty to encourage an art which so obviously ministers to the health of the community, and what our course should be towards the movement is plain. We should encourage the scientific development of it. At present the common error of the vegetarian is that he often mistakes quantity for quality, and takes water in what seems to him solid vegetable substance, instead of the parts of food which should build up his tissues, and keep him warm. We should, consequently, encourage instruction in the process of such preparation of vegetable foods as will supply, through them, all the required principles of food. We ought, further, to encourage that chemical art which must one day be reached, and which aims to transmute, in the laboratory, vegetable products into something like the condensed form of food presented by animal structures. Why should thousands of cows be kept, at immense cost and trouble, often in unwholesome sheds, to produce milk, for human consumption, out of the primary elements, supplied ready made by the vegetable world, in grass and clover? Why should not the chemist, from the same or similar primary supplies always existing in the vegetable kingdom, make the same fluid, or the exact equivalent of it, in the laboratory, by a process of faultless purity? It is a simple absurdity, in these days, to use cows as laboratories for the production of a food like milk, every constituent of which we are perfectly familiar with, in regard to its sources, its properties, and its uses, and the parts of which, if the requisite labour were given to the research, could be put together from the vegetable world just as effectively as if they had been through the body of a lower animal, and could be brewed daily in our great cities at less trouble than the beer from the breweries.

I do not want to omit altogether, while I need not dwell on, the subject of water, pure and unlimited, as a vital necessity for sanitation. This is a subject which, of all others, seems to be a natural study in our Society. There is not the slightest occasion, as the recent paper by Dr. Percy Frankland and the discussion on it have shown, to urge attention to it, except in the direction to which I refer in the last and immediate section of my paper.

Sanitary Administration.

To direct the public in matters relating to sanitary administration is a function of this Society of the most explicit character, and one on which its powers can scarcely be too rapidly or too earnestly expended. At this moment every part of sanitary administration, local and central, is chaotic. For nearly a quarter of a century the medical officers of health have been furnishing their reports. These reports are State papers in the true historical sense. The reports of Dr. Armstrong, of Newcastle; Dr. Dudfield, of Kensington; Mr. Wynter Blyth, of Marylebone, and many others which I could name, are local histories from which the writers of another age will collect the choicest and most reliable information respecting the present time. So valuable are these reports, that I would venture to beg every officer to send two copies of each of his reports regularly to Dr. Bond, the chief librarian of the British Museum, so that in the National Library they may be all classified according to time and locality, and be kept there as important parts of the literary treasures of this century.

When, however, we read these reports, we read the chaos which exists in administration in all its fullness. It looks as if all the labour were lost in the helpless confusion that prevails. No man seems to be speaking the other man's sanitary language in regard to administrative recommendations, or to know what the other man thinks, or what the central authorities think, on any matter that is administrative. Some things appear to be wanted which cannot be carried out; other things appear possible which are not wanted at all. One thing most wanted always seems wanting, power for instant action when there is most emergency.

In the next few years, when English statesmen can find time and temper to look at England, these faults must be remedied, and an Act passed which shall comprehensively unite existing local administrations into one great, and consistent, and workable system.

In helping forward this progress, we here shall have to consider, chiefly, the mode of combining effectively the local and central sanitary authorities, and of getting unification in the functions of both. Let me touch for a few moments on one or two subjects bearing first on the local and then on the central reformations, and so conclude.

Constitution of Local Authorities.

I think it good practice, in the selection of representatives of local boards to select from all classes of the community who are eligible for election. I began life with the notion that none but the best informed and most fortunate should rule in sanitary affairs. I have lived to see that if we do not take all classes into our councils, we can do nothing well; and that if we take in all representatives of respectable men, we can do anything that can be done, as they learn their duties and feel their responsibilities, both of which are acquired with remarkable facility. I would go so far as to let women become eligible for seats on local sanitary Boards; for women are by nature sanitarians; they see the lights of health and the shadows of disease much more acutely and keenly than men do. They are quick at suggesting sound and wholesome reforms, and they know infinitely more about the domestic life and the home than men know. When they are well informed and interested in sanitation, they are allies of the first order; while, when they are not informed, and are not interested in reforms, they are opponents which no man and no Board can withstand.

Some general system requires to be introduced for regulating the numbers that shall constitute a local sanitary council in each locality. At present the system, if that may be called a system which has nothing systematic in it, is altogether irrregular. In some places there are too many, in other places there are too few, local health legislators. In the largest places there ought to be one local representative of health to three thousand of the population, as a minimum of representation.

Again, in respect to the selection of sanitary Boards, more care than now exists should be taken to select members to serve in answer to local demands within the district itself. I mean by this that each person elected should have under his particular knowledge and interest his or her particular district, the requirements of which should be at all times before the mind. The district would in this manner be under the most perfect observation, and the Medical Officer of Health would at all times have the most valuable help at his command.

The Medical Officer of Health.

In every local district the Medical Officer of Health should have the true place that belongs to him in all that relates to official action bearing upon health. He should hold to the sanitary department just the same position as the Recorder does to the legal. He ought not merely to be the adviser of his Board, he ought, by virtue of his office, to be the chief and chairman of the sanitary department. He ought to be elected for a definite period; he ought to be upheld in every useful health reform he brings forward; he ought to be encouraged to inaugurate reforms; he ought to be placed in such an independent position that he can inaugurate any reform and correct any evil without being subjected to the risk and personal anxiety of dismissal for good service. He ought, in a word, to be able to put down disease of which he is the medical judge as freely, as unsparingly, as fearlessly, as the legal judge or magistrate puts down crime. Until this is the rule, medical officers of health will remain as mere clerks and chroniclers of disease; suggesters of placebos in sanitation; scapegoats of sanitary blunderers; gentlemen of education engaged by money for incomplete service.

Nor would it, I think—in parenthesis—be quite out of place to go a step further in recognition of national sanitary labours, and to crown those who all their lives have laboured for sanitation, with the same honours as are rendered to the representatives of the ruder and more savage arts. Scientific labours are their own reward, some say. To greatest minds they are. But as Burke so well expressed in his great speech on economical reform, "ordinary service must be secured by the motives to ordinary integrity. I do not hesitate to say that that State which lays its foundation on rare and heroic virtues, will be sure to have its superstructure in the basest profligacy and corruption."

Central Guiding Authority.

A larger share of sanitary work, committed to a larger community, should be accompanied by more certain rules of practice emanating from the central governmental and guiding authority. Such a central authority it is the business of a Society like ours to help to promote and consolidate; and if a committee of the Council were inaugurated to take the initiative in devising the best plan of reconstruction as a suggestion for the nation, it would be doing one of the most useful of national undertakings.

That which is required is a Board or Ministry of Health, distinctive in character and comprehensively simple in constitution. To such a Board should be referred all matters that relate to the health of the people. To it should be entrusted everything that relates to the registration of disease, mortality, vitality, marriage, birth. To this centre should pass for analysis and report all the meteorological records; to it should go for classification and report all the coroners' returns; under its direction the whole subject of adulteration of foods and drinks should be supervised. The inspection of factories should be brought under its control. To it should be transferred whatever is now done by the Veterinary Department of the Privy Council; to it also should be committed the inspection of prisons and of police establishments, in so far as health and regimen are concerned. To it, lastly, should be entrusted the supervision of public works in relation to their sanitary requirements.

You will say that to a central Board as here projected, there would be relegated some portion of the duties of many departments of the State, of the Privy Council, the Home Department, and the Local Government Board, not to go further. That is so, and so much the better. It is because there is so great a dispersion of supervising powers, that so little is done for the community.

A Ministry of Health would bring all work relating to health into a focus. It would ensure capable heads for each department, and it would give to the Government, from time to time, the appointment of a supreme head, or Minister of Health, to whom, not England alone, but our colonies and all the civilised world, would look up with respect; whose judgments would become precedents, and whose annual reports —if they were, as they should be, divested of all political vagaries—would represent the very heart and soul, the potential energy of the nation.

DISCUSSION.

The Chairman said he had paid great attention to the paper, and agreed with much that had been put forward, but on one or two points he might offer a word of correction. There was a central body for the administration of health, and every portion of the kingdom was under a sanitary Board, either urban or rural, which had power to appoint medical officers, and in many circumstances they were appointed. Local authorities also had power to erect infectious hospitals, and many of them were doing so. The separate system was the one acknowledged by the central Board, of which he was the chief of the engineering department, and it was taken up by sanitary engineers all over the civilised world. Miss Nightingale had initiated the idea that the hospitals should always be in excess of requirement to the extent of at least one-fourth, so that each one should lie fallow for at least three months out of twelve, and be thoroughly purified; in fact, no hospital should be continuously occupied by patients as they now were. The question of unwholesome food was of the utmost importance, and the statistics mentioned with regard to the Jews were worthy of attention. We had more knowledge of that race than of any other; it had shown wonderful vitality, and produced, perhaps, more governing and leading spirits than any we were acquainted with; and very possibly this was in great measure due to the care exercised in the choice of wholesome food. As an inspector under the Public Health Act, he had made inspections all over the country, and he could assure the meeting that the amount of unwholesome food consumed was something appalling. The wonder was that so little disease was occasioned by it. No country was farther advanced than England in the matter of water supply, but unfortunately, whatever chemists might say with regard to absolute purity, they were compelled to put up with what nature furnished, for it was impossible to obtain water absolutely pure unless by distillation.

Captain Douglas Galton said the only chance of real progress being made in sanitation was for every one in the community to feel the necessity for it; and he observed that these beautiful theories for the reconstruction of London which were now suggested could only be carried out provided the whole population were thoroughly impressed with the necessity of such efforts being made. Those now proposed were, perhaps, more feasible than the City of Hygeia, which Dr. Richardson described some years ago, but that had been put forward as the ideal that we should aim at. He quite agreed that the separate system of sewage should be adopted whereever it could, but in such large towns as London, there would be immense difficulties in the way; difficulties which had grown with the growth of the city itself. Although, as an engineer, he should be prepared to carry out any task set before him it seemed impossible to imagine that the whole refuse water of the community could be carried away in trucks by railways as suggested. He concurred in the importance of having a central sanitary authority, but we have the Local Government Board; this body might easily be made much more useful and efficient if outlying departments, such as the veterinary department and Ordnance Survey were transferred to it with advantage, but he should be sorry to see any more centralising authority given to it with regard to local action in different towns.

Mr. E. C. Robins, as an architect, could not approve of roadways on the tops of houses, an idea which did not commend itself to him either as a convenient mode of transit or access, or as beautiful in itself. It would also tend to perpetuate a great height in buildings, instead of having the buildings spread wider abroad, and there would be an excuse for not widening the streets and opening out the spaces. It seemed to him that one of the evils of the present day was, that when individual buildings were made thoroughly healthy, such as model lodging-houses, there was a temptation to make them over top every building in the locality, forgetting that the time might come when their sanitary arrangements might not be so perfect as they were now, and the death-rate might prove not so satisfactory. London had one great advantage in its squares and parks, and these should be increased. A great point about Dr. Richardson's suggestions was that hardly any of them could be carried out alone; each involved a whole series of improvements, even the high roadways could not be carried out without getting rid of the smoke, and for the sake of doing that, he should be willing to put up with them. Each thing accomplished would be an incitement to something better.

Mr. Westgarth said he had been much interested in the paper, especially in the first part, which contained much akin to his own ideas for the sanitation and reconstruction of central London, as expressed in the paper he recently read, in which he had adopted the idea of utilising the roofs. Notwithstanding the difficulties mentioned by the last speaker, it seemed to him that, with the vast resources of London, all these things could be easily accomplished if people only had the courage to set about them. Besides the roof-terraces, he thought there should be a terrace arrangement on an upper floor in the business centres of the city, by which pedestrians might pass along without being exposed to the dangers of the streets, in which were now killed about 270 persons per annum, besides a great number who were injured. Then, again, subterranean accommodation was urgently required for gas and water pipes, sewerage, and electric conductors for conveying the newest form of energy, for the development either of light or power, so as to avoid the constant breaking up of streets which now went on. He was not quite so despondent as Dr. Richardson as to these things being done in his own time. The Lord Mayor had taken an interest in his own scheme, and had kindly called a meeting for next Monday to consider it, when he hoped that Dr. Richardson would be present. His great object, at first, was to get the trust or company established which he had sketched out; and as soon as that was done, and a board of management constituted, they would at once proceed, with due reverence, to reconstruct and beautify the old city.

Mr. W. Lascelles-Scott congratulated the Society on the paper which had been read. Some years ago, Dr. Richardson published a series of what might be termed poetical aspirations with regard to sanitation, rather than practical suggestions for the bettering of our lives and homes, and he feared that at that time they created some little prejudice against the author; but to his later utterances, and especially to the eloquent words spoken that night, no such objection could be taken. Having studied for many years the question, not only of how the poor lived, but how they died, he thought the main proposals now put forward were neither so impracticable nor Utopian in character as some gentleman seemed to think. Low rooms, for instance, were not so easy to ventilate as lofty ones, and on the same principle, within due limits, better arrangements could be made of streets if the houses were of a fair height than if they were too low. With regard to the hanging gardens of this modern Babylon, it seemed to him that the mere presence of health-bearing plants on the roofs would be of much benefit, even if every particle of smoke or carbon were not removed. With regard to centralisation, he thought more could be done by well instructed private effort than by imperial centralisation, which would be extremely unpopular. He had paid some attention to the subject of food, and though he had no doubt that large quantities of unwholesome fruit and vegetables were consumed, yet it occurred to him that there was a natural craving for this kind of food at certain seasons of the year, and if the poor could not get the best, they would naturally obtain what they could, and if it were all destroyed, he doubted whether the remedy would not be worse than the disease. The whole tenor of the paper seemed to be that the question of the reconstructed cities of Great Britain was one, not of engineering, chemical, or sanitary science alone, but of nature herself, and if it were approached in that spirit, not in a spirit of narrow dogmatic theorising, no doubt by degrees immense good might be accomplished.

Mr. H. DOULTON had been much pleased with the paper, for it was always well to have an ideal before one. The principle of the rainfall to the river and the sewage to the land had always struck him as the right one, though no doubt there were many practical difficulties. He did not much like the idea of these flat roofs, for a beautiful or picturesque sky-line seemed to him far preferable. Nor did he like the idea of abolishing cows. There was, besides, it seemed to him, one important omission in the paper, and that was all allusion to the importance of preserving open spaces in and around London. Twenty-five years ago, Kennington-common might have been enlarged by many acres for a very small sum of money, but the apathy which then prevailed on this subject was astounding. When he first went to live at Tooting-common, the manorial rights over sixty-three acres were sold for £1,400; the right of the purchaser to enclose that land was contested, and about £13,000 or £14,000 were spent in litigation over it, which might have been all saved if those manorial rights had been purchased on behalf of the public. During the fight, however, he was glad to think that something was done which prevented the enclosure of commons in the neighbourhood of London for the future. At that time, he remembered that the then member for East Surrey, Mr. Alcock, who was the owner of Banstead Downs, said, that if there were any public body which had power to deal with open spaces and manage them, he would willingly give fourteen acres to the public for ever. But there was nobody to take the matter up, and now that beautiful spot was crowned by a hideous lunatic asylum. He would urge, therefore, the importance of preserving the open spaces which remained, and also of converting disused grave-yards into gardens and playgrounds, as had been done in Lambeth, with very great advantage.

Mr. WOLSTENCROFT drew attention to the question of infectious diseases being spread by means of laundries, which he suggested should be inspected and licensed. He also mentioned an invention by Mr. Buck for collecting rain water from house tops in a comparatively pure state, the first washings from the roofs being sent down the drains, and the remainder stored for use.

Mr. LIGGINS said he would venture to make a few remarks from the point of view of a vestryman of Kensington. There was a great variety of houses in that parish, and it was always the desire of the Vestry to do their best for their poorer neighbours, but in many cases they wanted more powers. With regard to the elevated terraces, he thought on such weather as the present, with a cold east wind, he should much prefer the shelter of the streets. Perhaps the greatest objection to them, however, would be the smoke, and he was glad to hear of another suggestion for getting rid of it. Dr. Dudfield's monthly reports were most valuable, and as far as the law allowed, the isolation of the sick was enforced in Kensington, but people had a great objection to their sick relatives being removed to hospitals, and he was not aware of any power to enforce such isolation. He also drew attention to some papers on the housing of the poor, which appeared in the *Nineteenth Century* recently, but took exception to the statement by Mr. Forster that no more law was required. There was power to turn people out of unhealthy dwellings, but it was out of the question to do so in many cases until other accommodation in the neighbourhood was provided for them, and that was a very large and difficult subject.

Mr. HENRY MAUDSLAY said there was one point not touched upon which seemed to him of some importance, viz., the distribution of population. If this could be better arranged there would be less disease, the hospitals would be less crowded, and Miss Nightingale's suggestion could be carried out; but so long as there was a superabundant population congregated together in particular districts, he did not see how the condition of things could be much improved. He had travelled all round the world, and in nearly every part of it, and found that there was plenty of room for our surplus population in places where there was abundance of animal and vegetable food to be consumed. If our population could be distributed in those lands, with its existing knowledge, Christianity, and energy, and with the power of communication by steam and electricity, immense benefits would result. If the Government would only put on board the vessels now lying idle some of the surplus population, and if the various parishes would contribute so much per head for those willing to emigrate, and to assist those willing to be assisted in colonising our own possessions, the sanitary condition of this country, and especially of the metropolis, would be so far improved, that the system so beautifully expounded by Dr. Richardson would soon become a possibility instead of an ideality only.

Dr. RICHARDSON, in reply, said he was very glad to hear the Chairman express his approval of the separate system of drainage so decidedly. The Chairman had always supported it, and no doubt the time would come when he would have his reward in the general recognition of the principle. He did not wish to say a word against the Local Government Board, the duties of which he thoroughly believed were well carried out; but there was so much which now lay outside its sphere, which ought to be combined with it, that at present everything was in a state of chaos. A Medical Officer of Health often did not know what to state or where to apply for information, and very frequently he was thwarted in his administrative duties. For instance, there were factory surgeons, who had certain functions under an Act passed early in the century—probably the first sanitary Act ever passed; they had to inspect children and determine the conditions under which they were to work in factories, and with regard to those duties they had the very best means of information; but, he believed, that if an epidemic broke out their function in respect to that was gone, and the Medical Officer of Health could step in. The centralisation which he advocated was not to force upon people any measures for which they were unwilling, nor to interfere with local legislation; but a centralisation to supply information, and thus bring about unity and harmony. He did not know that a Minister of Health should have power to enforce anything; the local authority should have the power, and the central authority should be the guide. Mr. Robins objected to upper London on account of the height of the houses, but that was not a part of the project at all. This suggestion applied to houses of the same height as those in Regent-street, which was about the proper height, and as to the idea of spreading the houses farther apart, they knew that with regard to the poorer population that was one of the greatest difficulties; the farther the poor were taken from their work the more time they had to spend in going backwards and forwards. So long as great cities existed, and it seemed a natural instinct for men to congregate in cities, it should be their aim to make them as healthy and beautiful and accessible as possible. He did not agree with too much extension, or they would have London extending all over the country, which was not at all desirable. He only wished he could set Mr. Robins to work to make the first roadway along the roofs, for he was sure it would be a beautiful work of art, which would immortalise him. Mr. Westgarth was more hopeful than he was, but in many points they were at one. Mr. Scott seemed to find a little fault with his earlier speculations, and to think that with increasing years he was getting wiser. He hoped it was so, but he could not admit that his ideal city of Hygeia had been useless. The intention with which he put it forward had been thoroughly carried out. In writing that project, of course he had no idea of its being instantly realised, but some people who read it thought it was real, some wrote to ask where the city was, and one gentleman declared he had seen it. The truth was, that he had remarked for years that the subject of sanitation did not seem to bite, so to speak; people were apathetic about it; they treated it as a disagreeable subject, connected only with drains and pipes; and so he thought he would strive to give it a start in a new way by drawing a picture of what might be. That picture had been exhibited, not only all over the country, but all over the world, and from the most distant colonies he had had letters thanking him for it. In Lancashire it had been printed with the "Pilgrims' Progress" and sold for 1d. It gave the public a taste for sanitation, and the result was that Hygeia was rising up everywhere, you saw a little bit of it in one house and a little bit in another. Jules Verne, in his own inimitable way, had constructed another city, which he said he had copied from it, and so the thing spread, and in time it would be all realised. Mr. Doulton objected to unbroken sky-line, and no doubt it was well to have a sky-line broken by towers or minarets, or domes like the dome of St Paul's; but when you walked along Whitechapel, and saw the sky-line there formed of irregular, dirty, and ugly houses, he should much prefer such a line as Regent-street, with a beautiful terrace and gardens on the top. He agreed with Mr. Doulton entirely as to open spaces and disused graveyards, and for years he had been endeavouring to get two of the latter in Marylebone converted into playgrounds. The question of laundries was very important, and though they might not be licensed, they would be all the better for voluntary inspection. With regard to the inconvenience of east winds on the terraces, he did not propose that any one should be compelled to walk there who preferred the streets; but he should prefer the top, especially when the weather was clear and the atmosphere free from smoke. He was glad to hear that isolation of sickness was carried out so thoroughly in Kensington, which was known to be one of the best sanitary districts. He quite agreed that, so far as population could be distributed throughout the planet, so far sanitation would prevail, presuming always that that distribution was on sound sanitary principles. But in proportion as that distribution did take place, so there would be again an increase of the human family, and therefore it was important that we, who considered ourselves the *crême sur crême* in sanitary knowledge, should set such examples as the coming nations might usefully copy and improve.

The CHAIRMAN then proposed a vote of thanks to Dr. Richardson, which was carried unanimously, and the meeting adjourned.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, eight o'clock:—

APRIL 2.—"The Dwellings of the Poor of Great Cities." By ELIJAH HOOLE. His Eminence Cardinal MANNING will preside.

The arrangements for meetings after Easter will be announced in the next number of the *Journal.*

Foreign and Colonial Section.

Tuesday evenings:—

April 1.—"The Rivers Congo and Niger entrances to Mid-Africa." By Robert Capper, Major-General Sir Frederick John Goldsmid, K.C.S.I., C.B., will preside.

Indian Section.

Friday evenings:—

March 28.—"Trade Routes in Afghanistan." By Griffin W. Vyse.

Cantor Lectures.

The Fourth Course will be on "The Alloys used for Coinage." By Prof. W. Chandler Roberts, F.R.S., Chemist of the Royal Mint.

Lecture III. March 31.—Methods by which Accuracy of Weight and "Fineness" of the Alloys is ensured.

Lecture IV. April 7.—Questions connected with the liability to Reduction in Weight and various Coins by Wear during Circulation.

MEETINGS FOR THE ENSUING WEEK.

Monday, March 31...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. W. Chandler Roberts, "The Alloys Used for Coinage." (Lecture III.)

Farmers' Club, Inns of Court Hotel, Holborn, W.C., 4 p.m. Mr. E. Packard, jun., "Experimental Farms."

Chemical, Burlington-house, W., 8 p.m. Anniversary Meeting. Election of Officers and Council.

Actuaries, the Quadrangle, King's College, W.C., 7 p.m. Mr. T. B. Sprague (President), "Some Remarks on the Application of the Principle of Non-Forfeiture to Ordinary Policies."

Institute of Agriculture, Lecture Theatre, South Kensington Museum, S.W., 8 p.m. Prof. G. T. Bettany, "The Germination of Seeds."

Medical, 11, Chandos-street, W., 8½ p.m.

Tuesday, April 1...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Foreign and Colonial Section.) Mr. Robert Capper, "The River Congo and Niger Entrances to Mid-Africa."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. A. Gamgee, "Animal Heat, its Origin, Distribution, and Regulation." (Lecture V.)

Central Chamber of Agriculture (at the House of the Society of Arts), 11 a.m.

Civil Engineers, 25, Great George-street, Westminster, S.W., 8 p.m. Mr. William Foster, "Experiments on the Composition and Destructive Distillation of Coal."

Pathological, 53, Berners-street, Oxford-street, W., 8½ p.m.

Biblical Archæology, 9, Conduit-street, W., 8 p.m. 1. Dr. Chotzner, "Notes on the Life and Social Position of the Hebrew Women in Biblical Times." 2. Rev. A. Löwy, "Technological Terms (Hebraic and non-Hebraic) marking the Progress of Ancient Culture."

Wednesday, April 2...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Elijah Hoole, "The Dwellings of the Poor of Great Cities."

Institution of Naval Architects (at the House of the Society of Arts), 12 noon. Annual Meeting. Address by the President, to be followed by the Reading of Papers and Discussion.

Geological, Burlington-house, W., 8 p.m. 1. Rev. E. Hill, "The Rocks of Guernsey." With an Appendix on the Microscopic Structures of some of the Rocks, by Prof. T. G. Bonney. 2. Prof L. C. Miall, "A New Specimen of *Megalichthys*. from the Yorkshire Coalfield." 3. Dr Bunjiro Kotô, "Studies on some Japanese Rocks."

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m. 1. Prof. Redwood, "Aqueous Extraction of Cinchona Bark." 2. Dr. Thresh, "Proximate Analysis of the Seeds of the *Amomum Melegneta*."

Entomological, 11, Chandos-street, W., 7 p.m.

Archæological Association, 32, Sackville-street, W., 8 p.m. Rev. S. M. Mayhew, "Tenby, and the Cathedral of St. David's."

Obstetrical, 53, Berners-street, W., 8 p.m.

College of Physicians, Pall-mall East, S.W., 5 p.m. (Lumleian Lecture.) Dr. James Andrew, "Ætiology of Phthisis." (Lecture II.)

Thursday, April 3...Institute of Naval Architects (at the House of the Society of Arts), 12 noon. Morning Meeting. Reading of Papers and Discussion. 7 p.m. Evening Meeting. Reading of Papers and Discussion continued.

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Prof. P. M. Duncan, "A Revision of the Families and genera of the *Sclerodermic Zooantheria*, the *Rugosa* excepted." 2. Mr. Charles F. White, "Pollen from the Egyptian Mummies." 3. Mr. T. J. Briant, "The Anatomy and Functions of the Tongue of the Honey Bee."

South London Photographic (at the House of the Society of Arts), 8 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Prof. Tyndall, "The Older Electricity, its Phenomena and Investigators." (Lecture VI.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Special Meeting.) Captain Andrew Noble, "Heat-action of Explosives."

Mathematical, 22, Albemarle-street, W., 8 p.m. 1. Prof. Cayley, "Double Algebra." 2. J. W. Russell, "A Direct Investigation of the Equation $F(x, y, z, p, q) = O$, with a Way of Remembering the Auxiliary System." 3. J. J. Walker, "The Floatation of a Triangular Prism."

Friday, April 4...Institution of Naval Architects (at the House of the Society of Arts), 12 noon. Morning Meeting. Reading of Papers and Discussion. 7 p.m. Evening Meeting. Reading of Papers and Discussion continued.

United Service Inst., Whitehall-yard, 3 p.m. Colonel Sir Charles B Nugent, "Imperial Defence. Part II.—Colonial Defence."

Royal Institution, Albemarle-street, W., 8 p.m. Prof T. G. Bonney, "The Building of the Alps."

College of Physicians, Pall-mall East, S.W., 5 p.m. (Lumleian Lectures.) Dr. James Andrew, "Ætiology of Phthisis." (Lecture III.)

Geologists' Association, University College, W.C., 8 p.m.

Philological, University College, W.C., 8 p.m. Mr. A. J. Ellis, "The Dialect of the Lowlands of Scotland Part II.—Insular.."

Saturday, April 5 ..Botanic, Inner Circle, Regent's-park, N.W., 3¾ p m.

Royal Institution, Albemarle-street, W., 3 p.m. Captain Abney, "Photographic Action considered as the Work of Radiation." (Lecture VI.)

Journal of the Society of Arts.

No. 1,637. Vol. XXXII.

FRIDAY, APRIL 4, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

DEATH OF H.R.H. PRINCE LEOPOLD, DUKE OF ALBANY.

At a meeting specially summoned for the purpose on Wednesday last, 2nd inst., the Council of the Society passed the following resolutions :—

"The Council of the Society of Arts desire humbly to offer to her Most Gracious Majesty the Queen the assurance of their profound sympathy on the occasion of the sudden and untimely death of His Royal Highness Prince Leopold George Duncan Albert, Duke of Albany, and their sorrow at this unexpected termination of a career so full of promise.

"The Council had confidently anticipated that, as one of the Society's Vice-Presidents, his Royal Highness, following the example of his distinguished father, would have rendered valuable aid in the advancement of those liberal arts and sciences for the promotion of which the Society was founded, and to whose study his Royal Highness devoted so much of his powers.

"The Society of Arts have, therefore, special reason to deplore the loss which they, in common with all her Majesty's subjects, have sustained."

"The Council of the Society of Arts desire to convey to his Royal Highness the Prince of Wales, the President of the Society, the expression of their deep regret at the heavy loss his Royal Highness has sustained by the death of his beloved brother, his Royal Highness Prince Leopold George Duncan Albert, Duke of Albany.

"While thus assuring his Royal Highness of their profound sympathy, the Council wish also to express their sorrow that they find themselves deprived of the prospect of that efficient aid which the distinguished abilities of his Royal Highness the Duke rendered him specially capable of affording the Society in his capacity as Vice-President."

"The Council of the Society of Arts desire sincerely to condole with her Royal Highness the Duchess of Albany in the sad bereavement she has sustained by the sudden and unexpected death of her beloved husband, and respectfully to assure her of their profound sympathy on this melancholy occasion."

INTERNATIONAL HEALTH EXHIBITION SEASON TICKETS.

The Executive Council of the International Health Exhibition have consented to allow Members of the Society of Arts the privilege of purchasing Season Tickets for the Exhibition at half-price (10s. 6d.). Each Member will only be allowed the privilege of purchasing a single ticket on these terms, which will be a personal admission, not transferable. Season tickets admit to the opening ceremony. As soon as the tickets are ready, due notice will be given in the *Journal*.

CANTOR LECTURES.

The third lecture of the course "On the Alloys used for Coinage," was delivered on Monday evening, 31st ult., by Professor W. Chandler Roberts, F.R.S. The history of the various methods of assaying gold and silver, from those officially adopted at the time of Pliny to the present day, was traced in detail, special attention being devoted to the gradual steps by which the minute accuracy that marks the present methods had been attained. For instance Geber, who wrote in the 8th century, gives, if mediæval translations of his works are to be trusted, a sufficiently accurate account of the method of the assay of silver by cupellation to enable the process to be conducted at the present day with no other aid than his, but his description more nearly corresponds to the cupellation of silver, as conducted on a large scale with a view to extract silver from lead, than to a mere method of assay. In the 12th century the assayer was instructed, in conducting official trials of the coin, to take an entire pound weight, and it was not until the reign of King Henry VI. that a record is found of small quantities being taken for the trial; at this later period, however, about twelve grains, or nearly the amount used at the present day, was used. The work of Sir Isaac Newton was alluded to, and the furnace with which he is supposed to have cupelled silver, in the Tower of London, was exhibited. After the history of the method of assaying gold had been dealt with, Professor Roberts showed how small a portion of the "remedy" or variation from the exact standards of weight and fineness, allowed by law, is actually used at the present day in Mints. He concluded by saying that these questions might appear to be somewhat abstract and unimportant, but that all questions connected with alloys, used for coinage, must have had a very vivid interest for those who lived at the period embraced between the reigns of King Henry VIII. and Queen Elizabeth, when the coinage was extremely debased, and at the present day the question was of hardly less importance, because vast commercial transactions were based on the integrity of the British gold coin.

ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal for 1884, early in May next. This medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce." The following is a list of those to whom the medal has already been awarded:—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S.

In 1865, to his Imperial Majesty, Napoleon III.

In 1866, to Professor Michael Faraday, D.C.L., F.R.S.

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S.

In 1868, to Mr. (now Sir) Joseph Whitworth, LL.D., F.R.S.

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, &c.

In 1870, to M. Ferdinand de Lesseps.

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B.

In 1872, to Mr. (now Sir) Henry Bessemer, F.R.S.

In 1873, to M. Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France.

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S.

In 1875, to M. Michel Chevalier.

In 1876, to Sir George B. Airy, K.C.B., F.R.S.

In 1877, to M. Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France.

In 1878, to Sir Wm. G. Armstrong, C.B., D.C.L., F.R.S.

In 1879, to Sir William Thomson, LL.D., D.C.L., F.R.S.

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S.

In 1881, to Professor August Wilhelm Hofmann, M.D., LL.D., F.R.S.

In 1882, to M. Louis Pasteur, Member of the Institute of France, For. Memb. R.S.

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S.

A full list of the services for which the medals were awarded was given in the *Journal* of March 14th.

The Council invite members of the Society to forward to the Secretary, on or before the 19th instant, the names of such men of high distinction as they may think worthy of this honour.

Proceedings of the Society.

INDIAN SECTION.

Friday, March 28, 1884; ANDREW CASSELS, Vice-President of the Society, in the chair.

The paper read was—

ROUTES THROUGH AFGHANISTAN.

By GRIFFIN W. VYSE.

I shall endeavour, in my paper this evening, to refute some of the statements recently made regarding the trade of, and routes through, Afghanistan. It seems hardly credible that one of our leading journals should have stated, only a few weeks ago, that there are only two passes from Afghanistan into India, that there is no trade in that country, which is a land of rocks and stones, and its people unfriendly to our rule. It is true that, until the late Afghan war, we knew of only three or four passes leading from India into Afghanistan, viz., the Khyber, Gûmul, Sanghar, and Bolan, but we now know of the existence of 289.* North of the Khyber two good roads exist, and between that pass and the Bolan lie all those celebrated routes dis-

* Q.M.G. Department: Intelligence Branch (confidential).

tinguished as being about the oldest highways in the world, traversed for thousands of years by the countless generations of the early traders (for the wealth and riches of India were transmitted to the great emporium of the west when Babylon was at the height of its glory), and traversed, too, by the hordes of conquerors who have poured into India from the steppes of Central Asia, the plains of Persia, or far-off Macedonia.

These old routes subsequently became for centuries the haunt of the most blood-thirsty determined robber tribes ever known, so that in modern times the Kafilas and trade convoys were compelled to abandon most of them for the more circuitous, but safer, lines of travel. Cleared of marauders, however, and under British control, they would doubtless become, as formerly, the chief roads for trading caravans from India to the heart of Central Asia.

Fertile and populous, India, with its enormous mineral wealth and varied products, has from pre-historic times, had a fascinating charm for the hardy adventurers of the North. Hindustan was the goal of their keenest ambition, and countless armies, and millions of the human race have been sacrificed in winning, or trying to win, that land of gold, the richest and brightest gem of Asia. Some of the fiercest battles on record have taken place along many of these Afghan routes. The very extensive graveyards, on almost every peak, pass, and gorge, prove that the country must have been at one time densely populated. One large grave-yard I saw in the deserted Luni Valley measured more than three square miles; it had been the battlefield of Biluch and Afghan tribes for over a hundred years.

Nearly all the great conquerors of India came from Central Asia and Persia. The roads chosen by Alexander, Baber, Nadir, and many other invaders, are still open, and all the routes, whether from Persia or the Oxus, converge upon Kandahar.

The chief trade routes are from Bokhara and Samarkhand, *viâ* Merv and Herat to Kandahar; from Persia, *viâ* Meshad to Herat; from Bokhara, *viâ* Karshi, Balk and Khulm to Kabul; from India, *viâ* the Khyber to Kabul; from the Punjab, through the Kûrûm Pass; from India, by the Gûmul to Ghuzni, to Kelat-i-Ghilzai, to Kandahar and Quetta; from Sind, *viâ* the Bolan to Quetta and Kandahar; and from East Turkestan by Chitral to Jellalabad, or to Peshawur, *viâ* Dir; and this latter route from East Turkestan is now a very good one.

Many of the old abandoned trade routes, supposed to be blocked or impassable, I have been through when field engineer with one of the columns, during the late war, and found them open, and capable of being used by all arms of the service, mountain artillery included. Extensive "deserts," so-called, on the map, we found rich fertile soil, watered by perennial streams, and capable of being turned into vast gardens; other parts of the country, marked "unexplored, supposed waterless tract," proved to be magnificent high plateaux 3,500 feet above the sea, where water was in abundance, the climate most agreeable, and where the land was ready for the plough.

Afghanistan is bounded on the north by the ancient Oxus, south by Biluchistan, east by British India, and west by Persia. Its length is about 900 miles, and its breadth about 600, which, in round numbers, gives a superficial area of 540,000 square miles; but although the late Amir Shere Ali was nominally sovereign over the whole of this territory, yet the present Amir's power does not extend over one-fifth of it. The semi-independent Khanates south of the Oxus, and the really independent tribes who dwell between our border and Afghanistan proper, such as the Waziris, Luni-Pathans, and the people of Kafiristan, defy the present Amir's authority, and the revenues through these provinces can only be occasionally and partially collected by force of arms, as also in the Kûrûm, Khost, Kakar, and the Hazara country.

There are, officially or theoretically, eight provinces in Afghanistan—Kabul, Jellalabad, Yusufzai, Seistan, Ghuzni, Kandahar, Herat, and Balk; but owing to clan feuds, it is deemed expedient, for the safe protection of the trade routes, to work by tribal divisions rather than by Government provinces.

Kabul is extremely mountainous, and the vast rugged mountain ranges north of Kabul, some of which are among the highest in the world, are an off-shoot of the "Bam-i-dunya," or "Roof of the World," and may, from their impregnability, be regarded, with the Hindu-Khush, as the natural boundary of India and Afghanistan. The Suliman mountains, running south towards the Indian Ocean, are of great geographical importance, and are full of interesting historical associations, from their having contained the old world's routes to the rich empire of Hindustan. From these, countless spurs of minor importance are formed, principally in parallel ranges, with lofty peaks, and deep gorges, through which the rivers flow towards the Indus, and these river-beds formed the old trade routes. The country between consists of many transverse ridges, parallel valleys, and remarkably fertile plateaux, where there is a grand field for the antiquarian, rich in archæological vestiges of lost cities and lost nations. The same is true of the country lying between that network of old routes in the Sulimans, and the road from Kabul to Kandahar, made ever famous by Roberts' brilliant march and complete victory over that renowned Asiatic soldier, Ayoob, in 1880.

The plants on the east of the Sulimans yield the sacred *soma* juice and wood mentioned in the Rig-Veda hymns, and give silent but unerring identification of the roads by which, says Markham, the earliest Aryan settlers found their way into the Valley of the Indus. It was by the perilous route on the northern face of the Safid-Koh, that the early Chinese pilgrims reached the revered sites of Gautama's ministrations, and by the same way the Greeks marched to the conquest of the Punjab.

About the year 999, Mahmûd of Ghuzni, with 15,000 horsemen, marched through the Kabul route, and returned by Sakki-Sawar. Mahomed Ghori traversed the Zhob route in 1191, and his general, Ilbuz, kept open the various routes from the Indus to Ghuzni, *viâ* the Kûrûm Pass. Down the same pass, says Markham, the heroic Prince Jalâlû-d-Din was hunted by Chingiz Khan, and driven into the Indus. The conquering Timour used the Kûrûm for the invasion of India. Baber, the founder of the dynasty of the Great Moguls, used the Khyber, Gûmul, Sakki-Sawar, and Sanghar Passes; he was the first geographer among the conquerors of India, and his descriptions are faithful and masterly. Baber's descendants afterwards reversed the current of invasion, and scaled the Sulimans with an Indian army; thus the Emperor Jehanghir marched through the Zhob and Tal-Chotiali routes to Kandahar, but the tide soon turned again, and in the last century, Nadir Shah and Ahmed Durani led conquering hordes down the Khyber, Pishin, and Bolan Passes; while in our own day British troops have renewed Jehanghir's experience in advancing from India by these very routes.

The chief rivers are the Oxus (or Amu Daria), a noble river capable of being made navigable; the classic Helmund (the river of ancient Persian tales, as related in the pages of Ferdosi) is navigable from Girishk to Nâdalî, and could be made so throughout its lower reach; and lastly, the Indus, which in Afghanistan is merely a torrent such as can be forded, except during floods or melting of the snows, when it swells into a river of considerable magnitude.

The climate is very variable, depending more on the elevation than on the latitude of the country. The Hazara country is terribly cold in winter, snow remaining for months on the ground, and the thermometer recording as much as 15° below zero. By the side of low plains, upon which the sun's rays scorch up all life, are high plateaux, where the climate is dry, bracing, and enjoyable, and mighty mountains, where there is perpetual winter, and the snow has never melted. In Herat, the temperature is moderate and the climate pleasant, resembling that of Naples. The heat of Kandahar is not greater than that experienced at Alexandria, and the winter is delightfully mild. Kabul closely resembles Vienna in temperature. In the high *shums* or plains of Southern Afghanistan, the climate is delightful for nine months in the year, and for the remaining three not so hot as in the mildest part of the Punjab plains; whereas, on the higher Suliman ranges, the Jindhran and other mountains, the climate is very much the same as in England, only drier, more bracing, and far healthier. At Sibi, at the mouth of the Bolan, the heat is appalling; the Kâchi desert indeed is the hottest place I was ever in, in the five quarters of the globe. The natives say of it—"Khûdá né is jhagar chordîr"—literally, God has let go His hold of this place, or, as we say, "A God-forsaken country." In point of fact, you can have any temperature you please in Afghanistan, and at any time of the year—from the most intense heat to almost Arctic cold.

The population is divided into two great and distinct classes—the Afghans, or Pushtoo-speaking, and the Parsivans, or Persian-speaking races; both are subdivided into many tribes, each speaking its own local dialect. In addition to these are a number of Hindus, Buddists, Armenians, Jews, and other settlers, whose political influence is of little note. The latest estimate of population is as follows:—Afghans, 2,800,000; Parsivans, 2,600,000; other races, 1,100,000; total, about 6,500,000. The Afghans, or Pushtoo-speaking tribes, are the dominant race; they are divided into two separate classes, viz., the fixed and nomad, the former of which dwell in

Kabul. They are all Mussalmans, chiefly of the Sunni sect, and as many of their ceremonies are closely allied to the Jewish rites, it is widely believed that they are of Semitic origin.

The prevailing language, Pushtoo, is a mixture of ancient Persian, Arabic, and Hindustani, but the invading armies who passed through Afghanistan all left colonies behind them, which have never quite amalgamated, and each has a provincial language which remains distinct.

The Afghans have really no literature of their own, and the imperfect notions of geography, astronomy, medicine, and history which they may have derived from Persian authors, have not much assisted in developing their faculties.

The chief clans are the Duranis, who dwell in Kabul, Kandahar, and Herat; the Kakars, who live in the south-east part of Afghanistan; the Ghilzies, who live on the western slopes of the Sulimans, and about Kabul and Kandahar; the Yusufzies about Peshawur; the Shinwaris, who reside east of Jellalabad, towards Kafirstan. The various semi-independent tribes, such as the Tajiks, Mongols, Jadrans, Gurbuz, and Parsivan Eimaks have little influence; and some of the larger independent tribes, the Waziris, Orakzis Afridis, and Swatis, though Afghans, acknowledge no allegiance to the present Amir, and form, as it were, a buffer between his country and ours.

The Duranis are a very powerful tribe in numbers and in political importance, and the reigning Afghan family has sprung from it. Nadir Shah, who conquered the Duranis, restored their country on condition that for every plough in their fields they should find a horseman for his army. This condition was fulfilled until recently, and the Durani Horse of the Afghan Army has played a great political part in the various conquests of the country. They are naturally, however, peaceful enough, and like the Scotch of old, who gloried in plundering and cattle-lifting, are quite ready to give that up and settle quietly down to honest avocations, on proof that these may be safely and profitably exercised. They are fine, robust, manly fellows, religious without bigotry, kind to their women, hospitable and courteous, preferring to do a good action rather than a bad one. I have employed them in thousands on public works, and they work more like Englishmen, without that constant supervision necessary with East Indians. They make good, trustworthy soldiers, and have done excellent service in our forces. Until quite recently, only the Hindus kept shops, but now the Duranis no longer consider it undignified to become traders. This radical movement was entirely due to British influence, enterprise, and example, during our occupation of Kandahar. They have great reverence for that city, where most of their holy men and chiefs are buried. The great bulk of the army was composed of Duranis, and in the old days of the Amir entirely depended on their loyalty. They display the highest military qualities, and their bravery is unequalled; they number about 800,000, and can muster 40,000 fighting men.

The Ghilzies are the second important Afghan tribe; they number about 600,000, and are sub-divided into many clans. Some are settlers, but the majority are travelling traders. This brave and gallant tribe was supreme in Afghanistan at the beginning of the last century, and once possessed the throne of Ispahan. They are of Turkish origin, and at one time were connected with a famous family of Delhi kings. The Powindahs are chiefly from this class, and accompanied by their wives and families, thread their way in large caravans through the various routes by way of the Sulimans, to vend their merchandise in every bazaar in India. They bring dried fruits from Bokhara, poshteens and sheepskin coats for our Punjab troops, also camel's-hair chogas, mats, carpets, rugs, &c., from Central Asia. These Ghilzi Powindahs, are as much soldiers as merchants, and when conveying their goods through the unused passes, have often to run the gauntlet of the robber tribes. They move in large bodies under an elected leader. In British territory they go unarmed, and consider a very few of their men sufficient to escort their caravans through India. They display a cunning quite commercial, says Sir William Andrew, never take the law into their own hands, but appeal to the justice of our magistrates. In the Waziri hills, however, they are hardy soldiers, and generally succeed in beating off any robber force that may oppose them. It is interesting to watch a Powindah caravan, with its long trains of gaudily equipped camels, their head-stalls ornamented with coloured beads and strings of shells, wending its way through one of the routes. On the best camels are slung the covered *khajawars*, containing the wives of the richer merchants—these form the main body of the procession, which is made up of other camels laden with bales of merchandise, of droves of sheep, goats, and of troops of children screaming and laughing. A few men guard the main portion, and a few hundred yards ahead may be seen a compact body of the fighting men of the clan, mounted and dismounted, all armed to the teeth, who form the vanguard. On either flank, crowning the heights, advance, with the greatest military exactitude, a similar body of footmen; whilst in rear follows a strong guard—all on the watch for their hereditary enemies, the Waziris. The Powindahs have long been on friendly terms with the British, and show themselves keenly alive to the advantages of civilisation; only twice since 1849 have they proved troublesome. They have, on the other hand, often aided us materially on the frontier, and many of our roads, canals, buildings, and outposts are their handiwork; while the men were thus employed, their women, for the time, have sometimes taken charge of the caravans.

The articles brought by the Powindahs into India are, from Bokhara and Samarkhand—silk, horses, drugs, wool, manna, gold coins, furs, gold and silver wire, some dried fruits, rugs, poshteens, thread, &c.; from Herat and Merv—Persian carpets, mats, jewels, wool, fine goats' hair, various dyes, antimony, dried fruits, seeds, Herat silks, &c.; from Kabul—fruits, seeds, spices, asafœtida, shawls, skins, dyes, silks, &c.; from Ghuzni and Kandahar*—madder, wool, rice, fruits, spices, chogas, camels' hair cloaks, Russia leather, native cloth and silk stuffs, nuts, seeds, &c.

The horse trade is with the Syads of Pishin, Kakars, and Ghuzni breeders. The Syads once dealt largely in slaves, the Hazaras being the principal victims. The goods which the Powindahs export from India, through the Suliman routes, are English cotton piece-goods, silks, European coloured cloth, merinos, velvets, copper, tin, tea, Indian muslins, indigo, salt, steel, firearms, gunpowder, cotton, English tinned goods, gaudily coloured German pictures, and patent medicines.

There can be no doubt that now steps have been taken by Sir Robert Sandeman and other distinguished frontier political officers to secure the safety of the routes, the traffic and commerce will increase enormously. The past Governments, both Liberal and Conservative, unfortunately, have by no means taken that keen interest in the development of trade with Central Asia which was desirable; and what has been done is due, in chief measure, to the independent action of British frontier officers, who have worked unprompted by, and perhaps unknown to, the supreme Government. The trade was, a few years ago, gradually being drawn north, and diverted from India, when proposals were made by the Derajat commissioner to undertake, in conjunction with the Amir, the defence of the Gûmul route* and the other principal highways of commerce, but the Government of India declined a policy of interference; fortunately, our frontier officers had the courage to act on their own responsibility, and carry out a necessary system of organisation.†

The Niazis are one of the principal Powindah clans; a great portion of them have settled at Isa-Kheyl, on the Indus, and become quiet, loyal agriculturists, though from this law-abiding tribe we have drawn many of our bravest and most faithful soldiers, ever ready to volunteer their services in times of need.

The Kakar tribe are also a powerful body of the Shiah sect, and were once very fanatical. They occupy the south-east country about Toba and the borders of Biluchistan, and are very friendly with the Ghilzis. During the late war, they had, on one occasion, a brush with us, and when beaten, their chiefs came in and said they would never fight us again. After this we trusted them, and had no cause to regret our confidence; we found them most useful to escort treasure, convoys, and caravans, as they proved thoroughly trustworthy, sometimes defending their charge even at the cost of their lives. Many of the old trade routes leading through their country, from Tal-Chotiali towards Kelat-i-Ghilzai, and in the Pai, Borai, Luni, and Zhob valleys, have recently been re-opened, and caravans now pass unmolested. The Kakars and Maris were old enemies, but owing to Sir Robert Sandeman's influence, are now good friends, and have lately taken to agriculture.

The Hazaras reside in the wild, rugged, extensive country, along the Hindu Khush Mountains, and on the way from Kabul towards Herat. They speak Persian, and are of the Mongol type;‡ they are *Shiahs*, or heretics, and never pay tribute to the Amir unless compelled. Some of the clan who have taken service in our forces, have proved excellent soldiers. The trade with this tribe has lately been somewhat revived, but the various routes through their impregnable

* Kandahar is the focus of all the Central Asian routes.

* Sir William P. Andrew, K.C.S.I.

† Commissioner, Derajat.

‡ Those caught by the Syads in battle, prior to 1842, were sold as slaves.

country, are rough, and require much engineering, particularly along the Argandab and Helmund rivers, and the Hindu Khush passes.

The Kazil-Bashis, also *Shiahs*, are Persianised Turks, they speak Persian and possess considerable influence with the Duranis. They are a superior class and better educated, furnishing many merchants, *hakims*, writers, &c. They are the descendants of the Persians whom Nadir Shah left in the country, and are fine, handsome men, composing indeed the flower of the Amir's cavalry. They can muster 30,000 fighting men; they greatly encourage British trade, and to their industry and intelligence the Parsivans of the country owe all their wealth, power, and influence.

Eimak is a term for a sept, or section of a tribe; it is generally applied to certain nomad tribes west of the Hazaras, and north of Herat. They were originally known as "the Four Eimaks," and are Sunis.

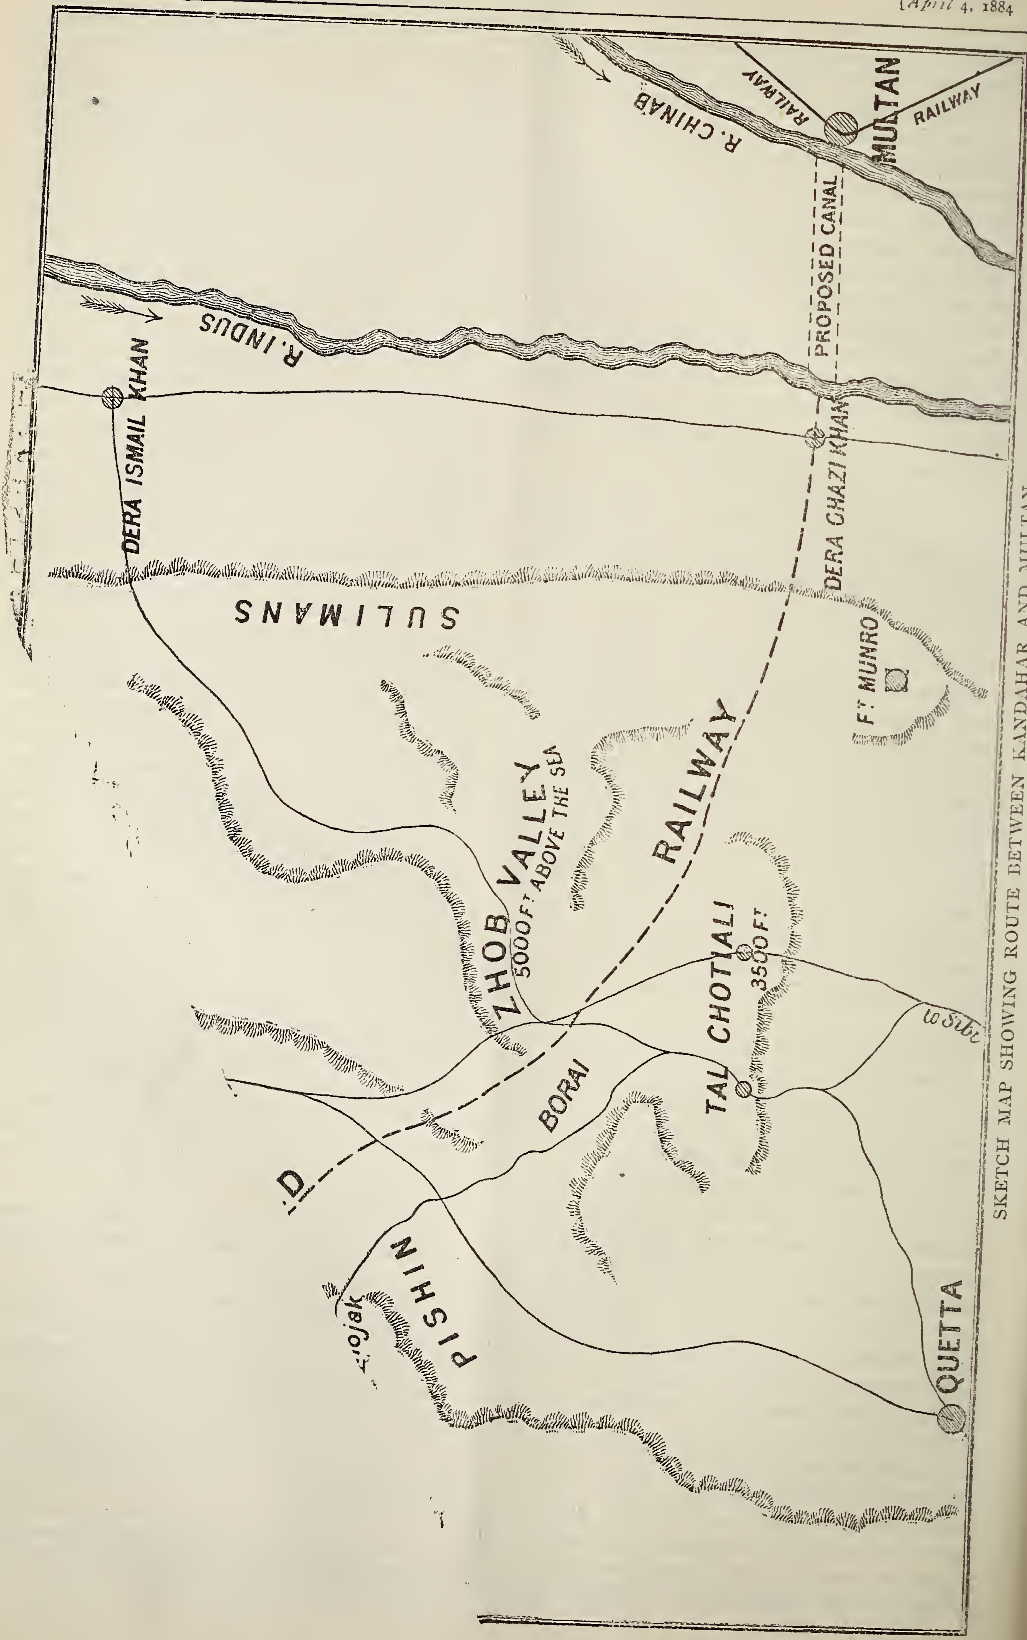
I have to describe only one more of the Afghan clans. The Tajiks, who number about 950,000, are scattered over a very large area, and are so much given to pastoral and agricultural pursuits, that their fighting men are comparatively few. They are descendants of the original Parsivan Suni settlers. The trade routes through their country are generally safe, for they refuse to give shelter to any robbers. Those who are driven by poverty to become soldiers in our service, have displayed the greatest courage; and, in times of danger, possess those rare qualities of faithfulness and loyalty which belong to a brave and noble race.

The Afghans have been called semi-savages, but with such grand material to work upon, education and civilisation will, under a sound and just Government, one day develop them into one of the finest races in the world. The typical Afghan is tall, active, strongly built, of an olive or fair complexion—some, indeed, are as fair as Englishmen, with light hair and well marked features. The Kakars, some of the Ghilzis and Duranis, imitate the Biluchis, and wear their hair in long curls round their head. The Afghans fully appreciate fun, and are generally very merry; they are brave to rashness, of great energy, enterprise, and endurance, and seem born for war. They require to be governed by a race like the English, for they make most excellent subjects, but, like most Asiatics, wretched masters, and as a people seem utterly incapable of organisation or management. Sober, generous and frank, courage with them is the supreme virtue. Their motto, "You give or I take," is being superseded by a higher principle, "Do unto others as you would be done by." Force, which was at one time their only argument, is regarded by those who know the English as no longer justifiable; and this race which has been condemned as the worst on earth, can, under the mild and just rule of England, produce honourable and good men, industrious law-abiding agriculturists, staunch and loyal soldiers, faithful and true to our cause, even unto death.

Kandahar* may be regarded as the great central point where, from the earliest of times, the chief trade routes met, either from Central Asia or Persia. The commerce of Khiva, Bokhara, Samarkand, Merv, and Herat was brought here, and was met by the great trading caravans from Persia, by way of the holy city of Meshad, and Herat. That renowned highway from Kabul, passing through Ghuzni and Kelat-i-Ghilzi, terminated at Kandahar. The chief Kafila road from Khelat Quetta, and Pishin also led to the same great mart, and it was here that the goods from Sind through the Bolan, the produce and merchandise of the Punjab, through the Tal-Chotiali, Sanghar, and Sakki-Sawar routes, were marketable. The inexhaustible supplies and riches of India were chiefly conveyed through the Gûmul Pass, North of the Takht-i-Suliman (*i.e.*, the throne or seat of Solomon). This renowned pass, one of the most interesting in the whole range, was the great trade route between Hindustan and Persia and Central Asia, for over 1,000 years; the various traffic routes by way of Zawa and Zhob valleys, in the direction of Toba peak, and again by some other passes south of the famous Takht-i-Suliman, were all feeders to this great trading highway, which from the mouth of the Gumul to Kandahar is 299 miles, to Ghuzni 233, to Kabul 318, and to Herat 380.

The Zhob valley route has been abandoned for over 100 years, owing to the robber tribes who infested it, but it is now likely to be reopened. I found there traces of a system of irrigation of a high order. The old *karez*, or subterranean aqueducts, conveying the waters of united springs to the surface, and the various bunds, made to catch the drainage and irrigate the lands at different elevations, give some idea of the great engineering talent of this lost people.

* Was once the capital of Central Asia. It is 3,000 years old, and after Alexander's visit was called after him, Iskandahar, Alickjalandar, Kandahar.



SKETCH MAP SHOWING ROUTE BETWEEN KANDAHAR AND MULTAN.

It is said that the Zhob, Borai, and Tal-Chotiali districts, covering an area of 14,000 square miles, once formed one of the most productive provinces in Afghanistan. In a climate which nearly reached perfection, the fruits of temperate and tropical countries grew at various elevations in profusion, and the soil teemed with vegetation and abundance.

Ages of bloodshed have, however, rendered unavailing the bounties of nature, but the land still remains full of hidden riches, and of mineral wealth untold. The natural elements of its ancient beauty and life still exist in the marvellous fertility of the soil, and in the manliness of character of the clans who reside outside these districts. The day cannot be far distant when this province will again become one of the finest and most prosperous in the East.

"We found," said Sir M. Biddulph, "three great valleys having theirorigin in the highlands east of Pishin, so disposed as to offer a choice of routes towards the Punjab. We never could have anticipated that this hitherto unexplored country would prove to be laid out so favourably for the routes we were in search of. We were first made completely acquainted with the whole arrangement of the internal part of the Pishin basin on gaining the top of the Surai Mugzai Pass, and in making the excursion in the Barshore Valley. This great open space is inhabited by a few Syuds, Turins, Kakars, and Achukzis, generally employed in agriculture and engaged in mercantile pursuits; they are decidedly peaceable in their habits, and would gladly be defended from the incursions of their more warlike neighbours. The country is abundantly well watered, and requires repose and the fostering care of a strong and good government. Before the next twenty years," adds Sir Michael Biddulph, "the railway will have passed on towards Persia, through tracts of country over which it is even now possible to drive a phaeton. Roads and railways will have been constructed down the easy and fertile valleys of the Kakur country to India. The area of cultivation will have increased, and groves will have sprung up around valleys and along the water courses. The people already traders will have benefited by the new communications, and in carrying their produce down to India, and returning with European goods, they will have learnt by their intercourse the value of commerce, and of a peaceable, just, and firm rule."

Speaking of this country, Sir Henry Rawlinson has said, "It was, in ancient times, a district of great wealth and consideration, it included Pishin, and took in all the western skirts of the hills. It was called Bálish or Válish, from a tribe of Turks who, in the 9th century, passed from the vicinity of Ghuzni; they left their name in the district of Malisan, near Ghuzni of to-day; they built large towns, and for 300 years maintained their celebrity, but their name has since vanished, and the towns are in ruins."

The late lamented Sir William Merewether said, in speaking of the routes between India and Kandahar, which we reconnoitered in 1879:—"The Tal-Chotiali Field Force has explored a region of the greatest importance. It was formerly well known as the easiest and best of routes between Central Asia and India. In earlier times, the capital of the Empire of Hindustan was Delhi, and naturally the products of Central Asia followed the shortest and best possible route to reach that city, *viâ* Dera Ghazi Khan to Delhi."

A little study of the map will show the great strategical and commercial importance of cantoning troops here, as a support to Quetta. We have troops at various stations along the low hot valley west of the Indus; these might be reduced in number, and brought here. Such concentration and placement would cover and protect the Punjab and Sind frontiers most effectually. The road leading from Tal and Khaja, at the head of the Zhob valley, commands the recently discovered easy road on Kandahar, which city is only eighty-nine miles off.* In a northerly direction it flanks all the passes leading from Afghanistan into the Punjab, and in the south it flanks the Bolan, which can be entered from it in many directions. I do not speak from mere guess-work, but from actual personal experience of the country, and many years residence on the frontier. Some years ago, I submitted a scheme to Government for colonising 15,000 square miles of the rich and fertile, but deserted plateaux, by granting lands to the loyal and industrious Sikhs, from the over-populated districts in the Punjab. It may be accepted as an axiom that, when once a people settle down as peaceable agriculturists, as the Sikhs have done, they become a tower of strength to the ruling Government, and will never throw in their lot with insurrectionists and invaders. The British Government have an opportunity of developing a great and

* An excellent road now crosses the Khojak; the proposed railway follows a still easier route at Gwaja; all the Pishin routes are open here.

powerful province at the head of the Khojak, by giving the Sikhs, Punjabis, and Gurkhas, plots of land, now lying waste and profitless. The whole country could be utilised and brought under cultivation, and these valleys and high plateaux lie on the chief direct route between Khorassan and India. A colony of such a people would be a strong outwork and barrier against invasion, and in times of emergency we might, as, indeed, to some extent we do now, draw our best and most loyal soldiers from these races.

The tranquility of this portion of Afghanistan would bring back the diverted commerce, and this great highway would become, as in ancient times, the chief route for trading caravans between India, and that great commercial and strategical centre, Kandahar.

My views, in short, may be condensed thus:—Constitute Multan a garrison of the first order, and make it the direct military base for all operations in Southern Afghanistan and Biluchistan; link the Chinab with the Indus at Dera Ghazi Khan by a navigable canal, and so place Multan in direct communication with the old Indus frontier at all seasons of the year. A line of railway from Dera Ghazi Khan, *viâ* the Chachar or Sakki-Sawar, which could be constructed very cheaply (there are no engineering obstacles along either alignment of country), would take you to a perfect climate at Tal and Zhob—which are neutral ground, commanding all the routes and passes on either flank, and where the land is capable of immense development, affording the grandest field for European enterprise.

Government experimental gardens were tried along most of the frequented routes in Afghanistan, with marked success. Model farms and depôts should be established along the best routes, and mules, hill ponies, and cattle bred for transport and commissariat purposes.

On the higher range of the Safed Koh, and in the Kûrûm heights, and on the higher Sulimans, grow magnificent trees, noble deodara pines, larch, yew, walnut, oak, and peach trees. At a lower elevation, varieties of rose, wild olive, honeysuckle, rhododendron, and dwarf palms are most common. In the high plateaux, acacias, palms, lilies, a variety of orchids and luxuriant shrubs bearing sweet scented flowers are to be found. In the cultivated parts the magnificent orchards yield abundantly all the fruits known in India, England, and the Continent. It should be remembered that the apple was originally indigenous in Afghanistan as the potato was in America.

There are, as in India, two harvests in the year. Kandahar supplied all the forces of Primrose, Roberts, and Ayoob Khan, in spite of two bad seasons, without difficulty, and at one-third of the Quetta prices. The granary supply of the district is practicable inexhaustible. Along the Kandahar routes tobacco grows to perfection, also wheat, barley, rice, jowar, sugar-cane, indigo, madder, castor oil, opium, dates, melons, &c. These and the celebrated grapes and other fruits of Pishin and Kandahar are renowned throughout Asia.

The horses of Northern and Southern Afghanistan, the Waziri country and Biluchistan, are justly famous all over the East; they are hardy, of extraordinary powers of endurance, up to great weight, capable of standing all weathers, and they are largely exported to India.

The cows are similar to the Guernsey breed, and, like them, give much milk. The flesh of the ox is excellent. The fat-tail species of sheep forms a great source of wealth to the nomad population. Owing to the richness of the grasses, the mutton is the best in Asia, and the wool trade with India has increased to 5,000,000 lbs. annually. The various goats of Southern Afghanistan are renowned for their hair, with which the natives make excellent winter clothes. The silk trade of Kandahar has lately been revived, and promises, ere long, to be very large. All goods in Afghanistan are carried on camels, stronger, more robust, and better built than the Indian kind. The Afghan camel is indeed very clever, can go over all sorts of rough mountainous roads, can climb hills of sharp gradients, cross roaring torrents, and is equally good in the barren sandy deserts.

Afghanistan is a magnificent country for the sportsman, large and small game, such as panthers, wolves, tiger cats, wild asses, pig, various sorts of antelope, elk, red, mouse, hog, and spotted deer, sambur, barra-singhar, wild sheep, and goats abound. Tigers and reptiles are, it is true, uncommon; of birds, there are eagles, vultures, herons, bustards, kulan, three kinds of partridges, four kinds of pheasants, sand grouse, syris, three kinds of quail, four kinds of snipe, jungle fowl, pigeon, and innumerable kinds of duck. Fish are very plentiful in all the streams and rivers.

The principal trade of Central Asia is managed by Hindus. The Merv, Meshad, Herat, Kandahar, and Pishin trade is, however, in the hands of Persians, who bring silk, horses, arms, rugs, and carpets, which latter are of excellent quality, soft, durable, and brilliant in colour, and are generally sold in England as "Persian." There is also a great trade in felts, goods woven from the hair of the camel, sheep, and goat. The Kandahar Persian merchants buy up the Powindah goods from India, such as piece goods, fabrics, skins, patent medicines, &c.

The mineral wealth of Afghanistan is prodigious. Gold is found in nearly all the rivers, and streams, and famous silver mines were worked at the head of the Panjshi Valley, near the Toba Peak, also in the Pishin, Tal and Zhob Valleys. Iron of excellent quality is found in Bajour, Kûrûm, Gûmul, and south of the Takht-i-Suliman. Iron ore is in abundance near the Bamian route and Hindu Khush; copper ore, lead, antimony, zinc, sulphur, nitre, coal and petroleum, are to be found all along the various routes traversed by our columns.

Will it be believed that, with all these *data* open before it, so renowned a journal as the *Saturday Review* should have committed itself to the absurdity of asserting that there were only two roads from Central Asia into India, viz., the Bolan and the Khyber, that Afghanistan itself was a barren country, and its people a despicable, fanatical race.

The same assertion might have been made with hardly more extravagance regarding Switzerland; that also is a country of rock and mountain, and where also large areas—which is not the case in Afghanistan—are covered by water, and, therefore, unproductive; yet, even the *Saturday Review* is aware that Switzerland, in many departments of commerce, is a formidable rival to England itself.

The Government returns of the Punjab, for 1883, show that the value of the foreign trade fell off by nearly 25 lacs during the past year. The decrease in exports (31½ lacs) is chiefly with Kabul and Bajaur, and the Lieutenant-Governor states it is due to the Russian trade policy in Central Asia. The chief decrease in exports to Cabul was 13 lacs in piece goods, 10 lacs in tea, and 2 lacs in indigo. The total Kabul trade fell from 48¼ to 42¾ per cent. of the whole Punjab foreign trade. The Kabul import trade shows a satisfactory increase in silk and madder. The import of silk from Central Asia, which was diverted to the Western Orenberg route and Bombay, has resumed its old course to India by the Punjab.

The most valuable Punjab import trade is that from Kashmir; the most valuable export trade that with Afghanistan. The Ladakh and Yarkhand trade shows a general improvement, owing to a more settled state under Chinese rule, and to the growing popularity of the Lahoul-Kulu route, due to the excellent state and safety of the road through British territory. Imports, 5½ lacs, exports, 3½ lacs. Opium is now largely imported from Kabul, Kandahar, and Herat.

There are registering posts at the head of all our frontier routes, and five new roads to Gandab were re-opened last year. The bulk of Kabul traffic passes by the Khyber. It is protected by our Government to Lundi Kotal, and by the Khan of Lalpura to Dakka.

The great falling off of the Punjab trade with Central Asia is due to the interdicts and prohibitive tariffs imposed by Russia, against which our Government has protested; but Russia maintains her right to protect her own industries, and is rather pleased than otherwise at our discomfiture. The railway to Kandahar would win back the trade that was once in our hands, would tranquilise the whole country, and be the pioneer of civilisation. The circulation of coin and bullion with Afghanistan and Central Asia cannot be accurately checked. The metal in both forms is conveyed secretly in considerable quantities. The excess of exports over imports is met partly by this importation of foreign gold coin and wire, and partly by Bombay exchange bills.

From the Kohat district the most used routes are *viâ* Thull and Manduri. The Admela Tarwari route is the safest. The only duty levied is at Kabul. The Government report that all is quiet in the Kûrûm, and that caravans can take the old routes as before. There is a large increase in imports over exports from Kabul at Kohat. The horse trade being the most important, next comes Kabuli coin, then leather, tobacco, and dried fruits.

The imports on the Gûmul route, show 53,356 Rs. more than for 1882. The Powindah camels which passed this way into India, were 52,000 against 46,000 in the previous year. There is a decrease of 12½ lacs on exports, due to the traders using the railway, together with the increased duties imposed by Russia.

The Tirah trade shows a considerable increase in imports—that of raw fibres was double that of 1882, and of food grains there is also a large increase, attributable to the good harvests, and perfect tranquility of that province. The Sewistan trade is very encouraging. Imports, for 1883, are 3¾ lacs, showing 99 per cent. increase since the late war; exports 7½ lacs, or 87 per cent. increase since that time.

The Bannu reports show an increase of imports, but a slight decrease of exports. The roads there are open, and no robberies of caravans are known to have occurred, though beyond British territory there was one Kafila looted. In the Dera Ishmail-Khan district, the Shiranis have have their routes re-oponed and trade has revived. The imports and exports of Tank Zam show a large increase, owing to the reduction of duties from one-sixth to one-twelfth.

The Vehowa route, which had been infested by Biluch robbers, was re-opened last year, and the robbers punished. Although there are 92 passes in the Dera Ghazi Khan district, only four are registered for trading purposes. The Sanghar route show an increase in imports; the trade had suffered from continued squabbles between the Kasranis, Bozdars, and others, but all disputes have now been amicably settled. The Fort Munro route shows an increase in exports of 121,000 Rs., and in imports of 31,000 Rs. This route is well guarded, and is even safer than the Sarri, which also leads into the Khetran Valley. Fort Munro is 7,000 feet above the sea, and is the hill station for the officials and officers from the garrisons in that district. The climate is very cool and bracing, with practically no rain. Government have there a model farm and English garden, where all kinds of fruits and vegetables grow to perfection. The most admirable arrangements have been made with the various chiefs of the frontier tribes to protect life and property, and the duties levied by them in their different districts are lower than formerly, but will bear further reduction. The Khyber imports are 18½ lacs, and exports 37 lacs; the Gûmul imports are 10½ lacs, and exports 18 lacs; the Bolan imports are 9 lacs, and exports 24 lacs.* These far exceed all others in importance. The total gross traffic registered with Afghanistan was, in 1862, imports 32 lacs, exports 30 lacs; 1880, imports 32½ lacs, exports 98 lacs; 1882, imports 35¾ lacs, exports 100 lacs; and by last returns, imports 41 lacs, exports 70 lacs. The total gross imports into the Punjab from Biluchistan, Afghanistan, and Central Asia were 104 lacs, and the exports 166 lacs, which gives 87 per cent. increase on the total gross imports and 98 per cent. on the total gross exports since 1870. These figures are taken from the Blue-books just presented to Parliament. The excess in the value of exports is due to the fact that imports of bullion escape registration, and also that Powindahs and others come down in winter and take back their earnings in kind; and it was noted in last year's report that *hundis* on Bombay were granted in exchange by the Bokhara Jews. Another reason for the great excess of exports over imports is found in the fact that the war disorganised the import trade, while the large amount of coin circulated there during our occupation increased the purchasing power of the country.

The construction of a railway to Kandahar is most essential, and the opening out of the roads into the heart of the rich prolific country of which that city is the central point, would cause the people, with their strong commercial instincts, to turn their tulwars into ploughshares, and become traders with our Indian Empire on a very large scale. The miraculous change in the Punjab since it has come under our rule will give us a fair picture of what the Zhob and Pishin provinces might speedily become.

I think I have shown, and I hope convincingly, that there is in Afghanistan a grand field for commerce, and that, far from being a barren land where there is no trade, its people are very keen traders, and the country only needs money and enterprise (which England has so largely at her command) to develop it into one of the richest countries in the East.

Since the old frontier of 1849 was annexed, we have constructed over 5,000 miles of district roads and feeders, and bridged most of the streams and canals. There are 375 serais and rest-houses erected for the natives, a thorough system of police has been organised, so that life and property are as safe there as in England. The trade returns show a rapid increase; the revenues, too, have developed in a marvellous manner, and the Tables annexed will show how crime has decreased under our rule. The Government have constructed or remodelled over 3,000 miles of canals for irrigating the lands, and nearly 5,500 square miles of country are under cultivation. The once barren frontier between the Sulimans and the Indus is now one rich garden, peopled by a happy, prosperous, law-abiding, agricultural race.

One word in conclusion. Our highest and most competent Indian authorities have, after careful consideration, deemed it expedient not to annex but to occupy Kandahar by friendly arrangement, as we now occupy Quetta.

* These figures show an increase of 250 per cent. since 1870.

Our history of India affords us no cause for pride, but our dealings on our north-west frontier can be read with the greatest satisfaction.

The work of pacification has required tact, energy, and gallantry, attributes common enough amongst the Englishmen who have been the pioneers of civilisation on the Afghan frontier. The Punjab School has produced such heroes as Nicholson, Taylor, Jacob, Lawrence, and scores of others whose glorious deeds are indelibly engraved on the blazing scroll of the best deeds ever performed by Englishmen. Others, alas! have gone to their graves after nobly doing their duty, unhonored, undecorated, and unknown; but there are still a host of others ready to follow in their footsteps, who would sport with the difficulties which would have to be overcome. Until now Southern Afghanistan has lain under the curse of Islam; robbery, tyranny, slavery, barbarism, and bloodshed were rampant, but it only needs the guiding spirits of men like Chamberlain, Probyn, Brownlow, Merewether, the Greens (one of whom is with us this evening), worthy followers of Jacob, and a host of others, to show this manly energetic people how their fertile soil can be cultivated, and their mineral wealth utilised, with the aid of British pluck and British gold.

If ever this country, as the mother of nations, had a duty to perform, it is to carry her civilising mission into these parts, and to teach the people "Peace on earth, and goodwill towards men." It is not in the name of this or of that Government, in this or of that policy, but in the name of civilisation and humanity, we desire the good work that has been begun under Sandeman and his lieutenants carried out.

The man who would thwart or in any way frustrate this noble work is not worthy of the name of Englishman.

APPENDIX.

District.	Per-centage of increased cultivation since annexation to 1884.	Per-centage showing the increase of population since annexation to 1884.	Canals and rajbahas open. In miles.	Decrease of crime since annexation to 1884.	Number of passes and routes leading into Afghanistan in each district.	Chiefly peopled by races now called
Peshawur	127·	18	195	86	38	Indo-Puthans, &c.
Kohat	141·5	15	124	79	47	Waziri-Puthans, &c.

The Khan of Khelat has long been our staunch ally, and no raiding has taken place along the British frontier since 1857.

BILUCHISTAN.

Biluchistan has an area of 168,000 square miles; some of the western part belongs to Persia (only about 55,000 square miles). The ruler is the Khan of Khelat, who resides at the capital (Khelat). Quetta commands the Bolan Pass route, so strategically is the most important city. The revenue is about £40,000, in addition to the subsidy we pay the Khan (*vide* treaty of 1854). The Government is despotic; the Khan's rule only extended to the province immediately around his capital, but now order and law prevails everywhere, owing to British influence. In past times, a great part of the country was held by tribal chiefs, over whom the Khan had but little control, unless in times of war, when they would furnish him with contingents, but taxes they always refused to pay, unless forced. Sir R. Sandeman, assisted by able officers, is settling the whole country in accordance with the British frontier rules, laws, and regulations. The occupation of Quetta by our troops was in accordance with the terms of treaty of 1854. The people are divided into two branches, Biluchis and Brahnis. Both are pastoral, kind, hospitable, brave, and are Sunis. Polygamy is universal; all have two, and some chiefs five wives; women are obtained by purchase, and paid for in sheep, goats, mares, &c. A man is expected to marry the widow of his deceased brother. All routes throughout the country open; mineral wealth enormous; trade increasing; manufactures insignificant; produce of soil prodigious. Climate, extreme heat and cold. Population about 1,875,000.

DISCUSSION.

Col. MALCOLM GREEN, C.B., said that although he agreed with most of what had been stated by Mr. Vyse, there was one small portion with which he differed. Mr. Vyse, he understood, advocated the policy of occupying or colonising with Sikhs a tract of country contingent to one of the trade routes, which lies beyond the British frontier and between the western and eastern Suliman ranges. Now this country does not belong to the Sikhs but to Belooch, or Pathan tribes, and unless England was prepared to advance the red line to that shown upon the map, and so protect her Sikh colonists within it, he was afraid the latter, as well as those frequenting the trade route, would lead but a sorry life of it. With regard to the country in and about our Sind frontier, including Jacobabad and the district surrounding it, together with those portions of the world, formerly amongst the most lawless on the confines of India, contained between E. longitude 66 and 68, and N. latitude 25 and 30, these, for the most part are, and have been, for many years past—thanks to the policy initiated by the late General John Jacob, C.B., and encouraged and supported by Sir Bartle Frere, sometime Commissioner in Sind—as safe for travellers and traffic as the roads between this and South Kensington.

Sir JOSEPH FAYRER, M.D., K.C.S.I., F.R.S., said he could bear testimony to what had been said by Mr. Vyse as to the grandeur of the physique of the race to which he had referred, and also as to the existence of the fruits, and the various textile fabrics which the natives brought down from the higher regions. Reference had been made to the various woollen fabrics made from the animals that throve in those mountainous regions, and it might not be generally known that all the animals residing in those elevations, where the winters were severe, had a peculiar development of the soft woolly hair, which only developed thoroughly in winter, which was used for spinning those excellent fabrics used for making clothes. The paper was interesting to him chiefly from its geographical and from its natural history aspects, and he was sorry he could not enlighten the meeting by any remarks of his own on other aspects of the paper. He should be glad if Mr. Vyse could give them some information as to the nature of the road between Merv and Herat.

Mr. CHARLES MARVIN said the paper which they had just listened to was most interesting. character. The material thing which struck one in connection with the map was that you had a frontier of a great Empire of 100,000,000 of people, and another frontier of a second Empire of 250,000,000 of people, the only thing separating the two being the small tract of country known as Afghanistan, which contained little more in population than London. Through this country ran various trade routes which had been described that evening, the most important being the one running from the Caspian region to Herat and then on to Kandahar and India. Very considerable importance had been given to this trade route by the recent Russian annexation of Merv. He had lately received a paper from Tiflis in which this subject was discussed, one thing mentioned being that the measures that were taken by England in Afghanistan in the region of Kandahar to check the Russian advance, ought to be, on the part of Russia, responded to by similar measures in the region between Merv, Sarakhs, and Herat. If England kept making preparations to resist the Russian advance, and Russia on her part continued to make preparations to strengthen her frontier, the two sets of measures, one operating north, and the other south, must have the effect of wiping out Afghanistan. He thought that opinion was generally becoming shared in England. The forces which were operating on both sides were so strong that, between the two, Afghanistan must be crushed out. This question could be argued from a commercial aspect as well as from a military one. Russia, besides being a great military power, was also a commercial power, and in India we were also a great commercial power, and our present policy was to establish a sort of barrier between these two great empires which would be untraversed by the traders of either country. It might be a very good policy from a certain point of view, but it was not a practical point of view, and that opinion was, he thought, shared by a good many. So far as the Russians were concerned, they were determined that that policy should not succeed, and he could not see what England could do to prevent it. The author of the paper had not gone very much into the question of what he might call the great trade route running through Herat and Kandahar to India.

The CHAIRMAN said he might, perhaps, be permitted to point out that it was not customary at these meetings to enter into politics.

Mr. MARVIN said he would try to avoid doing so. Of late years, there had been a large development of Russian commerce in the Caspian, and it was not many years ago that the Caspian was regarded as a sort of dead sea, in fact, quite altogether out of Europe; but Russia having linked the Caspian with he Black Sea by railway, had opened a great trade route, and before many years had elapsed, they would hear a great deal about Russian traders in this region. From what he had seen when out there, he knew that the Russian trade was developing in the Caspian and trans-Caspian regions. He could not see what right the English Government had to keep the Russian trader pure and simple out of Herat, and was persuaded that before many months they would hear of the Russians penetrating into the district round Herat. At the present moment, there were large consignments of Russian goods at Askabad, waiting sale, and large consignments were being dispatched to Merv.

Mr. MARTIN WOOD said the Chairman had stated that it was not the custom at these meetings to deal with politics, but he thought it was rather entering into the domain of politics when several speakers proposed to occupy a country which did not belong to them, and over which they had no control. Mr. Vyse had referred to a very large number of routes to Afghanistan, but he was of opinion that three or four main routes were quite enough to consider. In hearing the paper read, abounding as it did with modern information, he could not but recall some of the older writers on the trade routes to and from Central Asia, amongst whom he could specially mention Major James, whose records, were popularised by Sir Richard Davies. It was very desirable that every opportunity should be given to encourage Indian trade with Afghanistan, though he did not think that the construction of the railway to Kandahar was necessary for that purpose. The country was tolerably peaceful and settled until three or four years ago, when England, in the most unwarrantable manner, overran the country; one of the inevitable consequences of the invasion being that a large quantity of mulberry and other fruit trees were cut down, just when they had reached maturity after our former invasion. With regard to the railway which was proposed by Mr. Vyse, he could not see what it was essential to; it was not essential to India, though it might be essential to the demands of British commerce, and for war purposes; but if so, that was an Imperial purpose, and the cost of constructing the railway ought to rest with the Treasury of this country. He thought if that was borne in mind, the project would be looked at with a little more care than was frequently the case. His own impression was that in Afghanistan the policy of civilisation had not yet been thoroughly tried; and as to trade generally with Central Asia, there was the old method of holding periodical fairs within our borders, to which the traders should be freely invited; he strongly advocated this being done.

Mr. TRELAWNEY SAUNDERS said he was very grateful to Mr. Vyse for moving public opinion in the direction of a just judgment upon the productibility of Afghanistan. Because the country had been overrun by war, and devastated by plunderers for so many centuries, that was no reason why it should not be other than it was at the present day, as it had the same climate, the same soil, and an industrious people who would be peaceful if under a strong Government. Its existence as an independent Government between two great and powerful nations, one an advancing and conquering one, could not be looked upon as independent. If it was to be dependent, under what power was that to be. That was the question which stood paramount with regard to the question of trade, for they must remember that so far as the Russian boundary extended, so far was the rest of the world excluded from trading inside that line, but so far as the English line extended, others could freely follow, Russians included. It required no argument or advocacy to deal with this question or promote it, for it was one that was promoting itself, and there was no stopping it. Peaceful men and statesmen might do what they could to prevent the issue which was rapidly coming upon them, but that issue would have to be met and decided, not by statesmen but by force of arms, and the more they were prepared for that, the better it would be for English interests.

Mr. HYDE CLARKE was afraid the Chairman had rather confused the mind of Mr. Martin Wood by restricting the discussion to commerce, and refusing to allow them to touch upon politics, though, for himself, he believed that it was impossible in the present case to draw any absolute line. Mr. Wood seemed to suppose that there was some notion that England was not to interfere with countries which did not belong to it; but commerce, as was well known, interfered much more with other countries than war did, and English people were greater conquerors by commercial means than warlike means. Mr. Saunders, like other distinguished men, had laid down many of the lines of this warfare, political or commercial, which was still going on. One difference between the two combatants was this, that the Russians were in every degree assisted in their invasions, while Englishmen received but scant aid from the individual goodwill of political officers, in their endeavours in the promotion of civilisation. The Armenians, who had been the pioneers of trade in the district about Merv, had worked under a Russian banner, pushing commerce wherever they could, and these people would be most willing to aid Englishmen if they could receive any help from our Government. There ought to be no compunction in occupying any country by fair means if it could be done with advantage to the population, and with benefit to the world at large, because if they remained tranquil and inert, they would allow others to occupy the place with the consequence of being excluded from trade. He had watched the progress of the Russians from the Black Sea to the Caspian, and the free trade routes there were almost extirpated. It was desirable that England should take this question up in the spirit which had just been advocated, looking upon it as a great question, or, if Mr. Wood liked, as a great Imperial question. It was scarcely possible to understand how, in looking either at Indian interests, or in the interests of the world at large, it could be considered an undue influence to do what had been recommended by Mr. Vyse, namely, to carry on a railway to Kandahar, as the railway would be the means of bringing into Afghanistan the influence of that immense instrument of civilisation, the railway system of India; and it would place at the disposal of the population, so far as it reached, all those resources of civilisation which had been created in India. So far from there being any just argument against this project, there was every inducement to introduce it. With regard to the regions between the Suliman mountains, he would go much farther than Mr. Vyse. Why should not Englishmen be employed as chiefs in such a colonisation and occupation, not in the sense of cultivators of the land? If fair scope were given to English enterprise they would probably see such a barrier created in the Suliman region as would be a safeguard against all political dangers.

The CHAIRMAN said he came to listen to a lecture upon the trading routes of Afghanistan, and he feared they had strayed a little beyond that subject into the realms of politics, though no doubt it was exceedingly difficult for them to steer clear of that in dealing with such a subject. Afghanistan was between two great powers, and everyone knew what generally happened in a country so situated. Mr. Hyde Clarke had referred to the Russians as being a warlike nation, but if they looked back to history he thought they would find there was no more warlike nation under the sun than old England. Russia would have a great deal to do in order to win Afghanistan. He was a great advocate for promoting trade, and attached the greatest importance to opening up trade with Afghanistan. He was glad to think the railway was going to be made to Quetta, and trusted that it would be carried on to Kandahar, not with any view to conquest, but merely to encourage trade. As one way of doing that, Sir Robert Sandeman had lately made an agreement to take over the revenues of the State of Quetta by making an annual payment to the chief, and there was some reason to hope that the Indian officials would before long be able to diminish, if not to entirely abolish, the heavy tolls upon merchandise which was levied upon goods going through the Bolan Pass. It had almost taken his breath away to hear Mr. Vyse say that there were 298 routes into Afghanistan from the north-west frontier, and he supposed that many of them were not of any great value. His own impression was that the Bolan Pass was the one which England had to deal with, and to open up as much as possible. In conclusion, he begged to propose a most hearty vote of thanks to Mr. Vyse, for his interesting and valuable paper.

Mr. VYSE, in responding, said he had to thank Mr. Trelawney Saunders for the loan of the excellent map which had been of so much service that evening. As to the observations of Mr. Wood, he would advise that gentleman to read the lecture delivered by General Hamley, at the Royal Institution, when Sir Henry Rawlinson was in the chair. As to the 298 passes to which reference had been made, he could assure the Chairman that the whole of them could be used by cavalry, footmen, and camels. The gradients, even now, are not difficult, and the general alignment and contours of most of the old passes through the Sulimans are capable, without much cost or engineering, of being made excellent traffic feeders. The streams might easily have weir-dams constructed across them, so as to hold, as reservoirs, the flood water in times of emergency. The rainfall along the Sulimans is uncertain, but three inches of rain have been registered in twelve hours. The whole average for the year is about equal to the rainfall at Plymouth. In the Harnai, Peshin, and Sewistan districts, however, it is much greater. With reference to Colonel Malcolm Green's remarks, the Zhob and Harnai country he knew never belonged to the Sikhs; at present it is neutral waste land, only small patches here and there are claimed. It stands from 3,000 to 6,000 feet above the sea; the soil is rich and prolific, and well watered. It would make a grand site for colonies of Sikhs and Gurkhas, where regiments of these races should be stationed. The Gurkha regiments at Abbottabad, Buckloh, Jutogh, &c., all have small colonies, and their wives and families assist in looking after their gardens and farms. Some regiments of Sikhs on the Punjab frontier do the same, and it is such a scheme he would promote and encourage here. It should be remembered that trade always follows the flag of old England. In answer to Sir Joseph Fayrer, there are five roads between Merv and Herat; two are very good ones, by the Murghab route, the distance is 240 miles, and water obtainable the whole way. The banks of the Murghab river are very fertile, and grass, fodder, timber, and some supplies are procurable *en route*. The other route, from Merv to Herat, surveyed by Lessar, is 252 miles; it is fairly open, and good, without really any engineering difficulties for a line of railway. The highest rise in the hills is under 900 ft. above the surrounding country. The climate is most enjoyable, but Merv, so O'Donovan has said, is feverish for three months in the year. Of the other three roads little is known, except that one—165 miles—is reported to be even better than that visited by Lessar. The fertility of of the Herat country is unequalled, and its supplies are practically inexhaustible. According to the old Persian legends, Herat was the Garden of Eden. From Merv to Herat is 240 miles; from Quetta to Herat is 514 miles. The Russians then are nearer to Herat by 274 miles than we are, and, of course, their influence over the trade of Herat and Kandahar will now be keenly felt, and every year will show a marked falling off unless something be done at once

SEVENTEENTH ORDINARY MEETING.

Wednesday, April 2, 1884; His Eminence Cardinal MANNING in the chair.

The following candidates were proposed for election as members of the Society:—

Alldridge, Thomas Joshua, York Island, Sherbro, West Coast of Africa, and Old Charlton, Kent.
Allpress, Vincent Sydney, Cliefden, Eltham, Kent.
Bryce, Charles C., 141, West George-street, Glasgow.
Christie, John, Rosshead, Alexandria, N.B.
Gibson, John Merriman, Buckley, Chester.
Gothard, Frederic, 204, Ashby-road, Burton-on-Trent.
Kemp, William Joel, Copyhold-house, Redhill, Surrey.
Lovibond, Josiah W., 26, St. Ann's-street, Salisbury.
Muir, Rev. Robert H., The Manse, Dalmeny, Edinburgh.
Richardson, Frederick William, 40, Church-street, Bradford.
Rumpff, Carl, Schloss Aprath, near Elberfeld.
Wace, Rev. Prebendary Henry, D.D., King's College, Strand, W.C.
Wall, Robert Frederick, Thames Sugar Refinery, Silvertown, E.

The following candidates were balloted for and duly elected members of the Society:—

Christie, John, Clevedon-lodge, St. Margaret's, Twickenham.
Howard, Walter, Oaklands, Cricklewood, N.W.
Ince, Francis, St. Fagan's, 17, Fitzjohn's-avenue, Hampstead, N.W.
Kent, Arthur, 11, Wigmore-street, W.
Langton, Henry Currer, Docklands, Ingatestone, Essex.
Trench, George, Standard-house, Faversham, Kent.

His Eminence Cardinal MANNING, in introducing Mr. Hoole, expressed his regret that he could not remain to hear the paper, as he was suffering from a severe cold. This subject, however, was of such vital importance that he could not leave without saying a few words upon it. There were a large number of earnest benevolent people who seemed to think that houses unfit for human habitations ought to be demolished at once, and better houses erected in their stead. This reminded him of a county meeting at which three resolutions were passed—(1) that a new lunatic asylum be built, (2) that it occupy the site of the old one, (3) that the patients remain in the old one until the new one be finished. Some of these benevolent people overlooked the enormous difficulty of re-housing the labouring men of England and their families. There had been a great deal of demolition, which had only increased the overcrowding complained of. Families had been driven out into the suburbs of London, in some of which there were now as many evils as existed in central London; others, again, had been driven into neighbouring parishes, and overcrowded them; and others had gone into other houses in the same parish, and thus rendered far more intense the evils it was sought to remedy. Benevolent zeal, therefore, required to be tempered by knowledge, such as had been obtained by the evidence taken some years ago, and was now being taken again. If a man were taken to another house at a distance, he lost at least two hours a day, with a great accession of labour; he often lost his employment, and his wife lost the small industries by which she gained a few shillings a week, and thus the whole family was impoverished; whilst all articles of food were dearer in the suburbs than they were in the markets where the working man was used to buy his food. A great effort had been made to rehouse at least one-half of those who were unhoused, but the great block-buildings which were put up did not rehouse the class of whom he was thinking. They were filled by anticipation by skilled or half-skilled artisans, who could pay higher rents, and were, in other respects, more desirable tenants. The poor must not be pushed from the centres of industry where they worked, which formed one of the greatest difficulties. In the course of the evidence taken some years ago, very terrible statements had been made as to the immorality caused by overcrowding, and drunkenness which was both the cause and consequence of it. These were very grave and dark questions, but he would not dwell upon them, but would call attention to another point, which was to him even more vital, if possible. Was it possible for a man, with his wife and family growing up from infancy to man and womanhood, crowded in a room 9 ft. square, and 7 ft. high, to maintain domestic life in such a state? By domestic life he meant those feelings of affection, authority, submission, duty, and charity one to another, which bound together human and Christian families. All who had seen the life of the working people of this country, would agree with him that to cultivate the domestic life of the people was, at this moment, impossible, even in habitations which might be somewhat larger and better aired, but with only one room undivided. What was the foundation of the whole human society of mankind but the domestic life? Upon this all empires, kingdoms, and commonwealths were founded. There must be at present not less than 16,000,000 to 17,000,000 of population in the crowded centres and throughout the agricultural districts. What would be the condition of all those people, if more thought were not bestowed on their domestic life than had ever been given to it yet? He did not like to be a prophet of evil, but he felt sure that in these great centres families grew up without the relations which bound husband and wife, parent and children, together. Early in life the boys and girls began to earn a few shillings, and went and lodged by themselves. There was no domestic life under such circumstances, and it was precisely in these great centres that drunkenness was making its greatest havoc; and he looked at the future with great anxiety. Look at France; Paris was a centre liable at any moment to overflow like a volcano and deluge the whole country. By a good Providence, England had been saved from centralisation, and he looked forward to the creation of local centres, and the development of personal energy everywhere. If this were done, our great centres might become like the air-tight compartments of a large ironclad, where if one were pierced the others would be secure. There were a multitude of political questions which men were very ardent about, but as to which he cared but little; but there were three supreme questions which he believed lay at the root of the very life of English people. One was the preservation inviolate of the inheritance of the English national character in the English Christian schools. Secondly, a power whereby the enormous monopoly of the drink traffic could be controlled. Owing to the enormous amount of capital invested in this trade, it had been until lately quite hopeless to attempt to deal with it, but there seemed now an opportunity of doing so, and every social reformer ought to lay this great question to heart. He would not go into the question of what should be done, though he had very clear ideas about it. He would not commit to anybody the power of putting public houses anywhere without asking the people of that place whether they wished them or not. The third and last point was the domestic life of the people. He was no believer in State ownership or centralisation; or in social theories which would invest in the governing powers the control of houses; he would much rather that an Englishman's house should still continue to be his castle. On the other hand, he did not believe that this enormous work could be accomplished by the mere charitable, eleemosynary, or voluntary principle. But between these two extremes lay the great commercial principle which had covered the whole face of the country with the wonderful network of railroads, and by that means he hoped the housing of the poor would be accomplished.

Colonel Webber then took the chair.

The paper read was—

THE DWELLINGS OF THE POOR IN LARGE TOWNS.

By Elijah Hoole.

Happily, there is now no need to insist on the importance of housing the poor, or on the pressing necessity of putting an end to the squalor and to the degrading surroundings in which the labouring classes are crowded. Public attention is aroused, and the danger now seems to be, not that nothing will be done, but lest some great effort should be made to end at a stroke a condition of affairs which has been the growth of centuries, and has largely resulted from long-continued neglect.

It may be affirmed, without risk of contradiction, that no sudden remedy, however extensive, can possibly deal effectually with the degradation and poverty of the lowest stratum of our town populations. Could you put them all in the best-arranged model dwellings to-morrow, their condition would be worse instead of better, unless you are prepared at the same time to control and educate them by experienced and properly-qualified persons, who have themselves undergone a special training to fit them for this difficult work. The improvement of the condition of the labourer is necessarily gradual, since it depends, not on rebuilding the dwellings merely, but on dealing with the various causes which combine to produce the deplorable results which have lately had so much public attention.

In the meantime, while the work is still undone, any approach towards the solution of the very difficult problem thus presented may not be without value, especially when embodying the results of actual experience.

There are two main divisions of the subject which must be carefully distinguished at the outset—the housing of the artisan, and the housing of the labourer. These two terms may be allowed to stand for the two great divisions of the working class, the skilled and the unskilled workers.

The first half of the question has been successfully met. For the upper working class the various dwellings companies have provided decent and healthy homes which, though somewhat monotonous in appearance and arrangement, are an infinite improvement upon the courts and alleys they have usually replaced. The financial part of the problem has also been successfully treated, and it is now only necessary to repeat, with some obvious improvements, what the dwellings companies have done, and the entire artisan class may be housed in a healthy and comfortable manner, while the investment will return a fair per-centage on the capital employed. The excellent service which the dwellings companies have thus rendered the artisan is too well known, and their comfortable sets of rooms, better furnished with useful appliances than many houses of the middle class, are too familiar to need detailed description. The object of the present paper is to endeavour to point out how what has been so successfully done for the artisan may also be done for the labourer.

It appears to have been supposed by their promoters that, by providing sets of rooms in model dwellings, they would be able so to raise the condition of the labourer, that he would no longer live in the squalid manner in which he is still found, but would inhabit a set of rooms which would form a well arranged and cheerful home for his family. One can hardly believe that the class most in need of healthy housing—the lowest—would have been deliberately passed by without one effort for its improvement. Be this as it may, the fact remains that while the *élite* of the working class has been thus provided for, the squalid poor of the lowest stratum have been left almost entirely to their own misery.

In 1873, about 27,000 persons were living in the improved dwellings provided by the various companies, &c., and, in 1881, these tenants had increased to nearly 39,000, but only a small proportion of these were of the labouring class, the majority being artisans. Now, as the inhabitants of the slums of London are estimated at 200,000, it is obvious that even if all the improved dwellings were exclusively occupied by them, there would still be a great work to do. But so far from occupying the improved dwellings, the labourer is excluded from them almost without exception, both by the rent and by the kind of accommodation provided.

The dwellings companies provide a set of rooms, but he can only afford one, the rent of a set of rooms being quite beyond his means. He needs accommodation for carrying on his trade, but if they do not actually forbid its exercise, they can afford him no facilities or space for practising it. But if the dwellings do not suit the labourer, neither does the labourer, as a tenant, suit the proprietors of the dwellings. The lowest strata of our town population are the most difficult to control, and to keep within sanitary and orderly limits. There are very strong reasons for the apparent neglect of the squalid poor by the dwellings companies. They are by no means an easy class to deal with. Very destructive to their dwellings if not watched and controlled, using every artifice to avoid payment of rent, and constantly changing their lodgings, they require a special organisation for their management, an organisation which has time to inquire into the character and habits of the tenants, which recognises other crimes beside the non-payment of rent, and will either reform or eject the thief and the prostitute, though they can often pay higher rents than the labourer and the laundress.

An entirely different agency is thus required for collection, needing much more discretion and judgment than is necessary in dealing with the artisan, insisting on the payment of the rent, and yet ready to make allowance for illness, and even to distribute relief.

A serious difficulty arises from the fact that occupying rooms side by side with the honest and industrious are the vicious of both sexes, many of whom have sunk down to their present degraded position from a much higher level, and who infect their neighbours, while they themselves are debased by their own squalid surroundings.

It is hopeless to attempt to eliminate the vicious and debased from any scheme of housing the poor. If you select the deserving only, and provide for them, you merely leave the rest to a more hopeless degradation. To pick out the few good specimens that we can find, and to leave the rest, will never produce satisfactory results. The class must be dealt with as a whole. In considering how best to house the labourer, existing conditions must be accepted as fixed, since we have no power to alter them. The wages of the labourer are fixed by the supply and demand of labour in the market. House rent is fixed by the cost of building, the amount of taxation, and the value of land. To alter either wages or house rent is impossible, since they are regulated by conditions quite beyond our control.

It will be seen that the various questions with which we have to deal are thus much narrowed. We have not to make, or even to modify, the conditions under which the labourer exists, but we have to see what can be done to improve his position, while keeping strictly within their lines. Help him to higher wages if you can, help him to lay out his money to the best account, but do not offer him rooms at 5s. per week when he has only 3s. to spend, and above all, do not try to house him by charity, by giving him more than his money is worth. Such a proceeding can only be very partial in its application, is calculated to check rather than to extend the proper housing of the poor, and pauperises the recipient instead of benefiting him. In other matters beside that of price existing conditions must be accepted. It is useless to approach the subject with preconceived theories, such as, for instance, that every family ought to have three rooms, or that no room ought to be used both by day and night. What has to be done is to see how the labourer is lodged now, and how his dwelling may be improved without raising the rent above his means. As a rule, he, with his family, occupies one room only in an eight or ten-roomed house, originally planned for one family, but now containing one family in each room. When the house was built, it was provided with sanitary and washing appliances for one family, and these, in a more or less dilapidated condition, are now made to serve for eight families or more. We have had many descriptions of the state of such tenements of late. Suffice it to say that unless repairs are done by the tenant himself, at his own expense, they are often omitted altogether. Not only do families live and die in these single rooms, but in many of them trades are carried on. Tailoring, cobbling, laundry-work, and a host of small trades are practised in the single rooms, which are thus both sleeping rooms, living rooms, and workshops in one. On these trades thus exercised the livelihood of the family largely, if not entirely, depends. The rent of single room tenements in London ranges from about 2s. to 4s. per week, and includes all rates and taxes, with the cost of water supply, and of such repairs as the sanitary authority enforces.

This mode of living is by no means what could be wished for the labourer, whose exertions it might be supposed should surely procure for him some better surroundings, especially when the arduous nature of his work, and the risks and exposure he has to undergo in its pursuit, are considered.

To omit to provide single room tenements, under the plea that such a mode of housing the labourer ought not to be countenanced, is really to perpetuate the evils complained of in their worst form, since by carefnl superintendence they have been greatly mitigated, and by re-arrangement nearly, if not quite, abolished; nor would it succeed to give two rooms at the price of one, since this would be simply to make a present of so many shillings a-week to each family. It is clear that whatever is done must be done within the existing limits of wages, rent, and customary accommodation. The fact must be faced that hundreds of thousands of persons are living a family in a room, and that what is needed by them is the best room that can be had for the money they can afford to pay, with as much isolation from their neigbours, as much fresh air, pure water, and light, as we can secure for them under the circumstances in which they are obliged to live.

Two methods are thus open in dealing with the dwellings of the labouring class. Either the existing dwellings may be taken in hand and rendered as far as possible healthy and sound, or they may be demolished and rebuilt on an improved plan. The first method, that of maintenance, is being carried on with increasing success, and is substantially as follows:—Either the lease or freehold of existing labourers' dwellings is purchased, the most squalid tenement houses being selected by preference. They are taken over, tenants and all, just as they are. A superintendent is appointed to keep order, the premises are thoroughly cleansed, overcrowding is stopped, the drainage and water supply are made efficient, dangerous defects in the structure are remedied, while repairs of a decorative kind are left to be granted to tenants who pay puuctually and behave well. The tenants are not evicted, but they are put on trial, and only the incorrigible are at last displaced. This plan has worked exceedingly well, and can be quickly and easily adopted. It is also remunerative, and is often practicable where, from shortness of lease and other causes, rebuilding is impossible. The advantages to the tenants are immense and immediate. This system of management is a most valuable discovery, forming as it does the basis upon which alone any plan of improvement can safely be founded. It must, however, be regarded as a temporary measure, preparing the way for permanent improvement. This plan being eminently practical, the houses to which it is applied form an excellent training ground for superintendents, collectors, and managers, without whose experienced aid any scheme for housing the labourer must inevitably fail.

The form in which the labourers' dwellings in town must be rebuilt is decided by the price of land and by the necessities of superintendence. Cottage homes, such as have been so successfully provided near London, for a low-waged class, at Clapham, at Harrow-road, and elsewhere, are out of the question on land costing more than £500 per acre. Five or six stories must be built in London, to put enough people on the ground to pay the ground-rent; and staircases and entrances must not be too numerous, or the difficulties of management will be greatly increased. Rebuilding in large towns must thus take the form of blocks. But there is no need for the blank dismal exterior, or for the exact repetition of arrangement which characterise so many blocks of industrial dwellings. A much more homelike look might easily be given, and greater variety in the accommodation and arrangement might be secured, by the exercise of a little tact and thought. No doubt the policy of encouraging all labourers whose work will allow them to live out of town is excellent, but it is, unfortunately, inapplicable to a very considerable number who must live near their work, and it is just this part of the question that presses for solution. Rebuilding has advantages of its own which can never be shared by the old tenement houses. By rebuilding we get rid of the accumulations of filth and vermin which make old tenements so loathsome. Sanitary defects are also remedied, tenements are isolated, so that infection cannot pass from one to the other, and are so placed as to be properly inspected and controlled by the superintendent. So far from a block of labourers' dwellings being necessarily repulsive or monotonous, it is found that the more attractive and cheerful in appearance it can be made, the more eagerly are rooms in it sought after. Not merely does the value of land govern the form of building, but it has affected and will increasingly affect the position, if not the existence, of the lowest stratum of our town population. The labourer living in town is at the mercy of the speculator for his home, and probably for his very existence. An increased demand for warehouse or office accommodation would make it profitable to buy up and demolish labourers' dwellings, in order to erect a superior class of building; indeed, this is going on now, and has been going on for many years past. The labourer may thus at any time be practically evicted from London, and from our large towns, without power of resistance. Whether or not the conversion of the sites of labourers' dwellings to other purposes calls for legislative interference, is a question well worth consideration. At present there is nothing to restrain the speculator who chooses to purchase the labourers' dwelling, and the land on which it stands, from destroying the houses, and from devoting the land to purposes which will exclude such dwellings for ever. The class evicted is helpless in the matter, having no capital wherewith to secure their homes. Other classes similarly threatened can combine and purchase their dwellings, but the labouring class, by the very condition of its existence, cannot do this, and surely is entitled to some protection. Under the Artisans' Dwellings Act, accommodation at least equal to that destroyed has to be provided. It would surely be well to extend this provision somewhat further, so that whenever low-class dwellings are destroyed, an equal amount of houseroom should be simultaneously provided within a reasonable distance.

A case may be quoted which illustrates this necessity. The freehold of a court in the city is owned by a family living out of England. The number of interests in the freehold made it impossible to do anything but either to sell or to keep the old houses in repair as labourers' dwellings. To sell would have been more profitable, since the land is estimated at £2 per foot, but to sell would mean the displacement of the tenants, and through, consideration for them, the other alternative was chosen. After a time, the court is condemned by the authorities, and the tenants are turned out. But although the authorities can close the houses, they cannot compel the owner to build others for the labourer, and if things follow their natural course, the empty houses will be pulled down, and warehouses and offices will cover the site.

The rise in value of land from adjoining improvements furnishes another strong reason for securing the existing sites for labourers' dwellings from conversion to other purposes. The freeholder has usually extracted his rent from his tenants, and has expended little enough upon their dwellings. What little has been spent in repairs they have paid for perhaps several times over, but all round new buildings have sprung up, and have raised the price of land, and now it is too valuable for the purpose to which it has been so long applied. He, therefore, sells it for what it will fetch, and the tenants are turned out to crowd into slums already over full. Tenants who have passed their lives upon the soil have no claim to any part of the unearned increment which goes into the pocket of the absentee freeholder. It would at first sight appear a simple matter to secure a site for the kind of dwellings referred to, but in practice this is found to be one of the greatest difficulties which has to be encountered. Either the land is too highly priced, or is covered with worthless buildings bringing in a rental which must be paid for; or it is let on a lease too short to build on, or is the property of persons who cannot sell, or who are already pressing an undue profit from their wretched tenants. The leasehold system is a main obstacle in the way of rebuilding, and is a great encouragement to flimsy construction and scamping.

As an example of the difficulties in the way of improvement, take the case of a court in

St. Pancras, probably one of the worst in the parish, thirty houses in which have recently been purchased and are now being managed by a dwellings company. The houses contain eight rooms each, and though originally built for one family, they now contain eight each. The squalor and degradation of the tenants is extreme. One of the City companies owns the freehold, and, though anxious to do its duty as landlord, was all but powerless, as leaseholders stood between it and the miserable tenants. Every few years a raid was made upon the leaseholders by the solicitor and surveyor to the company, who, by serving notices of dilapidation and breach of covenants, enforced a number of repairs. The solicitor's and surveyor's fees for enforcing these repairs absorbed nearly the entire receipts from the ground-rent in the intervening years, and thus the City company gained little but the odium attaching to the owners of such mismanaged property. But while, as freeholders, they only received the low ground-rents of the original lease, an enormously increased ground-rent was paid by tenants, and the difference went into the pocket of a speculator. When such property as this is purchased, the outlay is usually too large to allow of rebuilding, since a price has to be paid in proportion to the rental for which the squalid tenements are let. After the purchase, a considerable further outlay has to be made in repairs. This case is one in which management only is practicable until the lease runs out.

Our building Acts contain no restriction upon the conversion of a house into tenements, and require no additional sanitary or other provision for the twenty or thirty extra people crowded into them, and no adaptation to their new purpose. Our building Acts define the size of a hearth to an inch, and they prescribe the thickness of a wall to half-an-inch, they enlarge at great length upon that sacred institution the party wall, but not one word do they say against making a house built for one family serve for ten, nor, if this is done, do they prescribe any addition whatever to the arrangements or accommodation.

The sites now occupied by the dwellings of the labourer will usually be found well placed for the convenience of the class they house, and though the existing dwellings may be overcrowded, the land now occupied, if properly laid out, would, without any crowding whatever, serve for a much larger number. For instance, in 1873, the population in some of the most crowded blocks in St. Giles was calculated at 400 to the acre. In Soho, the *Lancet* Commission of 1874 reported that there were 428 persons to the acre. Sir Sydney Waterlow, in 1875, said that it was easy enough to arrange for the accommodation of twice and thrice as many persons to the acre as there were at present. He could point to several blocks where there were more than 1,600 persons to the acre without the least overcrowding. In the sub-districts of St. Paul's, St. George's-in-the-East, and of Bethnal-green Church, two crowded East-end districts, the population, according to the census of 1871, was 281 and 202 to the acre. Mr. Moore, secretary to the Industrial Dwellings Company, says, speaking of the Whitechapel and Limehouse scheme, "The Metropolitan Association for Improving the Dwellings of the Poor, lodge 1,135 persons to the acre, including open spaces; and the Peabody Trustees have planned to lodge, on the sites they have bought from the Metropolitan Board of Works, 941 persons to the acre."

What price may safely be given for land on which to house the poor is one of the first questions which has to be considered when either purchase or rebuilding is contemplated. As the circumstances of each site vary, it is impossible to lay down a hard and fast rule to apply to all cases, but in favourable positions £20,000 per acre has not been found too high a price to yield a fair return upon the outlay. High-priced land has usually some special advantages to offer, and by utilising these, still more expensive sites may be brought well within the range of possibility. It is not necessary, or even desirable, when building labourers' dwellings, to mass a large number of this single class together and to build for them only. On the contrary, it is advisable, both from a financial point of view, and for many other reasons, not to separate the labouring class from the rest of the population. Room can be found for many of this class upon sites too expensive to be given up to them altogether. The lower floors in many places would let well as shops, workshops, or offices, and might be surmounted by an upper floor or two of labourers' dwellings, with separate access. The higher rents received for the lower floors would enable the upper rooms to be let at rents within reach of the labourer, while the buildings might be so arranged that no interference or inconvenience would result to either class of tenant from the proximity of the other. In an Italian palazzo you often find on the ground-floor a range of small shops and stables, while on the first-floor, perhaps, a duke lives, and the rents of the upper floors are gradually reduced, till the top terrace is reached. There are many buildings in London, and in our large towns, which would bear another storey or two, to which separate access and outlook could be given. In this way a large labouring population could be housed without giving up valuable land exclusively to the purpose, and the separation of class from class, already too great, would be to some extent avoided. Hand-in-hand with the provision of new dwellings must go the demolition of the old. Demolition is as important as reconstruction, and the destruction of the old is essential to the success of the new dwellings. Demolition is necessary because the existing dwellings are saturated with filth and alive with vermin; because, having been built for one family only, they are unsuitable to the purposes to which they are now applied; because inspection and control are more difficult than in buildings specially planned for these purposes; and because light and air must be let into the narrow courts and alleys where the poor are crowded together. But there is another and more cogent reason still, and that is, that, as a rule, the poor people prefer the rookery to the model dwelling. They are accustomed to the dirt and squalor which strike a visitor so painfully, and they prefer the freedom from control and inspection which the rookery affords them. Cleanliness, too, means a certain amount of additional work, which they require some stimulus to make them undertake. But control and inspection are the essential elements of any scheme for housing the labouring class, and model dwellings without them would be quite as bad or worse than the slums. It may be urged that the labourer has a right to his freedom, a right to go his own way. But this he has had, and look at his condition. Severe and repressive measures are not advocated; a friendly intercourse between the landlord and tenant is rather what is needed to restore the labourer's self-respect, and to lift him out of the degraded position in which he is so often found.

One of the most important points upon which correct information is essential before rebuilding, is that of the outlay which will be required. And here it may be stated positively, on the experience of many buildings erected during the last fifteen years, that there is no insurmountable financial difficulty. The rental received from the labourer will pay a fair percentage upon the outlay necessary to provide him with the amount of accommodation to which he is accustomed. The first cost of building labourers' dwellings in blocks in London may be taken at between 7d. and 8d. per cube foot for all expenses except land, and the cost per room, including share of staircase, laundry, sanitary arrangements, &c., would be a little under £60. The rooms can be let at an average of 2s. 9d. per week. We have then the following estimate of outlay, and of annual receipts and expenditure per room. The first cost, exclusive of land, is as above stated, £60. The annual receipts will be £7 3s., allowance being made for repairs and loss of rent by vacant rooms in the estimate for annual expenditure which will consist of these five items:—

	£	s.	d.
(1.) Dividend on first outlay, at 5 per cent.	3	0	0
(2.) Rates, taxes, and insurance, 25 per cent. on net receipts	1	10	9
(3.) Collections at 5 per cent. on net receipts	0	6	3
(4.) Ground-rent	0	18	0
(5.) Balance for repairs and loss of rent	1	8	0
	£7	3	0

The form of the building being necessarily a block, the grouping of the rooms, the access to them, and the sanitary and other arrangements have to be considered. While a certain number of single rooms are provided, it is by no means intended that families should continue to live in one room, unless absolutely compelled to do so by lack of means. Many are now living in one room, that could and ought to occupy two or three. The rooms should, therefore, be so grouped together and connected by entrances that, while they are independent of each other and can be let singly to separate families, they can also, without any alteration, be let in pairs, or three or four together. A certain proportion of two-roomed tenements should be provided. When the necessary height has been given to a room, the larger the floor space that can be secured the better. If a room is to be 12 ft. × 12 ft. × 8 ft. 6 in., it is better to make the floor 12 ft. × 12 ft. than 12 ft. × 8 ft. 6 in., the cubic content being the same in both cases.

The single-room tenement should contain a good and strong cooking range, with oven, but without boiler, a coal locker so arranged as to serve for a seat, and a cupboard to contain food and crockery. In planning the room, a comfortable corner should be reserved for the bed, with which neither window, door, nor fireplace must interfere. A broad window-sill for window gardening is desirable, and the door of each single-room tenement should open to the external air, to avoid the possibility of infection being conveyed from room to room. The balcony offers an advantageous mode of access to the one-room tenement, and should be reached by a broad stone staircase, open to the air. The staircase is apt to present great difficulties in management, if not very carefully considered. One of the great objections to converting an ordinary house into a tenement house is, that the front door being left open at night to suit the late hours of some of the tenants, the staircase becomes accessible to tramps and others. They enter the passages and sleep on the stairs of these houses, and by their vile behaviour contribute greatly to degrade the inhabitants. If the staircase is of stone, open to the air and rain, well lighted both by day and night, and overlooked by the superintendent's rooms, it cannot thus be misused. No other kind of staircase is admissible, and the fewer of these the better for cleaning and management, it being better to increase the size than the number. Outside the one-room tenement, and at a little distance from it on the same floor, or on the half-landing above or below, should be the pail service, where water can be drawn not from a cistern where it has been standing for days but direct from the main. A sink stone in the floor will take any water spilt in drawing, and will also take the waste water, which it is important should be emptied away over a sink stone, and should pass through small perforations before entering the drain, so as to separate from it the flannels, soap, scrubbing-brushes, and other things left forgotten in the pail, and sometimes, when precautions are omitted, introduced with disastrous effect into the drain. The arrangements connected with the water supply and drainage are by far the most difficult to manage, and give more trouble than any other. This trouble is increased by the regulations of the water companies, whose waste-preventing arrangements are frequently waste producers from their liability to get out of order. The screw down valve is a fruitful source of waste, as people will not take the time and trouble to close it completely. In the common laundry, the use of a copper for part of a day each week is assigned to each tenant of a single room, who also has access to a drying ground, upon the flat roof of the block. Separate sanitary arrangements cannot be given to each single-room tenement, but are assigned to every two or three tenements, and are kept under lock and key. The simpler and stronger these arrangements are the better. Iron traps and iron pipes are found to answer best. Lead is quite inadmissible, being easily damaged or stolen, besides being more costly. The drainage should be by glazed stoneware pipes, laid in straight lines and with good fall, manholes being substituted for bends and junctions, and ample means of examination and clearing being provided. Thorough ventilation of the drains, and their complete isolation from the sewer, is of course essential. A large dust-shoot, with an opening on each floor, should receive the ashes and refuse. Ventilating appliances must be provided to each room, and should be out of sight, or they will certainly be stuffed up and closed. An inlet for fresh air, without draught, can often be made over the architrave of the door. A small slot-hole, cut in the meeting-rails of the window sashes, is inexpensive and very useful, as it gives an upward current of air without draught, and imperceptibly changes the air of the room. It is also not easy to close up.

Repairs require a large expenditure when old tenement houses have to be maintained and managed. This arises from two causes. One that the labourer and his family are not very careful of their dwelling, the other that old tenement houses are often all but falling to pieces. The labourer is rough and strong, and requires surroundings not easily damaged. He usually knows good work when he sees it, and he despises and is, therefore, not careful of the miserable building in which he is compelled to live. Beside this, the materials, even if good, and the mode of construction of an ordinary dwelling-house, even before it has become so old as to have descended to the condition of a tenement house, are unsuitable in the highest degree. For instance, instead of the rooms being enclosed by brick walls able to resist a considerable amount of wear and tear without injury, the rooms in which the labourer and his family are usually lodged are enclosed with lath and plaster. This, when new, is very tender and easily damaged, but when in the state in which we usually find it, having lost its precarious hold upon the slight laths, is only held together by the layers of paper with which the walls are covered. The least touch causes this plaster to fall, and when once a hole is broken into it, the damage spreads with great rapidity, and in repairing it, it is difficult to know where to stop. Not only are the walls and ceiling in a condition very liable to damage, even when most carefully used, but the floor is usually worn so very thin in places that the legs of the furniture, and even the feet of the family, unexpectedly break through. Every other part of the room, the door, the window, and the fireplace, has long ago been worn out, and should have been replaced. Gradually, all parts of the building, except the foundations and the lower parts of the wall, have to be renewed. This process of rebuilding, bit by bit, is misnamed repair, and is supposed to be due to the destructiveness of the labourer. The fact is that the labourer is compelled, by necessity, to live in a house which is in such a state of decay that every other tenant has left it. His house is dilapidated, not because he has destroyed it, but because he cannot find a house to live in which is not in a state of dilapidation, and cannot compel his landlord to repair it. Vigorous action on the part of the sanitary authorities might easily prevent this. They have hitherto been far too chary in condemning premises unfit for human habitation.

It is not proposed to supersede the regular collector where he can deal satisfactorily with the tenants, as he probably can with the superior artisan. But at present a large proportion of tenement house property is in the hands of landlords very slightly removed from the class inhabiting it, and these landlords usually collect their own rents. The collector or agent is only called in when the property belongs to persons of a higher grade, and when the landlord is practically an absentee. It is, therefore, of great importance to train and employ collectors of education and intelligence, who can be trusted to recommend cases for relief, and who can distinguish genuine distress from that which arises from idleness and vice. The hold on the tenants is immensely increased by the knowledge that help is forthcoming in time of need. Also by shutting up other channels of relief, and by allowing it only to come through those best acquainted with the recipient, mendicancy and pauperism are much reduced. The collector receives the ordinary per-centage paid for collecting rents. In addition to the collector, there is a resident superintendent, who is by preference a retired policeman, soldier, or sailor. His duty is to keep order, to report any breach of rules, to see that the premises are kept clean, that the gas, water supply, and drainage are in proper order. Usually he is able to do some of the repairs himself, and having a pension or some means of his own, is glad to superintend in exchange for having his rooms free.

Into the entomology of tenement houses it is not proposed at present to enter. The subject is, however, both important and extensive, as those have reason to know who have seen tenement houses pulled down.

In new tenement buildings care is taken to use materials not easily damaged. Lath and plaster partitions are avoided, and brick walls are substituted for them. Iron balusters and stone steps supply the place of wood, and being incombustible, are not torn up for firewood. Everything being well chosen for its purpose, strong, and not in a state of decay, the damage of ordinary use is small, even with the labourer as tenant. Of course, whitewashing, colouring, and occasional painting have to be done, but very few other repairs ought to be required for many years, if in the first instance the buildings have been well constructed. There is no ground, therefore, to fear that the excessive amount of repairs needed in old tenement houses will also be required in new buildings.

We have heard a good deal about benevolence in connection with the subject of housing the poor; and, no doubt, those who have been longest at work in this department commenced it from motives of the purest benevolence. But has it not now outgrown this earlier stage, and having demonstrated that it has a sound financial basis, has it not passed into another phase, which fits it for larger adoption than if it were simply a work of charity? It is, of course, not to be looked at only from what may be called the stockbroking point of view, or merely as a means of getting so much annual income from so much capital laid out. It will bear the closest examination in this aspect, but there are other and important sides to the subject. It is akin both to legislation and to education. Those undertaking the management of the poor have to make regulations for them, and have to see that their laws are obeyed. They have to educate their tenants in habits of order, decency, frugality, and self-respect. We do not talk of the benevolence of a Member of Parliament, who spends the night in legislating for the benefit of the nation, or of the benevolence of the School Board member, who passes weary hours in debating the difficult questions inseparable from education. The same faculties of organision, of government, and of instruction will find a humbler, though an important, field for their exercise in making laws for, and in superintending communities of the working class.

If benevolence is really necessary in order that the labourer may be properly housed, is it not clear that he is being deprived of the fair share of the value of his labour by those above him, since, with all his exertions, he has to fall back on benevolence for several of the necessaries of life?

Superintendence is an essential element of success in housing the labourer. Without it, the rebuilt or repaired court would at once be as bad as ever. The present condition of the poor is the result of a let-alone policy, which leaves the lower working class to the mercy of the speculator, whose only consideration is how to get the most out of him with the least expenditure of time, trouble, and money. Without superintendence every kind of disorder will prevail; buildings will be damaged, rents unpaid, and any attempt to improve the condition of the tenant must fail. The work of re-housing the poor must be gradual, and cannot be done suddenly or wholesale. Experience must be acquired, and the discoveries already made must be acted upon, and the successes followed up. If the managing and superintending elements are outrun by the acquisition or building of dwellings, no success can be attained. A block of so-called model dwellings in the east of London is a lamentable instance of this. Built for a company without regard to the wants of the neighbourhood in which single-room tenements were needed, the sets of rooms did not let because they were too highly rented, and provided too much accommodation. In consequence the company failed, and the buildings came back into the hands of the builder, who let the rooms to any one who chose to pay the rent. There was no efficient superintendence, and the consequence was that the condition of the tenants was as bad as that of any we have had described of late. Now the sanitary authorities are interfering and compelling certain necessary changes. This block of dwellings furnishes a most instructive comment on the necessity of efficient superintendence.

In conclusion, there is no need to wait for further legislation to facilitate the housing of the poor, nor for some great commercial association to take the matter in hand. The work will be done, if ever it is done at all, by those interested in the well-being of the labouring class; it will be done gradually, and will grow out of what has already been successfully accomplished. As a first step, the capitalist will purchase the dwellings and the land on which they stand. Even if the movement stopped here, it would be an immense gain to the labourer to have a landlord interested in his welfare rather than in the amount of rent which could be wrung from him. Land suitable for dwellings will also be secured. By the activity of the sanitary and local authorities, unsound habitations will be condemned and destroyed, and will not then fetch the fancy prices often realised for property of this class. Those who have leisure will associate themselves with the existing agencies, will learn the secret of their success, and will be preparing to take charge of a small community of labourers when the opportunity arises. Others will assist by supporting the authorities and urging on them the administration of the existing laws against nuisances, overcrowding, facilities for intemperance and vice; they will call attention to dangerous structures, defective drainage, and water supply. All will assist by making friends with those of the labouring class to whom they have readiest access, and who will be found, despite their lack of many of the essentials to their well-being, to be far less unlike those who have all these advantages than want of acquaintance with their good qualities would lead many to suppose.

DISCUSSION.

Mr. CHATTERTON gave a description of his own experience in dwelling accommodation. He said he lived in a court near Drury-lane; in a house not a brick of which was sound, and portions of which were absolutely fastened together with floorcloth, but which produced nearly £156 a-year. For the wretched room in which he and his son lived, in which there was hardly room to turn, he had to pay 4s. a-week. He denounced the notion that this state of things could be remedied by charity or philanthropy, and said that if he could afford the rent asked in the model lodging-houses, he would not consent to live there subject to the restrictions which were imposed. He maintained that dwellings could be erected far more economically, which might be let at 1s. per week per room. The present Royal Commission was only another sham which would end in spending more of the working men's money, for they, after all, had to pay for everything by their labour.

Mr. HENRY MAUDSLAY said he had ventured on a previous occasion, when a similar subject was brought forward, to raise his voice on a question which seemed to have been overlooked, viz., emigration and the distribution of population, and he would again insist on the importance of considering this point. Population got concentrated in particular spots from local circumstances. At one time, for instance, Poplar got much overcrowded from activity in the iron ship-building trade; then, after a time, there was a strike; the trade left the district, and the population had to follow it. He was, therefore, in favour of assisting the emigration of certain classes of the population when there was no longer a need for their services where they were, and taking them to some country where there was more room for them, and less danger of overcrowding, whilst those who remained behind would also be relieved.

Mr. MUIR feared that unless great care were taken, the excitement on this subject would run the course of all epidemics, die out, and leave things as they were before. Coming from Glasgow, which had been held up as an example to other cities, it was his duty to state that the great Improvement Committee, which began work in Glasgow 17 years ago, and had not finished, had been a failure both sanitarily and financially. He agreed with Mr. Hoole that there were two modes of dealing with this question—destruction and reconstruction, and the utilisation of existing buildings. He had taken an interest in this question for the last forty years, from having observed the condition of the poor in Glasgow, when they suffered from the Irish famine fever, and he had come to the conclusion that the great source of disease, consequent on overcrowding, was the filthy condition in which circumstances compelled the people to live; and this arose to a great extent from the fact that courts, closes, and common stairs were liable to contamination by one or more filthily inclined tenants, against the wish of the majority. In Glasgow, the 'lands' or houses of flats would have, say, twelve tenants on a common stair, and the police regulation was that this stair should be cleansed once a day by the tenants in turn. But if one dirty woman neglected the duty, or was away from home when her turn came, none of the others would do it out of their turn, and so it went on until probably the whole of them were summoned. His remedy would be, instead of appointing inspectors to compel the people themselves to do these things, to appoint a man to do it. There should also be a rule requiring the walls of such tenement houses to be lime-washed once a year, for cleanliness outside induced people to be cleanly inside, whilst it required a very strong effort to keep a dwelling clean if the external surroundings were filthy. The huts of the crofters in the Highlands would not be considered fit for a pig to live in; but they were healthy because the inhabitants had only to open the door to get the beautiful mountain air. He remembered the Crimean war, and knew three gentlemen who went out as Commissioners, one only of whom, Sir Robert Rawlinson, survived; they restored the British army to health by enforcing cleanliness. It was the same in the navy, where a 4,000-ton ship would have 1,000 men on board, and their health was maintained, not by elaborate sanitary appliances, but simply by rigid attention to cleanliness.

Mr. WILLIAM BOTLY said the paper was most able and interesting, but it would have been more complete, if it had included the dwellings of the poor in the country. This had an effect on the overcrowding of the towns, because for the last half-century landed proprietors had generally been pulling down cottages and driving the poor into the towns. Some years ago he bought a small estate of some 170 acres in Wiltshire, and found there was not a cottage on the property, and the labourers upon it had to walk six miles from Salisbury. He immediately built four cottages, so that the men could live close to their work; they all had gardens, and he did not find that they frequented the public house. One question referred to in the paper was whether the conversion of the sites of labourers' dwellings to other purposes called for legislative intervention. He had advocated, twelve years ago, that all landlords should be compelled to have on their estates sufficient dwellings for the labourers employed upon it; and pointed out that if something of that kind were not done before long, some much more drastic measure would be called for.

Mr. O'LEARY said he had been a working man, and was at present connected with an organisation which was working on this question of housing the poor. One of the many evils which the working classes in London had to deal with, was having public houses placed indiscriminately in their midst. He knew one street with a number of courts leading out of it, and at the angle of almost every court was a public house, which was a source of injury to the neighbourhood. The accommodation for servants had not been alluded to, but he had seen it stated that in some of the large mansions at the West-end, the men of the servant class resided under worse conditions than many of the working population did. Again, there was the question of compensation. Mr. Hoole said it was as necessary to demolish as to reconstruct; and he knew a large railway which was about to take down a number of working-class dwellings. Many of these people had resided ten or fifteen years in the neighbourhood, and had become known there, so that if they were out of work, the local tradesmen, and even the landlords, would give them credit, which was a very substantial advantage. All these would be ejected at a fortnight's notice, without one shilling of compensation; but he contended that they had as much right to it as the leaseholder, the man of business, or even the freeholder. During the last decade, the number of agricultural labourers had decreased at the rate of 9 per cent., most of them coming to the towns, and his experience was that an unsanitary country made unsanitary towns. These men, whether coming from Connemara, the Highlands, or Devonshire, brought their primitive habits with them, and produced a general demoralisation wherever they went; whereas if they had a little social training in their own homes, much good would result. There were a large number of training schools and museums at South Kensington, but they were of no use in elevating the social habits of these men in different parts of the country. He had recently found, on inquiry, that fully 40 per cent. of the men who congregated daily at the dock-gates seeking work had to go away unemployed, and most of these were recruited from the country. What were these unfortunate people to do? Something beyond mere philanthropy was required. Emigration had been referred to, and he might say that he knew something about it, having travelled over the whole of the United States twice, and all through Canada and Manitoba. He admitted that a certain section of those who went out were benefited, but there was a very large proportion of those in London who were totally unfit to be sent across the Atlantic. Emigration might relieve the present congestion of population, but in another decade or two it would again be as bad as ever. Some remedy was required whereby the labourers should be employed on the soil instead of being imported into the towns. With regard to the dwellings themselves, he would not raise the question whether the Peabody buildings were the best, but he did think that those huge barrack-like buildings were not exactly the sort of places which high-spirited people would like to live in. He should not like to live there himself. He would rather advocate the improvement of the present dwellings, for in the suburbs, and places which were suburbs a few years ago, there were miles and miles of working-class houses which were suited to the population, if they were only taken in hand and improved by some authority, local or general. With reference to the statement made by Sir Sidney Waterlow, that 1,600 persons might be placed on an acre of ground, he believed sanitarians had considerable doubts whether it was desirable to do so, the necessary consequence being such a narrowing of streets that the free circulation of air was much impeded.

Mr. Liggins agreed with Cardinal Manning that before you could improve the dwellings you must improve the people themselves, and the best thing to do would be to deprive them of those attractive gin palaces which did so much harm both to their health and pockets. Local option in those parts of London would be the first step in the right direction. Overcrowding, particularly in the east end of London, could not be prevented, as it arose from altered conditions of trade and commerce. Some years ago, nearly all the fruit trade was carried on in small swift schooners, which were rapidly unloaded by large numbers of men; but of late those vessels had given place to large steamers, which had steam cranes on deck, and the whole of the work was done with very little manual labour, and consequently, many dock labourers—often far more than 40 per cent.—were unable to find employment. If they earned more money they would have better dwellings. The Peabody dwellings had done a great service for the better class of work-people, but they did not meet the wants of the unskilled labourers. He saw very little hope for the future, as he believed the trade of London was fast diminishing, and it would be highly desirable to establish a Government scheme of emigration. Mr. Hoole said the inspectors were too chary in condemning unsanitary buildings, but he believed this was very often because they knew that pulling down some would only cause more overcrowding in those which remained.

Mr. Westgarth said he was very sorry to hear that the Glasgow improvements had proved a failure, for he had expected better results, but it only showed that public bodies and corporations were not so well fitted to manage these matters as private enterprise. The first speaker had described the wretched accommodation for which he paid 4s. a week, which he said was not worth 1s.; but he said he abominated interference, and that was the real key to the difficulty, because it was only by the greatest order and discipline, so as to economise management, that it was possible to give the poorest classes the very cheap accommodation they required. In discussing the matter with Miss Octavia Hill, he found she was very emphatic on two points, first, that there should be no charity; and secondly, that the tightest hand should be kept over the tenants. In no other way was it possible to reduce the expenses to a minimum. He thought they were in a fair way of meeting the problem so far as the artisans were concerned, for there was a rapid increase of accommodation which was found to be remunerative, but the very poor were not provided for. The main reason for that was the difficulty of keeping them in order, and preventing destruction of property. This led to responsible people and companies shirking the duty, and leaving to speculators, who screwed out of them the last penny they could pay. The mode of dealing with this class seemed to be pointed out by the method adopted in the registered lodging-houses. In the lower part of the house there was a large common room, which served for kitchen and hall, and the sleeping rooms were above. There might also be a system by which, in consideration of a very small additional weekly payment, the tenant should eventually acquire the property themselves, and he thought it would also be a good plan to partly furnish the rooms with plain, strong, incombustible articles, which could not be easily destroyed.

Mr. E. Bayley said there was a practical effort now being made in Southwark to furnish the accommodation required. Southwark was one of the most overcrowded parts of London, and the worst part of it was the "Mint." Two years ago a piece of ground there, nine-tenths of an acre, was cleared under Sir Richard Cross's Act, which had been lying idle ever since. It was sold to Sir Sidney Waterlow's Company, but those for whom that company provided would not come to live in such a slum, and therefore the company now offered to sell it for £5,500, and a company was being formed to take it up. The architect said that 440 rooms could be erected in a building of four storeys, in the form of an E, for £20,000, with £4,500 for the foundations which had already been put in, or about £61 a room. This would enable them to let the rooms at an average of 2s., and pay 4 per cent., allowing 10 per cent. more for repairs and vacancies than was usual in artisans' dwellings, where it was usual to allow one-third of the total receipts. It was further proposed that the rents should be collected in the way Miss Hill found so advantageous, by the aid of ladies who would make friends of the tenants. The fittings would be simpler than in the industrial dwellings, and of course cheaper. This was, he believed, the first experiment of the kind, and if it succeeded, no doubt others would follow, and it would be taken up in a commercial spirit. He brought the scheme forward because they wanted not only shareholders, but also practical men to act as directors.

The CHAIRMAN said there was an enormous amount of leeway to be made up in London with regard to this matter, and anyone who felt inclined to help, must regard that leeway not only from a commercial and economic, but also from a legislative point of view. One point on which Mr. Hoole had touched as being of great importance was the deficiency of the Building Act, which had for so many years allowed buildings to be misappropriated, and to this was due the enormous crop of wretched tenements, with a common staircase. The fact that from 900 to 1,000 persons could be decently lodged on an acre which had hitherto only afforded wretched accommodation to 200, was very encouraging, for though they might agree that 900 to 1,100 per acre was overcrowding, still it was evident that the 200 could be placed in a much better condition than they now were in those wretched tenements and in the still more wretched buildings which had been springing up in some of the suburbs.

Mr. HOOLE, in reply, said they must all sympathise with the first speaker, who gave such a graphic account of his experience, but it was quite impossible to build small separate houses in the way he suggested while land in London was at its present price. The authority for the statement that cottages could not be built on land worth upwards of £500 an acre, was Lord Alwyne Compton, who held a prominent position in the Cottage Building Company. He knew of several blocks built for labourers, either by companies or private enterprise, and believed there were several others; but still they housed but a very small proportion of those requiring accommodation.

A vote of thanks was passed to Mr. Hoole, which concluded the proceedings.

Correspondence.

NATIONAL WATER REGULATION.

May I beg for a little space for some remarks on the subject brought before the Society by General Rundall (see *ante*. p. 377).

I wished particularly to have attended, but I am now hardly equal to long evening meetings, and my deafness prevents my following fully the discussion, so I trust I may be allowed to speak in this manner. I would begin with two remarks—First, I am delighted to see the subject of water regulation at last brought before the public as a whole, being convinced that it is impossible to settle anything effectively while the four branches of it are attempted to be dealt with separately. Secondly, the remark with which one of the speakers wound up his speech was very curious, that the idea of preventing floods by storage reservoirs was one that no engineer acquainted with the subject would dream of. This remark was made by an engineer whose experience was, I believe, gained from the little nullahs, trifling rainfall, and petty lilliputian works of England; while the reader of the paper is certainly, at this moment, the very first authority in the world on this subject of water regulation, having had thirty years of engineering experience on the largest hydraulic works in the world without any comparison, having himself projected and executed works for the control of one of its largest rivers, and having been for five years in charge of all the irrigation and navigation works of India. Compare its rivers, five of the largest in the world; its deluges of rain (10 and 12 inches in a night), its weirs across rivers from a mile to four miles broad, its canals, broader than the Thames at Teddington, its reservoirs, some 50,000 of all dimensions up to 30 miles round, and 100 feet deep, and containing 200,000,000 cubic yards, with anything in England, and then decide who has the best materials for forming a judgment on the subject of water regulation—the man who has had practical knowledge of a lifetime throughout India, or one who has had to deal with the insignificant rivers and works of England. The flood discharge of Indian rivers are from 20 to 80 times that of the Thames. One of them rises in one part 80 feet, and where it is four miles broad it rises 30 feet in the monsoon. These rivers have been controlled by weirs and embankments; their floods provided for; 10,000,000 acres are now irrigated, and several millions more will be when the works are completed; 3,000 miles of canals have been fitted for navigation with locks capable of passing boats of 250 tons, and drains have been cut to carry off the tremendous local rains from the irrigated lands, so that the engineer for all India must have had occasion for considerable calculation; and to talk of such a man being unacquainted with the subject is a curious mistake. General Rundall was taken from his own Presidency and placed at the head of the Irrigation Department of India, solely because he was the ablest and most experienced engineer of all the remarkable men of his time, that have executed a system of irrigation and navigation works incomparably greater than has ever been carried out in any other part of the world. With respect to the particular point of the storage of water for the control of the river floods, so far from it being one that nobody acquainted with the subject would dream of, five minutes' calculation will show that it is a matter a long way within the range of practicability in England. It is quite a small matter even in India. They have sunk £200,000,000 on railways; it would not require a fiftieth part of that sum to reduce all the floods of India. And so with England, with its insignificant rainfall. It seems strange that an engineer should say that a few inches of rise of the Thames would require 19,000 feet per second, equal to 2,500,000 cubic yards per hour. To raise the river 6 inches where it is 80 yards broad, with a current of about 2 miles, would only take about 70,000 cubic yards an hour, or 600 cubic feet a second, instead of 19,000; as anybody can calculate in five minutes. The measurement stated of a Thames flood at 20,000 cubic feet per second, or 2,500,000 cubic yards an hour, is probably very near the mark. A three days' flood would, then, be 180,000,000 cubic yards, and probably one-tenth of that retained till the river had fallen, would be quite sufficient to prevent all serious mischief. This would require a single reservoir one-tenth the size of the Poonah tank, and at £1 a 100 cubic yards, it would only cost £180,000, quite a trifle for the object in view.

I must say something about the water carriage, one of the great points referred to in the paper. How strange it seems that France should be so far ahead of us on this point. After forty years' trial of railways, France has now made the wonderful discovery that they cannot carry cheaply, and that the country dependent upon them cannot possibly contend with those who have water carriage, not even with us, who have only the imperfect and expensive transit by coast, with some few miles of effective canal carriage; and they are now spending, I believe, £35,000,000 on putting the whole internal water transit on a thoroughly effective footing. Nothing can be more certain than that, as this goes on. England will be completely beaten in a thousand productions and manufactures by France, unless we mend our water ways. One would have thought that people might have found out, in less than forty years, that railways cannot carry cheaply. The railway men have found it out, and have been compelled to buy the canals, or pay them a large per-centage on their capital, in order to compel the nation to carry at a high rate, when they could carry so cheaply by canal, even while the canals were in such a miserable state as most of them are in England. If England were provided with a system of canals suited for steamers of 150 or 200 tons, the area of her market for her manufactures and produce would be doubled or trebled; whereas if she remains in her present state as respects carriage, while the Continental countries provide themselves with effective internal transit, her area will terribly diminish. In fact her progress in wealth depends more upon this of cheaper transit than upon anything else. The progress she has made in ocean transit, of late years, has far surpassed the expectations of anybody. It is very curious that, while she has effected this far more difficult matter, she should be actually carrying internally much more dearly than she did before the railway men deprived her of her water carriage. But it is certain that the evidence published by the Committee on Canals will, before very long, rouse the manufacturing and producing classes to take effective measures to enable them to hold their own with the Continental nations. And, surely, I may fairly hope that this most able paper of General Rundall's, dealing with the whole subject of water control in a thoroughly masterly manner, will powerfully help forward so great and fundamental a question in the temporal affairs of England.

ARTHUR COTTON,
Gen. R.E., Madras.

Dorking, March 19th, 1884.

Sir Robert Rawlinson, having seen the above letter in proof, sends the following for publication :—

General Sir Arthur Cotton appears, in my opinion, to be unduly angry with me because I said that impounding reservoirs might be made for any purposes other than for preventing floods. My experience may be of a puny sort as compared with that of General Rundall, but small as it is, it may be practically useful. But are we certain that General Rundall, Sir A. Cotton, and myself, are looking on the question from the same point of view, as building weirs across rivers, forming navigable canals, and irrigating large areas of land may have little to do in preventing floods; and impounding reservoirs, unless these have the capacity of the North American and Canadian lakes, or of the Black Sea and the Mediteranean Sea, will not prevent floods; and here the sun does the work by co-operation from the vast area of water exposed to its heat influence. General Cotton alludes to deluges of rain, ten and twelve inches in one night; weirs across rivers from a mile to four miles broad; to canals broader than the Thames at Teddington; to 50,000 reservoirs, some of them 30 miles round and 100 feet deep, containing (in the aggregate I assume some) 200 million cubic yards of water; flood discharges, he states, are 80 times that of the Thames, and there are rivers rising in one part 80 feet, and where it is four miles broad, rising 30 feet, and that these rivers have been controlled by weirs and embankments, and their floods provided for; with some other overwhelming remarks about ten million acres of land being under irrigation, and some 3,000 miles of canals being navigable. Now, I fail to see how these works prove that the impounding reservoirs diminish the floods. Let me take the 50,000 reservoirs and the 200 million cubic yards of impounded water, and then, further, take the river weir four miles wide, and which rises vertically in the monsoon from 80 feet to 30 feet. The water flowing over such a weir, say three yards deep, would have a velocity and volume of water passing which, if all the 50,000 reservoirs were empty, would be filled several times over in one day. How, then, would such reservoirs diminish floods? The lakes in Cumberland and in Scotland do not prevent floods; the Swiss and Italian lakes do not prevent floods; how can they, with continuous rain after they are full? The water flows in, through, and out, as if the lake did not exist; and in this sense, the Indian streams and rivers flow into, through, and out of these 50,000 impounding reservoirs, when full, as if they did not exist.

ROBERT RAWLINSON.

P.S.—Surely 50,000 impounding reservoirs, even for India, seems to be a great number.

General Notes.

TECHNICAL EDUCATION IN NEW SOUTH WALES.—The New South Wales Government have just initiated a system of technical education, based largely upon that represented by the Department of Sicence and Art at South Kensington. Last year the amount expended for purposes of technical education in the Colony was £10,000; this year it will be increased to £25,000.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, eight o'clock:—

APRIL 23.—"Thames Communications." By J. B. REDMAN, M.Inst.C.E.

APRIL 30.—"The New Legislation as to Fresh-water Fisheries." By J. W. WILLIS-BUND.

MAY 7.—"Bicycles and Tricycles." By C. V. BOYS.

MAY 14.—"Telpherage." By Professor FLEEMING JENKIN, F.R.S.

MAY 21.—"Telegraph Tariffs." By Lieut.-Col. WEBBER, R.E.

MAY 28.—"Primary Batteries for Electric Lighting." By J. PROBERT.

FOREIGN AND COLONIAL SECTION.

Tuesday evenings:—

APRIL 29.—

APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings:—

APRIL 24.—"Economic Applications of Seaweed." By EDWARD C. STANFORD, F.C.S.

MAY 8.—"Cupro-Ammonium Solution and its Use in Waterproofing Paper and Vegetable Tissues." By C. R. ALDER WRIGHT, F.R.S., D.Sc. Prof. W. J. RUSSELL, Ph.D., F.R.S., will preside.

INDIAN SECTION.

Friday evenings:—

APRIL 25.—"The Existing Law of Laudlord and Tenant in India." By W. G. PEDDER.

MAY 9.—"Indigenous Education in India." By Dr. LEITNER.

MAY 30.—"Street Architecture in India." By C. PURDON CLARKE, C.I.E.

CANTOR LECTURES.

The Fourth Course will be on "The Alloys used for Coinage." By Prof. W. CHANDLER ROBERTS, F.R.S., Chemist of the Royal Mint.

LECTURE IV. April 7.—Questions connected with the liability to Reduction in Weight and various Coins by Wear during Circulation.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 7...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. W. Chandler Roberts, "The Alloys Used for Coinage." (Lecture IV.)

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, Westminster Town-hall, S.W., 7½ p.m. Capt. Wm. B. Barker, "An International System of Marine Course Signalling."

Chemical Industry (London Section), Burlington-house, W. 8 p.m. 1. Election of Local Committee. 2. Dr. Armstrong, "Preliminary Note on certain bye-products of the Pintsch Oil-gas Manufacture in relation to the question of the conditions under which Benzenes are formed." 3. Messrs. Giles and Shearer, "The Estimation of Sulphurous Acid in its Compounds." 4. Mr. W. J. Carpenter, "Further Note on the Solidification of Liquid Oils."

Institute of Agriculture, Lecture Theatre, South Kensington Museum, S.W., 8 p.m. Mr. F. Cheshire, "Bees as Friends of the Farmer."

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 7, Adelphi-terrace, W.C., 8 p.m. Mr. J. Hassell, "Evolution by Natural Selection."

TUESDAY, APRIL 8...Medical and Chirurgical, 53, Berners-street, Oxford-street, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. William Foster's paper, "Experiments on the Composition and Destructive Distillation of Coal."

Photographic, 5a, Pall-mall East, S.W., 8 p.m.

Colonial Inst., St. James's Banqueting-hall, Regent-street, W., 8 p.m. Mr. Alexander Begg, "Seventeen Years in the Canadian North-West."

WEDNESDAY, APRIL 9...Graphic, University College, W.C., 8 p.m.

Microscopical, King's College, W.C., 8 p.m. Dr. W. B. Carpenter, "Binocular Vision with the Microscope."

Royal Literary Fund, 10, John-street, Adelphi, W.C., 3 p.m.

Civil and Mechanical Engineers, 7, Westminster-chambers, S.W., 7 p.m. Mr. A. T. Walmesley, "Ventilation of Buildings."

Journal of the Society of Arts.

No. 1,638. Vol. XXXII.

FRIDAY, APRIL 11, 1884.

ll communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CANTOR LECTURES.

The subject of Prof. CHANDLER ROBERTS'S fourth and last lecture, delivered on Monday evening, 7th inst., was "On questions relating to the weight of coins, and their wear in circulation."

At the end of the 17th century, Rice Vaughan proposed that coins should be issued of indefinite weights, "the alloy being certain, but the weights uncertain," so that the coins would circulate solely by the value of the metal. He pointed out that this plan would have the advantage of preventing the possibility of making profits by sweating and clipping, but that, on the other hand, the objection to the method was the "extreme molestation the people would receive by its introduction," as every one would be required to carry scales to weigh the money tendered for even the smallest payments. Professor Roberts pointed out that few people bore in mind that this is exactly what the Coinage Act of 1870, the legislative enactment now in force, demands, by providing that "every person shall cut, break, or deface" light gold coin tendered to him, returning the same to the person who tenders it. The precautions adopted to secure accuracy in the weight of coins before they are issued from the Mint was then described, and it was shown how very accurate in weight individual pieces must be. The "life" of a coin after leaving the Mint was then traced, and it was demonstrated that the "fittest" coins, that is the heaviest, do not "survive" in the struggle they are specially created to sustain, as they are, for the most part, either withdrawn from circulation for exportation, or to be melted up. Experiments now in progress by Mr. R. A. Hill and Professor Roberts as to the relative rate of wear of different metals and alloys were then alluded to.

On the motion of the CHAIRMAN (Mr. John Biddulph Martin), a cordial vote of thanks was given to the lecturer for his valuable series of lectures.

SOCIETY OF ARTS PRIZES.

The Council of the Society of Arts are prepared to award the following prizes in connection with the International Health Exhibition:—

Under the *John Stock Trust*, a Society's Gold Medal or £20, for the best example of sanitary architectural construction, Classes 20, 28, 29, 30, and 32 of the Exhibition.

Under the *Shaw Trust*, a Society's Gold Medal or £20, for the most deserving exhibit in Classes 41, 42, 43, and 45 (relating to Industrial Hygiene).

Under the *North London Exhibition Trust* a Society's Gold Medal or £20, for the best set of specimens illustrating the handicraft teaching in any school—Classes 49 and 50.

Under the *Fothergill Trust*, Two Gold Medals (or two sums of £20), one for the best exhibit in Class 27 (Fire Prevention Apparatus), and one for the best exhibit in Class 26 (Lighting Apparatus).

From the *Trevelyan Prize Fund*, Five Gold Medals (or five sums of £20), for the best exhibit in each of the following Classes:—2, 3, 6, 7, and 11 (all comprised within Group 1, "Food").

The *Siemens Prize*, a Society's Gold Medal, or £20, for the best application of gas to heating and cooking in dwellings, Class 24.

Each prize will be a Gold Medal, or the sum of £20, at the option of the recipient.

The full list of the various classes referred to is given in the number of the *Journal* for March 14th.

The Council propose to ask the juries in each class to recommend for their consideration either two or three exhibits which they may consider deserving a prize. It will be assumed that all the exhibits in the Classes specified, which come under the above definitions, are eligible for the awards. It will not be necessary for any special application to be made in respect of these Prizes.

Proceedings of the Society.

FOREIGN & COLONIAL SECTION.

Tuesday, April 1st, 1884; HYDE CLARK in the chair.

The paper read was—

THE RIVERS CONGO AND NIGER, VIEWED AS ENTRANCES FOR COMMERCE INTO MID-AFRICA.

By ROBERT CAPPER, A.I.C.E., F.R.G.S.,
Lloyd's Agent for the District.

Although for 200 generations and more a large traffic has been carried on around the great desert in gold dust, the greater part of African produce is of so small value in comparison with its bulk, that it will not bear the heavy cost of slave carriage, the caravans of slaves being overweighted by their own food, and requiring some two or three months to traverse 500 miles. Up to within a very few years the Western African trade was confined to the seaboard alone, and not until the trade of the rivers Niger and Congo was seriously entered upon has it made rapid strides; in the last five years it is said to have quadrupled in value, and still grows at an increasing ratio. When I visited Africa, there was but one screw steamer a month, and none to the South Coast —the imports and exports by these steamers in 1868 amounted to about 28,000 tons. A new steamship company which started at that period in addition to the old company, now possesses 20 steamers, of an aggregate tonnage of 30,000 tons; whilst in 1882, the imports and exports by steam had grown to 200,000 tons, and in addition there are several private mercantile steamers, of a tonnage of 800 to 1,200 tons, constantly running between England and the Niger and the Congo, which rivers are destined to play a much more important part in the development of African commerce, and, as long as they are free, legitimate commerce will thrive apace.

It is certain that Africa, though now reduced to a low state, once had several kingdoms and states famous for arts, for wealth, for power, and for commerce. This Society was instituted in London 130 years ago, for the encouragement of Arts, Manufactures, and Commerce, for which the natives of antiquity in Africa were once so famous. The country is so old, that it is said by some that the figures we now use, though much modified and corrected in the course of time, were first introduced into Spain and Europe by the Moors from Northern Africa. Certainly our troy weight came from Cairo, and the carat found its way across Africa from the Gold Coast to Arabia, and thence to Europe. Numerous Libyan monuments and manuscripts are to be found in the interior to-day. Five hundredy ears ago, Dieppe, in France, traded with Sierra Leone, and still treasures its craft in ivory carving.

There are many interesting facts about Africa, not the least being the statement that the survey of the seaboard of the whole continent of Africa—one-third of the globe—was made by one man, Captain Vidal, R.N., who is said to have expended three ships' companies over the operation.

Amongst the higher and more intelligent people, I met with the signs and symbols of ancient freemasonry; many of the rulers are born gentlemen; the continent is scored with native roads from sea to sea, over whi chthe internal commerce is very great—a fractional part of it only being produced and exchanged with the civilised world.

The climate in the interior is not insalubrious, and if proper cultivation and the arts of civilised life were introduced again—which can only be done by commerce—it will prove of vast advantage to the Africans and ourselves. Europeans have the conveniences and appliances for crossing the seas which the Africans have not yet; therefore, avoiding all political allusions, I have sketched out this paper from a commercial point alone. Having traversed and traded both upon the Niger and the Congo some years ago, I will address you upon what is within my own knowledge, corrected down to the present time.

My sojourn there was, of course, not without its difficulties. I fell into the River Congo, and I suppose I am one of the very few men that ever came out again. I was wrecked on the desert of Sahara, amongst the marauding Arabs. The King of Dahomey was very desirous of taking my head off my shoulders. I have been capsized in the surf amongst the sharks many times, and cannot swim. My voyages up the Niger were during what I may call the "Pen and Sword Period." My first visit lasted for a period of close upon five years without any return home, during which time I not only lived amongst and passed through all the mangrove swamps in the Bight of Benin and the twenty-two mouths of the Niger, but I also had two rainy seasons on end, and witnessed the landing of the "jigger" from Brazil at Ambriz. Notwithstanding all this, it was gratifying for me to find, upon returning to England, and going into the question of my life assurance, that when I boldly demanded to be put upon the same terms that I was on before I left England, this, after due examination was agreed to. Beyond self, I am glad to add I never lost a member of my staff; all are doing well in one part of the world or another. I have never been molested or robbed—those representing commerce are welcomed with open arms; on the other hand, natives are shy of non-trading travellers, as though they were spies in the land.

It would be, perhaps, just as well to explain in advance the pedestal I stand upon, and with what eyes I steamed up and down these noble rivers. My life, thus far, has been broken up into four septennial periods, as I suppose it is with most of us; seven years I spent at Christ's Hospital, in the City of London, where I received all my education; seven years I spent in the employment of the late firm of Messrs. Peto, Betts, and Brassey, in the management of docks and railways at home and abroad, under the direct personal supervision of the late Thomas Brassey; seven years I resided in Western Equatorial Africa; and for the last seven years, I have managed the harbour, docks, and railways of Swansea, where the trade has increased three-fold in a marvellously short time, in which there is not much sentiment or romance, so that I can look back upon the past with an unprejudiced eye.

English legitimate trade with Africa commenced in 1553, but it was suspended by the slave trade some nine years afterwards, in the days of Queen Elizabeth. It is interesting to note that the first trading vessel brought back 150 lbs. weight of gold, and 80 tons of pepper, from Elmina and Benin, refusing large quantities of the latter, but leaving behind 100 men, including the chief of the expedition. Another expedition followed next year, bringing back this time 400 lbs. of gold, of 22 carats and 1 grain fineness, 26 butts of guinea grains, and 250 tusks of ivory, some weighing 90 lbs., for which the adventurers parted with all their cloth, except two or three packs. The next year, 1555, the Portuguese began to interfere with the English trading-vessels, and some conflicts took place off Elmina. In 1556 and 1557, the English vessels were not only fitted out for trading purposes, but also as privateers against the Portuguese. About this period the Portuguese are credited with commencing the slave trade. The English followed under the Queen's flag, but only continued it a couple of years, as the voyages terminated most miserably, and legitimate commerce on the part of Englishmen then again revived.

The first article of commerce with Western Africa is palm oil, mentioned in the early voyages as oil of palms. In the year 1556, thirty-two barrels were brought home; the quantity in 1880 is estimated at 50,000 tons, representing a value of over £1,500,000.

The 16th century was the era of African companies, exclusive privileges, and legislative encouragement; as a natural consequence, private enterprise and legitimate trade declined. None of the half-dozen companies prospered; indeed the whole of them, in the course of a very few years, failed, owing, perhaps, to the fact that many of them dealt largely in slaves, the royal concession to one being issued on the condition that the company supplied 3,000 negroes every year to the West Indies. The trade grew to very large proportions, until about 100 years ago, when no less than 192 ships are reported to have left England's shores for Africa as slavers. The abolition of the slave trade had something to do in putting an end to these companies.

The Arab trader in Central Africa is not at all deterred by the hardships he meets with, or the inhospitality served out upon the road; but those visiting the seaboard from the interior can only carry gold dust down to the Gold Coast, and ivory down to the South Coast, for want of the power of transporting large quantities of bulky produce cheaply. I have known caravans of ivory arriving at one time to number 7,000 bearers.

On glancing at the map of Western Africa, it will be observed that there are no broad navigable estuaries, no secure and capacious harbours, no land-locked bays and gulfs; therefore the finger of nature points to the Congo and the Niger as the proper entrances by which to approach the continent of Africa.

At the beginning of the present century, as late as the battle of Waterloo, the Niger and the Congo were thought to be one and the same stream. A Government expedition was sent to the Niger to descend that river, and the memorandum of instructions furnished Captain Tuckey, R.N., by the Admiralty at the same date, 1816, directed him to ascend the Congo, and find out if the two rivers were identical or not.

Before the introduction of railways in our own country, about eighty years ago nearly every important town in England was connected by canal; but for the last fifty years this seems to have been lost sight of, though there exists at the present time, through the length and breadth of Great Britain, no less than 4,000 miles of canal navigation. If we reflect upon what the effect of waterways and railways in our own country has been, there is no telling what the opening up of the great water system of Africa, by utilising the Niger and the Congo as entrances, may lead to; their enormous value and growth during the last few years are beginning to receive the attention they really demand. The Congo, one of the noblest rivers known to the world, discharging four times as much water as the Mississipi, has hitherto been free to all the world. That traffic thrives when free, is evidenced by what has been done in the Niger. For the Niger river, though not discovered until 300 years after the Congo, there are Admiralty charts now corrected up to the year 1875, as far as New Boussa, a few miles above the point were Mungo Park's canoe is reported to have been wrecked. That traveller likened the Niger at Timbuctoo to the Thames at Westminster, and on reaching Sego, the capital of Bambarra, he wrote that he found the crowd so great at the ferry that he had to sit down on the river banks, and wait for about two hours for an opportunity of crossing, looking upon the extensive city, the numerous canoes upon the river, the crowded population, and the cultivated state of the country. The picture which he gazed upon was one which he little expected to find in the bosom of Africa.

It is no wonder that the Niger was a puzzle to our older geographers, for, upon descending the river towards the sea, it gets shallower and narrower till a mile or so from the Bar. Louis's creek cannot be more than 100 feet wide; in it H.M.S. *Pioneer*—in which I was a passenger by favour of the Foreign-office—took the ground. The British Government of to-day has expressed an opinion that a good entry to the Niger can be made by way of Whydah, and that it is strange nobody had ever thought of this before; and those who know the land can only smile. The discovery of the Nun-mouth, within the memory, perhaps, of many, was, however, only about fifty years ago. No time was lost in sending a trading expedition up, the first being from Liverpool, fitted out at the expense of Mr. Robert Jamieson, of that city. The first five ventures were very favourable, but the trade was found to be springing up slowly and gradually. Mr. McGregor Laird said it must be a losing one for the first seven or ten years, and, when profitable, others would come in and reap the benefits with the first adventurers. To the late McGregor Laird—who pioneered in person these five expeditions, and who, upon one of them started with 49 Europeans, and returned only with the odd figure 9—is due the results which we now see; but the sacrifice of life stopped trade. Consul Beecroft, stationed at Fernando Po, nevertheless, continued the ascents of the river, though still with considerable loss of European life in each case. At length the British Government sent up an expedition in the year 1841, under the command of Captain Trotter, R.N., and though in the river only 62 days, out of a crew of 152 men, 42 white men died. This expedition crossed the bar on a Sunday, and lifted anchor to ascend the Niger on a Friday. Bishop Crowther, who is reputed to have been born on the banks of the Niger, and from thence captured and sold, accompanied this expedition, and in his journal there is to be found a significant remark, "The first intimation the interpreters offered to the villagers, in answer to inquiry, was always, that they were not Portuguese, but that they came as friends to the black people." The disasters accompanying these expeditions seemed to have put a damper on the enterprise, but the intrepid McGregor Laird, watching for an opportunity, found one in 1853, upon the supposition that the celebrated Dr. Barth was somewhere on the banks of the Niger. McGregor Laird succeeded in making a contract with the British Government to fit and send up a small screw steamer, called the *Pleiad*, giving a free passage to Bishop Crowther a second time; and though the expedition reached a point up the Binué, 250 miles higher than Captain Trotter's, and was 118 days on the river, no lives were lost. It is also a noteworthy fact, as the Bishop observed, that though twelve years before very few people were clothed, the condition in this respect was most marked. Thus a new era seemed to be opened up in African exploration. Without following too closely the history of the river, Mr. McGregor Laird no sooner worked up the trade to a paying point than he unfortunately died, and out of the ashes of his trade sprang the West African Company, uniting commerce with missionary efforts. But the trade did not make rapid strides until the advent of James Alexander Croft, commonly called "Niger Croft," sometimes "King of the Niger," to distinguish him from the Commodore of the African Steamship Company of the same name. The qualifications of a successful African traveller are rare; plenty of men can find the sinews of war, but the character of the man who has to bear the brunt must be almost unique. The constant excitement of travelling through new lands requires that his mind should be well balanced, added o which an iron constitution is indispensable.

I estimated the value of the produce brought down when I went up in 1870 at about £30,000. I believe it now exceeds £2,000,000.

It took me twenty-six days to go up the Niger first, now the same distance is easily accomplished in two days. There were then only two factories, now there are fifty-seven. There were only two trading steamers in the river, now there are some twenty steamers, exclusive of several iron lighters, carrying from 30 to 40 tons. One company alone has £57,000 invested in small river craft, and over a million of capital in the Niger. Produce is gathered now that was never gathered before. I passed 105 towns, some with a population of 10,000, but apart from that, the banks everywhere teemed with life. The end of my expedition was Bidda, 450 feet above the sea, where salt is better than fine gold—yielding greater happiness and luxury.

The Emir of Nupè, who pays tribute to the Sultan of Sokatoo, received us, and at the first interview, after saluting us three times according to the custom of the country, he immediately plunged into questions of trade and commerce; all reference to the Queen's messengers—captains of two men-of-war forming the expedition, in full uniform—became a secondary affair. These officers felt themselves very much in the shade. The Emir, or king, called for his pass-book, which was read out before us all, showing that he was indebted to the West African Company in the sum of £765 10s., chiefly for brass and copper rods, Dane fusee, and Tower guns and gunpowder. He expressed himself desirous of paying this off, on the condition that he should get more credit, the balance against him the year before having been nearly double, viz., £1,500. It was with extreme difficulty that the Emir was got to turn his face to the naval officers, and postpone his talk about his private trading for a later occasion; he did so, however, upon the mention of the murder of Consul Fell, stationed at Lokoja. There is a letter in existence, penned at Bidda, dated from that town on the 15th September, 1870, addressed to the Queen by Masaba, calling attention to the fact that no redress had been sought in consequence of this outrage and attack upon her Britannic Majesty's representative in the Niger, and upon the Bishop and his secretary.

Education I found to be generally enforced. The streets were broad and clean, and there were regular Courts of Justice.

As a passenger on this occasion on board of a man-of-war, I could not enter much into the trade; but I was permitted to put as much cloth as I could under my mattress in the captain's room, which proved sufficient not only to pay my expenses in a lordly fashion, but enabled me to buy something like 125 pieces of ivory. The trade of the Niger is now the trade of the coast; the African steamers get their largest cargoes there, and expect to do so.

Attention has been called to the fact that there is one piece of British land at the confluence of the Niger and the Binuè which carries with it the right to navigate the river.

Some steamers have been lost, but no lives, in these mishaps.

In turning from the Niger to the Congo, it may be right to state that Lagos, a settlement belonging to our British Crown, not twenty-five years old, has a population of 60,000, whilst Loanda, the capital of the Portuguese province of Angola, between 300 and 400 years old, has only 12,000, or is one-fifth the size.

The first trader in the Congo as far as the falls, was a Scotchman named George Maxwell, who long resided there, and published a chart of the Lower Congo, from the cataracts, downwards. When Captain Tuckey's expedition was sent out in 1816, Maxwell recommended the building of boats which could be portaged by thirty people round the cataracts.

There is no record of any trade by the Portuguese except in slaves.

Though Angola was discovered before the conquest of Peru, I do not propose troubling you with the history of that province, and the land of that innocent looking instrument of death, the "Palmatore," a flat circular piece of wood, pierced with five holes, affixed to a short handle. It may be enough to refer you to my late friend Mr. J. J. Monteiro's observations upon the Portuguese and their possessions, which are true to the letter.

The only Government expedition ever sent up the Congo was that of Captain Tuckey. By the courtesy of the Admiralty, I have been permitted to read the original journals, in Captain Tuckey's own handwriting. The expedition was most disastrous, about one-third of the crew, and all the scientific men, with three of the superior officers, dying from fatigue and exhaustion in a little more than three months. Captain Tuckey's last letter was dated from Banza-cooloo-Yallalla, addressed to Mr. J. W. Croker, at the Admiralty, on the 20th August, 1816. In fact the vessels, when at sea, seem to have been left without any officers at all, a Mr. Lewis Fitzmaurice styling himself senior officer of H.M. Sloop *Congo*, appointing himself Lieutenant, in a letter which is amongst the original documents, addressed to himself, written by himself, and sent to himself.

The commerce of the Congo is of recent growth. In my time, 12 years ago, there were four English houses, one French, and one Dutch, trading up the river as far as Nursuku and Noki—there are now 49 European factories on the banks, and the exports and imports are valued at £2,000,000. The first invoice I received at Banana was for £7,025 17s. 6d. Only some 15 years ago a change in the trade came about, for up to that time the Congo was the stronghold of the slave trade, and it is credibly stated that as many as 100,000 slaves a year were sent across the sea. As long as the slave trade could be carried on, the Portuguese Government remained silent for very obvious reasons—the dealers in the slaves were their own subjects. But now the Portuguese seek to repeat what they tried 25 years ago, *i.e.*, to force all the trade in bees-wax, gum, ivory, coffee, and other valuable products, through Loanda, where they possess a good deal of property. The move then made forced the establishment of the two free ports of Kinsembo and Ambrizette. There can be no doubt the Portuguese are losing their trade, in consequence of the exactions and restrictions of their own custom-houses, passports, and so forth, the more recent extensions of African commerce being on the Angola side of the River Congo beyond the dominion of Portugal.

When the *Journal of Commerce* of Lisbon attacks the English manufacturers for their opposition to the Congo treaty, and urges that Portugal will protect the natives from all risks of spoliation by numerous adventurers and so-called philanthropists, this must be looked upon as an attempt to mask the truth for selfish purposes.

It is no secret that the abolition of slavery in the Portuguese African possessions, though decreed years ago, remains to this day a dead letter. The complete abolition was, by Royal decree, to take place in the year 1878, and it has been recorded by one of our most intrepid African travellers, Commander Cameron, that during his travels slaves were still exported from Angola, a steamer entering the ports for an hour or two, shipping the slaves, and departing for a destination unknown. If the River Congo were handed over to the government of the Portuguese, this state of things would be perpetuated. Mr. Keith Johnston, in his book on Africa, describes the government of the Portuguese as utterly untrustworthy; abuses are practised, he says, by ill-paid officials, who prey upon the defenceless population, and in this manner prevent the development of the resources of this splendid country; and he adds, "so easy and successful have been the systematic extortions and robbery of produce, and labour, from the natives, that large sums of money have been spent and much interest employed for the sake of getting the post of Chefe of the more important districts even for a short time."

Portuguese ideas of colonising countries is first to erect a fort, secondly to fix up a custom-house, and thirdly to commence a cathedral, and there it ends; they have never made a road. Their custom-house must pay something to to the State at home, and as much as possible to the officials on the spot.

On the subject of the Congo Treaty, which it is stated will not affect the trade of the upper waters, but that the interior trade will be allowed to pass to and fro free, I do not believe anything of the kind; there are more ways of killing a dog than hanging him. It is said the duties will be light, but when they are demanded in cash where none is used, the duty is at once increased; moreover, there are eighty-seven rules of the most stringent nature scheduled to the treaty; everything is to be written out in a foreign tongue (Portuguese) in a limited time, and everything English literally wiped out. The Portuguese custom-house officials will, in all probability, insist upon everything being turned out of the ship on to the quay or wharf, weighed, measured, and compared with the manifest; here is a chance for fines and forfeitures, for what Portuguese official would let slip such a splendid opportunity of enriching himself by one big haul. The result will be that the forty-nine factories, established on the banks of the Congo will return to the old system of African trade from the ship's deck. Again, it is said that the same privileges that the subjects of Portugal enjoy are to be extended to the English; but who are the subjects of Portugal there? Convicts, men thankful for small mercies, though they are the most prosperous of Portuguese traders. Men condemned to transportation for murder, and abominations ten times worse, are the largest householders and landowners in the capital—Loanda; and English traders, though they are mere pioneers of commerce, are to be put upon the same platform with such men. Read the correspondence of my dear familiar friend, the late Consul David Hopkins, issued with the treaty. The native hate of the Portuguese is very bitter, and were they strong enough, friend Menteirs said the natives would drive them into the sea. Natives will not work for them unless compelled. The latest African authority innocently states:—"A regular system of apprenticeship, tantamount to slavery, is necessarily in vogue." But why necessarily? Nowhere in the British possessions is this found to be so.

The Portuguese speak of the lighting, buoying, and the preservation of peace in the waters of the Congo, but as to what they are likely to do in the future we judge by the past. How many lighthouses are there in the province of Angola? What protection has it afforded to its own settlements? How often has Mussula, where I had a factory, been plundered, we have often thought, at the instigation of the Portuguese themselves? What improvements and works of utility have ever been carried out at Loanda? Has it a pier? Is it supplied with water? Are there any railways? Certainly an English commodore, many years ago, turned the first sod of a railway, but that Englishman did all that has been done towards that railway, for there it ended.

The Portuguese Government officials know they need not be on good terms with the natives; the trader finds it to his interest to be so, and peaceful in all his transactions. Already the trade on the Congo is very considerable, and in a few years it promises to attain vast proportions. Mr. Johnston, in addressing you a few months ago, said that the idea of Portugal on the Congo is simply preposterous, she had no interest and no commerce to defend like the English or the Dutch; if she had, she would stick on differential duties, and try to divert the trade from Liverpool to Lisbon. So say I, and I will add to this through Loanda. To hand over the Congo to the Portuguese Government that has done nothing, the results of the present mercantile prosperity being due entirely to the large investments of capital and long years of labour, would be a cruel and disastrous act. There are no visible signs of Portuguese authority. The marble pillar which is reported to have been erected by the Portuguese on Point Padrone, in 1859, was washed away by an unusually high tide, and no further attempt has been made to put up another, a significant fact worth volumes.

As a simile to explain what "navigation dues" mean at a river mouth, I may refer to the River Scheldt. The prosperity of Antwerp did not make any strides until about 1863, when the right of levying navigation dues on that river, granted to Holland by the peace of 1839, was commuted for the sum of 36,000,000 francs, one-third paid by Belgium and the rest by other Powers interested. Who can say that the navigation dues on the Congo will not be valued at the same sum soon.

I am glad, at this time, of the opportunity that has been afforded me of reading a short paper touching upon the commerce of the Congo. I have recently seen a letter which appeared in the *Manchester Examiner*, written by a resident at Ponta-da-Lenha, complaining that the authors of the Congo Treaty had never resided in Africa, or had the slightest experience of the manner in which the trade was carried on, whilst those who, through a residence of many years had become acquainted with the wonderful capabilities of the Congo valleys, declined to come forward to state what they knew. Upon this I addressed the editor of the *Times*. I should like to know what Mr. Johnston can possibly mean in his letter to the same editor, written as one acquainted with the Congo and its politics, when he says:—

"The principal objections in England will come from commercial men, who will fear that the rising trade of the Congo will be hampered when the mouths of the river are placed under Portuguese rule; Portugal being a protectionist power, and given to the imposing of export and import duties; and from those objecting to the Congo Treaty, who, from some special reason, do not wish to have their doings too closely inquired into."

Certainly, the King of Portugal has wrapped up in one article of the treaty an undertaking not to punish any inhabitants of the Congo for what has taken place in the past. But to whom can it be supposed this is to apply; not to men of England, I know, for one. Mr. Johnston says that the Portuguese are good road makers, and that if they had any spark of enterprise they would at once commence a railway or a good cart road, there being a fair field for them on the Congo. Let me remind you, however, that they have had a fairer field in Angola for the last 300 or 400 years.

Stanley has stated that any power obtaining the mouth of the Congo would absorb to itself the whole commerce of Central Africa, and supply the wants of a dense population covering a million square miles. The development will be enormous, and the heavy income and property tax and dues, varying from 25 to 125 per cent. on the value of the imports and exports, at the expense of the English merchants, would be a gift to Portugal which it is difficult to understand. What do the Portuguese traders of the Congo themselves say? "What, hand us over to the wretched Portuguese Government!"

The African does not know how thoughtfully he is cared for by the civilised world, though he knows his own interests pretty well, and is ever alive to them, and not so dull as some would have us suppose. It has been stated that those who object to the Congo treaty must do something more than find fault; they must show a better practical course, which has not been done, and will not be easy to find out. Where is the hurry? What is the imperative necessity? Who can force England to come to a solution of the difficulty? The *Times* newspaper said, a few weeks ago, that it could not be denied that the best hopes of commerce were involved in the extension of the influence of the International Association, which asks for nothing more than to be allowed to remain the peaceful instrument in bringing various articles of foreign manufacture into the numerous markets that are to be reached by means of the Congo. But before the ink is fairly dry, all good is to be counteracted by the influence of the Portuguese. Without exaggerating the importance of the interior, Commander Cameron states that Africa contains everything that can be desired to make men rich, and that it is replete with vegetable and mineral wealth; the natives make good servants, the climate is delightful, and but for the Portuguese everything would be according to the emigrant's wish.

The first time the King of the Belgians came forward in the matter, as far as my memory serves me, was in January, 1876, when his Majesty offered to pay the expenses of Commander Cameron, who was reported to be then in difficulties in Central Africa. Some nine months afterwards a Conference was called of the different Geographical Societies of Europe, and from that grew the International African Association. I have seen it stated that no less than £400,000 has been expended in the opening up of the Congo. The opening up of new countries is of advantage to trade in more ways than one. One of the first steel boats ever constructed was one specially built for Dr. Livingstone's expedition on the Zambesi. It was built of puddled steel, a laminated material which, although playing an important part in the history of steel manufacture, is now no longer made, being entirely superseded. It was not a success, for Dr. Livingstone, writing to the Secretary of the Society of Arts, stated that the plates had worn so thin, and became so full of small holes, that the wretched craft might have been converted into a coffee-strainer for the use of the entire Society.

Captain Tuckey's expedition in 1816 took out a steamboat suggested by Sir Joseph Banks, a vessel drawing 4 feet, with engines of 24 horse-power, made by Boulton and Watt. This was nearly a generation before the general introduction of steam navigation. Reflect for a moment upon the numerous industries helped forward by the African markets. Why, it comprises every one. Even Ireland contributes to the supply. Africa is one-third of the known world, and next door to England.

But the great value of the free navigation of the Niger and the Congo is the facilities they will soon afford to the utilisation of the inland waters by steamboats, connected with railways which are not difficult to construct, the interior being described as one vast table land. With a good knowledge of Africa generally, and having thoughtfully considered the proper plan of opening it up, there is no doubt the unhealthy seaboard should be avoided, and the establishment of railways projected from the interior. This is an enterprise worthy of British pluck. Extensions would soon follow north and south, and the interior slave trade be annihilated. A route for a railway across the desert of Sahara is marked the whole way with the whitened skeletons of those who have perished *en route.*

To traverse that desert in twenty-four hours, a journey now requiring four months, and placing the very centre of African civilisation within ten days of London, is a feat worthy of the present age; and after what has been done in America, England should do something. If she does not, Portugal will not. The forests of the interior would supply the necessary wood for sleepers, and such a line could be easily laid at an average rate of one mile per day. Taking the desert as 600 miles broad, it would be two years in building. Labour in the interior is cheap, and the transport of plant by the Congo and Niger not expensive.

It should be observed that the wealth of the interior has not been exaggerated; a marked change for the better is observed in its inhabitants; the people are, to my mind, not uncivilised, and dependent upon agriculture for a living, growing all things necessary to their own comfort; and there are to be found merchants who, at moment's notice, can produce £50,000 or £60,000 more readily than many European bankers.

The length of a railway from the Mediterranean to the Cape of Good Hope, direct, would not be more than one-third of the length of the whole of the railways in Great Britain to-day, and could be constructed for two millions of money, one-hundredth part only of the cost of our present English railway system, without taking advantage of the great lakes in the interior. A railway so constructed would give two sides to work from, and would form a regular spine through the land; moreover, experience has shown nothing is more defensible against semi-barbarians, when met with, than a railway in the hands of a civilised power; the line affords facilities for defence at any threatened point in a way that baffles and overawes invisible assailants, and it would be always valuable, apart from the moral effect and the political force which it would exert, through the heart and centre of the African continent, as affording new outlets for our manufactures.

The Niger and the Congo are the present entrances to Africa, and if England is true to its trust, it will not let them be recklessly thrown away. There should be no secret about the trade, for, believe me, it will shortly show results, whilst free, that will literally burst and astonish the whole commercial world. I therefore append a list of goods finding a ready market in both rivers in my day.

APPENDIX.

Niger River, 1870.—Goods there, for Sale and Returns.

From Manchester.—Madapollams; Croydons, 28 yards each, 8s. 7½d.; taffeta, 2s. 10d.; grey bafts, 28 yards, 8s. 3d.; im. country cloths; nicannees; royal checks; stripe domestics; Turkey red and white stripes; Turkey red chintz; fancy prints; fancy satin prints; brilliants, ginghams.

From Glasgow.—Madras handkerchiefs; romalls; ground scarves; silk Corah handkerchiefs; fancy cotton ditto.

From Birmingham.—Guns of all kinds; tin cups and basins of all kinds; tin cups, with handles, of all sizes; mirrors of all sizes; pewter basins; assorted beads.

From the Potteries.—Crockery and glass ware of all kinds.

From Ireland.—Gunpowder.

Miscellaneous.—150 tons salt; green cased gin, 250 c.; 450 cases brass and copper rods; 600 bags cowries; English new florins, £300.

River Congo, 1872.—Goods for Sale and Return from Manchester. Invoice Costs.

		s.	d.	
Blue baft		11	6	per piece.
Citronella	48 yds.	16	6	,,
Chilloes	12 ,,	1	8	,,
Striped domestics......	24 ,,	3	9	,,
Checked ,, ...	18 ,,	3	11½	,,
Pano da costa	22 ,,	7	9	,,

Tower muskets	8	0	each.
French guns....................	7	6	,,

	s.	d.	
Brass rods, 70 lbs. and 86 lbs.	50	0	per box 200
Padlocks	1	1	per doz.
Negro balls	4	3	per gross.
Armlets, ½ lb. each	1	2	per pair.
Matchets	0	5	each.
Blue cut beads	0	3	per 1200

SUNDRIES.

Red cased gin	7	5	per c. 1 doz
Ginger wine	10	3	,,
Cyder	8	9	,,
Soap	17	6	per cwt.
Hoop iron	10	0	,,
Salt	2	0	,,
Pipes	2	6	per gross.
Gunny bags	0	5	each.
Rum	1	4	per gal.

Earthenware.—Jugs, cane gallon, painted, hooped white, lustre, tulip; soup plates, wash basins (white and painted), decanters, tumblers, and glass covered mugs.

From Ireland.—Men, women and boys; kegs of gunpowder, 14 lbs., 7 lbs., 4 lbs., at 35s. per barrel.

STOCK-SHEET OF A FACTORY ON THE CONGO, 1872:—

	English. £	s.	d.
Merchandise of all kinds	6,277	13	4
Factory itself and stores adjoining	1,608	10	8
Furniture	452	6	8
Boats and canoes	495	16	0
Casks and coopers' stores	180	14	6
Provisions	98	6	1
Marine and other stores	182	2	4
Live stock	67	14	0
Produce in store	158	3	2
Debts outstanding either way	*Nil.*		
	£9,521	6	9

N.B.—Everything of English production.

DISCUSSION.

Commander CAMERON said that the remark which had been ascribed to him to the effect that the climate of Africa was delightful, must not be taken to apply to the whole continent, but only to certain portions of it. There was no doubt that the Niger and the Congo were the two great arteries of the country. He would not enter into the question of politics, but he was sorry to say that England seemed to be such a poor little nation that she was always afraid of treading on anybody's corns, and there-ore seemed to want to interpose Portugal as a buffer between herself, or the International Association, or the French, or perhaps the privates who were chastised eight years ago by Admiral Hewett. The mouth of the Congo had been for many years almost entirely dependent on the British navy for police arrangements; and in 1862, Sir Eardley Wilmot, as Commodore, made certain treaties, not with subjects of Portugal, but with the native nations, and now all those treaties were apparently to be abrogated. If people on the Congo committed any acts of piracy, there had hitherto been a British man of war somewhere in the neighbourhood to punish them, but in future it would be Portugal which must be looked to. He remembered being at Kinsembo when there were four or five large factories which paid no duty to the Portugese; but now, even if they were on the same footing as Portuguese factories, they would have heavy duties to pay. The Logi river was alluded to as being the northern boundary of the Portuguese, but t was in fact a few miles north of it; and though Englishmen could walk about there unmolested, the Portuguese, if they came across, had to take their shoes off, and were sometimes illtreated besides. Unfortunately they heard nearly every year of a Niger expedition, the police of the Niger being also that of English men of war. If England, recognising the growing importance of her commerce there, were to establish a Resident on the Niger, with a small steamer at command, so that he could immediately investigate any differences that arose between the traders and the natives, which in many cases caused loss of life, most of these disturbances would be stopped at the outset. But, unfortunately, England, though the foremost nation in commerce, seemed to be the most apathetic of all in any matter relating to the protection of that commerce. A false economy prevailed in all her settlements, the only idea apparently being to keep money in the chest. Some time ago, there was a street in Cape Coast Castle which sadly wanted draining, the estimate being about £1,200; that certainly seemed a large sum to spend on one street, but the result was an order that the best that could be done should be effected for an outlay of 30s. The authorities at home had little or no knowledge of Africa, and they seemed to rely entirely on the reports of a few persons only. The traders of Africa had opened up a trade rather in spite of the Government than in consequence of any aid they received. For nine months the rivers had been without a Consul, but if Consul Hewitt's health did not allow him to go out there, surely someone might have been found to take his place; and during that time the French had been making treaties with the Okrekas. He wished the English public would interest themselves more about Africa, for he was persuaded that in that country there was a market for everything we could manufacture.

Mr. J. ALEXANDER CROFT said he was largely interested in the African trade, and had spent a great many years in developing it, and he did not like to say much upon the subject, as it would seem like blowing his own trumpet. He agreed with Commander Cameron that these expeditions up the Niger might be put a stop to by having a resident agent there, or a Vice-Consul. At present, there was no protection for traders whatever except these expeditions, which sometimes took place when they were not wanted. As to the Congo, he thought we were giving up a most important and valuable river to the Portuguese, who had never done anything to develop the trade there. He was glad to see by the papers that the Americans were taking up the question, and had heard, on very good authority, that the French would not recognise any treaty of the kind.

Mr. W. E. M. Tomlinson, M.P., said he had come to listen to this paper, because it might be his duty in another place to consider the question of the Congo treaty, and he was anxious to get all possible information from those who had practical knowledge on the subject. His own knowledge hitherto was derived from the papers issued on the subject, but he thought all must concur in the remark of Commander Cameron as to the vast importance of opening up Africa, by its two great outlets, the Niger and the Congo, to English trade and commerce. At present the trade of this country was suffering from that very want which Africa was capable of supplying, viz., a market for our goods; and the question was whether it was the duty of the nation and Parliament to endeavour to secure those markets for Great Britain or not. It was not a question whether those markets should be opened to this country or to another trading country, but whether the command of the markets should be given to a nation which was not really a commercial nation, as England was. The Portuguese had no manufactures and no commerce of the kind suitable for the African market. This treaty appeared to have been negotiated, as had been said, on the basis of trying to interpose Portugal as a buffer between us and other nations; that was the only rational explanation which could be given of it. It was pretty plain that, for some reason or other, the Foreign-office had not available the knowledge which it ought to possess of the commercial wants of this country. A strong effort was being made, both in Manchester and Liverpool, to have this treaty properly brought forward and discussed in Parliament. Of course, it was the great textile and hardware centres of industry which were most interested in this matter. Lord Granville seemed to be under the impression that the application of the Mozambique duties would simply add 10 per cent. to the cost of introducing goods to that country, and also that 10 per cent. was such a trifle that it need not be regarded. It was very curious that those statesmen who seemed to cling most closely to Cobden's theory of absolute free trade being a necessity for this country, seemed also to imagine that the question of duties had no influence whatever on the introduction of British goods into foreign countries. To him, this seemed the most extraordinary notion; he could not understand it at all. What he had heard to-night confirmed him in the opinion that it was the duty of Parliament to prevent, if possible, the ratification of this treaty. He believed that a strong expression of public opinion would be made outside Parliament to assist the discussion which would have to take place there. He thought there could be very little difference of opinion in Parliament outside the members of the Government, and he hoped that discussion would tend to arouse expressions of opinion from London and other parts of the country on the question. Even if they did not succeed in stopping this particular treaty, it might prevent similar mistakes being made in future.

Mr. Masterman said he understood Mr. Johnston's view to be that it did not much matter who commanded the mouth of the Congo, because the true approach to that part of the river, above the Stanley Pool, would be some river to the north of the Congo; he should, however, like to have a little light on the subject.

Mr. Margan said he went up the Congo last summer for the International Association, and the general opinion seemed to be that the river itself was beset by so many difficulties that it could not be made available as a trade route; but that a railway approach from the coast north of the Congo, should be made through the River Quilo. At the mouth of that river the International Association had a station, and there were several others also between that and the Congo. That was the route by which large quantities of ivory now reached the coast, and no doubt if a railway were made, it might become a very important means of approaching the dense populations in the interior. He could not speak of the Portuguese from any personal experience, but they had many trading establishments on the Congo, though the principal ones were in the hands of the Dutch. The Portuguese were always civil to him, but at the same time he was quite of opinion that there was no occasion to place the future of this magnificent country in the hands of one power, and that a power of which many complaints were made. As he went along the coast he saw no signs of British authority from the mouth of the Niger down to the Congo itself. Coming home, he saw one gunboat off Sierra Leone. The complaints were very general amongst the traders that differences with the natives could not be settled quickly owing to the distance of the consular agent, who, when he was reached, had to send for a gunboat, and very often, by the time the gunboat arrived, any question there was to settle had been decided. He believed that, with due precaution, the climate on the Congo was not very bad, and those who had been above Stanley Pool praised the climate very much. He thought one mistake which had been made in the navy was in serving out rations of quinine daily when in a fever district, so than when an attack came, the medicine failed to produce its effect.

Mr. Sutton asked what was the proportion of

Portuguese exports from the Congo as compared with those of other nations.

The CHAIRMAN said it must be a matter of great satisfaction to them all that the hon. member who had addressed the meeting had found some place in London where a subject of this nature could be discussed. It was with a view to this that, at a meeting of the British Association some years ago, he proposed the formation of this Section, first called the African Section, for the purpose of developing English trade with East and West Africa, the value of which was now so generally recognised. The Council of the Society, following the principles of its charter, liberally gave authority for the formation of the Section, and this step had been a matter of gratification to the whole of the Society, as it had been the means, year after year, for some years, of calling practical attention to these important subjects, and impressing the public, step by step, with the value of regions which were considered remote and of very little importance. It also had been the means of bringing forward men of eminence and enterprise who had been engaged in various parts of Africa, and who had come to the meetings to give their experience; and the information thus conveyed had not been limited simply to the audience present, for by means of the *Journal*, it had been made known throughout the length and breadth of the land. There was hardly a man of eminence connected with Africa whose name would not be found inscribed in the rolls of this Section, and this in itself was a very useful work, for it was only by the diffusion of such information that the public could be made to adequately comprehend the subject; even in the Foreign-office, where there were men of great ability and information, a subject like this was not sufficiently understood. His interest with regard to the relations of Portugal in this matter dated from some time back. He should be the last to speak in any depreciating way of Portugal, for it was more than half a century since he co-operated in the establishment of its independence. He could not, however, conceal from himself that with all the merits of that ancient historic country, their relations with ourselves had not been always satisfactory. Generation after generation, and century after century, the independence of Portugal had been saved by the exertions of Englishmen, but for that we had had no adequate reward or appreciation. The Portuguese were very apt to stand on their sovereign rights, and their national prerogative, and we in England were too apt perhaps readily to accede to those demands, forgetting the historic relations betweeen the two countries. We were certainly not equals. Whenever Portugal had been in difficulty, it was to England that she applied as an Imperial Power to protect her. Relations of that kind had their mutual duties. There was no derogation to the prerogative of Portugal in contending that when a time like this came, her relations should be adjusted with the imperial power on an amicable footing in justice to this country also, but that, however, had not been the case; other claims had been put forward, as Mr. Capper had very well indicated. When he first remembered the income of the Viceroy of Angolo or of Mozambique was certainly not derived from the enterprise and commerce of Portugal; and with regard to the Congo as the others, the whole development of those countries was due to English enterprise. The Portuguese had not been mindful of these facts; they now woke up to the importance of these possessions, forgetting who had made them important. It was of the greatest importance to Portugal itself that she should receive assistance and guidance from this country in the management of her possessions in Africa, for it was we who had made those possessions, not the Portuguese themselves. The direct trade of Portugal was of the smallest possible character, and was hampered by fiscal restrictions. There was no suitable manufacture to support a trade. There was nothing in the conduct of Portugal which justified her being assigned more than the title of sovereignty, and beyond that the conduct of these matters should be left in the hands of those competent to conduct them. The United States, as had been said by Mr. Croft, were looking with interest and anxiety on this unfortunate treaty, and it was to be hoped that, by the discussions in the papers and elsewhere, her Majesty's Government would be enlightened so that, as in the case of the Suez Canal, it might be induced to make better arrangements. Having watched these countries long before they were objects of interest to the public, he was fully assured, as had been proved year by year in that room, that the prospects of the trade of this country rested largely on the development of the trade of Africa, and it was deeply to be regretted that neither the Government nor the public at large were adequately acquainted with the facts. It was strange that even the romantic achievements of Livingstone, Stanley, and Cameron had not stimulated the zeal of Englishmen in this matter. Whoever investigated the ancient civilisation of Africa, would find that it must have been in ancient times one of the great countries of the world, and a region which had had such capabilities was capable, under proper government, of developing those resources again. He concluded by proposing a vote of thanks to Mr. Capper, which was carried unanimously.

Mr. CAPPER, in reply, said he had been asked the proportion of the Portuguese trade from the Congo compared with other countries. He was not in possession of the figures of different countries, but nothing made in Portugal found its way into the Congo. The only trade going from Angola, at the present time, was, perhaps, sufficient to one-third fill a steamer once a month, and it had nothing to do with the Congo. As to the Quilo river, from a commercial point of view, it did not do for people to go to new rivers, and commence laying down railways.

What a man of commerce liked was that his commerce should grow as he put his hands in his pocket. The principal part of the trade of the Congo came from the southern bank, and as the Quilo was some distance to the north, the whole of the trade would have to cross the river; there would be the same difficulties as at the Falls of Yallalla, there must be land carriage of some kind. It was due to British enterprise alone that matters of that kind had been already dealt with in Africa. In the River Volta, when their capitalists found the trade growing, they built their own railway, and on the Congo, if left to British commerce, it would not be long before the difficulties of land carriage would be surmounted by British enterprise, if only the Government would leave them alone. There were Portuguese traders up the Congo, but they were simply petty traders for large houses, mostly the servants of other nations. He had had many friends in Portugal, but still he must say that since the year 1666, a majority of the Portuguese had not been well spoken of. He put in the paragraph about himself to show that he had resided in that country for some time, and held that it was not so bad as it was painted. If he were a rich man, and did not know what to do with his money, he should certainly charter a ship to go out to the Congo and back; and every poor man who liked to go out he would feed him, and take him out, and bring him back again if he did not like it. The country was so rich you need not provide for the morrow; you required very little clothing; pea-nuts grew wild; there was plenty of water, and if you wanted anything further, you could climb up a palm-tree and get some palm wine. It was some years since he left the Congo, but when he was asked to prepare this paper, and look out his old diaries and books, his feelings became so strong with regard to this question, that he had thought it well to tone down several of the expressions which he had at first made use of, feeling as he did indignant at the mere notion of so ruinous an act as the throwing away of these large markets, when England wanted them so badly.

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION.

The following Sub-Committees have met at the Society of Arts since the meetings last recorded in the *Journal*:—

INDIA.

Wednesday, March 5th.—Present: Sir Joseph Fayrer, K.C.S.I., in the chair; Mr. W. Anderson; Sir George Birdwood, K.C.S.I.; Mr. R. A. Dalyell; Surgeon-General Gordon, M.D., C.B.; Colonel J. Michael, C.S.I.; Mr. W. G. Pedder; Mr. A. Stirling Surgeon-General Townsend, C.B.; Mr. F. Young.

THE DWELLING.—SUB-COMMITTEE A.

Wednesday, March 26th. — Present: Captain Douglas Galton, C.B., F.R.S., in the chair; Mr. H. H. Collins; Dr. W. H. Corfield; Mr. Rogers Field; Mr. Charles Heisch; Mr. Shirley F. Murphy; Mr. E. C. Robins; Mr. H. Saxon Snell; Mr. Ernest Turner; Mr. H. Trueman Wood.

EDUCATION.

Wednesday, March 26th.—Present: Lord Reay in the chair; Mr. T. R. Ashenhurst; Mr. B. St. John Ackers; Dr. T. R. Armitage; Mr. E. N. Buxton; Mr. Alfred Bourne; Mr. W. White Cooper; Mr. C. D. Dawson; The Ven. Archdeacon Emery; Mr. J. G. Fitch; Dr. J. H. Gladstone, F.R.S.; Rev. T. Graham, D.D.; Mr. J. J. Hummel; Mr. T. C. Horsfall; Mr. A. B. Kennedy; Mr. A. C. King; Lieut.-Col. W. R. Lewis, R.A.; Mr. Philip Magnus; Mr. K. B. Murray; Mr. J. F. Moss; Mr. J. H. Rigg; Mr. Gilbert R. Redgrave; Mr. A. B. Shand; Rev. T. W. Sharpe; Mr. W. H. Stour; Mr. F. Storr; Mr. Swire Smith; Hon. E. Lyulph Stanley, M.P.; Rev. W. P. Warburton; Mr. H. T. Wood.

NOTES ON THE REARING OF SILK-PRODUCING BOMBYCES IN 1883.

BY ALFRED WAILLY

(Membre Lauréat de la Société Nationale d'Acclimatation de France).

(Continued from page 360).

The second mode of rearing the *Yama-Maï* silkworm in Japan, which is resorted to after the third moulting of the worms, is the following:—Pits are dug one foot wide, and about one foot and a half deep. These pits are filled with bales of rice, which are well watered and covered with mats, through which oak branches are plunged to the bottom of the pits. The worms previously bred under cover are now reared in the open air, and uncovered up to the time of their transformation on the branches plunged in wet rice. The bales of rice receive every day a plentiful supply of water, which allows the foliage to keep fresh for a long time. When the branches are changed, the old ones are pulled out and placed on mats, in order that no sand or dust should touch the worms, for, if they swallowed any with their food, they would become sick and die. When the old branches have been removed, fresh ones are inserted in their places, and the old ones are then tied or otherwise fastened to the fresh branches.

This mode of rearing has not, as far as I know, been adopted anywhere in Europe or in India, and I do not think it ought to be adopted at all, as the third mode, that of rearing on trees, is by far the most simple and the best, especially when the worms are reared on a very large scale.

Third mode.—Rearing on trees in the open air. This last mode, like the second, is adopted after the worms have passed their third moult, that is, when they are in their fourth stage. The place chosen is a plantation in the plain in preference to one in the mountain, and the ground, twelve months beforehand, is cleared of all weeds, also of the useless shrubs and trees. The branches of the trees which are too long are cut down, so that all on which there are worms or cocoons should easily be reached.

Without going into further details respecting the mode of rearing in Japan, it is certain that if trees were planted in rows, and the branches cut or bent down so as to form a bush, eight, nine, or even ten feet high, immense quantities of silkworms could be reared in suitable climates by taking the two following and indispensable precautions:—1st, to keep the ground clear of all weeds which might harbour insects injurious to the worms; 2nd, to have, especially when the worms are large, men to watch the worms constantly, and keep the birds away, as these in a very short time might destroy the whole crop. The worms might be placed on the trees as soon as they are hatched, which would be a great saving of time and labour, and the rearing would have no other limit but that of the plantation. I will now pass to my notes on the rearings of last season.

Hybrid Roylei-Pernyi.—On referring to my articles on the rearings of silk-producers in 1881 and 1882, it will be seen that I obtained this remarkable hybrid in 1881 by the crossing of *Roylei*, the Himalaya oak silkworm, with *Pernyi*, a north China species. The new hybrid, contrary to what had taken place previously with other hybrids, was larger and superior in every respect to the parent species; its reproduction in 1882 from the cocoons obtained in 1881 was most wonderful—many hundreds of fertile eggs from a small number of moths. I then felt most certain that I had created a most valuable silkworm, easy to reproduce and rear. But in 1883, the third year of the existence of my hybrid, I was cruelly disappointed, for it disappeared entirely.

Degeneracy was certainly the principal, and perhaps the only cause of this failure. Now, was this degeneracy due to the fact that this new silkworm was a hybrid? I could not to a certainty declare that such was the cause, for the *Pernyi* silkworms reared at the same time, and under the same conditions as the hybrid, had degenerated to the same extent; so that it may be that the cause of degeneracy was due to the unfavourable conditions under which the larvæ were bred.

The few hybrid larvæ which I reared in London in 1882 on a small scale, in torrents of rain for the greater part of the time, could not be relied upon to produce strong healthy pupæ. On the other hand, the hybrid cocoons I had from one of my correspondents in Scotland, and those I obtained in Paris, at the Société d'Acclimatation, were the produce of larvæ reared in large numbers in warm rooms. My correspondent in Scotland, Mr. Turnbull, reared an immense quantity of the hybrid worms, together with *Pernyi* worms, in warm rooms, and it is a well-known fact that worms bred under these conditions often get the germ of disease in them; the *Pernyi* worms were affected just the same as the hybrid ones.

Another difficulty came in the way of the successful rearing for 1883. The hybrid moths in 1882, in consequence of warm weather, began to emerge in April, about three weeks before the usual time, so that two generations were obtained. Most of the moths emerged in the autumn, 1882, leaving but a small number of live cocoons for the year 1883, and these were very likely the weakest; at any rate, they were smaller than the cocoons obtained in 1881.

In 1883, the moths of the hybrid did not begin to emerge till June 2nd, considerably later than in 1882, when they commenced to emerge on April 23rd, and several of the cocoons died.

The moths, which kept on emerging till July, paired with the same facility as in 1882, but almost all the eggs were unfertile. Out of a small quantity of fertile ova, I obtained about eighty larvæ, in all appearance very healthy, which were placed on small oak trees in my garden. These oak, together with some other kind of trees, were under one large framework covered partly with wire, partly with fish-netting. I made use of all the old materials I had in London for economy's sake, and I had here, only one large frame instead of three smaller ones, as I had in 1882, in London. The hybrid larvæ grew rapidly, without showing any sign of disease, till they had reached for the most part the third stage, when one day I found the fish-netting, which must have been rotten, entirely torn from top to bottom on one side of the frame, and all the larvæ had disappeared, destroyed by birds, together with some other species. The tearing of the net had evidently been the work of cats, which I had frequently seen climbing up to the top of the frame. Fish-netting is, therefore, of little use. This fatal accident prevented a rearing and study which would have been very interesting and important to me, *i.e.*, the preservation of the hybrid, or, if the worms had had the germ of disease in them, to watch and see how long they would live in such a state. As I have before mentioned, they looked remarkably strong and healthy.

After this disaster, the fish-netting was mended, and several yards of new wire-netting were added to the framework, after which the worms of the few other species in the trees were left unmolested by the sparrows and other birds.

Actias Selene.—Of this species I had, in 1883, no cocoons imported from India, but only about twenty cocoons obtained from the rearings of 1882, and of these several died. The moths emerged as follows:—June the 4th, one male moth; on the 13th, one male; on the 17th, one male; on the 19th, one male and one female, which paired on the 21st, between 2 and 3.30 a.m. On the 22nd, one male; on the 23rd, one male; on the 25th, one male; on the 26th, one male;

on the 27th, one female. On the 28th, I obtained the second pairing. On the 28th, a third female moth emerged, which paired on the 29th of June. On the 4rh of July, a female moth emerged; on the 14th, one male; and on the 7th of August, the last moth, a female, emerged. By referring to this list of births registered, it will be seen that the first three female moths, which alone had a chance, all paired, and this is the greatest success I ever obtained with this species with respect to pairings, but the same success did not attend the hatching of the larvæ.

The first female moth laid 255 eggs, which were very good, and began to hatch on the 6th of July. The second female, which was smaller, laid only 154; none of these I kept. The third female, which was the finest and largest, laid 303 eggs, but none of the eggs I had kept of this last brood hatched, and this I attribute to a sudden change of temperature at the moment the larvæ should have hatched; but there may be some other cause unknown to me. Some of the larvæ of the first brood were reared in the house on walnut leaves, others on a pear-tree in the garden under the netting. The larvæ reared in the house reached their last stage in a very short time; on the contrary, those in the garden were very slow, and did not begin to spin before the 11th of October, when I had to bring into the house the few which were on the pear-tree in the garden.

Attacus Atlas.—With a large quantity of Ceylon and a few Himalaya *Atlas* cocoons, I had no better success in 1883 than in 1882. The moths emerged from the 11th of July to the 28th of September. As usual, a number of the cocoons died, while others kept alive for the following season (1884). Only ten Ceylon and four Himalaya *Atlas* moths emerged at intervals, never giving any chance of obtaining fertile ova.

Two of the Himalaya *Atlas* moths, one female emerged on the 4th of September, and one male on the 21st of the same month, were very perfect and extremely beautiful, both measuring over 10 inches in expanse of wings. These, with a wonderful aberration of the genus *Samia* or *Platysamia*, and a large number of other specimens of silk-producing Bombyces and other lepidotera were exhibited on the 3rd of October, 1883, at a meeting of the Entomological Society of London. Among these specimens was a series of about fifteen *Mylitta* moths, showing most of the various shades of colour, from the bright golden yellow to the darkest brown or grey. Reference will be made further on to the extraordinary specimen of the genus *Platysamia*, which I consider as an aberration of *Cecropia*. Besides these specimens, I exhibited some of the living larvæ of silk-producers, which were still to be found at that time on the trees in the garden, such as *Telea polyphemus* and *Hyperchiria io*.

Antheræa Mylitta or *Paphia*.—The notes I took on this species, the most important East Indian wild silkworm, cover six pages of my note-book. Therein is registered the birth of every moth, the pairings, &c., which it would be unnecessary to reproduce at length. The first *Mylitta* moth emerged on the 6th of June, the last on the 29th of October. I had a very large number of cocoons, some of which did not hatch, and are still alive, even after having hybernated twice. These cocoons came from four different parts—Calcutta, Madras, Ceylon, and Bombay. Those from Madras, only ten in number, had already hybernated during the winter 1881-82, and had remained in perfect condition. Two of these Madras cocoons still remain alive for the year 1884.

The first moth which emerged belonged to the Bombay race; then, from the 25th of June, Ceylon moths emerged, and the first pairing was obtained during the night of the 2nd and 3rd of July, and a second pairing of the same race took place on the 6th of July. The third pairing which took place during the night of the 9th of July, was by moths of the Bombay race; the fourth during the night of the 11th, and ended at 10.30 p.m. on the 12th of July, was a cross between a female of the Bombay, and a male of the Ceylon race. The number of eggs obtained from these four pairings was:—78 by the first, 183 by the second, 135 by the third, and 128 by the fourth, a total of 524 eggs. Later on, two more pairings were obtained, one from the 6th to the 7th of August, between a male Ceylon, and a female Bombay; the sixth and last took place in the night of the 19th and 20th of August, between two moths emerged from the cocoons sent to me from Calcutta. I lately heard that these cocoons sent from Calcutta had been collected in Assam. The number of pairings, six only, is very small, considering the large number of moths obtained from the cocoons, and undoubtedly shows that the temperature was not sufficiently high for this species. The eggs from the last two pairings in August were obtained much too late to be of any use in England for rearing; therefore I sent them to some American correspondents, but as yet I have not heard of the result. The eggs of the first pairing (Ceylon race), that of the 2nd and 3rd of July, began to hatch on the 25th of July; those of the third pairing (Bombay race), of the 9th of July, began to hatch on the 3rd of August; and the eggs of the fourth pairing, a cross between the Bombay and Ceylon race, which took place on the 11th and 12th of July, began to hatch on the 4th of August. The ova of the second pairing had all been distributed, together with some of the other three pairings, among European and American correspondents, and I shall be glad to hear of the result of their experiments. Though there were great differences in the shades of colours in the moths of the different races, all the larvæ were alike. The second stage of the larvæ took place on the 9th of August, fifteen days after they had hatched; the third stage commenced on the 24th of August, and the fourth on the 10th of September. The larvæ could not be reared beyond that date, the weather not being warm enough. It may be that oak leaves are not a proper kind of food for *Mylitta* larvæ; although they have been reared on oak, they did not seem to thrive well on it. Major Coussmaker lately informed me that *Mylilta* larvæ feed well on rose branches, and these should be used in future, together with oak and horn-beam, so as to find out on which plants they will thrive best.

A description of the larvæ in its six stages has already appeared in one of my previous reports, that for the year 1879. The interesting pamphlet on "The Tussur (*Mylitta*) Silkworm," by Major G. Coussmaker, gives full particulars on the cocoon, moth, egg, larvæ, and food-plants of this valuable wild silkworm. It was published in 1873, by E. and F. N. Spon.

As I have stated, the *Mylitta* larvæ I reared only up to the fourth stage. Many died at the different stages, but some were sent in all their stages to Mr. F. Moore, of the Bethnal-green Museum, and these were beautifully drawn and coloured, together with larvæ of other species, by Mr. Moore's son.

Attacus Cynthia or *Ailanthus Silkworm.*—This silkworm is the easiest to rear in the open air in England; next to it is *Antheræa Pernyi.* Moths of *Attacus Cynthia*, in 1883, commenced to emerge on the 3rd of June, and they continued emerging till the end of the same month. Thirty pairings were obtained, producing thousands of eggs and larvæ. Having had no Ailanthus trees bearing any foliage this year after their transplantation, I had to try the rearing of the worms on various trees. I placed the immense quantity of worms I obtained on rose-trees climbing against the house, on maples, on a mountain ash, on a common ash, on lilacs, and on laburnums—alone, those which had been placed on the laburnums thrived, but not near so well as they do on the Ailanthus tree, their natural food plant. A few larvæ, out of a large number, also thrived on the lilac trees and on the common ash. The thousands placed on the other trees disappeared in the first stage, and in all probability because the foliage did not suit them, as they could not have all been destroyed by the insects that prey upon them.

The sparrows, as usual, do not seem to have touched any of the *Cynthia* larvæ, which commenced to form their cocoons on the laburnum trees on the 3rd of August, and the last on the 27th of September.

North American Species.—Telea polyphemus.—Moths emerged from the 23rd of May to the 25th of June. Only three pairings were obtained, one on the 20th, and two on the 23rd of June. On the 25th, a female *Polyphemus* paired with a male *Cecropia*, but the eggs, as usual, were not fertile. The larvæ were very successfully reared in the open air, on the small trees in the garden, in spite of bad weather, during the last stage. The first cocoon was commenced on the 18th of September, and the last on the 7th of October.

Actias luna.—Of this species I had no cocoons, but eggs were sent to me from France, and from three American correspondents. Of the latter, some were sent from the State of Iowa, which hatched and died during the voyage; some sent from Illinois hatched on the 11th of June, the day of or after their arrival. Others I received from New York, which had hatched during the voyage, and died afterwards. On the 28th of July, I again received from New York two boxes, which, on being opened swarmed with young larvæ in splendid condition; these larvæ were from the second brood of *Actias luna*, the species being double-brooded.

Want of time prevented me from rearing such a quantity of *luna* larvæ, especially on account of the difficulty I have to obtain walnut leaves, on which they seem to thrive better than on other kinds of foliage. I therefore only reared a small number in the house.

Eggs sent from America are placed, as I suggested a few years ago, in a muslin bag containing leaves of the food plant, and then the bag is inserted in a tin box hermetically closed, so that the leaves keep, and arrive as fresh as if they had just been cut off the tree, although some small portions may decay or rot. If the eggs are sent as soon as they have been laid, many of them have time to arrive in England in good condition, after a voyage not exceeding fifteen or sixteen days. If some or all of the larvæ hatch during the voyage, they feed at once, and grow during the two, three, or four days they may have to remain in the box. It takes about twelve days for the *luna* larvæ to hatch; some other eggs require more time, and therefore can be sent with better chance of success. The great risk which the eggs and larvæ have to run is this, that the droppings of the feeding larvæ, falling on the moist leaves, create at once a rot or a fungus which is often fatal to the larvæ, and also to the eggs which have not hatched. But a proportionate number of larvæ and eggs escape, and arrive in good condition, especially if there is sufficient room for them in the box. Certain species can only be sent in the egg state, and this method of sending is the only one that can be adopted, and we must be satisfied if only a few eggs or larvæ are saved.

Hyperchiria io.—Moths of this bright and beautiful little species, described in former reports, began to emerge on the 4th of June, and continued to emerge till the first of July. The moths pair readily, if they are in good condition, *i.e.*, if the wings are fully developed, especially in males. Fourteen pairings were obtained, which must have brought the number of fertile eggs to about 5,000 and even more. I bred a quantity of the larvæ very successfully in the house, under glasses. They are easy to rear, but live a long time before forming their thin cocoons. I also bred a number of them in the open air on *salix caprea*; they were larger, and grew quite as fast as those I had in the house.

Samia promethea.—Moths of this species emerged from the 25th of June to the 16th of July; twelve pairings were obtained. On the 1st of July a male *Cynthia* paired with a female *Promethea*, but the eggs laid did not hatch. The pairings of this species, which are short, are easy to obtain, and they generally take place between 6 and 8 o'clock in the evening. A small number of *Promethea* larvæ were placed on a small cherry-tree in the garden, but they were destroyed when in the first stage. As mentioned in previous reports, they feed also on lilac.

Platysamia Cecropia.—Of this, the largest North American silk producer, I received an immense quantity of cocoons from various States: Iowa, Illinois, Delaware, New York, &c. With the cocoons I had preserved I obtained 19 or 20 pairings. On the 25th of June, a male *Cecropia* paired with a female *Polyphemus*, the eggs being unfertile. I record these pairings to show that whenever the species are not closely allied, the eggs have invariably been unfertile. I have heard of fertile ova obtained by the crossing *Promethea* and *Cynthia*, but I never obtained such fertile ova, although I have had many pairings between these two species.

The *Cecropia* moths emerged from the 24th of May to the 23rd of July. Ova of *Cecropiu*, sent to me from Iowa, all hatched on the day they arrived, and the larvæ thrived splendidly.

The thousands of larvæ which I obtained were, except a few, placed on all the apple, pear, and plum trees in the garden, and also on some currant bushes, but as soon as they had reached the second or third stage, they were all destroyed by the sparrows and other birds. Late in October, I found a full grown *Cecropia* larvæ, which had escaped the eye of the sparrows, on a currant bush. The weather being then very wet and cold, I brought it into the house,but it died while attempting to form its cocoon.

From one of the *Cecropia* cocoons, there emerged in June a most extraordinary specimen, remarkable alike for its size and the exquisite beauty of its various colours. As I have been asked whether the cocoon from which the moth emerged differed from the other *Cecropia* cocoons, I must state that I did not notice any difference in the cocoons, and there were about 100 in the cage. I was then so busy that I entirely neglected to examine the cocoons; in fact, I did not think of it, and I very much regret not to have examined the cocoons. Later on, the cocoons, together with *Cecropia* cocoons from other cages, were all thrown into a large box with cocoons of other species; and some were given or thrown away. However, had there been a difference, and especially a notable difference, between the cocoon which produced the wonderful specimen and the other cocoons, I should certainly have noticed it.

Up to the present time, I have not heard that any such specimen has ever been seen, and as I stated, I consider it as an extraordinary aberration of *Cecropia*. The specimen has been photographed, natural size, and I have coloured a few copies of it, so that persons wishing to see it may have a representation of it.

On taking the specimen to Mr. W. F. Kirby, at the British Museum, he wrote the following description of it for the Proceedings of the Entomological Society of London (1883).

ABNORMAL SPECIMEN OF THE GENUS SAMIA, BY W. T. KIRBY.

"This remarkable specimen, which has puzzled every entomologist who has seen it, was bred by M. Alfred Wailly, from a cocoon received from some part of North America. It may be a hybrid between *S. Cecropia* and some other species, but if so, it is so different from all the other known species, that it is difficult to guess with what it could have been crossed. It is equally difficult to imagine that it is a new species. The specimen is a female, and equals the largest specimen of *S. Cecropia* in size, measuring $6\frac{3}{4}$ inches in expanse; and the wings are more rounded and less oblique than in *Cecropia*. The body resembles that of *Cecropia*, except that the abdomen is banded with yellowish grey and black. The base of the fore-wings is brown, thickly scaled with white towards the costa; below this is a brick-red blotch, longer and narrower than in *Cecropia*. Beyond this is a white space extending nearly from the base to one-third of the length of the wing on the inner margin, but curving up to the costa in a rather narrow stripe. This is followed by a large irregular black blotch, broad at the costa (where it is thickly dusted with grey), and the narrow end extending to beyond the middle of the wing. On this stands the large kidney-shaped central spot, which is surrounded with red, and divided by a reddish stripe at the outer end of the black blotch; it extends beyond it into a broad red white-dusted band, followed by a black one, so very thickly dusted with yellowish grey, that it appears of that colour. This is succeeded by a grey space, divided by a black line (much less indented than in *Cecropia*) into darker and lighter; above is a blue space; on the inside is a row of rather large black spots, the uppermost, and the fourth and fifth being the largest. Hind wings, white at the base, followed by a broad slate-coloured space, on the outer half of which stands a large oval white spot, slightly surrounded with red, the outer part being incomplete, and it rests on a white band, much broader than in *Cecropia*, followed by a broad red band, three or four times as broad as in *Cecropia*, but followed outside by similar markings, only paler. The under surface differs from *Cecropia*, chiefly in the much paler colour, and in the different position of the central spots."

INDUSTRIAL ART EXHIBITION.

The first Brussels exhibition was held in 1853, and this was renewed on a larger scale at the Halles Centrales in 1874, with a result, both material and financial, that exceeded expectations. In connection with the national exhibition of 1880, when Belgium celebrated her 50th year of independence, two congresses, that of instruction and that of commerce and industry, both dealt with the subject of technical education. To these two congresses was due the constitution of a society, under the presidency of M. Ferréol Fourcault, director of the Compagnie des Bronzes, the object of which was to promote technical instruction generally. The new society soon became affiliated to the Union Syndicale of Brussels, as the section of industrial instruction, and was also materially aided by funds remaining over from the exhibition of 1874. It was subsequently decided to organise periodical competitions with special exhibitions of allied objects.

The first of these exhibitions and competitions, originally limited to lace and fans, but to which embroidery, trimmings, buttons, and artificial flowers were afterwards added, was opened in the Palais des Beaux Arts, Brussels, on 31st December, 1883, by the Minister of the Interior, and was kept open for three months, being largely attended. Under the patronage of the Count and Countess of Flanders, a large and exceedingly valuable collection of ancient fans, lace, and embroidery was got together; and many articles will be reproduced by photography, &c., to serve as models for present designers. No less than 270 fans, of ancient manufacture, including some rare gems of art, and one of quite historical interest, were contributed from various collections. There were examples of embroidery anterior to the fifteenth century, ecclesiastical ornaments, tapestry, objects, such as escutcheons and flags, belonging to the old guilds, and articles of ancient costume, including buckles and buttons, and various civil objects. The various classes of lace, both point and pillow, were well represented, the whole of Madame Montefiore Levi's large and valuable collection being laid under contribution; and a series of portraits, borrowed from various collections, exemplified the manner in which lace was worn at different periods.

Whether lace was first made in Belgium or in the North of Italy, a point which has not been satisfactorily cleared up, it is certain that, about the year 1661, there existed at Brussels a confraternity of lace-makers (*spelwerkers* in Flemish), and that in 1762 there were 15,000 lace-women, the number varying from 9,000 to 10,000 under the French dominion. Notwithstanding the present want of demand for lace, this industry is still practised in many towns and villages in the North-West of Belgium. Some information as to lace furnished by M. Baert and M. Sacré, both manufacturers and medallists at various exhibitions, is appended to the catalogue. It appears that Mechlin laces, which is made entirely on the pillow, is produced at Antwerp, Louvain, and Turnhout, the manufacture having almost died out at Mechlin itself. Brussels lace, and its numerous derivatives, are made at Brussels, Alost, and even at Ghent. It is produced especially with the needle, the ground only having originally been prepared on the pillow. This variety of ground, which was called "drochel," is not made now; and the specimens which remain are rare. Black lace, called "dentelle de Grammont," is made from Enghien (in Belgium) as far as Andewarde, but especially at Grammont; it is made entirely from silk, and on the pillow. What is known as Valenciennes lace is also made on the pillow, and includes several varieties: — the *dentelles torchon*, the primitive type; the *maille ronde* (round mesh), of Bruges; the *treille carrée* (square trellis), of Ypres; the *grande maille carrée*, of Courtrai; the Ghent point, or *maille carrée raccrochée*; and the *dentelle de Bruges sans treille à fond guipure*. Of late years, certain decorative industries have brought into fashion the styles of the 15th to 18th centuries; and several manufacturers have succeeded in copying Venetian point, Flemish guipure, ancient Mechlin, &c. Another school is of opinion that modern dress does not lend itself to the revival of these old styles, and that their vogue will be but temporary. They observe that pillow lace especially is very easy to imitate by machinery, and they point to the progress shown at recent exhibitions, where artists' designs have been faithfully reproduced by mechanical means.

There were fifteen exhibitions of modern lace, and reproductions of ancient models, and twelve exhibitions of embroidery; while the Mdlles. Marcelis and Van de Wade, the directresses respectively of the Brussels and the Antwerp technical schools for girls, put in designs executed by the pupils.

There were seventeen exhibitors of fans, including the Brussels, the Mons and the Antwerp technical schools The pupils of the last named showed some highly interesting and meritorious collections of the various parts of several artificial flowers, mounted on cards, to illustrate the various stages of manufacture.

There were three competitions in designs for a lace flounce, piece and fan, to match, and for each competition prizes of 300 francs (£12) and 200 francs (£8) were offered. In the first, to be executed entirely in *appliqué*, the first was awarded to M. A. De Spiegheler; and the second to M. Van Cutsem. The last-named carried off the first prize in both of the other two lace competition, viz., designs for the three objects above named to be executed in respectively *appliqué* mingled with other styles, and in any style chosen by the competitor.

There were also three fan competitions, in the first of which a first prize of 1,000 fr. (£40), and a second prize of 500 fr. (£20), were offered, and in the others prizes of 300 fr. (£12), and 200 fr. (£8), respectively, were offered. There were twenty-nine competitors for the first, the execution of a painted fan, either mounted or with design for the mounting. The first prize was awarded to M. A. L. de Mol, and the second to M. G. A. Launean, whose sketch of the mounting is remarkably effective. The first prize for the execution of a lace fan was taken by M. L. Sacré; and that for a fan in style, with sixteen competitors, by M. Royer de Fraene for the painting, and M.M. Bantmans and Hoosemans for the mounting.

A method was hit upon for preventing the possibility of competitors' identity being disclosed by the symbol or motto chosen. The papers containing the names and addresses were placed by the competitors in numbered envelopes, issued by the committee, with tickets gummed at the edges, and perforated in the same manner as the new card letters issued by the Belgium Post-office, for the purpose of covering the motto or symbol on the works entered. Thus the jury awarded the prize to the numbers before they knew the mottoes or symbols, and still less the names of the competitors. There were only three jurors in each competition, one chosen by the committee, and the other two balloted for by the competitors.

This first effort of the Instruction Section of the Union Syndicale has been eminently successful; and is to be followed by other exhibitions and competitions. The secretary is M. Paul Davreux, assistant inspector of technical instruction.

Correspondence.

LONDON WATER SUPPLY.

In the recent discussion there was one point to which none of the speakers alluded, viz., the fact that the waters drawn from the Thames, &c., while sufficiently soft for domestic use, yet contain enough lime, salts, &c., to cover the pipes through which they pass with a coating sufficient to preserve the water from metallic contamination. London water may pass through iron, lead, zinc, copper, brass, or indeed almost any metallic pipe without risk, and may be kept even for long periods in metallic cisterns without absorbing any metallic salts. The hot water, drawn from the circulating cistern, in connexion with the kitchen boiler, is found clear and bright although it may have been in the pipes for weeks. It is difficult for Londoners to realise the enormous trouble and difficulty of getting water from private wells, free from metallic contamination. At my country house, I have been driven to have the drinking water-pipes enamelled with glass, but even so it is not an absolute success. Our hot-water supply is always more or less the colour of coffee; and while water passed through a lead pipe is positively poisonous, it is impossible to use for laundry purposes water which has passed through an iron one. In a recent Government report, it was stated that a certain proportion of the seamen suffered from copper poisoning, derived from the stills, so that it appears that distilled water is far from being safe from impurities.

Notes on Books.

GUIDE TO METHODS OF INSECT LIFE, AND PREVENTION AND REMEDY OF INSECT RAVAGES. London: Simpkin, Marshall & Co. 1884. 8vo.

This little book comprises the substance of ten lectures delivered before the Institute of Agriculture, in the theatre of the South Kensington Museum last December. The descriptions of the different stages of insect life are plainly treated of in the first and second lectures, and in the succeeding ones details are given of the various insect pests, such as the daddy long-legs, wheat midge, carrot and onion flies, &c., and the methods and extent of their ravages. Miss Ormerod's remarks on the prevention of insect injury at the conclusion of her book may be cited, affecting, as it does, all growers of crops, and those who own a garden, however small. She says:—"Slugs and snails are most terrible pests, but need not be so bad if it was borne in mind that (however urgent the need may be) the precise time when the crops are in the tender growing state, which most attracts the slugs, is the time of all others when it is almost impossible to do anything on a good scale to get rid of them. In gardens, a very much more thorough clearing of all their shelters would do good, but the remedy of sprinkling lime slightly is often a mere waste of time, on account of the lime slaking so quickly that unless it falls on the slug it very likely does little or no good at all. The slug has a power of casting off a kind of skin of slime, and thus getting rid of any obnoxious dressing not strong enough to kill it. In this way lime, soot, or other similar applications, often fail in effect. But the slug has not power to continue the process many times, and when the application has been continued at dawn and dusk for a few times it has proved successful. When land is free, a heavy dressing of gas lime or alkali waste will kill even the slugs; but, as with other pests, thorough attention to clearing out their shelters and breeding places, and cultivating the ground so as to turn up the eggs, although it might not cure, would lessen the evil."

General Notes.

NUREMBERG EXHIBITION.—An International Exhibition of Gold and Silversmiths' Work, Jewellery, and Bronzes, will be held at Nuremberg, under the protection of the King of Bavaria, from 15th June to 30th September, 1855. The object of the Exhibition is to show the present condition of gold and silversmiths' work, &c., in the different countries. Those persons who wish to exhibit should notify the nature of the objects they intend to send, and the space required, to the Bayrisches Gewerbe Museum in Nuremberg, before the 1st June of the present year.

GERMAN TRADE IN TUNIS.—With a view of developing trade in German manufactures in competition with English, French, and Italian goods in the Tunis market, it has been suggested for the steamers, now regularly plying between Hamburg and Sicily, to be continued to the coast of Africa. One of the leading organs of the German textile industry has been devoting a long article to the subject of trade with Tunis as a part of the export commerce which is now being specially worked up under the auspices of the German Government and its representatives in foreign countries.

MEAT PRESERVATION.—In January, 1871, Mr. Richard Jones read a paper before the Society of Arts entitled "How Meat is Preserved" (*Journal*, vol. xxix. p. 14), in which he described his vacuum process; Mr. Jones has now adopted a new process, the results of which are said to be quite satisfactory. The principle he has adopted is the injection of a fluid preparation of boracic acid into the blood of an animal immediately after it has been stunned, and before the heart has ceased to beat, the whole operation, including the removal of all the blood and chemical fluid from the body of the animal, only taking a few minutes. The quantity of boracic acid used is very small, and though that little is almost immediately drawn out again with the blood, the preservation of the flesh is said to be thoroughly effected. The quantity of the chemical left in the flesh must therefore be very small, and can scarcely be injurious to the human system; for, as Professor Barff has proved by experiment, living animals, either of the human or other species, do not seem to be injured in any way by its consumption. A demonstration of the effects of the process was given last week at the Adelphi Hotel, when the joints cut from a sheep, which had been hanging for more than seven weeks at the House of the Society of Arts, were cooked in various ways, and those present agreed that the meat was equal to ordinary butchers' meat.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, eight o'clock :—

APRIL 23.—"Thames Communications." By J. B. REDMAN, M.Inst.C.E.

APRIL 30.—"The New Legislation as to Freshwater Fisheries." By J. W. WILLIS-BUND. EDWARD BIRKBECK, M.P., will preside.

MAY 7.—"Bicycles and Tricycles." By C. V. BOYS. Dr. B. W. RICHARDSON, F.R.S., will preside.

MAY 14.—"Telpherage." By Professor FLEEMING JENKIN, F.R.S.

MAY 21.—"Telegraph Tariffs." By Lieut.-Col. WEBBER, R.E.

MAY 28.—"Primary Batteries for Electric Lighting." By I. PROBERT.

FOREIGN AND COLONIAL SECTION.

Tuesday evenings :—

APRIL 29.—"The Transvaal Gold Fields; their Past, Present, and Future." By W. HENRY PENNING.

APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings :—

APRIL 21 (Monday).—Adjourned Discussion on Dr. PERCY FRANKLAND'S Paper, "The Upper Thames as a source of Water Supply." Sir FREDERICK ABEL, C.B., F.R.S., will preside.

APRIL 24.—"Economic Applications of Seaweed." By EDWARD C. STANFORD, F.C.S.

MAY 8.—"Cupro-Ammonium Solution and its Use in Waterproofing Paper and Vegetable Tissues." By C. R. ALDER WRIGHT, F.R.S., D.Sc. Prof. W. J. RUSSELL, Ph.D., F.R.S., will preside.

INDIAN SECTION.

Friday evenings :—

APRIL 25.—"The Existing Law of Landlord and Tenant in India." By W. G. PEDDER.

MAY 9.—"Indigenous Education in India." By Dr. LEITNER.

MAY 30.—"Street Architecture in India." By C. PURDON CLARKE, C.I.E. This paper will be illustrated by the Oxy-Hydrogen Light.

MEETINGS FOR THE ENSUING WEEK.

WEDNESDAY, APRIL 16...Meteorological, 25, Great George-street, S.W., 7 p.m. 1. Hon. Ralph Abercromby, "The Origin and Course of the Squall which Capsized H.M.S. *Eurydice*, March 24th, 1878." 2. Capt. J. W. C. Martyr, "Waterspouts and their Formation." 3. Mr. Cuthbert E. Peek, "The Weather Forecasts for October, November, and December, 1883." 4. Mr. William F. Stanley, "Certain Effects which may have been produced in the Atmosphere by Floating Particles of Volcanic Matter from the Eruptions of Krakatoa and Mount St. Augustin."

Archæological Association, 32, Sackville-street, W., 8 p.m. 1. Rev. S. M. Mayhew, "Tenby and St. David's Cathedral." (Conclusion.) 2. Dr. Wake Smart, "Antiquarian Researches at Nursling and its Locality."

Obstetrical, 53, Berners-street, W., 8 p.m.

THURSDAY, APRIL 17...Linnean, Burlington-house, W., 8 p.m. 1. Rev. J. M. Crombie, "Algo-Fungal-Lichen Theory," and discussion. 2. Mr. R. Bowdler Sharpe, "Ornithology of New Guinea." (No. 9.) 3. Mr. J. G. Otto Tepper, "Variation in Leaf of *Banksia marginata*."

Chemical, Burlington-house, W., 8 p.m.

Historical, 11, Chandos-street, W., 8 p.m.

Numismatic, 4, St. Martin's-place, W., 7 p.m.

FRIDAY, APRIL 18...Medical Officers of Health, 1, Adam-street, Adelphi, W.C., 7½ p.m.

Philological, University College, W.C., 8 p.m. 1. Prince Louis Lucien Bonaparte, "Italian and Uralic Possessive Suffixes Compared." 2. "Albanian in Terra D'Otranto."

Clinical, 53, Berners-street, W., 8½ p.m.

Journal of the Society of Arts.

No. 1,639. Vol. XXXII.

FRIDAY, APRIL 18, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal for 1884, at their first meeting next month. This medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce." The following is a list of those to whom the medal has already been awarded:—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S.

In 1865, to his Imperial Majesty, Napoleon III.

In 1866, to Professor Michael Faraday, D.C.L., F.R.S.

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S.

In 1868, to Mr. (now Sir) Joseph Whitworth, LL.D., F.R.S.

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, &c.

In 1870, to M. Ferdinand de Lesseps.

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B.

In 1872, to Mr. (now Sir) Henry Bessemer, F.R.S.

In 1873, to M. Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France.

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S.

In 1875, to M. Michel Chevalier.

In 1876, to Sir George B. Airy, K.C.B., F.R.S.

In 1877, to M. Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France.

In 1878, to Sir Wm. G. Armstrong, C.B., D.C.L., F.R.S.

In 1879, to Sir William Thomson, LL.D., D.C.L., F.R.S.

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S.

In 1881, to Professor August Wilhelm Hofmann, M.D., LL.D., F.R.S.

In 1882, to M. Louis Pasteur, Member of the Institute of France, For. Memb. R.S.

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S.

A full list of the services for which the medals were awarded was given in the *Journal* of March 14th.

Members are reminded that to-morrow (19th April) is the last day for receiving the names of such men of high distinction as they may think worthy of this honour.

INTERNATIONAL HEALTH EXHIBITION SEASON TICKETS.

The Executive Council of the International Health Exhibition have consented to allow Members of the Society of Arts the privilege of purchasing Season Tickets for the Exhibition at half-price (10s. 6d.). Each Member will only be allowed the privilege of purchasing a single ticket on these terms, which will be a personal admission, not transferable. Season tickets admit to the opening ceremony on the 8th May. The tickets will not be ready for issue till the end of the month, but it will be convenient if members desiring to avail themselves of the privilege will send word to the Secretary at once, enclosing 10s. 6d., the price of the ticket, which will be forwarded as soon as ready. It will be understood that all applications must be accompanied by the above-named remittance.

PRACTICAL EXAMINATION IN VOCAL OR INSTRUMENTAL MUSIC.

The next Examination in London will be held by Mr. W. A. Barrett, Mus.Bac. (Oxon), at the House of the Society of Arts, 18, John-street, Adelphi, W.C., during the week commencing on the 9th June, 1884.

Honours.

The Examination in Honours will consist of three sections, viz., a paper to be worked, an examination similar in form to the practical examination for a First and Second-class, and a *viva-voce* examination.

First and Second-class.

Vocal.

Candidates for a First or Second-class Certificate in Vocal Music will be required—

[1.] To sing a solo, or to take part with another candidate in a duet, already studied.

[2.] A key-note being sounded and named by the Examiner, the candidate to name sounds or intervals, or successions of sounds or intervals, played or sung by the Examiner.

[3.] To sing sol-fa at sight passages selected generally from classical music.

Instrumental.

Candidates for a First or Second-class Certificate in Instrumental Music will be required—

[1.] To play a short piece, or a portion of a larger work, already studied.

[2.] A key-note being sounded and named by the Examiner, the candidate to name sounds or intervals, played by the Examiner.

[3] To play a piece or portion of a piece at sight.

Full particulars can be obtained on application to the Secretary.

INTERNATIONAL HEALTH EXHIBITION HAND-BOOKS.

In addition to those Hand-books dealing with the various subjects included in the Exhibition programme which the Executive Council propose to issue already noticed in the *Journal* (see *ante* p. 427), the following have been arranged for—

Physiology of Digestion and the Digestive Organs. By Professor Arthur Gamgee, F.R.S.

Fermentation. By Dr. Duclaux. With a Preface by M. Louis Pasteur, Membre de l'Institut.

Spread of Infection. By Shirley F. Murphy.

Accidental Injuries; their Prevention and First Management. By James Cantlie, F.R.C.S., M.B.

The Influence of Schools of Art on Manufacturing Industry. By John Sparkes.

As already announced, the Executive Council propose, at the conclusion of the Exhibition, to present the copyright of the Hand-books to the Society of Arts, and the Council of the Society have readily undertaken to continue their publication after the Exhibition has closed.

Proceedings of the Society.

PREVENTION OF FIRES IN THEATRES.

The following papers submitted by Captain Shean and Mr. Ernest A. E. Woodrow, in competition for the Fothergill prize, offered for the best invention having for its object the Prevention or Extinction of Fires in Theatres, were determined by the Council of the Society of Arts to be the best of all the contributions sent in. The Council, however, were of opinion that these papers did not come within the terms of the offer of the prize, but they decided that the papers should be printed in the *Journal*:—

FIRE: ITS PREVENTION AND EXTINCTION IN THEATRES.

By Arthur W. C. Shean, Consulting Fire Brigade Engineer.

Fire, and the lamentable loss of life frequently resulting therefrom, periodically attract special attention, the periods being the occasions of serious disasters. To the terrible misfortune that occurred in the Ring Theatre at Vienna, on the 8th December, 1881, can be traced the special attention which has been directed in England, during the past two years, to theatres and music-halls.

To those, however, practically acquainted with the subject of fire prevention and extinction, the knowledge of the existing danger has been adequately appreciated.

On the 29th March, 1881, and again on the 30th September, 1881, months previous to the accident at Vienna, when nearly 1,000 lives were lost, I took the liberty of addressing the Lord Chamberlain on the "notoriously disgraceful" condition of many of our London theatres, with regard to the prevention and extinction of fire therein. In the reply of his Lordship, dated 28th September, to a letter of mine of the 27th September, 1881, the following sentence occurs:—"His Lordship would point out to you the unfairness of making vague and sweeping charges of this nature."

Mr. John Hebb (assistant architect and surveyor to the Metropolitan Board of Works), at the Society of Arts' meeting held on the 31st May, 1883, stated that the powers of the Board, under which radical improvements during the past two years have been effected in nearly every London theatre and music hall, whilst many have been entirely pulled down and rebuilt, were conferred on the Board by Parliament in 1878, in an amendment of the Metropolis Local Management and Building Act. Three years elapsed, however, and not until the occurrence of the Ring Theatre fire, and the prevalence of consequent excited public feeling and press agitation, did the Metropolitan Board of Works take any definite action. From 1855, however, Parliamentary powers have enabled certain jurisdictions to act for the safety of the public, and no theatre, by law, could perform stage plays without the license of the Lord Chamberlain. There are 472 places of amusement in London, accommodating nightly 302,000 people, and the buildings include theatres, music-halls, and concert-rooms, &c.

These places of amusement are under no less than six separate jurisdictions, neither of which powers have ever enforced such regulations as are absolutely necessary for the safety of the public.

The powers entrusted with the so-called "management" of these places of amusement, in the interest of the public, have of late years been so conflicting in their ruling, as, while causing those interested in theatrical enterprise considerable expense and annoyance, to lead to the result of little public benefit accruing.

With regard to the rules issued by the Lord Chamberlain, and supposed to be obeyed, I cannot do better than quote a statement published in the *Times* of 16th January, 1883, in a letter addressed by myself to the Editor:—

"I was at a place of public entertainment in London last Saturday night, where all the gangways were completely blocked up with camp stools and chairs. As an experiment, in the middle of a performance, I rose, with a friend, to leave the building, timing my exit. Every one assisted my egress as well as possible. I am not particularly clumsy, but I nearly fell over camp stools, lying on the ground shut up, several times; and when I reached an exit door, over five minutes had elapsed from my first rising to leave the building."

The leading article in the *Times* of 18th January, 1883, quotes the statement I then made:—

"That last Saturday night hundreds of people ran the risk of being roasted alive in a popular place of entertainment."

In the *Times* of 19th January, 1883, "A Dramatic Critic of Twenty-five years' standing," says:—

"Will you permit me not only to endorse in almost every particular the statements of Captain Shean, but to comment upon the almost systematic neglect of the orders, instructions, and regulations issued from time to time by the Lord Chamberlain?"

In a leading article of the *Evening Standard* of 16th January, 1883, the following comment is made, to the remarks made to me, by the acting manager of the place of amusement referred to, when I drew his attention to the utter disregard of the Lord Chamberlain's instructions. The reply of the acting manager was:—

"The Lord Chamberlain does not want to interfere with us, and we do not want to interfere with him."

The *Standard* says:—

"The Lord Chamberlain may be gratified to learn that he has no reason to apprehend interference from the acting managers. Playgoers, however, would like to know whether his Lordship has really entered into the affable little agreement, and whether his rules are made to be obeyed or derided?"

It may be as well to state here that Mr. Irving, in a letter to the *Times*, appearing 23rd January, 1883, with regard to my statement that the place of entertainment complained of was one that had gone to arbitration, says:—

"One of these theatres is the Lyceum, and as Captain Shean so delicately and frankly declares that in the theatre aforesaid 'hundreds of people ran the risk of being roasted alive,' he might, I think, with equal frankness, have stated that the Lyceum was not the one alluded to."

I have much pleasure in stating I did not allude to the Lyceum Theatre. With regard to the conflicting jurisdictions, I may state that a certain place of entertainment was visited by the authorities, and certain improvements ordered, which, at considerable expense, were effected. No sooner, however, were the "improvements" completed, than the Metropolitan Board of Works stepped in, and required further alterations, necessitating an additional outlay of several thousands of pounds sterling. That the soundest judgment has prevailed in respect to the alterations required at certain places of entertainment is open to question, and the following will prove this. The proprietor of the above place of entertainment availed himself of the opportunity of referring the matter to arbitration, as allowed by the Act of Parliament. The case was heard before Sir Henry Arthur Hunt, C.B., at the Institute of Surveyors, Great George-street, Westminster, and I was called upon, as a practical fireman, to give evidence. My opinion was against the Metropolitan Board of Works, who instigated the proceedings, and who ultimately lost their case, causing, it is almost needless to say, a considerable waste of public money, as the Metropolitan Board of Works had to pay the entire costs of the proceedings. As another instance of the utter disregard of the Lord Chamberlain's powers, I may mention the fact of the "Alcazar" Theatre being opened by Mr. Baum without his having first obtained a license to perform stage plays. The "house" was open nightly for some time, and a "pantomine" performed to a crowded audience. Neither had the Lord Chamberlain issued any order his Lordship may have considered necessary for public safety in the event of fire. The "Alcazar Theatre," in Holborn, opened at Christmas time, 1882, was totally unprovided with any appliance whatever for the extinction of fire. The Alcazar Theatre was in the end closed, and Mr. Baum fined, but not until many thousands of lives had been seriously jeopardised.

I lately had the honour of conducting Mr. Dixon-Hartland, M.P., and other members of Parliament, in an inspection of nearly every place of amusement in London. Mr. Dixon-Hartland, M.P., in a speech in the House of Commons on the 17th of April, 1882, says:—

"He only regretted that the Chairman of the Metropolitan Board of Works had not been with him, because, if he had, he might have seen reason to reverse the answer he had given to a question put to him some time ago, when he said he should hesitate to declare any theatre in London unsafe. He might have felt obliged to confess that he had great doubts whether many of those theatres were safe, whether, indeed, many of them were not perfect death-traps, owing partly to faulty construction, partly to the materials of which they were built, and partly to the dangers arising from the rapid shifting of scenes of inflammable materials near to unprotected lights. On a Saturday evening, at one theatre in the Strand, capable of containing 1,500 to 2,000 people, he found a workman reading a newspaper behind the scenes, near a flaring gas-light, where the least puff of wind might have set the whole house in a conflagration. As many as 187 theatres had been totally destroyed by fire during the period from 1861 to 1877, and 13 had been destroyed by fire yearly since, while the average life of a theatre was not more than 23 years."

Some few words may be said with regard to theatres actually inspected by Mr. Dixon-Hartland, M.P., and myself during the past year. The Prince of Wales's Theatre, during the performance of "The Colonel," was estimated to contain nightly fully 500 people. The "piece" had a run of over 18 months, so that during that period over 234,000 people witnessed the performance. The house was built almost entirely of wood, highly dried by the great heat from the gas, &c., nightly engendered. The exits were as bad as they could be, and the fire-extinguishing appliances were limited to a little tank on the roof of the stage, with an indiarubber pipe depending therefrom. About the time of the Vienna fire, a special exit for the use of Royalty was made at the Prince of Wales's Theatre.

As mentioned in a letter of mine appearing in the *Times* of 9th December, 1882, I suggested to the directors of the Alhambra, when inspecting that theatre, the desirability of providing extra hose for its protection. With such provision, adequately used, the late Alhambra should never have met the fate it did.

At the Park Theatre, Camden-town, also inspected, a length or two of rotten hose comprised the entire fire-extinguishing plant. At the Duke's Theatre, Holborn, also, the appliances were in anything but good order.

These theatres have since been consumed by fire—most fortunately without serious loss of life—together with the Philharmonic at Islington, where Mr. Dixon-Hartland, M.P., and myself found the exit doors so securely fastened and bolted that, on the arrival of the man with the key to open them, after waiting ten minutes, it took two or three men to force them open. At the Strand Theatre, before re-construction, the dressing-rooms of the ballet were approached from the stage up a spiral iron staircase, the heat there being so great as to compel Mr. Warton, M.P., who ascended the staircase with me, to beat a hasty retreat. It is only common reasoning to add that, in the event of fire at the Strand Theatre before re-construction, the ballet would have been burnt, as if in a cage, in the fire. The Criterion Theatre has also since been closed. The fact of its being considerably below the surface of the ground (air having to be pumped below), would have rendered the escape of an audience impossible in case of fire suffocation from the smoke, which would have filled the upper staircases, rendering breathing impossible. The late Royalty Theatre, with dwelling-house attached, and in communication, was also a notably dangerous structure; as was also the Olympic, now re-constructed. I quote such instances only as I can do so without detriment to vested interests, all the theatres I have mentioned being either burnt, or shut up, or re-constructed, at the present time; but they were open and nightly crowded at the time of my addressing the Lord Chamberlain. It may now be seen whether the term I then used as to their condition being "notoriously disgraceful," was an expression to which exception could be taken. At a theatre open at the present time—the Gaiety—conflicting authority has resulted in the bricking up of an important exit. As, however, Mr. Hollingshead has published a pamphlet giving the opinions of Mr. Phipps, the celebrated architect, and which flatly contradict many points raised by the Metropolitan Board of Works, the assertion previously made that the Metropolitan Board of Works has not allowed the soundest judgment to prevail in its dealings in "improvements" in theatres is again exemplified.* The annual inspection by the Lord Chamberlain I described at the Society of Arts' meeting on the 31st May, 1883, in the mildest language I could use, namely, as a "simple farce," The gentleman who makes that inspection knows nothing whatever of fire brigade work or appliances. The manager of a theatre receives a letter stating a gentleman from the Lord Chamberlain's office will call on a certain day, at a certain time; the fireman, or man doing duty as such, is told to put on his best coat and receive the gentleman, and escort him round the house. Whether the appliances are in good working order or not the "inspector" is unable to say, and the "inspection" serves no practical use in any sense whatever.

That the meeting of the Society of Arts so far endorsed my remarks, the following resolution, which was carried unanimously, will show:—

"That the present official system for inspection of theatres is unsatisfactory, and does not adequately provide for the protection of the public from the risk by fire."

I have called attention to the "fireman" employed at theatres, and a few further remarks may not be out of place. Having had theatres placed under my charge, I can testify to the fact of the "firemen" employed to guard such places having other employment in the day-time, and, therefore, it can only be reasonably supposed that while on "duty" at the theatre, a considerable part of such "duty" must be generally performed by most of them in a state of somnambulism. At the late Philharmonic Theatre, the "fireman," on being questioned, admitted knowing nothing whatever of the fire-brigade duties. He was gas-man, and acted as "fireman" he added, and in event of fire, he stated, he would give the alarm.

At the Alhambra, the fireman, at the time his services were of the greatest value, namely, the outbreak of the fire, instead of being able to direct all his energy to his duties, was engaged in rescuing his wife and child, who resided in apartments at the top of the building. The danger to surrounding property from such negligence of duty must be considered, as life is seriously imperilled in adjacent buildings by a conflagration such as results from the burning of a theatre.

In a paper circulated amongt firemen, styled *Police and Fire*, but now published as *The Fire Engine*, I advocated the establishment of a Fire Brigade reserve. The remarks are published in *Police and Fire* of 5th March, 1881, from which I take the following:—

"Then managers of theatres advertise for a fireman, and the man engaged is made to appear a kind of general officer of firemen in his epaulettes and paraphernalia, and acts the part of a fire policeman, and looks after fire when not otherwise engaged."

Now, why should a Fire Brigade reserve not be started in London, to band together all these men who look after buildings. Under good superintending officers, a much higher standard of efficiency in the matter of prevention could be attained, and while employers would not pay more than they now do, they would derive great benefit by being able to obtain men of known character and tried ability, coupled with the advantage of regular and stringent supervision. At present, each fireman is his own master; his employer does not understand his duties or their proper performance, and usually engages the man from his personal appearance, or some recommendation that, for practical purposes, may be worthless.

Being of opinion that the place for a fireman at a theatre is on the stage, I drew the attention of Mr. Bancroft, while I was inspecting the Haymarket Theatre, to his fireman parading the house. Mr. Bancroft's remark was, "Well, I am of opinion that it gives an audience confidence to see the fireman." "Certainly, if confidence is to be given by mere show," I

* On the 12th October, 1883, Messrs. Gatti were summoned to Bow-street, charged by the Metropolitan Board with making default in certain alterations ordered in the structure of the Adelphi Theatre by the Metropolitan Board of Works. Mr. Flowers, the magistrate, after hearing the evidence, said "that, as far as his judgment went, everything necessary had been done by the defendants." Messrs. Gatti had, however, to pay £3, the costs of the several adjournments that had taken place in connection with the matter. On October 13th, 1883, when application was made to the Croydon magistrates to renew the dramatic license for the Croydon Theatre, the Chairman drew attention to certain matters which he contended were not in accordance with the requirements of the Bench. A quantity of goods had been placed in a passage. A temporary license was granted, that structural defects might be remedied.

replied, "why not dress up a super as a fireman, and allow the man who understands the practical duties to remain where he is most likely to be required?" The fireman in charge on the stage holds a most responsible position.

It is the feeling of security amidst the greatest danger, fostered and believed in because of the comparative immunity from accident for some years, that leads to a carelessness and want of precaution that, in almost every instance, has led to ultimate disastrous results. So long as each proprietor or manager of a theatre can act independently, and be allowed to form his own opinion of what is necessary for public safety, so long will a most unsatisfactory state of affairs exist, and be dangerous in the extreme.

Whatever authority exists in the interest of the public for safety against fire in theatres, such jurisdiction should be the same, and made to apply in all parts of the kingdom. Offences against a law providing for the safety of the public in places of amusement should only in trivial instances be punishable by fine; wilful neglect, thereby involving risk to life, being made penal.

Another point worthy of consideration is the character of dramatic representations, and the attempts at realism which introduce a needless element of danger where it is so desirable to minimise risk, as accident may lead to such dire consequences.

Without diverging from the subject of fire extinction, it may well be offered as a matter for consideration whether such attempted realistic dramatic representations should, in the interest of dramatic art, be classed with stage performances of a character such as a theatre may reasonably be expected to produce. In the event of accident, with the most perfect system in every way, it is impossible safely to calculate on an absolutely safe exit of an entire audience of any magnitude. So many unforeseen circumstances are likely to occur in the best regulated houses, where so many people are assembled together under one roof, that will upset calculations made without sufficiently taking into account the great excitement and violently precipitate action of otherwise cool and law-abiding people; that danger cannot be too well guarded against.

As is only to be expected in the attempted realisation of any greatly desired end, numerous and unexpected difficulties arise that require careful study; and in regard to fires in theatres, panic may be accepted as one of the greatest dangers, as well as one of the greatest difficulties to contend with.

Panic, or terror, created by groundless fears, can only be averted by the adoption of such means in places of public amusement as will create a convincing proof of absolute safety. While absolute danger, by reason of insufficient means of exit and other causes, exists, the fear of its occurrence will remain, and the worst results will be possible from its incident.

Panic, produced from a feeling of insecurity, must be met by rendering individual personal safety a certainty, and under this condition panic is practically impossible. Until individual personal safety can be secured to the public, the danger of panic will exist with the ever probable and likely result of loss of life. Fire in a theatre completes its work with a rapidity simply astonishing.

Taking one of the last instances, namely, the Alhambra, the Chandos-street fire-engine station received the alarm immediately on the outbreak of the fire. The fire station was hardly two minutes' run from the fire. When the firemen reached the theatre, the fire had not gone beyond the dress circle, yet so great was the heat that the melting of gas-pipes in the roof was like rain on the auditorium, and the tunic of one of the firemen, which is now at the headquarters of the Metropolitan Fire Brigade, presents the appearance of a piece of metal rather than its texture, which is of course cloth. The fireman, whose coat this was, stationed in the stalls, was compelled to retire, the branch of a powerful steamer that he was directing proving useless to stop the progress of the flames.

Instances of the startling spread of fire that once gets a hold in a theatre are numerous. As I write, I notice the following in the *Times* of October 6, 1883, with reference to a fire at a theatre at Yokohama:—

> "The flames spread with awful rapidity, and in a few minutes enveloped the theatre. In the result 15 adults and 20 children were found to have been killed, and over 100 persons were seriously injured."

Modern appliances, invented more easily to extinguish fire, generally necessitate the exercise of judgment, ability, presence of mind, and even personal courage, for effective use in the moment of danger. Unless those who are to use such appliances as exist in theatres for fire extinction are accustomed to their use, and by continual practice made familiar with them, so that the full power of their effectiveness can be applied at the moment required, and with advantage, such appliances are, for all practical purposes, useless.

To attain the desired end, I have drawn up a code of "Rules and Regulations for the Prevention of Fire" for several of our leading theatres. For each theatre the code is specially adapted, and, as an example, I quote those written by myself for the Royal Comedy Theatre :—

"From the commencement to the finish of every performance, the fireman in charge must be in attendance on the stage, and must not leave for any purpose whatever.

"The fireman's duty is to keep a careful watch over the gas arrangements, and superintend the lighting-up and maintenance of all lights in use on the stage generally.

"Scene-shifters, &c., are not to block up the hydrants, free access to which must always be maintained; all branches with hose flaked must be kept ready for instant use. Two blankets on either side of the stage, well wetted, must be kept in readiness for use, and in convenient positions.

"The fire buckets on the stage must be kept full of water, and hand-pumps practically tested every night, previous to the commencement of the performance. A man in the "flies" to be entrusted nightly with the bucket and hydrants there, with instructions how to use them. No one, on any account whatever, is to make use of or tamper with any appliances kept for fire extinction.

"Fire-places and stoves must be guarded with wire screens; and gas-burners by wire-netting and protection plates. Wax and any kind of matches, other than patent safety, to ignite on the box only, must not be taken on the stage or into any dressing-room; smoking in these places is also strictly prohibited.

"The hydrants in the auditorium, pit, dress circle, upper circle and gallery to be entrusted nightly to a responsible person whose duty may require his attendance nearest to them. Windows and doors, on and near the stage, to be kept closed during every performance, strong draught being dangerous.

"'Mediums' and inflammable material used on the stage must be rendered non-combustible by the application of a solution of tungstate of soda, the fireman in charge being responsible for this being done as often as occasion may require. Highly inflammable wearing apparel, in process of washing, should, lastly, be dipped in a solution of alum.

"The fireman in charge to have free access to every part of the building.

"No one under the influence of drink to be allowed on the stage, or in the dressing-rooms.

"No intoxicating drink of any kind to be offered to or accepted by the fireman in charge of the theatre and on duty.

"At the close of every performance, and of the theatre, the fireman in charge must visit every part of the building. A signal should be known by all servants of the theatre to convey to them the presence of fire in any part of the building without giving the alarm to the public. Visitors are politely requested not to light cigars or pipes within the precincts of the theatre, or use matches.

"Absolutely careful and particular attention to these regulations being necessary and essential for the protection of the general public attending the theatre, anyone noticing any breach or non-performance of the above regulations, should at once report the same to the manager of the theatre."

The enforcement of such regulations at the present time is, unfortunately, left to the individual discretion of managers. The leading article in the *Daily Telegraph* of 21st December, 1881, however, says:—

"Captain Arthur W. Shean has submitted a set of rules for the consideration of the Lord Chamberlain, which, in conjunction with other practical suggestions, might be made to form the framework of an Act of Parliament. One of these rules provides for a signal which should be known by all servants at the theatre, to convey to them the presence of fire in any part of the building without taking the public into the secret of alarm."

Mr. Dixon-Hartland, M.P., in his speech in the House of Commons on 17th April, 1882, says:—

"Considering it his duty to become practically acquainted with the state of theatres in London, he (Mr. Dixon-Hartland) had, by the kindness and exertions of Captain Shean, a gentleman who had prepared the best rules he had seen for prevention and extinction of fires in theatres, been enabled to visit a great number of those places."

A theatrical manager of great experience addressed to me the following letter :—

"New Sadler's Wells Theatre,
"December 13th, 1881.

"Dear Sir.—On my taking possesion of this theatre, I found the fire appliances in most excellent condition—in fact, the arrangements made by you as a precaution against fire are of a more satisfactory nature than I have found at either the Drury-lane, Lyceum, Princess's, Adelphi, and St. James's Theatres.

"Yours faithfully,

"F. B. CHATTERTON.

"To Captain Shean."

The most perfect regulations, however, without actual practice, are of little use. At the fire at Cortachy Castle, reported in the *Times* of 17th September, 1883, the following occurs :—

"The castle had a complete water system for use in case of fire. The printed regulations for the manipulations of this apparatus were exposed on the walls, but none of Lord Dudley's servants made themselves acquainted with the details. To give the alarm of the fire, one of the servants seized the rope of the alarm bell, which immediately snapped."

Similarly, by reason of neglect, at the Karlsbad Theatre in Vienna, on September 10, 1883, in consequence of a panic, "the people fled through the windows and over the roof, instead of making use of the emergency exits, which were locked and bolted."

To provide against such neglect, and to ensure a proper use of appliances, I advocated and introduced a "fire drill," described by me in a letter appearing in the *Times* of 23rd November, 1882. It refers to the drill performed at the Brighton Theatre Royal, and is as follows :—

"At the close of the performance, the audience had but just quitted the theatre when the "fire drill" commenced. At a signal, known only to the *employés*, but which indicated to them the presence of fire in the theatre, the curtain was quickly dropped. At the same time every exit door opened, and a powerful lantern was held aloft by an attendant, clearly showing the way out, the gas being turned down. The stage manager also appeared in front of the curtain, and stated an accident had happened, but everyone in the theatre could leave with comfort, and without fear of anything whatever. As quick as thought the word was passed 'fire in the dressing-rooms.' The hose, with branch attached, was instantly married on to the hydrants. Hand-pumps were likewise immediately applied, and in the space of but a few seconds, such fire extinguishing appliances were brought into requisition as, under ordinary circumstances, would be sufficient to meet any ordinary emergency. And this 'fire drill' was performed by the whole staff of the theatre, and is practiced every fortnight throughout the year, a different part of the building being supposed in danger at every drill. What was done was performed in the most workman-like manner, quickly, but with no unnecessary bustle, and no confusion."

Especially in regard to fireman's work, use is second nature, the only hope of successfully attacking an outbreak of fire in a theatre being that of a simple and instant method of meeting the danger, with an effective handling of appliances, only to be attained by those on the spot being intimately acquainted with their use.

The safety of the public must, however, be studied by the enforcement of certain additional precautions that are indispensable. To describe these I propose, first, taking the auditorium, and afterwards the stage.

The seats in the auditorium should be fixed, every seat allowing at least two and a-half square feet of room for the occupant, and be so arranged as, while tending to prevent a "block," allow a free passage to the exit door. All the seats in a theatre should be licensed, and it should be an act against law for a manager to allow or permit more people in his theatre than he has licensed seats to accommodate.* All staircases should be constructed with hand-rails on either side, and where any turn of the passage may lead any one to doubt the direct way out, the word "Exit," with a hand pointing in that direction, should appear prominently. All exit doors should be distinctly labelled "Exit," and every such door should be opened nightly for egress. All exit gangways should be clear of any obstruction, and for outer exit doors, which should open outwards, carpet curtains should be used in place of doors, to prevent draught, &c. Every separate part of the building, such as pit, dress circle, gallery, &c., should have a separate and direct exit, no other exit leading into it at any junction whatever. Excepting the case of private boxes, there should be no movable seats capable of being overturned in any part of the theatre. Cloak rooms, refreshment rooms, and other public conveniences, should be situated at the farthest point from the exit door, thus leaving the exits clear of unnecessary traffic. No greater number of people should be contained in any part of the "house" than, by calculation of width of exit, &c., would allow of a clearance being effected under three minutes. Special attention should be directed to such parts of the house as are highest from the basement. Smoke ascends,

* From the *Referee*, a journal always well informed on matters connected with theatres, I quote the following, which appears in a copy of that journal of October 14, 1883. It alludes to the Adelphi Theatre :—"Boards—'standing room only'—have been out every night," &c. In a house so packed with human beings, a safe exit in case of accident would be next to an impossibility. It is as absolutely necessary for safety to license the "holding" capacity of a theatre as to limit the passenger accommodation of a ship.

and suffocation can be effected by causing insensibility in the space of one minute.

An outlet for smoke in the roof is desirable, although it may assist the spread of fire,* life being of greater value than property. All gas-pipes, &c., should be of iron, no metal piping being used. If the lighting power be by gas, it should be supplied from separate meters and mains, one for the auditorium, the other for the stage; while supplemental means, such as oil lamps, should provide against the contingency of total darkness. Where lighting is effected by means of electricity, the wires should be laid under responsible authority.

Lastly, the adoption of fire regulations and fire drill, as explained, should be enforced, and the building subjected to inspection after being closed, by constituted authority, that would ensure proper vigilance being exercised against an outbreak of fire.

The stage, a combination of wood, canvas, arrangements for lighting on an extensive scale, and properties generally of a naturally inflammable character, rendered still more so by the great heat nightly engendered, may be considered the part of the house requiring the greatest protection. The danger attending the lighting of a stage, generally effected by the use of coal-gas, must be considered.

The frequent shifting of scenes nessitates a constant re-arrangement of gas-pipes having joints of flexible india-rubber, the insecurity of any one of which, causing an escape of gas, being likely to lead to danger of the greatest magnitude. It is most desirable that lights, as much as possible, should be fixed and powerfully reflected—use being made of everything available, floor and backs of scenes—to increase the power of light, which would be advantageous from the point of view of safety from fire as well as economy.

Flexible gas joints should be under constant supervision, all pipes for the conveyance of gas throughout the "house" being of iron. No workshops of any description or "stores" should be attached to or form part of a theatre. Where scene painting is done inside a theatre, it should be executed under strict rules, provision being made, amongst other important items, against smoking. It is absolutely necessary that every licensed building should be placed under strict rules and regulations, providing for careful, vigilant, and ceaseless watching.

Stage properties generally may be rendered non-combustible by the use of chemicals, such use being approved at the Society of Arts meeting on May 31st, 1883, when the following resolution, proposed by Sir Frederick Abel and seconded by myself, was carried unanimously.

> "That it is important that attention should be given by managers of theatres to the known methods for reducing the inflammability of structural or decorative materials, and that it is desirable that more use should be made of such methods."

Practically, the recommendation is not appreciated, and little or no use is made of a valuable means of protection easily and inexpensively applied.

Water, and that of a most insufficient and scanty supply, is the only element upon which any reliance can be placed for the extinction of fire in theatres.

The pressure in the Strand district, where many of London theatres are situated together, I tested in February, 1882, and found to be under 45 lbs. on the square inch. The pressure varies from 30 lbs. to 50 lbs., the exception being a pressure of 55 lbs. This highest pressure is insufficient to reach to the roofs of many of our theatres, and there is only one remedy. Each theatre should be provided on the stage with a copper tank, containing about 100 gallons of water, with four deliveries, one for each side of the stage—"floor" and "flies." By means of an air-pump, air could be pumped into the cylinder, till, by guage, a pressure could be shown of at least 150 lbs. on the square inch—and the guage would continue to show the existence of the pressure or its decrease.

Theatre fires have, in almost every known instance, burnt themselves out. Density of volume or force of contact will alone stop a fire in a theatre, by, so to speak, suffocating it. For this reason I question the utility of a high proscenium wall as a means of stopping or preventing a "burn out" in event of fire. From practical experience, I should assert that unless fire in a theatre can be subdued locally, *i.e.*, that an outbreak can be checked within a reasonable limit by local appliances then and there at command, all hope of saving any part of the building might be deemed futile. The delivery of water from such a reservoir and with such pressure as I have named, through branches one-sixteenth of an inch in diameter, would prove an extinguishing agent of sufficient power for all ordinary purposes. Little discretion has been used, in numerous instances, in placing the hydrants and appliances in theatres

* Such outlet being made to act automatically by the action of heat.

for fire extinction. Exit gangways and similar places would, in event of fire, be crowded with a surging and excited crowd—and in these places are the appliances, in many instances, fixed. The hose is coiled, the branch and different parts of the gear laid apart "on view," the practical use of the appliances being seemingly ignored. On the occasion of accident, such parts of the appliances for fire extinction have to be joined together, and the hose rolled out, and thus the most valuable time, namely, that immediately following an outbreak of fire, would be wasted in completing work that should be kept perfect, and the appliances ready for instant use.

That part of the house used by the orchestra, if connected direct with the outside of the building by a subway, would be the most convenient for placing hydrants, &c., as the appliances, while being used, would be free from the turmoil of a crowd, and handy for use by the servants of the theatre, whose knowledge of a clear subway to the street would enable the appliances being advantageously worked for as long a time as possible in the direction of any part of the house. Supplementary aid and assistance could also, by means of the subway, gain easy access from outside the building, while the audience would be permitted to avail themselves of the ordinary exits, unencumbered with fire brigade appliances that, otherwise being got ready and used in their midst, could only tend to add to confusion, loss of time, and in every way prove highly dangerous and thoroughly inconvenient. In the event of fire occurring on the stage of a theatre, it is usual to cut away the burning portion. For additional safety it would be as well to have ready for use "trays" of close wire gauze, that might catch the material alight, and so tend to prevent an extension of the fire.

Buildings to be erected and intended for theatres or places of public amusement, should have all staircases constructed of concrete, with banisters of iron, and have a separate and distinct water servive for fire extinction. As danger is as likely to be apprehended from smoke as from fire, special attention should be directed to the gallery and upper parts of the building. At only one theatre, namely, the Savoy, has this been studied in the construction of the theatre, the gradient of the basement being utilised to afford equal advantages to the upper as to the lower parts of the house.

The Savoy being situated on the side of a hill leading from the Strand to the Thames Embankment, the pit audience entering at the bottom of the hill, and the gallery some distance up the hill, are equally well provided with an easy means of exit, the gradient of the ground saving a climbing up or descending of as many stairs as if the gradient of the basement was equally flat.

The side of the Strand above the Embankment, by reason of the gradient, offers a better site for theatres and places of entertainment than can be found equally advantageous in almost any capital of Europe.

A full and complete official investigation should follow the occurrence of any and every accident by fire in theatres, a report of the occurrence of which should be made compulsory to the duly appointed authority, the establishment of which, by the Government of the country, is a most necessary and pressing subject of home legislation. The entire English press has acknowledged the necessity for some decided action being taken, in the public interest, in the prevention of fires in theatres, and it is to be sincerely hoped the experiences of the past may not need repetition, in order to provide reasonable security in the future.

Relative to the question of expense, is not traffic in slaves less objectionable than submitting some hundreds of people to the risk of being burnt alive, from a desire to save outlay in providing adequate appliances?

Centralisation of power, and grandmotherly government, may be terms used to deride the action of Government in the matter. If placing the lives of 302,000 people nightly in safety from the risk of death by fire be called grandmotherly government, the same epithet might be applied to the sale of Food and Drugs Act, and Acts of Parliament tending to prevent the spread of epidemics and disease.

As our population increases, one of the principal moral and intellectual recreations for the populations of the large towns is that provided by the theatre under good management, and the misery and awful consequences that have attended the loss of life by reason of accident by fire in theatres have, it is to be hoped, been sufficiently well shown not to need repetition. Until what has been stated in this paper, and which is absolutely essential for safety, is properly carried out, the licenses of places of public entertainment being held subject to the enforcement of the conditions stated, buildings containing large public audiences will not be safe, and the chance of serious accidents happening at any time will be regulated by "luck," or the prospect of total immunity from any accident whatever.

If it be no concern of the State how the lives of its subjects are jeopardised and even destroyed, how very ridiculous it is to study any means whatever for the safety of the public or the preservation of life. Until such measures are passed by our legislature as will ensure the observance of such precautionary measures as alone will tend to prevent the occasion of serious accident, large audiences will be exposed to all the risks and terrors of death by fire in our theatres and public places of amusement. This fact, only too true, it is to be trusted will not afford a practical proof of my statements.

In concluding this paper, I feel it incumbent to recognise the valuable and much appreciated services of the police in the cause of fire prevention and extinction. Considering the invaluable services they have at all times rendered, and especially in our large towns, I cannot but think it would prove highly advantageous to connect all our places of public entertainment with the police stations by electric wire, that in case of need their valuable aid might be at once rendered.

I feel it necessary to draw attention to the manner in which certain theatres are at the present time being constructed. In one instance "the theatre" is contained in an inner shell, the outer shell comprising an hotel, residential chambers, and shops. The combination, through doubtless economical, is dangerous, and such a building should never be licensed for public entertainment. Risk by fire in theatres will ever be sufficiently great, but to add to the risk by enclosing such a building with an hotel, and chambers, and shops, can only be regarded, after recent experiences, as an act showing the grossest disregard of human life, and one that should never receive the sanction of the authorities.

Appendix.

The foregoing essay, in consequence of having to be delivered to the Society of Arts prior to 31st October, 1883, was written in September, 1883.

Since that date, an instance of gross abuse and neglect of all precautions for the safety of life in a large London theatre, came to my notice, particulars of which were published in a letter of mine to the Editor of the *Times*, on the 2nd January, 1884.

On the night of December 28th, 1883, I visited a large London theatre, only lately inspected by the Lord Chamberlain. The fire buckets were in their proper position, but everywhere empty, the fireman stating that 'the cleaners must have been using them.' The fireman in charge did not know the pressure of the hydrants, as they had never been tested. He stated also, on my asking what provision there was in the flies for fire extinction, that he "intended running up a line of hose there from one of the stage hydrants."

There were no hand pumps, and no fire hook for cutting away any portion of scenery that might catch fire. Three firemen were employed at the theatre, but they had no system for unity of action, and no signal to give alarm of fire without alarming the public. The few lengths of hose were, as I was informed, "just in time for the Lord Chamberlain's inspection," having only lately been delivered at the theatre.

A few remarks, may, I think, be appropriately added with special reference to music-halls. The character of music-halls (if I may use such an expression), will considerably alter if an extension be generally granted for dancing as at the present time is alone possessed by the Oxford Music-hall. The "Oxford," characterised by able management, may continue to hold the exceptional privilege; but should other places known as music-halls receive such an extension of license, greater attention will, of necessity, have to be directed to the question of fire prevention in such places. The combustible nature of music-halls may be generally held equal to that of theatres, a special feature, however, being, that whilst the audience of a theatre enter and leave the building almost at the same time, the audience of a music-hall is a changeable and continually shifting one. The entertainment of a music-hall being promiscuous, an increased attendance may generally be expected during the performance of a particular public "favourite," whose *debut* may not occupy more than fifteen minutes, before and after which not nearly so large an attendance may occur during an entire evening.

Music-halls generally, as at present licensed, have no need of moveable, side, or medium lights: but a change in the nature of the performance, placing them on the basis of a theatre, will naturally add the special danger attendant on increased light and illuminations that render stage productions often very dangerous. That music-halls will burn as quickly as theatres when once on fire, may be instanced in the case of Lusby's Music-hall, in the Mile-end-road, which was "gutted" by fire in 20 minutes, on the 20th January, this year. Music-halls in London at the present time may generally be considered fairly satisfactory as regards safety from fire. At the Oxford Music-hall, at a sudden call one night, the hose was connected with the hydrant, branch attached, and the water sent on to the roof of the building under two minutes. At the Oxford also the manager stopped suddenly at one of the bars, and said to the attendant, "What would you do in case of fire?" "Open this flap of counter sir, and shout 'this way out.'" Such care in training the servants of such an establishment to act in case of sudden emergency cannot be too highly commended. The Pavilion Music-hall, the property of the Metropolitan Board of Works, who purchased the building in August, 1879, at a cost of £109,000, and who at the present time let it to Mr. Villiers, at an annual rent of £7,000 a year, may soon be destroyed, as the Board made the purchase for the purpose of effecting certain improvements, and making a new street from Piccadilly-circus to Oxford-street, through Soho, their Parliamentary powers expiring in July, 1884. A peculiar fact, however, is worth stating, namely, that while the Board of Works have compelled numerous and extensive alterations in theatres and music-halls to be made of late years, not until November, 1883, were such alterations made by their own tenant as would give the public some chance of getting out of the Pavilion Music-hall in case of fire.

At another music-hall close to the Pavilion, namely, the Trocadero, in Windmill-street, it is satisfactory to find excellent fire-extinguishing appliances, and as good exits as exist anywhere. The exceedingly peculiar system (if such a term may be used with regard to licensing public buildings in London) that exists, whilst preventing the performance of plays, &c., on Ash Wednesday, on the north side of the Thames, not only permits their representation on the south side of the river, but the hours are specially extended to houses there situated, Last Ash Wednesday, 27th February, 1884, I visited one of these specially favoured resorts, namely, the Canterbury Music-hall, whose license on that night extended till 3 a.m. the following morning. As may be expected, the place was filled to a most dangerous limit, "packed," in fact, in every part, and "standing room" only freely acknowledged at the booking-office, whilst payment was being accepted to witness the performance. To gain as good an idea as possible of the enormous risk the thousands of people then present ran in event of accident by fire, I made my way to the gallery, approached by over fifty steps, about 4 ft. wide, and, in some places, covered with orange peel. Posters, with the following notice, were prominently displayed on the several landings:—

"Watch This.

"A reward of 5s. will be given to anyone for such information as will lead to a conviction of the person, or persons, turning off the gas on these stairs."

The gas-burners were, however, quite unprotected, and within easy reach of the lads to whom the notice may be presumed to have applied. I have visited places of amusement in London that I presume come under the category of music-halls, but of which an idea may be more correctly conveyed by describing them as public houses, with sitting accommodation for a number of people, to whom is supplied a certain amount of alcoholic drink, with a miscellaneous entertainment, including songs and dances, at a fixed price.

In many of these places no appliances whatever exist for fire extinction, and in one place in particular where there are such appliances, no one is employed with a practical knowledge of their use. Though the number of people who frequent these latter resorts are comparatively few, still, in the poorer neighbourhoods, they form the staple means of recreation, and require, by reason of the number of lives jeopardised in case of accident by fire, as much supervision to ensure safety as is considered necessary at the more refined and aristocratic establishments so popular in the West-end of London.

ARRANGEMENTS FOR THE PREVENTION AND EXTINCTION OF FIRES IN THEATRES.

By Ernest A. E. Woodrow, A.R.I.B.A.

Theatres should be entirely fire-resisting, and have nothing in their construction that will readily ignite, so that the ordinary methods of extinguishing fire will suffice. This can be attained by giving due consideration and study to the planning and the materials of which the building is constructed. How these buildings can be planned and constructed, carrying out a safer system than at present, is what I would wish to try and point out in as brief a manner as possible, touching, it is feared but imperfectly, on only some of the most important points.

When the principal material employed in the construction is thin wood, as is, or perhaps I should say was, so often the case, no possible hope of safety could be entertained either for the building or the public frequenting it.

That a theatre can be made safe in spite of the special dangers from the class of business carried on in it, there cannot be a doubt in the mind of anyone who has given attention to the subject. Like every other class of building, the special risks attending it can only be known by becoming thoroughly acquainted with the business carried on in it, and the special mode of conducting such business, with the accompanying dangers. Until this is ascertained, no one can possibly plan a theatre to avoid these risks, and ensure the safe and easy working of the house.

A theatre, of all buildings, should have a place for everything, and everything in its place; and it is necessary to know what this everything is before the place for it can be provided.

The first step to be taken, is to provide such means in the planning of the house as to enable the people to get out of the building in the shortest possible time, at the slightest provocation, in every way lessening the dangers from panic. Then the construction of a theatre, and the materials used, should be such as to render it wholly fire-resisting; this can be aided greatly by the manner in which the various departments are placed with relation to each other.

As a theatre can be made fire-resisting, no house should be allowed to remain open which is not so. It is no good to patch up the old wooden edifices with sheet iron and pugging, and expect that the buildings will be any the safer. If such theatres still exist in any part of the kingdom, they should be closed, even if the loss is sustained by the public themselves. When the slightest fire commences in one of these flimsy structures, as was seen at the fire at the Alhambra, no efforts, either from external or internal aid, can possibly extinguish it.

Judgment in the choice of materials with which to construct the building, requires such great care and study, that too much importance cannot be placed on this branch of the subject. The materials employed for the erection of places for the assembly of the public, whether for amusement, instruction, or devotion, must be in every sense of the words "the best of their several kinds." The scantlings, or thicknesses, must be far in excess of what would appear to be necessary for the actual or present work which they have to perform, so that they may resist any shock or pressure that may from any cause be brought on them.

In short, a theatre must of necessity, in comparison with other buildings, be exceedingly costly. In this, I refer only to the structural portions, leaving all decorations out of the question. In dealing with buildings where human beings are "packed," surely more care should be bestowed upon their construction than upon warehouses or factories. But as long as cheap theatres are erected danger will be rife.

Planning and Construction for Prevention of Fire.

No theatre should be allowed to stand that is "hemmed in on all sides with a narrow entrance, as a frontage in a public thoroughfare sufficient to carry a flaming gas device." The dangers accruing from the surrounding property are often as great as those in the theatre itself. In no case should people be allowed to live and sleep in or about this class of building; the many risks necessarily attending them, through their own special trade, should not be increased by the dangers generally to be met with in the dwellings of the lower class; and a building, or part of a building, not designed for the special business of a theatre, should never be used for such purposes, as it is nearly sure to be unfit for them.

The site should be isolated on all sides, wide streets running all round the building; but as this is difficult to obtain in crowded cities, a theatre might be designed with comparative safety having one side touching other buildings. To obtain perfect safety, a site isolated on all sides should be insisted on.

The most important item in the planning is what might be called the party-wall system, making every division of a theatre a separate building, with as few openings connecting the various sections and sub-sections as the smooth working of the house will allow. Commencing with the back of the building, I should place the workshop section, divided from the main building by an open area; then the stage, with dressing-rooms and wings on either side; then of course follows the auditorium, the corridors, the staircases, and the offices and saloons. Each of these many sections must be divided from the other, vertically, by strong brick walls, with the openings closed by fire-resisting doors, and, horizontally, by fire-resisting floors.

The various divisions within each section should be again separated by brick walls and strong, fire-resisting floors, so that, should one room be burnt out, no other part of the building would suffer. This system applies throughout the whole building.

The position of the workshops should be such as to ensure an entirely separate building, connected with the theatre by one opening only, which should be closed by a double fire-resisting door, which door should on no account be allowed to open during a performance. Should space permit, the open area should be made 12 ft. wide between the theatre proper and the workshops.

Where no area can be obtained, a thick brick wall passing through and above the roof should divide the workshop section from the stage section.

All stores for scenery, properties, &c., not in immediate use, should be in this building.

The painting gallery might be placed over the workshops, getting a top studio light, which should be protected by strong wire guards against falling sparks or materials. There is no special danger from scene-painting, oil not being the medium used, as is sometimes supposed.

The stage is too often used as a carpenter's shop. This should never be allowed; the many dangers thus incurred need no pointing out; yet it is strange that seldom is a special room provided for the carpenters. The work in some houses was carried on over the auditorium ceiling, but this is happily stopped. A special workshop should always be provided.

Dressing-rooms might be placed on either side of the stage for males and females, being divided from the stage horizontally by brick arches, and vertically by brick walls. Fire-resisting staircases, and separate exits into the street, are necessary for each wing, as also for the workshop.

The fire-places, where provided in the dressing-rooms, should be protected by tall wire-guards. A complete system of heating throughout by hot-water pipes is, however, preferable to open fire-places.

The stage floor and sliders must of necessity be of wood, for setting the scenes, but much of the machinery might be made of iron, keeping somewhat the same forms now used in wood, and making a stiffer stage, which could be more easily manipulated.

On a level with the stage floor there must be ample room for scene docks, for storing the scenes in nightly use, while shifting from one set to another. The mezzanine and cellars should be used only for the machinery for working the stage, and on no account should the stowage of rubbish or scenes be allowed here—it never would if proper provision were made for it elsewhere. It is here that the stage carpenter does such infinite harm with his match-board erections, after the building is out of the hands of the architect.

The band and other rooms are at times but portions of the mezzanine, match-boarded off, as if they had been forgotten when making the plans (which is more than likely). Proper accommodation must be supplied for band, band-master, stage-manager, firemen, bill-sticker, property-master, &c., &c.

The gridiron above the stage must be made sufficiently strong to carry the weight of the cloths, &c. Cases have been known where it has given way under the weight of the scenery, and let everything in dangerous confusion down on to the stage. The construction of the gridiron, flies, and fly-rails should be of iron. Communication is necessary from the flies to the stage, to enable the flymen to escape.

The stage should be divided from the auditorium by a thick, solid brick proscenium wall, which wall should go between the orchestra and mezzanine, and be arched over the opening, passing through and above the roof. There need only be one opening in this wall, in addition to the large or proscenium opening, namely, a pass door from the stage to the auditorium.

A separate fire-resisting passage-way should be provided for the exit of the orchestra, so that the musicians may avoid passing either through the audience or under the stage to gain the street.

The stage should undoubtedly be cut off from the auditorium by some sort of fire-resisting or smoke-proof curtain. The failure of some of the iron curtains used on the Continent, and in America, has shown that they are not always to be relied on, but they must be of some use in retarding the progress of the flames. A double thick felt or cloth curtain, made bag-shaped, with a water spray along the top that would damp the curtain whenever it was lowered, suggests itself as a method for shutting off the stage. Water curtains have been proposed, but as these could not be periodically tested on account of the destruction of property that would ensue, they cannot be recommended. Whatever is adopted must be in constant use, for anything designed to act only in case of need, or upon the outbreak of fire, is often liable to fail at the very moment it is most needed. Everything in and about a theatre must be always in use to be of any good. Where automatic appliances are provided, people are apt to put such faith in them that they ignore the ordinary and essential means of fighting against fire, and become careless of the importance of the great danger. An "emergency" curtain coming down unexpectedly, in the middle of a performance, would be but the signal for a panic. Appliances requiring the presence of the flames which they are supposed to extinguish before they can act, cannot be too strongly condemned.

I repeat, and cannot insist upon it too strongly, all appliances must be made so that there will be no way out of using them nightly. Therefore the smoke-proof curtain and the painted act drop should be made to fall always together.

The scenery should be protected by applying some of the numerous solutions recommended by our chemists, and all drapery should be similarly treated.

The wood-work in and about the stage should be periodically painted with asbestos paint, or other fire-resisting liquid, and no precaution left untried to mitigate the danger from fire.

In dealing with the stage, we have to contend with that portion of the house where there is the most danger from fire, the immense amount of gas used nightly, and sometimes in a careless manner, as pipes are being constantly connected and disconnected during the performance, causing small escapes near naked lights, makes one wonder that accidents occur as seldom as they do.

All lights must be protected by wire-guards, and an arrangement should always be used whereby the gas is automatically cut off at the place where the union is made during the process of shifting various battens, ground-lights, &c.

The gas should be under the control of a practical gas man, with a sufficient staff of subordinates. This man should be stationed at the gas plate, which is fixed on the stage, during the performance, on which plate each cock should be labelled indicating what section of the light it governs, so that no error can possibly be made, and the wrong part of the house put in darkness.

The mode of lighting up should be by the electric spark, and not by naked lights. The "flash" system should be applied to all battens and hanging lights, avoiding the use of the spirit, cotton, and cane moving among the scenery. When the electric light is used, many of the dangers of stage illumination will be done away with; yet great care will have to be taken in the manipulation of the light, which need not be touched on here.

The gas-meters should be placed in a specially prepared and ventilated room. The supply pipes must be of hard metal, visible, and coated to prevent corrosion. There should be a cut-off tap near the stage door, to turn off the gas from without in case of fire. Separate meters should be provided for every section of the house, and a double supply laid on to each. Every set of staircases, corridors, offices, dressing-rooms, workshops, as well as the stage and auditorium, should have a dual system of lighting.

Every burner should be protected by an incombustible guard, and fixed away from woodwork or inflammable material, with a metal flue over it. In the parts of the house frequented by the rougher class, the lights should be encased, or locked up, or placed out of reach.

Sun-burners are preferable to gaseliers; they must be periodically cleaned, and no woodwork fixed near them. Access should be provided to them from the roof.

Oil lamps should be placed about the buildings in all sections, in conspicuous positions, but out of the reach of the public, to take the place of gas on its extinction. Colza oil has been found preferable to any other. Red lamps, with the word "Exit" in white, should be placed over the exit doors. All lamps should be lit and in their places before the doors are open, and the gas, both on the stage and in the auditorium, should be lit before the audience is admitted.

Gas-burners fixed so that they can be tampered with are among the most prolific sources of producing fire. There should be no jointed brackets or swinging pendants; every fitting must be fixed, and all joints and appliances examined and approved before the house is licensed.

Proper precaution should be taken in the manipulation of the lime light, and the bags kept outside the buildings.

Provision for plenty of light should be made to enable the use of artificial light being discontinued during the day, thus avoiding one of the greatest risks in theatres, namely, the careless handling of lamps, candles, or matches. It is a frequent habit to drop the end of a semi-burnt match, and one to which great danger is attached. There could never be a greater mistake than making a theatre dark. The business could be better carried on if there were plenty of daylight, and the accumulation of the dirt of years would not then be suffered to remain unremoved, ready to flare up on coming in contact with the slightest spark. A theatre, for everybody's comfort, should be clean; but as long as it remains dark, it will be dirty and dangerous Therefore, the removal of rubbish should be insisted on daily, or an external furnace provided in which it could be consumed.

The roof should have easy access from various points, and be provided with cat ladders, leading from the different levels, to enable firemen to get about with ease. There should be a parapet wall all round to protect the firemen. The construction of the stage roof should be of iron; if of wood, the constant changes of temperature to which it would be subject, and the enormous heat, would desiccate the trusses and rafters, and convert them into something little better than touchwood, which would readily ignite.

A better mode of constructing an auditorium roof could not be cited than that of the new Alhambra Theatre, where iron and concrete, with a covering of asphalte, are the materials used. The ceiling of the auditorium should be formed of fire-resisting materials, such as Jackson's fibrous plaster, and never of canvas. There should be no space over the ceiling available for store or workshop.

The several divisions of the audience should each have their separate entrances, exits, passages, corridors, staircases, saloons, lavatories, &c. The best method of planning this portion of the house, having in view the safety of the people, would be to bring everybody as near the level of the street as possible. To do this, place the dress circle on the street level, go down to the pit, and up to the upper circle and gallery. By adopting this method, the various sections of the audience would have a better chance of gaining the street, the distances being more distributed. The fact of the building not being so high as it would be if the pit were on a level with the street, would give a better chance of aid in case of fire; and as the parts occupied by the administrative offices need not be carried so high as the main building, an intermediate roof could be obtained, whereby the principal roof could be easily reached from without. The people in the pit, being below the level of the street, would not be in any danger, as in going upstairs a crowd is not likely to stumble, there not being the same risk as when coming down stairs.

Each section of the audience should have two entrances and exits, one on each side of the house, such exits and their approaches leading directly into the street, and these should be used only by that section of the audience for which they are designed, there being no pass-doors or emergency exits leading from other parts of the house into them. A door that is known as an "emergency door" is only a trap; when opened, it, as a rule, leads into a corridor or staircase already full of people from another part of the house. All exits must be entrances, and entrances exits, and used nightly.

Staircases and passage-ways should be from 4 ft. 6 in. to 5 ft. wide. Where this width is insufficient for the number of people, an extra staircase should be provided rather than additional width being given beyond the 5 ft. The corridors immediately outside the various tiers should be of sufficient width to take the people occupying such tiers without crushing. These corridors must be divided from the auditorium by brick walls, and the openings fitted with fire-resisting doors.

There should be no winders or steps at half landings in the staircases, as all such are dangerous in a moving crowd. The flights should not be of more than eight or ten steps, and the treads and risers should be of easy and uniform go throughout. All steps and landings must have at least 4½ inches bearing on solid brick walls at both ends, and arches should be turned under the landings.

Strong hand-rails, on brackets built into the walls, should be fixed to both sides of all flights of steps and landings, leaving a space of three inches clear between the wall and the handrail. To acquire this, a chase should be cut in the wall, so as not to lessen the width of the staircase or passage-way by the projection of the handrail.

No single step, or flights of two or three, should be admitted, slopes should take their places.

The private box staircases should be made as important as the other staircases, with exits into the street, and communication at each level. As a rule, they are narrow or corkscrew staircases, only available for the private boxes.

There should be no unshipping of barriers; they should be made permanent, and hung so as to open outwards, and close against the wall.

No pay-box or barrier should be placed to obstruct the exits; the moveable box so often seen should be abolished, and the pay-box made part of the permanent building.

All doors and barriers must be hung so as to open outwards, and close against the walls, the larger doors being hung in two folds. The fastenings on the doors used by the public should be such as to allow them to open the doors from the inside with ease. Locks are bad, as keys are seldom forthcoming when most required. The danger attendant upon the ordinary barrel-bolt was terribly illustrated in the case of the Sunderland disaster. It is apt to slip and catch in the floor, fixing the doors. A fastening is wanted that will enable those inside to get out, while it will at the same time present an effectual barrier to those outside. This has been provided by an invention known as "Arnott's patent bolt," in which an ordinary spring square bolt has the lower portion knuckle-hinged. Pressure on the inside will cause this portion of the bolt to leave the socket, and become parallel with the floor, thus allowing the door to swing both ways. Pressure from the outside will only tighten the bolt. What are now known as "emergency" doors are too often found locked, and worse than useless.

If the public were acquainted with the means of getting out of a theatre, there is no doubt they would feel safer when visiting these places of amusement. A great number enter with the idea that they could never find their way out if they wanted; this is not to be wondered at, considering what some of these entrances are, and that the entrances are not always the exits, and the exits not always used nightly. Everything should be done to inspire the audience with the idea that they could save themselves without hurting others in case of accident. To do this they should be able to find their way easily about the house. Several ideas to attain this suggest themselves—placing ample notices on walls and doors, such as "Exit;" "This way out;" printing the plan of each section of the house separately on the programmes; placing large plans of the house in conspicuous positions; but above all, simplicity and uniformity in the plan at the first onset. Place the exits where they will be easily seen, and make both sides of the house as nearly alike as possible. Notices should be painted on lavatory, saloon-doors, &c., to distinguish them from exit doors. All notices should be painted in luminous paint. Never should such notices as "In case of need," "Exit in case of fire," "In case of panic," "Emergency," "Alarm exit," be seen; they only suggest danger to the people, and everything should be done to intimate safety and avoid panic among the nervous visitors to theatres.

All seats should be numbered, and the house licensed to hold that number, and no more admitted under penalty of heavy fines to manager and visitor alike, then the gangways would be left unobstructed; but until they are both equally fined, the passages will be blocked by people standing or seated on loose chairs. All seats should be fastened to the floor, and made to tip up, to allow more room between each row for exit.

As far as the contents of the auditorium are concerned, it may be presumed that it is impossible to do without carpets, curtains, and stuffing to the seats, otherwise there need be nothing inflammable in the furniture.

The floor should be laid with blocks of hard wood, over the fire-resisting floors, for comfort.

As many bodies which are incombustible under normal conditions become inflammable at a high temperature, every means should be taken to keep a theatre cool, adding to the health, comfort, and safety of all. When heat is much concentrated, it makes substances highly inflammable, which might at a low temperature be simply combustible; it is therefore necessary, to prevent fire, to provide proper ventilation in a theatre. How often is this done?

The stage should be well ventilated, and at the same time there must be no draught to cause the scenery to wave about. Metallic shafts, with gas jets burning in them, fixed in several places above the gridiron, would draw off the vitiated and heated atmosphere and smoke in case of fire; but should a fire break out, the upward draught would increase it to a very serious extent; but if the gas jets were turned out, and the proscenium curtain lowered, the draught would be greatly lessened.

Fresh air should be admitted to the auditorium as near the floor level as possible, being previously warmed. The number of inlet shafts should have some relation to the numbers occupying the seats, and the manner in which the vitiated air is drawn out of the building. Sun-burners play an important part in extracting the foul air, but, in addition, every gas-burner should have over it a funnel-shaped flue, up which the products of combustion might pass. It must be borne in mind that perfect ventilation is imperceptible; but to acquire such ventilation has been found a hard task, therefore theatres have been left to take care of themselves, and in but few cases the slightest provision taken to render them little better than death-traps. Whether the mode applied be what is known as the vacuum or natural system, or the plenum or mechanical, seems of little moment, provided fresh air is continually admitted throughout the whole house. The number of deaths occasioned through breathing the foul, poisonous, and heated air of our theatres is far in excess of those caused by fire and panic. It would be as well if some of the numerous authorities which govern places of entertainment in this country were to turn their attention to this fact; but I fear the familiar adage may only too truly be said of theatre regulation, that "too many cooks spoil the broth." Large sums of money have been expended in providing means to avert dangers that *may* occur some day, while the fact that thousands nightly breathe the poison that will bring disease and untimely death with it, even to the strong, is totally ignored.

Lightning conductors should be fixed at various points outside the building.

Materials for Prevention of Fire.

The accepted idea of what is fire-proof is a very mistaken one. Materials that are incombustible are not therefore fireproof; take iron and stone, both accepted legally as fire-proof, and both among the first substances that will succumb to the influence of heat and sudden change of temperature. To give an idea how totally mistaken some are as to the fire-resisting qualities of materials, I have known lead suggested as a substance to be used to render floors fire-proof. Lead, of all materials, is the most dangerous, and the most dreaded by the fireman.

The walls must be solid and very thick, well bonded into each other, of good sound bricks; bond timbers should not be admitted, but hoop iron bond should be used. Every opening should have an arch turned over it, the use of lintols, either of stone or wood, being discarded. The walls should be corbelled out to receive the floors.

The floors, where possible, should be supported on brick arches abutting against brickwork, but on no account against iron. When the floors are constructed of iron and concrete, the iron should be completely embedded in the concrete, and the concrete should have the aggregate of calcined material, such as broken bricks, clinkers, or broken pottery. The circles should either be constructed of iron and concrete, or of timber in large baulk, and of the hardest description, such as elm or oak, which should be thoroughly protected from the action of fire by thick coatings of plaster; gypsum, or plaster of Paris, is well adapted for this purpose.

Where iron columns are used, they should be protected by a thickness of fire-resisting plaster or cement, held to the columns with a good key. Strong posts of the harder woods would suffer less from the changes of temperature than iron, but their thickness would destroy a good deal of the sighting.

The ordinary thin iron doors are of no use to resist fire. If iron doors were placed on both faces of the walls the space between might be filled up with some wet materials to keep them cool; but it would be a very difficult task to do this to every door in a theatre. Thick oak doors would resist fire for a long time. Wooden doors, lined with sheet iron or zinc, would be more effective than the thin iron doors so often met with; none of these, however, would be *fire-proof*, although *fire-resisting* to a certain extent. A perfect fire-resisting door could be made on the same system as safe doors, having an inner case of iron packed with sawdust and alum, surrounded by a strong well-bound and well-hung outer case. These would be heavy and expensive, and as all fire-resisting doors must be hung to close automatically, they would be dangerous; but they should be fitted to divide the greatest risks, such as the workshop section from the stage, the stage from the auditorium.

Steps and landings should be made solid, of approved artificial stone, fire-clay, or concrete, whose aggregate has already been burnt. Stone should be avoided, as, in the words of Captain Shaw—a man whose opinion on such subjects is the best in the world—it yields to fire more rapidly than any other material, is the most dangerous of all materials, as at sudden changes of temperature it cracks, leaving a passage for smoke.

That unprotected iron is unsafe, owing to the risk of fracture, and the loss of strength attendant upon great heat, is a fact well known, and as it is sometimes applied, it is a source of great danger, assisting in the destruction of the building, as its contraction or expansion will thrust out or pull down the walls, and even when covered with cement, it will suffer in great heat. Wood is only a dangerous material when used in thin slices. "It will withstand a powerful dead heat upon its sides for an indefinite period without igniting, unless transverse sections of the fibre, such as a knot, presents itself to the action of fire." If used in large baulk of the harder kinds, and protected with plaster, it is infinitely safer than naked iron.

The use of plaster as a fire-protecting agent I would strongly advocate; it is light, and resists fire for an indefinite period.

It would perhaps be as well to enumerate some of the many causes from which fires in theatres have originated and become fatal, before considering the last part of our subject, namely, the extinction of fires.

Bad arrangement and planning of the various sections, and not making each an independent fire risk, and not providing separate accommodation for each department or trade.

Danger from contiguous houses, and from people living in and about the theatre.

Bad judgment in the choice of materials, and bad or faulty construction.

Foul or imperfect flues.

Darkness and dirt, and keeping rubbish, shavings, &c., on the premises.

Smoking in the theatre proper.

Overheating through lack of proper ventilation.

Unprotected gas lights, and escape of gas from imperfect fittings.

Upsetting oil lamps.

Using matches or other naked lights.

Imperfect system of electric lighting.

Accumulation of heat round the sun-burner, and not cleaning same.

Carelessness in the manipulation of the stage during a performance.

The use of firearms, fireworks, and coloured fires.

The want of a properly organised fire watch, defective fire appliances, and lack of water.

Carelessness among workmen, such as carpenters and plumbers.

Lightning, concentrated rays of the sun by means of lens, spontaneous combustion, and incendiarism.

Extinction of Fire.

When a building has been constucted that will in every way retard the spread of fire and panic, it should be considered how, should the fire, in spite of all the precautions, occur, it could be most effectually coped with.

A theatre, from the nature of its business and contents, cannot be *fire-proof*, although fire-resisting; but there is no reason why fires should not be localised and burn themselves out in the department in which they originate. Every means, therefore, should be taken to extinguish fire. Water is the element to overcome fire; it is cheap, and can be obtained in large quantities, and if there is some at hand when a fire first breaks out, a jug-full, judiciously used, would prevent the loss of much life and property.

As regards fire appliances, there should be an unsparing supply of fire-buckets, always full of water, in all parts and sections of the building; more good can be done with these, if used in time, than any elaborate appliance that may come into use when the fire has got a hold. These buckets should be made conspicuous, labelled "fire buckets," painted red, and never allowed out of their place. Hand-pumps, with and without pails, should be distributed about the building, with a few chemical engines. Hydrants should be mounted on the rising main on every floor, in every section, and every 40 feet apart, having the hose "married" and ready for action. All proper tools and implements should be near at hand, wet sponges, wet blankets, hatchets, axes, &c., &c., being distributed about the stage and other parts. There should be a cock on each hydrant to fill buckets from. Hydrants should also be placed outside the building, and on the roof.

All fire appliances in these buildings should be periodically tested by the authorities; for the lack of this they are too often, on an emergency, found to be useless. The pattern of the appliances should be similar to that of the brigade of the town in which the theatre is situated, so that the theatre and town appliances may be used indiscriminately.

Ladders should be fixed from the roof to within 20 feet of the ground, where external aid can easily reach them. Iron balconies should be provided to windows.

It seems almost needless to say that there should be a sufficient supply of water, at a pressure strong enough to reach the highest part of the building. In towers formed at a height above the roof, there should be large water tanks, as a secondary supply, supposing the main failed at any time, but too much reliance must not be placed on tank hydrants. Experience has taught us that the tanks are too often empty, or only partly full, owing to the want of a constant supply from the water companies.

So much has been said upon the desirability of employing brigade firemen, well versed in their business, in lieu of the, in more senses than one, "theatrical fireman," that I need not repeat the arguments in favour of the brigade men. Two trained firemen should be in charge of the house from an hour before the performance till daylight, and two others should have charge during the day, all four being present when the house is open. The stage should never be left during the performance, and at the same time it would inspire the audience with confidence to see firemen walking about the auditorium. By the day watch the appliances should be cleaned and kept in repair, everything being tested every day at a fixed hour, say 6 p.m., just before the audience is admitted.

It should be the duty of the firemen to keep everything in working order, and they should be required to do nothing else. Imagine a stage without a responsible fireman, if, in the full swing of a pantomime, a small fire occurred. It is easy to conceive the confusion there would be among the numerous young and nervous people employed on the stage. The noise behind, even supposing the curtain to be down, would cause fear and panic among the audience, and a stampede might be the result. But if steady, experienced men, always ready for action, are employed, and the buckets and appliances are always in their places and in order, with plenty of water at hand, there need be no fear of fires on the stage. Yet there are many theatres in which the water supply is insufficient, the appliances imperfect, and no organised fire watch in existence.

To extinguish fires on the stage, a suggestion has been made that a series of perforated pipes be fixed to the underside of the gridiron, or to the gas battens, governed by a series of stopcocks on the stage. By this means the scenery that had not already ignited might be moistened, and the spread of fire stopped, but a great destruction of property would ensue. Far better get at the heart of the fire with a hand-pump or bucket of water.

Telegraphic communication should be held with the nearest fire-station. Too much reliance should not be placed on emergency fire-alarms. People are apt to become careless when they put their confidence in these appliances; they are also liable to act when no danger exists, especially in this class of building, where the temperature at times is so high; and, on the other hand, when most needed they may be out of order through disuse.

All check-takers and attendants should wear uniform, to be conspicuous, so that they may be better able to manage the people on an emergency. They should attend fire-drills, and be able to help the firemen when needed. For the same reasons it is well to have a policeman or two about the building.

To extinguish fire, provide good and sound appliances, plenty of water, and a good watch.

Theatres are luxuries, and to enter some of them one pays dearly, both as regards money and the risk of losing one's life. If we pay so highly, surely we should be better protected while there. But the system seems to be to work the house as cheaply as possible, and to pack as many into it as it will hold, at as high a price as they will pay.

After every consideration is given to the disposition and construction of the building, and it has been passed by the authorities, the architect, under whose supervision the house has been built, hands it over to the manager for the rest of its existence, except in rare cases where the architect receives a fixed remuneration for periodical visits—which should be the case everywhere. As a rule, the manager is a man of refinement and education, who will do everything in his power to protect the public and make the house popular. But for all that there should be a further continuous inspection supervising the management, as is being advocated by Mr. Dixon-Hartland in his Bill now before the House of Commons. A staff of inspectors knowing the architectural arrangement, and the business peculiar to theatres, should be appointed, with power to visit the houses at all odd times, before, after, during the performance, in the day, and even in the middle of the night, unbeknown to the management. Reports as to the condition in which they find the house, and the way in which it is being worked, should then be made to the *one* recognised authority which should take the place of the many that now exist.

In theatres which at present hold certificates from the Metropolitan Board of Works as being structurally safe, fresh dangers may in a year or two arise, through alterations being made, perhaps trivial in themselves, but to which some risk is attached. There are other matters requiring supervision besides structural defect, *i.e.*, ventilation, water supply, and the general management of the whole establishment. Until these inspectors are appointed, the public cannot be protected as they ought to be; on the other hand, it would be useless to make managers suffer from more official inspection, unless the men can be found to fill the posts who are qualified through previous experience in the *modus operandi* of theatre management and construction.

Once more I would strongly urge that the best safeguards against fire are good planning and construction, perfect ventilation, light, and scrupulous cleanliness; that the best means to extinguish fire are a good fire-watch and plenty of water; and that on no account should "emergency" appliances be relied on in a theatre.

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION.

Owing to the death of the Duke of Albany, the ceremonial opening of the Health Exhibition at South Kensington, on May 8, will not be performed by the Prince of Wales, but by his Royal Highness the Duke of Cambridge, who has undertaken the duty on behalf of his Royal Highness the President. Although the date remains as originally fixed, the hour at which the ceremony is to take place has been altered from three p.m. to noon. The *Times* notes that the work of preparation is going on rapidly and continuously; relays of workmen are busied day and night in some parts of the building, the electric light equalising the value of all hours of the twenty-four, and van loads of exhibits are daily arriving. The greatest activity seems to be displayed in the completion of the large octagonal building which is to be the home of the London water companies' exhibits, each company having one bay to itself; in the annexe devoted to machinery in motion, where huge fly-wheels already fill the deep excavations made to give them room enough to work; and especially in the block of Old London, entered through a reproduction of the port of one of the ancient City gates, which is distinguishable already by the figure of the good bishop in a niche over the centre. Within this walled enclosure are gabled houses, of which the shops are to be occupied, each under the direction of a City guild—a master armourer, for instance, plying his craft in one, assisted by 'prentices. Detached buildings—which, to carry out the objects of the exhibition to the fullest extent, should be model — typhoid-proof farm houses, and dairies are being erected in the open garden between the long south gallery, where the deep-sea fisheries were illustrated, and the National Portrait Gallery. In the entrance hall a full-sized cast of Mr. Boehm's large equestrian statue of the Prince of Wales, which was erected in Bombay by Sir Albert Sassoon, C.S.I., to commemorate the visit of his Royal Highness to India in 1875-6, has the place of honour.

As some dissatisfaction with the awards of the jurors in certain classes at the Fisheries Exhibition was expressed by a section of the exhibitors, a scheme has been drawn up, to give competitors a voice in the selection of the jury. His Royal Highness the Prince of Wales, as President of the Health Exhibition, has delegated to a Commission, selected from among the members of the Executive Council, the duty of making arrangements for the effective performance of the work to be carried out by the international juries. The Commission is composed of Lord Reay (chairman), Sir James Paget, F.R.S., Sir Frederick Abel, C.B., Sir Philip Cunliffe-Owen, C.B., and Dr. George Buchanan, F.R.S., with Mr. H. Trueman Wood (secretary of the Society of Arts) and Mr. Gilbert R. Redgrave (Associate of the Institution of Civil Engineers) as joint secretaries. To this Commission on juries every exhibitor is to be requested to return on a printed form the names of three gentlemen whom he would wish to nominate as jurors in the particular class or classes he himself is individually interested in. The Duke of Buckingham and Chandos, the chairman of the Executive Council, who is devoting his time to the direction and superintendence of the minutest details of the exhibition arrangements, warns exhibitors, however, that while the Jury Commission will endeavour to give full weight to the opinions expressed by exhibitors, it must nevertheless be understood that they will not feel themselves restricted to the list of names suggested, especially as the gentlemen recommended by a majority of the exhibitors may in some cases be unwilling or unable to serve.

The Executive Council have assigned a large room in the Royal Albert-hall, to be used as a library and reading-room in connection with the Exhibition. Authors, publishers, and others have been invited to send copies of works on subjects embraced in either or both of the two divisions of the Exhibition—Health and Education.

The books received will be classified and catalogued, and made available for use, in the library and reading-room, of the public visiting the Exhibition. A catalogue will be printed. All packages containing books for the reading-room and library should be forwarded, carriage paid, to the Secretary of the

Library Committee, Royal Albert-hall, W. The Executive Council cannot hold themselves responsible for any loss or damage to books sent in by exhibitors, but a reference to the regulations will show that every precaution has been taken.

It is intended to illustrate by means of models, sections, and diagrams, in the pavilion previously referred to, the water supply of all the metropolitan water companies. The Sub-Committee will specially deal with sources of supply, methods of filtration (including full-sized sections of the filter-beds) and distribution, giving particulars respecting quantity and area under constant supply. They will also show the quality of the water as supplied by each company, bringing into the Exhibition water from each company; and they will publish analyses of the same, and generally display such other exhibits as will convey to the public at large an idea of the magnitude and importance of the metropolitan water supply.

The following countries have appointed Commissions in connection with the Exhibition:—Belgium, China, France, and Russia.

Correspondence.

WATER REGULATION.

I must thank you for your kindness in inserting my long letter about regulation of water, and also for the remarks of Sir Robert Rawlinson on the subject. Perhaps you could find room for two further remarks from myself. The first is that the 200,000,000 cubic yards of water I spoke of were not the contents of the 50,000 tanks of the Peninsula, but of the largest of them, constructed by General Fyfe at Poona. The other is that the calculation about reducing floods lies in the smallest compass. In the Godavery, for instance, the discharge is 200,000,000 cubic yards per hour in extreme floods. But when the river does mischief, it is usually by the last foot overtopping the bank. A foot higher or lower makes the difference between a tremendous destruction and a harmless fresh. To keep the river down one foot, would require the retention of 10,000,000 cubic yards per hour for two or three days, or 700,000,000 cubic yards in all. Two tanks have been surveyed and estimated for on one of the feeders of the Godavery; one to contain 2,000,000,000 cubic yards, and the other, I believe, rather less; together, perhaps, 3,500,000,000 cubic yards, or sufficient to lower the river a foot for fifteen days, or, if half full when the storm begins, for seven days, but these are in one corner of the vast basin of the river, an area of 150,000 square miles. If necessary, a number of these large tanks could be constructed, so that, if required, the river could be kept a yard or two below flood with ease. The two tanks, estimated, would cost about £100 per 1,000,000 cubic yards, or £350,000. The works of navigation and irrigation on this river will have cost £2,500,000 when completed, so that the addition of £350,000 would not be so very great. These two tanks alone would not only diminish the floods, but would provide for more than 1,000,000 acres of irrigation immediately under them, and would also keep 1,000 miles of river and canal navigation in an effective state throughout the dry season, as well as irrigate 5,000 acres in the Delta at that time. If the Government would make use of the vast experience collected in India in water regulation, there would be no difficulty in perfecting the regulation in England in all its four branches. Now that ocean navigation and land transit have been brought to such a state of perfection, the next most important thing, beyond all comparison, is the establishment of effective water transit in England. The owner of a saw-mill, employing forty hands, lately told me he paid £1,400 a year for railway carriage. With steam-boat canals this could certainly be carried for £200, in saving a small work of this kind, £1,200 a year. What would be the saving on all the manufactures and produce of England with a complete system of steam-boat canals on the present lines of ineffective water transit?

ARTHUR COTTON.

Dorking, April 9th, 1884.

Though long convinced that our waters are sadly neglected, I cannot account for the rate of $\frac{1}{10}$d. per ton per mile, assumed for water carriage by Sir A. Cotton and General Rundall. Mr. J. S. Watson (Q. 1,791, Canal Committee) estimates 5s. per ton for 247 miles—about $\frac{1}{4}$d. per ton per mile; but much naturally depends on the return freight. In France (Q. 2,373) it is hoped that, after the amortization of the national outlay, the rate may be $\frac{1}{5}$d. In India, it appears (p. 264) that the charge varies from $\frac{3}{8}$d. to $\frac{5}{8}$d. per ton per mile. The tables in Messrs. Meyer and Wernigh's book on rope-towage give, I think, $\frac{1}{2}$d. for mixed river and canal navigations in Germany. How then can the United Kingdom expect lower rates?

Such an important subject deserves full discussion in your *Journal*.

WALTER M. T. CAMPBELL.

Roxburghe Hotel, Edinburgh,
April 11, 1884.

Notes on Books.

THE ELECTRIC LIGHT IN OUR HOMES. By Robert Hammond. London: Frederick Warne & Co.

This little book contains the accumulated material resulting from the author's having, at various times and various places, delivered a number of lectures about the electric light. It explains in the most thoroughly popular form the principles of the science, the apparatus and fittings used, and the arrangements to be adopted in lighting a house or other building by electricity. The advantages of the electric light are fully set forth, together with the drawbacks to our existing systems. The book is fully illustrated with woodcuts, and there are also two photographs of rooms fitted with electric lamps, the drawing-room and dining-room of the author's residence.

SHORTHAND FOR EVERYBODY: with Course of Lessons for Self-Instruction. By W. Mattieu Williams. Second edition. London: Simpkin, Marshall & Co. 1884. 8vo.

The author does not attempt to teach a system of shorthand suitable for professional reporters, but his object is "to enable anybody to write about four times as fast as he can with common characters, and above all, to read with facility what he has written." This is the second edition of a treatise first published in 1867, and the author states that the elaboration, or rather reduction, of his system to its present form has been the work of above forty years.

THE WATCH AND CLOCK-MAKERS' HAND-BOOK, DICTIONARY, AND GUIDE. By F. J. Britten. London: W. Kent & Co. 1884. 8vo.

In this volume the author has given, in the convenient form of an alphabetical arrangement, a full description of the various points connected with the art of watch and clock-making, and he has added the French and German equivalents for the different terms. In addition to the definition of technical terms, short biographical notices of the men who have advanced the art are given, and in the appendix there are some useful tables. The book is fully illustrated.

Obituary.

DUKE OF BUCCLEUCH, K.G.—Walter Francis Montagu-Douglas-Scott, fifth Duke of Buccleuch, and seventh Duke of Queensberry, whose death occurred on Wednesday morning, April 16th, at Bowhill, Selkirkshire, had been a member of the Society of Arts for forty-six years, and for several years he occupied a seat in the Council as Vice-President of the Society. He was a member of the first Council, which was elected in 1845, and the last time that he presided at a meeting of the Society was in June, 1877, when Mr. Andrew Murray read a paper on the "Extirpation of Injurious Insects." The Duke of Buccleuch was born on November 25, 1806, and on the death of his father he succeeded to the title at the age of thirteen, so that he enjoyed the Dukedom for the long period of sixty-five years. He held the offices of Lord Privy Seal and President of the Council in Sir Robert Peel's Cabinet, but after that statesman's final resignation, he never held office. He was President of the British Association in 1867, on the occasion of the visit to Dundee, and in 1878, at the death of Sir William Stirling Maxwell, he was elected Chancellor of the University of Glasgow. He held other important offices, and many honours were awarded him. When quite a young man he carried out the great work of the erection of Granton Pier and Breakwater (three miles from Edinburgh), at a cost of half a million sterling, which expenditure he bore entirely himself.

General Notes.

ROYAL INSTITUTION.—The following are the arrangements for the lectures after Easter:—Dr. Klein, two lectures on the "Anatomy of Nerve and Muscle," on Tuesdays, April 22 and 29; Professor Gamgee, five lectures on the "Physiology of Nerve and Muscle," on Tuesdays, May 6 to June 3; Professor Dewar, seven lectures on "Flame and Oxidation," on Thursdays, April 24 to June 5; Mr. Hodder M. Westropp, three lectures on "Recent Discoveries in Roman Archæology," on Saturdays, April 26 to May 10; and Professor T. G. Bonney, four lectures on the "Bearing of Microscopical Research upon some large Geological Problems," on Saturdays, May 17 to June 7. The Friday evening meetings are resumed on April 25th, when Mr. Walter Besant is to give a discourse on "The Art of Fiction."

AUSTRALIAN EDIBLE FISHES.—The coasts of Australia abound in edible fish of every description, of which the schnapper (*Pagrus unicolor*, Cuv. and Val.) is the most valuable, not for its superior excellence, but for the abundant and regular supply which it affords of a very nutritious and wholesome kind of food. It is found on all parts of the Australian coast, but most abundantly on that of New South Wales. It is a deep-water fish, found generally on or near rocky points, or reefs running out for miles from the coasts. Schnapper-fishing forms one of the favourite pastimes of the Australians, the favourite fishing grounds being in the neighbourhood of Sydney Heads. Lines are used in fishing, but the tackle has to be strong, or, if the fish be an old one, he will often escape. "The tugging, jerking motion of the schnapper," says an Australian writer, "is unmistakeable, and, when he gets his shoulder to the line, he goes off with a rapidity that makes the cord whistle again, either through your fingers or over the boat's gunwale; a steady and continuous strain, no stray line, together with some skill, enables you to land him, at which time you can realise that your patience, toil, and anxiety are rewarded with a fish from 20 to 25 pounds weight, fit to embellish a noble banquet." The aboriginal name of the schnapper is "wollomai," and it was formerly captured in large quantities by the natives.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, eight o'clock :—

APRIL 23.—"Thames Communications." By J. B. REDMAN, M.Inst.C.E.

APRIL 30.—"The New Legislation as to Fresh-water Fisheries." By J. W. WILLIS-BUND. EDWARD BIRKBECK, M.P., will preside.

MAY 7.—"Bicycles and Tricycles." By C. V. BOYS. Dr. B. W. RICHARDSON, F.R.S., will preside.

MAY 14.—"Telpherage." By Professor FLEEMING JENKIN, F.R.S.

MAY 21.—"Telegraph Tariffs." By Lieut.-Col. WEBBER, R.E.

MAY 28.—"Primary Batteries for Electric Lighting." By I. PROBERT.

FOREIGN AND COLONIAL SECTION.

Tuesday evenings :—

APRIL 29.—"The Transvaal Gold Fields; their Past, Present, and Future." By W. HENRY PENNING.

APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings :—

APRIL 21 (Monday).—Adjourned Discussion on Dr. PERCY FRANKLAND'S Paper, "The Upper Thames as a source of Water Supply." Sir FREDERICK ABEL, C.B., F.R.S., will preside.

MAY 8.—"Cupro-Ammonium Solution and its Use in Waterproofing Paper and Vegetable Tissues." By C. R. ALDER WRIGHT, F.R.S., D.Sc. Prof. W. J. RUSSELL, Ph.D., F.R.S., will preside.

MAY 22.—"Economic Applications of Sea-weed." By EDWARD C. STANFORD, F.C.S. (This paper has been postponed from April 24th.

INDIAN SECTION.

Friday evenings :—

APRIL 25.—"The Existing Law of Landlord and Tenant in India." By W. G. PEDDER.

MAY 9.—"Indigenous Education in India." By Dr. LEITNER.

MAY 30.—"Street Architecture in India." By C. PURDON CLARKE, C.I.E. This paper will be illustrated by means of the Oxy-Hydrogen Light.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 21...SOCIETY OF ARTS, John-street, 8 p.m. Adjourned Discussion on Dr. Percy F. Frankland's paper, "The Upper Thames as a Source of Water Supply."

Surveyors, 12, Great George-street, S.W., 8 p.m.

British Architects, 9, Conduit-street, W., 8 p.m.

Institute of Agriculture, Lecture Theatre, South Kensington Museum, S.W., 8 p.m. Mr. W. G. Smith, "The Diseases of Corn Crops."

Medical, 11, Chandos-street, W., 8½ p.m.

Asiatic, 22, Albemarle-street, W., 4 p.m. Mr. F. V. Dickins, "The Rolls of Shiuten Doji, or the Liquor-laid Lad." (Translation from the Japanese.)

Victoria Institute, 7, Adelphi-terrace, W.C., 8 p.m. Mr. D. Mackintosh, "The Glacial Epoch."

TUESDAY, APRIL 22..Royal Institution, Albemarle-street, W., 3 p.m. Dr. Klein, "The Anatomy of Nerve and Muscle." (Lecture I.)

Medical and Chirurgical, 53, Berners-street, Oxford-street, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Wm. E. Rich, "On the Comparative Merits of Vertical and Horizontal Engines, and on Rotative Beam Engines for Pumping."

Statistical, School of Mines, Jermyn-street, S.W., 7¾ p.m. Lieut. H. B. Willock, "English Express Trains in 1871, and a comparison between them and those of 1883."

Anthropological, 3, Hanover-square, W., 8 p.m. 1. Exhibition, by the Marquis of Lorne, of a Collection of Ethnological Objects from Canada. 2. Sir Richard Owen, "Note on a Portrait of an Aboriginal Tasmanian." 3. Prof. A. H. Keane, "The Ethnology of the Sudan."

WEDNESDAY, APRIL 23...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. J. B. Redman, "Thames Communications."

Geological, Burlington-house, W., 8 p.m. 1. Principal Dawson, "Observations on the Geology of the Line of the Canadian Pacific Railway." 2. Rev. Alex. Irving, "The Dyas (Permian) and Trias of Central Europe, and the True Divisional Line of these Two Formations."

Royal Botanic, Gardens, Regent's-park, N.W. 2 p.m Exhibition of Spring Flowers.

Royal Society of Literature, 4, St. Martin's-place, W.C., 4½ p.m. Annual Meeting.

Hospitals Association, 1, Adam-street, Adelphi, W.C., 8 p.m. Paper on "How far our Hospitals should be Training Schools for Nurses."

Civil and Mechanical Engineers, 7, Westminster-chambers, S.W., 7 p.m. Mr. H. Michell Whitley, "Modern Locomotive Practice."

THURSDAY, APRIL 24...Royal, Burlington-house, W., 4½ p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor Dewar, "Flame and Oxidation." (Lecture I.)

Telegraph-Engineers and Electricians, 25, Great George-street, S.W., 8 p.m.

FRIDAY, APRIL 25...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Indian Section.) Mr. W. G. Pedder, "The Existing Law of Landlord and Tenant in India."

Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m. Mr. Walter Besant, "The Art of Fiction."

Quekett Microscopical Club, University College, W.C., 8 p.m.

Clinical, 53, Berners-street, W., 8½ p.m.

Browning, University College, W.C., 8 p.m. Mr. J. C. Morison, "Caliban."

SATURDAY, APRIL 26...Geologists' Association, University College, W.C. Excursion to Guildford under the direction of Lieut.-Col. H. H. Godwin-Austen.

Physical, Science Schools, South Kensingtou, S.W., 3 p.m. 1. Professors Ayrton and Perry, "The Indicator Diagram of a Gas-Engine." 2. Mr. W. T. Goolden, "A New Speed Indicator." 3. Mr. Walter Baily, "A Speed Indicator." 4. Dr. W. H. Stone, "A Metrical Barometer, and an Immersion Galvanometer."

Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Mr. H. M. Westropp, "Recent Discoveries in Roman Archæology." (Lecture I.) "The Colosseum."

Journal of the Society of Arts.

No. 1,640. Vol. XXXII.

FRIDAY, APRIL 25, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

INSTITUTIONS IN UNION.

The following Institution has been received into Union since the last announcement:—

East London Union for Advanced Education Evening Classes, 54, White Horse-lane, E.

SOCIETY OF ARTS PRIZES.

The Council of the Society of Arts are prepared to award the following prizes in connection with the International Health Exhibition:—

Under the *John Stock Trust*, a Society's Gold Medal or £20, for the best example of sanitary architectural construction, Classes 20, 28, 29, 30, and 32 of the Exhibition.

Under the *Shaw Trust*, a Society's Gold Medal or £20, for the most deserving exhibit in Classes 41, 42, 43, and 45 (relating to Industrial Hygiene).

Under the *North London Exhibition Trust*, a Society's Gold Medal or £20, for the best set of specimens illustrating the handicraft teaching in any school—Classes 49 and 50.

Under the *Fothergill Trust*, Two Gold Medals (or two sums of £20), one for the best exhibit in Class 27 (Fire Prevention Apparatus), and one for the best exhibit in Class 26 (Lighting Apparatus).

From the *Trevelyan Prize Fund*, Five Gold Medals (or five sums of £20), for the best exhibit in each of the following Classes:—2, 3, 6, 7, and 11 (all comprised within Group 1, "Food").

The *Siemens Prize*, a Society's Gold Medal, or £20, for the best application of gas to heating and cooking in dwellings, Class 24.

Each prize will be a Gold Medal, or the sum of £20, at the option of the recipient.

The full list of the various classes referred to is given in the number of the *Journal* for March 14th.

The Council propose to ask the juries in each class to recommend for their consideration either two or three exhibits which they may consider deserving a prize. It will be assumed that all the exhibits in the Classes specified, which come under the above definitions, are eligible for the awards. It will not be necessary for any special application to be made in respect of these Prizes.

INTERNATIONAL HEALTH EXHIBITION SEASON TICKETS.

The Executive Council of the International Health Exhibition have consented to allow Members of the Society of Arts the privilege of purchasing Season Tickets for the Exhibition at half-price (10s. 6d.). Each Member will only be allowed the privilege of purchasing a single ticket on these terms, which will be a personal admission, not transferable. Season tickets admit to the opening ceremony on the 8th May. The tickets will not be ready for issue till the end of the month, but it will be convenient if members desiring to avail themselves of the privilege will send word to the Secretary at once, enclosing 10s. 6d., the price of the ticket, which will be forwarded as soon as ready. It will be understood that all applications must be accompanied by the above-named remittance.

Proceedings of the Society.

EIGHTEENTH ORDINARY MEETING.

Wednesday, April 23, 1884; W. G. Pedder, Member of Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Beilby, George T., Midcalder, N.B.
Bridgford, Major Sidney Thomas, R.M.A., Army and Navy Club, Pall-mall, S.W.
Butler, Henry, 50, Lee-terrace, Blackheath, S.E.
Clarke, Caspar Purdon, C.I.E., 3, Sheffield-terrace, Campden-hill, W.

Gibbs, Surgeon-Major J. G., Riggindale-road, Streatham, S.W.
Guest, Rev. William, Ling Holme, Tunbridge-wells.
Morgan, William, Waverley, Albemarle-road, Beckenham.
Parlane, James, Appleby-lodge, Rusholme, Manchester.
Pearcy, Joseph, 127, Englefield-road, Islington, N.
Peel, Captain Francis, Boxted-house, Colchester.
Pleydell, F. G., Commercial Bank of South Australia, Lombard-street, E.C.
Ross, Rev. Henry, M.A., Dallas-house, Lancaster.
Samuel, Sir Saul, K.C.M.G., 15, Courtfield-gardens, S.W., and 5, Westminster-chambers, S.W.
Turpie, William, Bank-house, Derby.
Wight, Laurence Hill, M.A., 41, Chambers-street, Edinburgh.
Wilkin, Miss, Cossey-cottage, Hampstead, N.W.

The following candidates were balloted for and duly elected members of the Society:—

Cosedge, Hiram, 16, Clifford's-inn, E.C.
Crickmay, George Rackstraw, 17, Parliament-street, S.W
Esson, William B., European Telegraph Works, Dalston, E.
Glyn, Hon. and Rev. Edward Carr, M.A., the Vicarage, Kensington, W.
Hughes, Richard Deeton, 12, Bedford-row, W.C.
James, Edward, 22, Westbourne-terrace-road, W.
Kirkpatrick, Robert, 1, Queen-square, Strathbungo, Glasgow.
Lovett, Phillips Cosby, J.P., Liscombe-park, Leighton Buzzard.
Murphy, Shirley F., 158, Camden-road, N.W.

The paper read was—

THAMES COMMUNICATIONS.

By J. B. Redman, M.Inst.C.E.

The theme now selected, treating of one of the popular questions of the day, needs little preface. Cartoons are exhibited of plans for a high-level Tower-bridge, a Blackwall-tunnel, and a St. Paul's-bridge, also a plan of the Port of London.

The advocates of what has, doubtless, become a modern demand, due to eastern extension of the metropolis, down the river, viz., more rapid and certain inter-communication from the right to the left bank of its stream, appear, in the arguments at times put forward for this accommodation, to forget or ignore the fact that these north-eastern and south-eastern suburbs, co-extensive with some of our large manufacturing towns, owe their very origin, being, and existence to the floating commerce of the first tidal port of the world, and almost appear to regard their parent and benefactor as an absolute barrier to free intercourse amongst themselves, *i.e.*, between the eastern denizens of the metropolis

Representing as I do a family of merchants and ship-owners for generations past, and amongst the first customers of some of the earliest docks (the West India for example), and having been born and lived the early half of my life in the immediate neighbhourhood of those works, besides having being engaged on numerous dock, wharf, embankment, pier, and lighthouse works on the river, and having had control, for twenty-one years, of the roads and tramways leading to these docks, I may perhaps be allowed to volunteer an opinion respecting the character of the vehicular and pedestrian traffic of the eastern metropolis.

Both classes of traffic, on each side of the Thames, may be said truly to have one common loadstone of attraction—the City of London. Foreign goods find their way up to the various above-bridge warehouses, by lighters, for transhipment or carriage to the provinces, a large part passing by waggon along the main arterial roads parallel to the river, and a considerable portion now goes direct by railway to the manufacturing districts. On the Commercial-road tramway, leading to the West India Docks, more than a quarter of a million tons of sugars, teas, and other foreign goods, find their way each year to the Whitechapel sugar-houses for rectifying (now almost an extinct industry), and to the various up-town warehouses of the Dock Companies, and the numerous private warehouses within the City for bonding foreign produce and wines.

The heads of the various ship-building, engineering, and other manufacturing firms, as well as timber merchants and other contractors connected with the trade of the port of London, were (as also many of the merchants and ship-owners, sail-makers, ship-chandlers, and brokers) less than half-a-century back, as a rule, resident in the suburbs adjoining the river and below the pool, and they and their numerous *employés* resided at, or near, the scene of their daily work, while the heads of firms and managers, and senior clerks, found their way to the City in the afternoon to attend "Change," and the various coffee-houses, such as the "Jerusalem," "Lloyd's," "Garraway's," the "Baltic," &c., frequented by the various commercial sections, for effecting sales, purchases, and obtaining orders, finding their way back, late in the afternoon, to their several establishments or residences, in two nearly parallel streams on either side of the river.

The extension of the railway system has very considerably modified, without, however, altering the main feature of the traffic, as the heads and managers of firms now reside in almost every direction, making their twenty or thirty miles daily, and as in the case of Brighton, now really a London suburb, their fifty miles' journey to the City, and visiting in addition their establishments, on or near the river, from a couple to half-a-dozen miles from the common focus or centre.

But now, as in early days, the universal desire and want is to get to and from, or from and to, the common nucleus of daily commercial operations, viz., the City of London.

Thus, under these conditions, the inclination for intercourse between the two banks is, to a certain extent, either for goods or persons, somewhat exceptional; but at the same time, if the means are afforded, vast numbers of the working classes, obeying the modern centrifugal dispersion, will look further afield for purer air and healthier tenements for their wives and families than they have hitherto been content with. This is strikingly shown by the vast crowds of the labouring class who seek the early and late cheap trains of the East London (Thames Tunnel) line, and those also of the Metropolitan underground lines. The extensive and (at least at an early period) almost unlooked-for field for railways through the suburban districts, and leading to the metropolitan centre, was never more strikingly illustrated than in the case of the North London Railway, originally laid out as a goods line, pure and simple, to connect the East and West India Docks with the London and Birmingham (now the London and North-Western) Railway, and it developed a traffic which it was not originally laid out for, but to which it entirely owes its remarkable success.

So, doubtless, with the means given by bridges, tunnels, or ferries; a numerous section of the community will avail themselves of the opportunity for obtaining cheaper, healthier, and more comfortable lodgings on the opposite side of the river to that where they may be employed, hemmed in, possibly, by docks, or situate on marshy and unwholesome ground. But when the various reaches between London-bridge and Woolwich, with their surroundings, are examined, this is a much more complex problem than those who have not paid special attention to the subject might be prepared for.

Taking two positions to be granted, viz., that London-bridge is, from six centuries' usage, the natural head of the port, and that no mode of crossing offering any obstacle to the free and uninterrupted navigation of the river can be allowed, the question becomes still more difficult. Four methods present themselves:—

The high-level bridge, with approaches, which should be not less than 1 in 40, or mechanical lifts.

The low-level bridge, fixed throughout, or combined with opening spans.

The tunnel, also with approaches, of not less than 1 in 40, or with mechanical lifts at each end.

[As regards gradients, it should not be forgotten that in the Metropolis Management Act, obtained by Sir Benjamin Hall, 1 in 60 was the gradient fixed as the minimum for turnpike roads.]

And lastly, ferries worked by steam, say, by means of a submerged chain, as at Portsmouth and Southampton.

Any form of ferry-boat must, however, at least for vehicular traffic, be usable at any time of tide from approaches of 1 in 40. There would be with them, as with the high-level bridge or the tunnel, the same approach difficulty, though in a minor degree, as there would be from one-third to one-half of the amount of difference of level as compared with the two other modes of crossing.

Then, as regards the sites for these crossings, from the manner in which either bank is bounded by floating docks, and the long detours necessary to reach any main arterial line of traffic, but very few positions present themselves for a high-level bridge, or for a tunnel. The site east of the Tower appears, for very many reasons, the best site for a bridge (if bridge there is to be) east of London Bridge; but clearly here the best solution of the difficulty would be, a bridge fixed throughout, similar in level to London-bridge, which, if made without an opening arch, would involve the purchase of certain interests between the two bridges.

This, in effect, if a low level bridge, for square-rigged ships and the larger steamers, would be moving the head of the port from one-half to three-quarters of a mile lower down the river. Clearly, cutting off three-quarters of a mile from the head of a tidal port like London, the first in the world, is a momentous proposition, and certainly as opposed to all true principles of harbour conservancy as the equally questionable proposition of bringing the lockage down the river, instead of doing all that is possible to encourage the tidal momentum and flow upwards. This was recently proposed to be effected by the erection of locks and a weir at Isleworth, for the benefit of riparian interests immediately above, thus cutting off five miles of the tidal portion of the river, and thus diminishing, *pro tanto*, the tidal storage, and also affecting the commercial interests immediately below it, by reducing the flow and ebb, interfering with the navigation to the wharves, and promoting deposit in the river bed; instead of the counter-proposition, suggested for many years, of removing Teddington Lock, and encouraging the flow of the tide up to Kingston, some two miles higher. Here, even now, with the exceptional high tides we have had during the last seven years under certain meteorological combinations, the high water, topping Teddington Lock and Weir, makes a tide of from eighteen inches to two feet at Kingston—Nature, in effect, asserting herself. The Isleworth Lock scheme is, for the present, abandoned, on account of the decided veto put upon it by the Conservancy authorities.

Any movable or fixed bridge (except at a very great height) below the Tower site would be quite inadmissible, for very many obvious reasons, as prejudicial to the free waterway of our national river, which, when crowded with the commerce of the world, all intelligent foreigners assert, gives a more striking idea of the power of this country than aught else to be seen in the United Kingdom.

A high-level bridge over the Thames at Blackwall was proposed towards the end of the last century by Dodd, or some other equally sanguine projector, and perspective or birdseye views, with approaches pointing to the Essex and Kentish hills, were printed and published, and displayed in shop windows, as views of the "Duplex Tower Bridge" are at the present day; and this last is really in principle similar to a plan to be found in the large folio Report on the Port of London of the Commons Committee of 1793. How the traffic was to be got on to or off this Blackwall bridge was not illustrated, but the ships were shown with their royals and studding-sails set, sailing with unimpeded course under its lofty soffit.

Before directing attention to the best sites for crossing the river, it will be well to consider what are the difficulties barring the adoption of the very many ingenious plans that have, from time to time, been brought forward.

Either for a bridge or a tunnel, suitable approaches must be provided, or some mechanical means, by hydraulic or other machinery, adopted for raising and lowering the vehicles passing over. The Snow-hill incline down to the valley of the Fleet is now almost forgotten, since it was bridged by the Holborn Viaduct and its level approaches; but the effect of such a gradient on heavy vehicular traffic can be well studied now at Tower-hill, which should never have been opened to waggon traffic, with a gradient between Thames-street and Tower-street of 1 in 18½, to 1 in 20; but the severity of such an incline can be even better seen at the curved approach from Smithfield down to the metals of the underground railway, well adapted to its locality in one respect, being, as it is, a veritable instrument of torture. The excessive steepness of the incline require the addition of "leaders" to the teams of the heavily laden waggons, kept there for that special purpose.

This difficulty of approaches was one of the great objections to the high-level Tower-bridge promoted by the Metropolitan Board of Works, a few years back; and the same objection, in a less degree, tells against a tunnel, as the difference in level would be somewhat less than with a bridge. It was the absence of approaches for vehicular traffic that made Brunel's well-known tunnel at Wapping a dead letter for so many years, till it was utilised by the East London Railway; and it was the indifferent, tortuous, and narrow means of access to the ferry erected recently near the same site, which made it practically a failure, or at least one of the causes of its shipwreck.

With modern experience and appliances, a tunnel under the Thames may be constructed at any spot; but the cost would be very variable, from the great changes in the geological formation along the metropolitan river valley. Brunel's tunnel was mainly in sand and gravel, and so near the river bed that an artificial one was formed by throwing in clay in bags over the crown, and the excavation partly through it was effected by means of Brunel's well-known shield, the alternate compartments of which were pushed forward, after the material in advance of the polling boards had been removed by excavating from within. The frames, all connected at top by shafting, and provided with broad bases or feet, were pushed forward alternately, like (as Brunel used to say) a man's legs in walking.

A large per-centage of the material brought into the tunnel from the heading in advance of the shield, was clay with pieces of the bags adhering. This I have frequently seen when periodically measuring up the work with Mr. James Walker (the leader of our profession at that day) under whose certificates the Exchequer Loan Commissioners' advances were made.

This variability of substratum is well illustrated by the various attempts made to cross the river by tunnelling. Early in this century a tunnel was commenced at Gravesend; the large quantities of water met with in the chalk, were, it is said, the cause of the abandonment of the undertaking. Still, at the present time, with our enlarged experience and improved plant and apparatus, such a work is within the limits of possibility, and an Act of Parliament has been obtained for a railway tunnel in the chalk, to connect Gravesend with the county of Essex. Now, when it is remembered that there are from 40 to 60 feet depth of water, at low water in Northfleet Reach, upon a chalk bottom, it will be seen how great an undertaking such a work would prove, but still one that is practicable with the boring and air-compressing machinery of the day, at a certain cost.

An Act has been obtained for a tunnel or subway at Woolwich, and the works were commenced, but stopped from the abundance of water met with, mainly in sand and gravel.

In effect in certain portions of its valley, it amounts to attempting to pump the river dry—unless the work is done by pneumatic air—compressing tackle converting the tube or tunnel into one long diving-bell, provided with air-locks at one or each end, or by the dredging of a low water sub-marine channel, into which sectional lengths or compartments might be lowered, and the fixing all done by divers.

At Greenwich, for instance, a tunnel or subway to Millwall has been advocated in influential quarters; but when we have the broad fact before us that the river-bed, and down to the chalk substratum, is gravel and running sand for fully 100 feet in thickness, some idea of the character of such a work may be formed.

This is no mere theoretical speculation. About forty years back, Frederick Braithwaite, an engineer well-known for such works, sank a well at the hospital brewery, then situate within the hospital enclosure, behind the pier, but which has since been removed. So much sand was pumped up in sinking this well that serious settlements of the brewery walls commenced, and the hospital authorities became alarmed, and called in additional assistance. The well was ultimately sunk to the chalk.

I had again practical evidence of all this, being called in, some years back, by the directors of the Greenwich-pier, to advise them on the condition of that work, for in carrying out certain works of reparation to the pier and outfall drainage works, and tidal reservoirs for the "Ship" Hotel drainage, convincing evidence was afforded of the open porous nature of the soil, charged with water, increasing remarkably in volume after rains from the high ground behind.

The remarkable success achieved by Mr. Peter Barlow, with his small iron foot-subway west of the Tower, again shows how fickle are the surroundings of these works, and it has been quoted at times in support of projects whose surroundings are totally different. Mr. Barlow's tube passed through solid blue London clay, very much as a cheese-taster passes through a ripe "Stilton," and was, as the "navvies" say, as regards excavation, as "tight as a bottle."

Encouraged by its success, powers were recently sought for a carriage-way tunnel by enlarging the "Tower Subway," and the scheme had well-known responsible supporters, but the mechanical lifts, or at least the disposition of them, wrecked this seemingly taking project, for, on the Middlesex side, a very large area of Great Tower-hill was absorbed, coincident with the frontage of Myers' warehouses, impinging on, and rising above, the roadway level north-west of the Tower moat, and abutting on what must become a great line of traffic from the end of the new Tower-street, across Trinity-square to the Docks; this, undoubtedly, proved fatal to the project, as interfering with its development, besides almost sealing up the approaches to a lofty stack of warehouses and vaults, and taking a large part of the last, in which the late Mr. Myers, the well-known contractor, had invested a fortune. The practical difficulty with mechanical lifts appears to be this—how would a timber wain and long team of horses be accommodated, and such vehicles as sugar waggons, brewers' drays, &c., though the same difficulty, in a minor degree, applies to ferry-boats; but it really is these exceptional vehicles and teams that would be most likely to avail themselves of a short and practical crossing place

Proceeding down the river, the first site that presents itself with any reasonable prospect of reaching the arterial lines of traffic on either bank is the Nightingale-lane site, a narrow (only 30 ft. including footpaths) and by no means straight road between the boundary walls of the St. Katherine Docks on the west, and the London Docks on the east side, more than a quarter of a-mile in length, and leading from Wapping, or Lower East Smithfield, just west of the upper disused Hermitage entrance lock of the London Docks up to the main entrance gates to the London Docks in Upper East Smithfield. On the Surrey side it would be near Dockhead, Bermondsey, a favourable point for communicating with the main lines of traffic. This is the site chosen for a tunnel by the Metropolitan Board of Works, and if the idea of a bridge between the Tower and St. Catherine's Docks, with connection with the broad main avenue (the Minories), leading up the east side of the City, and connecting with the Aldgate approach into Essex, be abandoned (but not otherwise) it is, all things considered, a favourable site; but it must be remembered that it is only five hundred yards, or about one-third of a mile, lower down than the much-contested site just east of the Tower.

Owing to the insulation of the Wapping neighbourhood by the London Dock basins, there is no convenient site for a tunnel or ferry for three quarters of a mile futher down, until near the site of Brunel's tunnel, showing his sagacity in its selection; and also near the steam ferry recently opened, and still more recently closed.

Old Gravel-lane on the north side, leading to Ratcliffe-highway, and the projecting northern bend of the Lower Deptford-road on the Surrey side, might be approached with new inclined streets of approach within a moderate distance, and, either for a tunnel or ferry, the site is a fairly good one. It would also involve passing under the inner lock or cut of the London Docks. By crossing lower down, as proposed by Mr. Dunch, a site might, however, be selected for a vehicular tunnel, avoiding any crossing of dock property, being just east of the London Docks and west of the Surrey Commercial Docks.

Three-quarters of a mile lower, at Ratcliffe-cross, an admirable site for a foot subway or ferry presents itself from its propinquity to the Stepney Station of the Great Eastern Railway system, and with the neighbourhood surrounding, and interlaced by the Surrey and Commercial Docks, Rotherhithe, our main entrepôt for timber and grain.

Two and a-half miles lower, we have the Greenwich site (at present a ferry by steamboats); and from one and three-quarters to two miles still lower, the Blackwall and East Greenwich site at Lea Ness, or Blackwall Point. The feasibility of constructing here a carriage-way tunnel, with long approach roads, at an easy gradient for vehicular traffic, has been discussed for many years, from the transparent fact that it is the first site below London Bridge at which such approaches could be attained at anything but a fabulous outlay; and again its claims are great, arising from the fact that, on the north side, the property required from Blackwall Stairs to the East India Dock-road, east of Poplar Church, is of a very inferior character; and, that on the south side, across Bugsby's and Greenwich-marshes, to the Greenwich and Woolwich-road, opposite the workhouse, is almost entirely open land; but unless time be taken by the forelock, this will soon cease, as the promontory has recently been divided by the South Metropolitan Gas Company for a southern Beckton, and the South-Eastern Railway for a now somewhat visionary wet dock.

Mr. W. H. Barlow, F.R.S., the well-known engineer, at the instance of Mr. Richardson, of the Greenwich Board of Works, who has for so long advocated this site, examined and reported on the formation of a carriage-way tunnel for two lines of vehicles and footways as far back as the year 1874. It was urged at the time that here every facility existed for two main north and south arterial thoroughfares parallel to the river, viz., the East India Dock-road on the northern Middlesex side, and the Lower Woolwich-road on the southern Kentish side, presented themselves, which, connected, would form a new road or highway between these important home counties; and it was urged that, as a line of new road between the South Metropolitan Gas Company's eastern portion of the East Greenwich peninsula, and that of the South-Eastern East Greenwich Dock project on the western side, had been adopted by these two corporate bodies, the approach to the tunnel might be carried under it. But the necessity again of passing under the entrance locks of such docks appeared to be lost sight of. The land cleared on the north side by the Poplar Board of Works would have been admirably adapted—with a rearranged plan for artisans' buildings—for a north-west line of approach, and the necessary distance would have been afforded for an easy gradient to the eastern side of Poplar-churchyard.

Another special feature of this site is that a large proportion of the works would be in clay, which is found at a reasonable depth on either side of the river, and is, doubtless, continuous under the river bed.

This, in effect, will prove the touchstone of success as regards tunnels for vehicular traffic, or smaller subways for foot traffic alone, *i.e.*, whether at the site proposed, within reasonable depth, clay is met with, or whether it presents only for a great distance below the river bed the alluvium of the river valley covering the London clay. The difference means comparative ease of execution at a reasonable expense, or, on the other hand, a complex and difficult engineering work, at a proportionately enhanced rate of outlay. The question is, in effect, as much a geological one as it is a mechanical study, and the judicious selection of sites—bearing in mind this great variability of the London basin along the line of the river—means the avoidance of excessive expenditure, coupled, in some cases, with absolute disappointment.

As regards the surcharged traffic over London-bridge, viewed as a separate question, the greatest relief to it would be effected by a bridge between Blackfriars and Southwark bridges, opposite the eastern side of St. Paul's-churchyard; this I have for some years advocated; it was also proposed by Mr. Bennoch some twenty years back.

Shortly stated, its claims are these, viz.:—The diversion of the northern traffic to the southward and eastward, by avoiding the choked-up City streets. This traffic is quite separate from that flowing over Blackfriars-bridge by Farringdon-street, as it does coming from the higher level of Aldersgate-street, and over the Holborn-viaduct, whilst that passing over Blackfriars-bridge is at a level twenty to thirty feet lower, and runs under the Holborn-viaduct. These two north and south streams of traffic are separated from each other by the precipitous Ludgate-hill, with approaches of 1 in 24.

The traffic over a St. Paul's-bridge would be essentially from north and north-west to south and south-east, and would represent a large fraction of what now passes over London-bridge, with a Surrey approach of 1 in 20½ to 1 in 35.

Blackfriars - bridge presents two long gradients from the centre of the bridge, north and south, averaging about 1 in 40, and meeting at the centre of the bridge, a long dead pull on either side.

The St. Paul's north approach, for 500 ft. from St. Paul's-churchyard to Queen Victoria-street, would descend southward at 1 in 45; thence for 925 ft., to the centre of the bridge, would be level; and after that, for 1,025 ft., to Great Guildford street (to be raised 4 ft.), would descend southward, at 1 in 40; and for 600 ft. in continuation to Southwark-street, by Great Guildford-street, (widened westward) at the rate of 1 in 300. The combined lengths—bridge 850 ft., north approach 1,000 ft., and south approach 1,200 ft., amount to 3,050 ft., or nearly ⅝ of a mile.

A high-level Tower-bridge and approaches would be about double the length, and the cost would be proportionate; *i.e.*, at 87 ft. 6 in above high-water from road surface, inducing the necessity of passing over the railways on each side of the river. The viaducts, as warehouses, would, however, lease well. A Tower-bridge would divert the specially north-east and south-east traffic, and would be a great boon to the manufacturing interest of those quarters, but the great relief to the swollen north and south stream would be afforded by the St. Paul's-bridge.

The patent objection to a high-level Tower bridge and its approaches is the great length so that a large amount of the lateral riparian traffic—which more especially seeks accommodation—would not reach such distant points as the Whitechapel-road, or the Grange-road, Bermondsey; and, consequently, a large proportion of the traffic from the wharves would still take the present route.

It is this convincing objection that has resuscitated the advocacy of mechanical lifts, but to manipulate such a traffic as that to be expected over such a bridge, with long waggons and longer teams, must, to say the least, be allowed to present all the elements of a very complicated problem.

The approaches to our above-bridge bridges, are, with the bridges which may be termed low-level, from that fact not of extraordinary length, viz.:—

Vauxhall	1,680 feet.	Approaches—	1 in 30 to 1 in 46
Westminster	1,703 ,,	,,	1 in 35 to 1 in 56
Waterloo	2,700 ,,	,,	1 in 31 to 1 in 42 (Middlesex side level).
Blackfriars	1,783 ,,	,,	1 in 32 to 1 in 48
Southwark	1,990 ,,	,,	1 in 15 to 1 in 40 (recently improved).
London	1,930 ,,	,,	1 in 21 to 1 in 100
St Paul's site	3,050 ,,	,,	1 in 40 to 1 in 300
Tower high-level site	7,550 ,,	,,	1 in 40 to 1 in 80

From which it will be seen that the St. Paul's length is only 350 feet greater than Waterloo.

Such are the conditions surrounding what really is a very complex, though, at the same time, an exceedingly popular problem. Will its solution be found in what has been last put forward under authority? Will it attain the "El Dorado?" or, as a *Times* leader put it, is the land of Beulah to be found beneath the Thames at Nightingale-lane—sweet sounding cognomen of a tortuous and narrow thoroughfare. The proposed approach would, however, do away with all this, but an incline of 1 in 25 for over 2,000 feet is somewhat serious. The steep part of Waterloo-bridge, Surrey approach, at 1 in 31 to 1 in 35 is about half the length. The same remarks applies to the steep approaches to the "Iron Bridge" over Bow Creek.

Should powers be obtained for such a work on this site—should it be carried into effect —and, above all, should the traffic be conducted by steep approaches or mechanical lifts without let or hindrance, to the satisfaction of the public, and, above all, to that of contractors for team labour, the tunnel has gained the day, and that at Blackwall may quickly follow.

Pending such a solution, would not the establishment of interim ferries at the sites, or some of them now indicated, be a reasonable concession to what is, no doubt, a pressing public demand—assuming always that such ferries, like the mechanical lifts, are of a nature to avoid the possibility of break down, and of so simple a character that interruption to the traffic would be avoided. This appears to be proposed by the Metropolitan Board of Works at Stepney, Greenwich, and Woolwich.

These remarks are offered as possibly suggestive of discussion to illustrate the bearings of a modern metropolitan want.

It may occur to some minds that a defined plan for overcoming the difficulties surrounding this question might be put forward, but no attempt to do this has been essayed, from the fact that this is purely a metropolitan question, to be dealt with by the authorities who alone have the power of raising the necessary funds from the pockets of the ratepayers, for no toll-bridge or tunnel can be thought of at the present day, though ferries may, perhaps, be excepted, as of a more temporary character, and for these, at frequent points, the metropolitan pedestrian would doubtless willingly pay a small toll; but the Metropolitan Board of Works having freed all the toll-bridges, it is extremely improbable they will ever attempt to renew or perpetuate so obnoxious an impost for the maintenance of such colossal works as high-level bridges, or deep subaqueous tunnels.

I have the opportunity of exhibiting, through the liberality of the authors, various models, showing how diverse has been the treatment of the subject, and the ingenuity brought to play for the solution of the difficult demand for interchange between the river-banks, without hindrance to navigation.

The Duplex bridge by Mr. Barnett, with an oval, double road at the centre, alternately opening so as to have one road open at all times whilst a vessel is passing; the same idea is to be found in the House of Commons report of 1793.

A low-level opening swing bridge, by Mr. George B. Rennie, the leaves of several spans moving simultaneously, so as to leave 200 ft. free waterway, equal to that between the port tier moorings.

A rolling tray roadway on isolated piers, leaving always a majority of the spans open to navigation, by Mr. George Barclay Bruce, jun.

The Bascule bridge with lifting girders, by Mr. Horace Jones, similar in principle to those met with in the Low Countries, and to be seen on the canvases of the old Flemish painters.

An iron bridge on this principle was erected across the river Ouse for the Hull and Selby Railway, at Selby, in Yorkshire, and one was erected across the north-end of the haven of Great Yarmouth, where it joins Breydon lake, a few years back.

The plan for the high-level Tower-bridge, with road surface 100 ft. above high water, necessitates passing over the Great Eastern and South-Eastern systems, but the inclined approaches are no longer than had they started from the margins; but the entire length is rendered very great, and the junction with arterial lines of traffic far distant. The same remark applies to the East Greenwich tunnel, and both have been prepared with the object of showing how serious is the question of obtaining convenient and gentle approaches.

An ingenious combination of swing bridge and tunnel has been proposed by Messrs. Kinipple and Morris; this would involve descending from the upper roadway to the lower tunnel surface on one side, and re-ascending on the other side, at periods when the navigable span was open, so that the road traffic would never be interrupted, or the river navigation either. But here, as with the high-level bridge, or with the tunnel, we are met with the same difficulty of accommodating long wains and waggons, and longer teams, on the mechanical lifting trays prepared for their reception, circumscribed, as they would be in this case, by the horizontal sectional area of the two bridge piers.

The various authors of these ingenious designs, who have so liberally lent their models, will doubtless add to the obligation incurred, by explaining, *viva voce*, what they conceive to be the special merits of their inventions.

It may be added here that Captain Douglas Galton, R.E., and Mr. Armstrong proposed a single and double swing-bridge.

An old heathen proverb, *vox populi vox dei*, reverently interpreted the expressed and fulfilled will of the people as providential in character. Is the "Thames Communication" question of this nature? If so, the sooner it is met the better, by a low-level bridge, east of the Tower, or a tunnel at Nightingale-lane, nearly opposite Cherry-garden-stairs, names redolent of the past rather than the present, to be followed, say by a Blackwall tunnel with southern approach across the euphonious "Bugsby's" marshes.

My object has been alone to direct attention to the extremely difficult physical and topographical conditions by which the subject is hemmed in, and if I can induce a more practical and earnest consideration of these surrounding circumstances, discountenancing to ill-considered projects, my object is attained.

Drawings showing the application of hydraulic-lifts to a high-level bridge and to a tunnel, with trays 100 feet in length, have been sent by Messrs. Clark and Stanfield. Sir Joseph Bazalgette has also courteously lent his model of a Tower Bridge and large cartoon, showing the important arterial lines of traffic leading to the Nightingale-lane Tunnel.

DISCUSSION.

Mr. G. B. Rennie said this was perhaps the first time that all these different schemes had been brought together publicly, and they showed how difficult the subject under consideration was. Some seven or eight years ago, the City invited propositions to be sent in for crossing the river near the Tower, and amongst others, he submitted a plan. It then occurred to him that if too much consideration were given to the river, the roadway was damaged, and *vice-versâ*, and he therefore attempted to effect a compromise by giving a partial communication during sixteen hours of the day, opening the bridge two hours before and after high water, thus allowing eight hours communication to the river, which, practically speaking, was all that was required for the larger class of vessels. He then explained the model in detail, both when the bridge was open and shut; in the former case the only obstruction to the navigation was four piers, the centre span clear 200 feet, the next being 130 feet, and those at each margin 115 feet; in these latter there was a height of 30 feet under the crown of the arch, or 10 ft. more than at London-bridge. The communications on the Tower side were nearly level up to the abutments; on the other side the incline would be about 1 in 33, which was no doubt rather more severe than desirable, but still not so bad as was found in many parts of London He was inclined to think that unless very large sums were paid for compensation, some such mode of compromise would be the only one which could be carried out with advantage.

Mr. G. F. Blackmore apologised for the absence of Mr. Stanfield, and said he would endeavour to give a few additional details of the scheme for a rolling tray roadway described in the paper. The objection arising from the length of timber waggons, &c., was amply met; the trays could be easily made 100 ft. or 120 ft. long, which would take four or five waggons of the largest kind. The firm he represented were now engaged in constructing hydraulic lifts for the French and Belgian Governments, for canal purposes, the length of the tray being sufficient to hold a barge of 400 tons, viz., 130 ft., constructed of wrought iron. This tray would be balanced on a central hydraulic press, 2 metres in diameter, constructed of steel, the vertical lift being about 43 ft., and the traverse being effected in three minutes. In the case of the Thames communication, where the load would be variable—not spread uniformly over the whole length of the tray—they would prefer to use two or four hydraulic presses to each tray, provided with special appliances, which had been very carefully thought out, and, in some instances, carried into effect already, for maintaining the horizontality of the trays, and ensuring synchronous action, and safety generally. One special feature would be that in no case would it be necessary to interfere with the existing gradients; the existing approaches could be utilised, and the hydraulic lifts so arranged that the level on the opposite sides of of the river need not even be on the same plane.

Mr. Morris said his firm were asked last year to furnish a design for a means of crossing the river. On going into the matter, they found that the bulk of the traffic came up the river about one hour before high tide, and they, therefore, proposed the arrangement shown on the drawings, being a draw-bridge, each half of which was drawn back on the main portion when necessary. This, it was proposed, should be opened one hour before high water, and during that time the vehicular and passenger traffic would come up to the towers, and there be lowered by hydraulic power to the subway, and lifted again at the other end, so that the traffic would not be in any way interrupted. He agreed with Mr. Redman that the question of the hydraulic power would be a difficulty if it had to be employed throughout the day continuously, but in this case the bridge only being open for an hour or so at a time, it would not be so serious. During the remaining 22 hours the bridge would be fixed, and the traffic continuous, whilst the level of the bridge would allow of the ordinary traffic of small steamers being continued without interruption. He agreed with Mr. Rennie that the only way of meeting the case was by a compromise of some kind, and the plan suggested appeared to his firm the simplest and cheapest mode of providing for both the street and river traffic.

Mr. Henry Maudslay remarked that all engineers must have had their attention called to this question, and have recognised the muddle into which the public had got with regard to it. The number of schemes now described would show some of the difficulties which surrounded the subject, but numbers of others had been brought forward for the purpose of affording accommodation to the general passenger traffic, and, at the same time, to the river traffic, which was so important to the City of London. At the present time people seemed in such a complete state of confusion as to what should be done, that hardly anything could make it worse. There was such an enormous diversity of opinion that hardly any two engineers, commercial men, or even members of the ordinary public, would agree on any one plan as being the best. Still, taking the question as a whole, the necessity for communication between the right and left banks of the river was so great, and the commercial interests at stake so enormous, that almost any plan would, to some extent, improve the present condition of things. His father years ago suggested the throwing out of cantilevers on London-bridge, so that the foot passengers should have accommodation outside, and the width of the footways be thrown into the road; but, at that time, the idea was rather laughed at. Now there was a proposition put forward for an additional bridge between Southwark and Blackfriars. At the time when the Government took up the Thames Tunnel, it was considered a great blunder, and for years it was only used by a few old women who sold ginger-bread, and by people who paid 6d. to look at it; but now a railroad ran through it, and it was used by thousands. A ferry-boat going from side to side, if disconnected with everything else, became a comparative failure, but now they were talking of a hydraulic lift 150 ft. long, with a ram 6 ft. 6 in. in diameter, rising 34 ft. A much simpler thing would be a sort of half-swinging bridge, rising and falling with the tide, and admitting of the traffic being carried by a ferry-boat. It was said that this would necessitate a floating wharf of great length, but still the same thing was done, on a smaller scale, in bringing passengers off the steamers, and why should it not be done on a larger, as it was very effectively at Liverpool. He could not help thinking that one or other of these schemes ought to be carried out, but unfortunately, the great obstacle was that so many people were always concerned who thought not of the benefit to the community, but of how they could put money into their own pockets.

Mr. Duckham then explained, in detail, the model of the lifting presses of the Thames Steam Ferry Company, which was opened in 1877, between Wapping and Rotherhithe. One difficulty the company had to contend with was the limited distance they were allowed to project the piers into the river, and another was the great rise and fall of the tides, which was about 20 ft. 6 in. Again, there was a distance of 100 ft. between the lifts and the shore, which, by the rules of the Thames Conservancy, had to be kept 8 ft. above Trinity high water mark; so that if the traffic were coming at low water there would be a lift of about 26 ft. from the vessel's deck to the level of the quay. It was calculated that with quarter of an hour trips there would be from eight to twelve vehicles each trip, and it was thought better to transfer those bodily from the high to the low level, rather than take them separately, and the lift was constructed accordingly. There were four hydraulic rams, the lift was 70 ft. long by 35 ft. wide, which would take four ranks of vehicles, three in each rank. The hydraulic machinery was on shore, connected by pipes with the rams, which were so tied together by connecting rods and chains, as to equalise the pressure upon them, supposing the load to be much heavier at one corner of the lift that at another, thus ensuring that it should work horizontally. The lift itself weighed sixty or seventy tons, and it was at first intended to have two rams connected directly with the accumulator to act simply as a counter weight, whilst the two others would operate in lifting; but owing to the company not raising sufficient capital, it was decided to use a dead-weight counterbalance, as shown in the model. It was arranged that vehicles coming on to the lift from the vessel were placed in one rank, whilst those passing on to the vessel went off from the other. The lift worked perfectly well, but the scheme was a failure from two principal causes; one, the deficiency of capital, only about one-fifth of that originally contemplated (£100,000) being raised; and the other, the defective approaches on each side. At the beginning, there were two or three breakages in the chains, owing to defects from over cheapness, but thanks to the safety grabs devised by Messrs. Maudslay, which acted immediately on safety bars at the sides, the lift was simply held fast until the tide rose to the level at which it happened to be. The iron chains were afterwards replaced by steel ones, and during the last twelve months the machinery was at work, not the slightest hitch occurred, and it was finally stopped from causes entirely unconnected with the mechanical arrangements. The ferry boats were 80 ft. long by 6 ft. beam, fitted with double engines and independent paddles, and as a rule the passage was made in four minutes; he had known vehicles pass from High-street, Wapping, to Rotherhithe, including the lifting, in nine minutes. The capital of £100,000 was intended to provide also for building some large warehouses, but even if the whole were required for a ferry, it compared very favourably with the one or two millions required for a bridge. In fact, 30 or 40 ferries could be started for the cost of one bridge and if it were not found exactly suitable at one place, it could be readily shifted at a small expense.

Mr. MARTIN WOOD referred to the lecture given by Sir Frederick Bramwell, at the Royal Institution, on the same topic as that dealt with in the present paper, in which he spoke eloquently of the scandal it was to the metropolis that the whole east of London should be left without communication across what he described as a puny stream. In one sense that was quite true; but, as Mr. Redman had pointed out, the whole commerce of the City was owing to that puny stream. It seemed to him the common-sense mode of meeting the difficulty was to take advantage of the river itself, in the manner pointed out by the last speaker. The principal difficulty was the rise and fall of the tide, but that had been got over in other places by very simple methods, and without machinery except a stationary engine, by having movable approaches or landing stages, which could be adjusted within the limits fixed by the Thames Conservancy. He hoped the public would look at the subject in a reasonable way, going back to first principles, and not allow themselves to be baffled and kept waiting year after year, for unless this great river were properly utilised, trade would go elsewhere, and London would lose its supremacy.

Mr. LIGGINS said the whole importance of this subject was with regard to vehicular traffic, because there were ferries at very many points which were available for passengers. He had known the river all his life, having traded to the West India Docks forty years ago, and he considered that if a communication were made across the river anywhere, it should be at Limehouse Hole; it would be approached through very inexpensive property on the north side by Bond's, the mast-makers' premises, and would be easy of access from the Commercial-road, and convenient to all the warehouses. But it was a question with him whether such a communication was required at all, considering the altered circumstances of the trade of London. Going down the river to Greenwich, it would be seen that nearly every warehouse on each side had boards up "these premises to let," and the extent of the trade in the upper portion of the river was nothing to what it used to be. When he was a boy you could scarcely get through the Pool to London-bridge, but the development of railways had entirely altered the course of trade. The coal barges were far less numerous, and they were towed, six or eight together, by small steamers. Owing to the increase in the size of ships, again, St. Katherine's Docks, which were formerly crowded, were now often empty, and the company had constructed larger ones lower down the river, viz., the Victoria and Royal Albert Docks. But goods going to be loaded in these docks did not go by waggon but by lighter, and thus there was not so much heavy road traffic. With regard to a bridge, he was sure that it would be impracticable to put one at all, however cleverly it might be constructed, below London-bridge. Two hundred feet was wide enough for a ship to pass through, but you had to swing the ship, and there might be three or four ships coming up the same tide, and to swing a ship in a flowing tide, when others were coming out to go to sea, was no easy matter. There would be such a complication with three or four large ships, and their attendant steam-tugs, that it would be quite impracticable; no pilot would take the responsibility of attempting it. The process of moving the docks lower down was going on very fast, and everything tended in that direction. The West India Dock Company's trade was seriously affected by the Albert and Victoria Docks, and the directors were now going to Tilbury, and providing for still larger ships; and all this was destroying the vehicular traffic to and from those ships. If merchants would submit to sending their goods as far as Tilbury, he thought it highly probable the shipping would go to Southampton, whereby 300 miles of navigation would be saved; and the railway companies now charged the same rates from Manchester to Southampton, as they did to London. He had often advocated the widening of London-bridge, and throwing the whole of the existing breadth into the roadway.

Mr. JOHN SPARKS observed that if ships no longer came up the river to deliver their cargoes, it would seem to remove the objection to a bridge at the Tower, near to which place all the great railways on the northern side now had depôts. If, therefore, any communication were made across the river, that seemed the most suitable place. He should also say that if they were going to make a road-way, it should be level, as had been found so necessary in the Holborn valley, and the City were now proposing to fill up another valley at George-street and Postern-row, near the Tower. This communication—which in all probability would be used to four or five times the extent of the Holborn-viaduct—certainly ought to be a level roadway also. It seemed to him that, in this matter there must be a compromise between the shipping and the road traffic, and he did not see how that could be effected better than by a low-level bridge, with an opening to let ships through, when they wanted to come up. By doing it in that way the present generation would be accommodated, and if in the next generation it happened that all the shipping remained at Tilbury, it would not be found that they had made a gigantic mistake by causing every ton of goods to be taken up 100 ft. above the level of the river. Some of the plans suggested would, perhaps, be useful lower down the river, but he did not think a steam ferry at the Tower would be of any service at all.

Mr. REDMAN said there seemed to be such a concensus of opinion that he had fairly treated the different schemes put forward, that it was not necessary for him to add anything further to the discussion.

The CHAIRMAN then proposed a hearty vote of thanks to Mr. Redman for his paper, which was carried unanimously, and the proceedings terminated.

APPLIED CHEMISTRY AND PHYSICS SECTION.

Monday, April 21st, 1884; Sir FREDERICK ABEL, C.B., F.R.S., in the chair. The adjourned discussion on Dr. Percy Frankland's paper on "The Upper Thames as a Source of Water Supply," was resumed.

Mr. E. K. BURSTAL said, from the title of the paper, it would appear that it was not of any great interest to engineers engaged in the construction and management of waterworks; but when the paper itself was considered, the title appeared to some extent a misnomer, for it was, in reality, an attack on the London waterworks. The statements of Dr. Frankland were, to some extent, a re-production of a paper of his in the August number of the *Nineteenth Century*, where he stated that the sewage from a population estimated at upwards of half a million entered the river above Teddington, and that it was Thames water mixed with the sewage of that half-million of human beings which the companies abstracted for the consumption of the ratepayers. To anyone acquainted with the Thames, such a statement could only be described by the word "monstrous." To imagine that the sewage of a population of half a-million persons, some of them living miles from the river, without any system of water carriage drainage, could ever reach the Thames, was what no human being would ever believe. Passing to the statistics given of the water supply to towns in the Upper Thames basin, he must impugn the veracity of the diagram, for the simple reason that he found statements in the report of the Royal Commission on Urban Water Supply, published in 1879, which did not accord with it. For instance, at Aldershot, at page 2 of that statement, an artesian well had been lately bored, but was not yet in action; in fact, the well was only just constructed, and the greater number of houses took their supply from shallow wells there. Again, at Oxford the supply was stated to be a spring in the gravel, but turning to the report he found, at page 20, that Oxford was supplied with water from a lake formed by the Great Western Railway Company, excavated for gravel, and partly from the River Thames. That showed that it could not be called a spring in the gravel. Then coming to Richmond, he thought the artesian well there was a thing of the future. Reading, again, took its water from the Kennet, and Banbury from the Cherwell. Therefore there were three or four large towns which did not bear out the statement made in the diagram. Tottenham was said to draw its supply from a well in the chalk, and on that he should like to say something. The water supply of Tottenham had been considered exceedingly good, but it appeared from Professor Frankland's returns, that from May up to August, 1883, during six months it was of excellent quality, but on the 27th of May, 1883, they actually took a large portion of that supply from the East London Water Company, which fact was never discovered by the analyst until his attention was drawn to it. If, therefore, the difference could not be discovered by the analyst, it showed that the supply taken from the East London Water Company ought, at any rate, to be above suspicion. The statement also which Professor Frankland made in his remarks on the paper, that the Royal Commission which sat in 1869 gave a modified derogatory opinion of the Thames as a source of water supply, was hardly correct, for that Commission spoke exceedingly favourably of the Thames water supply. In the commencement of Dr. Frankland's paper there was a letter from the Vicar of Staines, one of the chief points in which was the increase of house-boats on the river which were likely to cause contamination. Now, only ten days ago, he came down the river from Oxford to Windsor, and had occasion to see several house-boats, and without exception, he found they were supplied with earth-closets, and, therefore, they did not foul the stream. That was only a small point, but it was these small points which were brought up against the Thames water, and which so much influenced the mind of the public, who did not know the real facts. Passing to the results of the analyses of the A B C Company's process, those were taken from a paper fourteen years old. Of course, every undertaking at its commencement must have some failures, but speaking from a knowledge of

Aylesbury, having constructed the works there under Mr. Hawksley, and knowing something of the Company, although he was not interested in it in any way, he must say that the results were very satisfactory, and were very different to those given in the paper. Dr. Frankland said, that so far as he was aware, the only places where precipitation was in operation on the Upper Thames was at Aylesbury and Aldershot; but at Windsor, the works had been in work over five years employing precipitation supplemented by filtration, and they had given very good results, at any rate they had satisfied the Thames Conservators, and anyone who knew the Thames, and was in the constant habit of being on the river, knew how different the state of the river now was to what it was when the Conservators took it over in 1866. With respect to the analyses of the water given in the paper, the organic carbon at Windsor and Chertsey, or Hampton, and the organic nitrogen, he would compare with the analyses of the Antwerp water. Now Antwerp had recently had a supply afforded by a river a short distance from the town. The state of that river was so unsatisfactory, that they were only allowed to take it about one hour each tide. The sewage from a population of about 40,000 entered the river above it, and went down with the flood, and the sewage from an equal population below went up with the ebb. Dr. Frankland had visited Antwerp, and on examining that water, after filtration through spongy iron, he described it as being very good. He did not know the exact terms of the report, but in a paper read at the Institution of Civil Engineers, about a year ago, they were informed that filtration through spongy iron destroyed all the lower organisms, and rendered the water perfectly safe for consumption. Now, when he compared the state of the Antwerp water before and after filtration through spongy iron, there was certainly a very great improvement, but even after filtration in that manner, it did not compare favourably with the Thames water. For instance, the organic carbon at Hampton was ·285 as compared with the Antwerp ·24. The organic nitrogen of the Thames was ·061, at Antwerp ·05. Therefore, if at Antwerp the water was considered good, and so reported upon by Dr. Frankland, he could not see why similar water in the Thames should create such alarm. If spongy iron had this effect—which he did not pretend to know anything about—how was it that it was not recommended for the Thames water companies? The cost of the process at Antwerp was stated to be £7,000 or £8,000, which, if correct, would show that an expenditure of £350,000 in London would give the same results; and he could not see why they could not have such a system in London, and then all this excitement would be allayed. If any improvement could be made in the Thames water by a comparatively small expenditure like that, it ought to have been mentioned in the paper; the closing sentence of the paper, however, contained the gist of the whole matter, viz., "The great obstacle in the way of a similar supply being obtained for the metropolis is the great capital invested." Persons had subscribed their capital in past years to do that which public bodies had not done; they had done an immense deal of good, as Dr. Frankland had fully recognised, for he said he did not wish these companies to be disestablished and disendowed. But that was not what the current feeling was. He thought that, when the companies had, by the expenditure of capital, enabled a very large population to be supplied with water, some little justice was due to them; and that would have been meted out if Dr. Frankland had pointed out how the water could be improved.

Mr. HOMERSHAM said he could speak from full knowledge on some of the points mentioned by the last speaker. In the first place, he thought Dr. Frankland had been under the mark in giving the quantity of population residing on the drainage-ground of the Thames. He had carefully taken out the population residing on the drainage-ground above Hampton, and found it to be about one million; Dr. Frankland estimated that the population of certain towns draining direct into the Thames, in round numbers, was a little over a quarter of a million, and he put another quarter of a million for the suburban districts, only giving the sewage of half the total population as going into the Thames. It was all very well to say that some of these places were situated some miles from the river, but no town could be drained, no place could get rid of drainage, unless it went into a river of some kind. The natural drainage of the district was by small streams which ran into the Thames, and it was the same thing in the end as if it went direct into the Thames itself. He was not very well acquainted with some places which had been mentioned, but he could speak certainly with regard to Richmond, where nearly the whole of the water used in the year was supplied from an artesian well. This well yielded from 220,000 to 230,000 gallons a day, and had done so for years, and the remainder was made up at times from subterranean water that came from gravel. Therefore, to say because newspapers had published reports about Richmond which were utterly untrue, that the supply did not come from artesian wells, was wrong. They all knew what could be done by persons who had the ear of a newspaper. With regard to Tottenham, it was quite true to say that they took their water for some time from the East London Water Company; it was only for a short time while the well was being sunk deeper. When he heard Dr. Tidy speaking the other evening, it took him back to some thirty years ago, for he remembered the time when the question was not between the Thames water above Teddington Lock, and spring water, or water from the chalk, but between Thames water below Teddington Lock and above it, for all the companies at that time took their water below, some from Hungerford, others, like the Grand Junction, a little higher up; and the West Middlesex, which was the highest, about Hammersmith. Then chemists of equal eminence with Dr. Tidy, said in the most absolute manner that the water was perfectly pure and would create no illness of any kind. The chairman of the Southwark Company said, in a report in 1849, "of this I am certain, that water taken either at Kew or Barnes, at any time of the tide, or at Battersea during the ebb, and properly filtered, cannot be shown either by sight, taste, or smell, or by the most careful analysis, to be inferior in any respect, while in some respects it would be superior to water taken at Henley or Oxford." Now he knew the late Sir William Clay, who wrote that, very well, and a more conscientious man did not exist; of course he stated it, not on his own knowledge, but on the faith of analyses made by chemists. In 1853 or 1854, there was a visitation of cholera, and 3,467 deaths took place in the district of the Southwark Company, which was proved in the most absolute manner to arise from drinking that water. At this time the Lambeth Company had moved their intake from Hungerford to above Teddington Lock, and it was found on examination that the cholera existed to a much greater extent in the districts supplied by the Southwark Company than those supplied by the Lambeth Company; a very able report was drawn up by Mr. Simon at that time, which proved the case conclusively. Therefore some of the statements made now must be taken with the same reserve as those made by Sir William Clay in earlier times. Putting aside the sentimental part of the question, there were important points in the difference between river water and spring water, if taken from proper sources. In river water, do what you would with it, there was a great difference of temperature between summer and winter; in winter it was frequently as low as 34° and rarely less than 38°, and thus very readily got frozen and burst pipes; in the summer it was up to 70°, and with water at that temperature there is naturally a less quantity of oxygen gas, and the quality was inferior, and it nursed insects and ova of different animalcula, which colder water would not. Again, river water after rain was always opaque and devoid of transparency; when the blossoms fell from the trees and when the leaves fell in autumn it was necessarily contaminated. Then again you could not prevent the manures on the land, independently from sewage of towns, being washed into the river. It was not a pleasant subject to speak of, but sewage consisted of fluid matter as well as solid, and how could that fluid matter be got rid of. If persons were ill in the district of typhoid fever or cholera, the water necessarily became contaminated, and there were no known means by which it could be prevented. On all these grounds river water was not desirable for a public supply. Comparing that with spring water, what did you find; the water was of an even temperature all the year round, generally about 52°, and, therefore, even in winter it was very difficult to freeze. It was well aërated, and had more oxygen gas in solution, and was always bright and clear. It wanted no filtering, and was entirely devoid of animalcula. He had it tested over and over again by the most eminent microscopists and others. If, then, this water, so superior in all its qualities, leaving alone the question of sewage, could be got, why not have it; there was no difficulty about getting it; the whole of the Kent water company's supply was entirely derived from well water, and it was not an inconsiderable quantity. In the north of London the water from these springs represented one-twelfth of the whole supply, and in the south of London one-fifth, or, taking the whole of London together, one-eighth, and though this was all that was pumped, a great deal more could be got. The Kent Company, which in the summer supplied 11,000,000 gallons a day, had the means of giving 14,000,000, therefore the difficulty of getting water from the chalk did not arise from any physical difficulties; it was simply because they were not allowed to have free competition. If London were divided into eight districts, and there were butchers and bakers to supply the whole of those eight districts from eight central establishments, with shops in different parts, no one being allowed to compete with them, what what would be the price of bread and meat? The companies had contrived, not by honest means, but by Parliamentary means and Parliamentary influence, to prevent any competition in their districts. If he were asked how to avoid this, he should say it was the easiest thing in the world. When Diogenes was asked by Alexander what he could do for him, he said, "Get out of the sunlight;" and if the Government asked what they could do for the people of London, as regards water supply, the answer would be simply, "Get out of the way, and let the London people manage their own affairs," then they would soon get a good supply. The Kent Water Company used to supply water from the Ravensbourne, but under competition it abandoned that source, and adopted the chalk well supply; now they supplied the whole district with water from the chalk, and their shares at the present moment stood, in proportion to their original cost, higher than those of any other company in London, so that the company, in the long run, was really not injured by this competition.

Dr. THUDICHUM said the question of supplying water to the metropolis had been surrounded by so many fallacies that it was necessary to clear some of them away. For example, it was constantly said that the supply to the metropolis was thirty-five gallons per head per day, but this was quite erroneous; each individual in London received on an average only about twelve gallons a head, and he could bring his authority for that statement if it were challenged. In fact, there was no arrangement which could supply that large quantity; even if it were possible to deliver such a quantity, the people could not receive it. Then another fallacy was that Thames water was sufficiently pure to be supplied with safety to the public. He would take, not one place in the Thames Valley, but twenty or thirty, where water was defiled in such a manner that it was as disgusting as could be. He had not relied on books, or on other persons' statements, but had followed some of the tributaries of the Thames from their sources to where they entered the Thames, and what had he seen? The River Wey rose above Alton out of clear springs, but as it went through Alton, it received a vast amount of Alton sewage; of course you could not see it from the street—you must go into the houses and see the closets, and see how the sewage went direct into the river. Then, again, in the Basingstoke Valley, there were splendid springs of every kind. Some time ago the water closets were placed on the borders of those fine springs, and the ordure went direct into the water which went into the Thames. The local sanitary authority objected to that, and compelled the people to build privies; the result of it was that what formerly flowed away fresh was now collected, and created an abominable nuisance; but below the privies the proprietors made a little hole, and through that hole the rotten stuff now flowed into the springs; the only difference was that formerly it went in fresh, and now it went in putrid. The springs irrigated watercress beds; the cress lived on this sewage, and we lived on the cress, and there was another source of danger. It was utterly unsafe that this putrid sewage should be allowed to flow into the water-cress bed, for it was certain that, at one time or another, infection would be conveyed to the persons who ate that cress. Were there any remedies for this state of things? Of course there were. The precipitation processes were very useful, though they did not purify the water, so as to make it fit for drinking. He had been up the River Lea, and had taken water from the Lea after the Hertford sewage was mixed with it, and looked at it in various ways, and he could only say it was perfectly unfit for drinking water. Speaking not as a chemist or a physician, but as a simple man of sense, if he were asked whether water so defiled was fit for drinking, he should say, No, and three times No. If anybody flattered himself that with the progress of culture, the science of health, propriety, and cleanliness, this defilement of water with sewage, and its supply to people's houses for them to drink, would be allowed for any length of time, he was mistaken, the people would insist upon having pure water. But could they have pure water? Of course they could. It had been shown over and over again that they could have it. The springs which Mr. Homersham had mentioned gave water which was not open to suspicion; but they could have it much more easily if they went a little way up the Thames valley to the North Downs; that was a high plateau formed of chalk rocks, on which the water which fell from the hills soaked into the ground. On an average from 25 to 35 inches of rain per annum fell on those Downs, and sank into the ground, where by a natural process it was filtered, and at the bottom of those Downs, in the valley, the water rose in the shape of most magnificent pure springs, and all that was necessary was to catch them and lead them to London, in order to have the purest water possible. That was a perfectly practical problem, and it had been so recognised by the best engineers the country could produce. Why should not consideration be given to the plans of the Metropolitan Board of Works, which had been formed by those three distinguished engineers, Sir Joseph Bazalgette, Sir Frederick Bramwell, and Mr. Easton; they made a plan for supplying London with drinking water. They would take the water out of the wells constructed according to Mr. Homersham's excellent precedent; but they need not rely upon them, because every day you had over 25,000,000 gallons of the purest water in the valley of Basing; the Metropolitan Board of Works only required 8,000,000. If they wanted more they could go a little further, say to King's Clere, and could get 70,000,000 of gallons perfectly pure. Having stated that the water was defiled, and remained dangerous, that pure water could be obtained, and that the authorities had formed a plan for supplying it, why should the question be surrounded with so much collateral talk about confiscation? They did not want to confiscate anything. These who had expended their money would have it back with a fair profit, therefore there would be no confiscation. On the contrary, they were defending themselves from confiscation, for they were now compelled to pay more than the value of the water they received. They wanted to get that which belonged to them as citizens, their liberty, with power to make such domestic and sanitary arrangements as they desired. There were plenty of places in the world where such arrangements had been effected. For example, no country in the world was supplied with water like the kingdom of Wurtemburg, partly by the action of the communities, and partly by the action of the State. Even the poorest villages in the mountains brought a supply of pure water to their houses, and in some towns, as in Stuttgart, where water pure enough for drinking was not to be obtained in sufficient quantity for all purposes, there was a double supply, one for drinking and domestic purposes, and the other for cleaning, &c. If that could be done in a small state like Wurtemburg, and in poor villages, could not the richest city in the world afford to bring to perfection a system which would for once and all put an end to this perpetual wrangling about the emperor's beard. To hear the fallacies quoted again and again, on one side or the other, was perfectly intolerable. Comparisons were drawn between the health statistics of districts supplied with one water or another; but it was absurd to quote London vital statistics in support of any proposition whatever; there was an immense number of immigrants into London annually, not only of the English but of other nations, from the ages of fourteen up to the prime of manhood and womanhood. Some of the statements made in the paper were open to the objections which had been taken to them. For instance, it was stated that Basingstoke was supplied by a well; there was no doubt one well in Basingstoke which supplied a few houses, but the majority of the population were supplied with water drawn from ground soaked with sewage. He hoped that this paper would have some influence in inducing people to unanimously demand that their water should be pure, and free from all suspicion.

Mr. Baldwin Latham, M.Inst.C.E., remarked that the last speaker was entirely under a mistake in his estimate of the quantity of water delivered by the companies. There was abundant check upon the companies' own figures in the gauging of the London sewers, and the evidence was all confirmatory of the volume reported by Sir Francis Bolton. With regard to the general question, any one who had studied the history of the question must know that the London companies had been far a-head of the public on all these questions. There had never been an improvement carried out by the companies which had not met with the most strenuous opposition, occasioning very large expenditure. The Lambeth Company began to move its works above the tidal influence in 1848; but it was not until 1852 that a general Act was passed, compelling the whole of the water companies to take their water above Teddington Lock. Again, when the Lambeth Company found that the water which they took just below the Mole was liable to become turbid from the influence of that stream, they, at their own instance and cost, moved their own intake farther up the river, to get a more perfect source of supply. That was only one of many instances. There was no doubt the words quoted from Sir William Clay, in 1849, with regard to the Thames water at Kew and Barnes, were absolutely correct. Those who knew anything of the tidal movement of the water in the Thames, knew that there had been a considerable alteration in the tidal currents, and that formerly the water was quite as good in those neighbourhoods as it was now above Teddington, for tidal action had greatly increased in recent years. At an earlier period still, the water at London-bridge was remarkably good, and for generations the City of London was supplied from the old water works at London-bridge. In fact, it was partly owing to the pulling down of old London-bridge that the tidal influence had been increased. There was not one of the water companies but what would have done still more to improve the supply if they had only been permitted, but the strong opposition they had always met with, when going to Parliament, had curtailed the schemes many of them had in hand. For instance, the East London Company were desirous of taking their supply from the upper reaches of the Lea, but were prevented doing so by the opposition of the Government, who declared that nothing would compensate them for the interference with certain water rights used in connection with powder mills. With regard to the supply of water from the chalk, he would say that the million of population which were supposed to inhabit the watershed of the Thames, only came to about 270 per square mile, and he thought it would be difficult to find any square mile on the chalk which had not as many inhabitants as that. The only difference would be that in the one case the sewage was purified, and the effluent only passed into the stream direct; in the other case the sewage would percolate through the ground, to the subterranean water supply. He should prefer to take the effluent which had been exposed to the influence of light and air in the body of a river to that pollution which took place underground, under the influence of darkness. There was no security with reference to wells in the chalk. He would draw Mr. Homersham's attention to a well, or rather series of wells, which had been sunk by that gentleman himself, at Caterham, to supply 200,000 gallons a day, but that supply had never been obtained, and only recently another small company in the valley had been bought up, in order to be able to furnish a supply to the district. Again, they had been told that Richmond was supplied from an artesian well, which supplied 180,000 gallons per day, and the balance had to be made up from water from the gravel, which was the same gravel which Dr. Thudichum spoke of in the neighbourhood of all populous towns as being soaked with sewage. They had heard a great deal in the newspapers with regard to the very deep well which had been sunk which, after an expenditure of many thousand pounds, yielded eight gallons a minute, or about 11,000 gallons a day; and they had had to call in the aid of the Southwark and Vauxhall Company to give them an auxiliary supply. All these things showed that this question of supplying water from chalk had to be considered with a good deal of caution. Before sitting down, he would say a word with reference to the sewage portion of the paper, for he had never been more surprised than he was in seeing some of the results tabulated. When, however, Mr. Cresswell explained that the analysis of the sewage of the A B C process was really a very ancient document, the whole secret was out. He might say that, just about that time, he recollected going to the Leeds Sewage Works to see the process, when he thought it was such humbug that he recorded that opinion in the visitors' book. Since then, however, he had carefully watched the A B C process; it had made very considerable strides of improvement, and he was bound to acknowledge that, on visiting the works of Aylesbury, it did produce an effluent which contained a green confervoid growth, which was a great mark of its purity. He, therefore, confessed himself a convert, and had himself carried out the process with very great satisfaction at Wellington College, where some of the most perfect works for the purification of sewage ever seen were carried out entirely by the process. Not only so, but in the interests of the health of the people of the college, he thought it was desirable even to do away with irrigation, because he found that there they had a very deep well into which there was a chance of the water, after irrigation, percolating; and, therefore, in order to avoid all suspicion, he deemed it extremely important that this sewage should be treated by some chemical which should destroy any noxious properties in it, if they did exist. The result had been that, since the works were carried out, the health of the college had been better than at any previous time. He himself was a great believer in statistics, he thought they did show whether or not a process was beneficial. If you found the sanitary arrangements of a town were not good, you would be sure to find it out, probably not in the general death-rate, but in the zymotic death-rate, not only amongst young children, but even those of mature age being effected. Mr. Norman Bazalgette quoted some tables he had prepared with reference to the health of various parts of London, which showed at least that there was no difference whatever in the health, judged either by the general death-rate or the zymotic death-rate, in those districts supplied from the chalk or from the river, but, if anything, the difference was in favour of the river supply. When they came to know more about the effect of these particular poisons on health, he believed it would be found that there were influences at work, such probably as light, which Professor Tyndall had shown, a little over twelve months ago, was unfavourable to the growth of bacteria, so that if merely by the influence of light, such an exposure as that obtained in a river might be the means of checking and destroying bacterial life, it showed how these noxious properties which were supposed to abide in sewage might be removed; and the experience of various towns fully confirmed that. Wakefield had its waterworks below its own sewage outfall; Dewsbury and Halifax were on the same river above it; their water was supplied from a collecting area, that is, it was impounded on moorland; but at Wakefield, bad as its conditions were, its other conditions would compare favourably with both Dewsbury and Halifax, and judging by the health statistics, it came out much more favourably than either of those towns. That was a case where they had the highest degree of impurity in the water supply, but a most perfect system had been adopted for the filtration of the water, and the result had shown that, although it might be very objectionable—for he was not going to say it was not very improper to turn the sewage into rivers, and means ought to be adopted in every instance to prevent it—still it showed that Nature had not left us in the unprotected state which many people supposed. In fact, if it were so, there would be no such thing as wholesome water to be found, whereas experience showed that the public were not subject to those evils which were so frightfully depicted in the paper.

Mr. HOMERSHAM, without detaining the meeting at length, said he must ask leave to protest against the statement made by Mr. Latham with regard to the Caterham wells.

Mr. BISCHOF said the question raised by the paper was the supply of the metropolis from deep wells versus a supply from the Upper Thames, and he should endeavour to keep to that question, though others had travelled a good deal beyond it. What were the respective merits of these supplies? It must be borne in mind that all water pumped out of deep wells must come from the surface, and therefore the question resolved itself into this, how far could we expect that water was purified in passing from the surface to the bottom of the well. They had heard a great deal about exhaustive purification, when water filtered through a hundred or more feet of solid rock. He did not know that such filtration had been proved conclusively. Most of them had seen in quarries long yellow lines resembling ribbons, which in fact were the deposit of ferric hydrate and calcic carbonate by the water which passed through fissures, and not through the solid rock. What would be the effect if water did actually pass, year after year, through the substance of permeable rock. Just the same as took place when a leaky water-butt was made tight by passing through it water in which lime or some similar matter was suspended; the further passage of the water was prevented by the suspended matter which was taken out of it. In his father's "Geology," he found a description of a deep well at Tours, in France, which was 364 feet deep. It quite penetrated the limestone, and yet the water brought up numbers of seeds, and the stems and roots of certain marsh plants, proving that it could not have passed entirely through the solid substance of rock. Again, at 156 feet deep, at Bochum, in Westphalia, the water of a deep well brought up fishes two or three inches long, and shells. These, again, could not have passed through solid rock; in fact these instances led Sir Charles Lyell to conclude that deep wells were, in all probability, very frequently fed by the leaky beds of rivers; and this would make one pause before deciding to incur a very large expense in sinking such wells, the more as the danger of contaminating the deep well water was increased in proportion to the pumping, and the consequent lowering of the ground water. Apart from what chemical analysis could show, most people agreed that the main point was how far certain low forms of organic life, which were believed to constitute the zymotic poison, might be removed in the passage of water from the surface to the bottom of a deep well. He was not aware of a single fact which would show that these low forms o life were thus removed. If they were, the water ought be altogether free from germs, but this had not yet been proved. It would not be so very difficult to take water from the bottom of the deep well before it was contaminated by atmospheric contact in the well itself, and then subject it to a test; he might refer to the proceedings of the Royal Society, where a test would be found which he applied in a similar instance, and he ventured to say that, if tried, the result would be that 100 feet of filtration through the solid substance of rock of any kind, or however this might take place, were not as efficient in separating or destroying the low forms of organic life, as filtration through a few inches of spongy iron. A great deal was said about the exhaustive chemical purification of deep-well water, but he could conceive that this might be only a multiplication of the action of the ordinary sand filter. If instead of 6 ft. or 8 ft., we had 60 ft. or 80 ft., or still more, we would get a proportionately increased purification, but then the fact would remain, as Dr. Frankland himself pointed out, that even after the passage through 100 ft. of sand, germ life would still be detected. In conclusion, he would ask Dr. Frankland two questions. First, whether he would give an explanation of the comparatively large fluctuation in the contamination of deep-well waters, which, though nothing in comparison to that shown by the river water supply, yet did show considerable increase at certain periods, in one case amounting to nearly seven times what it was at another time? He referred to the Kent water, which—taking the average amount of organic impurity contained in a given volume of the Kent Company's water, during the nine years ending December, 1876, as unity—showed an organic contamination on one occasion, in 1877, equal to only 0·3, while in the same year it rose to 1·7, and in 1882, even to 2·0. The second question was—On what theoretical grounds did Dr. Frankland consider the filtration which water underwent in its passage from the surface to the bottom of a deep well, made the separation of any zymotic poison more certain than the unusually efficient natural filtration which the water underwent at Lausen during the epidemic of 1872?

Professor Dewar, F.R.S., said he should confine himself simply to certain ideas which had occurred to him with reference to the conduct of this debate, and the admirable paper of Dr. Frankland, not having much personal knowledge either of the individual companies or the individual supplies. In the first place, t seemed to him that they were all liable either to be misinformed, or that the facts were placed before them in a very curious way. The report on the London water supply for this month contained the following statement:—"According, however, to the eporter's own figures, the mean amount of organic matter in the five samples only of the Thames-derived water examined by him during the month was a little under four-tenths of a grain per gallon, and the maximum found in any one sample five-tenths of a grain. That maximum fell far short of the one-thousandth part of 1 per cent. of organic matter in the case even of the worst of the two waters, both reported to be considerably polluted by the presence of a very large proportion of organic matter." He presumed that was intended to convey the impression that one-thousandth part of 1 per cent. did not mean very much; but, unfortunately, in this particular case, it meant a very great deal, and they could easily arrive at the maximum or minimum value. They had heard it said on the one hand that there was the something like 250,000 persons draining into the Upper Thames Valley; and Dr. Tidy, some years ago, unhesitatingly said that there was something like 1,000,000. Assume a population of 500,000, and supposing a large dilution of the sewage, it might be taken to be at 20 gallons per head. The question was, how were they to estimate the average amount of Thames pollution. He would point out that they had the means of doing that, and he believed it had not been co-ordinated in this way before. Take the minimum supply of water during a dry period; that would be represented by between 400,000,000 and 500,000,000 gallons passing over Teddington Weir; consequently, if you took the average daily pollution, you could easily find the percentage of impurity. 20,000,000 gallons of dilute sewage are mixed with between 400,000,000 and 500,000,000 gallons of water, the consequence being a potential impurity represented by what might be from 2 to 4 per cent. of this dilute sewage. The difficulty was that on one side it was said all this impurity is as nothing, because it is removed in a very short period of time by natural oxidation; whilst, on the other hand, Dr. Frankland said that rivers had very little power of transforming organic impurities. Then it was only in exceptional cases that the sewage got into the river, namely, in the case of floods. But, again, there were some results which, on being examined, would give another definite basis to go upon. A few years ago, when this discussion was little more rampant than it was now, there were a series of analyses made by Dr. Tidy to represent the effect of the natural purification. He would abstract these analyses in a simple way. Dr. Tidy's object was to add different per-centages of London sewage to one of the London waters, passing from 1 per cent. to something like 8 or 10 per cent., and to ascertain what was the effect on various runs after exposure. The object of adding these different per-centages was that there might not be one analysis, but a mean deduction from a curve which represented the actual impurity registered from a given per-centage of sewage. Now he found, after plotting these numbers, that the amount of impurity was proportional to the amount of sewage added, but the actual amount was that a single per-centage of London sewage added to water gave a very definite increase, equivalent, in simpler language, to one-twentieth of a grain of organic carbon per gallon. Now, in accordance with the representation that a thousandth part of 1 per cent.

did not mean very much, one-twentieth of a grain of organic carbon increase in the London water was equivalent in the case of London filtered sewage to an increase of 1 per cent. in the sewage contamination—he did not say actual, but potential. That was conclusively proved from results which Dr. Tidy had so carefully recorded. Consequently the oscillation of one-twentieth of a grain of organic carbon in the London water supply might come from the addition of 1 per cent. of sewage, and it was sufficient to look at those curves to show that there was an alteration which corresponded very often to at least 2 per cent. That being the case both from the statistical and analytical point of view, they were on tolerably firm ground; it was undeniable and also undesirable that this impurity should be even potentially present, and that a variation, corresponding to such a large increase of that amount, should occur. All chemists, at some time or other, who had had to deal with these matters commercially, had formed different opinions, and even Professor Frankland and himself had differed on some occasions, but still the present occasion was not one for individual opinion, the question was, what was the real position of this problem? Was river water to be absolutely condemned? Was there really no purification, or was there not a great amount of purification? A great deal could be said for Dr. Tidy's view. If they applied the same method of calculation to the percentage of organic nitrogen which ought to be present in Thames water, the organic carbon represented the organic elements, but what had become of the nitrogen? If the nitrogen of the sewage went into the river, the calculation, which was as fair as the other, would represent an amount of ammonia in Thames water which would be perfectly surprising; and if there was one fact admitted by all analysts it was this, that Thames water contained, on many occasions, no free ammonia, that is to say, no ammonia got from bodies like urea, &c., which were discharged with the sewage. What had become of it? Another remarkable fact, which was proved by the analyses of Dr. Frankland, was this, that between Oxford and Hampton the increase in the nitric acid was represented by one-tenth of a grain per mile; yet there was no free ammonia to represent anything like the amount of sewage which went into the river. Therefore, they must admit, in fairness, that it must have been taken out by some agent; it was not there in its oxidised form—at least they could not account for it all, and the result was that five-sixths of the nitrogen, which was easily transformed, had disappeared. He presumed it had not passed into nitric acid, and, therefore, it must have been transformed into something else, and he could only presume that it had passed into vegetable life; that it had been assimilated and fixed by plants. Therefore, from this point of view, there was an enormous purification taking place. It was undeniable that the natural operations going on in the river, apart altogether from the modern applications for the purification of sewage, had tended towards improvement taking place in the Thames. The serious matter to be considered was this, was not the Thames very much in the condition of many streams in Scotland, which he knew more about, which had become most seriously contaminated from modern methods of disposing of sewage? Forty years ago, they were very pure streams, and no one complained of them, but the modern mode of disposing of sewage had contaminated them very much, and something had to be done in order to meet this difficulty. This improvement might be very much greater than it was. In the few years since this application of irrigation or some chemical treatment had been applied, the water certainly had been much improved, and as we were progressing much more quickly in knowledge of sanitary improvements now, amelioration ought to go on at a much greater ratio. With regard to the question of the vitality of these germs, Dr. Frankland said they were almost indestructible, that no chemical agent would kill them, they resisted enormous pressure, and that even cyanogen could not do anything to kill them. But that was hardly a fair view. It was true they resisted many very powerful chemical agents, but at the same time science had been continually proving, in the most remarkable way, that even these particular germs, which were recognised as invariable concomitants of disease of the most persistent kind, were readily destroyed by very slight differences of acidity or alkalinity, or by very small differences in the composition of the fluid in which they were. Now what did that mean in the case of a river? He had often put this problem to himself, in order to explain this purification. He could quite understand the difficulty of ascertaining the facts, but what had occurred to him as the explanation, was that in the case of a river receiving sewage, as the Thames did, from the main source, even the pernicious germs —because Dr. Frankland said the healthy germs did no harm—would never be in any constant environment for even a short period of time. The composition of the river was always altering; chemical interactions took place, variations in the dissolved oxygen, and there was a complete difference in the composition of the river from part to part. All this was entirely antagonistic to the active growth of many of these products. When you combined that with the fact that the modern treatment of disease was very much like the treatment given to sewage, not only in the separation of the solid matter, but also in the employment of chemical agents, and that in the treatment of infectious diseases, the discharges, for the sake of those around, not for the sake of the river, were disinfected, it was evident there were other agents at work which were likely to prevent any serious result arising from the growth of these deleterious micro-organisms. No doubt it was desirable to get a pure water, and some persons, perhaps, would prefer rain water; but if they were to look into the average composition of rain water, they would find it was a good deal worse than the London water as far as the amount of organic carbon, nitrogen, and even nitric acid was concerned. To place the problem in a simple light, would Dr. Frankland or Dr. Tidy tell him, if he gave them two specimens of the same London water, which of the two had been operated upon. The simple experiment was this; he had done it to undeceive himself. Take two litres of London water, and after boiling one, test them, not of course, for the hardness of the water, nor the dissolved oxygen, but merely the organic carbon and nitrogen. To his surprise, he was wrong in selecting the water which had been boiled. He said the water which had been boiled was the worst water, which, at first sight, seemed far from reasonable; but no doubt the fact was, the boiling did destroy the germs and the probability was a million to one it destroyed the whole of them, but the organic matter remaining was more readily oxidisable, and, consequently, was more easily detected by the permanganate test. He at first thought he had made a mistake, but after a little consideration he saw the reason of it. Therefore, people's minds must not be prejudiced by imagining that this problem was one which could not be met. He thought a great deal might still be done; for instance, he thought if they had a guarantee that the London waters were stored for a longer period, if the reservoirs were large and open, so that vegetation might actively develop, it would be a great improvement; and there were other suggestions which might be brought forward which would be found a very sufficient guarantee, because the mere question of organic carbon or nitrogen did not show that the water was positively deleterious, but merely that it was inferentially, from its source, one which might be liable to cause injury. At the same time he was not prepared to say, as a chemist, having given the most unbiassed thought to the matter, that it would be correct to absolutely condemn a river supply as unsuitable for the supply of the metropolis.

Mr. Liggins said that Sir Francis Bolton, in his last official report, stated that the state of the water in the Thames, at Hampton, Moulsey, and Sunbury, was bad throughout the whole month of February, and he unhesitatingly declared, in his opinion, that the water was bad because it was highly contaminated with sewage. The purity of water to the eye had nothing to do with its quality as drinking water. Therefore they could not judge by the effluent water that the A B C, or any other process allowed to run into the river, that it was fit to drink. He went to Windsor to hear a dissertation on the A B C process, which seemed a very favourite way of getting rid of the sewage, but how many towns had adopted it? Only Aylesbury. The sewage of every large town, such as Uxbridge, ran into the Colne, only seven miles from the Thames, and the refuse of stables and piggeries, and the washings from hospitals. London was determined to have a better supply of water, and there were organisations forming in every parish of London for the purpose. Only a few evenings ago he was at a large meeting where a resolution was carried unanimously on the subject. He accepted the authority of Sir Joseph Bazalgette, Sir Frederick Bramwell, and Mr. Easton, and what did they say in their report to the Metropolitan Board: that it was because of the quality of the Thames water and the Lee water, that complaints were made by the public. It was urged that the best system of filtration was only a palliative, and, even if it were more, it could not disguise the fact that the water being drunk was derived from rivers that had received the sewage of a large portion of the residents in the Thames Valley above the intakes of the water companies, as well as the drainage from the highly-farmed and manured surfaces around those basins. Therefore, it was not unreasonable, in the wealthiest city in the world, and the healthiest for the inhabitants, to demand as pure as a supply as any other cities were able to obtain, and they were determined to have it. The water companies had done their best, and the A B C Company had done its best, in stopping a very large amount of mechanical impurity; the foulest matter, no doubt, was precipitated by the process of filtration and subsidence, and the A B C process did this chemically; but still, if the water consisted partly of sewage, no chemical or mechanical process could change it.

Mr. Maignen said he was prepared to show that liquid sewage could be removed from water. He could put on the table in five minutes a system of filtration, by which water containing 25 per cent. of pure sewage should be so purified that it would stand the permanganate test.

Dr. Percy Frankland, in reply, said as the discussion had occupied the greater part of three evenings, it was with some little embarrassment that he rose to deal with the multifarious remarks that had fallen from the many distinguished gentlemen who had taken part in it, and if he appeared to treat any of those remarks too briefly it was not from want of appreciation of their value, but from lack of time. There appeared to be no less than four distinct parties in this controversy. First, those who had been kind enough to support the opinions expressed in the paper, and who agreed with him in thinking that the Upper Thames was not a desirable source of water supply; secondly, those who did not deny that sewage and other pollutions entered the river, but who were of opionion that such pollutions could have no influence on those drinking the water; thirdly, those who maintained that no sewage practically did enter the river at all; and, finally, there was a fourth party to whom it was perfectly immaterial whether the river received sewage or not, because they asserted unhesitatingly that any amount of pollution which the river might undergo in its course, must of necessity be destroyed before it reached that particular point where the water companies chanced to have pitched their intakes. The first speaker, Mr. Norman Bazalgette, said he had done great injustice both to the Thames Conservancy and to the riparian towns, because he said in the paper that no measures had been taken for excluding sewage from the river; but if he had read a few lines further on, he would have come to the passage where he stated very distinctly that numerous improvements had been made, both on the banks of the river, and to a less extent on the tributaries, but that these improvements had been one and all in the direction of sewage purification, and not of sewage exclusion. He could only refer Mr. Bazalgette further to the diagram representing the numerous expensive improvements which had been made. Mr. Bazalgette did not appear to apprehend the difference between sewage exclusion and sewage purification. The Thames Conservancy did not require the riparian towns to exclude sewage, but only to purify it by some means before discharging it into the river, and he therefore failed to see where he had been guilty of any injustice. Mr. Bazalgette then went on to speak about the germ theory, and asked whether he had discovered by chemical analysis such germs in the Thames water at the intakes, and if not, what right he had to infer that the water taken by the companies could at any time contain that which was injurious. He gathered from this that Mr. Bazalgette had no acquaintance with the germ theory beyond its name, because the detection of germs was not a chemical problem at all, and, except in a very few cases, they had never been detected, even by microscopists, in whose province their discovery lay. According to Mr. Bazalgette, it would be equally unreasonable to attribute any dangerous properties to the fresh excreta of a typhoid patient, because even there neither chemical nor microscopical analysis could detect anything specifically injurious. He then expressed himself on the subject of the self-purification of river water, about which he appeared to have made up his mind, although he did not say on what grounds. He (Dr. Frankland) should like to point out to Mr. Bazalgette that if oxidation were really such a great power as he seemed to believe, it was rather surprising that his eminent father, Sir Joseph Bazalgette, in carrying out that vast scheme of the metropolitan main drainage, should have been obliged to take the metropolitan sewage all the way down to Barking and Crossness before putting it into the river. If self-purification really took place to the extent which some persons would make believe it did, it would have been rather cheaper to turn the sewage into the river nearer home; but even at Barking and Crossness the sewage was not sufficiently remote from the metropolis, in the eyes of the present Royal Commission sitting on the subject, as not to create a nuisance within the metropolitan area. Then, Mr. Bazalgette brought forward mortality statistics since 1868, showing that the mortality varied in an inverse ratio to the proportion of organic matter discovered in the water supplied to London. This had become a stock question with the advocates of a sewage polluted water-supply, and betrayed entire ignorance both of the scope and meaning of water-analysis. A chemist was able only to discover whether water contained a large or small proportion of organic matter, and sometimes to say whether this was derived from an animal or vegetable source, but he could never say that a particular sample was dangerous to human health, because even if he found the water contaminated with sewage, healthy sewage was probably perfectly innocuous. They all knew that water highly impregnated with excremental matter was constantly drunk without any injury to health. Was the chemist on that account to advocate the use of such polluted water? The chemist could furnish far more important information than merely whether the particular gallon of water submitted to him was dangerous at the time of analysis. There was absolutely no relevancy between the quantity of organic matter supplied to London and even the probability of an increased death-rate. No one, as far as he knew, ever attributed dangerous properties to Thames water on account of the quantity of organic matter it contained; it was on account of the origin, and not the amount of the organic matter, that the water was regarded with suspicion. There might not occur in a whole century a striking proof, by death-rate statistics, that a particular sewage-polluted water was capable of working mischief; such a proof had been furnished by the Lower Thames at the time of the cholera epidemics, and the difference between the Lower Thames and the Upper Thames was great no doubt, but it was only a difference in degree. Sir Frederick Nicolson also objected that he had not done justice to the important work carried out by the Board of which he was the distinguished representative; but all who had listened to his remarks would, if they had closely followed his observations, see that they coincided with the contents of the diagram illustrating the numerous and expensive improvements that had been carried out. He must, however, urge that the term "sewage diversion," which Sir. F. Nicolson had used, was somewhat misleading; to divert the sewage of a town would be generally understood to mean excluding the sewage of that town from the river, but the Thames Conservancy had nothing to do with sewage exclusion; they simply required that these riparian towns should purify, by some means more or less efficient, the sewage before passing it into the river. From Sir Robert Rawlinson's remarks, his opinions on the subject of the Upper Thames as a source of water supply, and, indeed, his opinion regarding the importance of a pure water supply generally, seemed to have underergone a very marked modification since 1865, when he was chairman of the first Rivers Pollution Commission, in whose report were these words:—"The Thames, polluted by the sewage of the inhabitants of the river basin, is open in kind, if not in degree, to the same objections as well-water infiltrated by liquid from an adjoining cesspool. Well-water, so tainted, may appear to sight, taste, and smell, to be harmless, and has been known to have been drunk for a length of time without apparent mischief, but beyond all doubt that same water is liable, under particular conditions, to become poisonous. The London drinker of Thames water may be drinking with it some remnant of the filth of Oxford. Again, it is the general opinion of medical men, that what causes the presence of organic matter in water to be poisonous, is not its quantity, but its quality, and this special quality cannot, as yet, be detected by either microscopic or chemical analysis, and is indeed at present known only by its occasionally noxious effects." Then Mr. Bryan, engineer of the East London Waterworks Company, endeavoured to convince them of the incontestable quality of the London water supply, by comparing the mortality of the metropolis with certain towns in Lancashire, which were provided with water of undisputed quality, but whose mortality was much greater than that of London. But was there not very good reason for those towns having a very high rate of mortality? The enormous population concentrated in Lancashire was owing to the large development of the manufacturing industries; and it was only surprising to him, considering the habit of life of these multitudes of factory-hands, that the death-rate was so low as it was. Mr. Bryan's reasoning seemed to be exceedingly dangerous, and to lead to the conclusion that London should not contemplate any further sanitary reform until its death-rate exceeded that of those Lancashire towns. Then Mr. Burstal said he had over-estimated the population draining into the Upper Thames. It was only necessary to refer again to the report of Sir R. Rawlinson's Commission to show that, on the contrary, he had very much understated it. The population draining into the river at the present day was much greater, not because the population had increased, because in some places it had diminished, but because the sewerage system, which was then only in very partial operation, had been greatly developed since. The same gentleman criticised the diagram with regard to the source of the water supply, and with regard to that, he must say that he was not acquainted personally with many of those towns, but took his statement from the latest edition of the Water Companies Directory; but probably he knew as much as Mr. Burstal about Richmond and Tottenham. With regard to the latter, it was a perfectly erroneous statement that the samples of water reported upon to the Registrar General and the Local Government Board last year were mixtures from the Tottenham well and the East London Company's water. He had the authority of the engineer of the Tottenham Local Board, and he had sent this information to the daily press, though probably Mr. Burstal had not seen it, that all those samples were derived solely from the well, and were not mixed with the East London Company's water. Then he spoke about the Antwerp water. The supply there was an excessively foul one, and the only ground on which it could be considered at all satisfactory, and he did not consider it satisfactory then, was that it was filtered through spongy iron, not through sand only. During the last few years, it had been proved that this spongy iron possessed properties which were altogether absent in sand. In the paper, he referred to an experiment with columns of sand 100 ft. in depth which were quite inadequate to remove bacterial life, but such was not the case with spongy iron, which seemed to exert a poisonous influence on bacteria. Whether this action was successful in the case of the Antwerp water, where it was carried out on a large scale, it would be rather venturesome to say; but, at any rate, it was more satisfactory than filtration through sand only. Mr. Baldwin Latham said that bacteria did not develop in sunlight, which seemed to be quite contrary to every day experience. If you put a leg of mutton in the sun, would it not putrify? and that process was only due to the development of bacteria. Dr. Bischof spoke about deep wells, and the impurities contained in some sunk in limestone districts, where fish and other large bodies had been extracted. But these sources of supply did not seem at all similar to the chalk round London; there must have been subterranean rivers which possibly passed underground in large cavernous fissures, as was not uncommon in limestone districts, but he believed that was not at all the case with the chalk. The filtration of water through this vast mass of chalk took several months to accomplish, because, when heavy rains took place on the downs, it was a considerable time before the deep wells were influenced by it. Then he put two questions, first as to the comparative contamination of certain deep well waters, and next with regard to the case of Lausen. With regard to the contamination of the Kent water; on one or two occasions the Kent Company's water did contain more organic matter than appeared normal; that was in 1882, and at that time the samples of water were collected at a place which was afterwards found to be supplied from a cistern, and not direct from the main. Since the place of collection had been changed, the quality of the water had been almost uniformly pure. As to the filtration which appeared to have taken place in the case of the Lausen water, which yet communicated typhoid fever, he did not think it could have been anything like as efficient as in the case of chalk, because although it was sufficient to remove flour, as had been proved, yet it distinctly partook of the nature of a subterranean river. With regard to Dr. Tidy, whatever might be their opinion of the value of his remarks, they must all be grateful to him for having so much beguiled the dreariness of a technical debate. He commenced his attack with the oxidation theory of organic matter, a doctrine which he had learnt from the late Dr. Letheby. He asserted without any hesitation that in the flow of a river two things took place; firstly, the removal of organic matter; secondly, the destruction of disease germs, or *materies morbi*. The organic matter he maintained was oxidised or assimilated by plant life, whilst the *materies morbi* was devoured by fish. They had heard all this before the Chemical Society over and over again. But the upshot of those discussions had been to show that there was evidence, indeed, of slight oxidation taking place in the flow of a river, especially during warm weather, but an examination of all those cases which were alleged to prove that this process took place to any very marked extent, had shown that the reduction in the proportion of organic matter was due to some other cause, in nearly all cases to mere dilution, some to precipitation, by means of clay and suspended matters in the river, or even to filtration through a porous river bed. The analyses, which he (Dr. Frankland) had placed before the Society, clearly showed that the process of oxidation, in the case of the Thames, was insufficient to compensate for the ingress of fresh pollutions during its course, the water reaching Hampton with more organic matter than it possessed at points higher up the river. The experiments made by the Rivers Commission on the Rivers Mersey, Irwell, and Darwen, proved that in those rivers, at least, no marked self-purification took place; but Dr. Tidy claimed some of those experiments in supporting his theory, for he said that in one case the organic matter was reduced by 41 per cent.; in another by 31 per cent.; but, characteristically, he omitted to state that in those two cases the reduction was obviously due to dilution, because the chlorine was also reduced. Indeed, he felt that those results did not really answer his purpose, for he said, "rivers more preeminently unfitted for determining oxidation in running water it would be impossible to imagine;" and he then went on to say that they were "rivers which along their whole course were receiving constant supplies of impurities." He believed that to be absolutely contrary to fact. In the case of the Darwen, the Commissioners walked over every inch of the course, both of the main stream and affluents, and he had their authority for stating that the amount of pollution gaining access to the river during the flow was practically *nil*. Again, the case of the Shannon had been cited by Dr. Tidy, as affording a striking instance of this oxidation. Above a certain fall the Shannon was absolutely black with dissolved peaty matter, but below the fall in the same river the colour was almost destroyed. That case was brought forward in great confidence, but it was subsequently investigated by Professor Noel Hartley, and the results of his investigations were brought before the Society twelve months ago. Dr. Tidy said:—"Certain it is the peat could not have evaporated, and I confess I can invent no possible explanation of its disappearance except by believing that, in the course of its flow, it has been oxidised by the oxygen held in solution by the water." Upon this Mr. Noel Hartley remarks:—"Dr. Tidy's results, which I conjecture were obtained from an examination of the waters on the Limerick side of the river only, above the falls, may be easily reconciled with the fact that the lessening of organic matter is not caused by oxidation. When we consider that the ferruginous mineral matter, free from bog waters, is discharged on the Clare side, that when mingling with the bog drainage it precipitates the peat. It is nothing more than the mixing of two waters, followed by a precipitation of organic matter contained in one of them." He did not hesitate to say that the evidence of this experiment of Mr. Noel Hartley, and those of the Royal Commission on the pollution of rivers, together with those of his own on the Thames—undertaken, as they all were, quite independently, and in a truly scientific spirit, for no other purpose than the service of truth—were worth more than the whole mass of evidence which Dr. Tidy had paraded. What were they to think of the statement that the *materies morbi*, which he acknowledged might be present in sewage, was destroyed by being swallowed up by fish. A few years ago he said they were at once destroyed on entering the river by bursting their envelopes, owing to the dilution of the medium in which they were suspended. On another occasion he heard him say he did not believe in germs, that he believed the so-called zymotic diseases were communicated by some specific poison, like cyanogen; indeed, he said he would not say it was not cyanogen. The fact was Dr. Tidy was bound to get rid of these morbific matters somehow, and it mattered to him little how he effected their removal. If there was no guarantee, and there was absolutely none, that this *materies morbi* was destroyed, what mattered it whether the other organic matter was removed or not? In fact, the question of the self-purification of a river was, from a sanitary point of view, a wholly idle one. But was this self-purification ever practically admitted by those who had charge of the rivers? To their credit, be it said, it was not. The Thames Conservators did not believe in it, or why did they condemn riparian towns to spend hundreds of thousands of pounds in purifying their sewage before passing it into the river? Not long ago, he had visited the sewage farm of one of these towns in the Upper Thames basin. He had there seen a quantity of stationary machinery, which, he was told, had been put up at great expense to the town, by an eminent engineer, for the purpose of treating the sewage by some chemical process, after which it was to be discharged into the river, there to be rapidly oxidised, but the Thames Conservators stepped in, and said they must purify it by some more efficient means, and it was now being purified by irrigation. From what Dr. Tidy said the other evening, they might imagine that he was pledged to the process of oxidation as the most perfect means of purifying water, but he did not always think as highly of this process as was shown by a report of his on a private well, where he said, "The water is much polluted by sewage or animal contamination. It is true that this sewage is at the moment undergoing oxidation, but even this action is incomplete, whilst as a process it cannot be relied upon. Were it for a moment to fail, the water would be dangerous in the extreme. The well ought not to be allowed to remain open a day." In that report he entirely concurred, having analysed the same water afterwards. That really expressed Dr. Tidy's unbiassed opinion concerning the efficacy of oxidation to destroy organic, and more especially morbific, matter. Again, Dr. Tidy had quoted from the report of the Royal Commission on sewage discharge; but did that Commission countenance the process of oxidation as an efficient means of river purification? He did not think so; for, although they admitted, as did everyone else, that some oxidation took place, yet they pronounced the opinion that the process was wholly inadequate to deal with the nuisance occasioned by the metropolitan sewage discharge. Dr. Tidy read a passage from their report stating, "the net result of these complex processes—pollution by sewage, oxidation of the sewage, consumption by minute animals, and re-oxygenation of the river by the action of vegetable life, and by renewed absorption of oxygen from the air;" but he stopped there, and did not finish the sentence, which concludes:—"That in cold weather, and in cool wet summers, the pollution of the river water exists indeed, but does not increase; the above processes being adequate to prevent that. But during hot, dry weather, the pollution increases, exceeding the purifying power of the agents for its removal; and the river then becomes a nuisance, more or less great, and within greater or less limits." Moreover, Dr. Tidy gave evidence before the Commission in favour of the Port of London against the Metropolitan Board of Works, and in his evidence asserted that he found at Hammersmith sewage matters which had been imported into the river at Barking and Crossness. That was a distance of twenty-one miles, so that this sewage was not oxidised at the same rate as the Uxbridge sewage, which took only half a mile. But it was given in evidence before the Commission that it took thirty days for the sewage-water to get out of the Thames, so that in that thirty days it did not get oxidised, because Dr. Tidy found it at Hammersmith. There was, therefore, this extraordinary phenomenon of Dr. Tidy upholding the efficiency of oxidation above Teddington Lock, and denouncing it below. Dr. Tidy had told them that history repeated itself, and so it did, for thirty-three years ago chemists were engaged by the metropolitan water companies to bolster up the supply from the tidal Thames, at Hungerford-market and Battersea-bridge. "Oxidation" was the dust thrown by them in the eyes of those demanding reform. To-day Dr. Tidy was propping up a source of water supply which, although pure as compared with that, was not of the quality which present scientific knowledge demanded, and it was this sickly cry of oxidation which he revived for the purpose. But all who heard Dr. Tidy's words the other evening—"I unhesitatingly assert that Dr. Frankland has not proved his point, and that no better supply of water can ever be found for London than the supply which at present is drawn from the Thames and Lea"—must have felt that the water companies had more to fear from the exaggerations of their own chemist, than from the Parliamentary measures of the Corporation of London, or the Metropolitan Board of Works. In conclusion, he begged to express his thanks to the Chairman and the Society for the patience with which they had listened, not only to the paper, but to the discussion which followed.

The CHAIRMAN said it remained for him to move a vote of thanks to Dr. Percy Frankland for his very elaborate paper, which had elicited a most valuable and interesting discussion. For himself, as a chemist, and one of the body for whom Mr. Liggins entertained but small respect, he had listened to much that had been said almost as in a dream, he had heard it so often before; but, at the same time, he regretted that whenever these water discussions came up, chemists, to some extent, did warrant the statement which occurred at the commencement of Dr. Frankland's paper (when he referred to ithe nquiry of the First Royal Commission), that their evidence and opinions "were highly conflicting, as usual." Chemists were supposed to deal only with facts concerning which, if properly determined, there should be no difference of opinion, and if chemists would only deal with facts conscientiously, and to the best of their power, it would be better. If they were to allow those who wished to make use of those facts to do what they themselves were generally anxious to do, to build theories and start assumptions upon, they might after a time come forward with very valuable aid, and, from their knowledge of the true bearing of accumulated facts might guide those who speculated. He had often noticed how the very best amongst them had a tendency, when once they had established in their minds a theory, to go out of the way to produce numerical results, which would appear to support the theory. He had also often noticed how dangerous a thing in the hands of chemists was the reasoning upon average results, and how difficult it was to withstand the temptation so to collect material for the attainment of facts from which to deduce those average results, that these could not be considered absolutely honest. Facts coming to the knowledge of chemists which appeared to support their views were quoted on every occasion, while other facts which almost went alongside of them, but were unfavourable to the theory, were comparatively speaking, neglected. As an illustration of the danger of basing important general conclusions upon a limited series of observations in one particular direction, he might be allowed to refer to the statement which had been so frequently made, and repeated during this discussion, that bacteria were endowed with very special indestructibility. He did not in the least doubt what was stated, that bacteria could be boiled for any length of time without feeling uncomfortable; that they would exist comfortably in hydrocyanic acid, or that they rather liked sulphurous acid than otherwise, but he wished to point out that this was no peculiarity of those little animals. There were much more highly organised creatures which would stand quite as much as that. He had lately a letter from a well known chemist and accurate observer, Mr. Frederick Field, which presents a good illustration of this fact. When in South America, he was interested in preventing the incrustation of the growth of animals on ships' bottoms, and tried a variety of coating materials upon them, assuming that metallic compounds would act as poisons, but he said, referring to barnacles, which grew there in great luxuriance, that a coating of red lead was quite useless, for these animals throve wonderfully upon it, and he had taken basketsful off the bottom of vessels, although they were rooted and grounded in the poison. This led him to place some of these gentry in a strong solution of cyanide of potassium, but he found that it had not the slightest effect upon them. There was, therefore, not much difference between their tastes that way and those of bacteria. But it happened that as soon as a vessel covered with barnacles came into fresh water, the barnacles died; and, that being so, how could they say that this supposed indestructibility of bacteria had any reference to their powers of resisting such changes of the conditions under which they had to exist, as Professor Dewar had pointed out they were constantly exposed to? They were all desirous of having pure water, and if they could have a water from which sewage was excluded, they would hail it with delight. They did not desire to be supplied with a water polluted with sewage, and, supposing they could obtain a sufficient unlimited supply from deep wells, they would hail it with satisfaction, provided it could be relied upon as being pure under all conditions. But here, again, he would refer to facts which were used sometimes, and dangerously used, in order to support theories, and which rather told against wells than defended them when properly considered. They had just heard in the strongest terms a condemnation of the so-called self-purification of water; but to those who utterly opposed the views of Dr. Tidy he would say this, that he had occasion, quite independently of that chemist, to look into the question of the oxidation of sewage matter in running waters, and he could positively state that this oxidation took place continuously, and to a very considerable extent. He drew no conclusion as to a river being absolutely purified within half a-mile or ten miles of its flow by such oxidation, but that oxidation was unquestionably very important in extent. The disappearance of oxygen constantly absorbed by water, and the disappearance of organic matter, *pari passu*, would be admitted by all to be proofs of the oxidation of organic matter. At any rate, he thought if Dr. Percy Frankland would look carefully into the results which he and his colleagues had furnished to the Royal Commission, he would admit that there was considerable oxidation taking place continuously in running water. Reference had been made to polluting matter in water of certain wells not being oxidised, but the cases were not parallel, and he did not think the example Dr. Frankland had brought forward with regard to a particular well was at all similar to the case Dr. Tidy defended, namely, the oxidation of polluting matters in water being continually exposed to conditions favourable to the continuous absorption of oxygen, as in a stream. This led him to another instance of what he termed the dangerous, because illegitimate, use of facts. They were constantly told, almost *ad nauseam*, of the case of well-pollution at Caterham. No doubt the facts were as stated, but then the water was not under the same conditions as the water in a river, which was continually being reoxygenated. That water passed through pipes, or through small culverts, and consequently there was but a very remote chance of any great portion of polluting matter in the water being oxidised. It was a dangerously misleading illustration to quote, because it fed alarmist views; things were bad enough as they were, and they were all more or less alive to them, but that was no reason why they should make up their minds that it was impossible that these bacteria, which were so indestructible when exposed to active chemical agents, might not be destroyed more or less by oxidation in running water. At the same time, he must say at once, that there could be no security that such destruction would take place. Granted there was considerable oxidation, they could not know that that oxidation was so complete that, supposing dangerous organisms to exist, they could rely on their removal by such self-purification. But even when they had recourse to well-water, could they be sure that it would always be delivered undefiled? Dr. Bischof's remarks seemed to lead to the belief that they could not, however perfect or deep the well. He himself had had some experience of deep wells, for there were a large number most carefully constructed in the Arsenal at Woolwich; and for a reason which was perfectly explicable, those wells were always defiled. That was because there was a great "fault" in the chalk in that neighbourhood; but the same thing might occur in other places; and if the whole supply for the metropolis were drawn from the chalk, wells would have to be very numerous, and then he feared there would be still more danger of their being defiled. Dr. Percy Frankland had given one instance, in the case of a brewery, where one well was defiled by another; it was true they were in close proximity, but they could not tell how far that contamination might have extended; nor could they be sure that deep wells, however carefully constructed, would not be contaminated by surface water. But, supposing all means within human power were adopted to secure the supply of pure water, what would this avail if little care was taken—as had hitherto been the case—how it was dealt with after it was delivered into the houses? In a similar discussion recently held at the Society of Chemical Industry, the case of Millbank-prison was mentioned, where the mortality was very high until it was supplied with water from the deep wells at Trafalgar-square, when the mortality sank considerably. But he could mention an opposite case. The Government buildings at the Horse Guards, like many others, were supplied from those same wells; but not so very long ago, a sad death occurred, from typhoid fever, of one of the most talented engineer officers, who used to work there constantly, and other cases of illness having occurred, they were unmistakably traced to the regular consumption, by the sufferers, of drinking water from a tank in that building, which, though supplied from the Trafalgar-square wells, was contaminated after delivery by sewer gas. So that, although they discussed and fought these battles over and over again of self-purification, or of the absolute impossibility of removing sewage from water, but little advance would be made towards the attainment of the conditions which should ensure a supply of pure water to the community, if they did not attain absolutely, under every possible circumstances, the maintenance of that water perfectly free from any chance of contamination when delivered. No doubt a constant supply would effect very much in this way; but other reforms with regard to houses and their sanitary arrangements were absolutely necessary if they were to rely upon the enjoyment of that pure water which Dr. Frankland maintained could not be obtained from the Upper Thames, which some people thought they could obtain from deep wells, whilst others shook their heads even at that proposition, and thus left the people, whose confidence in the whole soundness of the present supply they had destroyed, in a sad dilemma.

The vote of thanks was carried unanimously.

Major-General A. de C. Scott, R.E., writes:—

"There is a proposition regarding water which I will venture to lay down, and which, I think, will be accepted by practical men. It is, that water for domestic use, if it is to be considered satisfactory, ought to be above suspicion. People may by circumstances be condemned to use water which may have been exposed to pollution, and which may contain the elements of danger, but they do not, if they are prudent, use such water, if they can avoid doing so.

"The danger of polluted water, the extraordinary vigour of the specific poisons which produce disease, and the common-sense view that domestic water should be above suspicion, are the premises which the body of consumers may accept and apply to the case presented to them.

"The first part of the question is that which relates to the pollution of the Thames, and the effects of Conservancy in preventing the entry of polluted matter. It seems to me that Dr. Percy Frankland has detailed in moderate language, and yet with conclusive effect, the various causes which inevitably led to the pollution of the river. It is not difficult for any one of ordinary discernment to grasp the physical condition of the Upper Thames basin. The knowledge that about one million human beings live within the area in question, most of them on the banks of the Thames or its tributaries, and that, in addition, there are there about one and a quarter million of the lower animals, such as cattle, horses, sheep, and pigs, affords in itself an indication of the degree of pollution of the soil which must exist, except in so far as it is reduced by periodical washing by rain, which carries the impurities into the river.

"The general conclusion which consumers should draw from the evidence relating to the condition of the river is, I think, that it is considerably polluted, and that no possible legislation can prevent the entry of polluting matter.

"It seems to me that the consumers cannot but come to the conclusion that the assertion, that the water of the Thames is sufficiently purified by oxidation to render it safe for use, rests on no satisfactory evidence, and that the Thames is not a proper source of supply. This common-sense view of the question was taken by Mr. Simon, the Medical Officer of the Privy Council, and Sir Benjamin Brodie, in their evidence before the Royal Commission on Water Supply, in 1869. The former gave it as his opinion that a source of public water supply should be incontaminable with sewage. The latter stated emphatically that no chemical analysis could inform us whether the deleterious quality of polluted water had disappeared.

"Space does not admit of my doing more than allude very briefly to the suggestion made by Dr. Percy Frankland, that recourse should be had to the spring and well water of the chalk for the metropolitan supply. The summer flow of the Thames at Teddington Lock represents the leakage by springs into drains and water-courses, of the subterranean reservoir over an area of 3,676 square miles, and comprising the drainage basin of the Upper Thames. This flow amounts to about 500,000,000 gallons a-day, and the water companies take toll of it to the extent of about 70,000,000 gallons daily. It is argued that, instead of drawing water from the river after it has been polluted, the supply should be intercepted (by tapping springs and sinking wells) before it reaches the river.

"Those who speak in support of the present system of supply often conclude their remarks by observing that to seek a new source would be merely wasting the money of the ratepayers. It is difficult to see how that argument applies to the present case. The ratepayers of London are now paying the water companies about £1,600,000 annually, the condition of such payment being, under the Act of 1847, a pure and wholesome supply of water. Surely it is the duty of the companies to incur any expense which may be necessary in order to comply with the conditions on which they draw their revenue?"

Mr. A. Le Grand, of the Magdala Works, 100, Bunhill-row, E.C., writes as follows:—

"From what has transpired in the course of the discussion upon Dr. Frankland's important paper, it would almost appear as though some hold it a condition precedent that water should, as a preliminary stage, be diluted with sewage in order to be subsequently purified by either natural or artificial processes, while others consider that nothing but deep well water is safe to drink; but from whatever source it may be obtained, the common sense desire must be to keep all possible pollution away from it; in other words, if we are compelled to travel along a dangerous road, instead of trying to see how near we can drive to precipices with safety, we should give them the widest berth possible.

"I happen to have sunk some hundreds of tube wells along the banks of the Thames, between Windsor and Gravesend, and have thus become acquainted with the water obtained. Many people are under the impression that because a well is sunk near a river, the water drawn from it must of necessity come from the river; whereas, under certain commonly existing conditions, such as a porous subsoil in communication with the adjacent higher ground, the conclusion arrived at is erroneous.

"I have met with numerous instances where the present water has been obtained at no great depth, close alongside the Thames, the foulness of which latter, as it flowed by, needing no analysis to prove it. The fact is, instead of the river supplying the wells in question, the very converse of this frequently is taking place, springs from higher elevations flowing steadily into the river, and thus, in sinking the wells in question, you are simply intercepting the springs which go to swell the volume of the river. I would, therefore, here remark that the analyses of samples of water drawn from the river at various points may lead to erroneous conclusions, if any of the samples in question happen to be taken at spots where these unseen tributaries of pure water are flowing with considerable strength into the river, and thus largely diluting its foul water.

"The foregoing facts further point out that, if we are obliged to take the bulk of the London water supply from river sources, it would be far better to intercept the clean underground springs flowing into the Thames, than to take the water after it has been mixed with the many pollutions to which the stream is so liable. The adoption of such a course, while not only securing greater initial purity, would largely, if not entirely, do away with the work of filtration. An experiment in this direction was made upon a somewhat large scale about two years since, at Shrewsbury, where the river is polluted and turbid. Fifteen three-inch tube-wells, about 22 feet deep, were driven upon a small island, which is at times covered with water; these were connected to one receiver, or main, about a hundred yards long, and yielded a supply of about three-quarters of a million gallons per diem. The quality of this water was rather harder than that of the river, but otherwise it was not only perfectly clear, but remarkably pure.

"Referring to the theory of purification by atmospheric influence, the following circumstance, which came under my notice a few years back, may be of interest as bearing upon the subject. The water from a more or less polluted river formed the supply of an important town in the north of England, and samples drawn direct from the stream were from time to time sent up to London to be tested by a well-known analyst, so that he was quite familiar with its characteristics; upon one occasion the engineer caused the water, as drawn from the river, to be forced up into the air, in a jet, and falling in a spray was caught and a bottle of it sent up to the analyst. So great was the change effected by this simple process, in the direction of purity, that the analyst was with difficulty convinced there had not been a mistake made as to the source from whence the sample was derived.

"Dr. Frankland mentions the deep well water supplies of several towns near the river, and I must say, from my experience of a large number of artesian tube wells I have sunk in the London basin, ranging from 150 feet to nearly 500 feet deep, the water so obtained is extremely pure and wholesome, and there can be no doubt whatever that such sources (where proper care is taken to exclude surface drainage, to which dug wells are liable) are the most reliable for purity; still, as the case of Ballard v. Tomlinson goes to show, ignorance or carelessness may jeopardise such a source, though incidentally I may observe, from an intimate acquaintance with all the facts of this particular case, they have perhaps been magnified much beyond its actual merits; not so, however, with regard to its bearing upon the whole question of the pollution of underground sources of water, which is a subject that unquestionably demands the urgent attention of sanitarians with a view to effective legislation.

"It may hardly be generally realised, but it is none the less certain, that deep cesspools are daily being sunk, as the readiest, but none the less most improper, means of getting rid of sewage, not only for isolated dwellings, but in populous districts. In some cases these cesspools are dug 50 ft. or 60 ft. deep, and in others borings are actually made to considerably greater depths for the same object, and I have more than once drawn the attention of the Local Government Board to this practice, which is fraught with much danger to the community at large."

Miscellaneous.

NOTES ON SOME MALAY TIMBER TREES.

By James Collins.

The subject of a regular and large supply of timber is a most important one, and a few notes on the question as regards the Straits Settlements will, it is hoped, be found of use. These will be but brief and preliminary, as the materials at command are too scanty at present to deal with the question otherwise. Johore, although an independent State, under the rule of his Highness the Maharajah of Johore, K.C.S.I., &c., is also included in the present note.

The extent of forests has been variously stated, but the following figures may be taken as an approximation:—

Singapore	20 to 30	square miles.
Malacca	160 to 170	,,
Penang and Province Wellesley	110 to 120	,,
Johore and adjacent Islands..........	10,000	,,

To this must be added Selangor, Perak, and the other native States of the Malayan Peninsula, some of which are more or less under British Government control.

The forests of the Straits Settlements, properly so called, are the sole property of the Government, as is the case also with those under the Maharajah's rule. They are, however, in all cases rapidly decreasing, and no means are taken to stop this. The system of working them is as follows:—A person wanting a tract of land applies to the land office, and pays tenths on the value of the timber cut. Forest rangers, and occasionally the police, have to see that none but those having this license or permit cut timber.

This land may be required for the timber on it, or for clearing for the cultivation of various products, and the forest supply of timber suffers most materially if the occupation of the land is not permanent but temporary. Thus a tract of land having been secured, the primeval forest is cut or burned down, and the timber left to rot. Between the fallen trunks, gambier, pepper, rice, tapioca or other products are raised, and after a few crops have been taken off, the ground becomes exhausted. To procure and clear a fresh spot is often cheaper than manuring the old soil, so the previous plantation is abandoned to white ants, secondary jungle—as a rule of lalang grass—low scrub, with here and there small and useless trees. This lalang grass *(Andropogon caricosus)*, when once it gets possession of the ground, stifles everything else, and its long fibrous and tough roots resist all native efforts to eradicate it; even a prairie plough would possibly reclaim the land at too great a cost.* The pretty little sensitive plant *(Mimosa)* soon carpets the ground with its flaming yellow flowers, and it is most difficult to eradicate.

Singapore hardly cuts any timber at all for her own use, being chiefly supplied from Rhio and the adjacent islands, and also from Johore. In Malacca a greater quantity can be cut, but from want of roads or streams, it is very difficult to get timber from a greater distance than fifteen to twenty miles from the town. Penang and Province Wellesley cannot cut much timber, unless the risk of climatic disturbance be run. The Straits Settlements exports no timber to speak of; what little Tampinis and other hard woods which have been shipped occasionally to Ceylon and Mauritius, being chiefly from other islands.

With the territory of Johore, the case is different. Some years ago, H.H. the Maharajah erected extensive steam saw mills, and these mills, under the enlightened and able management of Mr. James Meldrum, have placed in the markets a large quantity of fine timber.

The following figures have been supplied me by Mr. Meldrum. Exports of timber from Johore, 1864-1874:—

	Loads.		Value.
To British India	15,000	..	$115,000
,, China	7,000	..	84,000
,, Mauritius	3,000	..	36,000
,, Java	2,700	..	27,000

Taking in "sundry places," about 40,000 loads of hard wood has been exported, principally in the form of logs or railway sleepers; the trade in the latter has fallen off, through the more general employment of iron cradles. About 60,000 loads of soft woods, in the form of logs, planks, boards, &c., have been exported. Of these soft woods, 25,000 loads were taken by Singapore, at a value of $270,000.

Mr. Meldrum states, as the result of about twenty years' experience, that the Johore forests are diminishing rapidly, that the sea-shores, islands, and other easily attainable localities are cleared, and that a good supply cannot be hoped for, till the rivers are made more navigable, and good roads pushed into the interior.

As will be seen, no steps have been taken as to conservancy or cultivation, and this calls for immediate attention. As to how this is to be managed, need not be entered on here, but in parenthesis, we may state that following in the lines of the Indian Forest Conservancy, with a few modifications, would amply meet the case.

As to the climatic changes brought about by the clearance of forests in this part of the world, very little can be said. The late Dr. Randell, Principal

* The lalang would, I believe, prove one of the best sand-binding plants. When coming through the Suez Canal, I could not help thinking that if this were planted along the banks, much dredging would be saved, and render the passage through much more endurable

Experiments on the Stiffness of some of the principal Woods of Singapore, Malacca, and Johore.*

Name of Wood. I.	Average weight per cubic foot. II.	Deflection in inches. III.	Weight producing deflection in lbs. IV.	Breaking weight in lbs. V.	Remarks. VI.
Krangee	77	$\frac{5}{8}$	980	1,339	Very hard, close-grained, well adapted for beams of every description. White ants or other insects do not touch this timber. It is well adapted for piles for bridges in fresh or salt water; it is also used for junks' masts; stands well when sawn, ranks with Tampenis for durability. Fracture long, fibres tough, colour dark red.
Panaga	72	$\frac{5}{10}$	688	1,310	Is a bright red wood, very hard and durable, well adapted for roofing timbers, joists, and timber work of bridges; is very cross-grained and difficult to work; can be obtained in any quantity to 9'' square. Fracture short.
Tamboosoo	67	$\frac{5}{10}$	306	548	Is a capital wood for piles, or for any wood-work which is exposed to the action of fresh or salt water; is not attacked by worms or white ants. Fracture short.
Billian Wangy	72	$\frac{5}{10}$	473	1,038	Is a very hard, durable, and heavy wood, close-grained, fibre long, is not liable to be attacked by worms or white ants; beams of 50 ft. long and 18 in. square can be obtained. Very suitable for roofing timber, girders, joists, and timber bridges.
Billian Chingy	60	$\frac{5}{10}$	408	913	A hard, close-grained, fine-fibred wood, but very much inferior to Billian Wangy, of a brownish grey colour; readily attacked by insects and dry rot; is used for flooring joists.
Marbow, Murboo, or Marraboo	61	[illegible]/10 to $\frac{5}{8}$	399 to 578	894 to 987	Is a durable wood, principally used for furniture, is readily worked, and takes polish well; it is also used for flooring beams, timber bridges, carriage bodies, and framing of vessels. Trees 4 ft. in diameter are sometimes obtained. It is not readily attacked by white ants, but is by worms. The colour is almost like English oak.
Johore Teak, or Ballow	73	$\frac{5}{8}$	737	1,210	Well adapted for permanent sleepers, beams, piles, shipbuilding, engineering, and general purposes where strength and durability are required. Piles which have been in the ground for 100 years have been found in a good state of preservation. It is one of the few woods which will really stand the climate of India. Colour dull grey.
Johore Cedar	$40\frac{1}{2}$	$\frac{5}{8}$	410	616	Well adapted for house-building purposes, as in the manufacture of doors, windows, and flooring planks. Fracture short, timber open-grained, and is not liable to be worm-eaten.
Kruen	50	$\frac{5}{8}$	472	$625\frac{1}{3}$	Close-grained, tough fibres, and resembling yellow pine. Used for native boats, planks, &c. Contains a kind of dammar-like oleo-resin.
Darroo	61	$\frac{7}{10}$	840	1,300	Is much used for beams of houses and door frames; is durable, if kept either wet or dry, but rots soon if exposed to sun and rain; colour white, close-grained, fracture long; has an agreeable smell.
Tampénis	67	$\frac{7}{10}$ +	802	1,599 +	Very hard, close-grained, red-coloured, long-fibred, and tough wood. Well adapted for beams of every description; white ants and other insects do not touch it. Used largely for bridge piles in fresh or salt water; considered one of the most lasting timbers; it warps if cut in planks.
Kulim, or Johore Ironwood	73	$\frac{5}{8}$	706	1,141	Somewhat similar to Ballow (*vide ante*). Used for planking cargo boats; fracture short; makes superior beams and telegraph posts, as it lasts well in the ground.
Johore Rosewood, or Kayu Merah (two samples)	38	$\frac{5}{8}$	583	952	Resembles rosewood in appearance, and used largely in cabinet work and household furniture.
Samaran	42	$\frac{5}{8}$	326	532	Well adapted for doors, windows, moulding, and other house-building purposes; is close and even grained, dull red colour, short fracture, but liable to attacks of white ants.
Jolotong	29	$\frac{5}{8}$	280	732	Well adapted for patterns and mouldings, excellent for carving purposes, grain very close, scarcely any knots, colour whitish yellow, fracture short, but the wood is not very durable.
Seriah	47	$\frac{5}{8}$	438	$737\frac{1}{3}$	Of a dull red colour, close-grained, and largely used in house-building, for boxes, boards, &c.

* From the Tables of Dr. Maingay, Captain Mayne, R.E., Mr. W. D. Baylis, of the Public Works Department, Strait Settlements, and Mr. J. Meldrum, Manager of the Johore Steam Saw Mills. The billets of wood tried were 3' × 1½' × 1½'. The average three billets of each kind is given.

Medical Officer, S.S., in his Annual Meteorological Abstract for 1873, has the following:—

"The only causes that appears to me to exist, or have existed, to which this great decrease of rainfall may be attributed, is the extensive clearing of forest on the mainland of Johore, contiguous to this island (Singapore), which has been effected principally during the period under notice; and I would suggest that the conservancy of portions of forests may be taken into the consideration of Government."

Certainly, many old inhabitants have informed me, that the heat is greater and the rainfall less in the Straits Settlements than it used to be. One thing, however, has done largely to mitigate and render less apparent the great destruction of forests, and that is the enormous extent to which the cocoa-nut palm and other fruit trees are cultivated.

AUSTRIAN STATE AGRICULTURAL ESTABLISHMENTS.

It appears from the last report of her Majesty's Secretary of Legation, at Vienna, that great attention is paid in Austria to the proper education of agricultural teachers; in 1881, there were 69 schools, State, provincial and private, but all under the supervision of the Agricultural Department. They consist of 1 university, 13 middle, and 55 lower schools. In the State University there were 38 teachers, in the middle schools 126, and in the lower schools 265. In these schools the attendance of scholars averaged 2,721, and those who passed amounted in 1881 to 1,014. Those students who have passed through these schools as teachers are distributed throughout the Empire, and assist the farmers, instructing them as to the best means of increasing their production, advising them on all points where knowledge is required, as to the best machines in use, and in respect to the best and most useful breeds of cattle, &c. There is a class of teachers called "wandering teachers," who travel about giving instruction to poor farmers and to those whose farming is bad; in many cases, however, but little attention is paid to the advice given. The candidates for teachers have to possess a knowledge of climate, soil, geology, agricultural chemistry, plant production, technology, animal physiology and production, forest planting, use of and protection of forests, practical geometry, forest science, vineyard, fruit and silk cultivation, wine and cellar handling, also a knowledge of brewery and distillery work, according to their respective callings. There are, besides the agricultural schools, six mining schools with fourteen teachers and a hundred and ten students. Agricultural exhibitions are held in the provinces at different seasons, when prizes are given both in coin and medals. Subventions are given for drainage and irrigation purposes, and for assisting those districts where inundations have occurred; seed is also given and machines lent to agricultural societies when necessary. State grants are given to societies to buy and plant trees; grants are given to agricultural societies to enable them to purchase good breeds of cattle, which are then sold by auction, the surplus proceeds going to a general fund to purchase again later. Great attention is paid to bee and fish cultivation. Publications are issued and distributed to those interested in the best means of eradicating phylloxera, the potato disease, and fungus on the roots of vines. Great consideration is shown to the improvement of the breed of horses in the Austrian Empire, the establishment for which, and the studs, are on a very large scale, giving employment to many. There are also private breeding establishments—but which have to conform to statutes imposed by the Agricultural Department—which is in communication with the different Land Commissions, for the purpose of assisting the improvement of the different breeds of horses in the Empire. At Vienna, there is a central weather station, and a regular telegraph weather report issued and sent to all societies and private individuals who choose to subscribe to it; the Empire has been divided into weather districts for this purpose, the Ministry of Commerce aiding by permitting telegrams to be sent at half the usual cost; it appears, however, that the Austrian agriculturists have not availed themselves of this benefit to any great extent, in Moravia, Lower Austria, and Bohemia they have a little, and in the other provinces not at all. This, says Mr. Victor Drummond, is greatly to be regretted, as the prognostications show that 70 to 85 per cent. are correct. All decisions in water, forest, and shooting rights are determined by the Ministry of Agriculture; appeal, however, can be made to the High Courts of Justice, but this is seldom required. All provincial laws concerning fishing, forest, and shooting rights, must be subjected to the sanction of the Emperor.

THE PRODUCTION OF OIL IN GREECE.

According to a consular report, made to the German Government from Athens, the production of oil is, for the most part, effected in Greece by a primitive kind of oil mill, which exists in thousands, and is of similar construction to those of ancient times. Small presses are also sometimes to be found in the houses of peasants, which are worked by hand or by horses. The first steam oil-press was introduced into Greece in the year 1857. These are now to be found in various parts, but the people as a rule favour the old style of mill.

On account of the imperfect character of the oil-mills, it is not surprising to learn that much oleaginous matter remains behind, and that the cakes are an article of commerce, besides being used for feeding pigs, &c. Of late years, however, a process has come into use by which the residue is subjected to chemical action, and the oil extracted is used for soap. Several soap works are in existence where the oil thus obtained is used. One factory was started on a large scale in 1879, at Eleusis, and last summer a factory was started at Piraeus of less importance, but on the same general plan.

Greek olive oil is powerful in its nature, of agreeable taste and aromatic smell, being in the opinion of experts quite comparable with the products of Italy and France. In its unpurified state is is, however, disagreeable in smell. It is remarked that the absence of oil refineries in Greece is explained by the fact that the need for such has not been felt. Hotels and the best families import French and Italian oils, while the people at large use the native product, to which they are accustomed. It is, however, remarked, that if refineries existed there would probably arise a demand for their productions, as living is gradually become more in accordance with Western tastes.

SILK MANUFACTURES IN SWITZERLAND.

The periods from 1850 to 1860, and from 1860 to 1870, were specially favourable to the prosperity of the silk industry in Switzerland, demand being steady for the articles produced, and there being no special necessity for Swiss manufacturers to introduce new features into their industrial activity.

Exports to the United States were naturally affected by the outbreak of civil war in 1861, but this was not productive of appreciably injurious results, inasmuch as the free trade measures taken by England in 1860, and the similar action of France in 1864, opened important European outlets for Swiss goods. With the restoration of peace in America, the transatlantic relations of Swiss manufacturers again became active, and the years 1866 to 1872 have been recently described by a Swiss authority, as displaying "an unbroken chain of conjunctures favourable to the silk trade."

The tendency of public taste in American and English markets to prefer the heavy tissues called *failles*, to the lighter and more brilliant taffetas makes, began to act unfavourably on the Swiss manufacturing industry after the year 1872. This branch of the trade having considered the change of fashion only temporary, refrained, at first, from carrying out the needful alteration of looms. When the necessity of such a measure was no longer a matter of doubt, and Switzerland produced the class of goods in question, fashion had already begun to take up other articles. The important development of the satin trade, which took place towards the year 1880, has resulted in about one-third of the hand-looms in Switzerland being devoted to that class of tissues. The fancy articles made on Jacquard looms, which have within the last few years taken up such an important position in the silk trade, have not been produced in quantities of any importance by Swiss manufacturers.

In bringing forward the above facts, and other details of interest affecting the subject referred to, the *Central Blatt für Textil Industrie* calls attention to a project for introducing into Switzerland the manufacture of velvets. It is stated that the alteration of looms would not be very expensive, while the favour enjoyed by the article gives the proposal a fair chance of its realisation being a commercial success.

Obituary.

Jean Baptiste Dumas.—This distinguished chemist, who received the Albert Medal of the Society of Arts in 1877, in recognition of his researches, which have, in the terms of the award, "exercised a very material influence on the advancement of the industrial arts," died at Cannes on Good Friday, the 11th inst. Dumas was born at Alais, July 14, 1800; and, in 1823, was appointed Assistant Professor of Chemistry in the Ecole Polytechnique, Paris. In the following year he founded the *Annales des Sciences Naturelles*, in conjunction with Brogniart and Milne Edwards. In 1849, he was appointed Minister of Agriculture and Commerce, but retired from the Ministry in 1851. In 1855, he became President of the Municipal Council of the Seine, and in that position he worked hard to obtain for Paris proper drainage and sanitary works. He was Vice-President of the Senate from 1861 to 1863; and, in 1868, was elected Permanent Secretary of the Academy of Science. In 1876, he succeeded M. Guizot as Member of the French Academy. As far back as 1840, the Royal Society elected him one of their Foreign members; and, in 1843, they gave him the Copley Medal.

Philip Palmer.—By the death of Mr. Palmer on the 17th inst., the Society of Arts loses its oldest member. He was elected as far back as 1829, and for many years was a constant attendant at the meetings, and a frequent speaker in the discussions. He was in the 73rd year of his age at the time of his death.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, eight o'clock :—

April 30.—"The New Legislation as to Fresh-water Fisheries." By J. W. Willis-Bund Edward Birkbeck, M.P., will preside.

MAY 7.—"Bicycles and Tricycles." By C. V. BOYS. Dr. B. W. RICHARDSON, F.R.S., will preside.

MAY 14.—"Telpherage." By Professor FLEEMING JENKIN, F.R.S.

MAY 21.—"Telegraph Tariffs." By Lieut.-Col. WEBBER, R.E.

MAY 28.—"Primary Batteries for Electric Lighting." By I. PROBERT.

FOREIGN AND COLONIAL SECTION.

Tuesday evenings:—

APRIL 29.—"The Transvaal Gold Fields; their Past, Present, and Future." By W. HENRY PENNING.

APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings:—

MAY 8.—"Cupro-Ammonium Solution and its Use in Waterproofing Paper and Vegetable Tissues." By C. R. ALDER WRIGHT, F.R.S., D.Sc. Prof. W. J. RUSSELL, Ph.D., F.R.S., will preside.

MAY 22.—"Economic Applications of Seaweed." By EDWARD C. STANFORD, F.C.S. (This paper has been postponed from April 24th.)

INDIAN SECTION.

Friday evenings:—

APRIL 25.—"The Existing Law of Landlord and Tenant in India." By W. G. PEDDER. The Hon. Sir ASHLEY EDEN, K.C.S.I., will preside.

MAY 9.—"Indigenous Education in India." By Dr. LEITNER.

MAY 30.—"Street Architecture in India." By C. PURDON CLARKE, C.I.E. This paper will be illustrated by means of the Oxy-Hydrogen Light.

CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Fifth Course will be on "Some New Optical Instruments and Arrangements." By J. NORMAN LOCKYER, F.R.S., F.R.A.S.

LECTURE I. April 28.

LECTURE II. May 5.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 28...SOCIETY OF ARTS, John-street, 8 p.m. (Cantor Lectures) "Mr. J. Norman Lockyer, "Some New Optical Instruments and Arrangements." (Lecture I.)

Geographical, University of London, Burlington-gardens, W., 8½ p.m. Mr. H. E. O'Neill, "Journey from Mozambique to Lake Shirwa, and Discovery of Lake Amaramba."

Actuaries, the Quadrangle, King's College, W.C., 7 p.m. Messrs. Francis William White and William J. H. Whittall, "Extra Mortality."

Institute of Agriculture, Lecture Theatre, South Kensington Museum, S.W., 8 p.m. Professor H. Tanner, "Variations in Food."

Medical, 11, Chandos-street, W., 8½ p.m.

TUESDAY, APRIL 29...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Foreign and Colonial Section.) Mr. W. Henry Penning, "The Transvaal Gold Fields; their Past, Present, and Future."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. Klein, "The Anatomy of Nerve and Muscle." (Lecture II.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Wm. E. Rich, "The Comparative Merits of Vertical and Horizontal Engines, and on Rotative Beam Engines for Pumping."

Institute of British Carriage Manufacturers, Westminster New Town-hall, S.W., 7½ p.m. Mr. H. Julian, "Art applied to Coachbuilding."

Zoological, 11, Hanover-square, W., 1 p.m. Annual Meeting.

WEDNESDAY, APRIL 30...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. J. W. Willis-Bund, "The New Legislation as to Freshwater Fisheries."

THURSDAY, MAY 1...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. R. A. Rolfe, "Flora of the Philippines and its derivation." 2. Mr. George Brook, "Embryology of the Weever Fish." 3. Mr. George C. Druce, "*Melampyrum Pratense*." 4. Prof. M. Duncan, "New Germs of Fungida allied to Micrabacia of Cretaceous Age."

Chemical, Burlington-house, W., 8 p.m. 1. Mr. W. H. Perkin, jun., "Benzoylactic Acid and some of its derivatives." (Part I.) 2. Mr. W. R. E. Hodgkinson, "Fluorene."

Society for the Encouragement of Fine Arts, 9, Conduit-street, W., 8 p.m. Dr. Phené, "Art in America."

South London Photographic (at the HOUSE OF THE SOCIETY OF ARTS), 8 p.m.

Royal Institution, Albemarle-street, W., 1 p.m. Annual Meeting. 3 p.m. Prof. Dewar, "Flame and Oxidation." (Lecture II.)

Mechanical Engineers, 25, Great George-street, S.W., 7½ p.m. 1. M. Georges Marié, "The Consumption of Fuel in Locomotives." 2. M. Paul Decauville, "Portable Railways." 3. Mr. Michael Longridge, "The Moscrop Engine Recorder, and the Knowles Supplementary Governor."

Archæological Institution, 16, New Burlington-street, W., 4 p.m.

FRIDAY, MAY 2...United Service Inst., Whitehall-yard, 3 p.m. Captain Samuel Long, "Libraries Considered as Subsidiary to Education: and on the Best Means of Diffusing Information among the Officers and Men of H.M. Navy."

Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m. Prof. J. W. Judd, "Krakatoa."

Geologists' Association, University College, W.C., 8 p.m.

Philological, University College, W.C., 8 p.m. Paper by Mr. Henry Sweet.

Mechanical Engineers, 25, Great George-street, Westminster, S.W., 7½ p.m. 1. Mr. A. Slater Savill, "Description of the Automatic and Exhaust-Steam Injector." 2. Mr. Robert Gordon, "Description of the Apparatus used for Testing Current-Meters, at the Admiralty Works at Torquay, for Experimenting on Models of Ships." 3. Mr. Edgar P. Rathbone, "Description of the Francke 'Tina' or Vat Process for the Amalgamation of Silver Ores."

SATURDAY, MAY 3...Royal Institution, Albemarle-street, W., 3 p.m. Mr. H. M. Westropp, "Recent Discoveries in Roman Archæology." (Lecture II.) "The Forum."

Journal of the Society of Arts.

No. 1,641. Vol. XXXII.

FRIDAY, MAY 2, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CANTOR LECTURES.

The first of Mr. Norman Lockyer's course of Cantor Lectures, on "Some New Optical Instruments and Arrangements," was delivered on Monday, the 28th inst. In this first lecture, Mr. Lockyer dealt with some of the recent improvements in telescopes. The two principal pieces of apparatus which he described were the dome for an astronomical observatory, designed by M. Eiffel, and the bent equatorial telescope of M. Loewy. The dome, instead of being supported on wheels or rollers, as in the ordinary form, is floated in an annular trough, filled with a solution of chloride of magnesium. A caisson surrounding the base of the dome fits in the trough. From the dome is hung the observatory floor, which carries the observing chair. The effect of this is that, on motion being given in the ordinary way to the dome, the floor, together with the observing chair, all partake of the same movement, which is timed with that of the telescope. If for any reason the dome, &c., should be lowered a couple of millemetres, the whole structure is then received on wheels, properly mounted below the floor, and then runs upon them. This provision is only intended for use in case of the floating arrangement not working properly. Mr. Lockyer compared this with the ordinary arrangements for the observer's comfort, and dwelt on the effect which the fact of the observations being made in comfort had upon their accuracy.

In the equatorial, instead of the eye-piece and object-glass being mounted at opposite ends of one continuous tube, the tube is bent at right angles, about its middle, and a mirror placed in the angle, so as to direct the rays received by the object-glass into the eye-piece, which is at the upper extremity of the part of the tube, parallel to the earth's axis. On a rotation being imparted to the tube in the usual manner, the other limb of the tube of course moves through an arc, extending from the horizon on one side to the horizon on the other. Beyond the object-glass is fitted a mirror capable of being turned to any angle, so that a combination of the motion of the mirror and the motion of the telescope itself consequently enables the whole sky to be brought within the range of observation. The special advantage of this arrangement is that the necessity for a costly dome is done away with, as only the eye-piece end of the telescope required to be covered; the rest projected beyond the walls of the building, only requiring a rolling hut or similar arrangement to protect it from the weather when not in use. Mr. Lockyer defended the arrangement from the criticisms which has been brought against it, and stated that there was no difficulty in constructing mirrors of the size required, nor did their use at all interfere with the accuracy of the observations; in fact, he believed the beauty of the images, and the condition of precise observations in the "equatorial coudé," as the new instrument is to be called, to be unsurpassed.

INTERNATIONAL HEALTH EXHIBITION SEASON TICKETS.

The Executive Council of the International Health Exhibition have consented to allow Members of the Society of Arts the privilege of purchasing Season Tickets for the Exhibition at half-price (10s. 6d.). Each Member will only be allowed the privilege of purchasing a single ticket on these terms, which will be a personal admission, not transferable.

Season tickets admit to the opening ceremony on the 8th May.

The tickets are now ready, and have been issued to all who have already applied. Members desiring to avail themselves of the privilege should apply to the Secretary. It will be understood that all applications must be accompanied by a remittance of the price of the ticket. Tickets at the reduced rate can only be obtained through the Secretary of the Society of Arts.

PRACTICAL EXAMINATION IN VOCAL OR INSTRUMENTAL MUSIC.

The next Examination in London will be held by Mr. W. A. Barrett, Mus.Bac. (Oxon), at the House of the Society of Arts, 18, John-street, Adelphi, W.C., during the week commencing on the 9th June, 1884.

Full particulars can be obtained on application to the Secretary.

PRELIMINARY REPORT ON COLLISIONS OF STEAMERS IN FOGS.

The following Report has been drawn up by Admiral A.P. Ryder, Chairman of the Committee of the Society of Arts on Collisions in Fogs, for the consideration of that Committee :—

To the Council of the Society of Arts.

1. This Committee was appointed by the Council on March 12th, 1883, to consider the question of collisions at sea. On further consideration it was determined that the work of the Committee should be confined to the question of collisions in *fogs*. The first action of the Committee was to insert a notice in the Society's *Journal*, inviting communications and suggestions from persons interested in the subject. In response to this notice they have received sixty-nine communications. A summary of all these will be given as an appendix to the final Report. The Committee feel much indebted to the many gentlemen who have submitted these suggestions, but they do not consider themselves in a position to recommend any one of the systems described in preference to the others.

2. Nearly all the methods proposed assume the desirability of a code, international or not, of fog signals, and in many of the inventions great ingenuity has been displayed. Supposing the objections to an elaborate code to be got over, there can be little doubt that several of the systems proposed would be very well adapted for the purposes required. The Committee, however, after giving special attention to the question of an international code of fog signals, have come to the conclusion that the introduction of an international code for use by merchant ships would be more likely to cause confusion or disaster than to conduce to safety, first, because the difficulty of making intelligible signals in a fog is very great; and, secondly, because it is to be feared that the authorisation of such a code would foster a fancied feeling of security, and encourage the practice of steaming at high speed under dangerous circumstances. The Committee believe that the utmost that could be done would be an indication of the direction of the ship's head as regards the vessel she is signalling to, as proposed by Mr. Rothery; and, in crowded channels, the indication by steamers of the fact that they were outward or homeward bound. At the same time the Committee are fully sensible of the desirability of increasing by all possible means the power of fog horns, and the general adoption of some form of "siren" (an improved steam whistle) for use on board ship.

3. The Committee on Collisions in Fogs has confined its attention, in this preliminary report, to collisions of *steamers* in fogs. The Committee has examined orally, and by aid of printed questions widely distributed, a considerable number of witnesses, including shipowners, officers of the Royal Navy, and of the merchant service.

4. It has been the Committee's aim, among other important questions, to ascertain what is the general practice in *steamers*, including both Men-of-War and merchant ships, as to the *very* important question of the *speeds* maintained by steamers during fogs, both in the *open ocean* and in *narrow waters*.

5. The law laid down in the International Regulations for Preventing Collisions at Sea,* is that every ship shall in a fog go at "moderate speed."† The Committee has no doubt, judging by the evidence, that the illegal practice, pursued by many steamers, of proceeding in fogs at speeds other than "moderate," is not only very common in the merchant service, both in the "open ocean" and in "narrow waters," but is the almost invariable practice in the "open ocean" by many of the most important lines of steamers.

6. The Committee has no reason to doubt that the 'law' is fairly well observed in Vessels of War. The Naval Regulations prescribe *four knots* as the speed of vessels in a fog in a fleet, and this appears to be rarely exceeded

* The Regulations for Preventing Collisions at Sea have been prepared by the English Government, and submitted to all foreign mercantile nations, and adopted by twenty-eight of them, and thus made international. These nations are:— Austria-Hungary, Belgium, Brazil, Chili, Cochin, Denmark, Ecuador, France, Germany, Great Britain, Greece, Hawai, Italy, Japan, Kattywar, Khelat, Kutch, Netherlands, Muscat, Norway, Portugal, Russia, Spain, Sweden, Travancore, Turkey, United States, Zanzibar. These Regulations can be obtained of J. D. Potter, 31, Poultry; and of E. Stanford, 55, Charing-cross, for twopence.

† Art. 13 urges that "every ship, whether a sailing ship or steamship, shall, in fog, mist, or falling snow, go at a moderate speed."

in fleets. In single ships-of-war the assumed urgency of the sailing orders would probably in some cases lead to the speed being in excess of a "moderate" speed, but the International Regulations are as binding on captains of Men-of-War as on the captains of merchant ships, and damages have been recovered in the same way from captains of Men-of-War as from the captains or owners of merchant ships.

7. In a great deal of the evidence the Committee has obtained from captains of merchant vessels, the witnesses have not hesitated to state plainly to the following effect, viz., that the practice of proceeding in fogs at speeds other than "moderate" is very common, if not universal, in the *open ocean*, in the principal lines of steamers. This evidence has been given to the Committee on the understanding that the names of the witnesses should not be disclosed.

8. The readers of this report must, therefore, take the above statement on trust, as also that evidence has been invited and obtained from officers of the principal lines of steam packets, with consent of the directors or owners.

9. The question that the Committee had to determine, so soon as it arrived at the conclusion that many of its witnesses were confessedly engaged in deliberately and frequently breaking the law, is not a little embarassing. It appeared to the Committee that the question submitted to them had now assumed a very grave aspect, and that it might be well to record all the circumstances of the case in a *preliminary* report, and place it before the Council of the Society of Arts, for their decision as to the further pursuit of the inquiry by this Committee; or whether, after careful consideration, it may not be better that such an important inquiry be transferred to some official body clothed with wider powers, and enabled to examine witnesses on oath.

10. If loss of life were caused by a collision of ships in a fog, and was followed by a civil action, and it was proved that one or other of the captains was driving his vessel at a speed other than "moderate," it would be open to the jury to bring in a verdict of manslaughter against the captain. The Courts that take cognisance of collisions are given below.*

11. The Committee has no reason to doubt, after receiving the evidence alluded to above, that numerous vessels belonging to some of the most important steam-ship companies—ships of great value, crowded with passengers—are daily and hourly being driven through fogs in the open ocean, by captains who are knowingly breaking the law, and in danger of the above punishment. Now if the "law" is a wise one, or, in other words, if "moderate" speed in a fog be the safest to all concerned, and if speed other than moderate be dangerous, these captains are wrongly imperilling the lives of their passengers and crews, and should be restrained in so doing.

12. It is evident that even the fear of the penalties incurred for manslaughter, when added to other punishments, such as forfeiture of "certificate," loss of position, &c., has no sufficient deterrent effect in this case. Whether the captains referred to share the opinion of the law-makers, that there is more danger of collision, and from collision, when going *fast*—or rather at speed other than "moderate"—in a fog than there is when going at "moderate" speed; or, on the other hand, entertain the opinion that there is more safety in going at a higher speed than "moderate," their practice appears to be the same.

11. But even in the former case, viz., in that of captains whose opinion (as seamen) is in favour, as a matter of prudence—of prudence apart from law—of limiting their speed to "moderate" in a fog, other considerations step in—the *requirements of the Post-office*, the *passengers' anxiety for a quick passage*, the *desire of the owners of the cargo for quick transit*, or the *owners' wishes*; and full speed in fogs in the open ocean is the rule, moderate speed the exception.

12. For whatever reason, the practice appears to be almost universal to break the law, and maintain full speed in fogs in the *open ocean*. Is this satisfactory? The Committee is unanimous in opinion that it is not satisfactory.

* The proceedings in collision cases are as follows:—

A quasi-*Criminal* proceeding in the Wreck Commission Court, in which the question to be decided is whether the master or officers of one or both ships were to blame, and whether it would be proper, under the circumstances, to suspend or cancel their "certificates."

2. A purely *Civil* proceeding in the Admiralty Division of the High Court, before the Judge and two Assessors, as to which vessel was in fault, and by which of them the damage should be paid.

3. A purely *Civil* proceeding before any of the Judges of the High Court, and a jury, to decide precisely the same question.

4. A *Criminal* proceeding before a Judge and jury, to determine whether the master or officers, whose conduct is impugned, shall be punished criminally.

In the *first* of these cases, there is an appeal to a Divisional Court, thence to the Lord Justices. In the *second* and *third* there is an appeal to the Court of Appeal (with sometimes an intermediate hearing before the Divisional Court), and, finally, all three to the House of Lords. In the *fourth* case, the criminal trial, there is an appeal, only in certain cases, to the Court of Criminal Appeal. The findings in all the Courts may differ.

13. Three courses appear to be open to the Legislature, if the evidence this Committee has received is confirmed on oath.

(*a*) To preserve the "*status quo*."

(*b*) To make the punishment for infringement of the law more stringent and deterrent, and define more clearly the word "moderate"; as, for instance, say, not exceeding 6 *knots*, or the lowest speed at which steerage-way can be maintained, if in any case that speed be more than 6 knots.

(*c*) To alter the law, and free the captains from the existing obligation to lower the speed to "*moderate*" in *fogs* on the *open ocean*; leaving the existing law applicable to ships in "*narrow waters*." N.B.—The the latter expression is defined further on.

14. The Committee need hardly say that there are difficulties surrounding each of these courses—it is, and must be, a choice of evils—and in the Committee's opinion it will be well that this, their *preliminary* report, should be submitted to the Admiralty, to the Board of Trade, and be made public. So that, after the question has been well ventilated, it may be re-approached either by this Committee or by some other body.

15. The Committee do not hesitate to say, however, that they are unanimously of opinion that to adopt the *first* course, the "*statu quo*," would be most objectionable; and that without giving any positive opinion at present, they are more in favour of the *third* course than of the *second*, and see no fatal objection to certain large open portions of the ocean being defined in the new Regulations, say all positions outside 50 miles' distance from land, as by implication exempt from the obligation on steamers in such positions to go at moderate speed in fogs. N.B.—The distance, whether 50 miles or more, is a detail, but requires careful consideration. Any land such as the Madeira, Azores, &c., would be protected by a 50-mile limit, within which the privileges of "open ocean" should not extend.

16. There are objections of course to such a modification of the existing law; but the proposal, in the opinion of the Committee, without binding themselves to its approval, is well deserving of consideration by shipowners, seamen, &c. Large tracts of the ocean would be, so to say, privileged in fogs as "open ocean," and in much smaller tracts, under the designation of "narrow waters," ships would be protected from vessels at "immoderate" speeds. Its effect on the navigation of steam vessels would probably be this, that captains on passing in fogs from "open ocean" to "narrow waters," or in other words when within fifty miles from land, would either comply with the law, and proceed at "moderate" speed, or would redouble their precautions and multiply their "look outs;" for if they did not comply with the law, and there and then "moderate" their speed, and a collision with loss of life ensued, the jury (in view of the alteration of the law into a closer conformity with almost universal usage) would probably not hesitate to award the full penalty attached to manslaughter.

17. At present, the practice of running at full speed in fogs in the open ocean is so nearly universal, and so ably defended and ingeniously justified, that it is very possible no jury would convict.

18. Were the above suggestions adopted, the offences now constantly practiced against the law imposing "moderate" speed in fogs, would be confined to vessels *not on the open ocean*, would be infinitely diminished in frequency, and therefore more controllable. The new law would probably be regarded by shipowners, captains, owners of goods, passengers, the Post-office, as *reasonable*, or at all events more reasonable than the present law, and obedience would be more readily given. Vessels that had crossed the Atlantic at full speed in a fog, under sanction of the amended law, would be more likely to "moderate" the speed in "narrow waters" than would be the case under the present law.

19. Vessels would still occasionally be run in "narrow waters" at higher speeds than "moderate:" collisions would still occur, and some loss of life, but the whole question would have advanced a stage, and the minds of the public would be prepared for further changes if found necessary. At present, and this is a very important consideration, the infraction of the law as to "moderate" speed in fogs is *never* taken cognizance of *except in cases of collision*, but if the proposed changes were made, the evidence of the logbooks might procure conviction at the end of the voyage, which, if followed by a fine levied on the captain, even if paid by the owners, would have a deterrent effect, especially if the fine were increased at each conviction.

20. The Committee have had the advantage of receiving the evidence of shipowners of wide experience, who look upon the question from a different point of view from the Committee, as also from that of their own captains, &c., and

the opinions on this matter of the former class viz., shipowners require careful attention.

21. The managing director of a very important line of steamers produced the printed orders issued by the directors to their captains. In *one* set of regulations, said to specially apply to the management of the ship in fogs in "narrow waters" the official international regulations were emphasized with great stringency; no language could be stronger than the orders of the directors that reduction to "*moderate*" speed, down to "*stopping*," should be always practised in fogs." In another set of orders, from the same directors, applicable to the *open ocean*, the directions were confined to a few words, saying, "the captains were in fogs to "*comply with the law*."

22. The directors of these companies are well aware that their captains break the law constantly, in fact that they navigate their vessels on almost every voyage, and sometimes throughout whole voyages, with, metaphorically speaking, ropes round their necks, and at first sight it might be supposed that the directors of a company whose ships were so conducted in defiance of the law would welcome the prospect of a change in the law; or would, at all events, when in the *open ocean*, wish to see their captains relieved of this inconvenient appendage; but, surprising to state, it is not so, these directors wish for the *statu quo*, and the reason may probably be as follows, and although it is not likely that they would assert it, they might admit it if pressed.

23. The general purport of the evidence from shipowners, directors, and captains of merchant steamers in the most important "lines," may be summarised as follows:—Our 'Company' is able to build *first-class* vessels of *great speed* and *handiness*, and *perfect* in all their fittings, *lights*, *sirens*, &c., and able to pay such salaries as to secure the *best captains* and *numerous* and *efficient crews*. The present law is wrong, is absurd, is unseamanlike, and more calculated to produce collisions than to prevent them; nevertheless, let the law remain as it is." But why? this Committee asks. The following is the outspoken answer of some of the captains, the implied answer of others:—"There ought (but we know it is impossible) to be two laws, one for vessels like ours, *of great speed, perfectly handy, thoroughly well found, commanded by men like us of great nerve and vast experience, with subordinate officers like ours, all with masters' certificates*, &c. Such vessels should not be interfered with or embarrassed by any law against full speed under any circumstances; but slower, less handy, less well found vessels, commanded by comparatively inexperienced nervous men, become a nuisance if they attempt to go at full speeds in fogs — and, therefore, in theory, there should be a *second* law, constraining such vessels not merely to go at '*moderate*' speed but to '*stop*' in a fog, and *keep on signalling their position;* they are dangerous to themselves and to us if they attempt to move in a fog, and some of them are aware of the fact, and do stop.*" Finally, *we must break the law*, or we shall lose our positions, and our company will lose its *freight*, *passengers*, and *mails*. On the whole, therefore, recognising the impossibility of there being two laws, one for well found, handy vessels of great speed, and one for other vessels, we prefer the *status quo*, and will take our chance of collisions, and convictions of manslaughter, loss of certificates, &c."

24. This view of the matter the Committee believes, judging by the evidence, to largely prevail among the directors and captains in first-class lines of steamers. The evidence given by many persons in this inquiry is liable (very often quite unconsciously to the witnesses themselves) to be twisted by oblique motives, whether personal or caused by *esprit de service*, and this must be carefully borne in mind on any future inquiry.

Proceedings of the Society.

INDIAN SECTION.

Friday, April 25, 1884; the Hon. Sir ASHLEY EDEN, K.C.S.I., in the chair.

The paper read was—

THE LAW OF LANDLORD AND TENANT IN INDIA.

BY W. G. PEDDER.

I had, last year, the honour of reading before this Society a paper in which I endea-

* A blindfolded man, walking about in a room, would much prefer that all other blindfolded persons should stop and indicate their positions instead of continuing to walk about. A person obliged to move quickly in a dark room would rightly consider his chances of collision with the furniture increased if the articles were also moving instead of at rest.

voured to sketch the history and nature of proprietary rights in land in India. It was then suggested to me that it would be useful to show, in a somewhat similar form, the relations of the proprietors and their tenants. I attempt this task to-night with diffidence, but I hope that, as circumstances have led to my paying much attention to the subject, a general view of it may be useful, even to those who are far more intimately acquainted with it than I can pretend to be, as regards the particular provinces in which they have served. I shall confine myself to a description of existing tenancy laws, and of the circumstances which led to their enactment; and this paper will not deal with the ryotwari provinces, not that tenant-right questions have no existence in them, but that they are of minor importance where the majority of the actual cultivators are proprietors, not tenants, of their holdings, and pay revenue to Government, not rent to a landlord.

The most experienced Indian officials have always held that, in whomsoever the proprietary right might be vested, at least one very large class of the cultivators, variously described as permanent, hereditary, or settled ryots, have from time immemorial enjoyed a customary right of retaining their holdings as long as the fair or usual rent is paid. This proposition lies at the very root of the landlord and tenant question in India, and I think it well, therefore, to cite a few among many authorities in support of it, selecting those which are of earliest date, and which, therefore, relate to the position of the cultivator before it was modified by many years of British law and administration.

The Instructions to the Supervisors of Revenue, in 1769, laid down among the objects at which they were to aim, that the ryot should be secured in the enjoyment of his property, subject to the legal due of Government. In 1779, Warren Hastings said that his purpose in certain measures was to secure to the ryots the perpetual and undisturbed possession of their lands, and to guard them against arbitrary exactions. And in a subsequent controversy with Sir Philip Francis (the reputed author of the letters of Junius) regarding those measures, Hastings explained that the words just cited were not meant to imply "any positive or exclusive right of possession, contradictory to the rights of property vested in the zemindar;" but that, "while the ryot pays his rent, the zemindar has no right to dispossess him, nor can he by any legal right exact a higher rent than the 'potta' prescribes." Francis, who opposed these views, still admitted that "though the ryot has no direct permanent property in his land, it does not follow that he has no right." Mr. Shore, in his celebrated minute on the permanent settlement, remarked that, "it is generally understood that the ryots, by long occupancy, acquire a right of possession in the soil, and are not liable to be removed;" though this right did not carry the right of sale, and was, so far, short of what Mr. Shore called a "right of property," evidently meaning the *plenum dominium* of the Roman jurists. Lord Cornwallis, in 1790, while arguing against Mr. Shore in favour of the immediate enactment of the permanent settlement, observed that "the privilege which the ryots in many parts of Bengal enjoy of holding possession of the spots of land which they cultivate, so long as they pay the revenue assessed on them, is by no means incompatible with the proprietary rights of the zemindars." In sanctioning the permanent settlement in 1792, the Court of Directors said that they reserved to themselves the power of future interference, "to prevent the ryots from being improperly disturbed in their possession, or loaded with unwarrantable exactions." In 1808, Mr. Hodgson, a high authority, remarked that "two rights can exist under the words 'proprietary right,' of the regulations; the zemindar could possess one right, the ryot another, yet both be distinct rights." In 1812, Mr. Colebrook, another high authority, spoke of "the ancient and undoubted privilege of the resident cultivator, of retaining the ground occupied by him, so long as he pays the rent justly demandable for it." These citations relate to Bengal proper; the following refer to other provinces also. In 1815, the Government of India observed that, "It is a principle, equally applicable to the whole of India, that the resident ryots have an established permanent hereditary interest in the soil they cultivate, so long as they continue to pay the rent justly demandable with punctuality." In 1822, the Government of India, in a resolution on the settlement of the North-West Provinces, recognised "the possession by the great body of resident ryots of a permanent right of occupancy." In 1825, the Court of Directors observed that "the cultivators or ryots" in Guzerat, a province in Western India which had lately come under British rule, "have this in common with the same class in most other parts of India, that they consist of two classes, one proprietary, and one not proprietary," and that "the former class cannot legally be dispossessed of their lands as long as they pay the Government demand." The author of "Land Tenures," a book of authority in Upper India, published about 1830, says that "under the ancient *régime*, hereditary cultivators, as long as they paid the prescribed amount of tax leviable upon the crop they might raise on the land, could not be ousted from it." Finally, in his evidence before the Select Committee in 1832, Mr. Bird said that the class of ryots who, in Bengal proper, are usually called "khoodkasts," were "cultivators possessing a fixed hereditary right of occupancy in the fields cultivated by them, their tenure being independent of any known contract, and they could not justly be ousted as long as they pay the amount or value demandable from them, that being determined according to local usage."

These quotations, covering the first half century of British rule in India, though they have not all precisely the same meaning, still, I think, sufficiently establish the truth of the general principle I have stated. Before, however, proceeding with my argument, I must make one explanation. I have used the phrase, "customary right" of the cultivator. This expression, it has been pointed out by, I think, Sir H. Maine, is an inaccurate one. Rights, as Bentham says, are the creatures of law; a right is an advantage which may be enforced by law; a custom is something regarding which there is no positive law. Now, one of the principal difficulties which encompass the question of the real position of the Indian cultivator is that, before British legislation, there was no law to which he could appeal to maintain him in possession of his holding; his security depended not on positive law, but on the force of the opinion of his neighbours, the sense of justice of his chief or zemindar, and the relative power of the body of cultivators and of the Government or superior holder. I once asked a peasant, on the estate of a petty chief in Kathiawár, if the Thakur could eject him as long as he paid his rent according to the village custom. "Of course he can," he replied; "is he not 'dhani,' (the lord); who can prevent him?" "But," he added, "it would be 'zulum,'" or injustice. In the same way, one of the leading zemindars in Bengal, while arguing during the discussions on the proposed Bengal Rent Law against the existence of any legal right of his tenants in their holdings, admitted that they possessed what he called a "moral right" of occupancy.

It must, then, not be forgotten that the occupancy right of the ryot, though a real, was a vague, undefined, inchoate right only. But it must also be remembered that, previous to British rule, the right of the zemindar himself was very little stronger. In 1789, the position of a Bengal zemindar was thus described by one of the highest authorities, Mr. Harrington. He was entitled to the management of his "zemindari," or estate; yet was liable to be set aside at any moment at the will of the Government. He was privileged to inherit, yet was obliged to renew his title at its demise, on payment of an arbitrary fine. He was authorised to fix (subject, however, to the customary standard of assessment) the rent or revenue of his ryots, yet was liable to have it fixed for him by the ruler. He was entitled to the profits of his management during the period for which his "jama" or revenue demand was fixed, yet was bound to account for all his receipts.

Such was the position of the class whom the legislation of 1793 made proprietors of the soil of Bengal, yet with limitations in respect of the subsidiary rights of the ryot which, as will be seen, were not very clearly defined.

We have now ascertained that, by what may be called the common law of India, certain classes of ryots enjoyed a certain occupancy right. Who were these classes? This is by no means an easy question to answer, especially as the answer must vary in different provinces. Mr. Halhed, in 1832, enumerated eight classes of the agricultural community as generally distinguishable in the North-West Provinces and Behar, the lowest of whom alone could be said to have no connection with the lands they tilled, independent of agreement with the superior holder or landlord. But, perhaps, the classification adopted by Lord W. Bentinck and by Mr. Thomason, when the principles of the settlement of the North-West Provinces were under consideration, may be accepted as generally accurate. These authorities divided cultivators all over India under three great classes.

First, those who cultivated land in a village to which they did not hereditarily belong; cultivators of the "seer" or domain land of proprietors; sub-tenants of permanent or occupancy ryots; cultivators of land newly reclaimed by the proprietors; and persons generally of the lower castes or classes who did not depend solely on cultivation, but supplemented the wages of their labour or the returns of their handicrafts by tilling a little land. Such persons were tenants at will (or, more correctly, since by universal custom any man who ploughs land may reap the crop, tenants from year to year) entirely dependant on the proprietor, and claiming no right not derived from him.

Secondly, the great mass of ryots hereditarily belonging to a village, permanently settled and resident in it. These ryots had acquired by prescription "a sort of possessory title" or occupancy right, not necessarily transferable, terminating if the ryot ceased to cultivate, at a rent liable to enhancement, but still not to exceed what was usual or established, but indefeasible as long as that rent was paid.

Thirdly, those who had a proprietary right, entitling them (save when they held free of revenue) to have the settlement of the Government revenue made with them or their representatives, whether in respect of the lands they themselves cultivated only, as the "mirasdars" of the Deccan, or in respect of the whole village, as the members of a proprietary community, or the village zemindars of the North-West Provinces.

To decide to which of these classes each ryot belonged, which was never done in Bengal, was one of the most difficult and most important duties of the original settlement of the North-West Provinces. And it must be remembered that a process of interchange between the classes was always going on. "Paikhasts," or new ryots, were first induced by the proprietors to settle on an estate; then, by uninterrupted residence and occupation for two or three generations, they acquired a prescriptive right to the fields they tilled, and rose into the second class. On the other hand, proprietors who lost their estates by sale for arrears of revenue, or under decree of court for debt, retained, as hereditary ryots of the second class, the occupancy right in their own domain lands or the fields they themselves cultivated, and are the "ex-proprietary tenants" of modern law.

Finally, it is important to notice that Bengal differs much from Upper India in this, that whereas in the latter provinces the settlement was generally made with the class of proprietary ryots, in the former it was made with the totally different class of zemindars, and that, consequently, the ryots of the third class, so far as they existed in Bengal at the time of the permanent settlement (which, from the long prevalence of the zemindari system there, was probably to no great extent), lost their proprietary rights. In Bengal, consequently, ryots are generally now of either the first or second classes only.

The second question involved in the proposition which we have established is also a difficult and obscure one. What is the usual, customary, or fair rent which the occupancy ryot is liable to pay to his landlord; and how is it limited?

In my former paper, I hope I made it clear that the large landlords of India, the zemindars, talukdars, jaghirdars, &c., as distinct from the cultivating proprietors, are of two classes. Either descendants or representatives of ancient chiefs to whom the Government share of produce—in native revenue parlance, the "Raj-bhag"—belonged; or collectors or assignees of the Government share. It follows that the rents they received from the ryots were originally neither more nor less than the Government revenue. It is a curious proof of this that the early Bengal authorities whom I have quoted speak indifferently of the ryots' legal rent or legal revenue. As I showed before, rents in kind are derived from the old Hindu produce due of the ruler; rents in money from the Mahomedan "bigoti," or cash commutation of that due. These payments, of course, underwent, during the troublous times which preceded the establishment of British rule, all sorts of changes, from local circumstances, from individual caprice, and especially from the rapacity of the Government or of the landlord. Still, it is generally true that, a century or less ago, every village had its own recorded or acknowledged custom of rents, which could not justly be exceeded, and if exceeded, was so by the imposition of some burden extra to the established rent.

Many years ago, I was employed on settlement work in Ahmedabad, a district of Western India, which had suffered terribly during the 17th and 18th centuries from successive waves of Mahomedan and Mahratta conquest. I found that, soon after the introduction of British rule, a paper had been drawn up for each village, showing, from its records and the information of old Patels, its history and customs. Among other curious information was a detailed statement of the customary rates of rent or revenue, whether, as the case might be, shares of produce, cash crop-rates, rates according to the quality of the soil, or any of these varying with the caste of the cultivator. But almost always these rates were supplemented by the cesses or extra imposts which, in Bengal, are called "abwab," and in Western India "veeras," or "babtis;" some directly on the land or crop; some on the plough; some on the house or family; and each for a particular purpose, as to provide for the marriage of the lord's son; for the travelling expenses of the district officials, and the like. Now, the meaning of these cesses, which have always formed an important feature in the rent question in Bengal, was that the people preferred to pay a new exaction in this shape rather than in that of a direct enhancement of the rate, hoping that at some time the lord or ruler would remit the extra demand, avowedly imposed for a special and temporary purpose.

It must be observed that the customary rates regulated or limited the payments of tenants at will as well as those of permanent or occupancy cultivators. These rates were, as Lord Cornwallis observed, commonly quite as high as any ryot could afford to pay. In fact, the rents paid by tenants at will were usually not more but less than the customary rates. A tenant at will bargained for the temporary cultivation of a field at a rate lower than the established rate; when by prescription he acquired its permanent occupation, his fixity of tenure enabled him to pay, and justified his landlord in demanding, the full rate.

I now come to an inquiry, the answer to which will probably explain the shape assumed by British rent-law legislation. Since the rents received by private landlords were based on customary rates derived from State authority in some shape, and since a probable result of the establishment of regular tribunals is that custom, interpreted and enforced by them, hardens into legal right, why did not the earlier British rulers adopt generally the principle of the Judicial Rent?

In the first place, while they felt strongly the difficulty of Government fixing the rent of particular holdings, or even laying down any standard by which rents in general might be adjusted, they believed that usage was strong enough to regulate rents, that the relations of landlord and tenant were sufficiently defined by popular feeling to enable the courts to ascertain individual rights in case of dispute, and that, therefore, the people might safely be left to settle rents themselves. This view was strongly urged by Sir P. Francis as long ago as in 1771, and has often prevailed in more recent times, notably, when the Oudh rent-law was enacted. It was overlooked, I think, that the increasing pressure of population on the land would tend to strengthen the landlord; that the desire of immediate advantage would generally influence him more than a traditional sense of justice; and that British courts would lean to English doctrines of landed property.

Next, an opinion, now unfashionable enough, was held half a century ago as hardly admitting of question, that the English notion of the contract relation of landlord and tenant is economically preferable to the Indian notion of the status relation. Lord W. Bentinck, when rejecting, in 1832, Mr. Bird's proposal that the rents of all resident cultivators in the North-Western Provinces should be fixed by Government for the term of the settlement, cited with approval a dictum of the Government ten years earlier, that "the system which attaches to the land various permanent interests, independent of any contract between the parties, though it cannot without cruel injustice be destroyed where it exists, is not one desirable to establish." It is not surprising that the earlier British authorities, holding this view, should have contented themselves with refraining from direct interference with rights which they thought economically injurious, and should have left them to take care of themselves, not without some hope that they would gradually give place to a preferable system.

I now come to the second part of my subject, and shall attempt to show how far the rights I have tried to describe are protected by existing enactments. The law differs considerably in different provinces, and because the Bengal law is the foundation of much other legislation, I must begin with Bengal, though its land law has lately been treated of before this Society by a much higher authority than I am, Mr. Seton-Karr.

The Code of 1793, which gave legislative force to the permanent settlement, acknowledged the zemindars to be proprietors of the soil, and, at the same time, declared it to be their duty to "conduct themselves with good faith and moderation" towards their tenants, and reserved to Government the power of at any time legislating for the protection and welfare of the latter. It is, however, a mistake to suppose that the Government of Lord Cornwallis confined themselves to the expression of a hope that the zemindar would respect the rights of the cultivators. On the contrary, they, at the same time, enacted elaborate provisions for the protection of those rights, which, believing as they did that the fixing of the Government revenue, the mutual interest of the parties, the popular sense of justice, and usage if reduced to writing and made enforceable by the Courts, would all operate in that direction, they were perhaps justified in anticipating would prove fully adequate for the purpose.

These provisions are contained in the "Potta" Regulations, VIII. of 1793, and IV. of 1794. I must explain that the word "potta" is sometimes rendered "lease," and on this mis-translation an argument that the ryot's tenure depends on his lease, and, therefore, on contract, has been founded. In fact, as what follows will show, a "potta" is an instrument defining an existing tenancy.

The regulations enacted that every ryot was to receive a "potta," containing either a specific sum as the rent of the holding, being the "usul," or customary rent, consolidated with the existing established cesses; or, where rents in kind or crop rates were usual, an exact specification of the terms. That no new cess was to be imposed on any pretence. That the form of "potta" was to be subject to the collector's approval. That if a dispute arose between landlord and tenant as to the amount or rate of rent to be entered in the "potta," it was to be determined in the Civil Court, according to the rates established in the 'pargana' for similar lands. That "pottas" were to be perpetually renewable at rates not exceeding the established pargana rates. That regular receipts were to be given for all rent payments; and that village accountants and village accounts were to be maintained.

In these rules, it will be observed, there are no provisions relating to either enhancement of rents or transferability of ryot's holdings. As regards the latter point, I do not think that it was intended to confer on the ryot the power of transfer, which, Mr. Shore distinctly held, he did not then possess. But the subsequent action of the Courts, which will always sell in execution anything in possession of a debtor which anyone will buy, has since, I believe, made transferability of a ryot's holding the usual rule. As regards the first point, it has been plausibly argued that the "established rate" was not meant to be enhanceable. I cannot discuss the grounds of this opinion, regarding which Mr. Justice Field has an argument which seems to me conclusive, but would point out that the fact of rent and revenue being originally identical shows that rent was always, though within certain limits, liable to enhancement. But I cannot but suspect that the framers of the regulations overlooked the question of enhancement. They knew that, in Lord Cornwallis' words, the established rent was generally equal to the utmost the cultivator could afford to pay, and it is not surprisiug that they did not foresee the economic causes which would soon render it inadequate.

If the potta regulations had been enforced, they might have afforded to the permanent ryot all the protection he could justly claim. But "never," says Mr. Justice Field, "did a legislative measure fail more absolutely." The chief among many causes of this failure seem to have been these. It was not the interest of the zemindars to give pottas which would limit their power over their tenants; they declined to do so; and the district officers were not powerful enough to enforce obedience. The ryots did not demand pottas for reasons to which I have already referred. They thought that to accept a written potta would weaken their status right, and they objected to the consolidation with the established rates of the cesses, which they looked on as illegal exactions. It was found impracticable to enforce the maintenance of the authoritative village records, contemplated by the regulations, and in their absence the Courts found it impossible to determine the prevalent pargana rates. Hence, rents and holdings were never defined, regular reeeipts were disused, illegal cesses continued to be exacted, and evictions and arbitrary enhancements became common.

Subsequent legislation all tended to weaken the rights of the ryots. Regulation VII. of 1799 gave the zemindar summary power of distraining for rent, and the effect was that, in case of a dispute regarding the amount of rent, the ryot was compelled either to pay at once the sum demanded, and thus to admit that he owed at that rate, or to enter on expensive and doubtful litigation. Regulation V. of 1812, abolished the collector's control over the form of pottas, and, in effect, the principle of determining the amount of disputed rents in accordance with established pargana rates. The Sale Laws, Regulation XI. of 1822, and Act XII. of 1841, under which existing pottas were made cancellable on the sale of an estate for arrears of revenue, and the latter of which, for the first time, made it legal for a purchaser to enhance at discretion the rents of, or to eject any ryot, save one who had held at a fixed rate from a period anterior to the permanent settlement, practically placed it in the power of a purchaser, or even, by means of a collusive sale, of any landlord, to get rid of all rights of his ryots but those of the few holding at fixed rates. The practice of sub-infeudation, which, always common in Bengal, received in the early part of the present century a calamitous extension, placed the ryots under the control of speculators in land whose only object was to exact the highest possible profit on their bargain. Finally, not only was the law greatly in favour of the landlord, but the cost, trouble, and complication of legal proceedings, and the power of wearying out an opponent by appeals, gave the richer party so great an advantage in litigation, that to refer the ryot to Court for a remedy against his landlord was tantamouut to a denial of justice; while the power of compelling the attendance of a recusant ryot at the zemindar's office, where he was liable to all sorts of ill-usage with practical impunity, afforded to the landlord a tremendous engine of illegal oppression.

During the whole of this period, while local legislation and practice were rapidly destroying the rights of the ryots, the Government of India and the Home Government uniformly acknowledged and regretted the injustice of this result. And, in 1859, a determined and not altogether unsuccessful effort was made to remedy the evil.

The following are the most important provisions of Act X. of 1859:—

Every ryot is entitled to a potta, showing the area of his holding, the amount of his rent, and its instalments. Ryots who hold at rates unaltered since the permanent settlement, are entitled to pottas at those rates, and the rate having been unaltered for twenty years, raises a presumption of its having been unchanged since 1793. Ryots having occupancy rights are entitled to hold at fair and equitable rates, and the existing rates are to be presumed fair till either party shows the contrary in a suit. Every ryot (not being a sub-tenant of an occupancy ryot) who has cultivated or held land for twelve years, is to have occupancy right in that land (not being domain land of his landlord) so long as he pays the rent payable on account of it. The rent of an occupancy ryot is liable to enhancement on three grounds only; (*a*), that the existing is below the prevailing rent payable for similar land by the same class of ryots in the neighbourhood; (*b*), that the value of the produce, or the productive power of the land, has been increased otherwise than by the agency of the ryot; (*c*), that the actual area of the holding is greater than the ryot has been paying for. An occupancy ryot is entitled to claim reduction of rent on two grounds, the converse of the two latter grounds of enhancement. The acquisition of occupancy right can be barred by written contract. A ryot not having occupancy right is entitled to a potta only at such rent as he may agree on with his landlord. The exaction of cesses, or of anything in excess of the rent specified in the potta, is prohibited. All ryots and sub-tenants are to receive detailed receipts. No ryot or sub-tenant is liable to enhancement unless served with notice of enhancement for the ensuing year, and is entitled to contest such enhancement in Court. Any ryot is entitled to relinquish his holding on notice. A ryot is liable to ejectment if in arrear of rent at the end of the year, but if an occupancy ryot, or holding on an unexpired lease for a term, he can be ejected only under a decree of Court. The rent is recoverable either by suit or by distraint of produce before it is stored, but only of the land on which the arrear is due, and for one year's arrear.

This law, re-enacted in substance by Act IX. of 1868, is the existing land-law of Bengal. It must be allowed to be, on the whole, fair and just in principle. Some of the reasons why it has failed, at least in great parts of the province, effectually to protect the rights of the cultivator, and why the fresh legislation now in contemplation has become necessary, will be seen when I come to the law of the North-West Provinces. I will now mention two only. The first is a cause peculiar to Bengal. In that province alone of India there has never been a general cadastral survey, nor any regular record founded upon it of holdings, rents, and payments on account of rent, while, as has been stated, it was found impossible to maintain the village accountants and village records, contemplated by the Code of 1793. Now it will have been seen that the decision of almost all suits under Act X. turns upon one of three points, whether the tenant has actually possessed the land in dispute for a certain period; whether he has paid the rent for it; or what is the existing rate of rent for that land, or similar adjacent land. These points, in default of an authoritative record, such as that which exists, for instance, in the permanently settled districts of the North-West Provinces, the Courts can decide only on evidence adduced by the parties; and Bengal has long been notorious for the prevalence of perjury, a character which it has in no small degree obtained from the temptation which the absence of public records has given to the people, both landlords and tenants, to strengthen their cases in land suits by false evidence. Hence the Courts have commonly failed to do justice in rent suits, because all the evidence on which they can decide is either oral, commonly false, or documentary, produced by the parties, at least under a strong suspicion of being forged.

The other reason is this: Act X. has been interpreted (wrongly it has lately been decided) to mean, not that a tenant who has held continuously for twelve years has occupancy right, but that an occupancy tenant is one who has held continuously for twelve years. This interpretation has deprived of their customary rights the permanent ryots, khoodkasts, kadims, and the like, who could not prove continuous possession, and has enabled landlords, by shifting the tenant's fields within twelve years, to bar the accrual of occupancy right.

I now proceed to the land law of the North-West Provinces.

It has been stated that it was originally proposed by Mr. Bird that the settlement officer should, when making a settlement, fix for its term the rents of all permanent tenant cultivators. This proposal was rejected by the Government of Lord W. Bentinck, but still what were considered to be existing occupancy rights were recorded by the settlement officer. In course of time, however, the necessity for a more definite law on the subject became apparent, and Act X. of 1859 was made applicable to the North-West Provinces. After a few years' experience of the working of this law, it was found to be defective in several particulars. A landlord could worry his tenants by bringing enhancement suits at short intervals. The rights of occupancy tenants as regards inheritance, transfer, and sub-letting, were not clearly defined. There were no provisions for compensation for tenants' improvements. No power was given to the settlement officer to fix the rents of occupancy tenants, and consequently, landlord and tenant were obliged to settle—by tedious, expensive, and irritating litigation—the adjustment of rents which a revision of settlement made necessary. Finally, there were no provisions for the protection of ex-proprietary tenants. A proprietor who had lost his proprietary right by sale under decree of Court for debt still cultivated his "seer," his domain land or home farm, and considered it in the highest degree cruel and unjust that the new proprietor should be able to evict him from it, or to enhance his rent at discretion.

Acts XVIII. and XIX. of 1873 were passed to remedy these defects, and are still the land law of the North-Western Provinces, though the former Act was repealed and re-enacted with some modification by Act XII. of 1881. This law retained in substance the provisions of Act X. of 1859 regarding tenants at fixed rates in permanently settled districts; regarding the accrual of occupancy right by twelve years continuous possession; and regarding the grounds on which the rent of an occupancy tenant may be enhanced or reduced. But it added many new and important provisions, the chief of which are the following:—

A person who loses his proprietary right in any estate is entitled to occupancy right in his "seer" land, at a rent of 25 per cent. lower than the prevailing rate payable by tenants at will. Occupancy rights (except of tenants at fixed rates, which are heritable and transferable), are declared generally heritable, but not transferable except between co-sharers. If a tenant holds on a written lease for a fixed term, the period of twelve years, possession during which confers occupancy right, begins to count from the expiration of the lease, and neither enhancement nor reduction of the rent stipulated is claimable during the currency of such a lease. Otherwise, the rent of an occupancy tenant once fixed by the settlement officer or on suit, cannot ordinarily be enhanced for ten years, or until a revision of settlement; but, during the period of fixation, the landlord may sue to enhance on two grounds only, increase of area of the holding, as by alluvion, and increase in its productiveness, effected otherwise than by the agency of the tenant; and the tenant can sue for reduction on the converse grounds. The record of right made on the revision of a settlement is to specify every tenant, the area and details of his holding, and the conditions of his tenure, whether he is a tenant at fixed rates, an exproprietary tenant, an occupancy tenant, or a tenant without right of occupancy. As regards the latter class, the existing rent, and the number of years for which the tenant has held, are to be recorded. Occupancy rents are to be fixed at settlement, for exproprietary tenants at 25 per cent. lower than the prevailing rates of similar adjacent lands held by non-occupancy tenants; for occupancy tenants, if there is any claim for enhancement, or reduction, or dispute as to the actual rent, with reference either to the standard rent-rate of the circle of villages, or to the customary rate paid by the same class of tenants in the circle. Rents in kind are commutable to cash rents by the settlement officer, on the application of the landlord or tenant. Occupancy rents may, after ten years from the date of fixation, be enhanced or reduced by written agreement recorded in the village accounts, or by suit, on the grounds of enhancement laid down by Act X. of 1859. And the collector may, on the application of a tenant, determine at any time the class to which he belongs. The rent of a tenant at will is determinable solely by agreement with his landlord, but he cannot be called on to pay rent higher than that paid the previous year, unless an agreement to that effect has been recorded in the village accounts. Non-payment of rent renders any tenant liable to eviction, but an occupancy tenant only by decree of Court; a tenant at will, only by written notice for the ensuing year, which the tenant may contest in Court. If ejected, any tenant is entitled to compensation for the value of any improvements he has made which have permanently increased the letting value of the land. Any tenant, not holding on a lease for a term, may relinquish his land by written notice for the ensuing year. And rent is recoverable by suit or distraint. The number of tenants is not stated in the North-West Provinces returns. But of the total occupied area, $37\frac{1}{2}$ per cent. is cultivated by tenants having some occupancy right, $38\frac{1}{2}$ per cent. by tenants at will, and the remaining 24 per cent. by proprietors.

The existing law of the North-West Provinces is, it will be observed, based upon Act X. of 1859. This is not the case with the land law of the Punjab, which I will now describe.

Upon the annexation of that province, no law defining all rights in land was enacted, but the principles of the settlement of the North-West Provinces were, in general, applied; and tenants who had held continuously for twelve years were recorded as possessing occupancy right, and their rents were fixed for the term of settlement. In 1855, however, the Chief Commissioner, Sir J. Lawrence, expressed some doubt of the accuracy of this practice, observing that it was rather the nature than the length of a tenancy which entitled the cultivator to privilege. To understand the controversy which followed, one which greatly divided opinion in India, and even in the Council of the Secretary of State, it must be borne in mind that the Punjab is a country of small cultivating proprietors, and that, therefore, nearly all the ryots, who elsewhere would be occupancy tenants, are there themselves landlords. In 1868, there were over 1,700,000 proprietors, some representing each several co-sharers, while there were only 1,650,000 tenants, of whom only about one-fourth were recorded by the original settlement as possessing occupancy right.

When, in 1863, the first original settlements in the Punjab came to be revised, the Settlement Commissioner, Mr. Prinsep, proposed to strike occupancy rights generally off the new settlement record, considering them to have been unjustly admitted at the first settlements. In three districts he reduced 46,000 out of 60,000 tenants, originally recorded as possessing occupancy rights, to the position of tenants at will. His arguments were briefly that, in the times of Sikh rule, a proprietor had an undisputed customary right of ejecting any tenant, no matter what his length of possession; that if this right was then seldom exercised, the reason was that there was nothing to be gained from it, as the Sikh revenue assessment absorbed the full rent of land; but that it was unjust to forbid its exercise when, under moderate assessments, it had become profitable to its possessor. It was replied that a customary right of the exercise of which there were no instances was no custom at all, and could not be established; that under Sikh rule tenants of long standing had a reasonable expectation of continuing to hold as long as they paid their rent; that as a matter of fact, the Sikh Government did sometimes interfere between landlord and tenant; that, therefore, the original settlement was right in protecting the tenants of long standing from the eviction which only the limitation of the Government demand on the proprietor rendered likely; and that it would be unjust, on a revision of settlement, to take away rights which had been acknowledged for twenty years.

So strong, in 1868, was the feeling in favour of the unrestricted rights of proprietors, a feeling which, as will be seen, had just found expression in the Oudh rent-law, that it was probably only the great authority of the Viceroy, Lord Lawrence, "*Clarum et venerabile nomen*," and the powerful advocacy of Sir H. Maine, which secured the enactment of the existing Punjab law, Act XXVIII. of 1868, which was a compromise between the conflicting views. Its general principle was that of confirming the occupancy rights recorded by the first settlements, but of preventing the accrual of fresh ones. Its chief provisions are the following.

In the future, no occupancy right is to accrue by mere lapse of time. But ex-proprietors, and certain other small classes of cultivators, are entitled to occupancy right at privileged rents, 30 per cent. to 50 per cent. below full prevailing rates, and tenants recorded at the original settlement as having occupancy right were to be presumed to possess such right, at rents 15 per cent. below prevailing rates, until the landlord should rebut the presumption in a regular suit. The landlord can sue, once in five years, to enhance the rent of an occupancy tenant, up to the amount limited by his privilege. The occupancy right is heritable, and the tenant may sub-let, and may alienate, in the case of ex-proprietors, &c., subject to a right of pre-emption of his landlord, in other cases with his consent. An occupancy tenant can be evicted only by decree of Court; in the case of ex-proprietors, &c., only for non-payment of rent; in that of others, also on payment of compensation, the amount of which is to be settled by the Court. Tenants at will are entitled to compensation for their improvements; they can be ejected only on written notice for the ensuing year; and their rent can be enhanced only by decree of Court, or on written agreement. There are now in the Punjab about 1,640,000 tenants, about 540,000 of whom possess some occupancy right.

The history of the Oudh tenancy law I can describe only very inadequately. When Oudh was annexed in 1856, two-thirds of the province belonged to a landed aristocracy, the taluqdárs, who, however they had acquired it, actually possessed the ownership of the soil, limited only by certain ill-defined subordinate rights. A settlement of the province was immediately introduced, which, professing to be based on the principles of the North-West Provinces settlement, was, in fact, opposed to the first of those principles. Instead of taking the actual state of property as the basis of operations, and ascertaining, defining, and maintaining existing rights, the policy then in vogue of favouring the cultivator (a policy which, after a violent revulsion of opinion after the Mutiny, appears again to have become predominant) led to the taluqdárs being set aside as mere middlemen, collectors of revenue whose services were no longer needed; and to the settlement being generally made with the actual occupants of the soil, village zemindars and co-parcenaries. The taluqdárs, thus deprived at a blow of their position and their incomes, rushed into revolt in 1857, and were joined by the classes whom the settlement was intended to benefit. On the recapture of Lucknow, early in 1858, Lord Canning issued his famous proclamation, confiscating, with some exceptions, all proprietary rights in the soil of Oudh. But, with a view to the pacification of the province, he granted in the same year to the taluqdárs who submitted an absolute permanent hereditary and transferable right of property in the estates they possessed at annexation, subject only "to any measure which the Government might think proper to take for the purpose of protecting the village occupants from extortion, and of upholding their rights in the soil in subordination to the taluqdárs." This policy, however necessary, was perhaps not much more just to some of the subordinate proprietors and ryots than was the previous policy to the taluqdárs. It is no part of my subject to describe the arrangements ultimately made with respect to sub-proprietors; but as regards the ryots, the present Act (XIX. of 1868) is the outcome of the power reserved by Lord Canning to interfere in their behalf. It is, in fact, the result of a compromise between the view of those who, with Lord Lawrence, held that the reserved power ought to be exercised to give hereditary ryots a large measure of tenant right, and those who, with Sir C. Wingfield, believed that such a policy would both be in violation of the pledges to the taluqdárs, by which the pacification of Oudh was effected, and would be inexpedient, all interference between landlord and tenant being politically and economically undesirable. As will be seen, the latter view prevailed in the compromise, but the Act, as passed, had the great advantage of being assented to by the taluqdárs. It gave occupancy right, heritable but not transferable, at a privileged rent—12½ per cent. below the prevailing rates of the vicinity paid by tenants at will—to a very small class of ex-proprietors, not exceeding 2 per cent. of the whole number of tenants. All other tenants are tenants at will, liable to ejectment or enhancement on written notice from the landlord, but entitled to compensation for their own improvements, to written detailed leases, and to regular receipts.

The last tenancy law of importance is that of the Central Provinces. Here the settlement made certain persons, the Malguzars, proprietors of villages, and gave large classes of the ryots occupancy rights, either absolute or conditional, while the Bengal Law, Act X. of 1859, was extended to the province as its land law. This Act, however, which is inappropriate to the circumstances of the country, did not work well; and, in 1883, a new Act, No. IX., was passed, which differs materially from other Indian tenancy legislation. Its principle is that of confirming occupancy rights already acquired, but of forbidding their accrual for the future by mere lapse of time, while it gives a certain protection to all tenants. Its chief provisions are these:—

An absolute occupancy tenant is one already recorded as such. His rent is fixed by the settlement officer for the term of settlement; he cannot be ejected, and his right is heritable and transferable, subject to pre-emption by the landlord.

An occupancy tenant is either an ex-proprietor, a person who, when the Act came into force, had held continuously for twelve years, or an ordinary tenant, who may hereafter exercise his power of purchasing occupancy right. He cannot be ejected, except on suit for non-payment of rent; his rent is fixed at settlement by the settlement officer, but may be enhanced every ten years, under certain limitations; his right is heritable in the direct line, but not saleable in execution, or transferable without the landlord's consent.

An ordinary tenant is liable to pay such rent as may be fixed by agreement with the landlord; he cannot be ejected, except on suit for non-payment of rent, or for refusing to an enhancement demanded by written notice once in seven years, and, in the latter case, is entitled to compensation for disturbance. He can claim to purchase occupancy right at any time, on payment of two and a-half years' existing rent, and his tenancy is heritable, but not saleable. A sub-tenant holds only on terms of contract. But all these tenancies are subject to certain general provisions, which are these:—

Except during the currency of a lease for a term, any rent is enhanceable at any time, on the application of the landlord, on account of the landlord's improvements. A contract rent may be altered by the revenue officer on a revision of settlement. The revenue officer may, on application of landlord or tenant, enhance or decrease any rent at any time, on account of natural alterations in the land, such as alluvion or diluvion. Rents in kind are commutable to cash rents on the application of either party. An occupancy tenant is entitled to improve his own holding; the landlord, the holding of an ordinary tenant; but in either case, the party not entitled to improve may call on the other party to make the improvement, and make it himself if he declines; and any tenant is entitled to compensation for improvements he has legally made. Rent is recoverable only by suit, and in a suit, the rent payable the preceding year is to be presumed the rent due till the contrary is proved. Distraint is forbidden, but the landlord may prohibit the removal of a crop pending a suit. The details of all tenancies are recorded in the village papers. There are now about 940,000 tenants in the Central Provinces, about 465,000 of whom possess some occupancy right.

No one who candidly examines the laws I have tried to describe, can doubt that they are the outcome of a sincere desire to do justice between proprietor and tenant. At the same time, it may, perhaps, be thought that the ancient rights of the cultivators have not always been maintained to a sufficient extent. The modern occupancy tenant has all he could justly expect; but, perhaps, all the ryots who ought to have had occupancy right do not now possess it. I am myself inclined to this view, and wish that at the introduction of British rule a greater extension had been given to the principle of tenant right. But it does not follow that this would now be expedient or just. Nothing can be more dangerous than to be always tampering with people's property, in accordance with the economical views which may happen to be in the ascendant. To modify rights which have long had a legal sanction, and in accordance with which the relations of the agricultural classes have adjusted themselves, is a serious matter. And it must be remembered that cultivation in British India has doubled itself in the last century, and that the new lands have, to a great extent, been taken up on contract terms.

In what I have just said, I must not be understood as referring to pending legislation in Bengal. The justification for that legislation is that tenant rights, which have been acknowledged by the law ever since the introduction of British rule, the law has hitherto failed effectually to secure.

DISCUSSION.

Sir GEORGE CAMPBELL, K.C.S.I., M.P., thought they must all be exceedingly obliged to Mr. Pedder for having brought into a focus the different tenancy laws existing in India. In India they were apt to be a little provincial. He did not use the word "provincial" in a bad sense, but India was a great Empire, and they were apt to be a good deal confined to particular provinces. So far as he was able to judge with regard to all the greater provinces of Northern India, Mr. Pedder had focussed them in an excellent way. If he might express any disappointment with the paper, it would be that Mr. Pedder had not thought it worth his while to tell them the state of things with regard to tenancy in Bombay and Madras. The prevailing tenures in those presidencies were proprietary, but still he believed there were some considerable tenures, the proprietary right of which was not held exclusively by the cultivators. In Madras there were large tenures under the name of ryot tenures, and he should like to know whether in Bombay and Madras a considerable system of sub-letting had grown up, and if so, upon what terms and conditions, whether the rights of the sub-tenants were regulated by law or by custom, and what had been the outcome of that system. As regards Bengal, the North-West Provinces, and the Punjaub, he could not add anything to what had been said by Mr. Pedder, though he might, perhaps, be allowed to express his entire concurrence in what had been said as to those presidencies. It was sad indeed to find the oscillation of opinion which took place in India, but experience in this country had led him to believe that such oscillation was not peculiar to India. It was almost incredible that, with regard to Ireland, an Act was passed by a Liberal Administration in 1860, which by statute abolished all status tenure, and provided that tenure should be by contract only; that ten years later an Act was passed which took a totally opposite view, and ten years after that came an Act which revolutionised English ideas upon these subjects. Oudh and the Central Provinces had suffered under the system of extreme oscillation of opinion, and the result was very peculiar, but, to a certain extent, Mr. Pedder had scarcely realised the position of things in Oudh. In the beginning of the present century, the modern Oudh was almost identical, with regard to the Government, and population, and tenures, with the North-West Provinces. When Oudh was annexed at the end of Lord Dalhousie's reign, and the beginning of Lord Canning's reign, an order was issued that, in case of doubt, preference should be given to the village zemindars, the larger talukdars being left to prove their right; but when the Mutiny broke out, the talukdars were, for the most part, in possession of their forts and powers, and it was not until sometime later that this class went into rebellion. In order to put a stop to the rebellion, the estates were confiscated; they were re-granted to the talukdars upon the terms stated in the paper, and he thought it was very lamentable that a different settlement had been made from any other part of India, the claims of the ryots being ignored. As regards the Central Provinces, the position was the converse of Oudh. In Nagpore and the Mahratta country everything was identical with that which existed in Bombay, where the ryotwari system existed; and in the Nerbudda Provinces the rights of the ryots were maintained. When the Central Provinces were united under one Chief Commissioner, the wave of opinion had oscillated on the side of great proprietors, and, contrary to facts and justice the headmen were turned into proprietors. Then it was felt that an injustice had been done, and the arrangements which had been described by Mr. Pedder were made. No doubt there was a considerable quantity of rent laws now existing which it would be desirable to revise and consolidate. Taking all the provinces of India, except Oudh, he might accept Mr. Pedder's proposition that so grave an injustice had not been done that it was desirable to abandon the principles of the existing state of things, but that they should proceed in the main on the lines which had been established on the laws which had been in force for some time. He was strongly of opinion that great injustice had been done in Oudh, and that justice should be done to the ryots there.

Mr. E. Kimber said he had looked upon Sir George Campbell as an authority upon Indian affairs, and consequently he came to that meeting for the purpose of ascertaining what was the state of the law in Bombay and Madras, but, unfortunately, he was quite in the dark after having listened to the observations of Sir George Campbell, and also the paper which had been read that evening. Sir George Campbell said he understood that such tenancies had grown up, that such proprietary rights had increased in Bombay and Madras, but there was nothing definite about the statement. The reader of the paper had disclosed something of which the great majority of that audience was ignorant before—he had told them of the difference between the Government and the talukdars. After the Mutiny the talukdars made a demand which was not granted, but something was granted on the condition of their laying down their arms; and if it was just to refuse the demand in the first instance to the talukdars, he should like to know why it was not refused. First they made a demand, then came the Mutiny, and then the grant of the demand. They had that night heard the truth of the matter from Mr. Pedder. Then they were told by Sir George Campbell that there was oscillation both in India and in England, but why was that? Simply because a law was passed, some thirteen or fourteen years ago, making the ryot's interest not only heritable, but transferable, and then another law was introduced in 1883, making it only heritable, but not transferable. Why that law was introduced they had not been told, but he supposed the producers of it were reasonable people, and he should like to know how it was the law was made.

Mr. Pedder wished to point out that the Act which had just been referred to never gave any right to transfer property in the Central Provinces.

Mr. Kimber said he certainly understood Mr. Pedder to say that thirteen or fourteen years ago transferable rights were given to the ryots in some provinces, and that they were taken away in 1883. He had no knowledge himself upon the subject, never having been to India, and he should like to know whether the gentleman who introduced the law thirteen or fourteen years ago in those particular provinces, understood the law as it was then introduced and regulated by the natives themselves. Similar things had occurred in England, where distinguished Judges had interpreted the law as they had understood it, and the House of Lords had afterwards held that the law thus administered was wrong. Having had occasion to discuss the law with the Advocate-General of Madras, he found out that even that gentleman did not understand the law as it was commonly received among the natives themselves.

Mr. Seton-Karr said he never approached this subject without being reminded of an anecdote he had heard many years ago. M. Jacquemont, the French traveller, said to Mr. Holt Mackenzie, "I want half-an-hour's talk with you, to make me understand clearly the land tenures of India." Mr. Mackenzie replied, "I have studied them for the last twenty-five years, and I am not sure that I understand them yet." Without pretending to know as much as Mr. Holt Mackenzie, he (Mr. Seton-Karr) did know more than M. Jacquemont, and he had been struck by Sir George Campbell's remark as to the oscillation of opinion in India. About the time when the Bengal zemindar system had taken root, it was deemed advisable to extend it to Madras, but the revenue authorities there had taken fright, and the ryotwari system was introduced. In his younger days, he heard of nothing but the wonderful system which had been introduced into the North-West Provinces, which, no doubt, in the hands of Mr. Thomason, was a marvel. Then came the Mutiny, and then the indigo disputes occurred, after which a strong wave of opinion set in for substantial zemindars having a stake in the country, but now the tide had turned against the zemindars. When districts were large, and communication imperfect, the zemindars, if they were tolerably strong, had it their own way with the ryots, but if the zemindars were weak, the ryots had it their own way, and consequently the zemindars could not get their rent. The zemindar had power to summon his ryot to his local *kutcherry* for the rent, but it was understood that he had not the power to compel his attendance; and so if the man, when summoned, was strong enough, he turned round and broke the bearer's head; and if he was not strong he had to pay *abwabs* and *dustoori*. That state of things had been considerably altered, though not entirely, by Act X. Act X. might need revision, but at the time it was passed it was no doubt a fulfilment of the pledge made by Lord Cornwallis. That Act was passed by such able men as Colvile, Grant, Currie, Harington, Le Geyt, Sir Barnes Peacock, and, he believed, Mr. A. J. M. Mills, all of whom were most competent men to deal with such a vast and extensive subject. The Act, no doubt, had not done all that was expected, and it might very well be amended; but it was an instalment of the justice due to the ryot.

Mr. J. M. Maclean said he did not possess sufficient technical knowledge to enter into a discussion of the question on the lines laid down by Sir G. Campbell and Mr. Seton-Karr, but he should like to attempt, having heard the paper and listened to it with great interest, to draw the moral of the paper as regards the mistakes that had been made in the land legislation of India. He could not help thinking that the cause of the failure might be summed up in the expression of Mr. Shore, that the most mischievous person in India was the zealous revenue official. Almost all the mistakes had arisen from this cause, that the persons charged with the government in the different provinces had some preconceived theory of their own to carry out, and had set about attempting to provide one uniform system for the settlement of the land throughout India. In Bengal, no doubt, a great mistake was made at the time of the permanent settlement, by creating the system of landlords holding great estates, with tenants holding under them. In Oudh, the pendulum had swung to the opposite extreme, and large landlords were deprived of their estates, because some people had got hold of the fixed idea that it was necessary to create a great system of tenant right. That system had to be abolished, because the talukdars took up arms against the authority of the British Government. In the Southern Mahratta country, the idea prevailing amongst the modern settlement officers had been not very different from that which found favour with Mr. Henry George, that was to say, in favour of the nationalisation of the land. The effect of a good many of the recent revisions of land assessment in that part of the country had been to raise the Government demand to a point above what the tenant ought to pay. So far had it gone that the State had been actually obliged to pass a law to exempt certain property of the ryots from attachment, the result of the law being naturally that capital had been driven away from the land, the ryots being more pauperised than ever they were, and the State would have to collect its rents from a pauper tenancy. These were all mistakes which arose from the same cause, the adoption of some fixed idea that a particular system of land legislation must be the best for all countries. What they had to do was to recognise the existing rights of landlords and tenants as far as they could. The Government ought to have regard to its own prospects, and what would be the result of making revolutionary changes. The great danger now was with regard to the zemindars. Bengal had no permanent settlement at all, owing to the way in which power was reserved to the Government to interfere in favour of ryots, and so long as that power was left in the hands of the Government, the ryots would never be satisfied until the whole of the property of the zemindars was transferred to them. He hoped the Government would divest itself of the power of interfering, on behalf of the ryots, and give Bengal a permanent settlement.

Sir William Rose Robinson, K.C.S.I., observed that Mr. Pedder was much to be commeserated in his study of the history and of the provisions of British legislation on the subject of landlord (or "proprietor" as he terms the zemindar) and tenant. The expressions, of course, traverse Hindu agrarian common law, whose language has no equivalents for the terms "rent," "tenant," "occupancy," and the like, throughout the various provinces of North India. Mr. Pedder's precis may be accepted as accurate and exhaustive, so far as it goes, but it presents a sad hotch-pot of confused and provincial enactment, characterised throughout by the same alien and hybrid strain, with modifications in different provinces to suit the taste of local promoters; but everywhere likewise by the same wide divergence from (perhaps from contempt of) the true prescriptive conditions of Indian agrarian law, and the institutions of Oriental society. Now there is, he observed, no provincialism or isolation about the ancient agrarian common law of India—of all India, he held, because, broadly speaking, the ancient land law was homogeneous and all-pervading in respect to the ryotwari ownership of land, and the regulation of the burdens its holders had to bear, and as to the position of the zemindar as a hereditary owner, collector, or assignee of the land tax; and no more assured, wise and equitable law ever ruled the relations of all the constituents of rural life in any country than that which governed the prosperous civilisation of India from times far prior to the Christian era. By withdrawing what he calls the ryotwari provinces from his own consideration, and from the contemplation of the meeting, Mr. Pedder shuts off the best evidence in respect to the legal bearings of this matter from a national standpoint, and closes the most important field of research and means of correct judgment. He would remark incidentally that a ryot is not as a rule a cultivator, as apparently assumed by Mr. Pedder, but a prescriptive proprietor with tenants (properly so-called) under him. As proprietor, he pays the State taxes; but under the prescriptive law of the country he possessed a title of the most complete character to his land. It is not the fact, as frequently alleged in this paper, that the ryot of India held his land on the condition of paying either taxes to the State, or rent to some superior claimant in this respect. Eviction and ouster are absolutely creations of British legislation, so far as India is concerned. Under moderate taxation, such as characterised legal Indian fiscal adjustments, the contingency did not arise, and rack-rents had no existence under the conditions of its rural society. A fee, or regulated per-centage on the collections (termed in the south the Poligar's "merah" or some equivalent expression), was the only due which the hereditary chief, collector, or assignee of the public demand, could rightfully claim; and the "abwâbs" which he added to his income were a direct acknowledgment that he was not entitled to increase the regulated fiscal assessment of the ryot's property to public taxation—call it "tumâr," "tiruvah," "kandâyam," or what we may. In short, it would be impossible to conceive a more complete and indefensible title to property than that recognised by the ancient Hindu common law on behalf of the ryot of India. It would be impossible to employ language wider from the fact than the terms used by Mr. Pedder, when he tells this meeting that "It must not be forgotten that the ('occupancy' is not a Hindo legal term) right of the ryot was vague, undefined ,inchoate right only." At no time was this the case; and the instructions to the superiors of revenue in 1769, as well as Mr. Hastings's minutes, *passim*, clearly show that it was not the case, even in Bengal, when the British rule intervened towards the end of last century. Mr. Pedder had failed, he observed, to apprehend the object and nature of the "potta," which he describes as "an instrument defining existing tenancy." It was an instrument intended to distribute the recognised revenue demand proportionately amongst the prescriptive owners of land, and not a muniment of title or "defining existing tenancy."

Mr. Seton-Karr said it was so in Bengal.

Sir William Robinson gathered from the remark, that the misapprehension is more wide-spread than he was prepared to learn. The "potta," where it existed, might be received in courts of justice as evidence of occupation, because there is a presumption that the person who pays the taxes is in occupation, but under what conditions it was not intended to show. But this is the only function which it fulfils. The legislation in respect thereto proved wholly inoperative, and was, he understood, early removed from the statute book. Zemindars had no intention to extend to ryots the benevolent limitation of the public demand accorded to them by the permanent settlement of the revenue; and the ryots were slow to believe that their prescriptive legal rights had been abrogated, and did not seek a new and unintelligible title deed for property which their own prescriptive law already held sacred.

Mr. Martin Wood objected to the title of the paper, "Landlord and Tenant," those names being entirely inapplicable to India. The terms were exotic, and could only have been used in deference to the superstition that the plutocratic system in this country was the only proper land system in the world. The proper title, in his opinion, should be "Landowners and Cultivators." With regard to what had been said about oscillation and changing of opinion, he thought the oscillation has been a deviation from the original law of India, which had been established for many centuries, that the first right in the soil was that of cultivators to reap a beneficiary interest in it. Nearly all the troubles about land in India had arisen from disregarding that ancient right of the Indian peasant, which, though often grossly encroached upon, still remained the only true basis of landed rights in India.

Mr. T. H. THORNTON, C.S.I., thought that the land law in the Punjab had been very accurately described by Mr. Pedder. That land law was the result of an "oscillation," which occurred in this way; the first settlements were made under the Irish Chief Commissioner (Sir John Lawrence) with strong feeling in favour of Ulster tenant right; the second settlements were commenced under a Scotch Lieutenant-Governor (Sir Donald McLeod) with a strong predilection in favour of proprietary despotism. Then came a four years' struggle between the advocates of tenant rights on the one hand and landlordism on the other, and ultimately a compromise embodied in the Punjab Tenancy Act of 1868. The result, on the whole, has been very satisfactory. In the case of the tenant, nearly 600,000 agricultural households have been secured from liability to rack-rent and arbitrary eviction. As for the landlord, when the Act was passed, it was asserted that his rights were confiscated and that the whole agricultural community would be plunged into litigation. But litigation had been extremely moderate in amount, and as to the alleged confiscation of proprietary rights, since the passing of the Act, the average selling price of agricultural land had more than doubled. In the last report of his administration, Sir Robert Egerton, the late Lieutenant-Governor of the Punjab, after fifteen years' experience of the working of the Punjab Tenancy Act, described it as "the bulwark and charter of a con tented peasantry." Adverting to the remarks of Sir William Robinson, Mr. Thornton remarked that if the principles advocated by that gentleman had been followed in the Punjab, that is to say, if we had accepted and stereotyped the land system we found existing at the time of annexation, we should have stereotyped one of the most oppressive systems ever known; for the land system of the Sikhs was this—that the State, as proprietor-in-chief, took all that it could get, that is to say, it confiscated, so far as possible, all private rents, and reduced proprietor and cultivator to one dead level of poverty. One of the first acts of the British Government was to reduce the oppressive taxation of the Sikhs, and thus leave a margin for rent, and the revival, under altered conditions, of the status of proprietors. Such was the situation in the Punjab, when the first settlements of land revenue were made, and the first records of rights in land were prepared under the administration of Sir John Lawrence. In such circumstances, the equitable determination of the relations of proprietor and tenant was a matter of extreme difficulty. But the difficulty could not be solved by antiquarian researches into the land system of the Vedas, nor by reference to agricultural custom, for custom had been more or less in abeyance for years. The only way of properly dealing with the situation was the way which was adopted, viz., by making as equitable a settlement as was possible under the circumstances—following custom, where custom was in existence, and where custom was no longer applicable, the law of common sense.

Mr. DATTA wished to point out that the condition of the tenants in Bombay and Bengal was not of the miserable nature which had been described that evening. A great deal had been said as to the tenancies being made permanent, but he should very much like to see the condition of the people of Bengal mitigated.

Mr. PEDDER, in reply, while thanking Sir G. Campbell for his remarks, would point out that the Oudh tenancy law was enacted under the influence of Sir C. Wingfield, afterwards an eminent Liberal member of Parliament. With regard to the statement of Mr. Kimber that the account given in the paper of the origin of the Oudh tenancy law was new to him, he would remark that a Blue-book on the subject had been issued, which could be purchased by anyone for a trifle. He could not, at that hour, attempt to reply to the arguments of Sir W. Robinson, but he thought he had ground for complaint against some of the remarks of that gentleman, whose criticisms of some of the statements in the paper were founded on misconception of their meaning. The paper had distinctly stated that the rents payable by tenants are based upon, or derived from revenue rates, and that a "potta" is an instrument defining the conditions of an existing tenancy, and this was nearly what Sir William said himself. Mr. Maclean had somewhat exaggerated the incidence of the land revenue in Bombay. Under the old native system, the revenue was usually one-third or one-fourth of the gross produce, which from careful estimates lately made, it appeared not now to exceed $7\frac{1}{2}$ per cent. of the gross produce. As to Mr. Wood's complaint that the title of the paper was misleading, it might be an unfortunate title, but still it was the title by which the law on the subject in India is known.

The CHAIRMAN, in proposing a vote of thanks to Mr. Pedder, said that he considered the paper a very valuable one. Mr. Pedder had had the good fortune to be placed in a position in which he had a kind of bird's-eye view of all the systems in India, and, therefore, he knew no one better qualified than he was to give an instructive sketch of the whole subject. It was true that Mr. Pedder did not appear to have satisfied all his critics, but he thought some of the criticism was hardly just. The land laws of the different provinces of India, though they have their origin in the same principles, have, by the force of local circumstances, grown into separate systems, and, as a consequence, have produced a number of different schools of land revenue officers, who, probably, from want of an intimate acquaintance with the working of the system of any other province than that in which they serve, are apt to think theirs the only good system, and to condemn all others. Mr. Pedder had been blamed because his paper did not deal with Madras and Bombay, but it should be remembered that he had commenced his paper by saying that on this occasion he proposed to confine himself to the non-ryotwari provinces, and that the expectation that he would have dealt with the ryotwari provinces, Madras and Bombay, was hardly reasonable. Then he had been blamed because he had not given us a history of the ancient Hindu land system, but his paper was on the existing land laws, and not upon the land laws of the Hindus; in fact, if Mr. Pedder had dealt with all the matters which it was said he should have dealt with, his paper would have extended over several nights. Mr. Pedder had alluded to the position of the zemindar as a landed proprietor under the permanent settlement, and had explained what was clearly the intention of the framers of that measure in respect to the proprietary right then conferred. It was very unfortunate that the word proprietor was ever used, because it has a meaning to English ears entirely different from that which it was intended to convey, and English writers could not get over the idea that the zemindar had the same proprietary right over the land in his estate that an English landlord had. The Bengal proprietary right was, however, much restricted. It was limited on both sides; on one side by the rights of the ruling power, on the other by the rights of the cultivator of the soil. When the settlement was made with the zemindars they contracted to take their estates, subject to a liability to pay to the State the collections calculated on the existing rent-roll, a certain proportion of the collections being left in their hands. They were to get all receipts in excess of this, and would profit by all new collections, but if they did not have the amount by sunset of a certain day the estate was put up to auction by Government. That is the existing law, and it is difficult to say how anyone can see any analogy between such a proprietor and the English landlord. Then the right, as explained by Mr. Pedder, was limited by the right of the resident cultivator to hold the land he cultivates so long as he pays the rent justly demandable for it; the unadmitted existence of this right is fully supported by the extracts just read to them. On the whole, therefore, it seemed to be a great pity that the zemindars were declared proprietors of the land when they were really created proprietors of only a limited interest in it. He might take exception to Mr. Pedder's statement as to the two causes why, in his opinion, the legislation of 1859 had not answered its purpose. He stated that in Bengal "there had never been a general cadastral survey, nor any regular record founded upon it of holdings, rents, and payments on account of rent, while, as has been stated, it was found impossible to maintain the village accountants and village records, contemplated by the Code of 1793." That seemed to imply that at the time of the permanent settlement these village records and establishments really had existed, and that a complete system was made over to the English officers, and that it was through their carelessness that the system had been allowed to disappear, but this was not the case now. A reference to the report of the Parliamentary Committee of 1812, would show that at the time of the permanent settlement in Bengal Proper there were no traces of the village system, and that even in Behar, there was only a nominal trace of the village system. It was shown in that report, that the system, where it existed, had fallen into disuse under the Moghul Government. Therefore, it was clearly impossible that the Bengal revenue officers could have allowed a system to fall out of sight which really never existed. It was entirely on account of the absence of the village system that no cadastral survey had been made up to the present time, and no such survey could now be made, as they would have to begin with a quasi-law suit for every little holding in Bengal. The right in each holding would have to be determined before it could be recorded. The framers of the permanent settlement, if they failed in anything, failed in want of foresight as to the success of their own measure; they did not foresee that in the course of half a century the population would become so prosperous, and the cultivation so far increase, that the whole condition of the country would be changed; they relied upon the state of things which they found when the land was far in excess of the requirements of the agricultural community, and believed that the zemindar, in his own interest, would maintain the old law under which the ryot was left in the possession of the land which he cultivated. They did not foresee that sixty years of peace, prosperity, good government, and freedom from harassing resettlements, would lead to such an increase of the agricultural population that the land available would not suffice for all, and that the consequent competition for land would lead to a frequent enhancement of rent, and a tendency to get rid of ryots who would not pay the highest rent.

The vote of thanks was carried unanimously.

FOREIGN & COLONIAL SECTION.

Tuesday, April 29, 1884; F. W. RUDLER, F.G.S., in the chair.

The paper read was "The Transvaal Gold Fields; their Past, Present, and Future," by W. HENRY PENNING.

The paper and discussion will be published in next week's *Journal*.

NINETEENTH ORDINARY MEETING.

Wednesday, April 30, 1884; EDWARD BIRKBECK, M.P., in the chair.

The following candidates were proposed for election as members of the Society:—

Barclay, Robert, 17, Major-street, Manchester.
Bishop, Frederic Sillery, M.A., Welwyn-lodge, Swansea.
Ellis, Herbert, 62, New-walk, Leicester.
Francis, George Bult, 5, Coleman-street, E.C., and 21, Taviton-street, W.C.
Guttmann, Charles, 16, Brownswood-park, South Hornsey, N.

The following candidates were balloted for and duly elected members of the Society:—

Alldridge, Thomas Joshua, York Island, Sherbro, West Coast of Africa, and Old Charlton, Kent.
Allpress, Vincent Sydney, Cliefden, Eltham, Kent.
Bryce, Charles C., 141, West George-street, Glasgow.
Christie, John, Rosshead, Alexandria, N.B.
Gibson, John Merriman, Buckley, Chester.
Gothard, Frederic, 204, Ashby-road, Burton-on-Trent.
Kemp, William Joel, Copyhold-house, Redhill, Surrey.
Lovibond, Joseph W., 26, St. Ann's-street, Salisbury.
Muir, Rev. Robert H., The Manse, Dalmeny, Edinburgh.
Richardson, Frederick William, 40, Church-street, Bradford.
Rumpff, Carl, Schloss Aprath, near Elberfeld.
Wace, Rev. Prebendary Henry, D.D., King's College, Strand, W.C.
Wall, Robert Frederick, Thames Sugar Refinery, Silvertown, E.

The CHAIRMAN, in introducing Mr. Willis-Bund, said the subject on which he was to speak, the Freshwater Fisheries Amendment Bill, was one of great interest and importance to anglers not only of London but especially to those in the country; and they were very fortunate in having it explained by the highest authority in England on freshwater fishery legislation. This Bill, which was introduced by the Government early in the Session, was a very short Bill, having at first only two clauses, but as passed on Monday last it had nine, and only now awaited the Royal assent to become an Act of Parliament. He had every reason to hope that it would have the effect of putting a stop to the extensive system of poaching which had hitherto been carried on, and which no previous legislation had been able to cope with. From the very introduction he had taken a deep interest in this Bill, and thought it was a good opportunity for introducing such clauses as would remedy the defects of existing legislation. He had been guided in the attempts he had made to improve the Bill, by his experience of the working of the Norfolk and Suffolk Fisheries Act, 1877, under which poaching had been, to a considerable extent, put a stop to, and the supply of fish had been greatly increased in the Eastern counties. He was confident that under this Bill the same thing would, to a great extent, be carried out throughout the country. There might be some disappointment felt that no clause was introduced with reference to undersized fish, a question which was discussed at a large meeting in that room two years ago. He knew that this subject had been brought before the authorities by several gentlemen, but Mr. Hibbert, who had charge of the Bill, after giving the matter his deepest consideration, could not see his way to introduce any such clause, and after several interviews with him, he found that if any such attempt was made to force such a clause, it would jeopardise the passage of the Bill. His own opinion was, therefore, that existing legislation with regard to salmon and other freshwater fisheries in England was so complicated, that it would be indispensable for the Government next year, or the year after, to introduce a consolidation Bill, and that that would be an admirable opportunity for introducing, with due care, and possibly after a Select Committee had gone into the question in order to satisfy all parties concerned, a clause with regard to under-sized fish. He would take this opportunity to express not only on his own, but also on behalf of all the anglers of England, his deepest obligation to the Home Secretary for the great assistance he had rendered them, and especially for his desire, as expressed to him both publicly and privately, to make this Bill what anglers really required. Mr. Hibbert was also entitled to their special thanks, for the able manner in which he had carried the Bill through the House of Commons amidst many difficulties.

The paper read was—

THE NEW LEGISLATION ON FRESH-WATER FISHERIES.

By J. W. WILLIS-BUND.

One of the most striking features in modern fishery legislation is the re-enactment of provisions that were formerly law, but which have from time to time been repealed as useless and mischievous. A few years ago, it was considered that the true principle in fishery legislation was to allow perfect freedom to all parties to take fish when and as they thought best. The old laws, which had placed restrictions on the size of the fish it was lawful to take, on the times at which, and the mode by which, fish might be taken, were considered to be absurd restrictions on the liberty of the subject, and were repealed. It was said—I believe it is still said—that the natural fecundity of fish is so great, that it is impossible to over-fish our rivers, and that any laws that placed restrictions on fishing were useless, or worse than useless. That from time immemorial complaints had been made on the decrease of fish in our rivers, but that on these complaints being investigated, they had turned out to be groundless. So Act after Act was repealed, and every one was, in fishery matters, legally allowed to do as he liked. These repeals were carried out in two ways. (1.) By consolidation Acts, such as the salmon Fishery Act, 1861, which repealed some twenty-six public Acts and seven local Acts relating to fisheries without re-enacting any provision in their place for fish other than salmon. (2.) By statute law revision Acts, which repealed a number of statutes that their framers, who knew nothing about fish or fishing, were pleased to consider obsolete and useless merely because they were old. No one took any interest in the matter; the revision Act made the Statute-book more symmetrical, and passed almost as a matter of course. Hence, no general law existed to protect freshwater fish. Salmon were, it is true, protected, but salmon only; all other fish were delivered over to the tender mercy of the poacher, and our only ource on which we could rely for keeping our rivers stocked with fish was the natural fecundity of the fish themselves.

In old times the law as to the protection of fish was enforced by the Court Leet in each manor, and in many of the Court rolls of our manors are curious entries showing the way in which the law and local customs were applied; but Court Leets gradually went into disuse, and there remained no body whose duty it was to carry out the law. For a time voluntary effort endeavoured to supply the place, but in most instances voluntary effort failed, and the fisheries were wholly neglected. In 1865, a change was made. Boards of Conservators were appointed for salmon fisheries, and power given to form fishery districts; certain powers as to trout were given to these Boards, but, with this exception, the powers were limited to salmon, and salmon alone. It did not seem to have occurred to Parliament that if the fisheries of a district are to be properly looked after, the body in whose care they are placed should have power over all the fisheries, not only over one class. Under the Act of 1865, numerous Boards of Conservators have been formed, but these bodies are confined, with the exception of three small Boards in Kent and Sussex, to the north of England, Wales, and the west of England. The Thames fisheries were under the jurisdiction of the Thames Conservancy, and their Acts enabled them to make a series of bye-laws prohibiting netting, restricting the time at which fish can be caught, and the size of fish that may be caught, but beyond this no protection existed. A further advance was made in 1873, but only indirectly. The Salmon Fishery Act of that year gave Boards of Conservators power to make bye-laws fixing the mesh of nets, regulating the mode of using nets, and the kind of net that might be used, and prohibiting night fishing. But still these provisions only applied to fishery districts. In 1877, the Norfolk and Suffolk Fisheries Act constituted a Board of Conservators for those counties, and gave them very large power to protect all fish in the public waters in their district. In 1878 came Mr. Mundella's Act, which fixed a general close time for freshwater fish, and gave power to form Boards for trout and char, as well as for salmon. I believe that the last power has not been exercised. In the present year the Government introduced a Bill which, as originally drawn, simply gave to Boards of Conservators power to fix by bye-law the mesh of net for fish other than salmon. Fortunately, advantage was taken of the opportunity to obtain far more extended powers for the protection of freshwater fish, and to make the Bill a means for giving protection to freshwater fish throughout the country. Shortly, what the Bill does is this, it applies to all fish other than salmon that are found permanently or temporarily in fresh water. It enables a Board of Conservators to be appointed for every river in the country, and such Board, when appointed, will be able to to employ watchers, who will have the large powers for the protection of fish given by the Salmon Fishery Act, 1873. They will also be able to say what nets may be used on any river, what shall be the size of the mesh of net that may be used, and in what way it shall be legal to take fish. As I read the Act, it will be within the power of a Board to say that no nets shall be used in the district but landing nets; that the only modes of taking fish shall be by angling with a rod and line. I do not offer any opinion whether it would be wise or not in a Board of Conservators to make such regulation, all I say is that they have power to do so, subject, of course, to the confirmation by the Secretary of State.

Throughout England and Wales, therefore, the law as to freshwater fish will now be—

1. That it is illegal to take or sell fresh-

water fish during the close time between the 15th March and the 15th June.

That where there is a Board, fish can only be taken during such time and in such manner as the Board permits.

That the water bailiffs have power to search for and seize all fish illegally caught, and if they find any illegal fishing at night, to arrest the offenders.

Although by no means a perfect code, still I think the very large powers here given to Board of Conservators, if properly used, will be the means of effecting a great reform in our fisheries. One provision is omitted, and one that should be supplied at the earliest possible date, namely, a prohibition on the possession of undersized fish. It was the law of the land until 1861, and I fail to see the reason why it should not be law now throughout the country, especially as it is still law in certain parts of the country.

Having stated what the powers given by the new Act are, I may, perhaps, be allowed to say a word on how I think they should be exercised. I feel that I am treading on very dangerous ground. Probably every one who hears me has his own ideas on the matter, and consider that any one who differs from him must be wrong. At the risk of offending some of my audience, I will venture to put forward my views for what they are worth.

The first thing to point out is the absolute necessity of using the powers with discretion and moderation. Two things should be remembered, that they apply equally to public and private property, and that they impose very serious restriction on the enjoyment of the rights of property. Those of you who have had any experience in the working of the Salmon Fishery Acts will remember the opposition that one continually meets with on the ground that the powers thereby given are an interference with the rights of property. For migratory fish, such as the salmon, of course much may be said in support of those powers, but many of these arguments will not apply to non-migratory fish. I breed a number of trout; I turn them into my pond; may I not take them in any way I please? No, says the Act, only in the way the Board of Conservators allow. I am far from saying that a man ought to be allowed to take his own fish as he likes, but what I want to point out is, that unless great discretion is used in exercising these powers, the Board will infallibly make the landowners their enemies, and protection will be impossible. The object of the powers are to stop poaching, not fair fishing, and they should be, as far as possible, confined to this. I have long ago come to the conclusion that the ideal state of fishing is to allow no freshwater netting at all for any sort of fish. I am quite aware such a state of things is impracticable, but yet when I look at the Thames, I think that some approach may be made towards it. At all events, certain kinds of nets can be done away with; the old legal maxim, that a man has no right to use his own property to his neighbour's prejudice, can be safely acted upon, and all those modes of taking fish that really injure the stream should be and ought to be forbidden. For instance, netting after floods in backwater should be put down with unflinching severity. Again, I think a Board might not unfairly prohibit new netting stations being opened. Existing rights should certainly be secured; but a man who has never used a net should not, some few years hence—when, by the labour and expense of his neighbour, without any effort of his own, the fishing has become valuable—be able to reap the benefit of his neighbour's industry. So again, dragging fords, the use of nets by barges, the use of nets at night—all these should be prohibited. The principle seems to me to be that no attempt should be made to interfere with the exercise of the rights of property, as long as such exercise does not interfere with the enjoyment of his property by a neighbour. Netting is an evil, and the object of all regulations should be to minimise the evil as much as possible.

Assuming that netting is necessary, the question arises whether it is possible to fix upon one or more forms of net that should be the legal modes of netting. Power is given to do this—can it be properly carried out? I think it can; and I also venture to think that if only two forms of net were legal—the ordinary sheet or draught-net, and the trammel or armoured-net—much poaching would be done away with. Of course, if a draught-net could be used in all rivers, that net would be the best; but in certain rivers its use is, from the nature of the bed of the stream, impossible, hence recourse must be had to the trammel, a much more deadly and destructive net. I am strongly of opinion that an attempt should be made to put down all fixed nets in freshwater absolutely, and to limit the kinds of net that may be legally used. A difficult question will arise as to casting-nets. They are largely used as a means of taking live bait and, if legitimately used for this purpose, are harmless, and perhaps necessary; but I am convinced that more poaching is done by the use of casting-nets than by anything else; they look so fair, no one suspects that they are so deadly, or that in experienced hands they can undo the result of the work of years. If they are to be allowed at all, it should be under the most stringent regulations as to the time and place where they are to be used. Of course, it will be borne in mind that legitimate netting must not be interfered with; but, I think, regulations should be made even for this. By legitimate netting, I understand netting, by the owner, or his agent, of a stream, either for the purpose of sport, or for sale, or for bait, or for scientific purposes, or what is perhaps the most important of all, for the purpose of destroying fish unsuited for the river. There is not much difficulty as to all but the last, in case where a person is the owner of the whole stream. When a person owns only half the stream, it would not be fair that he should net to the prejudice of his neighbour who does not. What I have already said as to regulating the netting would apply very forcibly to the case. As to destroying unsuitable fish, grave difficulties arise; in a Hampshire trout stream, it is imperative to kill down the pike, and whatever form of netting would kill them down in the quickest and most effectual way, should be the mode employed. But it would never do to allow indiscriminate netting; or, otherwise, in killing the pike, the trout would be killed also. To me it seems that some such system as that now adopted on the Usk would be the true way of meeting the difficulty; there the Association do all the netting, and give the riparian owners a share of the fish. If the Board of Conservators took in hand the duty of keeping down the pike, then there would be no objection—at least if the Board did their duty there should be no objection—to the most effectual means being taken for the purpose, however objectionable the means might be in other hands.

This brings me to a point that it seems requires further legislation. It is impossible to make all our streams salmon or trout streams, even if such a state of things were desirable. But each river can produce fish of some sort, and the duty of the Board is to find out for what fish the stream is best adapted, and to stock it with those fish. Having done this, they should have power to prevent any kind of fish they do not approve of being placed in the stream. I will give an instance of what I mean. Some gentlemen went to considerable expense in stocking a mountain lake of about five or six acres in extent with trout. They got a good supply of fish, and very good sport could be had in that lake. It had a rocky bottom, and could not be netted, and the few who were allowed to fish it looked forward to its being a piscatorial paradise. A discharged keeper had his own ideas of serving out his employers, and placed in the lake a bucketful of small pike; he had committed no offence for which he could be punished, but he had ruined the fishing in that lake. It seems to me that Boards should have power to make it an offence for a person to turn any kind of fish into a river or lake without their assent. I am one of those that think all fishing is good, even fishing for frogs if I cannot get any other; but I also think that each stream should be devoted to produce the fish that will thrive best in it, be they what they may, and that one of the duties of Boards of Conservators should be to carry this out. The *raison d'être* of these Boards is to produce the greatest and best quantity of fish in each river, and it may be equally necessary to restrict the kinds of fish in the river as to restrict the modes and times of taking them.

Another most important power given to Boards of Conservators is to determine the mode in which nets may be used. Perhaps the mode of using the net is even more important than the kind of net that may be used; a draught-net improperly used may be the most poaching of instruments, as, for example, a draught-net dragged over fords; a draught-net placed at the end of a mill race, and the wheel being suddenly stopped. The mode of using nets will depend, of course, greatly upon the place where the net is used, but I trust that the Boards will be most stringent in placing restrictions on the mode of using nets. I may mention, as to this, a mode of using nets for salmon that, to my opinion, does more harm than anything else to the Severn. Between Gloucester and Tewkesbury, just as the tide begins to run, and the fish ascend with the tide, the fishermen shoot the net right across the river, and thereby stop and catch all the ascending fish. This mode of using the net is not now, but I trust soon will be, illegal; yet had the Board not power to make bye-laws to determine the mode of using nets, nothing short of an Act of Parliament could stop it.

I am rather unwilling to say anything about the mesh of nets; it is a subject on which I never found two persons agree. All I will venture to say is this, that it appears to me most desirable that a standard mesh should be arrived at, that would be available for all fish and all nets. Nothing that I know is more vexatious and gives more trouble than the necessity that at present exists for two sorts of nets, one for the migratory salmonidæ, the other for all other fish. It is also mischievous in that it leads to nets for fish other than salmon being made of a smaller mesh than would otherwise be the case. With the kind of net fixed, a uniform mesh of net for all nets fixed so that all other nets of any kind would be illegal, a water bailiff's duties would be greatly simplified, and a stop put to much illegal netting.

A most valuable power is given to Boards by which they are enabled to prohibit the use of any mode or instrument of fishing that appears to be prejudicial to the fisheries. It is to be hoped that the Boards, will promptly use their power to make an end of the use of night lines, trimmers, eel spears, and pike snares, and other poaching instruments. The habit of lading out hooks in dry weather, causing the wholesale destruction of the fish, and grouping or tickling trout, should also be made illegal. The same principle that prohibits taking game by certain modes, equally applies to taking fish, and the reason which justify the one will also justify the other. A more difficult question arises as to use of traps at mills. Any one with any experience in fishing knows that more poaching is done at mills than anywhere else on the river, and that the traps so often found at mills are usually most destructive. On salmon rivers, regulations as to these traps have already been made by statute, but on non-salmon rivers they can be used as the owner pleases, and the mode that most pleases him is the mode whereby most fish are caught.

It will have been gathered from what I have said, that all the regulations I have recommended are in favour of angling as opposed to other modes of fishing. I have done this, as angling has become the most important and nearly the only legitimate means of taking freshwater fish. Very few, if any, persons make a living, or even profess to make a living, by fishing for freshwater fish apart from angling, and those persons who do, only use fishing as a cloak for poaching. Year by year the number of professional fishermen for freshwater fish, other than anglers, have decreased, until at last they have become as rare as Thames salmon. The number of anglers has, on the other hand, largely increased, and angling has become a most important interest in the country. It is difficult to estimate the number of anglers; over 5,000 last year took out licenses on the Severn alone, and the anglers in London, Nottingham, and Sheffield are legion. It is therefore only right that the restrictions and rules as to freshwater fish should be framed in the interest of the most important body connected with the fisheries.

There are various other points in connection with the new Bill upon which I should have liked, had time permitted, to have said something, but those I have mentioned seem to me the most important. The whole question whether the Act will be a great success or a great failure, turns upon the way in which these powers are exercised by the Boards. I cannot urge too strongly that it is all important that the powers should be so exercised as to procure harmonious relation between the Fishery Boards and the riparian owners. The amount of water in which the public have a legal right to angle is exceedingly small, and if any bad feeling arise between the Board and the riparian proprietors, the result would most likely be that the public would be refused leave to fish in water where leave is now given, and hence the general body of anglers would suffer. Speaking, after eighteen years' experience of the work of a Fishery Board, I say most emphatically that harmonious relations with the land owners will do more in the way of preservation than any amount of Acts of Parliament, bye-laws, or rules. The great mistake that the Salmon Fishery Boards made at the start was that they tried to force the law down the proprietors' throats and act on their utmost legal rights; they used their powers as the policeman used his staff—break someone's head as soon as possible, in order to show they are entitled to do so. And hence it is that these Boards have not been so successful as they ought to have been. I hope I shall not be thought impertinent in urging the Boards that will be constituted under this Bill to take warning by the example of the Salmon Boards, and attach the utmost importance to being in harmony with the riparian owners. Fishing we know was an apostolic pursuit, and in no case is the apostolic maxim, "If it be possible, live peaceably with all men," more required.

In conclusion, I would venture to make two practical suggestions that it seems to me will tend to facilitate, if they do nothing else, the enforcement of the powers given by the new Bill. First, that as it is desirable to have the same law applying, as far as possible, to all rivers, a conference of the different Boards should be held to settle, if possible, the kind of net it should be lawful to use, and the mesh of net, to prohibit certain modes of using nets, and to determine what modes and instruments of fishing are prejudicial to the fisheries. Let each Board add, afterwards, such additional rules as local circumstances require; but as the great object of all Boards in the suppression of illegal fishing, let those illegalities that are common to all the country be put down by all Boards. A conference, such as I propose, would at least do this, it would show what is the opinion of those who know each locality, and the necessities of each locality in the protection of the fisheries. Secondly, it might lead, unless some other body will take up the work, to what we so greatly need, an executive society in London, charged with the duty of watching and protecting the interests of fishing in general, and angling in particular. As has been said, while Parliament is sitting, no interest is safe, and as we see every trade and every interest has a protection society, it is time the great angling interest also had one. The work would be the protection of fishing interests, by opposing all measures detrimental to fish, by promoting any measures that tended to help and encourage the fisheries. There is much work to do. The fishing laws want reducing from their present unintelligible chaotic state into a form that he who runs may read it. Amended powers and increased powers are required by Boards of Conservators to enable them properly to do their duty. The anomalies in the existing law require to be abolished, and, above all, there is the greatest and most important question—the prevention of the pollution of streams by some cheap, summary, and effective means. There are numbers of persons ready and willing to embark in the work, and all that is required is unity of action to accomplish two most important objects—the increase of the health and enjoyment of a great number of the public, and the increase in a valuable supply of food for the public.

DISCUSSION.

Mr. Marston asked whether eels were protected by the new Act; and also whether the Board would be constituted on an application being made, irrespective of the wishes of the owners of the river. He mentioned that, because in the case of the River Lea there were many private fisheries on which anglers could go and fish even through the close season; and he should like to know whether that could be stopped.

Mr. Willis-Bund thought eels were certainly included in the definition of "all fish which are found temporarily or permanently in fresh water except salmon." The question about the Board was one of more difficulty; but as he understood it, it would be the same thing as under the Salmon Acts. If the Quarter Sessions of any county through which a river ran, chose to apply to the Secretary of State to have a fishery district formed, the Secretary of State could do so; and then quite irrespective of the opposition of landowners or any one else. The first step was to put the Court of Quarter Sessions in motion, as that was the only body which could apply to the Secretary of State.

Mr. J. A. Youl, C.M.G. said he had no personal knowledge of freshwater fishing in England, but he had come there to thank Mr. Willis-Bund publicly for the many millions of salmon eggs which he had contributed, and which he (Mr. Youl) had sent out to the Australian colonies. He intended to send out a copy of the paper to Tasmania, which colony had just appointed Mr. Saville Kent their inspector of fisheries, and he thought it would be useful to him to have this paper, and a copy of the new Act, as soon as passed, as a guide for his own operations.

Mr. J. C. Bloomfield said he had been a conservator in Ireland for some years, and he must say that there the system was somewhat different from what had been described. There were three inspectors in Dublin, who formed districts all over Ireland, and constituted Boards altogether independent of the riparian proprietors. Those who had fishing rights in the estuaries had a certain number of votes and so had other parties interested in other parts of the rivers, but a certain number of conservators must be elected, and they looked after all other fish as well as salmon. In his early days eels were of very small account, and he had seen them sold in London at 2d. or 3d. a lb., but this was not the case now. He formerly had an eel weir which brought him in £120 a year, and the present owner was making £600 a year by it. Eels were to be found in every bit of water, however small. There was the migratory or silver eel, which went down to the sea, and sometimes weighed two or three lbs., and another kind which did not migrate, which now sold for 1s. 2d. a lb. A very small mesh would be required for them, if they were to be taken in a net at all. In Lough Erne they were taken by long lines, sometimes up to three miles in length, laid zigzag, and he had known of five stone being taken in a day in that way. Last year Major D'Arcy took three tons at one particular part of the shore. In Ireland they did not dream of having nets in rivers, but in ponds and lakes he thought they were necessary, if fish were to be taken as a source of food supply, though that point had not been alluded to. There were twenty-seven lakes to be seen from one hill in the neighbourhood of Lough Erne, which might all be made to produce food, if means were taken such as had been adopted in America. There they had imported carp from Germany and distributed them to about 860 different points some 1,500 miles from the coast, where fresh fish would have been otherwise unattainable. A friend of his, Sir Victor Brook, had a large river running through his estate which was a pure salmon-breeding river, and no fish ever went into it that was not killed before it came down again; but he induced Sir Victor to pay attention to the matter, and now no fish were allowed to be killed there. The extent of salmon fishery was the extent of water you could have for their breeding, and that could only be secured by the upper waters being protected. This new legislation seemed to be in the right direction, but there were still several things required to make it perfect.

Mr. C. S. Bentley agreed with the view taken in the paper that netting should be put down altogether; and to avoid difficulties with regard to catching bait, suggested that certain waters should be set apart for the cultivation of bait fish. There would then be no excuse for smuggling large fish on the pretence of getting bait.

Mr. William Botly remarked that there were many rivers which ran through property owned by different proprietors on the opposite sides, and sometimes they divided different counties, and he wished to know whether, in such cases, the regulations made by a Board would apply to both sides; if not, it might give rise to considerable disagreement.

Mr. Senior said they must all be greatly obliged to Mr. Willis-Bund for having so clearly explained the provisions of the new Bill, which after the amendments and resolutions and re-amendments, had become somewhat complicated. The day would no doubt come when the various complicated laws affecting freshwater fisheries would have to be codified, but meanwhile he was sure that he repeated the feelings of every freshwater fisherman, in throwing out the suggestion that Mr. Willis-Bund should publish a cheap and comprehensive work, explaining all the details of the new system about to be inaugurated. By so doing he would not only confer a boon on all anglers, but would do a great deal to ensure the proper working of the new Act. So far as he understood it, the new Act would be something like a local option measure. First of all, there must be a petition from a public meeting, or some resolutions passed by which the Court of Quarter Sessions might be persuaded that a conservancy was required in the district, and then the Quarter Sessions must make their recommendation which would require the Secretary of State's approval. It seemed a very simple arrangement, but it was hedged about by a great many provisions which would prevent abuses. Ireland and Scotland were excluded from the Act, and so were Norfolk and Suffolk, but he presumed they would be included when any comprehensive legislation on the subject was undertaken. He would take the opportunity of thanking the Chairman for all the efforts he had put forward in piloting this Bill through the House of Commons, for although it was a Government measure, he thought it ought to be known as the Birkbeck Bill, for it bore his mark on almost every one of its nine clauses.

Mr. Dipnall said he had a great respect for anglers; but he thought the real ground for legislative interference should be the improvement of the food supply, and if there were any great expense attending the machinery of this new Bill, there should be some productive character given to the industry which might provide for those expenses, and should tend to preserve in the rivers and lakes such a head of fish as was essential to the welfare of the population. Without wishing to criticise the Bill too closely, it seemed to him to go rather far in the way of nursing and protection; and he should like to know whether a gentleman could not have his own private fish-pond, and fish in it when he pleased; if not, he thought the legislation was carried rather too far. At the same time he was quite of opinion, with regard to fisheries in rivers of any importance from a food point of view that a close time should be established, that restrictions should be placed upon the use of nets, and poaching prevented. With regard to the great estuaries lakes, such as those of Norfolk and Ireland, it was of great importance that there should be some general laws governing the mode and time of fishing.

Mr. Marston said he had been often asked by fishing-tackle makers whether they might sell live bait at this season. He should like to know whether the new Act would cover that point.

Mr. Willis-Bund, in reply, said he had the gravest doubt whether it was legal to sell bait at all, now. Under Mr. Mundella's Act, the capture of bait would appear to be legal, but he thought the sale would be illegal; certainly the safest plan would be not to sell it. He did not think there had been any decision on the point, but, in his opinion, you might catch bait for your own use during the close time, but not sell it. He knew of no way in which Mr. Mundella's Act was more evaded than this. Men went out fishing with nets, and if they were caught, they said they were only taking bait. The capture of bait at this time was an abuse, which ought to be put down. It was generally used for catching pike, but, in his opinion, pike ought not to be caught now; the bait used for trout fishing was quite different.

Mr. Bloomfield remarked that in Ireland small perch were used as bait for trout, but the bait were not to be had early in the season, and therefore they were caught in the autumn and kept in trenches dug on purpose, through the winter, until they were wanted in February.

Mr. Senior said that bleek and small dace were mainly used in the Thames for trout fishing, and it was probably that to which Mr. Marston alluded.

Mr. Willis-Bund said the words of the Act were —"If any person during the close season, buys, sells, or exposes for sale, or has in his possession, any fresh-water fish, he shall be liable to a penalty of 40s.," and there was no exception to that at all. Therefore he took it that it was illegal to sell live bait. With regard to the formation of Boards, any magistrate could move at the Quarter Sessions that any river flowing through that county, or that the whole of the rivers, or any one of them, should be formed into a fishery district. If the motion were agreed to, it would be forwarded to the Secretary of State, and he acted simply on his own discretion, and said how large or how small a district should be formed. It did not matter whether the river formed the division between two properties, counties, parishes, or anything else. He had in his mind a river, part of which was under a Fishery Board in one place, and the whole of it in another, and it was very puzzling. He referred to the Avon between Stratford and Evesham. So much of it as was in the counties of Gloucester and Worcester was under the Severn Fishery Board; but in one part it formed the division between Gloucester, Worcester, and Warwick, and sometimes they had the whole river, then for half a mile half the river, the next mile the other half, and so on. Whenever the Acts were amended and consolidated there ought to be some provision for cases of this kind. But it rested wholly with the Secretary of State. The district being once formed, very large powers were given under the new Bill to water bailiffs, quite as large as could be desired. They had power to traverse the banks of all streams in which fish were found; to arrest at night any person they found taking fish illegally, or whom they suspected of so doing, or who had fish upon him suspected to have been illegally taken; if they had authority from the chairman of the Board, they could remain upon lands for a limited time to detect offences, and they had powers of searching suspected persons. With regard to the application of the Act to fish-ponds, he could only say he believed the Act applied to all ponds that had any communication with any stream, so that you could say they were tributaries. The question what was a tributary had been much discussed, in two cases in the Court of Queen's Bench. One of the Judges said a tributary was what contributed, but afterwards the same learned Judge took a different view, and said it depended on other circumstances. One Judge said that if that were so, the ornamental water in St. James's-park might be a tributary of the Thames. He might mention one case which had occurred. A noble lord in a Western county had a son who was Clerk of Assize, who, on one occasion, took two friends over to fish in his father's pond, which was full of trout. The Act of 1878, provided that Boards of Conservators might issue licenses for trout fishing, and any-one fishing without a license was liable to a penalty. This young gentleman and his friends, one of whom was the Recorder of a borough in the west, and the other a barrister on the circuit, caught some trout which had been bred by this nobleman, and they were summoned for fishing without a license, and convicted. There was an appeal, but they thought discretion was the better part of valour, and dropped it; and he had no doubt the conviction would have been affirmed. He mentioned that to show that if there were any communication whatever, as there was in that case, with a stream or river, the Act applied. As the Chairman reminded him, all dykes, ditches, or backwaters of any kind, which communicated with a river in which fish were found, were within the Act; and these were the great places where fish were poached after a flood. When any water came down them, the fish worked up them to spawn. These were protected under the Act, and the water-bailiffs would have power to go up and down them, and arrest and search people as he had described. He was very sore on the subject of netting. Only recently he was told there was a deal of bait-netting going on in the neighbourhood of Shrewsbury; and he was informed that one gentleman, under the pretence of taking bait, had caught 110 dozen samlets, part of which he disposed of in the neighbourhood, and the remainder were sent to Birmingham for sale. With regard to eels, he might say, that part of his income was derived from eels, and he had some experience of eel fishing. They only caught them in the autumn, either in large fixed nets, or in traps, but they did not think anything of half a ton of eels in a night during the short time they ran. Eels were a poor man's fish, and any quantity could be disposed of in the Black Country. He thought eel fisheries ought to be promoted in every possible way. He also thought it most important to settle how far netting in freshwater ought to be allowed; and he hoped the angling societies, who were most interested in it, would endeavour to meet and discuss the question. Illegal netting must be put down, and, in public fisheries, strict legislation should be enforced. With regard to setting apart certain water for bait, there was this practical difficulty, that as soon as you began to net any place regularly the fish left it; consequently, unless a very large stretch of water were set apart, the complaint would be that it was of no use fishing in the fixed places. The only way he could see of regulating it would be to say that in certain places bait nets should not be used under any circumstances. Lastly, he might say that he had partially prepared, and hoped soon to publish, a little book showing what the Freshwater Fisheries Acts had done, and how the new Act amended it; and he intended to make it rather a popular than a legal book, so that people might know what they might and might not do. He only hoped these new powers would be used with discretion, so that not only would they all be grateful to Mr. Birkbeck for what he had done, but that he would be proud of the work he had accomplished.

The CHAIRMAN said there were many points which not only those present, but people throughout the country, had been in doubt about, with regard to this new legislation which Mr. Willis-Bund had now made clear, and they must be very grateful to him for the information he had given. He attached great importance to the suggestion he had made that there should be a conference in London, with a view of drawing up such bye-laws as should be best adapted for Fishery Boards to be formed under the new Act, and it was very desirable that such conference should be held as early as possible after the Royal assent was given to the Bill. Some might think that the machinery in connection with these Boards would be very expensive, but that was not the experience in Norfolk and Suffolk, where the Board had been in existence nearly seven years. £80 or £100 was subscribed at the outset for the expenses which were anticipated, but he was glad to say that no further appeal whatever had been made, and he believed that, beyond the expense of printing the bye-laws, and a few post-cards for summoning the Conservators, there had been no expense whatever, and the fund originally raised was almost intact. In many districts licenses were issued, but that course was not adopted in Norfolk, and he anticipated that in many other districts it would be unnecessary. He might say that the food supply had been enormously increased by the stop put to poaching practices, and he was confident that wherever a district was formed, and these powers put in force, similar results would follow. He concluded by proposing a vote of thanks to Mr. Willis-Bund for his valuable paper, which was carried unanimously.

Correspondence.

WATER REGULATION.

Colonel Walter Campbell, after quoting certain rates given in evidence before the Select Committee on Canals, asks how can the United Kingdom expect lower rates than those now obtaining on the Continental and other lines of canals, and adds, that he cannot account for a rate of d. assumed for water carriage by Sir Arthur Cotton and myself. In his memorandum, at page 289 of the Canals Committee Report, Sir A. Cotton has given the data by which he arrives at the rate at which canals may be worked. As regards my own calculation, I assume that the items which go to make up the rate are—

1. A toll sufficient to pay the interest on the capital cost of the line.
2. Cost of maintenance.
3. Cost of haulage, inclusive (*a*) of interest on cost of plant, and (*b*) working expenses; in the case of independent carriers (*c*) a margin for profit.

It will not be disputed that the lower the charge the greater will be the traffic, especially in goods of very small value, which cannot, at present rates, be moved except for very short distances, but could at low rates be carried to any part of the United Kingdom when required.

In an address given by Sir James Caird, some few years ago, to the Statistical Society, he observed, as quoted by the *Times*, "a $\frac{1}{2}$d. a ton per mile is now the average railroad charge, and this will be further reduced by the competition of water carriage—by the rivers and canals. Wheat can be carried from Chicago to New York at half this rate, or $\frac{1}{8}$d., and by barges on the Mississippi from St. Louis to the sea board an equal distance, the same work is now being done for $\frac{1}{5}$d. of it or $\frac{1}{10}$d." As carriage by canal can be conducted more cheaply than by river; a rate of $\frac{1}{10}$d. per ton is perfectly practicable. I have not the rates charged on American waterways now at hand, but I think I am right in saying that they are in some cases as low as 1·5 millimes. per ton per mile, which which would be only $\frac{1}{20}$d.

But by way of illustration, let it be assumed that the cost of a first-class steam navigation between London and Liverpool would cost £15,000 per mile.

	£	s.	d.
1. Interest on capital, say 4 per cent., would be	600	0	0
2. Maintenance at $1\frac{1}{2}$ per cent. would be	225	0	0
Total toll	£825	0	0

A traffic of 4,000,000 tons, with a toll of $\frac{1}{20}$d., would cover those items.

3. The cost of haulage, at the rate obtaining on the Aire and Calder Canal, need not exceed $\frac{1}{30}$d., so that a charge of $\frac{1}{20}$d. × $\frac{1}{30}$d. = $\frac{1}{12}$d., would suffice to yield the requisite return.

I gather from Mr. Watson's paper (p. 230 of the Canals Committee Report) that if the carrier owned his own plant, the cost between London and Liverpool could be reduced to 2s. per ton or $\frac{1}{10}$d. At very low rates, it is certain the traffic would very soon assume proportionately large dimensions.

F. H. RUNDALL.

April 23rd, 1884.

M. Gobert's analysis of the Willebroek canal (10 ft. deep, and running through sloping country from Brussels, seawards) gives:—

	millimes.
Steam-traction on sunk chain (allowing 4 per cent. on cost of appliances, for interest and depreciation) ..	3 per tonne kilometrique
Boats (if full each way) and their personnel, going 10 miles a day including stoppages	5 „ „
Add, as boats probably return empty each alternate trip	1·6 „ „
	9·6

Besides this (equal to about ·155d. per ton-mile), *for boat costs alone*, there are interest on construction-money, maintenance of canal, and pay of lock-keepers, &c., expenses which vary inversely with the tons carried.

With a mean annual traffic of 900,000 tonnes per kilometre; interest at 4 per cent. on 180,000 fr. (the estimated average cost of a kilometre); and 1,450 fr. for its annual maintenance, we get a total of about ·31d. per ton-mile.

There may be errors in the above estimate; but reference to other foreign authors seems to show that *we* cannot well carry under ·4d. per ton mile.

An analysis of the cost of carriage on the Lea (given by Mr. Conder, C.E., at ·33d. per ton-mile) would be interesting.

It may be safer to adopt the following approximation:—

		s.	d.
Glasgow to Grangemouth	about	1	0
Leeds to Goole..............	„	1	3
Sheffield to Goole	„	1	6
Wolverhampton to Gloucester	„	2	3
Birmingham to Gloucester....	„	1	11
Dublin to Limerick	„	5	0

Such possibilities seem worth thought. Very slowly, the public mind is realising that waters should be freed from railway control; but the question goes much further than that. When railways were introduced, a reduction of one-twelfth on the cost of road-transport would not have sufficed; and, in the parallel case of steam being applied to waterways, the public weal requires that loads be transported as skilfully as possible, at rates based on customary interest. Much is said about *uniformity* of locks; but in these wet isles they can seldom be too large. It is usually size that they want.

WALTER M. T. CAMPBELL.

Edinburgh, 28th April, 1884.

CORRECTIONS.—Mr. G. F. Blackmore writes that his remarks (see *ante* p. 551) "referred only to the two proposals submitted by Messrs. Clark and Standfield, *i.e.*, a high level bridge and a double iron tunnel, both fitted with hydraulic lifts." Mr. Le Grand's letter (p. 569, col 1, line 38) *for* present *read* purest.

Notes on Books.

Manuals of Technology, edited by Professor Ayrton, F.R.S., and R. Wormell, D.Sc., M.A. London: Cassell & Company. 1882-4.

These manuals are intended as text-books for technical students, in which the language of the professor is translated into the language of the workshop, with the design of making workmen thinkers, and not merely human tools.

CUTTING TOOLS WORKED BY HAND AND MACHINE. By Robert H. Smith.

Mr. Robert Smith does not attempt to enumerate all the cutting tools in use, nor to explain all the details of construction of the machines referred to; but he states that his chief object is "to guide the mechanical student into a correct scientific way of thinking about tools, so that he may able, aided by practice, to judge intelligently whether a tool is good or bad, to criticise its details, and eventually to design new tools scientifically."

PRACTICAL MECHANICS. By John Perry, M.E.

Professor Perry adopts in his treatise a method which he has tested in practice for twelve years, which is to approach the subject from the point of view of the workman rather than to compel the workman to approach it from that of the scientific man.

STEEL AND IRON: comprising Practice and Theory of the several Methods pursued in their Manufacture, and of their Treatment in the Rolling Mills, the Forge, and the Foundry. By W. H. Greenwood.

Mr. Greenwood, without entering into minute detail, gives an account of the several processes connected with iron and steel, and states the scientific principles upon which the success of these processes depend.

SPINNING WOOLLEN AND WORSTED: being a practical treatise for the use of all persons engaged in these trades. By Walter S. B. McLaren.

Mr. McLaren in his work, while dealing with woollen and worsted spinning, pays special attention to the latter, upon which, he says, no book had previously been written.

All these hand-books are fully illustrated with diagrams.

WORLD LIFE, OR COMPARATIVE GEOLOGY. By Alexander Winchell, LL.D. Chicago: S. C. Griggs & Co. London: Trübner & Co. 1883.

The author has attempted to construct, from the standpoint of a nebular cosmogony, a scheme of the constitution and the course of nature in which the processes of world formation, world growth, and world decadence, shall find a place. The book is divided into four parts, the first dealing with cosmical dust and nebular life; the second with the origin of the solar system, the condition of the planetary bodies, planetary decay, and the question of the habitability of other worlds; the third with general cosmogony; and the fourth with the evolution of cosmogonic doctrine.

The Art of Soap-making: a Practical Handbook of the Manufacture of Hard and Soft Soaps, Toilet Soaps, &c. By Alexander Watt. London: Crosby Lockwood & Co. 1884.

The first patent for improvements in the manufacture of soap was obtained in 1622, by Messrs. Jones and Palmer, but it was not until the present century that Chevreul raised soap-making from empiricism to the position of a scientific art. The author describes the various processes in use, and has added to his book a chapter on the recovery of glycerine from waste leys.

Obituary.

Michael Thomas Bass.—Mr. Bass, the head of the great brewery establishment, died at his residence, Rangemoor, Burton-on-Trent, on Tuesday, the 29th inst., at the age of 84. He was Member of Parliament for the town of Derby from 1847 to 1883, and he had been connected with the Society of Arts since 1863.

Sir Michael Costa, who died at Brighton on Tuesday, 29th inst., was elected a member of the Society of Arts in the same year (1863) as Mr. Bass. He conducted the series of concerts at the Royal Albert-hall in 1871, which was organised by the Society in aid of the National Training School for Music. Sir Michael Costa was born at Geneva on February 4, 1810, and obtained his musical education at the Royal Academy of Music, at Naples. At an early age he began the composition of cantatas and operas, and he was only eighteen when his opera "Il Carcre d'Ildegonda" was publicly performed at the Teatro Nuovo, Naples. In 1831, he was appointed conductor of Her Majesty's Opera House, and here he continued till his secession to the Royal Italian Opera, Covent-garden, in 1847. He composed several operas, but his fame as a composer chiefly rests on his two oratorios, "Eli" and "Naaman." In 1849, he became conductor of the Sacred Harmonic Society, and the success of the Handel Festivals, at the Crystal Palace, was largely due to the renown of Sir Michael Costa as a conductor.

General Notes.

Carpentry Exhibition.—At the Exhibition of Carpentry and Joinery to be held at Carpenters'-hall the Council of the Royal Institute of British Architects have promised to exhibit some of the drawings, &c., illustrative of those subjects in their library. The Royal Architectural Museum will exhibit the well-known drawings of the Flèche of Amiens Cathedral, by the late William Burges, and Mr. Street will contribute his father's drawings for the roof and flèche over the Law Courts.

Ancient Leather.—The Leathersellers' Company propose to exhibit specimens of leather manufacture in one of the shops in the street of Old London, now in course of erection at the International Health Exhibition, and will be grateful to any possessors of articles of leather of ancient or mediæval date who may be willing to aid the Company by the loan of them for the purpose of exhibition. The Clerk of the Company, at the Hall, St. Helen's-place, Bishopsgate-street, will give any further information, and he announces that the greatest possible care will be taken of any articles lent.

Grape Seed Oil.—Grape seed oil is (according to the *Corps Gras Industriels*) used in Italy for purposes of illumination. The extraction is principally effected at Modena. It has also long been used for similar purposes in Germany and the Levant. Thirty-three pounds of seed yield about 13 quarts of oil (or about 18 per cent.). The seeds of white grapes yield less oil than those of the dark variety, and young vines are said to be more fruitful in this respect than older ones. As to the French varieties, the Rossillar, Aube and Herault seeds yield 2 per cent. more than Bordeaux seeds. The colour is a golden yellow, and the oil loses about 25 per cent. in purification.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, eight o'clock:—

May 7.—"Bicycles and Tricycles." By C. V. Boys. Dr. B. W. Richardson, F.R.S., will preside.

May 14.—"Telpherage." By Professor Fleeming Jenkin, F.R.S.

May 21.—"Telegraph Tariffs." By Lieut.-Col. Webber, R.E. Dr. Cameron, M.P., will preside.

May 28.—"Primary Batteries for Electric Lighting." By I. Probert. W. H. Preece, F.R.S., will preside.

Applied Chemistry and Physics Section.

Thursday evenings:—

May 8.—"Cupro-Ammonium Solution and its Use in Waterproofing Paper and Vegetable Tissues." By C. R. Alder Wright, F.R.S., D.Sc. Prof. W. J. Russell, Ph.D., F.R.S., will preside.

May 22.—"Economic Applications of Seaweed." By Edward C. Stanford, F.C.S.

INDIAN SECTION.

Friday evenings :—

MAY 9.—"Indigenous Education in India." By Dr. LEITNER. Sir LEPEL GRIFFIN, K.C.S.I., will preside.

MAY 30.—"Street Architecture in India." By C. PURDON CLARKE, C.I.E. This paper will be illustrated by means of the Oxy-Hydrogen Light.

CANTOR LECTURES.

Monday evenings, at eight o'clock :—

The Fifth Course will be on "Some New Optical Instruments and Arrangements." By J. NORMAN LOCKYER, F.R.S., F.R.A.S.

LECTURE II. May 5.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 5...SOCIETY OF ARTS, John-street, 8 p.m. (Cantor Lectures.) Mr. J. Norman Lockyer, "Some New Optical Instruments and Arrangements." (Lecture II.)

Farmers' Club, Inns of Court Hotel, Holborn, W.C. 4 p.m. Mr. H. M. Jenkins, "Ensilage."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, Westminster Town-hall, S.W., 7½ p.m. Mr. H. Stopes, "The Engineering of Malting."

Chemical Industry (London Section), Burlington-house, W. 8 p.m. 1. Dr. Percy Frankland, "The Composition and Illuminating Power of Coal Gas." 2. Mr. W. J. Dibdin, "The Estimation of the Illuminating Power of Gas Burners, especially those of large size "

Surveyors, 12, Great George-street, S.W., 8 p.m. Adjourned Discussion on Mr. T. Chatfeild Clarke's Paper, "Improved Dwellings for Labourers and Artisans."

British Architects, 9, Conduit-street, W., 8 p.m. Annual Meeting.

Institute of Agriculture, Lecture Theatre, South Kensington Museum, S.W., 8 p.m. Professor H. Tanner, "Science Teachers, and Colonial Life."

Medical, 11, Chandos-street, W., 8½ p.m. Annual Oration.

National Indian Association, Council-room, Exeter-hall, Strand, W.C , 4 p m. Mr. Narendra Nath Mitra, "Child Marriage in India, and its Remedy."

TUESDAY, MAY 6...Victoria Institute, (at the HOUSE OF THE SOCIETY OF ARTS), 8 p.m. Vice Chancellor J. W. Dawson, "Prehistoric Man in Egypt and the Lebanon."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. Gamgee, "The Physiology of Nerve and Muscle." (Lecture I.)

Central Chamber of Agriculture (at the HOUSE OF THE SOCIETY OF ARTS), 11 a.m.

Civil Engineers, 25, Great George-street, Westminster, S.W., 8 p.m. Mr. S. B. Boulton, "The Antiseptic Treatment of Timber."

Pathological, 53, Berners-street, Oxford-street, W., 8½ p.m.

Photographic, 5a, Pall-mall East, S.W., 8 p.m.

Biblical Archæology, 9, Conduit-street, W., 8 p.m. Dr. Theo. G. Pinches and Mr. Ernest A. Budge "New Texts in the Babylonian Character, principally referring to the Restoration of Temples."

Zoological, 11, Hanover-square, W., 8½ p.m.

WEDNESDAY, MAY 7...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. C. V. Boys, "Bicycles and Tricycles."

Entomological, 11, Chandos-street, W., 7 p.m.

Archæological Association, 32, Sackville-street, W., 4½ p.m. Annual Meeting.

Obstetrical, 53, Berners-street, W., 8 p.m.

Shorthand, 55, Chancery-lane, W.C., 8 p.m.

Civil and Mechanical Engineers, 7, Westminster-chambers, S.W., 7 p.m. General Meeting to receive Report, &c.

THURSDAY, MAY 8...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Chemical and Physical Section.) Mr. C. R. Alder Wright, "Cupro-Ammonium Solution and its use in Waterproofing Paper and Vegetable Tissues."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Society for the Encouragement of Fine Arts, 8 p.m. Conversazione, at the Galleries of the Royal Institute of Painters in Water Colours, Piccadilly.

Royal Institution, Albemarle-street, W., 1 p.m. Annual Meeting. 3 p.m. Prof. Dewar, "Flame and Oxidation." (Lecture III.)

Telegraph-Engineers and Electricians, 25, Great George-street, S.W., 8 p.m. 1. Mr. Henry C. Mance, "A Method of Eliminating the Effects of Polarisation and Earth Currents from Fault Tests." 2. Mr. Latimer Clark, "Some Supplementary Remarks and Illustrative Experiments."

Mathematical, 22, Albemarle-street, W., 8 p.m. 1. Mr. E. J. Ronth, "Motion of a Network of Particles with some analogies to Conjugate Functions." 2. Mr. J. Griffiths, "A Subsidiary Elliptic Function."

FRIDAY, APRIL 9...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p m. (Indian Section.) Dr. G. W. Leitner, "Indigenous Education in India."

United Service Inst., Whitehall-yard, 3 p.m. Mr. A. F. Yarrow, "Torpedo Boats; having special reference to those built by Messrs. Yarrow and Co."

Royal Institution, Albemarle-street, W., 3 p.m. Weekly Meeting. 9 p.m. Prof. W. Robertson Smith, "Mohammedan Mahdis."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. A. R. Sennett, "The Electric Light."

Astronomical, Burlington-house, W., 8 p.m.

Quekett Microscopical Club, University College, W.C., 8 p.m.

Clinical, 53, Berners-street, W., 8½ p.m.

New Shakspere, University College, W.C., 8 p.m. A second Selection of Shakspere Madrigals, Glees, and Songs, in chronological order, under the direc- of Mr. J. Greenhill.

SATURDAY, MAY 10...Royal Institution, Albemarle-street, W., 3 p.m. Mr. H. M. Westropp. "Recent Discoveries in Roman Archæology." (Lecture III.) "The Palatine Hill."

Physical, Science Schools, South Kensingtou, S.W., 3 p.m.

Botanic, Inner Circle, Regent's-park, N.W., 3.45 p.m.

Geologists' Association, University College, W.C. Excursion to the Crystal Palace under the direction of Dr. David Price.

Journal of the Society of Arts.

No. 1,642. Vol. XXXII.

FRIDAY, MAY 9, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CANTOR LECTURES.

In his second lecture on "Some New Optical Instruments and Arrangements," delivered on Monday, 5th May, 1884, Mr. Norman Lockyer, F.R.S., laid great stress upon the want of proper arrangements for the manufacture of optical glass. The great want for instruments such as those described in the last lecture, was a mirror of sufficient size; and if it were possible to cast a disc of glass of eight feet diameter, and of the necessary thickness (which would be for a disc of that size about one foot) there was no difficulty whatever in silvering the surface. The largest amount of glass which could be run at the present time was about a ton, and this amount would not give sufficient thickness in a disc of the size mentioned. Mr. Lockyer laid great stress upon the importance of this point, and expressed a hope that the Society of Arts would take the matter up. He then proceeded to give some account of the progress which had been made in photographing celestial objects, by Mons. Janssen in photographing the sun, by Mr. Huggins in obtaining photographs of spectra of the stars, and by Mr. Common in obtaining photographs of the stars and nebulæ themselves. He exhibited and described the instantaneous shutter arrangement used by Mons. Janssen, and described the methods employed by the two other observers in their work. In the case of the long exposure rendered necessary by the faintness of the light of the stars, the motion of the clock was not sufficiently accurate to keep the image of the star always in the same position on the photographic plate, and it was necessary for the observer, by means of apparatus which Mr. Lockyer described, continually to regulate the position of the photographic plate by hand. Mr. Lockyer pointed out the importance of these photographic observations, which were not influenced by the idiosyncrasy of the observer, and which possessed the advantage of dealing with larger portions of the heavens, and more rapidly than the observer's eye. He expressed the view that it was now a waste of time to employ the eye in astronomical observations, and sketched an instrument having an aperture of eight feet, and costing only half the price of the domes now being built in Paris, by which photographic plates exposed by electro-magnets should be alone employed. By this means a complete reference library of the heavens at the present epoch could be secured for the benefit of those who come after us, giving forms of nebulæ and clusters, photometer star maps, double stars, and stellar and nebular spectra. He had suggested this idea to the French astronomers, and the matter was being discussed in Paris. He believed the permanent records to be secured by such a comparatively inexpensive instrument as this, would make the results obtained by other telescopes ridiculous, and that it was sure to be largely employed in the future if glass could be procured. At the conclusion of the lecture, a cordial vote of thanks to the lecturer was unanimously passed on the motion of Dr. R. J. Mann, F.R.C.S.

PRACTICAL EXAMINATION IN VOCAL OR INSTRUMENTAL MUSIC.

The next Examination in London will be held by Mr. W. A. Barrett, Mus.Bac. (Oxon), at the House of the Society of Arts, 18, John-street, Adelphi, W.C., during the week commencing on the 9th June, 1884.

Full particulars can be obtained on application to the Secretary.

Proceedings of the Society.

FOREIGN & COLONIAL SECTION.

Tuesday, April 29, 1884; F. W. Rudler, F.G.S., in the chair.

The paper read was—

THE TRANSVAAL GOLD-FIELDS; THEIR PAST, PRESENT, AND FUTURE.

By W. Henry Penning, F.G.S.
(Late of H.M. Geological Survey of England.)

In submitting the following remarks to the consideration of the Society, I may state that this paper was "written with a purpose," to bring prominently before the public certain facts relating to these fields which are, or ought to be, quite beyond question, and to remove, if possible, some wide-spread false impressions in regard to them. These false impressions I find to be numerous, but not always adverse; those, however, that are favourable should, I consider, be modified in accordance with the truth quite as much as those which are unfavourable, and which sometimes amount even to prejudice. For what is essential at this juncture is a just understanding and a true appreciation of the wealth of the Transvaal, from which alone can a reliable opinion be formed as to its future. In this future, Europeans cannot fail to play an important part; they may be misled by too glowing reports, and, in search of wealth, find poverty and disappointment; or, through apathy and ignorance of the true state of affairs, may fail to realise the wealth which undoubtedly lies before them in the Transvaal.

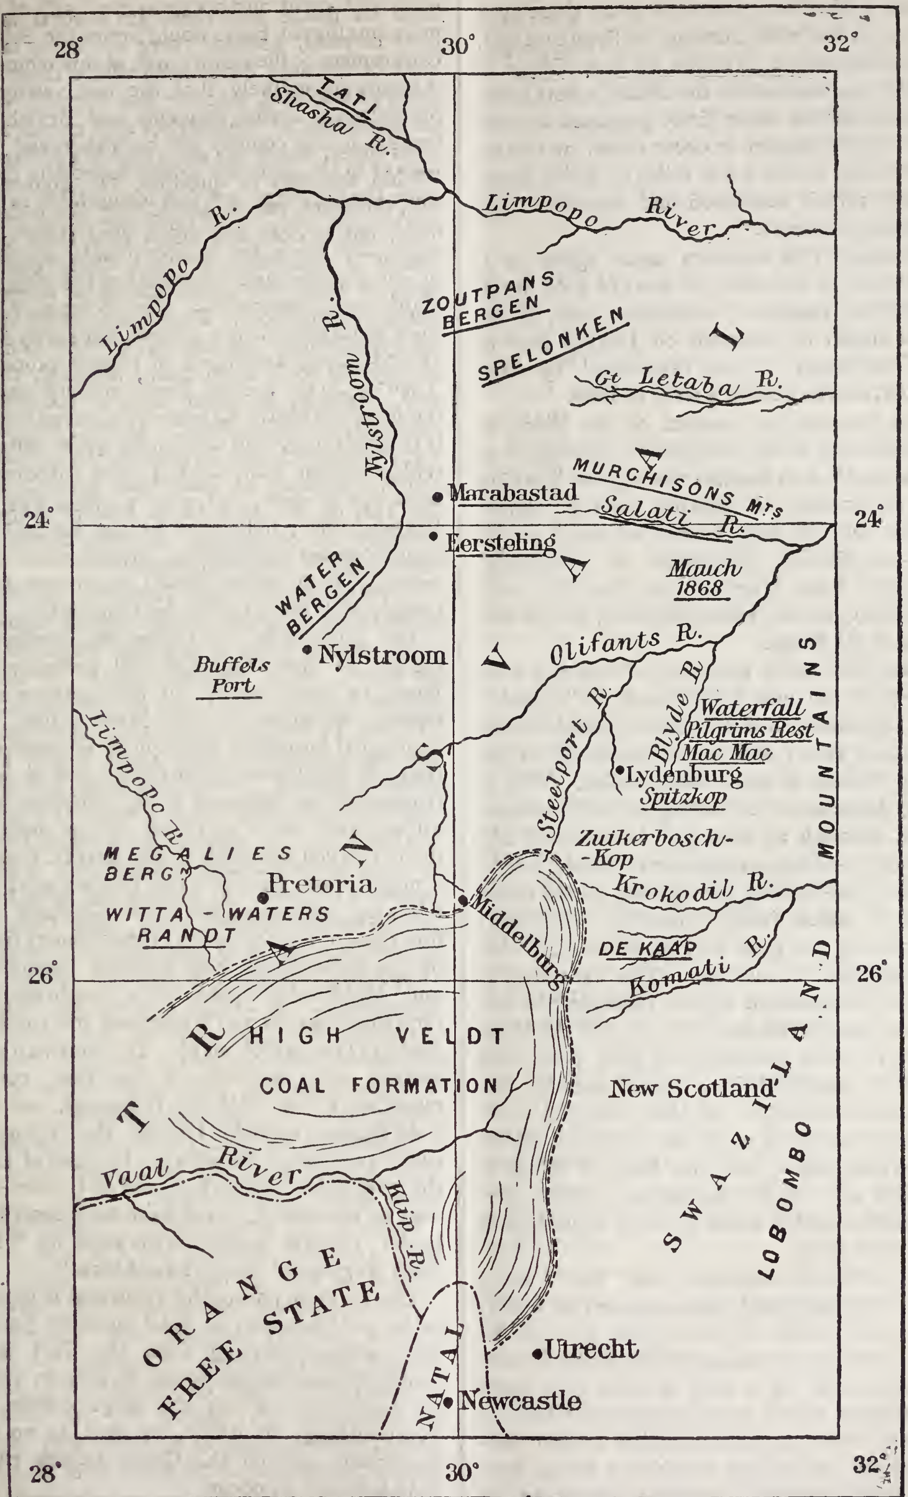
To this end I have not hesitated to avail myself of the published writings of others, or to criticise them freely from my own point of view; in all cases, where possible, giving the names of the writers and the titles of their works, that I may be open to correction if, through inadvertence, I have failed to catch or fairly represent their meaning. In many cases, details are given entirely from my own observations, for which, of course, I alone am responsible. In these, as well as in my deductions from all the facts before me, I am also open to, and will gladly receive, correction. Firmly believing that the true state of the case has only to be known, to render these the busiest gold-fields, as they are naturally the richest yet known in the world, I have exaggerated nothing. On the other hand, although well aware of the difficulties of political situation, of laws (or the want of them), and of the antipathy of the Boers to the Englishman, I have "set down nought in malice."

In a paper of this kind, I would keep clear of all political discussion, but cannot refrain from drawing attention to two significant facts:—A great number (possibly half) of the more intelligent Boers would prefer the British Government to their own; and, at this moment, it seems not unlikely, that the last vestige of protection to British residents and British interests in the country will be withdrawn. In regard to the first, the Boers, especially those upon the diggings, are fast losing faith in the justice and integrity of their own government, especially since the indiscriminate granting of concessions, and the denial of the digger's claims to compensation. The Boers may sell their birthright if they choose, but surely they should respect the rights of private property. Then, as to the second, the suzerainty may be the most shallow of all pretences, nevertheless, it is something, and something upon which a reality may be built; but if once withdrawn, what can be done, and what position will the British subject hold here in the future? It may be added that, before any alteration can be made, both parties should, up to date, fully comply with the terms of the Convention.

The gold-fields, or rather the auriferous region, of the Transvaal will probably be found to cover nearly all the northern and eastern districts of the State. For the geological formation throughout is similar to that of the known gold-fields, and it may reasonably be expected to be auriferous over all the area north and east of an elevated district called the High Veldt; that is, beyond a more or less irregular line passing near the following points:—From New Scotland the line runs across the heads of the Komati river, by the Zuikerbosch Kop between Lydenburg and Middelburg, then in a south-western direction towards and far beyoud the south of Pretoria (see sketch map). The northern and eastern area, bounded by this line, covers much more than half the Transvaal, and the gold-region extends beyond the Limpopo river, its northern boundary. In proof of this, the gold-fields at the Tati and at Hartley-hill may be mentioned, which have been described by Mr. Thomas Baines in his work on "The Gold Regions of South-East Africa."

The northern part of the Transvaal is proved to be gold-bearing, at least in some parts; for instance, coming from the Tati in a southerly direction along the Nylstroom river, we have on our left the large district of Zoutpansberg, in which, as well as on the Spelonken, and on the Great Letaba river, gold is known to occur.

Passing by Marabastadt, also a gold district, we come to Eersteling, where there are some



SKETCH MAP OF PART OF THE TRANSVAAL.

The names underlined represent the gold localities.

mines, worked for gold a few years since by a company, but which, during the Sekukuni war, were abandoned. Thence by the village of Nylstroom, near which the Buffel's Port Company, about the same time, proposed to mine for the gold known to occur there, and so on to Pretoria, within a few miles of which town, I have myself examined and reported upon payable gold-reefs.*

Crossing this northern area again in a north-eastern direction, we hear of gold in the Murchison range of mountains, and, a few miles south, as recorded on Jeppe's map of the Transvaal, it was discovered by Carl Mauch, on the Olifant's river in 1868.

The intermediate district of the Salati is also asserted to be auriferous. Turning now to the south, and leaving the regions in which the occurrence of payable gold is almost certain, but not fully known, we come to the well-established gold-fields at Waterfall, Pilgrim's Rest, MacMac, and Spitzkop, and, continuing in the same direction, to the new fields at De Kaap.

Some few miles westward of this last line, gold-reefs are now being found, for instance, near Lydenburg and towards the heads of the Krokrodil river; and to the eastward, in the Kaap Valley, at least twenty miles. This is a very large area—extending, in the Transvaal alone, through at least $3\frac{1}{2}^{\circ}$ latitude and $2\frac{1}{2}^{\circ}$ longitude—which, as a matter of course, would not be gold-bearing throughout, but in many parts of which (with a possible exception) prospecting for gold may be carried on with fair chances of success. The exception is that in the northern region there may be one or more coal-fields similar to that of the High Veldt, to which reference has been made, and recently described in a paper sent to the Geological Society. In that case the coal-bearing formation would mask that in which gold-veins occur; but the beds of which it consists are chiefly sandstone, readily distinguished, and in which it would be useless to search for gold.

It will thus be seen that the "belt" along which only reef-gold was supposed to occur, and about which we were wont to hear so much, has so great an extent as really to form no belt at all. It is only a short time since speculators would not entertain the idea of buying farms anywhere outside of the supposed belt which was considered to run from the older gold-fields towards the Kaap. I have no doubt that there are several main lines of reefs, because there are many main lines of volcanic dykes with which these are always associated, more or less parallel, with the exception of cross-dykes and consequent cross-lodes, which are often highly auriferous. Within the area in question, the gold-reefs will, therefore, run in something like definite lines, but it does not follow that their continuity is unbroken, or that where quartz-reefs, or veins, are found, they must be gold-bearing throughout. Farms absolutely upon the hypothetical belt are quite likely to have no payable reefs upon them, although there may, perhaps, be good ones in immediate contiguity on either hand. In fact, the gold-belt embraces the whole gold-region indicated above, extending at least from Pretoria and the Tati on the west to its eastern margin, probably at, or possibly beyond, Bondine's randt and the Lobombo mountains.

In many parts of the Transvaal, as elsewhere in South Africa, the traveller or explorer comes across holes of peculiar character in the earth, which present features of some interest, although their real nature cannot, at all times, be readily ascertained. These holes may be classified under three heads, and briefly described, as they have some, although very little, practical bearing upon the question before us. 1. More or less circular holes, in some cases partially refilled with a subterranean channel. 2. Similar but more irregularly-formed cavities, and open trenches with artificial heaps of *debris* upon the margin without any apparent attempt at system or arrangement. 3. Pits, or quarries, sometimes of considerable depth, shafts, open trenches and tunnels, with the refuse material stacked in heaps, or built up to form platforms or retaining walls, in a systematic manner.

Those of the first kind (1) are natural swallow-holes, formed, generally, in or near limestone rocks, by the action of water.

Those of the second kind (2) frequently so much resemble those of the first, that it is difficult to say, at once, whether they are natural or artificial, the heaps of *debris* having become partially levelled, and completely covered with vegetation. They are, however, undoubtedly the work of the natives, perhaps some centuries ago; and as they are found in several different kinds of material, they afford but small indication of the presence of precious metals. These old workings may be in beds, or veins, of the ores of iron or copper; in beds of ochre used by the natives as a pigment; in

* See also "Transvaal," Silver and Co., 1878, p. 20, and Jeppe's "Transvaal Book Almanac," 1881, p. 107.

veins of specular iron, which they use with grease as an ornament for the hair; or even in beds of pot-clay. Mr. Thomas Baines, in his work on "South-East Africa" (p. 26), refers to some of these pits made by the natives, "from which their forefathers used to dig a kind of metal, of which they professed ignorance." He continues (p. 28), speaking of some gold-reefs in the same district, "The reefs seem to be the greater part of a mile in length, but were so covered with refuse, thrown from the old surface workings, that their exact limit could not be easily determined; the holes were three or four feet wide, and sometimes ten or twelve feet deep. Here and there a group of holes had been worked into one, forming a large pit, and, in many of these, mimosa and other trees, from three to ten inches thick, were growing; proving that many years must have elapsed since they were worked, but not establishing for them a high antiquity." He also speaks (p. 42) of a present that he received of "a few grains of gold in a quill," as "invaluable, not that it showed me more than I knew in 1859, but as the means of proving the existence of a gold-field, worked by the natives, to our company at home."

The pits of the third class (3) are, doubtless, the work of white men, probably of the Portuguese, who are known to have mined for gold in this country several centuries ago. The supposition is strengthened by their similarity to the ancient workings, known to be Portuguese, in Brazil, and elsewhere in South America. But the nationality of these early miners is comparatively unimportant; their work proves that gold is sufficiently plentiful in this region to have been discovered ages ago, by those who were ignorant of scientific methods of research, and worked to advantage even by primitive methods and appliances. The old workings are very numerous in some parts of the gold-fields, and, indeed, in many parts also where the existence of gold veins is unknown; it is probable, therefore, that the old miners worked for other metals, as well as for gold.

Like other gold-fields, those of the Transvaal have had a rapid growth, with intervening periods of stagnation, sometimes even almost of abandonment. In 1868, Carl Manch, as before observed, discovered gold on the Olifant's River, and in the following year it was found at Lydenburg and at Marabastadt. In 1870, auriferous veins were reported in the Murchison range, and in 1871 at Spitzkop, which was, however, afterwards abandoned. Then Mac-Mac was opened, but after a time many left for the rich creek at Pilgrim's Rest, which was discovered in 1873, and which has yielded many nuggets of exceptional size. Then followed Waterfall in 1874, Rotunda Creek, and several other "new rushes." But the war with Sekukuni stopped further prospecting, and indeed nearly all kind of work at the gold-fields, for a considerable time. Although gold had been discovered in the valley of the Kaap in 1875, nothing was done there until the rush took place, early in 1882, to the high land overlooking this valley, where nuggets were being found literally on the surface.*

During the last year and half there has been, instead of the earlier spasmodic efforts, a steady development of the Transvaal gold-fields, owing, mainly, to the attention attracted to them by the discoveries at the Kaap. These took place during the recent crisis—almost panic—at the Diamond-fields, where so many hundreds of men were thrown out of work, and thus set free to try their fortune at the gold-fields. A great number from all districts flocked to the new fields, and for the most part met with great loss and disappointment. This was to be expected, as the great majority of them were new to the work, and as water was scarce, without which profitable gold digging was impossible. But they partially opened up many creeks and terraces, which eventually proved auriferous, and although at a loss to themselves, they paved the way for future discoveries. On the other hand, the depression at the Diamond-fields acted prejudicially, because, in consequence of the large withdrawal of capital from the country (to which, and over-speculation, the depression was due), it left but little cash available for Transvaal investments. But, after a time, speculators began to turn their attention in the direction of the gold-fields, which would then have received a great impetus had sufficient capital been forthcoming. Farms were taken under offer by them, and by many others also, with the option of purchase within a given time, and in the hope of re-selling in the meantime. This appeared so easy a method of realising a fortune that the natural result followed. In every direction men were getting farms under offer, and the prices rose enormously in consequence. Farms which were, as farms, worth a few hundred pounds, would be given, under such

* For fuller details of this history, see the "Guide to the Gold-Fields," published in Pretoria, in 1883.

conditions, only for as many thousands; and if they happened to be within the so-called "gold-belt," a very much larger sum was demanded. But the re-sale of unproved farms was found to be not so easy as anticipated. In many cases the stipulated time elapsed without a purchase being effected, and in consequence of this, more reasonable prices now prevail. But, even yet, very high figures are demanded for farms given under offer, which could be purchased for cash at a reasonable sum. Two thousand pounds down would buy farms in promising situations for gold, which would not be given for a time, with option of purchase, for less than six or eight thousand.

The state of things described necessitated a more definite search for gold. If a man had a farm under offer, he would endeavour to test its value before the time of that offer should expire. Consequently much prospecting has been done during the last twelve months, by men competent and incompetent, and with varied results. Certainly, gold has been found in places where its occurrence was before not even suspected. Moreover, almost every Boer now thinks his farm has gold upon it, and sets his "boys" to dig in all sorts of likely and unlikely places; whilst it is rare to meet one who has not a sample of quartz in his pocket, from a reef on his own property.

In the present stage of these fields, systematic search by competent men is greatly to be desired, and could not fail to yield valuable results. This may be accomplished by any or all of three separate methods: 1. By official survey, commencing at the known gold regions, and working towards the unknown; but this, in the present condition of the country, is scarcely to be expected.* 2. By the offer, on the part of the Government, of rewards for the discovery of gold-reefs and of alluvial fields. Such terms should be liberal, and immediate payment thereof guaranteed upon proof of success. The conditions and terms should be well defined—so much for reefs, so much for alluvial—and, on the other hand, the yield of gold that shall entitle prospectors to the reward must be equally definite. One ounce per ton average yield from reefs, two ounces from thin leaders, and one ounce from thirty cubic yards of alluvial ground, in a new field of given minimum area, would offer good chances to prospectors, and amply repay the Government. 3. By private prospecting by parties of men, under competent supervision, on behalf of speculators or companies, such men to be paid in wages, fully-equipped, directed to the more likely localities, judging from scientific observations, and to have their interest and co-operation secured by a small share in the results, in the event of success. The last plan is the one that seems at present most feasible in the Transvaal, having regard to its financial position, and it offers the greatest promise to those who are seeking good investments.

* See "Guide to Gold-fields," p. 73.

But in this many points have to be taken into consideration. The probabilities of good ground being discovered; the existence and the possibilities of ample supplies of water; the difficulties and facilities of travel; and last, but not least, that which has an important bearing upon the others, and upon the chances of success, a knowledge of the geological, physical, and climatal features of the Transvaal.

If a country be rich in mineral resources, it is beyond question to the interest of that country to develope and to utilise such native wealth. But development can only be stimulated by liberal laws, which shall provide not only for the encouragement of prospecting, in other words, of discovery, but also for security of tenure; for freedom from over-burden of taxation; and for facilities of working or sale. Until recently, it could not be said that laws of such a character existed in the Transvaal, nor is the new Gold Law, adopted in the recent Session of the Volksraad, all that could be desired. It is, however, a step in the right dlrection, its main features being briefly sketched as follows:—

Articles 2 and 3.—The Government reserves the right to all minerals, and can proclaim Government ground an open gold-field.

In regard to Government lands, such right is, of course, indisputable; but where private property is concerned, the case is decidedly different, as suggested in the following extract from the "Guide to the Gold-fields," p. 5. "It is hardly necessary to point out that the principle laid down is not maintained upon Australian and Californian gold-fields, where the rights to mine for gold are vested in the owner of the soil; nor, to quote an instance nearer home, does the Government of the Cape Colony assert a right to lease or concede privileges to mine for diamonds on private property." But the wrong to the owner is partially redressed, upon payment of royalty, in the succeeding article:—

Article 4.—The owner can claim a concession (if gold be found on his property) within six months of its published discovery. If he fail to do so, the Government can buy compulsorily and register it as Government ground.

This is somewhat arbitrary, as the proprietor may not, in all cases, however he may wish to do so, be able to pay the fees for getting the ground surveyed, and the first year's royalty, without which no concession is granted. He may, because his farm happens to be rich in gold, be turned out of his house and home, receiving only the amount, whatever it may be, awarded him by arbitration. But this clause, however hardly it may press on individuals, will, doubtless, tend to the opening of the gold-fields.

Article 5.—The Government can grant concessions upon any Government ground (originally so, or whether purchased under Article 4) not proclaimed as a public gold-field.

Articles 10 and 11.—The Gold Commissioner may grant prospecting-licences within twenty-five miles of proclaimed gold-fields, and a Landdrost within his district, but not on private property without the consent of the owner.

Articles 12 and 15.—A Diggers' Committee to be formed for the purpose of making local regulations, the members to be chosen by licence-holders in public election.

Article 22.—Licences will be issued, at a charge of 10s. per month, to prospect or dig on Government ground; also on private property under permit from the owner, who shall receive 7s. 6d. out of every such 10s.

Articles 23 and 24.—Any person shall have the right to one claim 150 by 150 feet only, but he may buy any number.

The law does not state, but it may reasonably be assumed, that after such claim is worked out (whether sold or not), the claim-holder will then be at liberty to take out another.

Article 31.—The prospector is entitled to 5 per cent. of the revenue derived by Government from the gold-field, in addition to his prospecting area.

Article 32.—Claims are protected for six months, upon which £500 has been expended for improvements or machinery, or which have been purchased for £300.

Article 33.—The Government to receive 2½ per cent. upon all finds.

These provisions are fair, although the collection of a per-centage upon finds from private diggers is open to several objections—not the least being the temptation to concealment. This, however, is met by the next clause, which was (amongst others) inserted at my suggestion, and which offers an inducement to diggers to declare the full value of gold discovered.

Articles 34 and 35.—Claims on a proclaimed gold-field can be resumed by Government on payment of compensation, the amount being fixed by an appointed commissioner, and based upon the percentage paid by the claim-holder. But if so resumed for the purpose of granting a concession thereon, the claim-holders shall have the preference if applying for such concession.

The principle here enunciated is just, and had it been adopted earlier, much trouble would have been saved, and much more gold extracted. But diggers have hitherto been in a state of uncertainty, especially at the Kaap, where a proclamation was actually made that the government reserved the right to refuse the renewal of licenses without being liable to claims for compensation.

A few words may be said here upon the concessions which it has recently been the policy of the Transvaal Government to grant, greatly to the future detriment of the country. It may be reasonably argued that these concessions, or some of them, have opened up lines of industry which otherwise would have remained in abeyance. But still they are monopolies, and this for the manufacture or production of those things most in demand by the population. Some of these are, iron, woollen and leather goods, hats, gunpowder, spirits, and so on, the prices of which will be unduly high in the absence of unfettered competition. These remarks do not, of course, apply to the concessions of gold-bearing properties, but in them also the plan pursued is much less to the advantage of the country than to that of speculators. Each mining-concession, except those on odd pieces of government ground, covers 500 morgen, that is, 1,000 acres, an extent quite unnecessary for gold-mining purposes. It is possible for there to be several reefs crossing such an area, and of these but one probably would be worked by the concessionaire or company. Had the ground been given out in small concessions on the reefs, say five to twenty claims, it would have been ample for all purposes, many men would have made fortunes, and the country would have derived immense direct revenues from the royalties payable upon extraction of the gold, and indirect from the increase of population.

Brief descriptions of the geological and physical features of the South African gold-fields have been given in the "Guide," to which previous reference has been made, and they need not be repeated here, as this paper is intended to regard them mainly from the point of view of the political economist. But to this end, and to prove the richness of the fields, a few descriptions are necessary, based upon published and authenticated reports, and upon my own observations; and to indicate the extent of the rich area, the points thus described and remarked upon will be selected from localities separated by wide distances.

(*a*) Commencing on the south, there is said to be much gold in Swaziland, but of this I have no authentic information, beyond that a *bonâ-fide* offer was made of several thousand pounds for a concession over a certain area granted by the King Mbondine.*

(*b*.) Some way north of this, in the Kaap Valley, coarse scaly gold is found in the alluvial deposits. I have seen some rich patches near the junction of the two main branches of the Kaap River, also towards the sources of the more northern stream. There are reefs also in this valley, a sample from one of which, sent to me for assay, yielded gold at the rate of 103·0 dwt. 20 grs. to the ton of 2,000 lbs.

(*c*.) Upon the Godwaan plateau (De Kaap) two rich reefs have been known for more than twelve months; but owing to difficulties about the boundaries of the farm "Berlin," on which they occur, and the claims of the diggers, they have been worked but very little. These are the "Homeward Bound" reef, containing much fine gold, and "Rautenbach's," a so-called "rotten reef," which, in parts, is wonderfully rich in very fine "flour-gold." Another quartz reef (or it may be a continuation of one of the above) has recently been opened, about two miles north, from 4 oz. of which, taken at hazard, I washed out two large specks of gold; and about two miles below the crest of the mountain, on the east of those just referred to, a quartz reef has recently been discovered. I washed a few ounces of this, and found one very large speck of gold, with two or three colours.

(*d*) At the "Devil's Kantoor," the head-quarters of the Kaap gold-fields, also at "Barrett's Rush," and elsewhere, many nuggets have been found on and just beneath the surface of the ground. Of course the majority of these are small, but those of large size are numerous. I have myself seen many taken out from 1 oz. up to 13 oz. in weight, and one has recently been reported of about 60 oz. from the Kaap Valley.

(*e*) Thirty miles or so, as the crow flies, north of the Kaap, is the district of "Spitzkop," in which many valuable auriferous deposits have been opened, and partially worked. Here is "Ross Hill," for the purchase of the mineral rights on which, and for machinery and working, a company was formed, with a capital of £75,000. Three diggers who held claims on this hill were bought out for £2,000 each, and they took away with them, as the result of two or three years' labour, gold worth £15,000.

(*f.*) Some claims upon the farm "Spitzkop" were examined by myself during the current year, and the following are extracts from my report, which was based upon assays and careful investigations:—

"Average samples were taken from this 'rich layer.' The relative proportions, by weight, were as 2¼ of the so-called 'rotten-reef' to 1 of quartz—the rotten-reef representing the 'pay-dirt,' from which gold is at present derived by sluicing, the stone being thrown away, in the absence of machinery for crushing.

"Upon assay the average sample of the rotten-reef was found to yield 16 dwt. 5 grs. of gold to the ton (2,000 lbs.)

"Some ferruginous quartz from a rich leader was crushed and washed on the ground, and yielded fine gold, estimated at 17½ oz. to the ton.

"Some samples were previously assayed by me, with results, as under:—

No. 1.	2 oz.	12 dwt.	11 grs.	to the ton.
,, 2.	4 ,,	10 ,,	21 ,,	,, ,,

"*Shaft No.* 1 *and Drive.*—This shaft is 25 ft. deep, down to the dyke, along the top of which a drive has been made 35 ft. to the N.N.W., following the downward dip to the 'rich layer,' that here consists 3 ft. of rotten-reef, with 1 to 2 ft. of poorer wash between it and the dyke. The shaft is sunk through contorted and partially decomposed shales, with quartz-leaders that are auriferous. This section proves the continuation of the gold-bearing veins and of the rich layer, without any diminution in thickness, as far as the boundary line between the two claims.

"Assays of quartz, with oxide of iron and manganese, from these leaders:—

No. 1.	1 oz.	10 dwt.	11 grs.	to the ton.
,, 2.	3 ,,	6 ,,	16 ,,	,, ,,
,, 3.	0 ,,	9 ,,	2 ,,	,, ,,

* Reported, since this paper was written, to have been sold for £60,000.

"*Shaft No.* 4 *and Cutting.*—Samples were taken, as before, from top to bottom of this section—the proportion of wash to stone is found to be as 3 to 1. The 'rotten-reef,' on assay, yields 1 oz. 13 dwt. 8 grs. to the ton. From this it is found that each ton of the strata passed through comprises 500 lbs. of stone and 1,500 lbs. of 'rotten-reef,' which contains throughout the mass 1 oz. 5 dwt. 1 gr. of gold.

"The 'rich layer' extends over all the unworked area of claims (each 400 by 300 ft.), and may be taken as having an average thickness of 3 ft.

"The quality of gold found is good, it occurs chiefly as very fine 'flour-gold,' about 20 per cent. only being of coarser grain."

As showing the value of this ground for sluicing by hydraulic appliances, for which there is ample water during a greater part of the year, the following example may be given:—One paddock, 35 ft. square and 12 ft. deep, was removed, and the gold obtained by sluicing, without crushing any of the quartz, weighed 107 ounces; equal to 4 dwts. to the ton of rotten-reef, leaders, and the shale in which they occur—the latter not being auriferous in itself, but the whole mass is so decomposed and mixed up in this case as to prevent separation.

I am able to vouch for the accuracy of the foregoing results, as they are based entirely upon my own work on the ground and in the laboratory.

(g.) The diggings at Mac Mac, a few miles north of Spitzkop, are well-known as having yielded much alluvial gold; and the "rotten-reefs" at and near Pilgrim's Rest, still farther north, have recently attracted mueh attention. The immediate future of the fields will depend greatly upon the results obtained by the machinery now being erected here, by the "Transvaal Gold-land and Exploration Company," which purchased the concessions granted to Mr. David Benjamin. The results can scarcely fail to be satisfactory, if the large amounts paid to diggers, as compensation for the loss of their claims, be any criterion. The total amount paid for a few of the best claims, could not have fallen far, if any, short of £50,000.

(h.) A few miles beyond Pilgrim's Rest, is the property called "Waterfall," consisting of two farms purchased by Mr. H. Gwynne Owen, and which has been fully investigated, with a view to the formation of a company, by the South African Syndicate. "Save me from my friends," might well be adopted as the motto of those interested in this undoubtedly valuable property, the failure of whose efforts to secure the confidence of the public, I believe to be due to too glowing representation. Some of the accounts to which publication was given are almost fabulous, and anyone who impartially examines the ground must fail to see whence they can have arisen. Still the veins are rich beyond question, and the existence of much water at a high level (so essential to successful gold-mining), renders Waterfall one of the most desirable properties in this or in any other country. A few brief extracts from reports, and other published documents, with remarks thereon, should be sufficient for the formation of an unbiassed opinion.

In a pamphlet entitled "The Transvaal Gold-fields," Mr. Owen states (p. 3) as to the farm Waterfall or Lisbon,* that "the extent of ground known to contain gold on this side hill, is not less than 5,000 acres, The average depth of the gravel on the side hill containing gold is about 20 ft. Experienced miners who have visited this ground, estimate the yield per ton of earth removed and washed will be 1 oz. per ton. The owner took many shovelsful from various parts of the ground (which he knows to be fair), assayed by Johnson, Matthey and Co., at 1½ oz. per ton." (£5 5s. per ton!)

Now, Mr. J. M. Stuart, in his "Report on the farm Lisbon" (p. 13), says, "the alluvial will average 15 feet in depth, and I estimate that there is not less than 300 acres of this gold-bearing ground. Careful tests on my part, by panning, lead me to the conclusion that the mass will pay from 1s. to 7s. the cubic yard."†

In my own notes upon Waterfall, I find that one man, with three or four Kaffirs, has been able to take out, from some of the best claims, an ounce of gold per day. Assuming them to have moved twenty cubic yards, this gives a value of 3s. 6d. per yard, or 2s. 4d. per ton, thus fairly agreeing with Mr. Stuart's observations. And I consider his estimate of the extent of alluvial ground to be low, as it cannot be much, if any, less than 500 acres; but, on the other hand, the average depth is not more than ten feet, the resulting quantity of available ground thus being about the same.

But I differ widely from Mr. Stuart in much more important particulars:—

* "Waterfall" includes the two farms "Berlin" and "Lisbon."

† Note in the pamphlet referred to:—"A cubic yard of gravel is equivalent to 1½ tons." Therefore Mr. Stuart's estimate of the yield of this material is 8d to 4s. 8d. per ton.

1. In his estimate of the yield of the leaders.
2. In his estimate of the yield of the shales.
3. In his interpretation of the geology of the district.

1. Mr. Stuart "made hundreds of tests on the ground, and the lowest tests showed over 10 ozs., and the highest about 1,000 ozs. per ton. . . . . I took samples from the eleven veins . . . . . being most careful that they should be a fair average. . . . . They were opened by Messrs. Johnson, Matthey & Co., who made assays of them:—average of 11 bags and 27 samples, produce of gold 48·5 ozs. per ton of 20 cwt. of ore.

The following are extracts from my own report upon Waterfall, dated May, 1883:—"In the following cases, where samples were assayed . . . . collected from all parts of the leaders and carefully averaged, all stone in which pieces of gold were visible was rejected.

No. 1.	2 oz.	1 dwt.	16 grs.	Mean 3 oz. 11 dwt. 14 grs. to the ton of 2,000 lbs.
,, 2.	6 ,,	8 ,,	12 ,,	
,, 3.	2 ,,	4 ,,	15 ,,	

To this mean yield may safely be added the odd 8 dwt. 10 grs. for nuggets and visible gold (rejected in the samples) . . . . and an average is thus obtained of 4 oz. per ton."

The proportion of slate to leaders being as 80 to 1, this would give a yield of 1 dwt. to the ton for the whole mass, which would yield enormous returns for sluicing by hydraulic machinery, although not nearly so rich as in the Spitzkop example (see p. 22) quoted, where the mass runs 4 dwt. to the ton. But in that case the ground consists of rotten-reef in much greater proportion; on the other hand, there is a much larger supply of high-level water here, all the year round.

2. Mr. Stuart estimates the proportion of the slate to leader as $13\frac{1}{3}$ to 1—I make it 80 to 1—thus:—" In Howse's claims the average distance apart of the eight leaders is 22 ft., and rather less in the other claims; 20 ft. may be considered a fair average, and 3 in. . . . . as the average width of the leaders."

I am thus compelled to reduce Mr. Stuart's estimates to one-fifteenth of their original dimensions; that is to $\frac{1}{6}$ in quantity of auriferous material $\left(\frac{13\frac{1}{3}}{80} = \frac{1}{6}\right)$, and to $\frac{2}{5}\left(\frac{403}{1003} = \frac{2}{5}\right)$ of the asserted yield of that material ($\frac{1}{6}$ of $\frac{2}{5} = \frac{1}{15}$). Even thus, the veins which, "with their slate interlaminations, constitute practically one vein 80 feet wide, one mile long, and on an average 325 feet deep" (Stuart, p. 9) contain gold to the value of £1,693,125 (£25,396,875 ÷ 15). The cost of extraction, that is, excavating the ground, crushing the quartz, &c. (as per my report), would not exceed £6 per 80 tons, or 1s. 6d. per ton, leaving a net profit of £705,468. But this only on a strip of ground 80 feet wide, whereas the veins are proved by the present workings to extend over a much larger area, and they, doubtless, occur also in the ground still unopened. Therefore, taking into consideration the probable lateral extension of the veins, and their almost certain occurrence to an indefinite depth, and not merely to 325 feet as calculated, I (in the words of my report) "have no hesitation in declaring that Waterfall is an extremely valuable gold mining property."

Mr. Stuart says:—"As to the slate, the softer portion should yield $\frac{1}{2}$ oz., and the harder portion $\frac{1}{4}$ oz. to the ton; but I think it safer not to attach any value to the slate." In this opinion he is quite right, as beyond traces of fine gold in the immediate contiguity of the veins, it is, to my mind, impossible for gold to have traversed the pre-existing rock, in the fissures of which the veins themselves are formed. Even if it were possible, it is difficult to see why, in a homogenous stratified rock, there should be different quantities of gold in its harder and softer portions.

3. I venture to differ entirely from Mr. Stuart in his interpretation of the geology of this district. He says:—"The underlying formation of the hills is composed of igneous rocks." Of this there is no evidence whatever, and the strata are exposed, in the deep valleys, many hundreds of feet; nor does the statement agree with more than one of the six sections (Fig. 6 in Exhibit No. 1) on the twenty-fourth page of his Report. Nor is it possible that "these strata are in many places broken through by dolomite," although they are traversed in many directions by "basaltic rocks."

"*Exhibit I.*—This plate shows the general geological sections of the several farms of Lisbon and neighbourhood. It shows the the different positions in which the gold veins occur, they being marked by a tint of yellow."

Fig. 1. Gold veins, or rather beds, interstratified with decomposed slates, tilted and contorted.

Fig. 2. Gold veins interstratified between diorite and decomposed slates, horizontal.

Fig. 3. Gold veins tilted, and in diorite.

Fig. 4. Gold veins between diorite and slates, tilted also between a diorite dyke and the edges of the slates it breaks through.

This last I consider the only representation in accordance with the facts, or even with the possibilities, unless, like the "deep leads" of Ballarat and elsewhere in Australia, these gold-veins are old alluvial deposits. But the sharp unworn character of the gold, and its occurrence in thin transverse quartz leaders, entirely set aside this supposition.

Fig. 5. Gold veins between diorite and slates.

Fig. 6. Gold veins between slates and between diorite and slates, curved; also between decomposed slates and between diorite and decomposed slates, tilted; one vein is shown in a diorite dyke.

In this latter position, that is in a trap dyke, quartz-reefs and leaders occur, but they are seldom gold-bearing in or near the dyke. The same lodes traced away from the dyke into the slates or sandstones, as the case may be, frequently proved auriferous.

As stated in my Report, "there is an intimate connection between these diorite dykes and the gold-bearing lodes of this region—the main lodes are parallel to the dykes, either in immediate contact or at no great distance, and both have, generally, a north and south direction. . . . In some cases no main lode can be detected, but there are many transverse quartz leaders, or cross-courses, which were originally cracks in the strata, caused by the intrusion of the volcanic mass from below, which naturally terminate at the dyke, although they run through it in some instances."

(*i.*) A few miles farther down the Blyde river, I have traced a reef of qaartz in regular crystals, cemented by oxide of iron, more than 3 ft. wide, and any portion of which will yield gold in the proportion of at least 2 oz. to the ton, one assay having produced 18 oz. to the ton.

(*j.*) Passing now to the westward, gold has been found in reefs, and in payable quantity along the valley of the Orighstad river.

(*k.*) In the Speckboom valley, still farther westward, thin leaders containing gold have recently been opened, and alluvial gold has been found on the banks of the river.

(*l.*) In the vicinity of Pretoria, alluvial gold has been found, although not in large quantity hitherto, and one reef over 2 ft. wide has been opened, a specimen of which, sent to me for assay (that must have been exceptionally rich), yielded gold at the rate of more than 30 oz. to the ton.

(*m.*) A few miles off the road between Pretoria and Potchefstroom there are quartz-reefs, from which 100 lbs. weight were sent to me for examination, and this quartz produced an ounce of gold to the ton.

These instances, although they do not prove, yet go a long way towards substantiating the proposition advanced, that "the gold-fields will probably be found to cover nearly all the northern and eastern districts of the State." By brief comparison with some of the Australian fields, I believe it may be shown, but also not proved, that they are "the richest yet known in the world."

To quote from the *Cape Argus* of October 31st, 1883:—

"The total yield of gold (reef and alluvial) in Victoria, in 1882, was 864,000 ozs. . . . The estimated quantity of quartz raised was 1,027,826 tons, which yielded an average of 6 dwts. per ton. In Sandhurst, the average yield from quartz was $13\frac{1}{4}$ dwts. per ton; in Gipp's-hand, 1 oz. 4 dwts. 6 grs.; at Beechworth, 12 dwts. 16 grs.; at Maryborough, 8 dwt. 7 grs.; at Ballarat, 6 dwts. $14\frac{1}{2}$ grs.; at Castlemaine, 5 dwts. 20 grs.

The mean yield of these reefs is, therefore, just under 11 dwts. per ton.

Again, the *Melbourne Argus*, of August 13th, 1883, in its "Mining Notes" upon about 200 mines, gives its usual weekly statement of returns. In connection with some of these, the number of tons of quartz crushed is also published, so that the yield per ton can be calculated. The average yield of the forty mines which can be thus treated is 10 dwt. 7 grs., thus closely agreeing with the quotation from the *Cape Argus*, and may, I think, be considered as approximately correct for all the mines of Australia; in round numbers, say 10 dwts., or half an ounce to the ton.

Now, taking the South African examples, quoted above, in which results have been obtained, we arrive at the following results:—

	oz.	dwt.	grs.	
b..	1	0	20	(Kaap Valley).
f..	1	9	12	(Spitzkop).
Mean of *h*..	4	0	0	(Waterfall).
i..	2	0	0	(Blyde River).
Assumed average of *l* and *m*....	1	0	0	(Pretoria).
	9	10	8	
Mean yield per ton	1	18	1	

This mean yield is more than three times that of the Australian mines, and is arrived at after rejection of rich samples from Spitzkop, also of Mr. Stuart's fabulous estimates of Waterfall. In the above calculation, only actual assays are taken, many known rich reefs, as *c*, *e*, being omitted in the absence of such assays;

but their yield would probably be over rather than under the above average. I am convinced that the mean yield of the reefs, rotten reefs, and leaders which are at present known, and likely to be worked on an extensive scale, will be at least 1½ ozs. to 2 ozs. to the ton.

It has, however, been shown in section *h*, that where the gold occurs in thin leaders, much ground will have to be removed that is not auriferous. Taking Waterfall (*h*) as a fair example of this, the whole mass of barren slate and quartz leaders will yield 1 dwt. to the ton, value 3s. 6d., against a cost of 1s. 6d. for mining and extraction. This leaves a profit of 2s. per ton on the whole mass, which can be enormously increased where plenty of water is available at a high elevation. Mr. Stuart estimates the cost of working upon the hydraulic system at 6d. (p. 14). Where the gold occurs in "rotten reef," the yield of the mass, as in section *f*, is found to vary from 4 dwts. to 1 oz. 5 dwts. per ton, independent of the exceptionally rich leaders here and there, some of which have been proved by myself up to 17½ oz. per ton.

Looking at all the facts before us, and rejecting all fancy estimates and favourable probabilities, we can scarcely fail to admit that these fields are amongst the richest, if not absolutely the richest, yet known in the world. It is otherwise as regards alluvial gold, and this is the cause that, in South Africa, has so frequently led to failure and disappointment.

In the "Guide to the Gold-Fields," the following passages occur:—"It must be borne in mind that Australian and Californian diggers, although, many of them, men of great experience, came to this country with preconceived notions. Most of them sought for alluvial gold on the water-worn creek gravels, and the lower contiguous terraces. Little attention could have been paid to the general character of this country, which presents evidences of denudation upon a very extensive scale, or their efforts would have been directed as well to the upper terraces and old river-beds at a higher level. Where no signs of what is called 'made ground,' existed, scarcely a pick was put in or a sod turned. Wherever attention was drawn to the rich deposits of doubtful origin, but now locally known as 'rotten reef,' it was declared that the reef was 'calcined' and the gold 'burnt out.' Sufficient evidence of the fact that the experience of other gold-fields has been at fault here is shown by the number of shafts that have been sunk, and afterwards abandoned, through soils that are now proved of the richest quality. Instances of this may be seen where shafts have passed through large masses of soil rich in fine gold, more especially on the highest point of the mountain above Pilgrim's Rest, which afterwards became known as the 'Company's Reef' and is now worked for fine gold upon the same spots that were successively abandoned as worthless." (pp. 11 and 12). "As the creeks at the lower levels are the result of recent denudation, and contain but little gold—as the higher patches of alluvium are more ancient, and contain a greater proportion of gold—the same condition of things will hold good elsewhere. If so, payable alluvial fields will be discovered, not exactly along the course of the existing streams (although fine gold may be found here and there in such situations) but at a greater or less distance from them, on the hills and terraces where alluvial deposits now represent the lines of an ancient denudation" (p. 57). But it is doubtful, for those very reasons, if an extensive as well as a payable alluvial gold-field will ever be found in this part of Africa."

If this be so, then the future of the fields depends not upon the advent of a large population, but upon the influx of capital. This is essential to the working of the large concessions taken out under the existing laws. Had small concessions been granted on reefs, as previously suggested, a few diggers could have combined and worked their ground as amalgamated claims; but there appears no chance of this being conceded by the Government. Therefore the reefs will be worked only by companies or capitalists, and herein lies the germ of temporary failure, as well as of ultimate success. Ground, rich beyond dispute, is purchased, tested by experts, and the promoters of the proposed company, not content with stating facts in themselves good enough to command public confidence, issue glowing descriptions and estimates of profit which would be marvellous if they were not ridiculous. The public are not to be caught by such shallow methods, but, unfortunately, rush to the other conclusion, that there is no gold in the Transvaal, and that the whole thing is a swindle. Had facts been stated in the first place, and reasonable sums invited, we should have seen by this time many companies at work, producing large quantities of gold, and paying high dividends. Instead of that, we have an exactly analogous case of over-greed and consequent collapse to that of the Diamond-fields.

But these things will rectify themselves. The gold is here, and, sooner or later, will be extracted, and, after all, the lesson of the last few months will not have been lost if it lead to a more careful and healthy tone of speculation. It should lead also to a thorough detailed investigation of the opened mines, that a reliable report upon them may be issued by the authority of the Government. This, and this only, will hasten a return of that confidence which must, at no distant date, be restored in gold-fields of the Transvaal. Surely our own Government should take an interest, not to say an active part, in furthering an inquiry into the truth or falsity of the statements published regarding the wealth of this country. If the gold-fields are unworthy of confidence, let the fact be made known, so as to prevent a recurrence of the Indian experience; if worthy, let this fact be also known—wide and authoritatively known—as the fields will provide an outlet, not only for British capital but for emigration. At the present period of our history this surely is an important consideration—the point towards which, with advantage to them and to ourselves, we shall direct our surplus population. And now is the time, if these fields be good, to encourage a movement in this direction; now the Boers will gladly see an influx of diggers and companies, for then they will have a market for their produce which they have not had since the retrocession of the country.

The argument may be summed up in a few words:—That the Transvaal gold-fields were known in the past, is proved by the existence of old workings by the natives, and probably by the Portuguese; the earlier efforts having been suddenly terminated, as have those of more recent times, by wars between the white and black races. As regards the present, the wealth of the fields is known to a few, although doubted by many, but the doubt is evidently qualified by a suspicion that, after all, there may be in them something worthy of investment. The Transvaal always attracts attention if not capital, and if the former were to be properly directed, the latter would speedily follow. Hitherto this has not been the case, for wrong ideas prevailed regarding the gold-belt, and this limited the earlier prospecting; then the promised recent development was retarded by uncertain laws, by the granting of concessions, and by false speculation. The future may be easily foreseen, for that very attention will ensure at an early date, if not capital, at least funds for investigation. Then the extent and richness of the Transvaal gold-fields will be not only asserted but proved, and the comparison, briefly instituted above, between them and others will be substantiated. Peace between the whites and the blacks seems now to be assured for some years to come; the Government must soon see the necessity of increasing the revenues of the country, and better gold laws will be framed to that end. Then a tide of population and capital will set in, and the the gold now lying unutilised will be extracted from the ground. By this, not only will investors be benefited, but it will provide an outlet for the other resources of this country, as well as for the surplus population of our own. It will tend also to promote friendship between the European and the Africander, by the creation of mutual interests and of joint prosperity.

DISCUSSION.

Sir JOHN SWINBURNE, Bart., said that in 1869 he went up into the interior through the Orange Free State, across the Vaal River, and thence over the centre and western portion of the Transvaal Republic. He was accompanied by Mr. Auguste Greite, an Australian miner of great practical experience. Between Rustenberg and Potchefstroom, some twenty or thirty miles north of Wonder Fontein, they were struck with the appearance of some quartz reefs which cropped out on the surface, and Mr. Greite expressed a firm conviction that there was gold there. He now heard that this opinion had been verified. He could not say much as to the gold-fields of Pilgrim's Rest and the eastern portion of the Transvaal, as he had never visited that side of the Transvaal; but some nine or ten years ago, an old friend informed him that his son had worked for less than twelve months at those gold-fields, and had returned to England with a competency. He had also heard of parties returning to Australia with as much as £40,000 to £60,000, which they had earned in a space of two or three years. Many of the Europeans who went to the Transvaal were unable to keep their temper with the Kaffirs, who, no doubt, were frequently very trying to men accustomed to employ only white men, and the Kaffirs will not remain with any one who is hard towards them. His own manager had reported to him that the Zulus and other natives north of the Transvaal made splendid miners after a few weeks' training, but after twelve months' work they earned sufficient to purchase a gun, when they considered themselves gentlemen, and consequently declined to work any longer; but they generally induced some friend or relative to take their place before leaving. In the Transvaal you had a healthy climate, cheap provisions, and cheap labour; while in most places there was plenty of water power at command for working stamp mills and the usual mining machinery. After a few years occupied in the steady development of this country, he could not see why the South African Republic should not be equal, as a gold-producing country, to any portion of Australia or South America.

Captain MILLS, C.M.G., as representing the Cape Colony in this country, said he could not but be deeply interested in the paper which had just been read. There were many points in it which he could fully corroborate, such for instance as the knowledge of the existence of gold-fields for ages past in the Transvaal. He had himself seen a map executed in the year 1642, on which the gold-fields of the Transvaal were plainly laid down. That map was now in the possession of the Royal Geographical Society. One point which struck him as deserving of notice, was the suggestion that the Transvaal Government should offer prizes for the discovery of gold, in fact for the discovery of any mineral wealth; but he was totally opposed to prizes being given by the Government for such discoveries, as he considered it was the business of private enterprise to develop resources of that kind. As to the comparison between the finds in Australia and in the Transvaal, it struck him (without wishing for a moment to disparage the estimate of the finds in the Transvaal) that the Australian average was taken from the total amounts derived of the workings from all the mines, whereas the average in the Transvaal was taken from samples, which made an immense difference. He should like to know from Dr. Mann whether the estimate had been taken from sample, or from the total produce. Mention was made in the paper as to the gold-fields being visited by Europeans as well as Africanders. He himself did not like to see such distinctions drawn. He deprecated any national distinction. With the knowledge that they had such a rich gold-field in the Transvaal, surrounded as it is by British colonies, we ought to make up our minds that all nationalities should go hand in hand and help each other in developing the wealth and resources of the country. In California and other parts of the world the Chinese worked side by side with Europeans, and that being so, the English ought not to draw distinctions between themselves and the Dutch and the Africanders, or any one else.

The Hon. Major ERSKINE said that, being connected with the Lisbon mines, he had not intended to take any part in the discussion, but as allusion had been made to former mining operations in this part of South Africa, and he had studied that question very carefully lately, he felt that he might mention some results which he had arrived at. The English description of the old mines was to be found in "Miller's Geography," 100 years old, and the return given from the Portugese mines was fallacious, it being stated at three and a half millions per annum. Such a statement as that was enough to ruin belief in the whole matter. He was convinced that nothing of the kind had ever taken place, because if it had, the Portuguese would never have abandoned the territory. Nevertheless, enormous results were produced, considering that machinery was scarcely used, and in some cases, from the labour of Kaffir women alone, £40,000 worth of gold had been exported in one year from one mine. He had not been able to get any return of the whole amount which had been exported, although the Government had promised to supply this information. The most auriferous district was "Monica," extending to 27°, and the Lydenburg gold-fields were situate in 25½°. For 1,000 miles along that coast gold-fields had existed for centuries, and if £40,000 worth of gold could be produced from Kaffir labour alone from one mine annually, there was no reason why, if proper machinery was employed, £400,000 worth should not be produced from the "Lisbon and Berlyn" mines. He had lately received a letter from his son, who was at present at the gold-fields, stating that "Lisbon and Berlyn" was full of gold.

Mr. HYDE CLARKE said he had long taken a deep interest in South Africa, though he could not say that he had any practical experience of the Transvaal. He thought it important that prospecting should be encouraged in every way, but, at the same time, it was exceedingly desirable that persons should not expect too much in the early stages of work, and the writer of the paper had given some very good cautions upon that subject. As reference had been made in the paper to the subject of Indian gold, he might, perhaps, be permitted to say that the Indian gold mines could teach them a very good lesson. When the subject was previously discussed in that room, there was, upon the one hand, a strong disposition to represent that there was no gold in India at all; and, upon the other hand, there was a disposition to raise exaggerated expectations, and he then took the liberty of suggesting that the subject should be dealt with in a practical way. However, that had not been done, and gold-mining in India had been carried on from a Stock Exchange point of view, with what result every one knew. When the mines were taken over, too great a price was given for the land, and machinery was sent out before the grounds were developed, merely for the purpose of raising expectations amongst speculators. In Africa, as well as in India, they had examples of ancient workings, and it was absolutely necessary in all gold-mining operations that the work should be taken up in a practical spirit. He quite agreed with the remarks made by a previous speaker as to the necessity of Europeans working amicably with the Africanders. It is well known that the Transvaal delegates had not been received in some quarters with the attention which many desired should be shown to them, though, fortunately, her Majesty's Government had shown a great degree of attention, and the delegates entertained a very good feeling as to the reception which had been accorded them.

Mr. BARRETT said he had just arrived from the Transvaal, and had brought a few nuggets back with him, which he should be glad to exhibit. The nuggets had been found on the surface of the Berlin and De Kaap farms. One of the nuggets now exhibited weighed as much as 32 oz., another 14 oz. 14 dwt., and another 11 oz. 16 dwt. They were found during February and March, and in six weeks one man secured 105 oz. of gold, with the aid of one Kaffir and his son. He had also himself brought back to this country six tons of quartz which had been taken from the reefs "Homeward Bound," "Rautenbach," and "Collins," on the farms Berlin and De Kaap.

Dr. HUGH EXTON thought nothing could give greater weight to the paper which had been read than the specimens of gold which had just been produced by Mr. Barrett. He was himself one of those who had preceded Sir John Swinburne in a visit to the Tati fields, and he had listened with great interest to the paper, as well as to the remarks of Captain Mills with regard to the ancient map describing the gold-fields 200 years ago. Gold was first discovered at Tati by a hunter named Hartley, and upon an investigation, it was found that excavations had been made at this place many hundreds of years previously. In Tati the gold existed in extremely minute particles, though a small quantity had been obtained by means of crushing apparatus. In the Transvaal gold was also discovered in extremely small particles in the first instance, but as time had gone on, the yield had not only become larger, but the size of the nuggets found had also increased, and there was now no question, from the evidence which had been published, and the gold which had found its way into Natal, that a large quantity was being obtained. If prospectors had some security that they would reap the benefit of their finds, there was no doubt that a great stimulus to prospecting would take place.

Dr. MANN said, with regard to the question as to the estimate which had been made, the paper itself would show that Mr. Penning had exercised great care, having taken samples from many different places. No doubt some margin should be allowed with estimates of this class. His own impression, however, was, that Mr. Penning had taken care to have fair ground for the statements he had made. Captain Mills was no doubt right that the Australian returns were taken from the results of actual work.

Captain MILLS said he did not wish to throw any doubt upon Mr. Penning's statement. He only desired to guard against over sanguine statements which might lead to a mischievous reaction. He begged to propose a vote of thanks to Mr. Penning for the paper, and to Dr. Mann for reading it.

The Hon. Major ERSKINE seconded the resolution.

The CHAIRMAN said the paper was one of much value, its author being a trained scientific observer. Notwithstanding some observations which had been made upon it, Mr. Penning's view seemed, on the whole, moderate. It unfortunately happened, as Mr. Penning pointed out, that occasionally people who were naturally interested in the development of gold-fields in the colonies allowed their imagination too much scope; but, upon the other hand, there were people who, having been bitten before, were exceedingly shy in entering upon gold speculations. The author of the paper had taken a mean course, and had warned them against too brilliantly coloured reports, though he pointed out that the gold-producing rocks of the Transvaal were distributed over a very wide area. Any scepticism was disposed of by the wonderful specimens which had been exhibited that night. He had hoped that the paper would have dealt with the geological description of the gold-bearing area in the Transvaal; but no doubt this subject would be taken up on a future occasion. The relation between the auriferous reefs and the dykes of diorite was interesting in connexion with certain views held by the late Mr. David Forbes. Before concluding, he might refer to a globe which had been exhibited by Mr. J. Baddeley at the Geological Society, around which was marked a red line, cutting the equator obliquely in long. 10° E., and 170° W., and with its northern and southern intersections in lat. 45°. The circle corresponded nearly in position to some of the principal gold-producing mines in the world; in Australia, in several parts of North America (from California to Nova Scotia), in West Africa, and in the Transvaal. At the same time he was careful to explain that he regarded this as nothing more than a "curious coincidence.

The resolution was passed unanimously.

Dr. MANN said he would take care to convey to Mr. Penning, who was at present in the Transvaal, the vote of thanks which had just been passed by that meeting.

TWENTIETH ORDINARY MEETING.

Wednesday, May 7, 1884; B. W. RICHARDSON, M.A., M.D., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Flew, John Pearce, Fulham-park-gardens, S.W.
Habershon, Matthew Henry, Eversley, Richmond-road, New Barnet.

Harris, David, Caroline-park, Edinburgh.
Hope, R. C., F.S.A., Albion-crescent, Scarborough.
King, G. Swinburn, 1, Devonshire-terrace, Hyde-park, W.
Phillips, John Orwell, Gas Light and Coke Company, Horseferry-road, S.W.
Pocknell, George, Lonsdale, Exeter.
Shuter, James Legasick, 9, Steele's-road, Haverstock-hill, N.W.
Watson, Thomas Donald, 23, Cross-street, Finsbury, E.C.

The following candidates were balloted for and duly elected members of the Society :—

Beilby, George T., Midcalder, N.B.
Bridgford, Major Sidney Thomas, R.M.A., Army and Navy Club, Pall-mall, S.W.
Butler, Henry, 50, Lee-terrace, Blackheath, S.E.
Clarke, Caspar Purdon, C.I.E., 3, Sheffield-terrace, Campden-hill, W.
Gibbs, Surgeon-Major J. G., Riggindale-road, Streatham, S.W.
Morgan, William, Waverley, Albemarle-road, Beckenham.
Parlane, James, Appleby-lodge, Rusholme, Manchester.
Pearcy, Joseph, 127, Englefield-road, Islington, N.
Peel, Captain Francis, Boxted-house, Colchester.
Pleydell, Thomas George, Commercial Bank of South Australia, 24. Lombard-street, E.C.
Ross, Rev. Henry, M.A., Dallas-house, Lancaster.
Samuel, Sir Saul, K.C.M.G., 15, Courtfield-gardens, S.W., and 5, Westminster-chambers, S.W.
Turpie, William, Bank-house, Derby.
Wight, Laurence Hill, M.A., 41, Chambers-street, Edinburgh.
Wilkin, Miss, Cossey-cottage, Hampstead, N.W.

The paper read was—

BICYCLES AND TRICYCLES.

By C. V. Boys.

The subject of this paper is one of such wide interest, and of such great importance, that it is quite unnecessary for me to make any apology for bringing it before your notice. Exactly two months ago, I had the honour of dealing with the same subject at the Royal Institution. On that occasion I considered main principles only, and avoided anything in which none but riders were likely to take an interest, or which was in any way a matter of dispute. As it may be assumed that the audience here consists largely of riders, and of those who are following those matters of detail, the elaboration, simplification, and perfection of which have brought the art of constructing cycles to its present state of perfection, I purpose treating the subject from a totally different point of view. I do not intend, in general, to describe anything, assuming that the audience is familiar with the construction of the leading types of machines, but rather to consider the pros and cons of the various methods by which manufacturers have striven to attain perfection. As a discussion on the subject of this paper will doubtless follow—and I hope makers or riders of every class of machine will freely express their opinion, for by so doing they will lend an interest which I alone could not hope to awaken—I shall not consider it necessary to assume an absolutely neutral position, which might be expected of me if there were no discussion, but shall explain my own views without reserve.

The great variety of 'cycles may be grouped under the following heads :—

1. The Bicycle unmodified.
2. The Safety bicycle, a modification of 1.
3. The Centre-cycle
4. The Tricycle, which includes five general types.—
(a.) Rear steerer of any sort.
(b.) Coventry rotary.
(c.) Front steerer of any sort (except e).
(d.) Humber pattern.
(e.) The Oarsman.
5. Double machines: sociables and tandems.
6. The Otto.

It is perfectly obvious that not one machine is superior to all others in every respect, for if that were the case, the rest would rapidly become extinct. Not one shows any signs of becoming extinct, and, therefore, it may be assumed that each one possesses some points in which it is superior to others, the value of which is considered by its riders to far outweigh any points in which it may be inferior. The widely varying conditions under which, and purposes for which, machines are used, and the very different degrees of importance which differently constituted minds attach to the peculiarities of various machines will, probably, prevent any from becoming extinct. Nevertheless, the very great advantages which some of these possess over others will, no doubt, in time become evident by the preponderance of the better class of machines.

The bicycle, which surpasses all other machines in simplicity, lightness, and speed, will probably, for these reasons, always remain a favourite with a large class. The fact that it requires only one track places it at a great advantage with respect to other machines, for it is common for a road which is unpleasant from mud or stones to have a hard smooth edge, a kind of path, where the bicyclist can travel in peace, but which is of little advantage to other machines. Again, the bicycle can be wheeled through narrow gates or doorways, and so kept in places which are inaccessible to tricycles. One peculiarity of the bicycle, and to a certain extent of the centre-cycle, is that the plane of the machine always lies in the direction of the resultant force, that the machine leans over to an amount depending on the velocity and the sharpness of the curve described. For this reason all lateral strain on the parts is abolished, and if we except the slipping away of the wheel from under the rider, which can hardly occur on a country road, an upset from taking a curve too quickly is impossible. This leaning to either side by the machine and rider gives rise to that delightful gliding which none but the bicyclist or the skater can experience. In this respect the bicycle has an enormous advantage over any machine, tricycle or Otto, which must at all times remain upright, and which must, therefore, at a high speed, be taken round a curve with discretion.

The perfect and instantaneous steering of the bicycle, combined with its narrowness, counteract, to a great extent, the advantage which the tricyclist has of being able to stop so much more quickly, for the bicyclist can "dodge" past a thing for which the rider of the three-wheeler must pull up. In one other respect the bicyclist has an advantage, which, though of no real importance, has great weight with many people. The bicycle well ridden presents a picture of such perfect elegance that no one on anything else need expect to appear to advantage in comparison.

The chief disadvantage of the bicycle is the fact that a rider cannot stop for any purpose, or go back a little, without dismounting. For town riding, where a stoppage is frequently necessitated by the traffic, this perpetual mounting and dismounting is not only tiresome but wearying, so much so, that few bicyclists care to ride daily in town.

The position of the rider on a bicycle with respect to the treadles is by no means good, for if he is placed sufficiently far forward to be able to employ his weight to advantage without bending himself double, he will be in so critical a position that a mere touch will send him over the handles. He has, therefore, to balance stability and safety against comfort and power; the more forward he is, the more furiously he can drive his machine, and the less does he suffer from friction and the shaking of the little wheel; the more backward he is, the less is he likely to come to grief riding down hill, or over unseen stones. The bicyclist is no better off than the rider of any other machine with a little wheel, the vibration from which may weary him nearly as much as the work he does. The little wheel as a mud-throwing engine is still more effective on the bicycle than it is on any tricycle, for in general it is run at a higher speed.

I now come to the usual complaint about the bicycle. There is a fashion just now to call it dangerous, and the tricycle safe. But the difference in safety has been much exaggerated. The bicyclist is more likely to suffer from striking a stone than his friend on three wheels, but then he should not strike one where the tricyclist would strike a dozen. Properly ridden, neither class of machine can be considered dangerous; an accident should never happen except it be due to the action of others. People, carts, cattle, and dogs on the road are liable to such unexpected movements, that the real danger of the cyclist comes from the outside; to danger from absolute collapse due to a hidden flaw in the materials employed, every one is liable, but the bicyclist more remotely than the tricyclist, owing to the greater simplicity of his machine. The bicyclist, though he has further to fall in case of an accident from any of these causes, is in a better position than the tricyclist, for he is outside instead of inside his machine; he can in an instant get clear. It would appear that many tricyclists consider accidents of the kind next to impossible, for in several machines the rider is so involved, that an instantaneous dismount without a moment's notice, at any speed, is absolutely impossible. There remains one objection, which, however, should be of next to no importance—the difficulty of learning the bicycle prevents many from taking to the light and fast machine, because they are afraid of a little preliminary trouble.

The chief objections to the bicycle, then, are the liability of the rider to go over the handles, the impossibility of stopping very quickly, and the inability to remain at rest or go backwards, and the difficulty of learning.

The first two of these are, to a large extent, overcome in the safety bicycles, but not without the introduction of what is in comparison a certain degree of complication, or without the loss of the whole of the grace or elegance of the bicycle. On almost all these safety bicycles the rider is better placed than on the unmodified bicycle, but though safer I do not think bicyclists find them compete in speed, though, no doubt, they are superior in that respect to the tricycle. Though they do not allow the rider to stop without dismounting, the fatigue resulting from this cause is less than it is with a bicycle, owing to the fact that with the small machines the rider has so small a distance to climb. Of these machines, the "Extraordinary" leaves the rider high up in the air on a full-sized wheel, but places him further back and more over the pedals. The motion of these is peculiar, being not circular but oval, a form which has certain advantages.

In the Sun and Planet and Kangaroo bicycles, a small wheel is "geared up," that is, is made to turn faster than the pedals, so as to avoid the very rapid pedaling which is necessary to obtain an ordinary amount of speed out of a small wheel. In each of these the pedals move in a circular path, and their appearance is in consequence less peculiar than that of the Facile, which, in this respect, does not compare favourably with any good machine. The pedal motion on the Facile is merely reciprocating. Riders of machines where circular motion is employed, among them myself, do not believe that this reciprocating motion can be so good as circular, but I understand this view is not held by those who are used to it. Of course, the harmonic motion of the Facile pedal is superior to the equable reciprocating motion employed in some machines where speed is an object, especially with small wheels.

If I have overlooked anything typical in the modified bicycle class, I hope someone will afterwards supply the omission, and point out any peculiarities or advantages.

That very peculiar machine, the Centrecycle seems to combine many of the advantages of the bicycle and tricycle. On it the rider can remain at rest, or can move backwards; he can travel at any speed round curves without an upset being possible; he can ride over brickbats, or obstructions, not only without being upset, but if going slowly, without even touching them. As this machine is very little known, a few words of explanation may be interesting.

In the first place, the rider is placed over the main wheel, as in the bicycle, but much further forward. There are around him, on or near the ground, four little wheels, two before and two behind, supported in a manner the ingenuity of which calls for the utmost admiration. Turning the steering handle not only causes the front and rear pairs to turn opposite ways, but owing to their swivelling about an inward pointing axis, the machine is compelled to lean over towards the inside of the curve; not only is this the case, but each pair rises and falls with every inequality of the road, if the rider chooses that they run on the ground; but he can, if he pleases, arrange that in general they ride in the air, any one touching at such times as are necessary to keep him on the top of the one wheel on which alone he is practically riding. He can, if he likes, at any time, lift the main-wheel off the ground, and run along on the others only. The very few machines of the kind which I have seen have been provided with foot straps, to enable the rider to pull as well as push, which is a great advantage when climbing a hill, but this is on every machine except the Otto, of which I shall speak later, considered a dangerous practice.

Some of the objections to the bicycle to which I have referred were sufficient to prevent many, especially elderly men, from dreaming of becoming cyclists. So long as the tricycle was a crude and clumsy machine, there was no chance of cycling becoming a part, as it almost is, and certainly soon will be, of our national life. The tricycle has been brought to such a state of perfection, that it is difficult to imagine where further progress can be made.

Perhaps it will be well to mention what is necessary, in order that a three-wheeled machine may be made to roll freely in a straight line, and also round curves. At all times each wheel must be able to travel in its own plane in spite of the united action of the other two. To run straight, the axes of all the wheels must obviously be parallel. To run round a curve, the axis of each must, if continued, pass through the centre of curvature of the curve. If two wheels have a common axis, the intersection of the two lines forming the axes can only meet in one point. To steer such a combination, therefore, the plane of the third wheel only need be turned. If the axes of no two are common, then the planes of two of the wheels must be turned in order that the three axes may meet in a point.

Not only does free rolling depend on the suitable direction of the planes of the wheels, each wheel must be able to run at a speed proportional to its distance from the point of intersection of the three axes, *i.e.*, from the ever-shifting centre of curvature.

The most obvious way, then, of contriving a three-wheeler is to drive one wheel, steer with another, and leave the third, which must be opposite the driver, idle. The next in simplicity is to drive with one wheel, and steer with the other two, having one in front, and the other behind. So far then, the single driving rear-steerer and the Coventry rotary pattern, are easily understood. The evils of single driving, minimised, it is true, to a large extent, in the Coventry rotary, have led to the contrivance of means by which a wheel on each side may be driven without interfering with their differential motion in turning a corner. Three methods are commonly used, but as only two are employed on tricycles, I shall leave the third till I come to the special machine for which it is necessary. The most easy to understand is the clutch, a model of which I have on the table. If each main wheel is driven by means of one of these, though compelled to go forward by the crankshaft, it is yet free to go faster without restraint. By this means "double driving" is effected in several forms of tricycle. Differential gear, which is well understood, and of which there are several mechanically-equivalent forms, divides the applied driving power, whether forwards or backwards, between the main wheels, equally if the gear is perfect, unequally if imperfect. To understand the effect of the two systems of driving, and of single driving, let us place on grooves a block which offers resistance to a moving force. If we wish to move it, and apply our force at the end of one side, it will tend to turn round as well as move forward, and much friction will be spent on the guides by their keeping it straight. This is the single driver. If, instead of applying force at one side, we push the block bodily forward by a beam moving parallel to itself, then so long as the guides are straight no strain will be put upon them, even though one side of the block is resisted more than the other; if, however, the guides compelled the block to travel round a curve, then the power, instead of being divided between the two sides in such proportion as is necessary to relieve the guides of all strain, is suddenly applied only to the inside, and the effect is that of a single driver only. This is the clutch. Lastly, if the last-mentioned beam, instead of being pushed along parallel to itself, were pivoted in the middle, and that pivot only pushed, the same power would be applied to each side of the block, and no strain would be thrown on the guides, whether straight or curved, so long as the resistance opposed to the block on the two sides were equal; if, however, one side met with more resistance than the other, then the guides would have to keep the block straight. This is the differential gear. I have assumed that in the last case the force was applied to the middle of the beam; this corresponds to every evenly-balanced gear. In the gear employed by Singer, which is not evenly balanced, but which derives its good qualities from its simplicity, the same effect is produced as if the beam were pivoted on one side of the centre, instead of on the centre. Thus, though both sides are driven, one is driven more than the other. On the whole, there is no doubt that the balanced gear gives a superior action to the clutch, for except when the two sides of the machine meet with very different resistance, and then only when running straight, the clutch will not compare with the other. The clutch also gives rise to what is considered by most riders a grave defect, the inability to back treadle, while the free pedal, which is an immediate consequence, is considered by others a luxury. On the other hand, this same free pedal can be obtained on differentially-driven machines to which speed and power gear have been applied.

Of the relative merits of different forms of differential gear there is little to be said. Perhaps it will not be thought I am unduly thrusting myself forward, if I refer to a scheme of my own, in which no toothed wheels are employed, but in which two conical surfaces are driven by a series of balls lying in the groove between them, and jambed against them by a recessed ring. I have here a large wooden diagrammatic model, and a small working model in steel, which shows that the new principle employed is correct, namely, that a ball while jambed is free to turn, or if turning is able to jamb. All Humbers, and most front steerers, employ differential gearing; in some front steerers the clutch of necessity is used.

Neglecting for the present the different modes of transmitting power from the pedals to the main wheels, it is possible now to consider the four typical builds of tricycle. The only advantage that a rider can find in a rear-steerer is the open front, so that in case of accident he can more easily clear himself of his machine; as I have already remarked this power of instantly escaping seems to be considered by many as of no importance. In a rear-steerer which has not an open front, whether driven by a clutch or by differential gear, I fail to discover any good quality. The steering of a rear-steerer is so very uncertain, that such machines cannot safely be driven at any thing like a high speed, because any wheel meeting with an obstruction will, by checking the machine, diminish the weight on the steering wheel just at the time when a greater weight than usual should be applied. It is for the corresponding reason that the steering of a front-steerer is so excellent; the more the machine is checked by obstruction, by back treading or by the brake, the greater is the weight on the front wheel. For shooting hills, or for pulling up suddenly, no machine of any kind will compare with a good front-steerer. In all respects it is superior to the rear steerer if we except the open front, but against this may be set the fact that on many the rider can mount from behind, or can dismount in the same manner while the machine is in motion. Experience shows that the front-steerer is for general excellence, safety, easy management, and light running, the best all-round tricycle that is to be had.

The Humber build, which departs less from the ordinary bicycle than any other, is far superior to all others for speed; it is, however, somewhat difficult to manage, for the steering is not only delicate, but critical, requiring constant care lest a stone or other obstruction should take the rider unawares, and steer the machine for him. The control which a skilful rider of the Humber has over his machine is wonderful; the elegance of the machine among tricycles is unequalled. So great a favourite is this form, especially among the better class of riders, that almost every firm have brought out their own Humber, each with a distinguishing name. The only improvement or change, whichever it may be, that has been made by others with which I am acquainted, is the triple steering, in which the hind wheel moves the opposite way to the others. The corresponding change in the bicycle was soon discarded; I do not know what advantage can result from the increased delicacy of steering here, I should have thought it delicate enough already.

One noticeable change in the front-steering tricycle, which has been largely made, lately, is the substitution of central for side-gearing, in consequence of which, bicycle cranks can be employed, instead of the cranked axle, with its fixed throw. This gives an appearance of lightness which the older types of machine do not possess.

I now come to that very difficult and all-important subject, the method of transmitting power from the body of the rider to the main axle. Next to the structural arrangement, this is most important in distinguishing one type of machine from another.

The first to which I shall refer, is the direct action employed on the "National" and the "Monarch" tricycles. It is obvious that by having no separate crank shaft, much greater simplicity and cheapness, and less friction are attained, than can be possible when the extra bearings and gear generally used are employed. In this respect the direct action machines undoubtedly have an advantage, but an advantage of any kind may be too dearly bought, as it certainly is here. In the first place, the direct action can only be applied to a rear-steering, clutch-driven machine, or single driver, for if the wheels were not free to run ahead, it would be impossible to go round a curve. In the second place, the rider must be placed at such a height for his feet to work on the axle, that the machine of necessity is very unstable, and is likely to upset if ridden without great caution round a curve. Thirdly, to diminish as far as possible this last objection, miserable little wheels must be employed, which cannot be geared up, that is, made to travel faster than the treadles, and so be equivalent to larger wheels. Therefore, though it is likely that at such low speeds only as it is safe to run such a machine, it may move more easily than a machine of a recognised type, and though direct action would undoubtedly be advantageous if it did not entail defects of a most serious order of magnitude, we may dismiss this at once from our consideration. It is true that in the "Monarch" a few inches of height are gained by the hanging pedals, but I question very much whether one machine is much better than the other.

The chain which is used on almost every make of machine cannot be considered perfect; it is, on the whole, a dirty and noisy contrivance, giving rise to friction where the links take and leave the teeth of the pullies; stretching, or rather lengthening, by wear, and, finally, allowing back lash, which is most unpleasant. In spite of all this it affords a convenient and reliable means of transmitting power, which is applicable to every type of tricycle, except one.

Instead of a chain, an intermediate or idle wheel has been tried, but this has not been found advantageous. The intermediate wheel has been removed, and the crank and wheel pulley allowed to gear directly together, making reverse motion of the feet necessary, and possibly reduciug friction.

The crank and connecting rod are employed in some machines. If there are two only, they must not be placed in opposite positions, but be fixed at an angle, so that there are times when each rod is under compression, a strain which delicate rods cannot stand. In the three-throw crank, employed in the Matchless tricycle, this objection is obviated, for one, at least, is at all times in such a position as to be in tension. The objection to the crank is the fact that it weakens the shaft, and that it can only be used with a clutch, not with a differential gear.

The most silent, neatest, and cleanest driver, the one of which the working friction is least, is the endless steel band, so well known in connection with the Otto bicycle. This is not, as far as I am aware, employed on any tricycle, makers probably fearing lest it should slip. The Otto shows that it can safely be employed.

I have devised a scheme, of which I now show a model, which seems to me to be free from the objections which may be urged against other methods; but I, of course, cannot be considered in this respect a judge. Eccentrics are well known as equivalent to cranks, but if used in the same way, with a connecting rod, either fatal friction or enormous ball-bearings would be necessary. Instead of these, I connect two pair of equal eccentrics by an endless band embracing each, so that the band acts like a connecting rod without friction, and, at the same time, acts by its turning power as on the Otto, thus making two eccentrics sufficient instead of three, and carrying them over the dead points.

There is one more system of transmitting power employed on a few machines. In these, a band or line passes over the circumference of a sector or wheel, and the power is directly applied to it. The motion of the feet in the Omnicycle, and of the hands and body in the Oarsman, is therefore uniform. There would be no harm in this if it were not for the starting and the stopping, which cannot be gradual and at the same time effective in machines of this type. For this reason, a high speed cannot be obtained; nevertheless, these machines are better able to climb hills than are tricycles with the usual rotary motion, for, at all parts of the stroke—which may be of any length that the rider chooses—his driving power on the wheels is equal. The ingenious expanding drums on the Omnicycle makes this machine exceptionally good in this respect, for increased leverage is effected without increased friction, which is the result of "putting on the power" in some of the two speed contrivances.

Having spoken of the Oarsman tricycle, I must express regret that I have not been able to find an opportunity to ride on or with the machine, so that I cannot from observation form an opinion of its going qualities. There can be no doubt that the enormous amount of work that can be got from the body in each stroke on a sliding seat in a boat must, applied in the same manner on the Oarsman tricycle, make it shoot away in a surprising manner; whether such motion, when continued for hours, is more tiring than the ordinary leg motion only, I cannot say for certain, but I should imagine that it would be. The method by which the steering is effected by the feet, and can with one foot be locked to a rigidly straight course, is especially to be admired.

There is much difference of opinion with respect to the most suitable size for the wheels of machines. Except with certain machines, this has nothing to do with the speed at which the machine will travel at a given rate of pedalling, for the wheels may be geared up or down to any extent that is made to turn more quickly or slowly than the cranks. This the most suitable speeding is a separate question, and must be treated by itself.

Large wheels are far superior to small wheels in allowing comfortable easy motion, a matter of considerable importance in a long journey. They are also far better than small for running over loose or muddy ground, for, with a given weight upon them, they sink in less, from the longer bearing they present, and this, combined with their less curvature, makes the everlasting ascent which the mud presents to them far less than with a smaller wheel. On the other hand, the large wheel is heavier, and suffers more from air resistance than the small wheel. For racing purposes a little wheel, geared up of course, is certainly better than a high wheel; for comfortable travelling, and in general, the high wheel is preferable. Though this is certainly the case, it does not follow that large wheels are worth having on a machine when there is already one little wheel. If the rider is to be worried with the evils of a little wheel at all, it is possible that any advantage which large wheels would give him would be swamped by the vibration and mud-sticking properties of the small steering wheel. One firm, in their endeavours to minimise these evils, have designed machines without any very small wheels; all three wheels are large, and a steadier and more comfortable motion no doubt results.

High and low gearing are the natural sequel to high and low wheels. Of course the lower the gearing the greater is the mechanical advantage in favour of the rider when meeting with much resistance, whether from wind, mud, or steepness of slope. In spite of this, for some reason which I cannot divine, the machines with excessively low gear do not seem to obtain so great an advantage in climbing hills as might be expected. To make such a machine travel at a moderate speed only, excessively rapid pedalling is necessary, and the rider is made tired more by the motion of his legs than by any work he is doing. The slow, steady stroke by which a rider propels a high-geared machine is far more graceful and less wearying than the furious motion which is necessary on a low-geared machine. The height up to which the driving-wheels are usually geared may be taken as an indication of the ease with which any class of machines runs. A rider on a low-geared machine can start his machine much more quickly than an equal man on one that has high gearing, and therefore in a race he has an advantage at first, which he speedily loses as his rapid pedalling begins to tell. For ordinary riding the slight loss of time at starting is a matter of no importance whatever.

There are several devices which enable us to obtain the advantages of high and low gearing on the same machine, which at the same time give the rider the benefit of a free pedal whenever he wishes. On some single driving rear-steering tricycles the connection on one side is for speed, and that on the other for power, either being in action at the wish of the rider, or both speed and power combinations are applied on the same side. To drive with a power gear a single wheel only seems to me to be the height of folly; in my opinion no arrangement of this type is worthy of serious attention. Among the better class of machines there are three methods by which this change is effected—First, that employed on the Omnicycle, to which I have already referred; secondly, an epicyclic combination of wheelwork which moves as one piece when set for speed, thus adding nothing to the working friction except by its weight, but which works internally when set for power, thus reducing to a small extent, by the additional friction, the gain of power which the rider desires; thirdly, a double set of chains and pulleys, each set always in movement, so that whether set for speed or power, there is rather more friction than there would be if there were no additional chains, but these are free from that increased friction due to toothed wheel gearing, from which the epicyclic contrivances suffer only when set for power. There is much difference of opinion whether any of these arrangements are worth carrying, for perhaps nine miles, for the sake of any advantage that may be obtained in the tenth. It is on this account that the drums on the Omnicycle are so excellent; whether expanded or not, there is, on their account, no loss of work whatever, for there is no additional friction. The subject of these two speed gears will, I hope, be discussed; it is one which, though not new, is coming more to the front, and about which much may be said.

Having now dealt with the means by which tricycles are made to climb hills more easily, I wish to leave the subject of bicycles and tricycles altogether for a few minutes, to say a few words which may specially interest those who are fond of trying their power in riding up our best known hills. The difficulty of getting up depends to a large extent on the surface and on the wind, but chiefly on the steepness. The vague manner in which one hill is compared with another, and the wild ideas that many hold who have not made any measurements, induces me to describe a method which I have found specially applicable for the measurement of the steepness of any hill on which a cyclist may find himself, and also a scheme for the complete representation of the steepness and elevation of every part of a hill on a map so as to be taken in at a glance. The force required to move the thing up a slope is directly proportional not to the angle but to the trigonometrical sine of that angle. To measure this, place the tricycle, or Otto—a bicycle will not stand square to the road, and therefore cannot be used—pointing in direction at right angles to the slope of the hill, so that it will not tend to move. Clip on the top of the wheel a level, and mark that part of the road which is in the line of sight. Take a string made up of pieces alternately black and white, each exactly as long as the wheel is high, and stretch it between the mark and the top of the wheel. If there are n pieces of string included, the slope is 1 in n, for by similar triangles the diameter of the wheel is to the length of the string as the vertical rise is to the distance on the road. This gives the average steepness of a piece sufficiently long to be worth testing, because an incline, only a few feet in length, of almost any steepness can be mounted by the aid of momentum.

There is only one process, with which I am acquainted, which supplies a method of representing on a map the steepness of a road at every part. Contours, of course, show how far one has to go to rise 50 or 100 feet, but as to whether the ascent is made uniformly or in an irregular manner with steep and level places, they tell us nothing. Let the course of a road be indicated by a single line where it is level, and by a pair of lines where inclined. Let the distance between the lines be everywhere proportional to the steepness, then the greatest width will show the steepest part, and an intermediate width will show places of intermediate steepness, the crossing of the lines, which must be distinguishable from one another, will show where the direction of the slope changes. Further, the size of the figure bounded by the two lines will show the total rise; a great height being reached only by great steepness or by great length, a large figure being formed only by great width or by great length. Those who are mathematically inclined, will recognise here that I have differentiated the curve representing the slope of the hill, and laid the differential curve down in plan.

Having wandered off my subject, I must return to more mechanical things, and give the results of some experiments which I have made on the balls of ball bearings. There is no necessity to argue the case of ball *v.* plain bearings, the balls have so clearly won their case, that it would be waste of time to show why. Of the wear of the twelve balls forming one set belonging to the bearings of the wheels of my Otto, I have on a previous occasion spoken; I may, however, repeat that in running 1,000 miles, the twelve balls lost in weight only $\frac{1}{20.8}$ grain, or each ball lost only $\frac{1}{250}$ grain. The wear of the surface amounted to only $\frac{1}{158000}$ inch; at the same rate of wear, the loss in travelling from here to the moon would amount to only $\frac{1}{54.3}$ of their weight. I examined each ball every 200 miles, and was surprised to find that on the whole the wear of each, during each journey, varied very little. The balls experimented on were a new set obtained from Mr. Bown. I also had from him one ball of each of the following sizes 3, 4, 5, 6, and 7-16ths of an inch in diameter, as I was curious to know what weight they would support without crushing. As a preliminary experiment, I placed a spare $\frac{7}{16}$ ball between the crushing faces of the new testing machine at South Kensington, and applied a gradually increasing force up to 7 tons $9\frac{1}{2}$ cwt., at which it showed no signs of distress. On removing it I found that it had buried itself over an angle of about 60° in the hard steel faces, faces so hard that a file would not touch them. Those marks will be a permanent record of the stuff of which the ball was made. The ball itself is sealed in a tube, so that any one who is curious to see it can do so. Finding that the crushing faces were not sufficiently hard, I made two anvils of the best tool steel, and very carefully hardened them. These, though they were impressed slightly, were sufficiently good for the purpose. In the following Table are the results of the crushing experiments:—

$\frac{3}{16}$ ball at 2 tons 13 cwt. did not break, but crushed on removing part of the weight.

$\frac{1}{4}$ ball at 3 tons 15 cwt. did not break, but crushed on removing part of the weight.

$\frac{5}{16}$ ball at 4 tons 9 cwt. broke.

$\frac{3}{8}$ ball at 8 tons 6 cwt. did not break, crushed under another 120 lbs.

$\frac{7}{16}$ ball crushed before 3 tons, with which I was starting, had been applied. Examination showed that the steel bar of which it was made had been laminated.

These experiments do not tell much of importance; they are curious, and, perhaps, of sufficient interest to bring before your notice. The fragments are all preserved in tubes, and labelled so that anyone who likes to see them can do so.

Of the advantage which a machine which will collapse or fold up when desired, but retain its form on the road, offers in convenience, it is unnecessary for me to speak.

Of double machines, the Rucker tandem bicycle seems to me to be in every respect the best, but I should add that I speak only from imagination and not from experience. The independent steering, the impossibility of capsizing forwards or sideways, the position of the rider over his work, the absence of any little wheel with its mud throwing and vibrating tendencies, combine to make a machine which ought to be superior in almost every desirable quality to any other; what it may be in practice I hope to hear in the discussion.

Of double tricycles, the Sociable has been tried by many, and is practically a failure in so far as travelling quickly and easily is concerned. The Tandem, though it presents so objectionable an appearance, seems likely to become a favourite, for it surpasses any single tricycle, and rivals the bicycle in speed. How it may compare in comfort or in safety with the single machine, perhaps those few who are well acquainted with them will say; at any rate, in the case of the Humber, greater stability is given to the steering owing to the weight of the front rider.

Time will not allow me to say more of these machines, or to attack the subject of steam, electric, or magic tricycles, which I had hoped to do. With steam and electricity we are well acquainted; by magic tricycles, I mean those driven by a motor which, without any expense, will drive one twenty miles an hour, up or down hill, with perfect safety. Highway regulations, and certain reasons not well understood, have at present prevented these contrivances from making a revolution.

There remains one machine which must be considered separately, for it cannot be classed with any other. This is the Otto bicycle. My opinion of this machine is so pronounced that I do not care to state it fully. I shall merely give the reasons why I prefer it to anything else, and in so doing I shall be taking the first step in the discussion, in which it will be interesting to hear from riders of other machines the reasons for their preference.

In the first place, the evils of a third or little wheel, the cause of trouble in all tricycles, are avoided. There is none of the vibration which makes all other machines almost unbearable to Ottoists, vibration which tricyclists have learnt to consider a necessary accompaniment of cycling, but which has, no doubt, been diminished by the use of the spring support of the front-steering Humber. It would be presumptuous in me to make any remarks on the effect of this vibration on the human system; we shall all be anxious to hear what our Chairman has to say on this point. By having only two wheels, we have only two tracks, so that we can travel at a fair speed along those places in the country called roads, which consist of alternate lines of ruts and stones, where a three-track machine could not be driven, and where, from the quantity of loose limestone in the ruts, a little wheel of a two-track tricycle would be likely to suffer. By having no little wheel, we can ride in dirty weather without having the rest of our machine pelted with mud, so that cleaning takes less time than it does with anything else. As I have already remarked, the small wheel is the culprit which makes the bicycle and tricycle drive so heavily on a soft road. The ease with which the Otto can therefore be run through the mud, astonishes everyone. Having no little wheel, we can obtain the full advantage of the high 56-inch wheel, which almost everyone prefers. As I have ridden all combinations, from a 50-inch geared up to 60-inch, to a 60-inch geared level, I can speak from experience of the increased comfort to be derived from these large wheels, though for speed only they do not compare with the smaller and lighter wheels geared up. A further point gained by the use of two wheels only is the fact that the whole weight of machine and rider is on the driving-wheel, as it is also on the steering-wheels, so that by no possibility can the wheels be made to slip in the driving, or to fail in steering from want of pressure upon them.

The most important consequence, however, is the absence of any fixed frame. In all machines, bicycles and tricycles, with the usual fixed frame, a position is found for the saddle, which is, on the whole, most suitable. For some particular gradient it will be perfect, on a steeper gradient the treadles will be further in advance, but with a steeper gradient the rider should be more over the front of the treadles. To get his weight further to the front, he has to double up in the middle, and assume a position in which he cannot possibly work to advantage. The swinging frame of the Otto carries the treadles, of necessity, further back, so that the Ottoist, when working at his hardest, is still upright, with his hands in the line between his shoulders, and his feet and his arms straight, so that he can hold himself down, and employ his strength in a perfectly natural position. On going down a slope, the fixed frame of a bicycle or tricycle leans forward, and places the rider in such a position that extra weight is thrown on his arms and shoulders, whereas the swing frame of the Otto goes back, and the rider of necessity assumes that position in which his arms are relieved of all strain. In so far as the general position taken by the automatic Otto frame is concerned, nearly the same effect can be obtained by using the swing frame of the Devon tricycle, which can be shifted and locked in any position which the rider wishes, or by the sliding saddle which can be slid backwards or forwards and locked so as to place the rider in one of three positions. Though the rider can by these devices assume nearly that position with respect to the treadles which is most advantageous, he cannot obtain that curious fore and aft oscillation made use of by the Ottoist in climbing hills, which, as the model on the table shows, enables him to get past the dead points without even moving, and which, therefore, makes the Otto by far the best hill-climbing machine there is, if account is taken of the high speeding with which all Ottoists ride. This is a proposition which none who knows the machine will question for one moment.

The freedom of motion resulting from the swing of the frame of the Otto gives a pleasurable sensation, which those who have only experienced the constrained motion of a three-wheeler cannot even understand.

The very peculiar method of driving and steering which seems so puzzling to the novice, especially if he is a good rider of other machines —for in that case he is far worse off than one who has never ridden anything—give the rider, when he is familiar with them, a control over the machine which is still surprising to me. In the first place, the machine will run along straight, backwards or forwards, so long as the handles are let alone. This automatic straight running is a luxury, for till a deviation has to be made, the steering handles need not he touched, and the rider may, if sufficiently confident, travel with his arms folded or his hands in his pockets. The rigid connection between the cranks and the wheels does away with all the back-lash, which is so unpleasant with chain or toothed-wheel gearing. There is no differential gear or clutch, but the machine possesses the advantage of the clutch over the differential gear when meeting with unequal resistance on a straight course, for each wheel must travel at the same speed; but, in turning a corner, instead of driving the inner wheel only, which is done by the clutch or both wheels equally, which is the case with differential gear, each wheel is driven, but the outer one more than the inner. At high speeds, the steering of the Otto has this advantage, that whereas, with a given action on a tricycle, the same deviation will be effected in the same *space* at high as at low speeds, the same action on the Otto will, at high speeds, produce the same deviation in the same *time* as it does at low speeds; and so instead of becoming more sensitive at high speeds, as is the case with the tricycle, the steering of the Otto remains the same. This is because the steering of the tricycle depends on a kinematical, that of the Otto on a dynamical principle.

In another respect, no machine can approach the Otto; at almost any speed the rider can, if there is reason, instantly dismount, by which action he puts on the brakes, and the machine will save him from falling, stopping with him almost instantly. As is well known, we can move backwards and forwards, we can twist round and round in our own width, or can ride over bricks with impunity.

One objection to the machine is the difficulty of learning, which is considerable, but which presents no danger. This difficulty has been much exaggerated, for before the present powerful brake was applied, it did require considerable skill to ride it down a steep hill. The way to do this must still be learnt, but it is now comparatively easy. For going down steep hills, the front-steering tricycle is without a rival; I do not know what other machine will do this better than the Otto. Lastly, the foot straps, which would be a great advantage on any machine, if only they were safe, are not—though none but riders will believe it—in any way a source of danger on the Otto. Having ridden this machine for close upon 10,000 miles, I can speak with more authority on this point than can those who are not able to sit upon it for a moment.

The only disadvantage which the machine presents is the fact that it is impossible to remove the feet from the pedals while running without dismounting; but though they must at all times follow the pedals, the Ottoist is not, as is generally thought, working when descending a hill.

The enthusiastic terms in which every one who has mastered the peculiarities of the Otto speaks of it would be considered as evidence in its favour, if we were not all considered by other cyclists to be in various stages of lunacy.

A number of representative machines, kindly lent by the following firms, were exhibited at the meeting:—

T. H. Brooke-Hitching, Ludgate-hill, E.C., Monarch tricycle.

Brixton Cycle Company, Limited, Brixton-rise, S.W., Brixton Improved Merlin tricycle.

E. Burstow, Grove-cottage, East-parade, Horsham, Centre-cycle.

Crypto Cycle Company, 73A, Chiswell-street, E.C., Humber, National, and Premier tricycles, fitted with crypto-dynamic two-speed gearing.

Ellis and Company, 165, Fleet-street, E.C., the Facile Safety bicycle.

Exeter Bicycle and Tricycle Company, Exeter,e Special Devon tricycle, with swing frame.

H. Goy, 21, Leadenhall-street, E.C., the Nonpariel

Telescope tricycle; an original Bone Shaker, built by the celebrated Beck.

Hillman, Herbert and Cooper, 14, Holborn-viaduct, E.C., Sparbrook Two-gear tricycle, Premier and Cruiser tricycles.

Lloyd Bros., Harborne, Birmingham, Quadrant tricycle No. 1 (rear-steerer).

Otto Company, Newgate-street, E.C., Otto cycle, Bicycle, with corrugated spokes.

M. D. Rucker and Company, Litchfield-buildings, Bethnal-green-junction, E., Rucker's Tandem bicycle.

Safety Cycle Company, St. Paul-square, Bedford, Sun and Planet bicycle.

Singer and Company, 17, Holborn-viaduct, E.C., Xtraordinary Challenge bicycle, Traveller tricycle.

Taylor and Weatherhead, Seer-green Vicarage, Beaconsfield, the Oarsman tricycle.

DISCUSSION.

The CHAIRMAN said there were two remarkable features about the paper, one the thorough mastery of the subject which it displayed; and the other the writer's entire independence of thought in expressing his opinions. He hoped the same independence would be shown in the discussion, but that speakers would endeavour, as far as possible, to keep to general principles, and avoid going too much into detail. He agreed with Mr. Boys in almost every point he had advanced, particularly with regard to the rear-steerer, that it possessed no particular advantage, but had elements of danger connected with it, whilst the front-steerer was safe, particularly in going down hill. He did not think anything could be more graceful than the Humber, and he had often felt envious of those he had seen riding it. He had tried one himself, but not successfully. He was enjoying himself on it very much, in company with two friends, when coming down the Alpha-road, St. John's-wood, he suddenly, for no intelligible reason that he had been able to discover, found himself in the middle of the road. This was probably caused by something connected with his own bad steering, very likely from a difference of power in the two hands, for he had found by trial with a dynamometer that he was much stronger on the right side than the left. It had occurred to him that there might be a guide placed on the steering part, in the shape of a needle on a dial, which should indicate when the rider was not keeping an even course. He agreed with Mr. Boys that the band was a great improvement on the chain, and hoped at the next Exhibition to see a great many tricycles thus fitted. He was not surprised at the high terms in which the Omnicycle had been spoken of, for it was a very good machine, and, if it could only be made lighter, would for many persons be the best. He liked the propelling motion of the Omnicycle, it was not at all a tiring motion, and for hill climbing it was very good indeed. It seemed to him, however, that when the leverage was increased, the motion seemed to be loose, and he had heard other riders make the same observation. Again, the noise connected with it was not pleasant, but altogether it was a very good machine. He was not, however, quite sure whether it was of much advantage to change the power for ascents, and thought perhaps all riders would by-and-bye learn to climb hills without any change at all, and that it was, after all, more a matter of practice than anything else. He found, after riding a few days he did not care for change, and that when the machine was geared level it answered very well. He could not see much difference between a high wheel, and a small wheel geared up, and was rather surprised that high wheels had so much gone out; in fact he should not be surprised to see them come in again. The disadvantage lay in connecting a small wheel with the large wheels, the bad effect of which reduced the advantage obtained from the large wheels. There was one machine made with the wheels all the same size, and those who had tried it told him it had many advantages. The Oarsman would, no doubt, have a very powerful motion, but it certainly would not be so healthy in use. The great advantage in the bicycle and tricycle lay in this, that the body was moved by the legs, whilst, at the same time, the weight of the body was supported by the machine, and the upper part of the body was saved the work which would throw a back stroke on the heart. That was the reason why persons advanced in life could travel so much farther on a tricycle than in walking. [He then, by means of a diagram on the blackboard, explained the action on the valves of the heart of any violent exertion, by the upper part of the body especially.] He quite agreed with Mr. Boys that rapid pedalling was more exhausting than a slow, firm action. The single driver seemed altogether out of the field, and he need not allude further to it. There was nothing to lament in what had been said about motor power in the management of these machines; they did not want any other motor power than belonged to the bodies of the men and women who propelled them, and who improved their health at the same time that they enjoyed the exercise. If motor power were introduced, idle people would get on their machines and ride about where they pleased, but all the advantages of the exercise would be gone; the machines would be mere toys. If the Otto saved vibration it certainly stood pre-eminent, for vibration was a very exhausting process, and those machines which vibrated a great deal were not only very difficult, but very tiring, to ride. Every act of vibration was so much waste, and they could not be too grateful to those makers who managed to avoid this drawback.

Mr. ROUND wished to emphasise what had been said as to the advantage of the bicycle over the tricycle. The real difficulty of the bicycle was in learning, and no doubt it took some time and attention in the first place, but many failed because they did not pay sufficient attention to details. After seven years' experience, he could say that if there were any choice between the two on the score of safety, it lay with the bicycle, for he had known of fewer serious accidents with it than with the tricycle. One reason no doubt was, that people thought the tricycle did not require learning, and they were less cautious in going down hill, and so on, than they ought to be. The Tandem Rucker was a remarkable form of machine, not unlikely to come largely into use. He had ridden a short distance on the front wheel of one having two wheels behind. It was very rigid, with no possibility of falling backwards or forwards. but there seemed a little difficulty in steering. He thought no one, however advanced in years, if they were tolerably active, need be afraid of learning the bicycle, the Otto included.

Mr. KIRBY confirmed the observation of the previous speaker with regard to there being more accidents with tricycles than bicycles, and thought the difficulties of learning to ride were much exaggerated. He did not think the small back wheel was entitled to so much opprobrium as had been thrown upon it. It did not throw up mud because it travelled faster than the large wheel, but as the mud only adhered for a certain time, it was thrown off in a different direction. The same idea had occurred to him with regard to differential gearing, which Mr. Boys had described, only he had carried it out in rather a different way. There was another way in which it might be obtained, by employing india-rubber balls or rollers, in place of the steel balls, but the great drawback was that the india-rubber got set, and did not act perfectly. Mr. Boys had spoken of the impossibility of making machines of the National type double driving, but he had contrived a means of doing so, the gear being applied to the cranks. It had never been carried out practically—only as a scientific experiment. There were certain mechanical reasons why a small wheel had an advantage in going up hill which it would be difficult to explain without a diagram. The figures which had been given, with regard to the resistance of balls to crushing, were very valuable, especially to manufacturers.

Major KNOX HOLMES said he had no scientific knowledge on this matter, only practical experience, the result of which he would state. He found that with a Roadster 42 in., geared up to 56, he could ascend hills with more ease than when geared level, the reason for which he could not tell, except that the action was much slower and less fatiguing. There was also a common-sense explanation of the fact that a small wheel would be more effective in going up hill than a large one, viz., that at each revolution the weight was carried a less distance, and consequently was not lifted through so great an elevation. The advantages of wheels geared up were very great in descending and on the level, and in practice he had found no difficulty in climbing. He could travel on fair roads, eight, nine, or ten miles an hour without the slightest fatigue, and for a man of his age he thought that was enough. He had found the exercise very beneficial to his health, and it had removed a stiffness in his knees from which he had previously suffered. He lately went to Brighton and back in $12\frac{1}{2}$ hours, and the next day was able to walk five miles an hour, which he could not have done a short time ago.

Mr. W. T. SHAW said there was very little in the paper which was open to controversy, and he thought there was not one point on which he was not in entire accordance with Mr. Boys. He would rather leave the discussion of gear to others, but the point he had aimed at was the combination of a high and low gearing in one machine; not an immoderately high gearing, but one well within the powers of the rider. The height to which wheels could be geared, must depend first on the powers of the rider; that being determined, as the conditions of the road often differed very materially within the space of a few miles, the question arose whether some provision should not be made for contingencies beyond the control of the rider, such as the condition of the road, steepness of the hills, &c. He was not able to follow the gallant Major in asserting that a 56-inch wheel could be driven more easily than a 42-inch; though, of course, provided the rider could drive it comfortably, the higher the wheel was geared the better.

The CHAIRMAN suggested that perhaps the difference might be explained by differences of age. He could imagine that to young riders who could move their limbs with great rapidity, a change of gear might be an advantage, while to those who could only move more slowly, but with considerable force, a change would not be so important. But he saw no reason why the rider should not have the opportunity of changing the gear if he desired, and he thought the crypto-dynamic apparatus very beautiful and ingenious.

Mr. BOLT suggested that some of the difficulties referred to would be got over by the use of adjustable cranks, and was surprised to find they were not employed. He had known them used, and had used them himself on a bicycle fourteen years ago with great advantage. They could be adapted to bicycles, and to any tricycle with outside cranks. You had simply to turn the toes in or out, as the pedal was going up or down, to lengthen or shorten the stroke, and it might be reduced or lengthened by as much as three inches, or even more. There was no difficulty with friction, and the expense was not worth mentioning. He had often heard that the Coventry rotary was a difficult machine to drive, but on the other hand it was convenient in many ways. The Otto was a very pretty machine, but you could not take it through a narrow doorway. He should like to know which tricycle Mr. Boys recommended.

Mr. MORTON said the luggage-carrying power of the various tricycles had not been referred to, but it seemed to him a very important point, especially to those who might wish to make long journeys, who though they might adopt a costume suitable for riding, would prefer to appear in ordinary garb when they reached their destination.

Mr. WARNER JONES agreed that the Otto was the best machine in principle, but it did not seem to be so in practice, judging by the number of other machines in use. Everyone seemed to be inquiring what machine he should ride, and he thought the answer would be—the one that suited him best; but they did not seem always to pay so much attention to the question how they should ride it. A great deal of force was wasted from ignorance. As had been explained, the Otto had great advantages in regard to the power gained by leaning forward; but unfortunately, when riding on a rough road, you were sometimes bobbed forward when you did not require it, and had to recover yourself; and that was where the large wheels were so useful, as they gave you time to do so. The size of the wheels depended more on the road than anything else, and on the condition of the roads more than the gradient.

Mr. STARR said he had heard that the Otto was liable to land the rider on his face in the road, which would no doubt account for the prejudice against it, but the question was whether it could not be made safe in that respect. He should also wish to ask, the comparative merits of a front-steering tricycle and the Coventry Rotary, and other things being equal, which took the most muscular power to propel.

Mr. BOYS, in reply, said, that when he referred to the small wheel of a bicycle throwing more mud because it went faster, he was comparing it with the small wheel of a tricycle, not with the large wheel of the same machine. The linear velocity was the same, but the tendency of the mud to fly off was inversely as the size of the wheels. A wheel of 56 in. would have just half the tendency of one of 28 in. if going at the same speed. With regard to differential gear, he did not know if an india-rubber ball, apart from the difficulty of india-rubber versus grease, could be made sufficiently strong to resist the strain. One reason which induced him to make those crushing tests was the desire to find out whether balls could be relied on to withstand a pressure of cwts. or tons, because in the gear that he had devised that pressure was acting on a very short arm or a lever, and would be, therefore, very considerable. He was glad Major Holmes, from his great experience, had confirmed his opinion as to the advantages of high speeding; in fact, Major Holmes had gone farther than he had, and said he could climb hills better when the wheels were speeded than when they were level, which was certainly more than he had expected. He did not think the adjustable cranks Mr. Bolt had recommended would be altogether advisable for this reason. Before he had his present Otto he had one with 5 in. cranks, and was rather doubtful about changing to 6 in., though that was the usual length; he therefore went out several times with a friend who had a 6 in. crank machine, and they kept changing from time to time; each time he made the changes the machine felt at first as if it would not go, and he had to ride some distance before he could put out his full power. The change seemed more uncomfortable from 6 in. to 5 in. than from 5 in. to 6 in., so that determined him to have a 6 in. crank; but he thought that showed that a crank the length of which was being often changed would not be of any practical advantage, as the rider would not be able to exert his whole power for some distance after each change. He never recommended one machine more than another. He had given reasons why he preferred the Otto. Some people found it difficult, and they had better adopt some other, but those with ordinary perseverance and skill he would recommend to try it. Luggage-carrying was not a matter on which he cared to say much; he had managed to carry a bundle of clothes, and a large bag, from the north-west of London to Liverpool-street, where he sent the bag on by train, and that was the course he preferred to adopt. It was not worth carrying 10 or 12 lbs. of luggage all day for the sake of saving ninepence. He did not agree with Mr. Jones that the Otto, though excellent in principle, was not so in practice; nor did he find himself bobbed forward in riding on a rough road, and he had on occasions gone right over a brick. Mr. Starr suggested that it was possible to come out on your face, and perhaps it was, but there was not the slightest necessity for it. He had ridden the machine at all speeds, and had jumped out and stopped in about a yard and a-half. Over and over again, when riding in the dark, he had struck against something in the road, and come out suddenly, without the slightest warning, but he did not come on his face. With regard to the front-steerer, and the Coventry rotary, the latter possessed in many respects the advantages of the front and rear-steerer; you had an open front and very excellent steering, but then it was a single driver; and though there was great length, so as to resist the swaying tendency, he did not think the single driver would live. The narrowness of the machine was a great convenience, but there was a corresponding want of stability, which necessitated great care in going round curves.

The CHAIRMAN then proposed a vote of thanks to Mr. Boys for his able paper, which was carried unanimously, and the proceedings terminated.

Miscellaneous.

SEWAGE IN THE THAMES.

The Royal Commission on the discharge of sewage into the Thames, recently issued their first report, of which the following is a summary:—

The history goes back as far as to legislation in the reign of Henry III., at which time such sewers as existed were intended only to cover over or supply the place of natural streams and ditches, and so to carry away the rainfall from the fields, roads, and roofs of houses. From the time of Henry III. to Henry VIII. all enactments affecting drainage were of a local nature, but in the 23rd year of the reign of Henry VIII. (1531 A.D), the general "Bill of Sewers" was passed, which appears to have laid the foundation of modern legislation for all works of this kind. Many other Acts followed to amend and explain this celebrated Act, most of them applicable to the country in general. The rapid growth of London rendered necessary more frequent special enactments for making, enlarging, amending, and cleansing its "vaults, drains, and sewers." The formation of many new "districts," successively built upon, each with its own local governing body, led to a subdivision of the management of underground drainage; but throughout all the changes, sewers were regarded as the legitimate channels for surface waters only. All offensive house refuse was collected into cesspools, and carted into the country as manure; and at the commencement of the present century, it was penal to discharge what is now called "sewage," or other offensive matter into the sewers.

Such was the method of sewage and drainage till the invention of the water-closet, which completely revolutionised systems that had been followed for centuries. It was first introduced about 1810, and after 1830, its adoption rapidly became general. The cesspools were used as the receptacles of water-closet discharges, and the addition caused to their contents in this way rendered it necessary to introduce overflow drains from them into the street sewers, the effect of which was, of course, to pollute the sewers.

Here was the commencement of those sewer and Thames pollution troubles which have grown to such magnitude.

As the water supply of London was then largely drawn from the river in the neighbourhood of sewer outlets, it was early recognised that the purity of this supply was endangered. In 1834, John Martin, the artist, designed a plan to embank both sides of the Thames, and to construct an intercepting sewer in each embankment, for the purpose of collecting the sewage and conveying it to points in the river below the most populous parts of London.* The scheme, however, was in advance of the times, though its important features have been followed in the works which have been ultimately adopted. In 1845, the scheme was again suggested by Mr. Thomas Wicksteed, who proposed Barking Creek and Greenwich-marshes as the points of outlet, but it met with no better success than before.

At this time the drainage of the metropolis was under no less than eight local "Commissions of Sewers," each having its own regulations as to size of drains, shape, angle of inclination, &c. The evils of the consequent confusion were so manifest, that a consolidated Commission of Sewers was constituted by an Act of Parliament in 1848, and the same Act provided that every house should have a proper water-closet, and be drained into the main sewers. This completely reversed the legislation on this point as it existed at the beginning of the century. The Commission zealously began the improvement of house drainage, the abolition of cesspools, and the introduction of pipe-sewer communications between the houses and the main drains. In 1849, however, they were superseded by a fresh Commission, and this new body held that sewage should be kept out of the Thames altogether. They advertised for competitive plans, received 116, discussed them, came to no conclusion, and resigned. A third Commission examined the plans, decided none would do, and appointed Mr. Frank Foster to prepare a scheme. He adopted the fundamental principle of intercepting sewers, planning the outlets at Galleons Reach and at Woolwich-marshes. The Commission, however, decided nothing, nor did a fourth, nor a fifth, nor a sixth, appointed in 1854. Meanwhile the state of the Thames was becoming alarming, and in 1855 the Government, by an Act which received Royal assent on August 16th, created a new representative body, the Metropolitan Board of Works. Their most important office was to take charge of the main sewers of the metropolis, and in particular to construct works of a comprehensive system of main drainage. A very important section of the Act (18 and 19 Vic., cap 120), became a source of much controversy, and for three years proved a block to work. Section 135 provided, "and such Board shall make such sewers and works as they may think necessary for preventing all or any part of the sewage within the metropolis from flowing or passing into the River Thames, *in or near the metropolis*, ... and the said Board shall cause the sewers vested in them to be constructed, covered, and kept so as not to be a nuisance or injurious to health."

* A report on this was published April 23, 1836.

One of the first steps taken by the Board was to instruct its chief engineer, Mr. (now Sir Joseph) Bazalgette, to report on the works necessary. He took the old proposals of Mr. Foster, which were in essential points similar to those of Martin, as his basis, and prepared a plan which gave the north outfall at Barking, and the south at Plumstead. The plan was laid in accordance with the requirements of the Act, before the First Commissioner. This was in June, 1856. The First Commissioner applied to the Admiralty for information as to the extent of tidal action in the Thames, and Captain Burstal, R.N., was appointed by them to report. On receipt of his report, the First Commissioner wrote to the Board that the plan they had sent "actually provides that the sewage shall flow into the Thames," and that before any such scheme could be carried out, it would be necessary to ask Parliament to repeal such parts of the Act as Section 135 (quoted above), and he returned the plans. From this point in the history the question of the outfalls holds a prominent place.

In November, 1856, the Board submitted another plan with outfalls two or three miles lower down, and also reported that they had considered a scheme for discharging below Gravesend. Other plans were prepared, and eventually the whole question was referred to three Government referees, Captain Douglas Galton, Mr. James Simpson, and Mr. Thomas Blackwell. They sent in a report, which was published as a Parliamentary Paper, August 3, 1857. This report went into many matters in much detail, and on the subject of the outfalls recommended for the north a place near Mucking Lighthouse, in Sea Reach; and for the south, Higham Creek, in the Lower Hope. The Board, on receiving the report, objected, and much correspondence followed.

The Board then appointed Mr. Thomas Hawksley and Mr. G. P. Bidder to be associated with Mr. Bazalgette in drawing up a report on the whole question, and this was sent in on April 6th, 1858. A correspondence between these gentlemen and the Government referees continued for several months. During these deliberations, the state of the Thames was becoming worse, "and was exciting great alarm and indignation. The subject was repeatedly noticed in Parliament, and strong language was used in both Houses."

In February there had been a change of Government, and the new administration took the view that the metropolis, through its representative Board of Works, might carry out its drainage and sewerage without obtaining Government sanction. "As the metropolis paid for the work, they had a right to construct it in any way they pleased." After debates at every stage of progress, an Amendment Bill was passed, and became law August 2, 1858.

The clause which gave the Board power to carry out sewers and works, "according to such plan as to them may seem proper," also added, "and for preventing, *as far as may be practicable,* the sewage of the metropolis from passing into the River Thames, *within* the metropolis."

In commenting on this, the Commissioners, in Sec. 54 of the Report, say:—"It certainly appears remarkable that the Legislature should have withdrawn all control over the construction of gigantic works of this kind, which were certain to have influence of a wide national character. But if the debates which occurred at the time are carefully studied, it is not difficult to trace out the reasons which mainly influenced the decision." They point out (1) that the state of the river required immediate action. (2.) That all contending parties were agreed that intercepting the sewage by main drains running eastward was the correct principle. (3.) It was felt this might be commenced at once, leaving the ultimate mode of disposal of the sewage for later decision. It was considered that the plans of the Board were not necessarily final, but might be extended and amended at a future time. (4.) There was a confident expectation that the sewage would be treated by some process of deodorisation before entering the Thames. (Extracts from the debates are given.)

Immediately after the passing of the Act, the Board took the matter earnestly in hand, and by 1864 both the northern and southern outfalls were in use, and in 1875 they were pronounced complete.

The Thames Embankment, to limit the areas left dry at low water, was also completed about the same time.

Complaints, however, followed soon after the drainage works came into operation, and then ensued the two well-known inquiries, the Barking inquiry, 1868, and the Mud Bank inquiries, 1867 to 1880.

Part 2 of the Report describes the whole system of the metropolitan main drainage. In the "Remarks" which the Commissioners append, it is mentioned that the weak points are (1) the necessity for a large provision of storm outlets, and (2) the discharge of the sewage in its natural crude state.

1. There are hundreds of miles of sewers now in the metropolis, in which the sewage does not flow at the velocity necessary to prevent the sewer matters from depositing. When sudden heavy rains occur, great masses of deposited filthy material are washed out, and find their way directly into the urban reaches of the river.

As regards (2) the discharge in a crude state, it is pointed out that this is not a defect inherent in the system, and at the time of the passing of the Act it was distinctly understood that the construction of the works, and the management of the sewage, were separate considerations (see above). How far remedies can be applied will be the subject of future inquiry. Meanwhile facts have been ascertained with regard to the distribution of sewage by tidal influence.

The discharged sewage undergoes a daily oscillating movement due to the tide, and also a gradual displacement of these oscillations down the river, depending on the quantity of fresh water entering the river.

The oscillations have been studied by observing the movement of floats put in at various periods of the tide. This had been done in several previous inquiries, and a further large series of experiments were made for the purposes of this Commission. The floats were put into the river opposite the Barking (northern) outfall, at various periods of the tide. Each was watched, and its position and motion recorded during thirty and, in some cases, forty-five days. The chief results were—

1. The extent of tidal oscillation varied considerably, some parts of the river moving much more rapidly than others.

2. The maximum range of oscillation recorded was, at spring tides, eighteen miles; at neap, a little under seven.

3. A float, started at high water, ascended up to Greenwich, a distance of eight miles; another, started three hours after high water, ascended to between Putney and Hammersmith, twenty miles; a third, started at low water, ascended twenty-two miles.

These were the points reached with subsequent flowing tides, and the Commissioners consider that these experiments add important and novel information as to the distance which tidal currents may travel.

The practical inference drawn is that where the floats went, sewage discharged at the same times of the tide may also go; but it is mentioned (Section 83) that Sir J. Bazalgette "does not consider that the motion of a float is analogous to what would take place with the particles of sewage."

The rate of displacement, *i.e.*, progress downwards of the sewage, is a different question, and various calculations give it at a quarter, a third and a-half mile a day. A rough estimate is that sewage would take 150 days to travel from the outfalls to the sea, if its progress depended on the influx of upland water.

It is, however, necessary to take into consideration the mixing action which has such a remarkable influence on the distribution of sewage.

Taking the amount of chlorine in water as a test, it is seen that sea water so mingles with the river water, it has been traced as high as the tidal limit at Teddington. It is argued that since a mixing action is known to go on between the sea water and the fresh, there is every reason to believe that the same kind of action will go on between each of these and the sewage.

The data for the statements laid before the Commission, are derived from the determinations of the amounts of chlorine contained in certain samples of water, taken on certain days, at various points of the Thames from Teddington to Southend. To these are added the known quantities of land water and of sewage entering the river on each of the days in question.

The problem of the proportion of sewage present has been worked out by several independant methods with very concordant results. "Nobody has hitherto anticipated that liquid discharged into the river at Barking could be transported by any natural causes, many miles up the river, directly in the face of the powerful descending stream of land water; but that this effect is produced can no longer be doubted."

The Metropolitan Board of Works put forward that the sewage, during its oscillation, travel, and mixing, becomes so quickly oxidised and purified, as to lose almost immediately all its offensive qualities, and to become as innocuous as the natural water in the river. This argument receives consideration in the 3rd part.

Part 3 deals with the question whether any evils result from the system under which sewage is discharged into the Thames.

After noticing the voluminous evidence of various kinds given, the Commissioners state the summary of their conclusions in a series of concise paragraphs, twenty in number. Though the river is "not as it should be," no evil has yet been done to navigation. Fish, however, have disappeared below and above the outfalls. There is a partial purification of sewage by oxidation, and this purification is carried further by the action of animal and vegetable organisms. Between Greenwich and Greenhithe the effects of sewage discharge are apparent at all times, but above Greenwich there is not ground for serious complaint. It is, however, added, "that the evils and dangers are likely to increase with the increase of the population."

The question of remedies is reserved for further consideration.

ECONOMIC PLANTS IN TRINIDAD.

The report of Mr. Prestoe, the Government botanist in Trinidad, on the Botanic Gardens of that island for 1882, has lately been received. A large portion of this voluminous report is devoted to the consideration of economic plants.

Nutmegs.

Mr. Prestoe gives some notes on the cultivation of the nutmeg, from which the following facts are gathered. Regarding the effects of manure, he says that the whole of the trees have been treated with cattle-pen manure, so arranged on the slope to have its fertilising properties conveyed directly to the roots by the rain. The good effect was most marked, especially to the young trees, which at once produced leaves twice the size of those which preceded them on the branches, Mr. Prestoe says he cannot too strongly recommend the use of cattle-pen manure for pushing on young nutmeg trees. "The planting out," he says, "of successional nutmeg trees, during the last few years, has enabled me to determine the sexes in seedling plants under a foot high by characters presented in the leaf form, and with sufficient accuracy for all practical purposes; as also the proportion of male trees and female usually raised from seeds. These points having been determined by direct experiment with two sets of nine and eleven pairs of young nutmeg trees, respectively kept under observation in the one case for nine, and the other for five years, from the seeds.

"Male trees occur more numerously than females to the extent often to fifteen per cent. At the same time a walk or plantation of nutmeg trees would be effectively fertilised by male trees, standing at the rate of one to every eight or ten female trees. It is not to be recommended, however, that the definition of the sexes in the young trees be exercised for planting the male and female trees merely in this proportion, but for setting the trees in pairs of male and female as regularly as practicable.

"These pairs—the plants being 3 feet apart—should be planted at intervals where they are to be permanent, of about 25 feet or 30 feet, and when they have grown up to produce flowers—fourth or fifth year to show the sexes with certainty—the excess males (over 10 or 12 per cent.) can be removed. That is, one of each pair will be removed in a manner to leave one male to eight or ten females. In doing this, four or five feet lengths of the stem of the cut away, should be left to keep alive and serve as a support to the standing tree, as also to prevent the development of fungoid growths that would be likely to occur by sudden decay of the tree stumps.

"In order then to have the young nutmeg tree in pairs as regularly as possible, male and female, the form of the leaf and direction of the veins must be observed, the female leaf being the most perfectly elliptical with the straighter primary veins; the male leaf is broader towards the point than at the middle; that is of obovate shape, and furnished with a point much longer than that of the female; the veins are curved in towards the point much more roundly than n the female."

A large stock of nutmeg trees, it seems, is always in stock at the Trinidad gardens, and they are disposed of at a low rate, so that the system of double planting to ensure proper fertilisation is always practicable.

Mango.

Referring to the growth of the mango (*Mangifera indica*), Mr. Prestoe points out differences in the constitution of the tree which furnish the different varieties of fruit. The sap is, it is stated, at all times watery in the mild form; in some varieties it is watery at one season, and milky at another; in other varieties it is always milk like, and on exposure assumes the consistence of tough gum. As with European fruit trees, the better qualities of mangoes are propagated by grafting their stems or stocks raised from seed. Grafted mangoes thrive well in Trinidad, and some of the very largest trees in the gardens, as well as those distributed about the island, are grafted trees introduced from Martinique, Cayenne, and East India. Of the value of the fruit, Mr. Prestoe says that there can be no question that in the four varieties cultivated in Trinidad they have the finest fruit of the Western tropics, except the pine apple; nevertheless these few varieties are but little known, consequently mangoes on the whole are regarded with disfavour by those capable of judging, and whose appreciation would promote interest in the really good kinds.

"In the hands of an English gardener accustomed to grow peaches or pears, a number of the varieties of mango would be produced with the lusciousness and rich colouring scarcely to be matched in the peach and nectarine, or hot-house melon, as indeed, sometimes now occurs under anything but high culture. There are varieties where the melon and pine flavours are combined, the ribston pippin flavour with the mangoes' own; in another the consistence of apricot and flavour of rich strawberry are blended with delicate mango flavour."

Cocoa.

A large space of this report is devoted to the consideration of the cacao tree (*Theobroma cacao*), application for seeds of the best kinds of which are continually being received, which requests Mr. Prestoe points out cannot be entertained.

Caoutchouc.

As in most of our Colonies at the present time, the several sources of rubber or caoutchouc appear to be receiving much attention in Trinidad. The well-known Para-rubber (*Hevia brasiliensis*), as well as other species of this genus, are growing in perfection. It is said to answer well as a shade tree for cacao plantations, "a point on which it will be soon possible to speak with certainty. From the experience here, the tree might be regarded as of promise to figure as a valuable subject in the future agriculture of the island. As a rubber-yielding tree alone—considering the length of time it takes to mature, and its comparatively small yield of rubber, as described by travellers—it is not a tree to be recommended except for plots designed to be left to develop forest growth, soil and other conditions being sufficiently favourable."

Of the Demerara rubber (*Hevia spruceana*), the milk is said to turn yellow or brown immediately on exposure to the air; it forms a rubber of very good quality.

Ceara - rubber continues to thrive under conditions of soil which are most common on the hills about the north - west of the island. Mr. Prestoe regards it as a plant of much promise for cultivation about the hill slopes, where the soil is too poor or dry for cacao, coffee, or other hillside cultures. "The roots are of a fleshy character, and, as compared with the size of the tree, are of enormous development, and penetrating directly downwards; hence, its impatience of a stiff, or saturated condition of soil, the extraordinary root development being really a provision of nature to sustain the plant under conditions of prolonged drought in stony soils, and to which it appears subject in its native habitat."

With regard to the yield of rubber from these trees, the experimental tapping was limited to testing the conditions of the milk sap at intervals, the results showing that it varies in density very considerably in different trees under the same conditions, most dense and apparently to be obtained in largest quantity with the least harm to the tree on the maturation of new growths of leaf and branch, that is, during autumn to the middle of the dry season. Mr. Prestoe gives details as to the habit of the tree and the effects of tapping, amongst which he says:—"These considerations seem to imply that the method of tapping the tree at the trunk, or any point between the root and the leaf-bearing branches, is more or less objectionable according to the nature of the subject dealt with. And although the method of tapping the stem or trunk is generally practised by native rubber collectors, dealing with this growing in a state of nature, I do not think it should be accepted as the correct one for obtaining the largest supply of milk sap, with the least injury to the tree."

The Panama, or Central American rubber tree (*Castilloa elastica*), is reported as thriving well in Trinidad, as also the African rubbers—species of *Landolphia*. These latter, being climbing plants, and consequently requiring support, Mr. Prestoe does not think likely to be of much promise for the island, or indeed, for the West Indies generally. On this point he says:—"In the present state of the labour market, and the manner of life of the present proprietors and labourers, particularly about the outlying districts, I am afraid rubber at its present price could not be collected from vines growing promiscuously for the value it would realise, even if it were certain that the people would take to such work as rubber collecting, or being got, they could ever be induced to follow a method of tapping that would not be destructive to the source." Many other plants of more or less economic value are treated of in this paper, which is, perhaps, one of the fullest and most detailed that has been issued from a botanic garden.

General Notes.

Stuttgart Polytechnic Institution.—A laboratory has lately been organised in which tests of extension, pressure, &c., can be carried out upon cement, building-stones, wood, driving bands, ropes, metal bars, &c. This branch of the Institution is provided with machinery capable of exercising a strain of 60 tons. This addition to the utility of this establishment has been rendered possible by the surplus funds arising from the recent Industrial Exhibition.

Pasturage of the World.—Australia stands at the head of all the sheep-producing countries, New South Wales furnishing by far the greater proportion of colonial pastoral wealth. At the close of 1882, the number of sheep in Australia was 76,493,105, as against 76,230,000 on the River Plate; 49,237,000 in the United States; 48,820,000 in Russia; 27,237,000 in the United Kingdom; 25,420,000 in Spain and Portugal; 25,200,000 in Germany; 23,370,000 in France; 21,418,000 in Austria; and 11,280,000 in Cape Colony. New South Wales alone possesses as many sheep as the whole of the United Kingdom, Germany, and Cape Colony.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, eight o'clock:—

May 14.—"Telpherage." By Professor Fleeming Jenkin, F.R.S. Sir Frederick Abel, C.B., F.R.S., Chairman of the Council, will preside.

May 21.—"Telegraph Tariffs." By Lieut.-Col. Webber, R.E. Dr. Cameron, M.P., will preside.

May 28.—"Primary Batteries for Electric Lighting." By I. Probert. W. H. Preece, F.R.S., will preside.

Applied Chemistry and Physics Section.

Thursday evenings:—

May 22.—"Economic Applications of Seaweed." By Edward C. Stanford, F.C.S.

May 29.—"Some Economical Processes connected with the Woollen Industry." By Dr. William Ramsay.

Indian Section.

Friday evenings:—

May 9.—"Indigenous Education in India." By Dr. Leitner. Sir Lepel Griffin, K.C.S.I., will preside.

May 30.—"Street Architecture in India." By C. Purdon Clarke, C.I.E. This paper will be illustrated by means of the Oxy-Hydrogen Light.

Cantor Lectures.

Monday evenings, at eight o'clock:—

The Sixth Course will be on "Fermentation and Distillation." By W. N. Hartley, F.R.S.E., &c., Professor of Chemistry, Royal College of Science, Dublin.

Lecture I.—May 12th.

The production of alcohol and alcoholic products. The uses of alcohol in manufactures. The sources of alcohol. Technical processes. Grain and potato spirit. Grinding and washing grain. The action of water upon starch. The gelatinisation of starch. The addition of malt. The preparation of mash from potatoes. The estimation of starch in potatoes. The saccharification of potato mash (*a*) by malt, (*b*) by sulphuric acid. The chemistry of the mashing process. The properties of starch. The change of starch into sugar and dextrine. The most suitable temperature for mashing. Of diastase and other soluble ferments. The general action of soluble ferments. Their chemical action on glucoside and polysaccharides.

Lecture II.—May 19th.

Fermentation proper. The cause of fermentation. The nature of the yeast cell. Its mode of growth. The chemical action of fermentation. Rapidity of growth of yeast. Charasteristic appearances of exhausted and revived yeast. Of "high" and "low" fermentations. Conditions of a good fermentation. Healthy and foul yeast. Explanation of the custom of a "change of yeast." Methods devised for purifying yeast. Exhausted yeast not necessarily foul. Mineral food necessary for yeast. Explanation of the reason for fermenting with mixed yeast. Influence of temperature on fermentation. Heat evolved during fermentation. Methods of warming and cooling mash. The products of alcoholic fermentation.

Lecture III.—May 26th.

Alcohol produced by mould. Its existence in rain, river, and sea water. Its presence in the soil. The process whereby alcohol is separated from water. The simplest form of distillation by a still and worm. The boiling points of water and alcohol. Boiling of mixtures with low boiling points by means of vapours with high boiling points. Pot stills and patent stills. Langier's still. The principle of Coffey's still. Its mode of action described. Improved forms of still. Alcoholic beverages and other products.

Health Exhibition Season Tickets.

The Executive Council of the International Health Exhibition have consented to allow members of the Society of Arts the privilege of purchasing season tickets for the Exhibition at half price (10s. 6d.) Each member can purchase a single ticket only on the reduced terms, and these tickets can only be obtained through the Secretary of the Society of Arts. For further particulars see notice in the *Journal* for May 2, p. 575.

MEETINGS FOR THE ENSUING WEEK.

Monday, May 12...SOCIETY OF ARTS, John-street, 8 p.m. (Cantor Lectures.) Professor W. N. Hartley, "Fermentation and Distillation." (Lecture I.)

Geographical, University of London, Burlington-gardens, W., 8½ p.m. Mr. Robert Michell, "The Region of the Upper Oxus."

Tuesday, May 13...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Gamgee, "The Physiology of Nerve and Muscle." (Lecture II.)

Medical and Chirurgical, 53, Berners-street, Oxford-street, W., 8½ p.m.

Civil Engineers, 25, Great George-street, Westminster, S.W., 8 p.m. 1. Adjourned Discussion on Mr. S. B. Boulton's paper, "The Antiseptic Treatment of Timber." 2. Mr. R. W. Peregrine Birch, "The Progesss of Upland Water through a Tidal Estuary."

Anthropological, 3, Hanover-square, W., 8 p.m. 1. Mr. E. H. Man, "The Ethnology of the Andaman Islands." 2. Professor Flower, "Additional Observations on the Osteology of the Natives of the Andaman Islands."

Colonial Inst., St. James's Banqueting-hall, Regent-street, W., 8 p.m. Mr. R. Mosse, "Irrigation in Ceylon—Ancient and Modern."

Wednesday, May 14...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Prof. Fleeming Jenkin, "Telpherage."

Geological, Burlington-house, W., 8 p.m. 1. Dr. Henry Hicks, "The Pre-Cambrian Rocks of Pembrokeshire, with especial reference to the St. David's District." With an Appendix by Mr. Thomas Davies. 2. Mr. Herbert Green Spearing, "The Recent Encroachment of the Sea at Westward Ho, North Devon."

Microscopical, King's College, W.C., 8 p.m. Mr. P. Herbert Carpenter, "The Minute Organisation of the Nervous System of Crinoids."

Royal Literary Fund, 10, John-street, Adelphi, W.C., 3 p.m.

Thursday, May 15...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Chemical, Burlington-house, W., 8 p.m. 1. "Dr. J. H. Gladstone, "The Indices of Refraction of Organic Substances." 2. A. B. Griffiths, "Some Minor Researches on the Action of Ferrous Sulphate on Plant Life."

Society for the Encouragement of Fine Arts, 9, Conduit-street, W., 8 p.m. Mr. G. A. Storey, "Mysteries of Colour."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. Dewar, "Flame and Oxidation." (Lecture IV.)

Historical, 11, Chandos-street, W., 8 p.m.

Clerks of Works Association, St. James's (small) Hall, Regent-street, W., 8 p m. Mr. A. Reckenzaun, "Electricity: Its Application to Public Works and Buildings, Motive Power, &c., with Experimental Illustrations."

Numismatic, 4, St. Martin's-place, W., 7 p.m.

Friday, May 16...United Service Inst., Whitehall-yard, 3 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Weekly Meeting. 9 p.m. Prof. W. Odling, "The Dissolved Oxygen of Water."

Philological, University College, W.C., 8 p.m. Anniversary. President's Annual Address, by Dr. J. A. Murray.

Medical Officers of Health, 1, Adam-street, Adelphi, W.C., 7½ p.m.

Saturday, May 17...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Bonney, "The Bearing of Microscopical Research upon some large Geological Problems." (Lecture I.)

Geologists' Association, University College, W.C. Excursion to the New Docks at Tilbury, under direction of Mr. F. V. Holmes.

Erratum.—In Report on Collisions, in the last number (p. 576, col. 2, note 2) *for* "urges" *read* "states."

Journal of the Society of Arts.

No. 1,643. Vol. XXXII.

FRIDAY, MAY 16, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CANTOR LECTURES.

The first lecture of the Sixth Course was delivered by Professor W. N. HARTLEY, on Monday evening, 12th inst., the subject being "Fermentation and Distillation." The lecturer dealt with the production of alcohol, and its uses in manufactures, and described the change of starch into sugar and dextrine, and the chemical action which brings about this change.

The lectures will be printed in the *Journal* in the autumn recess.

PRACTICAL EXAMINATION IN VOCAL OR INSTRUMENTAL MUSIC.

The next Examination in London will be held by Mr. W. A. Barrett, Mus.Bac. (Oxon), at the House of the Society of Arts, 18, John-street, Adelphi, W.C., during the week commencing on the 9th June, 1884.

Full particulars can be obtained on application to the Secretary.

Proceedings of the Society.

APPLIED CHEMISTRY & PHYSICS SECTION.

Thursday, May 8, 1884; Professor W. J. RUSSELL, Ph.D., F.R.S., in the chair.

The paper read was—

CUPRO-AMMONIUM SOLUTIONS AND THEIR USE IN WATERPROOFING PAPER AND VEGETABLE TISSUES.

By C. R. ALDER WRIGHT, D.Sc., F.R.S.

The term "Cupro-ammonium Compound" is usually understood by chemists as indicating a member of the class of substances obtainable by the combination of ammonia with certain copper compounds, so as to give rise to a "metallo-ammonium" derivative containing copper. Salts of copper, *e.g.*, copper sulphate, usually combine with four proportions of ammonia; thus the *Cupro-tetrammonium sulphate* $(Cu.\ 4\ NH_3)\ SO_4, H_2O$, is obtainable in crystals, by simply pouring a concentrated solution of copper sulphate into a solution of ammonia, in such proportions as to obtain a clear deep blue liquid, and then precipitating the crystallised salt by adding a considerable quantity of highly concentrated ammonia solution, or by shaking with alcohol; in a similar fashion numerous other cupro-tetrammonium salts can be obtained. A closely related compound, but possessing somewhat different properties, is *cupro-ammonium hydroxide*, prepared by dissolving cupric hydrate in ammonia solution, or by agitating together metallic copper and ammonia solution in presence of air, when the copper oxidises and dissolves in the ammoniacal liquor, forming a deep blue liquid, sometimes termed "copperised ammonia;" probably the cupro-ammonium compound present is $(Cu.\ 4\ NH_3)\ (OH)_2$, related to the hydrated copper oxide formed as cupro-tetrammonium sulphate is to copper sulphate.

Most of these compounds are very unstable, breaking up under the influence of heat and water alone, or conjointly; thus cupro-tetrammonium sulphate treated with a large bulk of cold water is partly decomposed, forming a basic insoluble copper sulphate, together with free ammonia and ammonium sulphate; cupro-ammonium hydroxide solution is decomposed by simple addition of alcohol to its ammoniacal solution, a blue substance essentially consisting of hydrated copper oxide being precipitated; the same result ensues on boiling, save that anhydrous black copper oxide is then formed, ammonia being driven off. In presence of a large excess of ammonia, the instability is less marked in all cases; the strongly ammoniacal fluids formed by dissolving copper salts or copper hydroxide in a considerable excess of ammonia water are the "cupro-ammonium solutions" referred to in the present paper.

It has long been known that these solutions possess the power of apparently dissolving cellulose and various allied substances; thus paper, cotton wool, and similar materials, when digested with these fluids, disappear, and are apparently truly dissolved. It is held, however, by some chemists (*e.g.*, Erdmann, *Jour. Prakt Chem.* lxxvi., 385), that these are not cases of true solution, but that the substances are simply gelatinised and disseminated through the fluid in a transparent form, as starch is in water. On the other hand, on neutralising the fluid by an acid, or better still, on adding potassium cyanide solution until the blue tint is discharged, the cellulose reappears as a gelatinous precipitate; this result would suggest that the reappearance of the cellulose is brought about by the destruction of the solvent in which it was truly dissolved, viz., the cupro-ammonium compound, by conversion into ammonia and cupro-cyanide (or into ammonic and cupric salts, if an acid be used). On evaporation to dryness of a cupro-ammonium solution in which cellulose has been dissolved, a more or less gummy mass is formed, containing the cellulose intermixed with copper oxide, and with ammonia and copper salts if a cupro-ammonium salt were used, but containing copper oxide and a green copper derivative or compound of cellulose if cupro-ammonium hydroxide were employed. When the cellulose is in excess, *e.g.*, when the solution is evaporated on the surface of paper, calico, &c., just dipped in the solution, black oxide of copper is often not formed at all; but a green varnish-like mass of cellulose conjoined with copper-oxide, or of the copper salt of some feeble acid derived from and closely akin to cellulose, coats the surface of each filament of the fabric used, welding and cementing them together. This cement-like *cupro-cellulose*, as it may be termed, being insoluble in water, communicates water-resisting properties to the material so treated; moreover, the presence of copper renders the dipped and dried substance less prone than before to the attacks of insects and mould, so that animal and vegetable life of a parasitic nature and fungoid growths are rarely, if ever, to be observed in the substances, even when kept under conditions where boring worms, ants, rot, and mould, would be likely to attack them.

To produce the best results in this direction, solution of cupro-ammonium hydroxide is, for many reasons, preferable to solutions containing cupro-ammonium salts; not only is the action on cellulose more energetic for a given amount of copper and ammonia in solution, but various other advantages are gained. For example, if ammoniacal solution of cupro-ammonium sulphate be used, the dried treated fabrics will contain ammonium sulphate, and sometimes copper sulphate, soluble in water, rendering the material porous if exposed to the action of water in sufficient quantity to dissolve out the soluble matters, and causing more or less tendency to unsightly efflorescence under other conditions. Further, during the drying of materials treated with cupro-ammonium hydroxide solution, all the ammonia present is volatilised, and may be recovered by appropriate means; whereas, with cupro-ammonium sulphate solution, a considerable fraction of the ammonia is fixed in the fabric as sulphate, and so lost.

A peculiar property of cupro-ammonium solutions, and one most important from the manufacturing point of view, is that whereas iron is, as is well known, attacked and dissolved by solutions of ordinary copper salts (*e.g.*, the sulphate, "blue vitriol"), an equivalent quantity of copper being precipitated during the operation, no such action is observable with cupro-ammonium hydrate solutions; so that cast and wrought-iron tanks and baths for the reception of the liquor may be used with impunity, as may steel rollers and machinery of all kinds when employed in contact with the liquor, or with fabrics moistened therewith. On the other hand, copper and brass must be studiously avoided in the construction of such appliances, otherwise corrosion and injury is speedily brought about. This peculiarity, as regards the non-action of iron and steel, is the more remarkable in that it is not observed with zinc; this latter metal precipitating copper (and being itself dissolved) with about equal facility, whether the copper be in the form of an ordinary copper salt, or in that of a cupro-ammonium solution.

For certain purposes, a bath containing a mixture of cupro-ammonium and the analogous zinc-ammonium hydroxide solutions may be used with advantage; the zinc compound does not of itself sufficiently pectise cellulose to give good results, but when used in conjunction with cupro-ammonium hydroxide, pectising is brought about by the copper solution, whilst certain advantages are gained by the simultaneous presence of zinco-cellulose and cupro-cellulose in the finished goods. The subject of the manufacture of both cupro-ammonium and zinc-ammonium solutions having been already dealt with in a paper read before the Society of Chemical Industry (published in a recent number of the journal of that Society), it will suffice, on the present occasion, to state that the fluids are obtained by the simultaneous action of air and ammonia water on metallic copper (or brass, if a mixture of cupro- and zinco-ammonium hydroxides is required), due attention being paid to the recovery of the large amount of ammonia necessarily carried away by the "spent" air during the operation.

The manufacture of fabrics, notably paper and canvas, treated with cupro-ammonium solutions so as to waterproof them and render them rot-proof, and practically free from the attacks of insects and mould, has been recently commenced on the large scale, at Willesden, by the Patent Waterproof Paper and Canvas Company, Limited, after a laborious series of trials and experiments on the matter, lasting over several years. The earliest patent relating to the production of these substances; was taken out as far back as 1868, by the late Dr. John Scoffern, whilst laboratory-made specimens, and models, &c., were exhibited in the Exhibition at South Kensington, 1872 (Scientific Inventions Department). Owing to the promising nature of the results obtained at this time, Mr. A. E. Healey, the present managing director of the company, selected a site at Willesden, and started the process in an experimental way in 1873; but numerous practical difficulties were encountered, and many modifications of the first machines employed were tried before the present arrangements were arrived at, enabling layers of material to be rolled 4 feet 6 inches wide, and of any required continuous length, without ruckle, flaw, or inequality. After the expenditure of much labour and patience, during some five years, a considerable measure of success in this direction was attained, so that in the Paris Exhibition of 1878 some fairly well-made rolls were shown with other specimens, for which three prizes were awarded; and since this date, numerous further improvements have been made, both in the nature of the plant and machinery requisite for the carrying on the manufacture, and in the preparation of the cupro-ammonium solution forming the starting point of the process;* so that it is only within a very recent period that the manufacture has actually attained to such a condition of completeness and perfection as to enable the products to be put in the market on any considerable scale, and that it has been practicable to produce in almost any required quantity such well made and useful products as those of which I am enabled to-night to show you specimens, through the kindness of the Directors of the Willesden Company.

In the trade, these products are now known as "Willesden" goods, and are divisible into two classes, viz., (*a*) the round or made-up goods, such as Willesden rope and cordage, Willesden netting, &c., and (*b*) the rolled or flat goods turned out in roll at the Willesden Mills.

Goods of the first class (*a*) are prepared by simply dipping the made-up materials to be treated into a bath of cupro-ammonium solution, using certain precautions as to the mode of immersion and its duration, and the strength of the solution. On subsequently drying the dipped fabrics, they are obtained coated and impregnated with cupro-cellulose, which thus not merely forms a kind of varnish-like surface dressing, but further adds strength to the fibres by more or less intimately cementing them together. The freedom from liability to mildew and rot of these products is remarkable, whilst they possess many advantages as compared with similar goods protected by tarring, or dipping in the bark vat, or treatment with other preservative compositions.

Goods of the second class (*b*) constitute a much more important group, to which at present the Willesden Company more especially devotes its attention. These fabrics are essentially of three kinds, viz., Willesden Canvas, Willesden Scrim, and Willesden Paper. The former two of these classes possess many features in common with the round or made-up goods just described, being prepared in much the same way, saving that the fabric to be treated is usually unwound from one roller and re-wound upon another, after passing successively through the bath and a succession of drying rolls somewhat analogous to those of a paper mill. Like Willesden cordage and netting, they exhibit remarkable freedom from moulding and mildewing influences. This point is well exemplified by the illustrations exhibited.

[Specimens were here shown of strips of canvas and scrim of various kinds, kept partly immersed in water in loosely covered jars for periods varying from a few weeks to

* Of the various patents possessed by the Willesden Company, for successive improvements and modifications, the latest is that of Dr. Alder Wright, for improvements in the production of cupro-ammonium and other analogous metallic solutions, by means of which the manufacture of this essential fluid is greatly cheapened and facilitated.

about four months; in each case a strip of original untreated fabric and one of the same substance after "Willesdenising" being side by side. The untreated specimens were copiously mildewed to extents varying with their age from just perceptibly incipient growth to completely developed large fungoid masses. The "Willesdenised" samples were just as perfect and free from mildew as when first put in.]

Willesden Paper.—This manufacture may be subdivided into two departments, viz., (1) Willesden unwelded, (2) Willesden welded (rolled goods), the first class being a single web or ply of paper of indefinite length passed through the bath, and rolled and dried in much the same way as canvas and scrim; the second class consisting of more than one ply or layer of primary material, incorporated into one solid insoluble sheet or homogenous panel of indefinite continuous length.

1. Unwelded or "one-ply" paper exhibits much the same general resistance to mildewing and moulding influences as Willesden canvas and cordage, &c. According to the nature of the paper originally treated, different kinds of Willesden 1-ply (W.P.G. 1) result. Certain coarse varieties furnish a waterproof material excellently adapted for lining packages, and wrapping parcels, &c., liable to be exposed to damp during transit, and of special value as a first coat of paper to be applied to damp walls. Finer qualities furnish envelopes and stationery possessing the valuable property of not being affected by water. Letters written with such stationery would be as legible as ever (provided the ink were not washed away or bleached) even if the mail-bags containing them were sunk in the ocean or washed overboard, and not recovered until after long periods of immersion. In connection with this may be noticed a mode of fastening envelopes, affording security against opening and tampering with contents, impossible with ordinary gummed envelopes, or with those secured by sealing-wax, either of which, as is well known, can be readily opened by a skilled person, and re-closed without noticeable alteration (an impression of the seal being of course taken in the case of sealed letters, and subsequently used to re-seal them). This method consists in using as fastening material a concentrated cupro-ammonium solution; the edges of the envelope are moistened therewith, whereby the paper is gelatinised; the envelope is then closed and ironed with a warm flat iron, when the gelatinised cellulose is converted into an insoluble cupro-cellulose, and the cover is fastened down so securely that the only possible mode of opening is to tear the paper. No amount of steaming or treatment with water will undo the cement, as it would with a gummed envelope. Another application of this same principle consists in the use of a wafer of "Willesdenised" paper, moistened with cupro-ammonium solution before use. Obviously, the same principle may be applied in the direction of cementing together the edges of sheets of paper so as to form larger sheets, fixing firmly together paper, pasteboard, wood, and analogous surfaces, bookbinding, and in numerous other ways; troughs and dishes, watertight boxes and packing-case linings, &c., are readily prepared thus.

[Samples of the same kinds of paper before and after treatment, immersed in water for various periods, side by side, were here exhibited, the former being more or less completely softened and pulped, whilst the latter indicated no change whatever; practical illustrations of the effect of a few minutes' boiling in water on the different specimens were also given, the treated specimens being unaffected, whilst the untreated ones were more or less completely softened and disintegrated.]

2. Welded Willesden goods have undoubtedly the merit of being the most remarkable and interesting of all, on account of their novelty and important applications; they are all prepared in substantially the same way, viz., by simultaneously dipping more than one ply, and pressing into one compact homogeneous sheet the various layers, whilst still gelatinised or pectised by the action of the cupro-ammonium solution. According to the nature and thickness of the finished material, various sub-divisions of this class may be tabulated, *e.g.*:—

W.P.G. 8. Willesden 8-ply; panel board.

W.P.G. 4. Willesden 4-ply; for roofing, building, panelling, decorating, &c.

W.P.G. 2. Willesden 2-ply; for underlining, interior decoration, floors, damp walls, packing, leaky roofs, &c.

W.P.G. 1. Willesden 1-ply; described above as unwelded Willesden goods.

Besides these, various kinds of combination fabrics may be noticed, such as those obtainable by simultaneously treating paper and calico, and welding the two together so as to form an article resembling ordinary mounted drawing paper, but differing therefrom in the important character that long continued immersion and even long boiling in water causes not the least disintegration or separation of the two diverse fabrics thus combined; so that military and submarine engineers' and surveyors' plans, and the like, drawn on such paper would be uninjured by being exposed to wet and rain, if the colours or ink were of suitable kinds, so as to resist the action of the water.

Willesden 8-Ply.—This material is adapted for panel work and use where great strength is required, and is valuable owing to its being made (to special order) 54 or even 60 inches wide, and in continuous lengths; from the nature of this material there is no fear of its cracking or splitting like ordinary panel board. For boat-building and naval construction generally it is well adapted. [Specimen shown of 8-ply panel boiled under 60 lbs. pressure for eight consecutive weeks in one of the steam boilers at the Willesden factory, without undergoing any disintegration, or serious change of any kind beyond a slight cockling.]

Willesden 4-Ply.—Next to slates and tiles, this material stands pre-eminent as a durable roofing material, unassailable by weather of all kinds; whilst its strength, combined with lightness and flexibility, combine to render it a most valuable and unique article for practical use and service; more especially are these advantages manifest in connection with up-country and foreign employments. Mr. Healey furnishes me with the following statement, comparing the relative weights and covering powers of W.P.G. 4, and good galvanised iron:—

WEIGHT OF ONE SQUARE (100 SQUARE FEET) IN POUNDS.

W.P.G. 4.	Galvanised Iron.
15 to 18.	103 to 280.

AREA COVERED BY ONE TON.

800 to 2,170 square feet, or 8 to 22 squares.	12,500 to 15,000 square feet, or 125 to 150 squares.

It is hence abundantly manifest that Willesden 4-ply would come far cheaper than galvanised iron, in any district where the cost of transit is heavy, more especially in new districts where the means of communication with the seaboard are but imperfectly opened up. Again, being put up in compact rolls (ordinarily of 2 cwt. each), no space is wasted in packing. Another special advantage is, that being comparatively non-conducting, the heat of a tropical sun is less felt under a roof of this kind than under a metallic one; whilst, on the other hand, the condensation of moisture from warm air inside a hut thus roofed or walled is all but imperceptible, even on a cold night; whereas an iron building, under similar conditions, frequently gives an inconvenient drip of condensed water from the roof, and small streams running down the walls.

For building purposes generally, and interior use, W.P.G. 4 offers many advantages. Where the buildings are temporary and intended for subsequent removal elsewhere (*e.g.*, workmen's huts when engaged in railroad construction, &c.), the lightness of this material renders it eminently adapted for construction in removable sections; and for more permanent structures it is equally advantageous for numerous reasons. It does not harbour moths or other vermin; in the hottest weather, under a broiling tropical sun, it remains unchanged, and emits no unpleasant odour; it requires no painting, and exempts from the necessity of using pot and brush year after year to prevent corrosion, or to make a neat surface, or render water-tight, being weather-proof in itself. If required for internal decoration, however, it will take paint readily, and, indeed, forms an admirable foundation for the painter and decorator to work upon, in this respect having marked advantages over felt, with which material it has nothing in common, although the two can, if desired, be used in conjunction. In case of fire, although not absolutely indestructible, yet "Willesden" will not readily feed the flames, the copperising and compacting process by which it is made rendering it far less inflammable than such substances as painted or tarred felt, or wooden shingling; its lightness moreover renders much less massive timbering requisite for the support of roofs, thus again diminishing the risk of damage by conflagration, there being actually less combustible matter about a building erected with this material than is necessary when the weight of a slated or tiled roof has to be supported. It is to be noticed that a special method of fixing walls and roofs of Willesden paper is recommended, illustrations of which are exhibited. Many such roofs are now standing in perfectly good condition, after upwards of eight years' exposure to weather of all sorts: similarly, pipes conveying both water and steam, such as those exhibited, have been in use upwards of three years below ground at the Willesden Works, without any visible deterioration. [A number of experiments were here shown, and others described, illustrating the comparative effect of dry heat and of boiling water on W.P.G. 4, and on mackintosh, pitch papers, felt, tarpaulin, asphalte, Manchester packing, &c.; the former being unaffected, and the others rendered more or less unserviceable, and, in many instances, utterly spoiled.]

Willesden 2-Ply.—This material is susceptible of being used for many purposes for which 4-ply is applicable, more especially when a less degree of body and substance will suffice. One special purpose to which it is excellently well adapted, is for laying upon or under floorboards, upon joists, &c., to avoid damp and draughts. Used as a floor-cloth for stairs, offices, &c., it wears well and is most effective, the cost being only a fraction of that of linoleum, kamptulicon, and similar articles.

In conclusion, I am enabled, by the kindness of the Directors, to exhibit not merely the numerous examples of Willesden goods, and their applications surrounding us, but also a series of lime light enlargements of photographs of buildings and other structures of magnitude, erected of Willesden paper.

DISCUSSION.

The CHAIRMAN, in inviting discussion, said the subject was one of great interest to all parties, and the number of applications to which the manufacture might be applied, was certainly very numerous.

Dr. HATCHELEY said that, apart from the scientific value of the paper, he was much interested in the subject of cupro-ammonium, as he had had the privilege of a long and intimate acquaintance with Dr. John Scoffern, the original discoverer of the commercial value of this compound; and many were the interesting conversations which they had, in the infancy of the discovery, as to the probability of its great future, and the different purposes to which it might be applied. Dr. Scoffern was no visionary, but a man of great foresight, for he had rightly predicted the applications which cupro-ammonium would have, and it was much to be deplored that he had not lived to see his predictions verified.

Mr. J. M. THOMSON said, that having listened with very great interest to the paper, it struck him that Willesden paper might be used for the manufacture of light boats, which could be carried with ease; and, in the next place, in the manufacture of dishes for photographers. He should like to know whether a boat built of this paper would stand the action of sea water, and dishes the action of chemicals. It was well known that porcelain dishes were exceedingly heavy and unwieldly, and if dishes could be made of this paper, it would be a great advantage.

In reply to a question,

Dr. C. R. ALDER WRIGHT stated that there would be great difficulty in removing the whole of the copper from the paper by means of solvents such as acids.

The CHAIRMAN observed that the specimens of rope which had been exhibited had only been acted upon superficially by the coppery material, and he wished to know whether it was not possible to act upon the inner strands.

Mr. HALL said that Captain Abney, who had experimented upon this compound, found that the various developing solutions used in the fixing of photographs were not effected by Willesden paper, though in all cases he took the precaution to give the paper dishes a rinse out before putting in a fresh solution. He had also been informed by Mr. Whaite, the well known photographer, that he used dishes made of the paper.

Mr. A. E. HEALEY mentioned that a paper upon this subject had lately been read at the Photographic Society, when the whole subject was discussed, pans and dishes made of the paper being then exhibited.

The CHAIRMAN asked whether the paper dishes were cheaper than porcelain?

Mr. HEALEY said they were much cheaper.

Mr. J. O. CHADWICK suggested that the paper might be used by painters for works of art. Many of the works of the old masters had been preserved solely owing to the quality of the canvas used, and if this new material could be used, pictures would be almost undestructible. For the use of emigrants and colonials, it offered a field of unlimited extent, owing to its portability. Another remarkable property of the paper was its power of retaining the legibility of writing after being submerged in water for a lengthened period, which would be found of great service in the event of mail bags being recovered after a wreck. If the paper could be used for constructing the cells of galvanic batteries cheaply, and on a large scale, a great future was before it, as vulcanite, which was now used for this purpose, was very brittle and expensive.

Mr. E. W. BECKINGSALE inquired whether the material was capable of being moulded; if so, it might be used for cells. Perhaps Dr. Wright would tell them whether it was di-electric, and capable of withstanding the action of sulphuric acid.

Mr. LANT CARPENTER said that having had a summer-house roofed with this paper last year, he was able to speak in its favour, for it was as sound now as when put up. As far as he understood the manufacture of the paper, it was almost a case of superficial coating of the fabric treated, and therefore he should be glad to know whether any experiments had been made in the direction of incorporating the cupro-cellulose solution with paper pulp.

A MEMBER asked whether the copper was an essential part of the operation, because, if so, its presence might, in many cases, prevent the use of the paper. He rather thought that the cellulose was entirely changed, and that the copper became a sort of impurity. The paper might usefully be employed in South Africa and other places for the construction of light buildings, especially in places where they were troubled with white ants.

Dr. HATCHELY remarked that white ants would eat nearly everything but iron and stone; but from experiments made by a friend of his in a place infested with these insects, it was proved that they would not touch this paper.

A MEMBER asked if a paper prepared in this manner was the same as paper prepared with sulphuric acid, for vegetable parchment?

A MEMBER inquired whether the paper, when used for decorative purposes, had any effect upon pigments. As he had lately superintended the putting up of a decorative frieze in Westminster Hospital, he wished to know, as the medical staff had insisted upon the decoration being washable, whether his work was doomed in any way to suffer in the far future.

Dr. ALDER WRIGHT, in reply, said he had heard from various sources that white ants and other vermin would not touch the Willesden material, owing to the presence of the copper, so that, if the copper could be removed, as one speaker had suggested, the safety of the material in this respect would be gone. Boats had been made of the paper, and they answered very well in fresh water, but he could not say whether they had been tested in salt water. One advantage in making boats of the paper was that they were lighter than those made of wood, and, in the next place, they were very easily repaired. Photographic dishes could easily be made by taking a sheet and pinching up the corner, bulging being prevented by running a thread through the corners. These dishes could be used for chemicals, though it was not advisable to put in a second chemical if the first had remained in the dish for some time. As to the action of acids upon the card, that depended upon the concentration as well as the nature of the acid and the temperature. If the card were boiled in a beaker, with weak sulphuric or hydrochloric acid, beyond doubt copper in solution would be found, and, no doubt, there would be less copper in the card than there was before; but, in the cold, very little copper was dissolved out. He did not think that the solution of copper in this way would affect the stability of the material for such purposes as had been alluded to, more particularly in the use of galvanic cells. As to whether this material could be used for vats for bleaching purposes, that was a matter which experience alone could decide, though there was nothing in the character of the material which would unfit it for the purpose. At the same time, he was not prepared to assert that oil of vitriol could be kept in a vessel made of Willesden paper. With regard to the ropes being only superficially tinged with the coppery material, that partly arose from the circumstance that the rope had purposely not been immersed sufficiently long to enable the fluid to penetrate deeply. As the action of the solution was to dissolve and disintegrate fibres, if thin ropes were saturated all through, they were apt to lose a certain amount of strength. It was not necessary that a rope should be saturated throughout. As to the paper treated at Willesden, complete penetration of the fluid into each ply of paper was a necessity, in in order to obtain a proper product. The principal difficulty in carrying out the process consisted in exactly regulating the strength of the solution as regarded the amount of copper and ammonia, the nature of the paper and the length of time during which it had to pass through the vat, in order that the solution should pass into the interior of the paper to the proper extent and no more; for if the action of solution was overdone, the material became too soft and tender to be dealt with by the machine. As to the paper being used as a medium for painting, he might say, that both the canvas and paper were susceptible of use in this direction, though he was unable to speak with certainty as to canvas, owing to it not having been long in use; but there was every reason to believe that works of arts on canvas treated by this process would be less subject to deterioration through injury to the foundation. He was not aware that the paper would have any effect upon any mineral colour employed for decorative purposes. The action of copper upon certain organic dyes was well known, but these substances were rarely used for painting. The paper could be moulded into any shape, though this particular branch of the business had not yet been pushed, as the manufacture of the rolls appeared more promising. The production of thick plates for backing of armour plating was contemplated, and could be carried out by the action of the cupro-ammonium, either from paper pulp or cutting upon a mass which could be moulded into shape. As to the analogy between this paper and paper parchmentised with sulphuric acid, he might say the two processes were dissimilar, though chemically the change produced on the paper fibre was of much the same character. There was a certain amount of analogy between the processes; if, for example, a sheet of writing paper were impregnated with cupro-ammonium to a certain extent, it had much the same texture when finished as parchmentised paper, and microscopically there was the same kind of structure. The quantity of copper left in the paper after treatment would vary very much according to the length of time the paper was allowed to remain in the solution, and the quantity taken up. but in round figures, an analysis of 4 ply paper showed that it contained about 4 per cent. of metal. Among other uses to which the paper might be put, was for covering bricks in the brickfield, and for making shelters for vineries. Upon the question of whether Willesden paper was a non-conductor for electricity or not, he thought, if the material was rolled up into a pipe and used for telegraph cables, it would serve very efficiently, though he doubted whether it would be used with advantage as a substitute for gutta-percha. It certainly did not conduct electricity readily; but as it contained copper, if there happened to be a leaky wire, reduction of metallic copper might be caused, whereby metallic communication would be set up from the wire to the earth, and, therefore, he doubted whether the substance could serve for the purpose of insulation. For chemical laboratories, and household matters, there were a considerable number of applications where the material would come in most handily.

On the motion of the CHAIRMAN, a vote of thanks was passed to Dr. Wright for his interesting paper.

TWENTY-FIRST ORDINARY MEETING.

Wednesday, May 14, 1884; Sir FREDERICK ABEL, C.B., D.C.L., F.R.S., Chairman of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Atkins, Richard Day, 3, Sidney-place, Cork.
Chapman, Spencer, 84, Eccleston-square, S.W.
Clarke, Stewart, M.P., Bailey's Hotel, South Kensington, S.W.
Kendrew, John Anthony, The Ollands, Reepham, Norfolk.
Paget, Sir James, Bart., F.R.S., 1, Harewood-place, Hanover-square, W.
Pearson, Rev. H. D., M.A., St. James's Vicarage, Clapton, N.
Phillips, Henry Dominie, J.P., The Maples, Hampton-wick.
Stotherd, Colonel Richard Hugh, Ordnance-house. Southampton.

The following candidates were balloted for and duly elected members of the Society:—

Barclay, Robert, 17, Major-street, Manchester.
Bishop, Frederic Sillery, M.A., Welwyn-lodge, Swansea.
Ellis, Herbert, 62, New-walk, Leicester.
Francis, George Bult, 5, Coleman-street, E.C., and 21, Taviton-street, W.C.
Guttmann, Charles, 16, Brownswood-park, South Hornsey, N.

The paper read was—

TELPHERAGE.

BY PROF. FLEEMING JENKIN, LL.D., F.R.S.

In the first place, it is necessary that I should define what is meant by this word "telpherage," and perhaps that I should defend its formation. The word is intended to designate all modes of transport effected automatically with the aid of electricity. According to strict rules of derivation, the word would be "telephorage;" but in order to avoid confusion with "telephone," and to get rid of the double accent in one word, which is disagreeable to my ear, I have ventured to give the new word such a form as it might have received after a few centuries of usage by English tongues; and to substitute the English sounding "telpher" for "telephore."

In the most general sense, telpher lines include such electric railway lines as were first proposed by my colleagues, Messrs. Ayrton and Perry. The word would also describe lines such as I have seen proposed in the newspapers, for the conveyance of small parcels at extremely rapid rates. But to-night I shall confine myself entirely to the one specific form in which the telpher line first presented itself to my mind, and which it has fallen to my lot to develop. In this form telpher lines are adapted for the conveyance of minerals and other goods at a slow pace, and at a cheap rate.

The problem which occurred to me was this: Was it not really possible to send vehicles, by means of electricity, along a single suspended wire or rod—in fact, to telegraph goods and passengers instead of messages. The idea is familar as a joke, but, on consideration, it appeared that there might be good grounds for supposing both that the idea was practicable and useful. I am now able to show you the realisation of that idea, and the result of experiments on a large and practical scale has, I think, justified the arguments which have induced me to devote much time and labour to tepherage.

[Here the model was shown in action. This model consisted of two concentric octagons of wire, the length of each outer span being 5 ft. On each octagon there was a single locomotive and train, equal in length to that of the span. These trains ran well and steadily in opposite directions round the lines.]

These arguments may be stated as follows:—

We could not with steam employ a vast number of little one-horse engines to pull along a number of small trains or single waggons. There would be waste in the production of power, and great cost in the wages of the men employed at each engine. But an electric current, of, let us say, 50 horse-power, will, as it circulates through a conductor of moderate size, drive thirty small engines each of one horse-power, which require practically no supervision, and can be made nearly as economical in their action as a single electromotor of 30 horse-power could be.

But if the power can be distributed economically along a line, say, ten miles in length, this allows us to employ thirty small trains, corresponding each to a waggon pulled by one horse, instead of a single train such as might require 30 horse-power. If we further distribute the weight by making each train of considerable length, we are able to employ an extremely light form of road, such as a suspended rope or rod of, say, ¾ in. diameter. Later on in the paper I will show the amount of traffic which such a rod can practically convey. Meanwhile, I simply draw your attention to the general principles of the subdivision of power and the subdivision of weights. In distributing the power by means of electricity, it was clear that considerable waste must be incurred, but the amount of that waste is easily calculated, and is by no means prohibitory. Moreover, the power, being obtained from stationary engines, or in certain cases from falls of water, could be produced at a cheap rate in comparison with that obtained from locomotives or traction engines.

When I examined the various forms of possible road by which the distributed power and distributed load could be conveyed, it seemed to me that the single suspended rope or rod offered great advantages. The smallest railway involved embankments, cuttings, and bridges, fencing, and the purchase of land. A single stiff rail, with numerous supports, from which the train might hang, seemed better, and may, in some cases, be employed, but the supports would require to be numerous—say, one post every 10 or 15 feet—and even with these spans, the girder required to carry vehicles weighing 2 cwt. each, would be costly. With a single suspended rod or rope, we may have supports 60 or 70 feet apart. A ¾-inch rod, thus supported, will carry five vehicles, each bearing 2 cwt., without excessive strain. No purchase of land is necessary, no bridges, earthworks, or fencing. The line can be so far removed from the ground that it will not be meddled with, either by men or animals. A single wheel-path gives the minimum of friction, and the rolling stock can be much more easily managed than if we attempted to let vehicles run on double swinging ropes. On all those grounds it seemed well worth while to devise means by which trains could be electrically and automatically driven along the single suspended rod.

Before proceeding further, I had better state how far this idea has been realised. The Telpherage Company, Limited, was formed last year, to test and carry out my patented inventions and those of Professors Ayrton and Perry for electric locomotion. On the estate of Mr. M. R. Pryor, of Weston, two telpher lines, on my plan, have been erected. One of these is a mere straight road, with spans of 60 feet, and various forms of rod and rope. The first full-sized train was run on this line with a locomotive which we call the bicycle-wheel loco (Figs, 8 and 9, p. 653). The line was found inconveniently large and high, and the experiments were continued on a line ⅝-inch diameter, of round steel rods, with 50 feet span. This line is continuous, that is to say, it reenters on itself. It is 700 feet long, and we have run a train of more than one ton at a speed of five miles per hour on this line with complete success. The insulation has given no trouble. It need hardly be said that we see our way to great improvements in details. Thus, we can make the road more uniform, and stronger for its weight; we can lessen the quantity of material used, and greatly diminish the amount of skilled labour required in erection. We can improve the design of the posts. We can improve the trucks and locomotives, so that they will go round sharper angles, and so forth, but the main object has been practically carried out. We have had trains on a scale as large as I am prepared to recommend, running at the highest speed I have contemplated.

I trust it will be clear to you, from this description, that what I have contemplated and realised is not an electric railway destined to compete with steam railways in conveying goods and passengers at high speeds, neither is it a new form of communication destined for small parcels and high speeds; it is simply a cheap means of conveying heavy goods which, like coal or grain, can be carried in buckets or sacks, each containing two or three hundred weight. The speed on a telpher line will be that of a cart, and the object we aim at is to cart goods at a cheaper rate and more conveniently than with horses.

I assume that you all know that an electric motor is a machine which will run so as to exert power whenever an electric current is passed through it. You also know that a machine called a dynamo, driven by a steam-engine or other source of power, will produce an electric current which may be conveyed along a suspended and insulated rod, and used to drive an electric motor.

In describing the details of my system, the first point to be explained is, how the current produced by the dynamo, and conveyed along a single line, is taken from that line and directed round the motor.

In endeavouring to realise this idea, the first thought which occurred to me was that of dividing the line into lengths, equal to the length of the train, so that using the train to bridge over a gap between two sections at different potentials, the current could be conveyed from the leading to the trailing wheels of the train, round the motor. This idea is employed in the model now shown; but, in the first form which suggested itself, the gaps between the sections were opened by a switch worked by the front of the train, and closed by a switch worked by the end of the train. The first model, which may have been seen by some present, working in Fitzroy-street, was made on this plan. Trains driven in that way would all be coupled in series. The present model is differently arranged; there are no working parts or switches. Let the successive sides of the polygon be called the odd and even sides; the odd outer sides are connected with the even inner sides, and the even outer sides with the odd inner sides. We thus have two continuous conductors each going right round the model, but not joined to each other; these are connected to the two poles of a battery. So long as no train bridges a gap no current flows, but whenever the train bridges the gap, a current flows from the positive to the negative pole round the motor. This plan is called the cross-over system; all the trains are joined by it in parallel arc, and the current is reversed each time a train passes a gap. This reversal does not affect the working of the motor. This is the plan which has been carried out on a large scale at Weston. Its simplicity leads me to believe that it will be the plan most usually adopted, but several other methods of driving have been devised. A spark passes between the wheels and the line each time the current is stopped, but this spark occurs between large masses of metal, where it appears to be harmless; it has given no trouble whatever at Weston. Moreover, it has been found very easy to make connection between the line and the train. The ordinary truck wheels answer admirably, so that no complicated brushes are required. There are some absolute advantages in having interruptions at regular intervals, but the discussion of these would lead me too far for my present purpose.

Only one of the two continuous conductors requires to be insulated; this results in alternate insulated and uninsulated sections all along each line. Fig. 1 shows a saddle, as we call

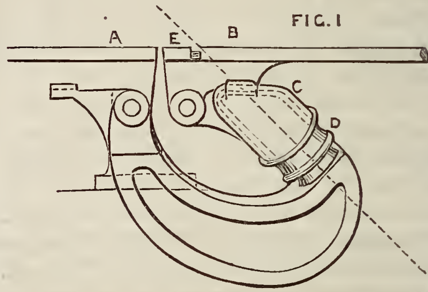


FIG. 1

it, with an insulated attachment, B, at the one end, and an uninsulated attachment, A, at the other, as used for a short sample line which has just been sent to Peru for the Nitrates Railway Company, Limited. The line itself is a three-quarter inch steel rod with forged ends, and Fig. 2 sufficiently shows the

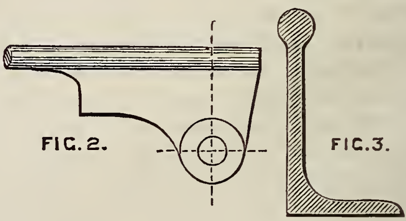

FIG. 2. FIG. 3.

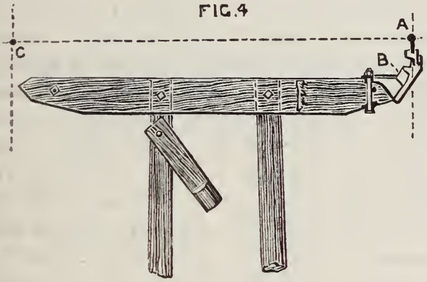
mode of attachment. The insulation is given by a vulcanite bell insulator, D, carrying a cast-iron cap, C. All the parts are designed to stand 2·2 tons strain; the vulcanite is secured between two layers of Siemens's cement. The experiments at Weston have shown that vulcanite answers perfectly, but the material is rather expensive. I have here a smaller porcelain insulator, which has been subjected to 2·2 tons' strain. I believe porcelain will answer well in all respects, but it has not yet been subjected to the test of actual traffic day by day. At Weston the vulcanite was used between layers of Portland cement, the only objection to which is, that it takes some time to set. The simple steel rod has been found preferable in all ways to rope. We find that there is less friction and less jar with the rod, and ample flexibility; it is also much easier to secure. Moreover, a solid rod with welded ends can be made so that the ends, where supported, are, to some extent, undercut, as is shown in the corresponding bulb angle-iron (Fig. 3, p. 650) used for rigid parts of the road, this undercutting allows much greater freedom of rolling than would be compatible with the horizontal gripping wheels, especially when gripping wheels are used which, like those in the model, actually hold on to the line so as to resist being lifted. A short piece, E, slightly insulated, prevents the sections from being short-circuited by the wheels.

Fig. 4 shows the posts and crosshead sup-

FIG. 4

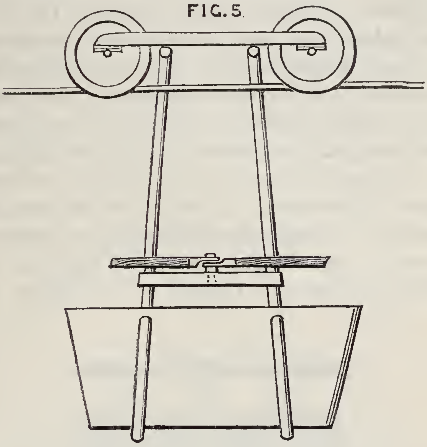


porting the line. In the one-inch example this design was fully carried out, and the posts stood the cross strain due to the overhanging load perfectly. In the five-eighth line an attempt was made to cheapen the construction, but the posts in wet weather work at the foundations; it is well that we are put on our guard against this danger. In the first design a sort of rocking saddle was employed, to allow the strain to be transmitted from one span to the next, but the flexibility of the posts provides amply for this object.

Abutment posts are required at intervals, and these can be made use of to provide compensation for changes of temperature, and to limit the stress on the rods. In straight lines I reckon about four abutment posts per mile.

In the short South American line, curves of 45 degrees at the posts will be employed, as shown in the model. At the stations where goods are to be handled, a rigid road will be more convenient than the flexible rod. A bulb angle-iron like that shown in Fig. 3, supported every ten feet, answers well at Weston, and a siding, leading the trucks off this line, has been satisfactorily carried out. The siding leads back to the line at a point between two flexible spans. In fine, it may be said to-night that the problem of the continuous line, whether straight, curved, rigid, or

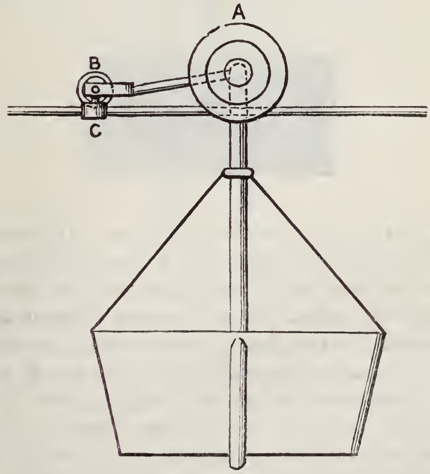
FIG. 5.



flexible, has been completely solved. Drawings and specifications can be put, without further delay or experiment, into the hands of contractors.

Trucks used on ordinary rope lines are

FIG. 6.



designed to be pulled by ropes on a road which is necessarily straight. When trucks of this description, with wheels 8 in. diameter and 22 in. wheel-base (Fig. 5), were tried at Weston, arranged in trains, some new difficulties presented themselves. Any sudden check to the motion was followed by a rearing action, throwing the truck off the line; similar results followed the application of any sudden pull. Moreover, trucks with two rollers on a rigid frame, even with so great a wheel-base as 22 in., require curves of considerable radius if we are to avoid serious binding at the flanges. Notwithstanding these difficulties, the trains at Weston, with a little care, run well and lightly, but the trucks which have gone to South America are on the plan adopted in the model, and run much more safely, and turn much sharper curves. They have two peculiarities—first, each wheel 7 in. diameter (Fig. 7), is pivoted on an axis, B, vertically over the centre of the wheels, A; this allows the truck to run with the freedom of a bicycle round curves; secondly, the weight carried is hung on a swinging arm, D, pivoted to the frame at

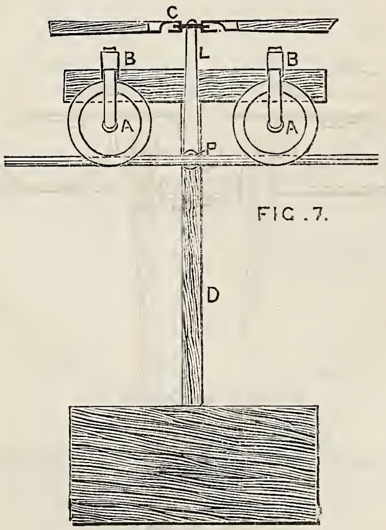


FIG. 7.

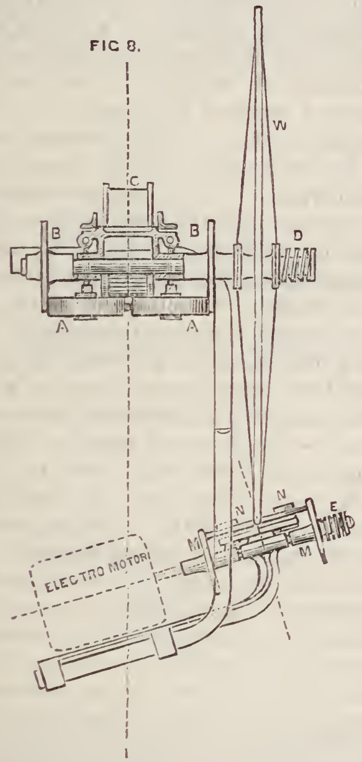
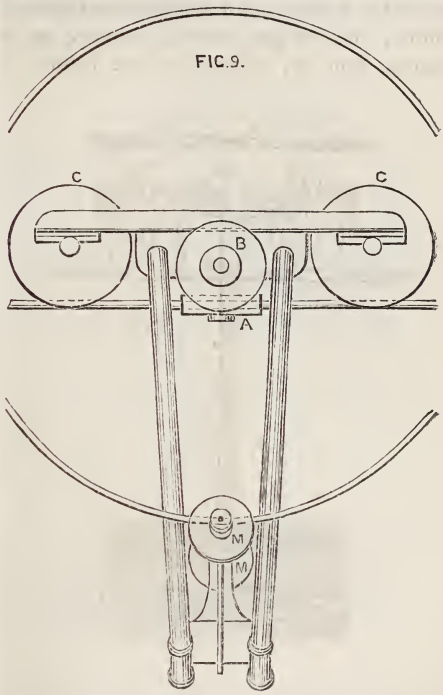
a point, P, on a level with the line. The result is that any force applied in a plane containing the line acts as if applied at the line itself, and will neither lift the wheels in front nor behind. In the model, the coupling, as you see, is on one line attached to the top of the swinging arm, where the coupling rods are well out of the way. In the other line the coupling is below the road. The swinging arm relieves the locomotive from all jerk at stopping or starting.

The truck is completed by a small hook or catch embracing the rod. In case of any accident causing the wheels to leave the line, this hook will prevent the truck from falling. The weight of the two-wheel stiff truck, shown in Fig. 5, with wrought-iron buckets, is 75 lbs. The weght of the two-wheel pivoted trucks, with wooden bucket, is 63 lbs. They are both adapted to carry 2 cwt. Fig. 6 (p. 651) shows a one-wheeled truck tested—the results were not favourable. A special form of bucket must be designed to suit such kind of traffic. Simple iron hooks for sacks will, in many cases, be available, and these hooks can be so contrived that on being struck they will drop the sack.

The first type of locomotive which was tried on a large scale is shown in Figs. 8 and 9 (p. 653). The motor lies horizontally across the line, and is connected by a form of frictional gearing, which I term right angle nest gearing, with the edge of a bicycle wheel, W. The shaft of the bicycle has on it two discs, B B, one of which is fixed on the shaft, while the other can slide longitudually on the shaft. These two discs are pressed together by a spring, D. Their edges bear on the horizontal gripping rollers, A and A, which seize the line. These rollers are supported in such a way as to be free to come together under the pressure of the spring transmitted by the discs, B and B. By tightening the spring, any required grip can be obtained with no injurious friction, either on the cross shaft or on the spindles of the rollers. This grip is a form of right angle nest gearing. The weight of the locomotive was taken by wheels, C C, fore and aft. The following defects were observed:—The frictional surfaces, both in the upper and lower nests, were too small, and the materials too soft, so that rapid wearing resulted with a consequent increase of friction. Moreover, the grip was so powerful, that the rollers, A A, were capable of supporting the weight, and thus a small inclination of their vertical axis was enough to cause the locomotive to rise, and even run off the line; moreover, the vertical curvature in the rope, or at the posts, required the rollers, A A, to be deep, thus limiting the extent to which rocking was admissible; moreover, very broad pulleys, fore and aft, would be required even for moderate horizontal curves. Nevertheless, this locomotive ran sufficiently well on the one-inch line during an exhibition to the shareholders last autumn. The weight for a five-eighth line of a somewhat improved form of this type, to exert one-half horse-power, on the average, is 200 lbs., an extra half hundredweight would give one horse-power. The driving wheels, A A, of this example are $6\frac{1}{2}$ in. diameter. The motor makes 9·23 revolutions for one of the driving wheels. One mile per hour corresponds to 473 revolutions per minute of the motor. 35·21 inch-pounds at the motor spindle are required for a pull of 100 lbs. at the rail.

Figs. 10 and 11 (p. 654) shows a locomotive designed by Mr. A. C. Jameson, when I was personally unable to attend to work. This locomotive, which is called the belt locomotive, shows a great advance on its predecessor. The general arrangement of the upper nest grip is retained, but a most ingenious modification has been introduced by which the discs, C C, run on one path on the rollers, A A, while the rod runs on another. In this way, the dirt from the line is never conveyed to the driving disc surface between A and C. Moreover, these frictional surfaces, which are points in the first form, have become lines in the second. This head answers admirably. The weight is carried by a roller, B, between the gripping discs, an arrangement contained in one of my first small models, and wrongly rejected in the first large locomotive. With this subdivision of weight, the gripping wheels are much less likely to rise, and can be made very shallow. In the actual locomotive, these gripping wheels are of an open inverted Λ shape, which has certainly run very well, although I prefer at present the upright V



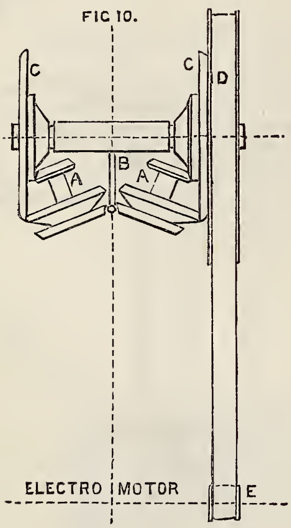


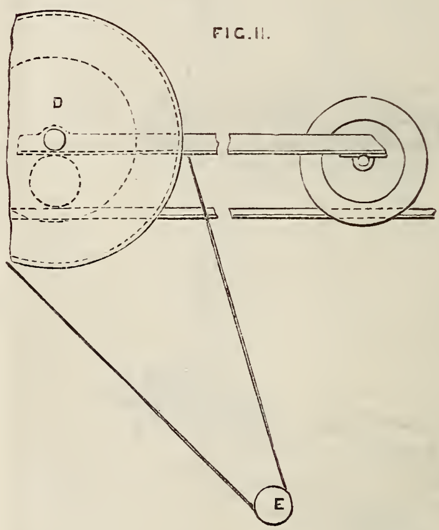
shape, which closes under the rail, as used in the model before you. Both of the gripping rollers drive, as in the first type. The cross shaft is driven by a belt on a 20-in. pulley, D; the other end of the belt runs on a 2-in. pulley, E, on the motor spindle. The friction due to the pull of this belt on the motor spindle is relieved by friction rollers. This locomotive runs extremely safely and steadily on the line; indeed I am not aware that it has ever been thrown off.

The following are particulars of its construction:—Weights with 96 lbs. one horse-power motor 269 lbs.; wheel-base 2 ft. 6in.; diameters of driving rollers 6 in.; 4·94 revolutions of motor per one revolution of driving wheel. A couple of 60·6-inch lbs. on motor is required for 100 lbs. pull at rail. 276 revolutions of motor correspond to one mile per hour on the rail.

The only improvements I have to suggest in this design are:—1st, the addition of gear which will give a higher speed of motor for the normal speed of four miles per hour, which we contemplate; 2nd, the addition of a swivel or bogie arm, such as is used in the model before you; 3rd, improvements in the belt connection. Moreover, the machine requires strengthening in some places. It will, however, be seen that none of these points touch the essential features of the design, which might at once be adopted in practice. Worked with motors of the Gramme type, the additional gear would not be required.

Before the belt locomotive had been completed, it was necessary to design a locomotive for the South American line, which I have several times mentioned. I had, meanwhile, constructed the model which is now before you; and this little locomotive, in which the power is transmitted by ordinary spur wheels, ran so extremely well, that I adopted the general arrangement for the next example on a large scale. This arrangement is shown in Figs. 12 and 13 (p. 655), the grip (C C and B B) is a third variety of the right angle nest, simpler than than that in the belt locomotive. In this form, also, we have line contacts, and two paths for the discs and rod. Where it is desired to drive from both sides, this arrangement is less powerful than that in the belt locomotive. In the South American locomotive, I drive from one side only, leaving the off side roller free to revolve as it pleases; this avoids grinding at rapid curves, and the adhesion given by one wheel will be ample in a dry country, such as that where this locomotive is to work. The arrangement of the gearing, E and F, is obvious; it allows the locomotive to lie fore and aft instead of across the line, and this design has some advantages in the adjustment of the weights. The surfaces of the gripping wheels are arranged





like an upright **V**, so as to hold on under the line. This makes it very difficult for the wheels to leave the line, both because of their absolute hold and because the inclination of the **V** is such as to favour the action of gravitation in overcoming the friction of the grip, instead of opposing it as in the inverted **V**.

Another feature of this machine is the arm pivoted at P, and carrying the leading wheel, which is again pivoted at M in the arm, as in the case of the trucks. This construction allows the locomotive to traverse curves of 6 ft. radius—a very remarkable result.

The full-sized locomotive has only just been completed, and run on three spans at Messrs. Easton and Anderson's. So far as I am able to judge from the trial, it is likely to be a complete success. It will be immediately shipped for its destination, so that its performance cannot be more fully tested in this country. The following particulars will show that it is much more powerful than the belt locomotive, but it is considerably heavier:—Wheel-base, 2 ft. 6 in.; weight, about 3 cwt. 14 lbs.; 15 revolutions of motor per revolution of driving wheels; diameter of driving wheels, 10 in.; 33·3 in. lbs. per 100 lbs. pull at rail; 504 revolutions of motor per minute for one mile per hour.

I am in doubt at this moment whether to adopt the belt locomotive or the spur wheel locomotive for the next example; it is simply a question of cost, weight, and durability. Either will do the work.

In all the arrangements it is essential that the second bearing wheel at M (Fig. 13), should lead, not follow the drivers in regular work. The reverse arrangement lets the rope lead on at an angle with the plane of the roller, causing an injurious grinding action.

Details of couplings have been well worked out, but space fails for their description.

As general features of the train running on the line, I may mention that the deflection of the rod within reasonable limits has very small influence on the resistance. When the deflection on a 50 ft. span was about 2·4 ft., the resistance for a train of trucks, weighing in all 1,260 lbs., was 22 lbs.; and no sensible difference could be detected when the deflection was materially reduced. This resistance was measured by pulling a train along, span after span, by one end of a rope passing over a pulley on the leading truck, and having a weight hanging vertically from the other end of the rope; the weight thus limited the pull. This pull differs extremely little as the train moves along, for when one part of the train is descending the curve the other part is ascending. It should be noted that during this experiment no special care had been taken to oil the bearings, and I have no doubt this pull can be materially reduced.

I have ventured to dwell at some length on the mechanical problems involved in this form of telpherage, because the experiments made

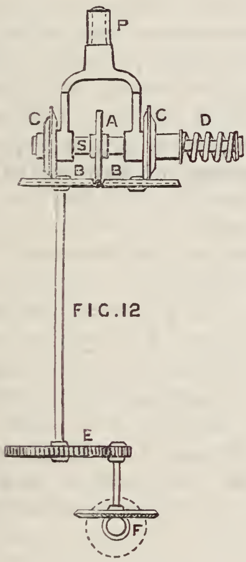


FIG. 12

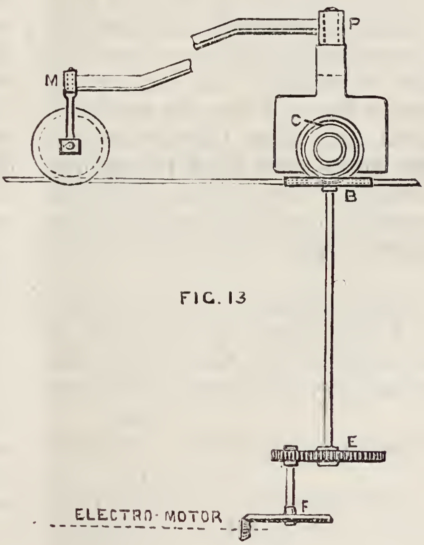

FIG. 13

so far have chiefly borne on questions of mechanics. The makers of dynamos can put at our disposal apparatus which will generate day after day, with perfect certainty and regularity, currents of electricity such as will transmit the horse-power generated by powerful steam-engines. These makers have already solved the chief electrical problems which present themselves in connection with telpher lines. They can give us at will constant current or constant electromotive force, high or low, as we may choose. They are now able to arrange their apparatus so that any number of incandescent lamps may be turned off or on, without disturbing the regularity with which other lamps are supplied, and by the same arrangement we are enabled to start or stop any nnmber of telpher trains without disturbing the running of others. The electrical problems of the telpher line, and those of electric lighting, run in absolutely parallel lines.

The electric motor, although it may be termed a mere inversion of the dynamo, has not as yet been brought to equal perfection, but month by month improved designs, proportions, and materials are being introduced, and the result already attained is sufficient for our purpose. It is all the more encouraging to feel that these results will certainly be surpassed, and far surpassed in the immediate future.

The following short summary of the problem of the transmission of power by means of electricity, may interest those who have not studied the subject. There are three steps in this transmission—1st, we convert mechanical power into electricity by means of a dynamo; in doing so we incur a loss of from 10 to 20 per cent.; 2nd, this electricity, in flowing along a conductor, generates heat, representing a further loss, analogous to that resulting from friction in mechanical gearing. This loss, depending on the distance of transmission, the size of the conductor, and the electromotive force employed, is easily computed. 3rd, We re-convert the electricity into mechanical power by means of an inverted dynamo, which we term an electric motor. With motors in which large weights of iron and copper are employed, the loss in re-conversion need not exceed 20 per cent., but with light motors, weighing from 70 lb. to 100 lbs. per horse-power, such as we must employ in the locomotives, I could not undertake with certainty at this moment to effect the re-conversion without a waste of one-half. The effect of all these sources of loss is, that at the stationary engine I must exert about 3 horse-power for every single horse-power which is employed usefully on the line. I look forward confidently to the time when 2 horse-power at the engine will be sufficient to give 1 horse-power to the motor.

To put these conclusions in a more scientific form, I may assume the efficiency of my dynamo as 80 per cent., that of my small motor as 50 per cent. The waste by heat expressed as horse-power is equal to $\frac{C^2R}{746}$ where C is the current in ampères, and R the resistance in ohms. The horse-power represented by the current is equal to $\frac{E \cdot C}{746}$ where E is the electro-motive force in volts, and C the current in ampères. It follows from the last expression that I may increase the horse-power in three ways, by increasing either E or C, or both. If I increase E, leaving C the same, I do not increase the loss during transmission along the line, no matter what horse-power the given line may transmit. A practical limit is set to the application of this law by the difficulty met with in dealing with electromotive forces above 2,000 volts. Marcel Deprez, taking advantage of this law—first pointed out by Sir William Thomson—has transmitted seven or eight horse-power over seven or eight miles, through an ordinary telegraph wire, and he obtained a useful duty of 63 per cent., taking into account all the three sources of loss which I have enumerated. With small motors I cannot yet promise a result so good as this, and I merely mention it to let you understand that, in speaking of 3 horse-power for one at the locomotive, I am leaving a very ample margin.

Quitting generalities, I will give some details as to the electrical and other conditions necessary, in two examples, for what may be considered as typical telpher lines:—

First Line.—Length, five miles. Length of circuit, out and in, ten miles. Twenty-five trains running at once, spaced one-fifth of a mile apart; speed, four miles per hour. Let each require 1 horse-power on the average; let the motor take on the average two ampères of electric current; let the electromotive force near the stationary engine be 840 volts; the electromotive force at the end of five miles will be about 746 volts. The total current entering the line will be fifty ampères at the near end of the line. Fifty ampères and 840 volts represent 56·5 horse-power; of this, 6·5 horse-power will be wasted in heating the line; the remaining 50 horse-power will do work in the motors equivalent to 25 horse-power. In order to give this current of fifty ampères with 840 volts, the stationary engine will require to exert $\frac{10}{8} \times 56 \cdot 5$ horse-power, or roughly, 70 indicated horse-power, or somewhat less than three times the useful horse-power. Let us now examine the economical results to be obtained from such a line as this. Mr. Dowson, in an interesting comparison between the cost of horse-power obtained from coal and gas, reckoned the cost per horse power for a 100 horse-power engine, at the rate of £3 6s. 9d. per annum, to include wages, coal, oil, and depreciation. Mr. Dowson would naturally be led to put the cost of steam power obtained from coal rather high than low. I will, however, adopt a very much higher figure, and assume that the power may cost as much £6 10s. per horse per annum; this gives £455 as the cost of the 70 horse-power required for my telpher line.

Let the 25 trains each convey a useful load of 15 cwt. In a day of 8 hours the line will have conveyed a traffic which we may express as 600 ton-miles—*i.e.* it will be equivalent to 600 tons conveyed 1 mile, or 60 tons on each line conveyed from end to end daily. If we count 300 working days in the year, the sum of £455 gives £1 10s. 4d. per diem, and the 600th part of this is about 0·604 of a penny, as the cost of the power required to carry a ton one mile.

In Great Britain we ought easily to be able reduce this below a halfpenny per ton per mile, which proves that the apparent great waste, even of two-thirds of the power in transmission, does not involve prohibitory expense. In calculating the whole cost of transport, we must further take into consideration the cost of the installation. Taking the spans at 70 ft., I estimate this cost as follows:—

Line £500 per mile	£2,500
Engine, boiler, and shed, at £20 per indicated horse-power	1,400
Dynamo and fittings	1,000
Twenty-five trains	2,500
Contingencies	600
Total cost	£8,000

Allowing 12½ per cent. for interest and depreciation, this represents an annual cost of £1,000. Allowing £100 as the salary of an electrician or young engineer, and adding £455 the cost of the power, this gives a total annual expenditure of £1,555 for a daily duty of 600 ton-miles. If we continue to assume the year as containing 300 working days, the total cost of conveying one ton one mile will be found equal to 2·07d. If goods are to be transmitted for long distances, the same calculation applies. We should simply have stations ten miles apart, working lines five miles long on each side of them. This, then, is the practical outcome of the general principles stated at the beginning of this paper. We may expect with great confidence that it will pay investors to convey goods for any distance at the rate of 2d. per ton per mile, by the agency of the suspended telpher line.

Matters are somewhat modified when the traffic is smaller. Making similar calculations for a line one mile long instead of five, with only four trains running at once, we might employ an electromotive force as low as 100 volts; the loss by heating would be insignificant; we should require about 12 horse-power; the work done in 8 hours would be 96 ton-miles. I estimate the cost of installation at £1,600, and the annual cost of working £344, without the annual salary of an electrician. This corresponds to 2·875d., or less than 3d. per ton per mile. One very important feature in respect to the cost of telpher lines is the fact that the larger part of that cost is due to plant, such as locomotives, trains, and dynamos. This plant can be increased in proportion to the work required; thus there is a very moderate increase of cost in the rate per ton per mile for a small traffic as compared with a large one, and, on the other hand, a line laid down for a small traffic will accommodate a much larger traffic with no fresh outlay on the line itself.

There are numerous minor electrical problems involved, but time does not permit me to enter into the consideration of these to-night. It will be sufficient for electricians when I say that I see my way to governing, blocking, and breaking the trains, without ever interrupting the current used to work the motor, except between the line and rolling wheels. We already know that the interruption at this point, although accompanied by a spark, does no injury whatever. I have often been asked whether the frequent reversals involved in the cross-over system do not tend either to injure the dynamo or the motor. I made special experiments on this very point lately with a compound wound Crompton dynamo and Mr. Reckenzaun's motor with thirty-six coils. I was unable at the commutator of the motor to detect the smallest change in the motion due to the most rapid reversal. At the dynamo commutator I could just see when the reversal occurred, but there was no change of a character to cause the smallest alarm. At the same time I may state that, when from any cause reversals may be thought undesirable, we are in possession of apparatus which we call "step overs," which, without diminishing the simplicity of the permanent way, enable us to send a continuous and unreversed current. These and similar electrical questions, such as the performance of Messrs. Ayrton and Perry's excellent motors, might possibly have had greater interest for electricians than some of the mechanical details discussed to-night; but I have felt that the main point to establish, in bringing this invention before the public, is that we have in telpher lines a means of conveying goods in an economical manner, by lines, locomotives, trucks, dynamos, and motors, which have undergone their preliminary trials with success, and can be at once applied to the more searching test of performing work for the public. If I have established this fact, I think you will have no difficulty in believing that the subsidiary electrical problems have been, or will be, readily solved. I hope that at a future period these will be brought before you in detail on many occasions by many men.

In conclusion, I will enumerate some of the uses to which telpher lines may be put. They will convey goods, such as grain, coals, and all kinds of minerals, gravel, sand, meat, fish, salt, manure, fruit, vegetables; in fact, all goods which can be divided conveniently into parcels of two or three hundredweight. If it were necessary, I should feel no hesitation in designing lines to carry weights of 5 or 6 cwt. in each truck. The lines will carry even larger weights, when these, like planks or poles, can be carried by suspension from several coupled trucks. The lines admit of steep inclines; they also admit of very sharp curves. Mere way leaves are required for their establishment, since they they do not interfere with the agricultural use of the ground. They could be established instead of piers, leading out to sea, where they would load and unload ships. With special designs, they could even take goods from the hold of a ship and deliver them into any floor of a warehouse miles away. When established in countries where no road exists, the line could bring up its own materials, as a railway does. Moreover, wherever these lines are established, they will be so many sources of power, which can be tapped at any point, for the execution of work by the wayside. Circular saws, or agricultural implements, could be driven by wires connected with the line, and this without stopping the traffic on the line itself. In fine, while I do not believe that the suspended telpher lines will ever compete successfully with railways, where the traffic is sufficient to pay a dividend on a large capital, I do believe that telpher lines will find a very extended use as feeders to railways in old countries, and as the cheapest mode of transport in new countries. In presenting this view to you, I rest my argument mainly on the cost of different modes of transport, which may, I believe, he stated approximately as follows:—Railway, 1d. per ton per mile; cartage, 1s. per ton per mile; telpher lines, 2d. per ton per mile; and let it be remembered that, in taking the cost of cartage at 1s. per mile, the first cost and maintenance of the road is left wholly out of account; whereas in my calculations for the telpher line, allowance has been made both for establishment and maintenance.

DISCUSSION.

Prof. PERRY said he never remembered feeling so much the want of his colleague, Professor Ayrton, who was unfortunately engaged elsewhere. At a very early period in the history of this invention, Professor Jenkin did his colleague and himself the honour to associate their names with his own, but their contributions, perhaps because they had in view the future much more than the present, were as nothing, compared to what had been done by Professor Jenkin. He never seemed to be floored when a difficulty presented itself, but after a month or two, when every body had fancied the difficulty was insuperable, he showed how he had overcome it. He could only say, therefore, that the success which had been achieved in the special form of telpherage exhibited there that evening was almost entirely due to Professor Jenkin's efforts.

Mr. ALEXANDER SIEMENS thought, that in working out the cost, Professor Jenkin had been in one direction too low, and in another perhaps too high. He did not think steam power could be obtained at the rate of £6 per horse-power per annum, but would cost nearer £10 or £12. On the other hand, these lines would be most generally useful, perhaps, in mountainous countries, were water power would be available at much less cost.

Mr. A. RECKENZAUN said Professor Jenkin had given a most elaborate account of the beautiful working of his telpher line, and he felt certain there was a great future for this method of transporting goods. In many cases, especially in mountainous countries, it would be exceedingly economical, and would be available where a railway would be quite out of the question, from the necessity of making expensive tunnels.

Mr. T. R. CRAMPTON thought every one must have been much pleased with the explanation which had been given, and that most persons would share his feeling of astonishment at the results which had been attained by such simple means. There was no part of the apparatus in which wear and tear might not be reduced to the minimum. The grip could not be expected to last for ever, but it was most simple in construction, and with the materials at command, could be made to last the maximum time. He thought Mr. Siemens was right in his statement of the probable cost of steam power, in the majority of cases, though no doubt £6 might be correct, if a large amount of power were required, and every modern improvement were brought to bear. The cost of 2d. or 3d. per mile was really nothing, for the purposes to which this mode of transit was proposed to be applied. In many cases, such a cost would be considered heavy, but in others, such as this would be applied to, people would gladly pay 6d.

Prof. GEORGE FORBES remarked that Professor Jenkin had evidently not brought forward this invention until he had got it into thorough working order, and he was surprised at the complete success that he had attained so soon. He should like to ask, however, whether he had succeeded in running several trains on the same line. Professor Jenkin had told them that any number of trains might be run simultaneously, in the same way that any number of lamps could be switched on to a circuit for electric lighting. But the analogy was not quite exact, because in the case of trains the length of the leads would vary, while in the case of incandescent lamps it was constant. One would expect that the electromotive force would fall off so much between the near train and the distant one, that the near one would overtake the other, and that even an attempt to equalise the resistance of the circuit through each train by a return wire would not be completely satisfactory; and that even with such a device there would still be such a difference of electromotive force as would tend to make one train pick up the other. He should be glad to know, therefore, if several trains had been run on one line. This had been done on an electric railway, where the same difficulty occurred, the only case which had come under his observation being the one at Vienna, but there the conductors of each car had the power of interposing resistances, so as to diminish the power if required. It would be very interesting to know if the same thing could be accomplished automatically.

Mr. Walter Hancock said he had not quite gathered what was the speed which could be obtained on this line, but he thought he understood Professor Jenkin to say that he had attained a speed higher than he considered it desirable to employ.

Prof. Jenkin, in reply, said he had invited Professors Ayrton and Perry to assist him, because they had already contemplated working electric railways automatically, and, therefore, the fundamental idea of telpherage was already familiar to them; and knowing their great abilities he anticipated that they could give him valuable aid. It had so happened, from various circumstances, that the working out of this particular form of idea had fallen more especially to his lot, but he had little doubt that, in a short time, those gentlemen would come forward with something quite as interesting as what he had now explained. This being his own particular idea, he had chiefly worked it out, and probably that was the way in which the best work would be done. With reference to Prof. Forbes's question he might say that there were a whole set of problems connected with the running of several trains together, which required special attention. Up to the present he had only run two trains, one each way, and there the special difficulty to which he had alluded did not arise, though another did, viz., that if one train ran away, it tended to send all the current through the other, and you had to provide for a certain balancing between the two. It was impossible to go into all the questions of electric arrangements at that moment, besides which he had determined to limit himself to a description of what had actually been accomplished. He might, however say this much. They had to provide for what might be called the electric governing of the train. Trains must sometimes be run down hill, sometimes up hill, and sometimes on the level, and they did not all take the same amount of power. Each must take just the amount it required, and the electromotive force along the line tending to drive the train must at every point be considerably above that which the train would require at the maximum. With a fall from 840 to 746, it would be easy to realise these conditions; but they were really much more complex than Mr. Forbes had assumed, necessitating such an arrangement of the electric governing that each train, while running at the same speed, should take just the amount of power required. At some future time he would explain that, but he preferred waiting until it had actually been done. Meanwhile, to prevent anyone supposing that he had set himself an impossible problem, he would say that he saw his way to doing it without ever interrupting the current, except between the rod and the wheels, where experience already showed that the interruption was harmless, the great difficulty in all these electrical manipulations was, that these powerful currents, which conveyed 1, 2, 20, or 40 horse-power, could not be broken and made without danger of arcing and sparking, and all sorts of difficulties which must be met. The governing which he had described, by means of which just the requisite amount of power should be taken off, existed at the present moment on paper to his own satisfaction, but he preferred not to describe it until it had been tested. The same thing might be said as to the breaking and blocking of trains without interrupting the current, or having a single spark from end to end anywhere, except the sparks between the rolling wheels and the line, and there they knew the maximum effect, which had not created any difficulty. With regard to speed, he might say that speed had nothing to do with the power or application of electricity. If a sufficient sum of money was placed at his disposal, he would design trains which should run at a speed of 150 miles an hour; it was entirely a question of cost. Such rapid travelling would cost a great deal, because you must have a rigid road, with very large curves. Where you had a flexible line, in which there were considerable dips, if the trains ran at a high speed, serious strains were thrown upon them, due to centrifugal force in going down the incline and up towards the supports; moreover, the acquired momentum would tend to throw the vehicles off the line at the vertical curves over the posts. He, therefore looked on the suspended line as essentially a carting, or low speed line. A high speed railway must have a rigid road, and was not the sort of thing he was competing with.

The Chairman remarked that the concluding observations of Professor Jenkin had pointed out a number of difficult problems which he had had, and which he might still have, to contend with; but they must all have been struck with the charming manner in which he had worked out the subject so far, and they would go away with a feeling of admiration for the manner in which he had applied his reatg scientific knowledge to this important purpose. He himself could see many directions, some of which might not have occurred to Professor Jenkin, certain paths of work in which he was engaged, in which telpherage ought very soon to be introduced, and he had no doubt that there were many respects in which this might be considered one of the most important applications of electricity in the future. He concluded by proposing a vote of thanks to Professor Jenkin, which was carried unanimously, and the meeting adjourned.

Miscellaneous.

VEGETABLE RESOURCES OF BRITISH HONDURAS AND ST. HELENA.

The development of the economic resources of our colonies is a subject to which considerable attention has been given of late, not only to the indigenous production, but also to the products of other climes, which have been introduced and become acclimatised. The very general desire to spread the cultivation of useful plants in our colonial dependencies has resulted in the establishment and extension of many very valuable commercial plants in widely different regions of the globe, and a great deal has been written on the commercial aspect as well as on the modes of cultivation. The establishment of nurseries and plantations, and the development of the resources of the botanic gardens already in existence, and the formation of other departments of a similar character, have all helped the work forward, of late years, in a wonderful degree. In connection with this subject, Mr. D. Morris, the Director of Public Gardens and Plantations in Jamaica, has recently published an account of a visit he paid, in 1882, to the colony of British Honduras. This account treats of the resources and prospects of the colony "with particular reference to its indigenous plants and economic productions." The first thing that needs attention in a hitherto uncared for land is the preservation of its forests, and what is still more important is the checking of the reckless cutting down of forest trees in inhabited or cultivated countries. Mr. Morris draws especial attention to this point, and expresses a hope that the question of retaining in permanent forest the chief watersheds of the country, as well as wooded belts in the neighbourhood of streams and springs, will receive the earnest and careful attention of the Legislature. "At present," it is stated, "several thousand acres of some of the finest lands to be found in any British dependency, produce an annual export value (in mahogany) of only £50,000. This sum is attained in Jamaica in the export value of such a minor product as oranges. That the export value of oranges from Jamaica is equal to that of mahogany—the great staple industry of British Honduras—is a new and somewhat startling fact. It serves, however, to show what a change is gradually taking place in the development of the West India Islands by means of the fruit trade with America.

"Wisely and generously regarded, the development of small industries, and especially the fruit trade i the West Indies, should lead, little by little, to th building up of a more wholesome as well as a mor permanent prosperity than anything which existed during the days of slavery.

"The fruit trade has initiated a system of cash payments on the spot which is fast extending to other industries; the result is, that the cultivator and the planter are placed at once in possession of means for continuing their cultural operations, and for extending them to their fullest extent. As a case in point, it may be mentioned that the development of the fruit trade in Jamaica is the means of circulating more than £150,000, annually amongst all classes of the community, and this large sum is immediately available, without the vexatious delays formerly experienced in establishing other and more permanent industries. Under the old system, the planter was for the most part in the hands of merchants and agents; he seldom had full control of his produce; and was so restricted in his selection of a market, that he often suffered much thereby.

"The new departure in the sale of West Indian produce is only beginning to be felt, but its ultimate effects will, no doubt, tend to such an emancipation of the planter, that these tropical lands will, in time, become as prosperous as they are beautiful and fair." Bananas, plantains, and cocoa-nuts are the staple articles of export to the American market; the prices are from 1s. 9d. to 2s. per bunch for bananas, 3s. to 4s. per 1,000 for plantains, and 70s. to 100s. per 1,000 for cocoa-nuts."

As is well known, the principal staples of British Honduras are mahogany and logwood, the average annual export of the former being about 3,000,000 feet, and of the latter 15,000 tons. Much of the finest timber, within easy reach of the principal rivers, has been cut down, but a good deal of fine timber is stated to be found in the interior.

Most of the mahogany forests are in the hands of a few proprietors, who adopt a rude system of forest conservancy, backed by a very strict trespass law. Government land may be bought at a dollar an acre, or, if preferred, short leases of five years are issued to persons desirous to occupy waste lands of the Crown, not less than fifty acres, at a yearly rent of 10 cents an acre, with right to purchase at any time during the tenancy.

To start a mahogany works, the first step is to employ a "hunter" or experienced woodman, who devotes several days to prospecting in the forest, after which he reports on the number and character of suitable trees to be found within easy reach of the works, which are always placed at a convenient place on the bank of the river, where the mahogany logs can be manufactured and easily tumbled into the river.

"The 'hunter' is paid so much for every tree which, on examination, is found suitable for cutting, *i.e.*, squaring 18 inches and upwards. The next step is to open a track to it, and proceed to cut it down. Owing to the huge buttresses which many mahogany trees possess, a platform is sometimes erected so as enable the men to cut the tree above them; when lopped, cleaned, and sawn to the available length, the log is ready to be handed to the works.

"During the dry months of the year, the logs are carried on trucks, drawn by bullocks. The truck is a ponderous framework, mounted on four broad wheels about 3 ft. in diameter, with 9 in. tread, the latter being made in a most primitive fashion by sawing pieces across from a log of Santa Maria. During wet weather, when the ground is too soft for the trucks to travel, mahogany is drawn on slides, or a kind of sleigh, which pass over 'skids.' The latter consist of long, hard wood posts, about 3 in. in diameter, placed across the track about a yard apart.

"Being imbedded in mud, the fresh slippery bark affords a suitable and handy surface for the passage of the slide with its heavy load. Sometimes mahogany logs are drawn, in the manner above described, distances of eight or ten miles. Mahogany is always trucked in the middle of the night, the cattle not being able to perform such laborious work during the heat of the day. It is a picturesque and striking scene this midnight trucking. The lowing of the oxen, the creaking of the wheels, the shrill cries of the men, the resounding cracks of their whips, and the red glare of the pine torches in the dense, dark forest, produce an effect approaching to sublimity.

"At the works the logs are regularly squared and prepared for the market. If, however, they are likely to be chafed and injured in transit, by going down shallow creeks, the squaring is done at Belize, or at the river's mouth.

"Trucking is generally carried on during the month of April and May, when the ground is hard, after a long period of dry weather. About the middle of June, after the May "seasons," or rains, the rivers are swollen, and advantage is taken of this opportunity to tumble the logs into the water, and float them down to about ten miles from the rivers mouth. Here a large iron chain or 'boom' is fixed, which stops the logs as they float down. At this point, the several owners select the logs by their respective marks, form them into rafts, and so float them down to the sea, and ultimately to Belize, whence they are shipped abroad.

"Logwood cutting appears to be a much simpler and much less laborious work. After the trees, which are seldom more than a foot in diameter, but often only half this size, are cut down, the outer or sage wood is removed, leaving nothing but the inner dark coloured heart wood. When thus prepared, the logwood is carried on trucks or "crooked" to the nearest bank, where, to prevent it from sinking, it is packed in "bark logs" or light, boyant cradles, capable of carrying a ton or two of log logwood. An immense train of these heavily freighted "bark logs" is often met with on its way down the river, or anchored at night in the middle of the stream.

"Most of the logwood is found in damp, moist districts of the north; but there are also many tracts to the south, where logwood is very plentiful.

"Growing with the mahogany is a member of the same family, the common cedar *(Cedrela odorata)*, which is in great demand for light indoor work, and from which the fragrant boxes for Havannah cigars are made. In the colony the trunks of the largest trees are hollowed out to make bungays, dorays, pitpans, and canoes, purposes for which, on account of the light and durable character of the wood, they are admirably adapted. The export of British Honduras cedar for the last five years amounts, on an average, to about 130,000 feet."

On this same subject of colonial planting, and the development of colonial resources, Mr. Morris has also written an account of a recent visit to St. Helena, made by him with the special intention of bringing about a more healthy and profitable state of things than already exists in the island. The title of this account is "A Report upon the Present Position and Prospects of the Agricultural Resources of the Island of St. Helena. Printed for the use of the Colonial-office." Notwithstanding the smallness of this island, being only $10\frac{1}{4}$ miles long, and $8\frac{1}{4}$ miles broad, and notwithstanding its present neglected condition, Mr. Morris looks upon St. Helena as a likely ground from whence many valuable economic vegetable products may be obtained. It has been proved that several species of cinchona will flourish, notably *Cinchona succirubra* and *C. officinalis*, but all things considered, Mr. Morris thinks it would not be well to continue their cultivation with the view of making it a commercial success, other valuable plants being very easily grown; of these, several well-known fibrous plants are enumerated, as coffee, tobacco, oranges, limes, citrons, lemons, the Cassava plant, and many others.

One of the few indigenous plants of the island still found growing there is thus described:—"A small vegetable much resembling celery is found growing wild on Diana's Peak, which formerly was sold, and eagerly bought, in the market at Jamestown. This is the Angelica (*Sium Helenium*, Hook. F.), a handsome umbelliferous plant, growing to the height of 6 ft. or 8 ft. amongst the cabbage trees and ferns on the central ridge. The inner portions of the stem, which is of a tender succulent character, may be eaten raw, and form an excellent substitute for celery. The native people eagerly eat it; as brought to market it is in short tubes, much like bamboo stems, and is sold under the name of 'Jellico.'"

As a recommendation for the better utilisation of the St. Helena soil, Mr. Morris proposes the appointment of an intelligent and competent gardener "to take up the entire question of the revival of agricultural pursuits."

Considering the fine and equable climate of St.

Helena, it is somewhat surprising that it has not become much more frequented as a health-restoring resort.

Correspondence.

THE WATER SUPPLY OF LONDON.

An action of considerable importance to London, in connection with its water supply, lately tried in the High Court of Justice, owing to the political excitement of the day, did not receive that attention which, in my opinion, it deserved. The action I refer to was brought by the Lea Conservancy Board against the Corporation of Hertford and the Rivers Purification Company to prevent the further pollution of the river Lea by effluent sewage water, and recover the sum paid for dredging 2,500 tons of mud from the bed of the river. The practical breakdown of the legal proceedings, so far as the prevention of pollution is concerned, show plainly enough that vested interests have got the whip-hand of public rights in all matters that relate to a pure water supply for London.

The great importance of the question must be my excuse for troubling you with a few remarks on the Hertford Corporation claim to pollute an open river of the importance of the Lea. The broad issue raised by the action of the Conservancy Board was whether, if an Act of Parliament gives a power of disposing of sewage treated in a certain way, and upon certain conditions observed and complied with as far as possible, an action is maintainable for pollution of a stream or river by the effluent water sent into it? The judgment delivered by Mr. Justice Williams in the Hertford case seems to imply that it is not. It must be observed, however, that the question of pollution became quite a secondary one, for the action turned upon points of law, as affecting the rights of the Corporation and the Purification Company acting for and under this body, and the Lea Conservancy Board.

The brief facts of the case are as follow:—

The town of Hertford, having a population of about 7,000 souls, down to 1854, was entirely without any regular system of drainage. The whole of the sewage, together with subsoil and flood water, was allowed to flow through ditches, black with mud and filth, directly into the River Lea. For very many years a large proportion of sewage found its way into the river at the north end of the town, above the "intake works" of the New River Water Company; and when, from increase of population and other causes, a larger quantity of sewage was daily sent into the stream at this point, it became absolutely necessary to take means to put some check upon the nuisance. An Act of Parliament was obtained, and intercepting sewers were constructed, which, when united, were made to terminate in a foul tributary of the Lea—"Manifold Ditch." So little was gained in the way of purification that, in 1860, further powers were sought and obtained; ultimately the Corporation, after having expended considerable sums, handed over its powers, with certain restrictions, to the Rivers Purification Company. Notwithstanding, numerous indignant complaints continued to reach the Lea Conservancy Board of the foul smells emitted by the effluent water, and the accumulations of stagnant mud about the banks of the river, so that ultimately it became necessary to frequently dredge the river below Ware Lock. The stuff dredged was described by the navigation engineer, "as sewage mud, the like of which he had only seen near the Tottenham Sewage Works." After many ineffectual efforts on the part of the Lea Conservancy Board to bring about some abatement of the nuisance, legal proceedings were commenced. the action was tried at great length, and at an enormous cost to the Board, the inquiry lasting some twelve or fourteen days; ultimately the judgment went in favour of the Hertford Corporation, virtually for the continuation of the pollution of the Lea.

That there is a very serious pollution of the river going on, no one who knows the river can possibly deny; indeed this was sworn to by a number of experts, supported by very many credible resident witnesses. The judge took the trouble to satisfy himself on the point by a visit to Manifold Ditch. His words were—"I went up the Lea along the towing path opposite the Priory Gardens, and here the river was tolerably clear, with ordinary weeds growing in it; but on proceeding towards Ware Lock the water became of a dark colour, and at Manifold Ditch there were pieces of matter floating on it (sewage fungus), and it emitted a decided smell of sewage. A little higher up, and near the point where the effluent water issues from the works of the company, the fluid had a peculiar metallic appearance (floating masses of living bacteria), with small particles of matter floating on it (more confervoid and fungus growths), and a very decided smell of sewage." This testimony is both conclusive and instructive, and places the question of pollution beyond a doubt; indeed, the dangerous state of the river is a grievous scandal, for with all the supervising care of the Lea Conservancy Board, it has been observed to be on the increase; in truth, it has increased during the past decade 136 per cent. The utter collapse of a constituted authority for the prevention of pollution is a lamentable fact—one which demands the attention of a Legislature that called it into existence in the public interest. Some two or three months ago I drew attention to the polluted condition of the River Lea. This fact was impugned by certain interested parties; but if one thing was more clearly brought out at the Hertford trial than that of another, it was the filthy pollution of the River Lea by effluent sewage, both above and below the in-take of two of the largest purveyors of London water—the New River and the East London Waterworks Company. JABEZ HOGG.

1, Bedford-square.

THAMES COMMUNICATIONS.

Reverting to remarks at the meeting on the 23rd ult., as to the present commercial condition of the Thames, as evidenced by empty premises, allow me to hand you the following list of such properties between London-bridge and Blackwall:—Springall's-wharf, Surrey side, to let, opposite London-docks, Hermitage entrance; Phœnix-wharf, above Tunnel-pier, Middlesex side; small wharf below Ferry-pier, Middlesex side; small wharf below New Crane-wharf; Queen's-wharf, above London-docks, Middlesex side; Globe Granary, &c., small property, Surrey side; Lavender-dock, old timber graving-dock, Surrey side; Limehouse-cut, small warehouse; "Bond's," mast-makers, Limehouse-reach;" small wharf three doors below; Nelson-dock, small wharf; small wharf, next Byas's, Rotherhithe; Napier's, Millwall; Scott Russell's, Millwall; wharf, Millwall, near Church; Blackwall-point, near Police-station, new frontage; number fifteen, in all. Not one-fifth of these are of any importance, and this on frontages of nearly fifteen miles of river, or one per mile.

Practically, the whole commercial portion of the river is actively employed, with small signs of "exodus" in the present, whatever may be in store for it in the future. Every foot of frontage, with the above exceptions, is fully utilised; and it must be remembered that one-fourth of it, viz., The Isle of Dogs and Bugsby's Marshes, half a century back, was composed of earthen river walls fronting open marsh.

J. W. REDMAN.

May, 10, 1884.

Obituary.

DR. ANGUS SMITH.—Robert Angus Smith, Ph.D., LL.D., F.R.S., F.C.S., the well-known Inspector-General of Alkali Works for the United Kingdom, died on the 12th inst., at the age of 67. Dr. Smith studied under Liebig at Giessen from 1839 to 1841. Among his works may be mentioned a "Life of Dalton," "Air and Rain," and papers in the "Philosophical Transactions" of the Royal Society, and the "Journal of the Chemical Society." He also contributed to this *Journal*, and frequently spoke at the meetings of the Society of Arts, when questions relating to the prevention of smoke arose for discussion.

DR. GOODFORD.—The Rev. Charles Old Goodford, D.D., Provost of Eton, who died on the 9th inst., had been a member of the Society of Arts since 1869. He was born in 1812, and was edncated upon the foundation at Eton. He held the office of assistant master at that school for many years, and became head master in 1853. In 1862 he succeeded Dr. Hawtrey as Provost.

H. BADEN PRITCHARD.—On Sunday last, Mr. Baden Pritchard expired at his residence at Blackheath, in consequence of an attack of pneumonia. Mr. Pritchard, third son of the late Mr. Andrew Pritchard, the author of the "History of Infusoria," and the constructor of the celebrated diamond microscope objectives, was well known in literary and scientific circles; his novels, together with his sketches, entitled "Peeps at the Pyrenees," and "Beauty Spots on the Continent," obtained for him a literary reputation, while his work in connection with photographic literature is well known to all photographers. Since 1861, he has been engaged in the Chemical Department at Woolwich Arsenal.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, eight o'clock:—

MAY 21.—"Telegraph Tariffs." By Lieut.-Col. WEBBER, R.E. Dr. CAMERON, M.P., will preside.

MAY 28.—"Primary Batteries for Electric Lighting." By I. PROBERT. W. H. PREECE, F.R.S., will preside.

APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings:—

MAY 22.—"Economic Applications of Seaweed." By EDWARD C. STANFORD, F.C.S. W. H. PERKIN, F.R.S., will preside.

MAY 29.—"Some Economical Processes connected with the Woollen Industry." By Dr. WILLIAM RAMSAY.

INDIAN SECTION.

Friday evenings:—

MAY 30.—"Street Architecture in India." By C. PURDON CLARKE, C.I.E. This paper will be illustrated by means of the Oxy-Hydrogen Light.

CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Sixth Course will be on "Fermentation and Distillation." By W. N. HARTLEY, F.R.S.E., &c., Professor of Chemistry, Royal College of Science, Dublin.

LECTURE II.—MAY 19TH.

Fermentation proper. The cause of fermentation. The nature of the yeast cell. Its mode of growth. The chemical action of fermentation. Rapidity of growth of yeast. Charasteristic appearances of exhausted and revived yeast. Of "high" and "low" fermentations. Conditions of a good fermentation. Healthy and foul yeast. Explanation of the custom of a "change of yeast." Methods devised for purifying yeast. Exhausted yeast not necessarily foul. Mineral food necessary for yeast. Explanation of the reason for fermenting with mixed yeast. Influence of temperature on fermentation. Heat evolved during fermentation. Methods of warming and cooling mash. The products of alcoholic fermentation.

LECTURE III.—MAY 26TH.

Alcohol produced by mould. Its existence in rain, river, and sea water. Its presence in the soil. The process whereby alcohol is separated from water. The simplest form of distillation by a still and worm. The boiling points of water and alcohol. Boiling of mixtures with low boiling points by means of vapours with high boiling points. Pot stills and patent stills. Langier's still. The principle of Coffey's still. Its mode of action described. Improved forms of still. Alcoholic beverages and other products.

HEALTH EXHIBITION SEASON TICKETS.

The Executive Council of the International Health Exhibition have consented to allow members of the Society of Arts the privilege of purchasing season tickets for the Exhibition at half price (10s. 6d.) Each member can purchase a single ticket only on the reduced terms, and these tickets can only be obtained through the Secretary of the Society of Arts. For further particulars see notice in the *Journal* for May 2, p. 575.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 19...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. W. N. Hartley, "Fermentation and Distillation." (Lecture II.)

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. H. H. Smith, "The Inclosure and Regulation of Commons."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. W. Emerson, "A Description of some Newly-erected Buildings at Allahabad and Bownuggur."

Asiatic, 22, Albemarle-street, W., 4 p.m. Annual Meeting.

Victoria Institute, 7, Adelphi-terrace, W.C., 8 p.m.

TUESDAY, MAY 20...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Gamgee, "The Anatomy and Physiology of Nerve and Muscle." (Lecture III.)

Civil Engineers, 25, Great George-street, Westminster, S.W., 8 p.m. Mr. R. W. Peregrine Birch, "The Progress of Upland Water through a Tidal Estuary."

Statistical, School of Mines, Jermyn-street, S.W., 7¾ p.m. Mr. C. Walford, "Statistical Review of Canada, including its Confederated Provinces."

Pathological, 53, Berners-street, Oxford-street, W., 8½ p.m.

Zoological, 11, Hanover-square, W., 8½ p.m. 1. Mr. F. E. Beddard, "Preliminary Notice of the Isopoda collected during the Voyage of H.M.S. *Challenger.*" (Part I.) "The Genus *Serolis.*" 2. Dr. J. Gwyn Jeffreys, "The Mollusca procured during the *Lightning* and *Porcupine* Expeditions, 1868-70. (Part VIII.) 3. Prof. Bell, "The Structural Characters of the Cotton-Spinner (*Holothuria nigra*), especially of its Cuvierian Organs." 4. Mr. F. Day, "Hybrids among the Salmonidæ." (Part II.)

WEDNESDAY, MAY 21...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Lieut.-Col. C. E. Webber, "Telegraph Tariffs."

Meteorological, 25, Great George-street, S.W., 7 p.m. 1. Mr. Robert H. Scott, "Note on the Proceedings of the International Polar Conference, held at Vienna, April 1884." 2. Dr. A. Tucker Wise, "Meteorological Observations on the Maloja Plateau, Upper Engadine, 6,000 feet above the Sea." 3. Mr. A. Naylor Pearson, "Some Results of an Examination of the Barometric Variations in Western India." 4. Mr. Richard Inwards, "Illustrations of the mode of taking Meteorological Averages by the method of weighing paper diagrams." 5. Mr. Rupert T. Smith, "Ten Years' Weather in the Midlands."

Pharmaceutical, 17, Bloomsbury-square, W.C., 11 a.m. Annual Meeting.

Botanic, Inner Circle, Regent's-park, N.W., 2 p.m. Summer Exhibition of Plants, Flowers and Fruits.

Archæological Association, 32, Sackville-street, W., 8 p.m. Signora Campion, "The Ancient Port of Luni, Italy."

Hospitals Association, 11, Chandos-street, Cavendish-square, W., 8 p.m. Mr. Henry C. Burdett, "How can the Hospital Sunday and Saturday Funds be made more useful to the Hospitals?"

THURSDAY, MAY 22 ... SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Chemical and Physical Section.) Mr. Edward C. Stanford, "Economic Applications of Seaweed."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. Dewar, "Flame and Oxidation." (Lecture V.)

Telegraph-Engineers and Electricians, 25, Great George-street, S.W., 8 p.m. 1. Mr. W. H. Preece, "The Electrical Congresses of Paris."

FRIDAY, MAY 23...United Service Inst., Whitehall-yard, 3 p.m. Lord Charles Beresford, "Machine-Guns in the Field."

Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m. Dr. David Gill, "Recent Researches on the Distances of the Fixed Stars, and Some Future Problems in Sidereal Astronomy."

Geologists' Association, University College, W.C. Excursion to Epsom and Dorking under the direction of Mr. W. H. Dalton and Mr. French.

Quekett Microscopical Club, University College, W.C., 8 p.m.

Clinical, 53, Berners-street, W., 8½ p.m.

Browning, University College, W.C., 8 p.m. Paper by Miss Drewry.

SATURDAY, MAY 24...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Bonney, "The Bearing of Microscopical Research upon some large Geological Problems." (Lecture II.)

Physical, Science Schools, South Kensington, S.W., 3 p.m. 1. Dr. W. H. Stone, "An Immersion Galvano-Meter; and Kohlransch's Metre Bridges for Alternating Currents." 2. Mr. Walter Baily, "A Speed Indicator." 3. Dr. Guthrie "Eutexia or Lowest Temperatures of Fusion."

Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.

Linnean, Burlington-house, W., 3 p.m. Anniversary.

Journal of the Society of Arts.

No. 1,644. Vol. XXXII.

FRIDAY, MAY 23, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CANTOR LECTURES.

Professor W. N. HARTLEY delivered the second lecture of his course on "Fermentation and Distillation," on Monday evening, 19th inst., in which he explained the cause of fermentation and its chemical action, and described the different classes of ferments. He treated of yeast, and showed the characteristic appearances of exhausted and revived yeast. In conclusion, he drew attention to the influence of heat on fermentation.

The lectures will be printed in the *Journal* during the autumn recess.

COMMITTEE ON PHYSICAL EDUCATION.

On the motion of Mr. EDWIN CHADWICK, C.B., the Council of the Society of Arts have appointed a committee to consider the question of the physical training of children in elementary schools.

HEALTH EXHIBITION SEASON TICKETS.

The Executive Council of the International Health Exhibition have consented to allow members of the Society of Arts the privilege of purchasing season tickets for the Exhibition at half price (10s. 6d.) Each member can purchase a single ticket only on the reduced terms, and these tickets can only be obtained through the Secretary of the Society of Arts. For further particulars see notice in the *Journal* for May 2, p. 575.

Proceedings of the Society.

TWENTY-SECOND ORDINARY MEETING.

Wednesday, May 21, 1884; Dr. CHARLES CAMERON, M.P., in the chair.

The following candidates were proposed for election as members of the Society:—

Ashworth, Edward, J.P., Staghills, near Waterfoot, Lancashire.
De Salis, Rodolph F., B.A., 1, Westminster-chambers, S.W.
Goolden, Walter T., M.A., 28, Westbourne-park, W.
Talbot, Colonel the Hon. Wellington Patrick M. C., 15, Cromwell-road, S.W.
Theobald, John Wilson, 1, Macaulay-road, Clapham-common, S.W.
Watson, John Cecil, The Rhyddings, Church, Accrington.

The following candidates were balloted for and duly elected members of the Society:—

Flew, John Pearce, Fulham-park-gardens, S.W.
Habershon, Matthew Henry, Eversley, Richmond-road, New Barnet.
Harris, David, Caroline-park, Edinburgh.
Hope, R. C., F.S.A., Albion-crescent, Scarborough.
King, G. Swinburn, 1, Devonshire-terrace, Hyde-park, W.
Phillips, John Orwell, Gas Light and Coke Company, Horseferry-road, S.W.
Pocknell, George, Lonsdale, Exeter.
Shuter, James Legasick, 9, Steele's-road, Haverstock-hill, N.W.
Watson, Thomas Donald, 23, Cross-street, Finsbury, E.C.

The paper read was—

TELEGRAPH TARIFFS.

By COLONEL WEBBER, C.B., R.E.

The subject which your Council has requested me to bring before you this evening, is one that would require far longer than the limited time at our disposal, to permit of its being exhaustively dealt with in all its branches.

As the introduction of the sixpenny rate in our own telegraph service has been so long under discussion, in and out of Parliament, and as a resolution "that the time had arrived for a reduction" was adopted by the House of Commons in March, 1883, and as the Chancellor of the Exchequer has, since that date, been carefully considering the conditions under which the reduction to a sixpenny uniform rate can be brought into force, it is hoped that the public ventilation of the subject within these walls may have the effect of establishing a cheaper rate, in one form or another, at an *earlier date* than is anticipated by the latest official announcements on the subject.

I am in great hopes that officers of the Post-office now present will find themselves in a position to discuss, criticise, or overthrow in fair argument, if they can do so, the propositions which I, as an old brother officer who hopes he has kept up his knowledge of telegraphy and its traffic, am able to lay before you.

In the public interest I shall urge on all who may wish to speak to endeavour to confine their remarks to the very narrow issue which you will find in the outcome of this paper.

To assist the audience in dwelling on the subject, tables are given with some foreign inland rates, and the corresponding value in English money for thirty-two words. Practically our rate of one shilling includes an average of twelve words in the addresses. By the following comparison, the figures of which are only approximate, it will be seen that, with the exception of Belgium, Holland, Switzerland, and Italy, we get most for our money, when it is considered that our free delivery is for one mile, and theirs for one kilometre.

INLAND TARIFFS.

Word rate with a minimum, addresses not free.

	At 32 words in message. s.	d.
France.		
First 10 words, 50 centimes	1	3
Belgium.		
First 15 words, 50 centimes	0	10¾
Each additional 5 words up to first 50, 10 centimes	0	8½
Each additional 10 words up to first 100, 10 centimes	0	4¾
Italy.		
First 15 words, 50 centimes	0	10¾
Each additional word, 5 centimes	0	5¾
Spain.		
First 15 words, 100 centimes	1	9½
Each additional word, 10 centimes	0	1
Local telegrams (half-rates)	0	10¾
Russia.		
First 10 words, 11d.	3	1½
Each additional word, 1d.	0	1
Local telegrams, 8d.	2	3
Holland.		
Surtax, 3d.; Each word in the message, ¼d.; Lowest charge ½ a franc.	0	11½
Switzerland.		
Nearly the same as Holland.		
Portugal.		
Surtax, 25 centimes; Each word in message, 5 centimes	1	6½
Germany.		
Surtax, ·20 marks; Each word, ·05 ,,	1	9
Towns, ·02 ,,	0	8½
Austria and Hungary.		
Surtax, 24 kreutzers, 60 centimes; Each word, 2 ,, 5 ,,	1	10
Towns, 1 ,, 2½ ,,	1	1½
New South Wales.		
Between all stations, except surburban—First ten words, 1s.; Each additional word, 1d.	3	0
Between suburban offices—First ten words, 6d.; Each additional word, 1d.	2	6
Delayed messages—First ten words, 6d.; Each additional word, ½d.	1	6

Some distances to which messages are transmitted at the above rates:—

Sydney to Tenterfield, North	475	miles.
,, Albury, South	386	,,
Tenterfield to Albury	161	,,
Sydney to Hay, S.W.	454	,,
,, Wentworth, S.W.	731	,,
,, Wilcaunia, N.W.	711	,,
,, Menindie, West	830	,,
,, Bourke, N.W.	574	,,

Account of the Nature of the Service Rendered by the Post-office in the Transmission of a Telegram.

The machinery of transmission may be classed as follows:—The offices; the *personnel;* the mechanical means; the electrical means; the porterage.

The public does not probably realise the extent or nature of these means, nor the organisation that is necessary to set them in motion, to keep them at work, to provide supervision, and to utilise these means profitably.

The Office.

Each telegram must pass through two, the forwarding office and the receiving office; often through more than two, having, more frequently, to be *transmitted* at one or more intermediate offices.

The forwarding office requires a counter where the sender writes his message, another where the clerk receives, passes, and prepares it, and a third where the telegraph clerk signals it to the next station on its route. For this operation the white paper Form A is used, and this, the original message, remains the property of the Postmaster-General.

The tariff of this message, as is well known, includes free addresses, one shilling being paid for twenty words; but as this rate increases for every additional five words, the principle is that of a word rate; in fact, it is altogether an empirical tariff. The *postal* feature of it is, that encouragement is given to full addresses. The counter clerk is not saved the labour of counting the words if the message is not written clearly in the spaces provided on the form, or if the four lines are nearly or quite filled. Passing twenty-one words by accident for twenty, and charging 1s. instead of 1s. 3d., would be visited on a clerk by the punishment of fining. If the sender's message is for a place beyond the United Kingdom, the counter clerk must also understand how to charge and deal with it.

The Instrument and its Clerk.

The instrument clerk, or the operator. His knowledge must not only include what may be called the language of telegraphy—meaning the various classifying code signals, which must be sent as well as the message itself—but also the actual art of signalling with the Morse code.

Omitting reference to the use of telephones or alphabetical instruments for signalling purposes, I will only draw your attention to this art, in which the young alone can become really efficient. Few realise its difficulty, and the fact that no one can become a thorough Morse clerk without years of practice. I do not refer to those who are just efficient enough to spell out the words slowly, either in sending or receiving, or who, even when quick at sending, must resort to the use of the printed Morse slip of paper to read, and whose ears have not acquired the wonderful power of reading groups of signals as words, but to those to whom the whole operation of sending and receiving has become a language of the hand and ear.

The Mechanism.

Part of the mechanical means by which the message reaches its destination sometimes consists of a pneumatic tube from the counter to the instrument-room, occasionally worked by a bellows.

The well-known mechanism of the Morse printing key, by which the long and short electrical impulses are communicated to the conductor, the source of energy in the battery, and the insulated conductor starting from the instrument, at first covered with gutta-percha, then crossing house-tops, roads, fields, and rivers, insulated by the air throughout its length, except where carried on insulators at the points of support, and so away to the distant station containing the receiving instrument, are too well known to need description. It is sufficient to give an idea of the value of such a line of communication 100 miles long, to say that if the poles conveying it carry several wires besides, the cost of such a plant is, roughly, not less than £1,300.

The Intermediate and Terminal Offices.

But if the message has not completed its journey on reaching the station at the first 100 miles, the receiving clerk, who has been warned by a special prefix, selects a yellow coloured form (B) in place of a red one, and the message, when taken down, is passed to the clerk working the instrument on the line reaching to the office of destination. Again, similar means, physical, mechanical, and electrical, are brought into use, very slightly varying in operation according to distance, and the message eventually reaches its terminus, to be taken down on a red coloured or C. Form, and duplicated by means of a second sheet with carbon paper between. The original is kept, and the manifold copy sent to the counter clerk in the public office, who, having recorded it, places it in an envelope, addresses it, marks outside the time of despatch, the charge of porterage beyond one mile, and despatches it by a telegraph messenger boy in waiting. The Post-office, it will be seen, preserves at least two, most frequently three, copies of each message that is carried. These copies are eventually brought together and checked in a clearing-house.

Approximate Cost.

The annual cost of the route for the transmission of the message described above may be very roughly computed as follows, excluding the value of adminstration, which it would be difficult for anyone outside the Post-office to assess.

Let us adopt, as an example, the case of three offices, containing, on an average (what would give) five instruments per office; and a route not passing through a first-class central station, the conditions of which are more complicated. Let us also use the simple example of a wire carried on a road line of telegraph, not on a railway line, where the Post-office pays exceptionally high rates for way leave and maintenance.

It works out as follows :—

Share of 3 offices at £20		£60
Share of 2 counter clerks at salaries of £70		30
3 instrument clerks at £50		150
1 boy (less receipts for delivery beyond 1 mile)		14
Share of office superintendence		30
Plant.—Cost of.		
3 instruments and batteries	£60	
200 miles of line	£2,600	
	£2,660	
Interest and depreciation at 7 per cent.		186
Maintenance of road line at 12s. a mile		120
Supervision and sundries		30
Total		£680

This total, after striking off a few for Sundays, represents an average of forty-three shilling messages a day.

At a low rate of speed this work would occupy two hours a day. Probably in practice it would be spread over three or four hours. Thus, taking this example as a mere indication for the guidance of my audience, there remains twenty-one hours out of the twenty-four for this route to earn a profit. As the conditions of no two routes are precisely similar, and as some vary widely from that which has been given you, there is no desire to quote these figures as the basis of any but the most general conclusions. The object in laying this example before you is to give as simply as possibly a general idea of the nature and value of the service rendered.

The Distance Rate.

At the earliest establishment of the electric telegraph, every one connected with it seems to have thought of no other classification of rates except that governed by distance. This was rational enough, as the administration of those early lines was largely in the hands of people who were connected with railway traffic, who at once turned their attention to making each communication pay for itself. While there were comparatively few messages, and any speed greater than that of a railway train was worth paying for, no better mode of charging could be suggested. All the means were expensive, the manipulation, the instruments, and the line, and no acceleration was attempted which increased their cost; hence distance rates commended themselves at once. With three great companies competing before 1870, the mode of charging by distance lent itself effectively to competition. The United Kingdom Company, which started with a uniform shilling rate, was nearly stifled, and had to adopt the distance rate.

Sir James Anderson on the Effect of Reduced Tariffs on Telegraphy.

In 1872, this well-known telegraph manager published a pamphlet on telegraph tariffs. At the time he wrote (1872), it was still under discussion if private undertakings could afford to reduce rates, although the results in Switzerland, Belgium, and the United Kingdom gave ample proof that judicious reduction gives splendid results. His conclusion was that the highest return upon the capital invested is obtained from a high tariff, and that competition would always check the extension of unproductive facilities to the public. Hence he believed that a monopoly was essential to the creation of a system which would be self-supporting, for the benefit of the public. We know that Mr. Scudamore never shared that belief with the Government of the day which obtained it from the House of Commons, and we know how that monopoly acted fatally in checking the reduction of tariff in this country (long since overdue), by inflating the capital account of the business.

Sir James Anderson goes carefully into the reports from Belgium, and shows how the conditions of the *international* differ from those of the *internal* traffic. He eliminates from actual returns the abnormal stimulus of increased facilities, and discovers a normal rate of progression in the fourteen years with which he deals, of 12½ per cent., which being independent of increased plant, is a measure of the clear natural increment. He then obtains a comparison between the rate of progression of expenses and that of the abnormal augmentation of correspondence. With each of these figures he endeavours to show the large amount of profit sacrificed by lowering the tariff. His contention that the results of the working of *international* service in Belgium, on which reductions of tariff to the same extent did not take place, at first covered a deficit on the *internal* traffic, seems to be proved, and makes us cautious in accepting the Belgium figures of those days in their entirety.

There is one point which I wish you to consider, which is that Sir James's personal experience was more built on the service of great arterial communications than on a network system. From this point of view, a word rate, subject to distance, would be most rational. Cables have a different capacity. If there is but one communication, nothing can prevent delay on messages. For example, if the offices at both ends are clear of message work at 9 a.m., and messages at the rate of twenty an hour be handed in by the public up till twelve o'clock, and the cable can only carry ten an hour, it is plain that the message handed in just before noon cannot be sent on till three o'clock, bearing with it three hours' delay in comparison with the message handed in at 9 a.m. Acceleration, therefore, in the first instance, would have little affect on the calculations of a tariff for such a line.

Competition, as between the United Kingdom and America, immediately gives rise to the obligation to accelerate by duplication of the cable. The rate founded on distance, or in other words, on outlay, then becomes subordinate to time, and the application of that coefficient becomes a source of expense, showing that acceleration raises working cost.

The converse of this receives illustration in the Proceedings of the Select Committee of the House of Commons in 1868 on the Electric Telegraphs Bill. In the Appendix to the Report, No. I., page 8, there is a quotation of the view then held in Belgium by the Director of Telegraphs. He points out "that in fixing lower rates the Government by no means assured the same facilities to the public." They were told that—

"They must not consider the half-franc telegrams would assure them either speed or accuracy. The message at the reduced rate should be considered as one that would be conveyed at about the speed of a railway train. If the public require acceleration they must not rely on the half-franc message. For extra speed, or preference, or an 'express message' two higher rates must be used."

No really important sacrifice of speed was contemplated, for in the same report he claims for Belgium, then, a higher mean speed than in any other country; in fact, he made the ordinary message third class, and accelerated messages, for which more was paid, as second and first class messages.

The Telegraph Circuit, and its Working Conditions.

The term circuit, as many of those present know, is a telegraphic expression, intended to describe the popularly understood path, between the terminal offices of the electric current in the one direction by the wire, in the other or return direction through the earth. A completely equipped circuit must include the operators.

The conditions under which a telegraphic circuit is worked vary considerably in one country, and between countries. Some of these conditions may be described briefly, for instance, as regards the services of operators. They may be highly skilled male clerks, able to work at high speed for many hours at a stretch, possessing great readiness of resource; equally skilled female clerks, but with less physical capacity for endurance, and less resource in difficulties; clerks who, in addition, understand the simple maintenance of the instruments and batteries; others who require more or less the assistance of skilled maintenance men; clerks who are mere learners, or who have only experience acquired on needle instruments; others in country post-offices, who are members of the postmaster's family, and occasionally his aged wife, or youthful grandchild.

In the United Kingdom there is a considerable variety of instruments in use, partly due to the original acquisition by the Post-office of the plant of various companies, and partly to the varying powers of the operators that have been mentioned.

I am indebted to my friend Mr. Preece for an approximate list of the number of instruments of each kind in use in the postal telegraphs, exclusive of telephones.

Wheatstone A B C instruments	4,183
Needle instruments	3,883
Morse recording instruments	1,107
Morse sounder instruments	1,712
Morse recording instrument, worked duplex	283
Morse sounder instrument, worked duplex	357
Quadruplex, worked with sounders ..	27
Wheatstone automatic	173
Wheatstone automatic, worked duplex	64

Besides, there are conditions of speed of minor importance to the subject before us, and also conditions of maintenance of the lines due to weather, which are certainly different in a mild and moist, to those in a rigorous or dry climate.

Lastly, there are conditions of supervision and superintendence, which are most evident to those who have been engaged in the operations of the service. It may be said that, in common with kindred operations, efficiency of service and remunerative results largely depend on these. A telegraph system such as ours is a huge machine, working day and night, stretching over a vast area, dependent on varying local circumstances, and yet subject to one general code of laws, rigid and yet elastic in their imposition. With nothing else that I know of can it be so well compared as the nervous system as described by Herbert Spencer. It is the most perfect example of centralisation, tempered by decentralisation, the balance between them being preserved exactly as the administrators are guided by the indications of demand and supply. And the more I have studied the subject, the more it has struck me that only where the administrators have strained the application of natural laws, there only has the service failed to extract the maximum of possible result.

The superintendents of this beautiful machine must have an intimate acquaintance, not only with the best possible work obtainable from the means used, both human and material, but also with the thousand militating occurrences to which every part of it is liable; so that, while always striving for excellence, too much shall not be demanded, and waste arise in the opposite direction.

That this supervision has been well guided, experience proves. And I will endeavour to show you that the success of the ultimate objects for which it is contending, namely, producing efficiency of service for the public, must all turn on the proper understanding and use of one co-efficient, namely, *time*. That the measure of cost and of accuracy must be subordinate to the expenditure of *time*.

Those who have been engaged in this supervision, and who have had to investigate complaints about accuracy or delay, will be the first to acknowledge that the ultimate conclusion of their research had been chiefly governed by the condition of *time;* if any improvement in the future is to be reaped, it will be through tracing the fault, whether physical, mechanical, or electrical, home to its true cause.

The Capacity of a Circuit.

Like other machines, a telegraph circuit has a measurable capacity for work. As in the case of a line of railway, it can carry traffic continuously, subject to working conditions of speed and safety, service and maintenance. Railway managers could give you many examples of lines worked fully up to their maximum capacity, even verging on the insecure, and they would add that out of the needs of the public have arisen classifications of traffic, namely, into various speeds, that some lines have to be devoted entirely to high speed, other to slow speed traffic, and that from some lines the maximum result of capacity is obtained by working both, confining each to different periods of the 24 hours.

We can all understand that in few cases will practice attain the theoretical capacity of a line worked with trains following one another, travelling at equal speeds, and with safe intervals, and equally we can understand that the best commercial result will be obtained by the manager who best adopts and dovetails all the means at his disposal to meet the demands of his customers.

Again, we can all clearly appreciate that traffic itself is subject to classification in its varieties. Thus with passenger traffic: it can be subdivided according as persons are ready, from various motives, to pay for various rates of speed. Similarly with the carriage of live animals, and perishable and imperishable goods. But while the powers of the railway manager to meet these demands in equal variety are limited, it is undoubtedly the case that the first object is to do so, especially when under the pressure of competition.

Telegraph Traffic Commercially Worked.

Now, to a much smaller degree, telegraphic traffic is subject to the same influences, if its management is truly commercial in its instincts. In using the word "commercial," I ask my audience to admit that in whatever way we regard the service of the public by a Department of the State, the word "commercial" equally applies whether the system is worked at a loss, or without loss, or at a profit. Whatever the result, "commercial" working will mean working on a basis. First, of extending telegraphic facilities to every point to which private undertakings would extend it under the influence of competition. Second, of working on sound economical principles.

It is true that when the State first took over the telegraph companies' business, many of the early extensions were very uncommercial, but this was a weakness from the effects of which fifteen years working has long ago recovered, and which for many years has been counteracted by the exactions from localities of guarantees to cover at least working expenses, before extensions are permitted.

If true commercial instinct is to be exercised in the management of our telegraphy, it would appear that, somewhat in the way I am attempting to describe, every circuit should be used in such a way as to obtain from its use the maximum gross revenue. As for all other kinds of means of transport there is a market; the commercial instinct seeks the market and developes it, which means organising a system which will extract from it all that can be gained. Thus Pickford, Chaplin and Horne, in England, and Bianconi in Ireland, created a business; if the demand had not been latent, they could not have made it pay.

A Department of the State serving the public, if the object is not to pay, should obtain still better results. If it is seeking to bring revenue into the Exchequer, it ought to produce quite as good results, with several advantages which no private undertaking can have.

Development of the Postal Telegraphs.

Let us inquire for a moment how far the Post-office has developed the latent telegraph business in the country. They carry, say, 26,000,000 of telegrams, as against 8,000,000 before 1870 carried by the companies. This marvellous result has been obtained, working on almost precisely the same main lines as when the Government first took the telegraphs in hand.

Those broad lines have been a maximum of speed at a nominally uniform charge; and, without considering the lessening of speed due to the means, which, for economy of working, have been adopted in circuits of least importance, doubtless the highest results possible under those conditions have been obtained.

The question then remains—Has the rigid adherence of these main lines of procedure obscured their vision, and prevented their discovering outlying regions of profit waiting to be reaped, greatly to the advantage of the public, and to the increase of revenue on the lowering of rates? Ought we, out of pure gratitude for what has been done, to shut our eyes to this inquiry, and decline to allow that the Post-office may err, or have its vision narrowed within the range of the great reservoir of custom, which it has not only tapped exhaustively, but also developed in size?

The Society of Arts, years ago in the van of the movement which led to the acquisition of the telegraphs by the State, and always ready to place its arena at the disposal of the public for discussion, ensures, by its countenance of such an investigation as this, that it will be treated in the fairest spirit, and that every question or objection shall have the most serious consideration.

Possible and Actual Capacity of Existing Circuits.

Let us look at the possible capacity of the instruments of which I have already given a list.

	Messages per annum.
A Wheatstone A B C instrument has an hourly capacity for 34 word messages of 15, or in 12 hours of 180. This, for 2,092 instruments for 310 days, gives a total of	116,705,700
A needle instrument has an hourly capacity for 25 messages of 34 words each, or in 12 hours of 300 messages. This for 1,942 instruments in use gives for 310 days..	180,559,500
	297,265,200

The figures are so enormous, and representative of nothing within the range of probability, that it is only necessary to mention the gross receipts at a shilling a message would amount to £14,863,260.

In actual practice these instruments, at a very low estimate, probably forward on an average—

Every 2 A B C instruments, 6 } messages a day.
,, 2 needle ,, 10 }

		Per annum.
Representing—	A B C	3,891,120
	Needle	6,018,200
	Total....	9,909,320

Which, at one shilling, amounts to £495,466, or 1-29th of the possible capacity.

The same calculation applied to the Morse recorders and sounders, allowing them a message of 34 words capacity of 30 and 35 respectively, gives a possible capacity representing £8,663,880; and this in actual practice, allowing 20 messages a day for recorders, and 25 for sounders, amounts to £513,440, or 1-17th of the possible capacity.

These figures, however approximate in their accuracy, are sufficiently based on fact to convince you that there is a very large margin of time during each day when circuits are idle, and when the mechanical and electrical machinery is at a stand-still.

Utilisation of Spare Capacity.

The question immediately arises how to utilise a portion of it. I have only dealt with twelve out of the twenty-four hours. The Post-office already utilises a proportion of the remainder of the twenty-four hours on many circuits, by working them for press messages, at rates so unremunerative that it is doubtful if they pay for the actual manipulation. I have only dealt with twelve hours of the twenty-four because all offices are already open during that time, and in offices with one instrument only, a manipulator is always present. This manipulator, I have assumed, now deals with 6, 10, 20, or 25 messages a day, according to the class of office and instrument. If he worked away steadily for eight of the twelve hours he would deal with 120, 200, 240, and 280 messages. It is not straining this demand on his or her powers to expect that half those numbers could be dealt with without increasing the labour staff. Again, in offices with two or more instruments, periods occur daily when neither instruments nor clerks are fully occupied. The larger the offices, the fewer or less frequent are these periods, for the following reason :—Although an office may open at 7 a.m. and not close till 9 p.m., the time during which all the instruments are at work, is probably limited to between 11 a.m. and 3 p.m., then all the clerks are hard at work. For about two hours before and after those hours but half the clerks need be present, probably early and late, only one or two are wanted. Thus, by judicious dovetailing of the hours of work of each operator, the full time of each is fairly occupied throughout most of his working hours. In the largest offices this can be carried out with great perfection, but in the vast majority of medium-size offices there exists a margin of available labour which can only be adjusted by having too small an establishment of clerks. Its effect is a certain delay in every message during the busiest hours, and the accomplishment of work during times of slight abnormal pressure of business, by allowing the operators to work *overtime*.

High Standard of Time aimed at in Postal Telegraphs.

Fortunately for the public, and the well-earned and maintained credit for speed won by our postal telegraphs, the Department has always aimed at accomplishing what is highly creditable, and unequalled in most other countries, namely, that a message is considered to be delayed when the time taken to deal with it in any one office exceeds ten minutes.

Now, this is a very high standard to aim at, and it can only be maintained, in all but the largest offices, by a redundancy of the manipulating staff, so that the very effort to serve the public will, in the matter of time, necessarily result in a margin of unutilised labour, as well as of mechanical and electrical means.

I know that post-masters exercise great judgment in applying spare telegraphic labour to postal work, and *vice versâ*, but there must still remain hours during which some labour is still available to work the machinery lying idle under its hand.

But where are the messages which will require transmission ? My answer is, they will be forthcoming by a lowering of rates, when accepted on the understanding that they are to be sent during those periods that the machinery is now idle. The history of all telegraphs places it beyond discussion that every lowering of rates of any kind produces increased traffic of one kind or another.

If the increase proves to be greater than can be dealt with by the margin of labour I claim to exist, then additional labour and working expenses at cost price must be added. I believe that 1½d. per message in each office which deals with it, will amply suffice.

If the demand exists for cheap telegraphy under conditions of speed less than those now aimed at by the Post Office, why not supply it ? Why give the public a uniform speed on all messages ? Is it not rational to suppose that these are messages which will fulfil their purpose equally well in the mind of the sender if delivered in three or four hours after being handed in ? Does it not at once appear evident that the elimination of every fresh message, now sent in its code turn with the most pressing messages, will add to the punctuality of the latter ? Whether we call the first messages express, or the slow-speed messages, deferred, does not matter. Does not a classification of this kind coincide with the fundamental law of the government by time of all the conditions of telegraphic supply and demand ? If we analyse the means used in telegraphy for increasing speed, we find that it is entirely a question of cost.

Cause of Delay.

If a message is handed in at an office between 11 and 11.5 with six others, including counter work, the first of the seven is completed in, say three minutes, the next in three minutes more, and so on, the seventh message will have accumulated over sixteen minutes delay on reaching the transmitting stations. Here other delays may occur, and while the first is got through within ten or twelve minutes, the fifth is not ready for delivery for more than half an-hour after receipt.

All delays of such a kind can be lessened by increasing means, duplexing wires, doubling the operators, and so on. The greatest speed of a Wheatstone automatic circuit is achieved by costly apparatus and unlimited labour at each end of the wire. Increasing the wire, accommodation may have to be resorted to to keep down delay when all other means fail. Is it not a much simpler experiment, to save expenditure and maintain speed, to offer the public inducements, by cheaper rates for less speed, to select of its own accord the slower route, when first-class speed is not essential? If the only gain were to reduce the work during the busiest hours of the day, and confine it to the supply of the demand for higher speed, the result would justify the change. When it also means the occupation of circuits, where otherwise they would be comparatively idle, by work eminently not suffering from such delay, through the selection of the customers, there would appear to be a large balance of evidence in its favour. But if, also, the cheaper rate taps a reserve of message-sending not now sounded, and if the increase of traffic of this character largely exceeds the loss on the messages for which the cheaper means have been selected by customers in preference to the old rate, surely this increased efficiency of the fast service, and the added facility to the public of the slower service, would alone more than prove the soundness of such a measure.

Dr. Playfair's Committee.

I will now refer my hearers to a paper laid by me in evidence before Sir Lyon Playfair's Committee of the House of Commons, in 1876, suggestive of a scheme of "deferred" or "second-class" messages, and descriptive of the means by which I proposed to bring it into force. This had been the result of several years of constant observance of the daily working of the system in the district of which I was the divisional engineeer, and of careful inquiry amongst all the persons in that district upon whom would fall the labour of bringing it into force. I was not met by one dissentient as to the practicability of the proposal. If I ever encountered objections, they were derived from the experience of the great central stations, where slackness of work is never apparent.

I claimed, in 1876, no novelty for the proposal except that its essential feature was its perfect adaptability to the postal telegraph system. It claimed to tap a new source of revenue without materially diverting existing channels, and to utilise existing spare means with little change. It designs to leave the one shilling message alone with its existing conditions and facilities, and that the Post-office should accept a new kind of *petite vitesse* message, and forward it under certain conditions for sixpence. This message, if thought well, might be called "second-class" or "deferred." The main condition of transmission of the messages to be, that no second-class is forwarded while a first-class message is on hand. The effect of this would be:—

1. That the 1s. message would remain as it is (subject to alterations as to payment of sender's address).

2. In practice, the second-class messages would only experience serious delay in busy offices, on busy lines, during busy hours.

3. Local telegraphing in country districts and towns would be developed; and circuits now only occupied with a dozen messages a day at 1s. would probably lose half these, but carry twenty or thirty at 6d., when it was found that on local traffic no real delay occurred by using the lower class.

4. It was suggested that this class of message should include only ten words, and that free delivery should be only for half a mile, and the second half-mile be charged 3d.; but there is no reason why the delivery should not remain as it is for 1s. messages.

5. It was foreseen that the public might at first adopt more largely the use of second-class messages than the revenue could bear, but it was pointed out that as soon as those who did so found their messages suffer in speed, they would revert to the shilling rate, with the greater satisfaction of obtaining a somewhat accelerated service for their money.

The working was provided for by distinguishing second-class message of forms by a different tint, or by strongly marked black bands, or by large figures.

At the instrument it was proposed that second-class messages should be placed at the bottom of those lying before the operator, below the first-class ones, and as long as any of the latter were waiting to be sent, to allow the former to accumulate. But immediately a clerk had "got off" all his first-class, he was to go on with the second-class till a fresh first-class reached him.

A Table is exhibited showing the number of words that would be transmitted under the two rates. It will be seen, assuming that a wire carries on an average twenty words a minute, it could earn 6d. a minute at the second rate.

First Class.				Second Class.			
Estimated words in address.	Words in message.	Total.	Charge.	Estimated words in address.	Words in message.	Total.	Charge.
			s. d.				s. d.
12	20	32	1 0	12	10	22	0 6
12	25	37	1 3	12	20	32	0 9
12	30	42	1 6	12	30	42	1 0
12	35	47	1 9	12	40	52	1 3
12	40	52	2 0	12	50	62	1 6
12	45	57	2 3	—	—	—	—
12	50	62	2 6	—	—	—	—

The report of the House of Commons Committee referred to this in the following terms:—

"The essence of this plan is that in small localities telegrams would be largely multiplied, and that wires which now remain comparatively idle for a considerable portion of the day would have fuller and more evenly distributed work. This proposal has the merit of not disturbing the ordinary 1s. messages, and offers cheaper rates for such as can be delayed with a minimum dislocation of the present system. There is no greater disturbance of uniformity in this plan than in the various changes of the postal system, in which higher rates are charged for greater facilities."

The Postmaster-General's Opinion on Deferred Messages.

On 23rd July, 1880, Mr. Fawcett expressed himself adverse to the proposal, when replying to a deputation of this Society, in the following terms, thus:—

"There has been another suggestion made which I think it well to refer to, as I believe it has been discussed in public, that you should have two rates of charge; what are known as 'deferred' telegrams, charged at cheaper rates. For instance, those persons who go to a City telegraph office and pay 1s. for a telegram, should have it sent off at once; those persons paying sixpence, should have their telegrams sent off when all the shilling telegrams have been got rid of. So far as I am concerned, I never could sanction such a scheme as that. It seems to me to have this fatal blemish, that it would always impress the public with a sense of unfairness, and every person who did not get his telegram sent off, or receive it so quickly as he expected, would think the delay was owing to a preference given to a more influential or wealthy sender. It seems to me a principle of cardinal importance to maintain that there should be no distinction of persons—no distinctions with regard to preference—but that, as regards the first person who goes into a telegraph office, that the office should send his message first. If any departure is made from this principle, I am afraid that all confidence in the fairness of the telegraph service would be removed."

It is with the greatest deference to his wisdom and position, that I venture to ask the meeting to consider, for one moment, the Postmaster-General's objections to establishing two classes of speed, for two rates of payment, for the carriage of telegrams.

How far his reply was satisfactory to the deputation from this Society I cannot say, but you will not be surprised if I ask you all not to feel in any way satisfied with it.

The Postmaster-General recognises none of the financial and commercial advantages of the plan; he offers no objections to it on account of any difficulty in working; it he simply adopts what I may call an eminently postal view of it. When I call it by that name, I mean that it is one of the oldest forms of answer employed by the Post-office, when pressed from the outside to make any changes not originating within its own walls, namely, to say that the public would not like any change. This well-known objection has been in its time used against the Post-office Savings Bank, Insurance, and Parcel Post, prior to the birth of each, and their greatest opponents dwelt within the walls of St. Martin's-le-Grand. However, like all sound schemes, after an interval in each case, the wisdom which predominates within that world-famed establishment weighed down the scale, and the boon was granted.

I must say that I am too great a believer in the soundness of Mr. Fawcett's own teaching, to believe that he really thinks the public will object to two kinds of telegrams, more than they object to two classes of railway carriages or trains.

They do not object to the different speeds in book and parcel post. They are quite able to understand paying differently for different speeds, and when the payment and selection is in their own hands, where is the reasonable suspicion of preference or unfairness?

Uniform rates possess a fascination for some people, but what has become of the uniform rates within the Post Office itself? Is not its uniformity subject to the co-efficient of weight for letters, and number of words for telegrams? Why not try the time rate?

It is true the British public has been educated by the postal telegraph system, on unsound principles, to know nothing about the costliness of speed in respect of telegrams, and they mostly believe that the value of the service rendered is measurable by the number of words. But is it ever too late to restore the British mind to a healthy state on any subject?

In Belgium the value of acceleration in the transmission of letters is recognised as having a distinct value, and facilities are given by which letters can be sent from place to place in less time than is occupied by the ordinary post. By writing the word "express" conspicuously on the envelope, and attaching an additional stamp of the value of 25 centimes to a letter bearing a 10 centime stamp, the sender secures preference for his letter over others, and it is sent to its destination by the quickest means. For instance, an "express" letter is sent by the next train leaving the place of collection by the Post-office, and is delivered at the other end of its journey by a special messenger. We do not hear that the Belgians look upon this as conducive to unfairness, or as giving the rich a preference over the poor man.

One word more about the uniformity of rate question. There is a good deal about it in the proceedings of the House of Commons Committee, on the Electric Bill of 1868; and it is frequently alluded to in the examinations of the late Mr. Scudamore; also of Messrs. Harrison and Patterson, and of Professor Jevons.

I am led to think, by a careful perusal of their evidence, that the uniformity they were advocating was, as against what they called, the irregularity and even "injustice" of the old companies; and that the uniformity to which there has since been a tendency to wed us is an exaggeration and distortion of their views.

Mr. Scudamore speaks of the advantage of uniformity of rate, as "permitting the use of stamps," and as "simplifying telegraphy." He evidently alludes to the complications of the existing distance tariff, for later on, he approves of the twenty word message at 1s. and to the fifteen word message at 6d., with a 1d. added for five words additional.

Again, uniformity was advocated by several witnesses as a necessary consequence on obtaining from Parliament a monopoly for the Post-office; but Professor W. S. Jevons considered that the "sounder" principle was to arrange rates so that each communication should more or less pay for itself, and he expressly stated that he did not advocate a monopoly, and would rather re-arrange rates than protect the sytem in that way.

All the witnesses referred to the success of the uniform rate for postage, and examples were given. How, in some cases, the actual cost of the transport of letters to the Post-office was 2d. and 3d., in others only ½d., as a justification for doing away with the distance tariff, then in existence, of 1s. for 100 miles, 1s. 6d. 200 miles, and so on. Looking back on these records, it looks as if the dislike to the existing tariffs, more than a real similarity between telegraph and postal work, weighed most with the advocates of a uniform word-rate under all conditions (amongst whom Mr. Goschen was prominent).

Lastly, all the witnesses who spoke on the subject had then had no practical experience of the working of telegraphs. The difficulties which influenced their minds have long since disappeared, and exceptional alterations in tariff have been introduced into the postal Telegraph Service without observation. The caution which is slow in adopting alterations as improvements, cannot be too much admired; but it is well known that the backwardness of public Departments in this respect is more due to the inertia which "rests and is thankful," to the instinct of heavily worked officials to retard the introduction of thankless reforms, and to the deadening effect of official routine, which nips in the bud the energy of most of the men who, in other walks, would be in the van of advancement.

The Indian Telegraph Department.

Although administered under several essentially different conditions, its working and procedure as regards tariffs will interest the audience. One or two great differences are worth bearing in mind. The telegraph in India is esentially a European service, and English is used; it cannot yet be said to be in use by the millions of our fellow subjects in that country. It is much used by the State and by local governments, the numbers in 1882-3 of State messages to private having been as 247,000 to 1,103,688. The distances in India being very great, a telegram often takes the place of a letter. As regards a very large proportion of the traffic, time is of less importance than here, distance is a more influential condition.

Founded on the experience of a far longer period of State control than this country has enjoyed, we find the Government of India expressing itself in November, 1881, as "willing and anxious to forward any scheme for developing and facilitating communication by telegraph, so for as this can be done without risk to the interest of the general tax-paying community; but in the interest of that community it is esential that the telegraph service should be self-supporting."

In pursuance of this object, we find that the Government approved on that date of a scheme for the "revision of the tariff, which, affording room for a very considerable future reduction in rates, will admit of a large expansion of the traffic without necessitating additional expenditure on increasing the number of the wires. The main feature of this scheme consists in the introduction of arrangements which will permit of the disposal of message traffic in order of urgency. instead of, as at present, in order of presentation of messages. The minute in Council recognises that in the case of commercial and State telegrams, almost the whole are tendered for transmission during the business hours of the day, the result being a great pressure of work for a few hours, while for the rest of the day and night the wires are comparatively idle."

As the "telegraph officials cannot be the judges of the comparative urgency of messages," it authorises the "Director-General to introduce, in addition to the 'ordinary' class of messages, two other classes, 'deferred' and 'urgent;'" the latter taking priority, and the former following the ordinary, when they have been worked out, the rates being:—

	Rs.	
Urgent	2	With free address.
Ordinary	1	
Deferred	½	

His Excellency the Governor-General in Council "believes that the introduction of the deferred message system . . . . will prove a very great convenience to the public in improving the service for transmission of really urgent messages, and will enable a large reduction in average cost of telegraphing to be made, owing to the facilities it would give for utilising the wires for a greater proportion of the twenty-four hours than is possible under the present system."

The special suitability of the deferred system to the long distances in India is exemplified by the condition that the Department does not bind itself to deliver these messages at their destination before early the following morning.

Although the nature of traffic thus provided for in India, would largely be carried by the post in this country, it is vital evidence to the existence of unearned revenue and undeveloped public facility, that the system of "deferred" messages has been adopted in our great dependency.

The Departmental Report for 1882-83, gives the total per-centage of each class of inland messages, dealt with in the last two years, as follows:—

STATE MESSAGES.

	1881-82.	1882-83.
Local	0·65	1·04
Deferred	62·70	56·06
Ordinary	7·12	11·10
Urgent	29·53	31·80

PRIVATE MESSAGES.

	1881-82.	1882-83.
Local	0·43	0·64
Deferred	22·03	32·06
Ordinary	72·64	60·90
Urgent	4·90	6·40

The large increase in the last year of private deferred messages over ordinary, shows the popularity of the former class. The value of the inland traffic in the above two years, and in the previous two, before the new system was introduced, shows great encouragement, viz., under private messages.

	Number.	Value Rs.
1879-80	1,037,330	15,32,153
1880-81	1,044,107	14,08,582
1881-82	1,035,137	13,16,851
1882-83	1,189,437	13,86,630

The increase in wire mileage between the last two years was as 58,219 to 61,184.

DISCUSSION.

The CHAIRMAN said he had much pleasure in presiding on this occasion, because the Society had done good work in the matter of telegraph reform; it pressed the acquisition of the system by the State, and advocated very powerfully the adoption of sixpenny telegrams. He was a member of the committee to which Colonel Webber had referred, and he remembered the difficulty which was found in getting evidence in favour of telegraph reforms. The system was not then paying, and the Treasury proposed to increase the charges for press messages, to add an extra 6d. for Sunday and night messages, and an extra 3d. for those handed in at railway stations. On the committee, he opposed the Treasury, and found great difficulty in getting witnesses to support him. At that time the Post-office was against any increase of facilities, and said that deferred messages could not be introduced with any hope of success. Colonel Webber was then the telegraph officer in charge of the one district in England which was managed by the Royal Engineers; he was free from departmental trammels, and came forward with the courage of his profession, and gave most valuable evidence. They were now within a measurable distance of sixpenny telegrams, the House of Commons having passed a resolution in favour of such a change, but he did not think that had any direct bearing on the question of deferred messages. The public had been educated to look for despatch, and the Post-office was preparing to lay out £500,000, to increase the wire accommodation on the main lines, which were at present most busily occupied; so that the increased number of messages which were expected to arise from the reduction to 6d. must be dealt with without any deterioration in speed. This would leave them in the same position as at present, with the wires lying idle for the same proportion of time. There were some six thousand telegraph offices in the kingdom, and the total number of messages gave an average of only about fourteen per day to each office. Now, a very second-class instrument and operator would send off fourteen messages in a little over half an hour, so that the telegraph offices, on the average, were doing half an hour's work per day each. That seemed to show that there was a large field open for deferred messages, and he did not see why, after the 6d. rate had been introduced, deferred messages might not be taken at a further reduction. He looked upon the 6d. telegram as simply the commencement of reforms which would at last place them far ahead of any other country in this respect. They were already in that position with regard to Press telegrams. Mr. Saunders pressed the committee which sat to consider the acquirement of the telegraphs by the State very much on that point, and, the Government being then very squeezable, he obtained such good terms that press messages were sent at the rate of 1s. for 100 words to one address, and 2d. extra for every additional address. Thus, a message could be sent to 100 newspapers at a cost of 2d. each, and $\frac{1}{100}$ of a shilling for the original. It was at one time proposed to raise the press tariff, but the Committee of 1876 at once put its foot down on any such proposal. Several schemes for the 6d. telegram were put forward; one, 12 words for 6d., and $\frac{1}{2}$d. for every word afterwards, including the address; another, that the address of the receiver should be free, with a $\frac{1}{2}$d. per word, and a minimum charge of 6d; and a third, that the address of both sender and receiver should be free, with a scale of $\frac{1}{2}$d. per word for the message, and a minimum of 6d. On the whole, he should prefer the second, which he thought would be an excellent plan for the public. But even then they need not consider that as final. If with a 1s. rate deferred messages could be sent for 6d., he did not see why, with a 6d. rate, a deferred message should not be taken at 3d. or 4d., or longer messages for 6d. Again, it had been suggested by the postmaster of Glasgow that, in many instances, persons in the country who wanted to come to London on business, could transact their business quite as well if they were allowed the use of a wire for an hour, with an operator at each end, at a specified chaage—say £5 from Glasgow to London. In many cases that would be a great convenience; and of course the wire would be only used in such a way at a time when it would otherwise be idle; so that the only cost incurred would be a few shillings for the clerks. Another suggestion was for an increased use of pneumatic tubes. In Paris, this system had been developed to a large extent, there being two classes of pneumatic telegrams—the card, and the closed telegram; the charge for the former was 2$\frac{1}{2}$d.; it could be handed in at any office, and was despatched by pneumatic tube to its destination; the other was practically a letter, which was sent in the same way at double the charge. It might be said that this was a slow method, but the greater the variety of accommodation offered to the public the better. There seemed to him to be no substance whatever in Mr. Fawcett's objections to different rates; there were already differences in the Post-office charges—different rates for letters, books, and parcels, and also for expediting letters, late letters being sent on if they bore an extra stamp, while others, posted at the same time, were delayed. Service telegrams, again, were expedited, and so were Government messages, and very properly. He had seen so much accomplished in the way of telegraphy, that he hardly despaired of anything, and he thought these Government experiments ought not to be regarded from too narrow a commercial standpoint. If narrow views had prevailed at the outset, the public would never have had the telegraphic service; in the same way the sixpenny telegrams might cost something at first, but he believed any loss would soon be made up. He agreed with Jeremy Bentham, that the Minister of Public Communications was one of the most important ministers in the country, and that his operations should be carried on with a view to the convenience of the public, rather than with an eye to making as many pence as he could.

Mr. MATHEW, as an old military officer who had considerable experience in India, had been very much pleased with the paper. He did not think cheap telegrams need necessarily be slow, but the highest profit to the public, and the greatest benefit to the country, would be obtained by the lowest possible rates.

Mr. WM. SAUNDERS said the observations of Colonel Webber were so eminently sensible that it was very difficult to criticise them. He had said all that could be said, and as well as it could be said, in favour of his proposal, and he (Mr. Saunders) certainly had no wish to say anything on the other side. He must, however, first refer to two instances in which the system of deferred telegrams at a cheaper rate was found to work well. The first was that of Press messages between England and the United States, which were taken at one-fourth the ordinary rate, subject to being sent when the wires were at liberty. That enabled a large amount of communication to take place between the two countries which would otherwise be impossible. Again, in the United States there had been for many years a system of half-rates after six in the evening. That was of great importance there, because in some cases the postal system extended over a period of several days, and commercial men found it an immense advantage to be able to send a telegram in the evening instead of of waiting for the post. In England, night messages would not be so useful, but Colonel Webber's proposition of receiving deferred messages, to be sent on whenever the wires were unoccupied, would exactly meet the case. It scarcely meant slow traffic; it simply meant distributed traffic, and those who wished to take advantage of the cheap rate would simply have to ascertain the time when the wires would be free from pressure. It was quite certain that the adoption of this system would tend to prevent the delay of urgent messages, which now often arose from the pressure of unimportant work. With regard to press messages, he noticed that Colonel Webber had omitted reading one paragraph in the paper where he said it was doubtful whether those messages paid. If they did not it was not because the messages were not profitable, but because they were limited to one class of the community instead of being extended to the whole. Press messages were only sent to newspapers, clubs, and newsrooms; but if they were also sent to private persons, a large profit would be made. Perhaps a thousand persons wished to know the result of the Oxford and Cambridge boat race. To send a separate message to each one involved the transmission of about 15,000 words, whereas if it were done in the same way as press messages were carried, viz., if all who wished to receive the result were placed on a list at the Post-office, and their addresses given to the various post-offices from which the message had to be delivered, about ten words only would have to be transmitted instead of 15,000. The addresses being prepared beforehand, they would only have to send from Mortlake, "No. 7"—which would represent the list, —"Cambridge has won;" and the Government would receive for sending those five words a thousand two-pences. Now they would receive a thousand shillings, but they had an immense deal of work to do to earn it. Every item of important general news might be treated in the same way, and he thought this was a species of economy in telegraphic work which was well worth attention.

Mr. Graves remarked that Col. Webber, in inviting officers of the Post-office to express their opinions on this question, had apparently overlooked the necessity they were under of being reticent. The matter was now under the consideration of the Post-office authorities, and he could not separate his personality from his official position, because, if he expressed his own individual views, he might be understood to be indicating the official opinion. He should have much liked to express his assent to, or dissent from, many of the propositions Colonel Webber had advanced; but the remarks which had fallen from the chairman and Mr. Saunders showed him that the subject branched out into so wide a field, and covered so many controversial points, that he had better remain silent. He might, however, say that he was quite certain the Postmaster-General had no other wish than to introduce as low a tariff as possible for the convenience of the public, provided it did not throw a burden on the general body of tax-payers.

Mr. Walter Hancock, although he had for many years been connected with one branch of telegraphy, must admit that the paper had opened up a number of points which had never occurred to his mind; and it certainly was very rich in suggestions for the improvement of the telegraph system. The main point, no doubt, was that of deferred messages, and he thought there were very many who would prefer a cheaper message, even with some delay, whilst others would always prefer to pay the full rate, or even something extra, for the sake o expedition. Again, much labour would be saved by shorter messages, which, in many cases, would answer every purpose. They had been accustomed to a uniform rate on account of the postal system, but in telegraphy the same conditions did not apply.

Mr. Alexander Siemens said he should welcome 6d. telegrams, of course, but there were some points which seemed to have been overlooked. Who were the people who telegraphed, and what was their object? In most cases it was expedition. They could not compare England with India, or with the United States, where the distances were so great that a letter took several days, and a deferred telegram, which took only a night, would ensure a great saving of time. In England, a letter was delivered the next morning at almost all the important towns, and a deferred telegram would possess no advantage. It seemed to him that the present charge could not be reduced without causing a deficit, because more wires would have to be employed. The chief telegraphic traffic was between business firms, who wanted speed above all things; and if with a 1s. telegram they could ensure speed, and for 6d. they had to take their chance, no man of business would adopt them. Other people only used the telegraph occasionally, and a reduction to 6d. would not much affect them. It seemed to him, therefore, that cheaper telegrams meant either delay or more taxes.

Colonel WEBBER, in reply, said this was a subject which required a great deal of consideration, and he could hardly expect much to be said on the details. They were much indebted to the Chairman for the interest he took in the subject, and for the very clear manner in which he had enlarged on the propositions brought forward in the paper. The American practice to which Mr. Saunders had referred was within his knowledge, and he should have referred to it as well as to India, and pointed out that, as Mr. Siemens had remarked, the conditions were not quite the same as in England, the distances being so great; but the experience of telegraphy in America was much more difficult to get at, and, therefore, he preferred relying on the published statistics of India. It would be a great advantage if the Americans would publish their results, showing the average distance over the wires which these deferred messages were carried. In inviting Post-office officials to join in the discussion, it was very far from his intention to suggest that they should deal with any points which were under the consideration of the Postmaster-General; but he thought there were some points on which they might have spoken; and he was particularly anxious to hear any objections they might have to his proposal. The great difficulty he had encountered during the last eight years was to find out the objections; for, with the exception of those who had to deal with large central offices, he had failed to meet with any. Of course, in those large offices there was no idle time; the work was so dovetailed in, and there was so much press work at night that the want of work was not appreciated; but when you went to country districts and small offices, and found that the operator was standing idle nine hours out of ten—when there were hundreds of people willing to send messages at 6d., and the postmaster was obliged to refuse them, it seemed to him that the policy was purely that of the dog in the manger. It was chiefly at the extremes of this great system that the wants of the public could be felt. Then came the objection of Mr. Siemens—what sort of messages would be sent under this category? It was always difficult to say exactly what the demand would be until they were prepared to supply it. He could only say that the experiment had been tried in other countries, and had succeeded. In New South Wales there were "delayed" messages, sent for 6d. in the least busy hours, over a circuit of 830 miles. There was also the experience of India and America; and though the conditions were not the same, it afforded some ground for supposing that there would also be a demand for deferred messages here. There were many messages which would answer every purpose if they were delivered the same afternoon or evening; and a person who knew that such would be the result would not mind the delay, even if he handed the message in at eleven o'clock in the morning. Within distances of 60 or 100 miles of London, a letter posted in the middle of the day would indeed be delivered the same night; but a telegram delivered before 5 would have an advantage. Again, there would very likely be a large traffic on Sundays, when no letters were delivered. No one could say what the exact nature of the traffic would be; but it was undeniable that a reduction of rate produced an increase of messages.

The CHAIRMAN having proposed a vote of thanks to Colonel Webber, which was carried unanimously, the proceedings terminated.

Miscellaneous.

REPORT ON TECHNICAL INSTRUCTION.

The second Report of the Royal Commissioners on Technical Instruction has just been published. The first volume contains the general reports, and the second volume a report by Mr. H. M. Jenkins, on Agricultural Education in North Germany, France, Denmark, Belgium, Holland, and the United Kingdom, and another by Mr. William Mather, on Technical Instruction in the United States of America and Canada. The third, fourth, and fifth volumes will contain the evidence and the remaining appendixes.

Public attention was first directed to the influence of technical instruction on Continental industry by the letter of Dr. (now Sir Lyon) Playfair, of May 15. 1867, to Lord Taunton, Chairman of the Schools Inquiry Commission. In that letter, Dr. Playfair, who was one of the jurors at the Paris Exhibition of 1867, stated his opinion, which he shared with "some of our chief mechanical and civil engineers," and with "our chemical and even textile manufacturers," that other nations were making "wonderful advances," while with us there was "want of progress.' "So far as he could gather opinions by conversation, the one cause upon which there was most unanimity of conviction was, that France, Prussia, Austria, Belgium, and Switzerland possess good systems of industrial education for the masters and managers of factories and workshops, and that England possesses none." The Schools Inquiry Commission, on receipt of this letter, addressed a circular to a number of "eminent English jurors," asking whether they agreed with its substance. The replies were such as to induce the Commission to report that the "inferior rate of progress recently made in manufacturing and mechanical industry in England, compared with other countries," was "due in a great measure to the want of technical education," and they suggested for the consideration of the Government, whether a special inquiry into the state and effects of technical education abroad should not be instituted.

In conformity with this recommendation, inquiries on the subject were addressed by the Foreign-office to our representatives abroad, to which numerous replies were received; and Mr. Samuelson, M.P., made a report (Parl. Pro., Nov. 26, 1867) to the Vice-President of the Council, of his observations during a journey in France, Switzerland, Germany, and Belgium, in the autumn of 1867, undertaken with the special object of inquiring into the industrial and educational establishments of those countries. In the following year, a Select Committee of the House of Commons, of which Mr. Samuelson was the chairman, inquired into the education of the industrial classes in this country, and the subject has since been followed up abroad by various other persons, among others, by Messrs. Beaumont and M'Laren, Dr. Silvanus Thompson, and Mr. Felkin; and it was also dealt with incidentally by the Royal Commission on Scientific Instruction. In consequence partly of these inquiries, there arose a movement in favour of technical education in this country, among the practical results of which may be mentioned the foundation or enlargement of several technical schools, of which the Bradford Technical School, opened by the Prince of Wales in 1882, is probably the most conspicuous example; the technological examinations founded by the Society of Arts; and the scheme for technical instruction of the City and Guilds Institute, &c. The demand for informa- as to the state of technical education in other countries led to the appointment of the Commission whose report has just been printed as a Parliamentary paper.

The following are the recommendations made by the Commissioners:—

I.—As to Public Elementary Schools.

(*a*) That rudimentary drawing be incorporated with writing as a single elementary subject, and that instruction in elementary drawing be continued throughout the standards. That the inspectors of the Education Department, Whitehall, be responsible for the instruction in drawing. That drawing from casts and models be required as part of the work, and that modelling be encouraged by grant.

(*b*) That there be only two class subjects, instead of three, in the lower division of elementary schools, and that the object lessons for teaching elementary science shall include the science of geography.

(*c*) That, after reasonable notice, a school shall not be deemed to be provided with proper "apparatus of elementary instruction" under Article 115 of the Code, unless it have a proper supply of casts and models for drawing.

(*d*) That proficiency in the use of tools for working in wood and iron be paid for as a "specific subject," arrangements being made for the work being done, so far as practicable, out of school hours. That special grants be made to schools in aid of collections of natural objects, casts, drawings, &c., suitable for school museums.

(*e*) That in rural schools instructions in the principles and facts of agriculture, after suitable introductory object lessons, shall be made obligatory in the upper standards.

(*f*) That the provision at present confined to Scotland, which prescribes that children under the age of 14 shall not be allowed to work as full timers in factories and workshops unless they have passed in the Fifth Standard, be extended to England and Wales.

II.—As to Classes under the Science and Art Department, and Grants by the Department.

(*a*) That School Boards have power to establish, conduct, and contribute to the maintenance of classes for young persons and adults (being artisans) under the Science and Art Department. That in localities having no School Board the local authority have analogous powers.

(*b*) That the Science and Art Department shal arrange that the instruction in those science subjects, which admit of it, shall be of a more practical character than it is at present, especially in the "honours" stage; that payment on results be increased in the advanced stages of all subjects, at least to those now made for practical chemistry and metallurgy, and that greater encouragement be given to grouping.

(*c*) That the examinations in agriculture be made to have a more practical bearing.

(*f*) That it shall not be a requirement of the Science and Art Department that payment of fees be demanded from artisans for instruction in the science and art classes.

(*g*) That in the awards for industrial design more attention be paid by the Department, than is the case at present, to the applicability of the design to the material in which it is to be executed, and that special grants be made for the actual execution of the designs under proper safeguards. That the limits of the building grants, under the Science and Art Department, to £500 each for schools of art and science should be abolished.

III.—Training Colleges for Elementary Teachers.

(*a*) That the teaching of science and art in training colleges, and its inspection by the Science and Art Department, be made efficient, and that arrangements be made for giving to selected students in those colleges greater facilities and inducements for the study of art and science in the National Art Training School and the Normal School of Science at South Kensington, the Royal College of Science for

Ireland, and other institutions of a similar class approved of by the Government.

IV.—Secondary and Technical Instruction.

(*a*) That steps be taken to accelerate the application of ancient endowments, under amended schemes, to secondary and technical instruction.

(*b*) That provision be made by the Charity Commissioners for the establishment, in suitable localities, of schools, or departments of schools, in which the study of natural science, drawing, mathematics, and modern languages shall take the place of Latin and Greek.

(*c*) That local authorities be empowered, if they think fit, to establish, maintain, and contribute to the establishment and maintenance of secondary and technical (including agricultural) schools and colleges.

V.—Public Libraries and Museums.

(*a*) That ratepayers have power, by vote, to sanction the increase of the expenditure, under the Public Libraries Act, beyond its present limit, and that the restriction of the Acts to localities having 5,000 inhabitants and upwards be repealed.

(*b*) That museums of art and science and technological collections be opened to the public on Sundays.

The sixth division consists of special recommendations in regard to Ireland. The first three being (*a*), "that steps be taken at the earliest moment for the gradual introduction of compulsory attendance at elementary schools in Ireland;" (*b*), "that payments be made by the National Board under proper regulations on the results of the teaching of home industries to children, young persons, and adults, as well as in aid of the salaries of industrial teachers;" (*c*), "that systematic instruction be given to primary school teachers, qualifying them to teach the use of tools for working in wood and iron, in the primary schools." The Commisioners make some further suggestions which do not necessitate action on the part of the legislature or of the public authorities.

IMMIGRATION INTO THE UNITED STATES.

Her Majesty's Minister at Washington says, that the immigration into the United States during the last year, ended June 30, 1883, was more than 25 per cent. below that of the preceding year, and 10 per cent. below that of the year before. The total number of immigrants arriving during the year 1881, was 669,431; in 1882, 770,422; and in 1883, 599,114. The total arrivals for the past ten years have been less than 4,000,000, and in no three years preceding had the total ever been much above 1,000,000. The number of immigrants who have arrived in the United States during the last fifty years exceeds 10,000,000. The smallest number of arrivals during this period was, in 1838, when only 38,914 arrived, and it was not until 1842 that the number for the first time exceeded 100,000. As regards the nationality of the immigrants who arrived during the last year, Germans showed the highest number, namely, 191,643, England furnished 79,852, Canada 64,000, Ireland 63,700, Scotland 19,612, Italy 31,715, Norway 21,894, Sweden 34,596, and other countries 92,102. Nearly three-fourths of the arrivals come in at the port of New York. The number of foreign-born persons, residents of the United States, is now about 7,000,000, or nearly one-eighth of the present population. Out of a total population of 5,000,000, New York contains 1,250,000 foreigners. 500,000 of these are from Ireland, and 350,000 from Germany. Pennsylvania and Illinois have each 600,000, and Ohio 400,000. Out of the 7,000,000 of foreign population, 2,225,600 are of German nationality, and nearly 2,000,000 are Irish. The per-centage of arrivals during the last few years shows a large increase from Germany, and a falling off from Ireland. During the last fifty years it is calculated that 3,500,000 Germans have arrived in the United States. Mr. West says that the German immigration generally tends to the Western States, and engages in farming enterprises; and the English and Scotch has the same tendency. The Mormons are still recruited in Wales. The Irish immigrants congregate in the large cities. The German element exercises decided influence in the State of Ohio, as does the Irish element in New York. The Swedes and Norwegians are to be found in the coasting trade navigation; and the Italians take their chance in any line of business which presents itself. French and Spanish immigration are insignificant; and Russian still more so.

ITALIAN CORAL INDUSTRY.

A pamphlet has lately been published under the auspices of the Italian Ministry of Agriculture and Commerce, relative to the coral industries in Italy, and contains some interesting information respecting the coral and its formation. It appears that of late years the most favoured localities for the fisheries have been the waters about the island of Sicily, the sea of Sciacca on the south coast of the island, Trapani, the island of Ustica, north of Sicily, and also the waters about the islands of Corsica and Sardinia, and the bays and seas upon the coast of Algeria. About five hundred Italian ships are engaged in the industry, either upon the Italian banks or upon those of foreign nations, giving employment to about 4,200 sailors. Of these five hundred ships, over three hundred sail from Torre del Greco. The quantity of coral collected annually by the vessels sailing under the Italian flag amounts to 56,000 kilogrammes, valued at 4,200,000 lire. In Algeria 10,000 kilogrammes of coral are taken annually, representing a value of 750,000 lire. Much of this is accomplished by fishermen from Torre del Greco, Leghorn, and other parts of Italy, who have emigrated and established themselves at La Calle and other points on the Tunisian coasts, where with more than a hundred vessels sailing under the French flag, they engage in this industry. In addition to the figures above given, the Spanish ships, about sixty in number, gather along the coast of Spain and elsewhere, about 12,000 kilogrammes of coral, in value about 800,000 lire. From these figures it will be seen that the quantity of coral gathered annually by ships not bearing the Italian flag, amounts to 22,000 kilogrammes, of the value of 1,550,000 lire. This, added to the figures already given as the direct results of Italian fisheries, amounts to 78,000 kilogrammes, valued at 5,750,000 lire, and these figures represent approximately the annual gathering of coal in different seas by Italian and foreign ships, and its value. There are in Italy sixty coral workshops, giving employment to about 6,000 men, women, and children. The men employed earn from 10d. to 3s. 6d. a-day, and the women and children from 8d. to 1s. 8d. At Torre del Greco there are forty workshops, where 3,200 persons are constantly employed, of whom 2,800 are women. The other workshops are situated in Genoa, Naples, Trapani, and Leghorn. A portion of the best coral is sent to England; much of a fine quality to France, whence it reaches Germany and America; but the greater part goes to Madras, Bombay, and Calcutta, and through them to Indo-China and Africa. The author of the pamphlet referred to says that although the profits of the fisheries are great, the condition of the fishermen themselves is "the most miserable that one can imagine."

THE TEXTILE INDUSTRIES OF AUSTRIA.

All the branches of textile industry are represented within the limits of the Austrian Empire, and the stage of development which has been attained in many cases bears witness to the energy and perseverance which have been brought to bear upon the advancement of manufactures.

Regarding cotton goods, there is less reason for approval than with respect to other branches of industry. On the other hand, the linen yarns produced are of excellent quality. The number of spindles at work in this trade is 350,000, and the manufacture of linen piece goods forms an important element in the industrial activity of Austria.

Woollen goods are largely made for men's and women's use, as well as for upholstery purposes.

Vienna is the centre of the silk trade, but some factories are established in the provinces. It would seem (according to a French paper) that the Austrian manufacturers purchase in Lyons certain articles and colourings which they cannot produce, and by mixing these amongst their own manufactures, give to the latter a character which they do not intrinsically possess. The same may be said of trimmings and buttons. There are 12,000 lace workers; and boot elastics are made in large quantities.

Correspondence.

WATER REGULATION.

Mr. J. S. Watson's estimate (*Journal*, March 14th) which provides an 18 horse-power engine, moving 450 cargo-tons 49½ miles daily, but ignores return trips, analyses thus:—

Motor (engineman, coal, oil, incidentals, and hire of machinery)	·027d.
Vehicles (boat-hire, crew-wages and incidentals)	·071d.
Profit	·005d.
	·123d.

The first only of these entries seems to correspond to ·034d. per ton-mile, on the Aire, which flows past pit mouths.

It does not appear whether Mr. Watson expects to pass 450 cargo-tons at one lockage; but if so, a mile of suitable canal cannot be made for £15,000. Mr. Conder, C.E., thinks that one for a 180-ton boat would cost that (Q. 2,489). The expediency of buying existing canals seems often doubtful. They were made when work was cheap, but engineering was timid, and are puny and indirect. Their curves would hardly suit General Rundall's 150 ft. boat.

The engineer of the Warwick canals, says (Q. 506), "I do not know that there would be a very large traffic right through from London to Liverpool."

Totals and averages are risky; but the following may be approximate. It rests on Continental precedents, but allows for higher wages here and for our national habit of loading useful works with costly preliminary struggles:—

Motor (as above)	·050d.	·160 boat-costs.
Vehicles (as above)....	·085d.	
Profit and management	·025d.	
Interest on £20,000 at 4¼ per cent.	·227d.	·280 way-costs.
Upkeep and management, at £200	·053d.	
	·440	
Add 10 per cent. contingencies	·044	
	·484	

Even if another 10 per cent. were added, the result would be less than half the present rail-rate.

Loss of cargo-space makes steam dear for light work. The "Baxter" experiment seemed to show that mules hauled a 246-ton boat for less. The cheapest ordinary unit of dispatch may prove to be two boats, one of them engined. The above assumes a normal annual traffic equal to that on the Willebroek Canal (Brussels to tide), say 900,000 tons a mile.

The interest provided corresponds to the average railway dividend; but if half the cost of works were lent by Government to local trusts, $4\frac{1}{4}$ per cent. would provide for its gradual redemption, and railways would feel the stimulus which cheap transport would give the country before having to compete with the lowest rates. When a local trust had repaid the first State loan, the Government might lend the other half at $4\frac{1}{4}$ per cent., but always with the right to accept 3 or $2\frac{1}{2}$ per cent. interest only, or even to remit that. In France, State aid was conditional on local co-operation, and each river basin was specially studied.

Unlike a railway, a waterway is for all vehicles, whether owned by a company or by individuals. The adoption of steam creates a parallel to a county road, open to traction engines as well as carts; and this new departure suggests special legislation, to protect the bye-trader and the public.

I regret that others have not joined in the correspondence begun by the two distinguished Indian engineers, whose main ideas I heartily follow. Ireland has certainly suffered from abortive attempts to sever those Siamese twins—navigation and drainage.

If each of our river-basins had water wardens, reporting to a "Waterstaat," the capabilities of rainfall might be gradually realised; and dams, of Settons or Gouffre d'enfer type (made, perhaps, by convicts), might enrich our valleys.

Meanwhile, public ideas are widening; land is cheapening; and the national rate of interest is falling.

WALTER M. J. CAMPBELL.

19th May, 1884.

Notes on Books.

PRACTICAL GUIDE TO PHOTOGRAPHY. London: Marion & Co. 1884.

This guide seems to be principally intended for the use of that numerous band of amateurs who have been led to take up photography by the recent improvements in photographic processes, improvements which, as is well known, have rendered the art one of the easiest known. Though published by a firm of photographic dealers, the book is not in any way a price list; it is what it pretends to be, a manual of the art, and beyond an occasional reference to the fact that some special piece of apparatus is produced by the publishers, or a casual statement as to the qualities of a particular "brand" of plates, there is really nothing of an advertising character about it. It assumes that (as is, of course, generally the case) the amateur photographer prefers to get everything he can ready-made, that he gets his plates ready prepared, and his solutions ready mixed. It also assumes (as is unhappily not always so true) that his selection of apparatus need not be limited by want of funds, and that he is in a position at once to possess himself of all the ingenious (but not absolutely necessary) appliances for facilitating the production of photographic pictures which dealers are so constantly producing, and photographers have so often to do without. The make-shift devices to which many artists are rendered are ignored by the authors; but apart from this excusable weakness, they give full direction for all the various manipulations required in the interesting art with which the manual deals.

SCIENCE AND SINGING. By Lennox Browne, F.R.C.S. Ed. London: Chappell and Co. 1884 8vo.

This essay is founded on a lecture delivered before the Society for the Encouragement of the Fine Arts. The author, after pointing out the necessity for scientific knowledge, as shown by instances of unscientific teaching, draws attention to the advantages of laryngoscopic self-observation of the mechanical art of singing as a groundwork of its development as a fine art. He also treats of the importance of pure air, and the danger to the voice of the impure air often breathed by singers. The concluding portion of the essay is occupied with tone production, and the various questions concerning the registers and the need of rest when the voice is breaking.

General Notes.

EXHIBITION OF GOLDSMITHS' WORK.—Information has been received from the Foreign-office, through the Science and Art Department, that an International Exhibition of Gold and Silversmiths' Work, Jewellery, and Bronzes, will be held at Nuremberg, in the summer of next year. The Exhibition will be held under the patronage of H.M. the King of Bavaria, and will be held in the Bavarian Museum of Industrial Art of Nuremberg, from 15th June to 30th September, 1885. Steps have been taken to ensure the admission free of duty of objects sent for exhibition, and for the return duty ree of objects which remain unsold. Measures will also be taken with a view of obtaining a reduction in the carriage of objects sent for exhibition. Applications for space and all communications should be addressed Bayrisches Gewerbe Museum, Nuremberg.

TAHITI.—The *Industriel Français* calls attention to the natural and climatic advantages which are enjoyed by the above island, the connection between which and France is a feature in the scheme of French acquisitions in the Pacific. For many years business was to a great extent monopolised by a few houses, but competition has now greatly increased, with the result of a diminution in the profits of trading. Special importance is attached to the position Tahiti will probably attain in the future, when the Panama Canal is completed, and the efforts of the French Government and of the mercantile community have succeeded in obtaining for French commerce a higher position than it now holds amongst the general trade of European nations in the Pacific waters. The necessity of improved harbour accommodation at Tahiti is likewise dwelt upon.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, eight o'clock:—

MAY 28.—"Primary Batteries for Electric Lighting." By I. PROBERT. W. H. PREECE, F.R.S., will preside.

APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings:—

MAY 29.—"Some Economical Processes connected with the Woollen Industry." By Dr. WILLIAM RAMSAY.

INDIAN SECTION.

Friday evenings:—

MAY 30.—"Street Architecture in India." By C. PURDON CLARKE, C.I.E. This paper will be illustrated by means of the Oxy-Hydrogen Light.

CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Sixth Course will be on "Fermentation and Distillation." By W. N. HARTLEY, F.R.S.E., &c., Professor of Chemistry, Royal College of Science, Dublin.

LECTURE III.—MAY 26TH.

Alcohol produced by mould. Its existence in rain, river, and sea water. Its presence in the soil. The process whereby alcohol is separated from water. The simplest form of distillation by a still and worm. The boiling points of water and alcohol. Boiling of mixtures with low boiling points by means of vapours with high boiling points. Pot stills and patent stills. Langier's still. The principle of Coffey's still. Its mode of action described. Improved forms of still. Alcoholic beverages and other products.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 26...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. W. N. Hartley, "Fermentation and Distillation." (Lecture III.)

Surveyors, 12, Great George-street, S.W., 8 p.m.

Geographical, University of London, Burlington-gardens, W., 2 p.m. Annual Meeting.

TUESDAY, MAY 27...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Gamgee, "The Anatomy and Physiology of Nerve and Muscle." (Lecture IV.)

Medical and Chirurgical, 53, Berners-street, Oxford-street, W., 8½ p.m.

Civil Engineers, 25, Great George-street, Westminster, S.W., 8 p.m. Mr. George H. Stayton, "Wood Pavement in the Metropolis."

Anthropological, 3, Hanover-square, W., 8 p.m. 1. Mr. Theodore Bent, "Notes on Remains from Cemeteries in the Island of Antiparos." 2. Mr. H. O. Forbes, "The Koeboes of Sumatra." 3. Dr. J. G. Garson, "The Osteology of the Koeboes of Sumatra."

East India Association, Westminster Town-hall, S.W., 3½ p.m. Dr. G. W. Leitner, "The Indigenous Elements of Self-Government in India, especially in the Panjab, and in matters of Education."

WEDNESDAY, MAY 28...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. I. Probert, "Primary Batteries for Electric Lighting."

Geological, Burlington-house, W., 8 p.m. 1 Dr. C. Callaway, "The Archæan and Lower Palæozoic Rocks of Anglesey." With an Appendix on some Rock-specimens, by Prof. T. G. Bonney. 2. Lieut.-Col. H. H. Godwin-Austin, and Mr. W. Whitaker, "The New Railway-cutting at Guildford." 3. Mr. Herbert Green Spearing, "The Recent Encroachment of Sea at Westward Ho, North Devon." 4. Mr. George Varty Smith, "Further Discoveries of Footprints of Vertebrate Animals in the Lower New Red of Penrith." 5. Mr. R. Kidston, "The Fructification of *Zeilleria (Sphenopteris) delicatula*, Sternb, sp., with remarks on *Ursatopteris tenella* and *Hymenophyllites quadridactylites*."

Royal Society of Literature, 4, St. Martin's-place, W.C., 8 p.m.

THURSDAY, MAY 29...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Chemistry and Physics Section.) Dr. William Ramsay, "Some Economical Processes connected with the Woollen Industry."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Society for the Encouragement of Fine Arts, Conversazione at the Galleries of the Royal Institute of Painters in Water Colours, Piccadilly, 8 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Prof. Dewar, "Flame and Oxidation." (Lecture VI.)

Civil Engineers, 25, Great George-street, S.W., 9 p.m. President's Conversazione at the South Kensington Museum.

FRIDAY, MAY 30...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Indian Section.) Mr. C. Purdon Clarke, "Street Architecture in India."

United Service Inst., Whitehall-yard, 3 p.m. Mr. R. Cust, "The Railway over the Sahara from Algeria to the Senegal, and the Destruction of Colonel Flatters."

Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m. Monsieur E. Mascart, "Sur les Couleurs."

SATURDAY, MAY 31...Royal Institution, Albemarle-street, W. 3 p.m. Prof. Bonney, "The Bearing of Microscopical Research upon some large Geological Problems." (Lecture III.)

Journal of the Society of Arts.

No. 1,645. Vol. XXXII.

FRIDAY, MAY 30, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CONVERSAZIONE.

The Society's Conversazione is fixed to take place at the International Health Exhibition, South Kensington, on Wednesday evening, 2nd of July.

Further particulars will be duly announced.

CANTOR LECTURES.

The third and last lecture of the sixth course of Cantor Lectures was delivered by Prof. W. N. Hartley, on Monday evening, 26th inst., the subject being "Fermentation and Distillation." The lecturer pointed out that alcohol existed in rain, river, and sea water, and explained the process by which alcohol is separated from water. He then described the simplest form of distillation by a still and worm, and showed the improvement that had been made in the forms of still.

On the motion of the Chairman (Dr. Mann), a cordial vote of thanks to the lecturer was passed unanimously.

The lectures will be printed in the *Journal* during the autumn recess.

FOG SIGNALS.

An abstract of the various Codes and Suggestions for Fog Signals, submitted to the Committee of the Society of Arts on Collisions at Sea, has been printed, and copies can be obtained on application to the Secretary of the Society of Arts.

EXHIBITION OF THE UNION DES ARTS DECORATIFS, PARIS.

The Council of the Society Arts desire to bring under the notice of English manufacturers the Exhibition of Art Industries which is being organised by the Central Union of Decorative Arts, Paris.

This Exhibition is the third of a series of Technological Exhibitions of Art Industries formed by the Union. That of 1880 was specially devoted to Metal Industries; that of 1882 to the Industries connected with Wood (Furniture), Textile Fabrics, and Paper. The forthcoming Exhibition will be devoted to Stone, Wood (Building), Ceramics, and Glass; and will be held in the Palais de l'Industrie, in the Champs Elysees, Paris, from the 1st of August, to the 21st November, 1884. It will comprise—

A Modern Exhibition, and a Retrospective Museum.

The heads of the classification to be adopted in the Exhibition are as follows:—

Group I.—Stone (Section 1, Natural Stone. Section 2, Artificial Stone. Section 3, Precious Stones and Gems. Section 4, Designs and Models.)

Group II.—Wood (Section 1, Natural Woods. Section 2, Decoration and Imitation of Wood, Lacquer Varnishes, &c. Section 3, Designs and Models.)

Group III.—Pottery and Glass (Section 1, Ceramics. Section 2, Glass. Section 3, Enamels. Section 4, Mosaics. Section 5, Designs and Models. Section 6, Application of Photography to Decoration.)

Further particulars can be obtained on application to the Secretary of the Society of Arts.

EXAMINATIONS, 1884.

The list of successful candidates in the examinations for the present year has been printed, and is forwarded to the Institutions in Union with the present number of the *Journal*. Copies will also be sent to the various committees for the successful candidates.

HEALTH EXHIBITION PRIZES.

Mr. J. Sargeant Stacey has placed the sum of £20 at the disposal of the Council of the Society of Arts for a prize to be offered in connection with the International Health Exhibition, and it has been decided to offer the prize for the best exhibit in Class 30 (objects for internal decoration and use in the dwelling; fittings and furniture).

Proceedings of the Society.

INDIAN SECTION.

Friday, May 9, 1884; Sir LEPEL GRIFFIN, K.C.S.I., in the chair.

The CHAIRMAN, in introducing Dr. Leitner, said it was now twenty years since he went to India as Principal of the Lahore Government College, when there was, indeed, a department, so called, of popular education in North India; but it was not popular education in the truest sense of the term. Dr. Leitner, first of his Department, understood that for education to be popular it was necessary for it to enlist in its favour the sympathies of the people, and these could only be secured by drawing to the side of progress and education the ruling classes—the chiefs and the gentry—not only those, but also the priestly classes; in India, as with all Orientals, religion and knowledge went hand-in-hand. The success had been conspicuous, as was proved by the establishment of the Oriental University of North India, at Lahore, which had been been founded to encourage popular education, and with a view not only of fostering the ancient classical languages of India, but also of creating a new vernacular literature, and being the germ of education for the people, and by the people.

The paper read was—

THOUGHTS SUGGESTED BY THE PAST AND PRESENT CONDITION OF INDIGENOUS EDUCATION IN INDIA.

By DR. G. W. LEITNER.

EXTENT OF INDIGENOUS EDUCATION.

In thanking the Chairman for his kind remarks, I would preface the communication which I intend to submit to you by the observation that the subject is not entirely new to the Society. In 1875, in a paper on the Roman Urdu question, from which I venture to dissent, with due deference for the authorities who are in favour of it, I gave expression to the following remarks, which may be deemed to be some sort of introduction to this paper:—"I find a panacea for the existing evil of ignorance in the development of the vernaculars through their legitimate sources—the Persian, Arabic, and Sanskrit—and in the co-operation of those very classes whose Oriental learning, and consequent influence, have been ignored under our present system." This was true then; it is not quite so true now, because I believe that the intention, and to a certain extent the practice, of the present Government is in favour of recognising indigenous education that had so long been ignored or persecuted. Whether they recognise that education on its own lines, which are the only ones that are likely to lead to success, is another question; but that the intention is thoroughly good for a hitherto neglected and most important agency of education, there can be no doubt. I went on to say; "Whilst, however, less than 100,000 are known to come under instruction (in the Punjab Government schools) there are many hundred thousands whom our system ignores. These learn, if Mohammedans, Arabic and Persian; or if Hindus, Sanscrit for religious purposes. Besides these, there are the traders, shawl-weavers, bankers, and others, who learn a peculiar kind of ciphering traditional to their occupation. The Sikhs learn Gurmukhi, the character in which their sacred books are written." Such a very strong influence had indigenous education on every class of India, which it endeavoured to train for the purpose for which either the Indian legislator or traditional circumstances had assigned it, that there was not a trade in India which did not possess a literary or a quasi-religious basis.

I will pass round for your inspection an "Analysis" of the shawl writing, which explains the fabrication and the use of colours in that manufacture. The volume is part of a series of what is called "a selection from the records of the Punjaub Government," showing that not only was there a technical but also a literary and linguistic basis to the trade of shawl-weavers, carpenters, masons, and others.

It is now known that there was scarcely a single village in which there was not at least one school for the denomination of the bulk of its inhabitants; that all the persons connected with the village were, to a certain extent, but no further—and that was precisely the beauty of the indigenous system—acquainted with whatever of religion and whatever of learning bore on their own work. This is very different indeed from the present state of things, which reminds us very much of what there is in France, where you will find in a recent book that you may have seen, that the prize pupil of a school, fought for among masters, gradually finds himself encumbered with an amount of information, and medals which his shabby coat and other surroundings do not set off to advantage, and finally vanishes into one of the French penal settlements, after trying everyone of those various occupations which attract educated despairing men, including that of sedition.

Caste.

The Indian legislator sought, above all, to make everybody satisfied with his work in life. And here I may point out that there is a great misconception existing on the subject of caste. It is not as class in Europe weighing on class, and where the way upwards has to be, more or less, forcibly broken through by superior merit, or luck, or intrigue; but the caste system seeks perfection within itself, and the lowest outcaste—the sweeper — the "mahtar," humorously called "the prince" —has his prototype in the House of God, where he performs his functions with a golden vessel. Now, this outcaste would be as much degraded by mixture with a class above him as that higher class would be degraded. I believe it is perfectly possible to conceive in Europe that if a king, whatever his origin, married a peasant, the relatives of the peasant would feel honoured. Now none of our great Chiefs who belong to the "kalal," or wine-selling class, would be allowed to intermarry with the lowest Brahmins, so far as social position is concerned; and it seems to me, that after many years of struggle, as regards social questions, we may yet arrive, in Europe, at conclusions that may not be altogether different from those of the Indian legislator, when he sought, within certain limits, and allowing certain latitudes, to make each class content.

I should be sorry to see the experiment fail of a Trade University, where carpenters and others would be brought up to consider there was nothing more glorious than the lives of illustrious carpenters and other artisans, and nothing better than to do their own work well, a view which may perhaps be impressed on the British workman of the present time, who seems very often to take his work rather easy.

One great advantage of the native system was that each man had a character to keep up, and would not disgrace himself. The village watchman, for instance, as he was—not the policeman with yellow inexpressibles, as he now is—was part and parcel of the village community, and so with the Maulvi, or other indigenous and often hereditary teacher, who dared not commit at any rate a great wrong, whereas the stranger who is imported now may do anything, as long as he pleases his official superior. We have destroyed the real native public opinion, which alone keeps teachers and officials in check. As to the greater safety of life and property, which our rule is supposed to have given, although the European is safe, it would be a bold assertion to say that a native is more safe than he was. The European is safe from plunder because he carries nothing about him that could be of any use to the plunderer. His clothes would not suit a Thug, or other native robber; his cheques could not be cashed; his pots and pans might defile the capturer's caste; he rarely carries jewels or gold mohurs about him, as a native traveller might, and there would moreover arise a hue and cry over the robbery that would not be worth the game. But it is a different question whether such a state of things now exists as is described in the days of Runjeet Sing, when it is currently stated that a maid could travel at night decked in jewels, and be perfectly safe.

Indigenous Literature.

I do not know that there is any subject in which we have not quite as much to learn as to teach in India. There is no science, even including engineering, in which a receptive mind may not learn much in India. In medical knowledge I am convinced that, although as far as surgery is concerned we have undoubtedly gone very much ahead of our Indian fellow-subjects, yet in the use of the drugs, and often in the theory and practice of medicine, there is much to be learnt from our Indian colleagues, for, after all, the leading European physicians would admit that our medicine is still in the empirical stage. I have been very much struck with certain remarks I heard made, only a few days ago, in Edinburgh, by the masters of the science in Europe—Virchow, Helmholtz, and others, who certainly do not share the impatient disregard of native systems which our more young and ardent medical men, who leave Europe with the fulness of newly acquired knowledge, are apt to show in dealing with indigenous fellow-practitioners. Instead of identifying in that branch of learning, and in every other, the traditional possessors of the lore with the cause of progress through the comparative method, and of identifying their children with a progressive profession, very much to the good of society, a class of men that has, as a rule, little hold on the confidence of the people is assuming the position of native doctors; whereas some members of that class would be better employed in earning larger sums by making better sweetmeats, or by tanning the hides confided to their care with the most modern appliances. Indeed, barring certain mechanical appliances, there is scarcely a subject, except that of sculpture—the delineation of the human figure, not architecture—in which we, as feeble imitators, after all, of the Greeks—can teach anything to India without having something to learn in return.

Greek Influence on India.

Once Europe endeavoured to discharge that duty in a manner which is not without its lesson on this occasion. In those classical books that we read at school, perhaps admire, and generally forget, there are references to Greek influence on India which are suggestive to ourselves, though we may not fully subscribe to the statement of Plutarch, who, after all, echoed the opinion of his contemporaries, that Alexander the Great—who preceded us in the conquest, and I hope in the true indigenous civilisation of India—is supposed to have permeated India with Greek arms, Κατέσπειρε 'Ασίαν 'Ελληνυυ κοῖς τέλεσι, a quotation to which Sir Edward Fry first drew my attention nine years ago.

The word "Asia" being used there, may perhaps lead you to believe that the whole of that Continent is vaguely meant; but we find that when Alexander's soldiers would not go beyond the Punjab, one of their chief grounds of complaint was "You have brought us here to make Asia Greek, but you are turning us Greeks into Asiatics."

Now, considering that where they spoke was the Punjab, I do not thing we are wrong in assuming that the word "Asia" used in the above narration by Arrian, a most accurate historian, in this instance means anything but India. We find that Aelian and others considered—I should be sorry to say they wrongly considered—that so great had been the Greek influence on India, that the Indians learnt to sing Homer in their own vernacular. If you pay attention to these photographs of sculpture found in India, of which I hand round specimens, you will be convinced that some of them have certainly been made by Greek sculptors, or by their Indian pupils. Indeed, there are striking analogies between the Indian and Greek mythologies, and it is a question how far the worship of idols may not have been introduced or promoted by the Greek invasion, the Hindus seeking to represent the supernatural by the exaggerated natural, and the Buddhists by the refined human. I might add, that Alexander receiving an Indian deputation, shortly before his death, congratulated himself on the fact of having recovered so many sculptures that Xerxes had taken from the Greeks and distributed all over "Asia." The lesson which I would draw is in the statement of the soldiers: "You have brought us to 'Asia' in order to make Asia Greek, but you are making us Greeks into Asiatics." If we are to identify and closely knit that Asiatic civilisation and all its treasures with ourselves in the maintenance of good government, and for the benefit of India and of science, then I think we should rather incur the reproach addressed to Alexander. Going as we must go to India, with the object of giving India the best of our associations, and the treasures of our language, as a complement to what exists, I think it would be infinitely better if the reproach could be addressed to us which amongst many reproaches could not now be addressed, that we have in any way become Oriental. If we were to become more Oriental than we are, I think we should make many more English in the best and truest sense. I do not know whether this was in the mind of the eminent Indian statesman and historian of the Punjab who now occupies the chair, when he wrote, as I believe he did, a passage in a "Review of Education in the Punjab," which I find in a Parliamentary report to the following effect. Whoever wrote it I think had imbibed some of the true spirit of sympathy which is to make India more English by making ourselves more Indian :—

English Education in India.

"Neither the English language nor literature is taught upon any scientific or intelligent system, and the success of English education, as a consequence, has not hitherto been marked in the Punjab. Nor has the system which produces few scholars been more successful in producing gentlemen. The Lieutenant-Governor desires that the department take especial care that the good manners natural to Oriental youth are not lost at school. This matter has hitherto been neglected. If the result of sending boys of good family to school is, as is now often the case, that they return pert, conceited, and studiously rude and familiar, - it is no wonder that parents desire to educate their children at home. English education is not a desirable thing if it only signifies sufficient acquaintance with the English language to write and speak ungrammatically, sufficient acquaintance with English literature to be shallow, and with English history to be insolent. English education is to be penetrated with the spirit of the great English authors, to imbibe some portion of their strength and beauty, and nobility, and gentleness, and wisdom; to mould the life and character upon the models they have furnished. This is the standard of education to which the department must endeavour to rise."

There is one other preliminary remark which I hope I may be allowed to make for fear of being misunderstood, viz., that if I criticise I do not mean to intimate that there are not a great many subjects on which I might not enlarge in terms of praise; probably no other country has done more for a foreign country than England has done for India, but "Excelsior" should be written on our standard, and if I ask for more sympathy, I do not assert that none already exists. I think that we can all cordially agree in this, that there is ever both room and desirability for more knowledge and sympathy.

Practical Philology and Indigenous Systems of Education.

To deal satisfactorily in the course of an evening's lecture with the indigenous systems of education of a population so vast and varied as that of India, would at first sight appear to be as hopeless a task as to give a lecture on the "Education of Europe." To have announced my communication as the possible forerunner of a series, might have reduced my audience to a few officials and specialists interested in the subject, while there is no branch of science, and no section of an educated public, which is not directly interested in a careful inquiry into matters apparently so removed from our intellectual horizon. Indeed, to take up one point only—that of an ethnographical and historical grammar—we can learn lessons from India which would be of the greatest importance in our relations not only with Eastern races, but also in our political and literary intercourse with the nations of Europe, in which misunderstandings often arise in consequence of the inadequate apprehension of shades of meanings in words and ideas common to them all. There is a task which yet remains for our philologists to undertake. That science has remained too much a matter of technical or scholastic skill instead of being brought into daily life. Yet language is of the very essence of everything that is expressed as regards daily life. So little have our greatest masters of the science attended to the historical, the traditional, the ethnic, and other meanings of words, that even in the relations of Frenchmen and Englishmen, misunderstandings arise which a more practical and, if I may say so, a more sensible method of dealing with the subject of language might have obviated. In Oriental languages we constantly have to deplore this. I may quote, as an instance, our translation, in Arabic, Turkish, Persian, and Hindustani missionary works, of such a word as "salvation" by "khalás," which means "getting out of a difficulty"—the Gnostic heresy; whilst the orthodox apprehension of the word would be that Christ *was* crucified. I have only hinted at one of many, in fact innumerable instances, in which error arises from the want of treating the science of language from an ethnographical and historical point of view.

The Genius of Europe and India.

Latet dolus in generalibus, and yet I may have to make general statements without having the opportunity of proving them. A further difficulty arises from the fact that the modern genius of Europe is analytical, whilst that of India has remained synthetical. Our danger, therefore, is, that we are often apt to criticise before we construct and to improve away, instead of improving those survivals that do not answer every modern requirement. *Ex oriente lux*, and whilst the Indian sun has his spots, which demand a careful scientific analysis, he can still throw, it may only be a side-light, or even a half-light, on questions that make all mankind kin in a common heritage of knowledge. I would even solicit your generous sympathy with the errors that incrustate the ancient civilisation of the great dependency entrusted to the care of an Empire on which the sun never sets.

Our immediate task is lightened by two considerations—the first, that, whereas the analytical spirit of Europe has constantly to seek a compromise with the abstract, generalising and impersonal phraseology, in which has to find expression, the East gives its thoughts in language that is concrete, personal, and dramatic, and, therefore, nearer to nature and to facts before they are grouped under one idea, as is the process in the West. Even the apparently far-fetched Oriental allegories are, after all, only pictures, whilst the subtle and bold reasoning that has forestalled several of our philosophical acquisitions often possesses the simplicity of a fairy tale, when studied by the light of customs, traditions, and local natural phenomena. For instance, a careful inquiry would show us in the words, say, for "mass" a peculiar tribal combination in some languages; in other languages, even such simple words as "up" and "down," would indicate the topography of the country in which they are used; words used for numbers are often connected with gestures which alone explain them.

The second consideration is that the history of European education offers a parallel to the "Indigenous Education of India." The study of Latin in the Middle Ages may be compared with that of Sanscrit. Hebrew is scarcely different from the more comprehensive Arabic, and the Rabbinical methods, in their often grotesque though ever instructive details of exegesis, greatly resemble those of Maulvis or Mahommedan learned priests. Persian holds the place in diplomacy and culture from which French has scarcely been dispossessed; even the development of Indian vernaculars from the above sources may be compared to the process that has given a national literature to the various countries of Europe, founded on the kindred faiths of Judaism, Christianity, and, in the south-eastern corner of our Continent, Mohammedanism; on the same basis of Roman laws, and, more or less, on a common civilisation. The comparatively homogeneous nations of Europe have, moreover, a classical and modern literature in which they all participate; and the 254,000,000 of Indians, who are far more divided by differences of race, creed, and caste, have also a common educational basis, in Sanscrit learning for Hindus; in Arabic learning for Mohammedans; in Persian literature for men of culture of all denominations; in Urdu for native officials, and, if I may seek for a specimen of a vernacular literature, in Gurmukhi for the Sikhs.

As regards so-called English education in India, it is, as yet, unfortunately, too bureaucratic and foreign an importation to belong to my subject this evening. I advocate its extension on both practical and literary grounds, as a complement to indigenous education, but not as a substitute for it, for then it becomes a mere word-teaching, unconnected with surrounding associations that alone can give it life.

Instances of the Misapplication of European Ideas.

I know a case of the grossest ingratitude justified by the ungrateful man saying, "Well, I am the Brutus of my country." Another person, "cutting" an examination for which he had been trained at the public expense, explained his sudden and dishonest departure on the ground of his wishing to become "the Messiah of India." This he hoped to achieve by studying commerce at Calcutta, where he became the sub-editor of a seditious paper. Take the case of Surendra Nath Banergi, who was imprisoned, rightly or wrongly, for contempt of court, referred to in Anglo-native papers as the beginning of an era of regeneration for India, just as Christianity dated from the advent of Christ. Nothing but a smattering of English, now the merest word-teaching, could, in my humble opinion, have led to such illustrations.

I am afraid I have already taxed your patience by this long introduction, and I will now address myself to give an account, as brief as I can make it, with any justice to the subject as well as to your forbearance, of the principal features of the indigenous educational systems among Mohammedans, Hindus, and Sikhs, including the ruling, the learned, the commercial, and the agricultural classes.

Buddhism at Home and Abroad.

Before doing so, I should like to say one word about the corners of India round which the Buddhists still cling, whereas from India they are expunged. The question of Buddhism, unfortunately, I think, has received too fashionable a prominence lately in English circles, and I was very glad to find in a lecture by Professor Max Müller on Buddhist charity, the statement that he was not dealing with any fancy Buddhism, esoteric or exoteric, such as seemed to engross a section of society, but with historical Buddhism. Buddhism, or the fringe of Buddhism, in Lahul, Spiti, and Burma is a very apt illustration of indigenous education. Every man and woman can read. This is due to education being a religious duty, and being in the hands of the priests; whether all can write is another question. The principal lesson of Buddhism, if I may be allowed this digression, is pity for all that has life. It looks upon even the worst of animals as erring brethren to whom sympathy should be shown. Its advantage is to dissipate that fear of death which I believe is the great curse of even those European nations that face death on the battlefield with the greatest fortitude. Another advantage of Buddhism, so far as I have seen it illustrated in the countries which I have visited—which are Middle, Southern, and Little Thibet—is that of bringing to bear the idea of pity on every relation of life. I should be very glad indeed were it possible for me to say that I know of any other country in which people are so honest, so truth-speaking, and so forbearing as are the Buddhists of Middle Thibet; where I have seen the nearest approach to the Christian injunction of giving one cheek when the other was struck—not that I have ventured on the experiment. The ease with which the Buddhists seem to bear privations, the care which they take of life, and yet the placidity with which they meet death, are lessons far more important, in my humble opinion, than those communications in excellent Yankee-English which are addressed through the ceiling to the esoteric school of Buddhists from "the brethren" in Thibet, of whose existence, while I was at some of the principal monasteries in Middle Thibet and elsewhere, I never heard at all.

Piety and Knowledge are One.

With all denominations piety is the basis of knowledge which, whether religious or secular, is treated as one and indivisible; a view that has insured the dissemination of education in India, unchecked by the dualism which threatens to dissociate religion from science in Europe. Taking the Punjab as a specimen province, respect for learning was its redeeming feature. All classes and sects vied with one another in preserving, and adding to, educational endowments. There was not a mosque, a temple, a Dharmsala (Sikh Hospice), that had not a school attached to it. Religious susceptibilities were consulted, by forbidding Hindus from learning the Koran when they attended a Mohammedan school for instruction in Persian, the official language. Elsewhere—to quote from Ludlow's "British India"—"In every Hindu village, there was not a child, except those of the outcasts, who was not able to read, to write, or to cipher."

Distribution of the "Three R's."

This is not quite correct. Some sections of the community can read, others can write, others can cipher, some can read and write, others write and cipher, others read and cipher; therefore the Census returns on this question must be taken with a grain of salt. The questions put were such as are couched in the peculiar Anglo-Urdu idiom, which is becoming almost a literary language. "*Can* you read or write?" is somewhat different from the ordinary question put in a Native State: "Are you *read?*" If that question were, for instance, addressed to a grain dealer or Mahajan, he would say "no;" because he is not a "read" or a "learned" person, and his not being able to read would mean that he could not read Hindi, or Sanskrit, or perhaps Persian. Yet the man can read something: what he can read is his own writing, which is the Mahajani writing. Even a Hindi or Nagari-reading person might also answer a question of the kind in the negative, yet he could read, and I have no doubt could also write, Hindi. At any rate, he could read his own writing, and that of his commercial correspondents. Different as the various specimens of commercial handwritings all over Upper India may appear to be, which I am now handing round for your inspection, they form a basis of elementary instruction which our official Educational Department has ignored. Again, if a woman were asked, as in the late Census, can you read *and* write (there was a note added that if a person could not do both, the answer should be "no.") she would say no, because no respectable woman will admit that she can write in Northern India. Very many more women than we think can read their religious books, and are indeed often proficient in poetry; but to be able to write is an accomplishment of the superior *hetairae*, and therefore would not be admitted by respectable women, except those who attend the Government female schools, and who are known to be able to write, unfortunately for themselves, and unfortunately for the spread of female education. Again, if a man were to ask a teacher in a Koran school, "can you understand the Koran?" the question at once implies a proficiency in the knowledge of the exegesis connected with the placing of the Arabic vowel points, and an ordinary priestly teacher or Mullah would not claim such knowledge. It would be very much like the question addressed to the Ethiopian of Queen Candace, "Dost thou understand what thou readest?" whose reply was, "How can I, unless some man should guide me." If an English Bishop were to go to an ordinary Sunday-school teacher, and ask him, "Do you understand the meaning of this passage?" the chance is that he would say, "No;" although, in a kind of way, I dare say, the teacher would understand, by his surrounding associations, by the prayers he is supposed to offer, and by the religious periodicals he reads, something or other of the meaning of the passage. So that a question like the above might lead to a mistake, unless the inquirer has a knowledge of surrounding circumstances. In fact, there was a larger proportion of persons who could read before the annexation of the Punjab, than there are now who cannot read after twenty-eight years of wasteful expenditure on the administrative portion of the Educational Department. In Hoshiarpur, for instance, there was one school to every 19·92 males. In Jullundur there was one to every 20·69. The girls were also instructed, though in reading only, writing being deemed an unwomanly accomplishment, because of the temptation to write a love letter. However, as it is the religious duty of a husband to teach his wife, and of a brother to teach his sister, a duty of course which is not always fulfilled, and which has not been fulfilled since the decay of the religious spirit in India to the same extent as before, the girl learns to write by just nestling up to her brother when he is engaged at home in that occupation, and by looking over his shoulder, and picking up what she can. To say, therefore, that women in India are absolutely ignorant of writing is not correct. There are some very superior women indeed, educated in their own way. A year after we had taken the province of the Punjab, a Sikh published a book on the illustrious women of the world, and pointed out that with such examples, and under the rule of Her Majesty the Queen Victoria, there was no reason why native women should not feel encouraged. Now, if there had not been a reading public among Sikh women, I do not think he would have published this book.

There are now, according to the last returns, only about one per cent. of the population under instruction, in both Government and indigenous schools. This is due to the decay of the religious feeling, the neglect of the traditional learned professions, including that of the teacher, the monopoly of education by the office-seeking community, and the resumption of a large number of rent-free tenures, formerly devoted to the support of teachers.

The Indigenous Teacher.

In the Punjab, I am glad to find that the Lieutenant-Governor has suggested "that much may be done towards developing and improving primary schools by granting small areas of land revenue free, and organising collections of grain at harvest time for their support." If this example were followed elsewhere, there might be a prospect of the revival of mass education; but so long as the native priesthood is not encouraged to resume its traditional position as teachers in various branches of knowledge, so long will intellectual darkness practically continue to reign over India as a whole. As regards the quality of these teachers, including the fakirs, who have been the chief means for the popularisation of religion, irrespective of caste, the Right Reverend T. V. French, D.D., Bishop of Lahore—whose opinion on the subject of fakirs is not likely to lean on the side of undue partiality in their favour—deposed in his evidence before the recent Education Commission, that "some of the best teachers in the world, I should think, are the Hindu fakirs, Sanyassis, Jogis, and the like, doing Guru's work; but they teach nothing at present except their own philosophies and religious systems."

There is not the least doubt that in the constant effort made by the indigenous teacher to illustrate his lessons by the natural, the concrete, the objects which are immediately surrounding the pupil, he comes nearer to eliciting that "development from within" in the direction that he means to guide the pupil than by our system of class-instruction, in which very often the dullard is sacrificed to the cleverest boy of the class—in which, for the sake of facility of returns and cheapness of teaching, the object of the teacher, which is simply and solely to develop the qualities of all his pupils, is often frustrated. Here, for instance, is an exercise by a humble indigenous teacher, which has been made over to me by Mr. Purdon Clarke. He is a Pundit, such as there are thousands, by no means a very learned Pundit, as will be obvious from the style of his communication, but I think Mr. Herbert Spencer need not be ashamed to endorse the sentiments which he expresses. He points out the various systems of philosophy which exist, as it really does not much matter what system of philosophy one endorses, so long as one philosophises to cultivate the mind—a latitudinarian spirit which very often induces Hindoos to accept Mohammedan or Christian principles, considering that there are many roads to a city, and that it is not necessary that every one should travel by the same road. He then goes on to show that the development of the pupil's mind is the main object of the teacher. He, finally, launches into the questions of government, showing that learning causes humility, humility causes ability, ability causes progress, and so forth, which, when put into the more generalising and abstract language of the West, would read like superior wisdom.

Mohammedan Education.

As regards Mohammedans, they emphatically value education for its own sake, and not for the sake of worldly advancement. I have myself been partially educated in a Mohammedan school, where I learnt Arabic, and committed large portions of the Koran to memory, as it has always been my practice "to go to school" among the various races or creeds which I desired to study. "Read" was the very first word which the Angel Gabriel told to the Arabian prophet. It is the first word of the Koran, though the order of its chapters is now changed. It is the key-stone of the Koran, which means, "the book that pre-eminently deserves to be read." Nor is reading to be confined to the study of the Mohammedan religion, or of any one religion, for when Abul Fazal, the wise minister of the wise Emperor Akbar, was called upon to justify his supporting all denominations alike as a Government official, he quoted the significant saying, which shows the duty of the State towards religion:—"Government and Religion are twins," for no Government can expect to be permanent that neglects the religion of its subjects. Again, "learning is obligatory on every Mohammedan man or woman," and the Hadis, or the tradition of the sayings and doings of the prophet, explains "learning or science" to consist of two integral parts, "the science of bodies (or of the material world) and the science of religions." Again, "Seek for knowledge even if you have to go to China," which clearly shows that whatever reputation for the cultivation of sciences distant China may have had in Arabia, these sciences were certainly not orthodox from a Mohammedan standpoint.

Advice to Reformers.

When I see all this, I marvel at the shortsightedness of statesmen, scholars, and missionaries—not all, but, alas, too many—in rather seeking for points of difference in dealing with Mohammedan and other creeds, than for common grounds of agreement It seems to me that we should further the common interests of humanity far better if we first ascertained what there is in the religion or belief of those with whom we have to deal before we discuss with them what there ought to be, and if we endeavoured in all our appeals to seek those methods that are most intelligible to those to whom they are addressed. I think, although they may require to be expressed with some circumlocution, it would be better to follow the native saying, that "the success of the teacher is in the hearer," and rather to say things in an Oriental way, with the view of uniting those with whom we have to deal in common aims of charity and progress, than to put things in a way that may, perhaps, only tell best when reported to a British audience. I believe that the eagerness for reform of British audiences is due to the best intentions; that they, above all, wish for information. If they were to get this information, they might be less eager in urging such reforms as I heard advocated the other day about child-marriage—the immediate abolition of which would give great latitude to immorality, whereas now it confers on betrothal, which precedes marriage, a dignity as well as a sense of domestic responsibility. Their sympathy, however, for India would not be a bit less warm, and, indeed, would be far more effective because more intelligent, and because based on accurate knowledge.

Arabic Literature.

What European science and literature owe to the Arabs can never be sufficiently recognised. The problems of ancient Persian chronology, which have baffled the most careful inquirers, have lately been solved by the production of a forgotten, or long supposed to be lost, manuscript of Al Birûni; and I cannot help regretting that the unchecked progress of a foreign veneer of civilisation in places like Batala, a former indigenous university town, should have led to the sale of several hundred-weight of Arabic, Persian, and Sanscrit manuscripts, amongst which there may have been some of importance, to the waste-paper merchants. I think the wholesale destruction which must come on an ancient literature by ignoring its traditional representatives, is a process that must be looked upon with grief by all, whatever view they may take as to the question of the precise value of indigenous education.

In comparative chronology Al-Birûni is still a master, whilst in saving portions of Plato and Aristotle from oblivion, and in laying the foundation of clinical medicine, the Mohammedans have laid Europe under an obligation which it has not yet discharged to the adherents of that creed in India. I may also refer to the important medical, legal, mathematical, astronomical, and philosophical works still studied in their schools. The following passages from the Koran or Hadis are interesting:—

"Of God's creation those alone fear God who are learned."

"One hour's teaching and learning is more righteous than a whole night's prayer."

"When a man dies his acts die with him, except three, namely, a perennial charity (a permanent charitable endowment) or his learning, whereby (posterity) is benefited, or a virtuous son."

"Two men are enviable; he who spends his wealth in alms and he who benefits others by his learning."

The very word for charity, "Sadaka," means a particular action which leads to religious righteousness, and it is the confusion of the application of these terms, which are common to both Arabic and Hebrew, that has led to the interminable struggle between "faith" and "good works," which in their etymology and in their essence are one.

The humblest kind of Mohammedan school is the Koran school, which is generally attached to mosques, or held in private houses, often by pious widows. Even where the meaning of the volume is not explained, the repetition at home of passages from it and of the usual prayers revives the recollection of the parent, who co-operates with the teacher in impressing their lessons on the youthful mind. Especially interesting is "the contract with the Deity" which the child enters into on leaving the Koran school for the practical duties of life; and it were to be wished that our "Bible schools" similarly consecrated each child to duty, God and the country. Then comes "the Arabic school," properly so-called, where that noble and most logical of languages is taught on a system that has extorted the admiration of our leading Arabic scholars in Europe.

Arabic in itself, not even counting its enormous literature, deserves to be called a science. As the Orientals define it, Arabic is science; Turkish is art, owing to the complication of its forms; Persian is sugar, owing to its elegance, it being emphatically the language of gentlemen; and Hindustani or Hindi is salt, owing to the piquancy of that vernacular. There is a school, a very large school, at Deoband, in the North-West Provinces, which, so far as it gives class-instruction, is like an English school or college, but, in so far as it follows native methods in the treatment of subjects, is an indigenous school which is attended by Hindoos as well as Mohammedans. In that school all sciences are taught, so far as they are found in Arabic literature. Putting India aside, it must not be thought for a moment that even in the trans-frontier districts there do not exist centres of learning. For instance, in the little known Gabriál, almost every third man is said to be a well-read Maulvi, and from Gabriál as well as Bokhara, and other places in Central Asia, we have had pupils to the Lahore Oriental College whose knowledge of Mohammedan law, of logic, and even mathematics, was surprising. The Lahore Oriental College, or the Punjab University in its teaching aspect, is the greatest recent instance of educational enterprise in India, and combines Eastern with Western instruction. As a centre of enlightenment among the traditional learned classes of the Punjab, if not of India, and of countries beyond the "frontier," its importance to the cause of comparative studies, to civilisation and to the Government cannot be overrated, and has been admitted by more than one Viceroy. It is, therefore, to be hoped that any attempt to conform it to the model of an English College will fail, that no official will be allowed to interfere with its management, and that its indigenous professional classes will be preserved. Otherwise faith will not have been kept with the donors, and an important lever to the confidence, affection, and further liberality of the contributing classes will be destroyed.

I would refer to the instance of the Bokhariot, Maulvi Abdulla, who, as so many others, teaching himself from Arabic mathematical works, aided by his genius, sought out the Mathematical Professor of our College, Professor Lindsay, a high Wrangler, who confessed that he had nothing to teach him in that discipline. Alas, this promising Central Asiatic, when he fell ill, insisted on being attended at an European hospital, where he died and was dissected, his remains being thrown in a sack to a Badakhshani fellow student Since this occurrence the class of native Hakims, or physicians, has had few accessions from those distant parts, much to the injury of the dissemination of European medical science beyond our frontier. In Mohammedan law, more than one Judge of our Punjab Chief Court has availed himself of the knowledge of some of the Maulvis of the Lahore Oriental College, whilst in engineering and architecture there still exist in India worthy successors of the great men who constructed the Mogol palaces and aqueducts. As for the books in use in the various Mohammedan schools, I must refer to the first volume of my "History of Indigenous Education," whilst, as regards the questions of discipline and of the remuneration of teachers, these are solved by the already mentioned co-operation with the parents, the personal interest of the teacher to secure both the affection of his pupil and a higher reward in the next world, without any of these formal rules which are the snare of official inspections and the delusion of Government schools. As stated in my evidence before a recent Education Commission and elsewhere :—

The Abolition of Mere Administrative Agencies.

"The abolition of the higher Inspectorships and of the Directorship in the Punjab only would eventually set free for purely educational purposes a saving of about Rs. 173,000 per annum; and if the pernicious book depôt were also abolished, which costs about Rs. 50,000, a spirit of educational and literary freedom would breathe throughout the country, the moral, intellectual, and pecuniary benefits of which cannot be over-estimated.

"The District Inspectors might remain for the present, but I would not fill up their places on vacancies occurring. If every Head-master of a High School were to inspect the Middle Schools of his district for a fortnight in the cold weather and for a month in the hot weather, as part of his regular duty, making arrangements for the conduct of his work during his absence, not only would there be relief afforded to him from constant teaching, and his subordinates learn to manage a school, but he would also exert a beneficial and constant influence on the schools in his district, which are the natural feeders of his own school. In the same way, each Head of a Middle School could inspect a certain number of Primary Schools, and with the same beneficial result of co-operation throughout the district.

"The High Schools themselves, which are generally at the head-quarters of the district, could easily and constantly be inspected by the district officers and by the Central Local Board, which would count a certain number of educated European non-officials and others among its members, the head-master, of course, also being one and possessing a vote, which I consider to be essential to his dignity and proper influence.

"In the course of a few years this system would work so well as to give an opportunity to dispense with the services of the district inspectors, should Government wish to avail itself of this opportunity, or should municipal and district committees prefer to give a larger proportion of their educational allotment to the substance of education, the teaching itself, than to its present expensive framework, the inspecting of the work of others. We should thus have gradually more and more schools, inspired by a healthy emulation, and under the supervision of those whose interest and sympathies alike must combine to render them more and more efficient and numerously attended.

"I would also point out that the various Indian Universities, like the Senate of the Punjab University College, now raised to the status of a complete University with extensive privileges, might, with propriety, be constituted Provincial Boards of Education. In the Punjab the Senate has already had twelve years' experience in educational administration, including matters connected with an extensive and varied system of examinations, teaching, and the encouragement of literature. Itself a pre-eminently representative body and the creation of people, it would be in natural sympathy with the Local Boards, and assist them with advice and the results of examinations. Any further inspection than that by district inspectors, head-masters, and the various Local Boards themselves already alluded to, can be provided by the Universities if required."

The Sanscrit Schools and the Brahmins.

I think I ought to say this much about the Sanscrit schools, that the ascendancy of the Brahmin was due to his imposing on himself a system of moral obligation and an onerous ceremonial, together with the obligation of teaching, which was to take away the envy of the other classes. Not to seek power; not to seek money; to have life made a burden to him by austerities and by innumerable ceremonial practices was the way by which the Brahmin thought, and rightly, that he would preserve his ascendancy in the Indian polity. It is true that he reserved to himself the teaching of religion and philosophy, but he allowed the Sudra to learn secular subjects. If any class in India, however low, such as the Baidyas, raised themselves in the social scale, as in this instance, by medical knowledge, they were welcome, and, indeed, even the lowest can rise superior to the gods by the practice of virtue and austerities, for whereas the gods chiefly represent one quality in nature either good or bad, which, for its strength, deserves worship, man, by the practice of virtue, is in a position to unite the various qualities of which the so-called deities are single representatives, and from that union must rise above them. So is it that Brahma means little more than the embodiment of the highest perfection of the Brahminical class, if it remains true to itself. The Brahmins might say, the supreme deity which we are to worship is the highest perfection of knowledge reached through the path of virtue, which, if our class reaches it, personifies

Brahma, who, therefore, has no temples, because he is to live in the good deeds of the most perfect men. The two principal deities are the Aryan Vishnu and the aboriginal Shiva, above whom rises the aspiration of Brahma, together with a number of personified qualities.

The work of the Brahmin, after being a pupil to his master (when he has to beg for him, more as an educational tax on the community than as charity), is after his student's life to devote himself to the life of a household. He is the worthy Brahmin who, after having been a successful student, becomes a good husband, and brings up virtuous sons. The saying is, "A father who contracts debts is an enemy, an unchaste mother is an enemy, a son that has not learning is an enemy;" meaning that these are sources of danger to the welfare of the Indian family. After having brought up his son in the path which he trod before him, he retires, first into ascetic life, in which he has to practise hospitality; and, finally, on the near approach of death, he has to throw everything aside, and become a wanderer, so as to be able cheerfully to enter into the unknown world. It is easy to laugh at the various regulations concerning the demeanour of pupils towards a master; the eating of certain food when prosecuting certain studies, and so on; but, believe me, it is better to examine these subjects, and when they are examined, a profound vein of wisdom will be discovered to underlie these maxims as regards food and demeanour. Even in our own experience, we must have noticed the difference of sensations connected with certain kinds of food. We might also be inclined to smile if a Buddhist, for instance, said that association with animals is a thing that enlarges the mind. I daresay there may be someone in this room who has had an animal as a pet, and who, if he will answer truly, will have to admit, on reflection, that he felt himself the better for caressing and being kind to an animal; the sensation of pity when we see overworked animals, and all those fellow-sentiments have their rise in that universal feeling of brotherhood in which should be contained not only our own kin but the whole of animate life. The Brahminical system of studies is both comprehensive and profound, and should be imparted for nothing. The probibition—which we condemn on a cursory examination—of widow-marriage, and other matters, have their roots deep in the sacredness of the marriage institution, and in the great ideal of the married life in India; and it is wrong to describe it as immoral, as I have often heard it described by well-meaning men. The philosophic teachings of Brahmins have forestalled, discussed, and dismissed many acquisitions which we consider to be European monopolies, and they are still a mine of information. As regards physical subjects, let me draw your attention to those monographs which will continue to perish day by day, unless scholars in Europe will come to the rescue, such as the inquiry into the influence of various sounds of nature on the senses and on the passions; the observations on the diseases of animals, and a number of other monographs which most certainly do not deserve the sweeping condemnation which is so often passed upon them.

The Sikhs and their Education.

Then coming to the Sikh; the Sikh is the Protestant of the northern part of India. His name shows that he is a "learner" or pupil. Men and women are equal, and there is no man or woman deserving the appellation of "Sikh" who cannot write. In this instance writing precedes reading. The initiation of the Sikh in the Amritvidia, or the instruction for giving the sacred drink of immortal learning, begins with the necessity of prayer and truthfulness; the obligation of respecting other Sikhs; the importance of learning Gurmukhi; and I wish to remark that Gurmukhi is not, as has been thought, a mere character, it also means the *language* which flowed from the mouth of Guru, or first teacher of the Sikh religion. The character, as may be seen in several mausoleums, is older, indeed, than the rise of Gurmukhi as a language. Sikhism was a protest, like Buddhism, against the monopoly, however deserved, of the Brahmins. Just as Buddhism sought a shorter cut to salvation, to getting rid of the troubles of life by doing away with the preliminary stages of studentship and householdership, and immediately launching into monkdom, so did the Sikhs endeavour to popularise Sanscrit learning by writing it in a vernacular, composed of several mediæval Hindi dialects, which is of the greatest importance for studying the vernaculars and the Punjabi of the present day. In this composite dialect is written the Adi Granth, a book which, if translated literally (as it has been by an admirable scholar, Dr. Trumpp), reads like nonsense; but if read by the light of custom, and with the traditional explanation of its indigenous expounders, is indeed wisdom.

There is another point which I may refer to. After all what we look upon as Sanscrit manuscripts are mere indexes, a mere *memoria technica* of the treasure which is handed down by oral communication from teacher to pupil, and which explains the hiatus between one sentence and the other, so that you can see the danger and unwisdom of ignoring the traditional exponents of Sanscrit learning, the Pandits.

Well, the Sikhs take the Amrit, or beverage of immortal learning, which is better than any Ambrosia, or drink of Valhalla: the component elements of it are sugar, spice, and honey. It may be administered by the teacher to the pupil, and by the pupil to the teacher. The fact that physical strength is considered one of the necessary elements of Sikhism, reminds one very much of what the ancient Persians were supposed to be, namely, brave, good horsemen, and truthful, which latter, it is said, the modern Persians are not. Anything more practical than the stages of instruction in the Sikh's school cannot be imagined. Of course, he begins writing his letters on the ground, but this is a very great advantage in countries that have to be economical in the use of paper. Indeed, some of our officers, like General Pollard and others, have themselves benefited by that system.

Then comes something like the "Kindergarten" system. Words are put down which are in immediate relation with surrounding objects. When the alphabet is taught, it is taught along with moral maxims, as, for instance, "G. g.—God is great." Other letters illustrate that virtue does not consist in the worship of the Brahmin's salver with its oil-lamps, bells, &c., but that it consists in doing good, and so forth. Lessons are taught of tolerance to members of other creeds. All miracle-worship is deprecated, and there is one instance on record in which Guru Govind anathematised a relative for having performed the miracle of recalling a dead cow to life. Anyhow, miracles, because they inflate the miracle-worker with pride, are against the essence of Sikhism. The Sikhs meet on platforms or Takhts; on the one platform sit the men, and around, divided by a groove, are women, and they, although they very rarely have been known to give expression to their views, are under a distinct obligation to express their opinion in matters on which they *can* speak. So that, after all, we are not even ahead of India in our theory of female emancipation. In the new Guru Singh Sabha Society, started at Amritsar, "the right of women to express an opinion, or to send it in writing," is expressly reserved. At the same time, when they do speak, I believe they speak with that modesty and self-respect, that faithfulness and tender regard for their families, which, I believe, are characteristics of native women.

The Commercial School.

One could not go very very much lower than the Landé or Commercial School. Here is a book, a dozen copies of which would cost a halfpenny. On the frontispiece you have the Elephant Deity of Wisdom, sitting under a rising sun, and the pupil presenting the book to the master; you are led by gradual stages into those "gurs" by which boys can solve problems in prices of grain which often puzzle our mathematical M.A.'s. Indeed, in the highest schools also, simple sentences connected with daily life illustrate even mathematical problems. For example, "if a mouse were to run along a certain wall, and then fall to the ground at a certain angle," and so on. These "gurs" are simpler than the examples of the Sanscrit Lilavati, but the pupils attain to a readiness in mental calculation which is perfectly astounding.

Photography and Persian Caligraphy.

In schools chiefly or mainly intended for the study of Persian, which is the language of gentlemen, just as Arabic is the language of scholars, and which bridges the way to other studies, caligraphy is considered to be of high importance. The day will come when we shall have a simpler and more beautiful process for the multiplication of books than printing, to which we owe so much. I hold in my hands several books which have been brought out by an improved photographic process, which is in its infancy as yet. Here is a *Hitopadesa*, which, in print, costs 7s. 6d., and which may be brought out by means of photography for a shilling. It is beautifully done. Here, again, is a Koran produced by a similar process. Surely those in India who practise caligraphy—and it is an art taught by absolute rules as to the distance of the dots between the curves of letters, &c.—are not wrong when they pay so much attention to it; and the lithographs of India, which spread education so cheaply, would be worse than they are—and some of them are very beautiful—if that art were not cultivated. I hope the day may come when England or Europe will be able to give her best teaching to the natives of India, and when the best native editions of Oriental poets and philosophers may be circulated at a cost which may place a whole literature within the reach of the poorest, just as the French have attempted to do it in the "Cent bons Livres" at ten centimes each, when a man can buy the little library for eight shillings. Here is a Persian book, brought out by a relative of the Shah, correcting the pictures that are drawn in it of ancient rulers by corresponding coins. The Shia Mahommedans, it may be incidentally stated, allow pictures of living objects, the Sunni Mahommedans do not; at the same time the latter cultivate the design of inanimate objects. When it is alleged that pupils in Government schools do not object to pictures, it is evidently forgotten that the first thing a Mohammedan boy does in a Government school is to drive his pen or a bit of wood through the eye of a picture of a human being, in order to reduce it from the condition of an animate being to that of an inanimate object.

Urdu and Hindi Schools.

Urdu and Hindi schools are of our creation. It would be a loss to discountenance any kind of school meant for any section of the community; every class should have its own share, and no more, in the good things of a country. It would be a misfortune if the clergy or the bar had everything in this country, and so it would be unfortunate for India, were the traditional office-seeking class to monopolise all the "loaves and fishes." Whilst, therefore, I have great admiration for Urdu, our official vernacular, I cannot conceal from myself that the Urdu schools are preferentially attended as an avenue to employment; and that our first duty would be rather to encourage the vernacular —whether it is in the form of Urdu, or Hindi, or Punjabi—of the agricultural classes, from whom the Educational Cess is raised, than to devote that fund to the education of classes that can pay for themselves.

Suggestions for the Revival and Improvement of Indigenous Education.

I would, in conclusion, submit a few suggestions for the revival and improvement of indigenous education :—

1. The assignment in every village of from one to five acres of land out of the Shamilát or common land to the best Maulvi, Pandit, or Guru of the place, to be held in perpetuity for the purpose of teaching; his lineal descendant or a relative, if competent, being appointed his successor, subject to the approval of the village Panchayet, or council of "five" elders. I believe that there will be no difficulty in inducing the village communities to give a few bigas of their common land to the permanent endowment of a school appreciated by them. In some cases waste lands would be available for the purpose; in others, the present jaghirdars would gladly "release," for the sake of establishing an indigenous school, the "Muafi" or rent-free land that they have resumed. In every case, Government revenue would be an eventual gainer by the endowment with land of indigenous schools, whilst the cost of primary education would actually be reduced rather than increased in proportion to the contemplated extension of mass-instruction.

2. The distribution, on public occasions, of presents of Oriental text-books, and of khillats or presents (not cash), to successful teachers, managers, and pupils, and the deferential treatment of recognised Maulvis, Pandits, Gurus, and other representatives of indigenous learning, when attending district durbars, municipalities, &c., for which they ought to have a vote irrespective of income, for poverty is the glory rather than the curse of native learning. The revered teacher or priest has as much right to a vote as the Anglicised youth who has taken the B.A. degree, or who has passed the entrance or even the middle school examination. I would deprecate any money grant being given to indigenous schools through any departmental agency, whether directly or indirectly, for this will at once induce their managers and supporters to look to Government for remuneration as well as compensation for having complied with official regulations, and for having departed, to however small extent, from their own systems of education. If, *e.g.*, in the Punjab a staff of nearly fifty inspectors and their assistants are unable to visit the 1,280 so-called Government village schools, they are manifestly unable to visit *in situ* the 13,000 indigenous schools which have now been ascertained to exist. To inspect them properly would require a staff of 100 inspectors, which could not be done without an increase of taxation. Now, the agriculturists are not willing to be taxed any more for schools, having paid to the Village School Cess hitherto, and not having, as understood by them, received a school in any locality of less than 3,000 inhabitants. Worse than all, any Government interference, whether to tax or to reward, would convert thousands of men, now studying for study's sake, into office-seekers, who like the present alumni

of Government schools, will consider that they have a claim to Government for employment, failing to obtain which, they edit seditious newspapers, chiefly intended for consumption in England. Any official supervision would be worse than the neglect or persecution from which indigenous schools have hitherto suffered. "The real education of the country, instead of being preserved and developed, will then give way to a pretentious and shallow system of preparation for office-hunters; the trades and traditional professions of the pupils will be abandoned; the religious feeling will be destroyed, and the country will be overrun by a hundred thousand semi-educated and needy men for whom it will be impossible to provide, and who will have been rendered unfit for their own occupations. I should indeed regret if my persistently drawing the attention of Government and of the public since 1865 to the neglect of indigenous and of religious education should only result in inflicting a death-blow on India's last hope of a genuine, because indigenous, civilisation." The above remarks would describe the success of such increased inspection or official interference as is contemplated. Should it, however, fail, as is probable from the circumstance that the inspectors have either no knowledge of or sympathy with Arabic or Sanscrit learning, their visits to mosques and temples with the bait of grants of money for secular subjects, will kindle a flame all over India to which the Mutiny may be a child's play, and they will do so at an increased annual cost to the State of, at least, 54 lakhs, if the recommendations of the recent Indian Education Commission are carried out in the spirit of their report. These recommendations are also calculated to suppress the traditional motives of native liberality, by ignoring the religious element as well as the independent action of donors, and the sense of obligation between the teacher and the parent who pays him in a direct manner, and not indirectly and problematically through a fee to a school, which is sent away into the Treasury. All that is required is the spread of a belief among the people that Government is friendly to indigenous primary and higher education, when I have no doubt, from my own very large experience of what can stir natives to liberality, that "all the noble, wealthy, and religious, of whatever denomination, will come forward in the traditional munificent support of an education, however advancing with the age, which they can understand, and that they will spare neither time nor thought in its efficient management. With the accretion of funds and the revival of the educational spirit, all education, including the spread of Western science and of the English language, will also prosper, whereas, without such funds and such spirit it must continue to starve," as I have already pointed out on another occasion.

3. The utilisation of the existing divisions of castes or classes in the cause of progress, by identifying the indigenous teachers, physicians, jurists, &c., with their respective professions, under the more enlightened or different auspices of the age. In other words, our native doctors should be recruited from the ranks of traditional Hakîms or Baids; our teachers should, preferentially, be the sons of Pundits, Maulvis, or other men belonging to the traditional learned classes, which still have the greatest influence, as is shown by natives allowing their girls to be taught by young Pundits, who have a character to lose if they misbehave.

The problem of female education, if it exists, can best be solved by employing the wives of priests, hakîms, &c., as teachers to women in their homes, and not in public schools. By doing this, we will encourage the religious obligation of husbands, especially if priests or professors, to teach their wives. In the same way, the commercial, industrial, and agricultural classes should be educated in a manner which will promote their traditional spheres in life, as far as possible, on indigenous lines. Without either barring the road to merit, or actually declaring the ascetic sweeper superior to the gods, it is caste that has preserved Indian society from disintegration, and that is the main cause of the "*pax britannica*" in India. After another century of struggle in Europe, where class weighs on class far more heavily than caste in India, we may arrive at conclusions not widely differing from those that inspired the Hindu legislator, when he endeavoured to make each section of the community seek perfection in its own work or station in life, whatever that may be, instead of intruding on another. It cannot be sufficiently made clear that "the Hindus are an agglomeration of innumerable commonwealths, each governed by its own social and religious laws. Each race, tribe and caste, cluster of families and family, is a republic in confederation with other republics, as the United States of Hinduism, each jealous of its prerogatives, but each a part of a great autonomy, with Panchayets in every trade, village, caste, and subsection of caste invested with judicial, social, commercial, and even sumptuary authority discussed in their own public meetings. What did it matter who the tyrant was that temporarily obscured their horizon, and took from them the surplus earnings which his death was sure to restore to the country? Even now, if the bulk of the lower castes did not settle their differences at the Councils of their Boards, and if the respectable and Conservative classes did not shrink from attendance at Courts of Justice, we might increase the area of litigation a hundredfold and yet not do a tenth of the work that is still done by the arbitration of the "Brotherhoods."

4. That the Indian Universities hold Oriental examinations to test the subjects taught in indigenous schools and colleges, without unnecessary prescriptions and over-regulations, and that these universities confer accepted indigenous titles on indigenous lines, such, for instance, as was done by the Punjab University College, in awarding various grades of Pandit, Maulvi, Bhai, Kazi, Munshi, Hakim, &c. There can be no objection to a National University giving scholarships to the successful indigenous pupils or teachers, in order to enable them to prosecute their studies to higher standards. Indeed, mere examinations and the award of degrees are the least important work of a national university.

5. The great importance, however, to science and to Government of indigenous learning will never be recognised unless a larger number of European Orientalists, than has hitherto been the case, is appointed to Professorships in Government and other colleges. The knowledge of Arabic, or Sanscrit, is the best if not the only key to the sympathies of Mohammedans and Hindus respectively, to whom Orientalists can appeal with effect, and whose learning they can help to preserve. Indeed, higher education requires to be strengthened, not in the direction of an increase of administrative machinery, which experience has taught me is *the* great obstacle to the progress of Indian education, but in that of more teachers and more colleges. Colleges are quite able to administer their own affairs, and, practically, already do so, whilst their studies are sufficiently guided by the requirements of Universities, and of the public without any further administrative interference from without.

6. The ability to read or write any of the vernacular characters might, after three years' notice, be insisted on as one of the *sine qua non* qualifications of a voter, or elector, a course by which an immense stimulus will be be given to primary education throughout the country.

7. "Whatever view may be held as regards the expediency of the so-called experiment of self-government in India, there can be little doubt as to the appropriateness of its introduction as regards education, at once the safest and the best concession. There should be no question as to the fulness of the educational powers at all events entrusted to Local Boards. Natives have at all times been anxious and scrupulous guardians of such education as they could appreciate, and this applies to those who, in the course of things, will take charge of primary, middle, and high schools respectively. There will be a saving and impetus to education in the abolition of the offices of the Director and the higher Inspectors of schools, who should retire on their pensions," whilst their work will be done with infinitely greater efficiency by following the course recommended in my evidence before the Education Commission, and in my draft on "Self-Government in the Punjab," from which I have quoted several passages.

8. "As regards the existing Government schools to be made over to local Boards, the first hour in each school should be devoted to the separate religious instruction, by accredited teachers, of the members of the various denominations attending such school, the remaining five hours of school-instruction being devoted, as hitherto, to the joint secular instruction of all denominations. Government may not be able to do this, but local bodies should have no difficulty in introducing a measure into the schools taken over from Government which will eventually tend to make education, to a very great extent, self-supporting, in accordance with the spirit and letter of the Educational Despatches of the Secretary of State for India. Solely to increase the number of grant-in-aid schools, however desirable as a recognition of private enterprise, side by side with the regular system of national education, would press hard on the poorer communities, especially on Mohammedans, and would, if successful, develop the spirit of sectarianism in the denominational grant-in-aid schools; a spirit which is modified by the joint secular instruction, as proposed, of all the denominations and their separate religious instruction. The suggested measure would also economise State aid, and conduce to efficiency in teaching, whereas the illimitable development of separate denomina-

tional grant-in-aid school, would involve the State in endless expenditure on generally less efficient schools." On this subject I have to refer to the resolution of an important native society, the Anjuman-i-Panjab, which has successfully endeavoured, since 1865, to popularise Government measures.

9. The only way in which Government could, with any advantage, encourage indigenous, or indeed, other learning, is by liberally rewarding research, discovery, and erudition, of which a brilliant example has been lately reported in the *Times*. I refer to the munificent reward and high decoration which have been given by the German Emperor to Dr. Koch on his return from Calcutta. In India the higher decorations are, apparently, reserved to civilians, military men, and native chiefs, whatever may be the services of others to Science, Education, and the State.

10. The co-operation of the European learned societies and authors with the Punjab University in the spread of Oriental learning and the diffusion of western knowledge through the medium of the vernaculars. This is being attempted here by the establishment of an Oriental University, Museum, and Free Guest house, at Woking, regarding which you may have seen particulars in the *Times* and the *Athenæum*.

11. "The immediate, instead of the prospective, abolition of the departmental monopoly in books would also throw open a large market to the enterprise of publishers and authors in Europe and India. I need not point out what wide field this offers for the activity of Orientalists, but when I add further that the University in question has already issued over 190 works, no doubt of varying degrees of merit, and chiefly translations or editions of existing works, that several hundred thousand copies of popular Persian, Urdu, and Punjabi poets are yearly lithographed by the unaided activity of the people of the Punjab; and that the 2,000 State schools of that province absorb about 68,000 copies of one Urdu reader only, while the 13,000 indigenous Arabic, Sanscrit, Gurmukhi, and other schools have more or less extensive courses of reading; and that all this only refers to one province of the Indian Empire, a vista for literary enterprise is still further opened for Oriental authors and publishers, whose publications will be as valuable to us as those of India may be to them."

12. The establishment of a Linguistic School in England, similar to that in Paris, for the study of the languages, customs, religions, &c., of the East. Had such a school, for which I have agitated since 1859, been started, many of the difficulties that confront us in Egypt, and, indeed, that confront Gordon in Khartoum, would have been avoided. We shall have another Soudan in the so-called "neutral zone" in Asia, unless we establish a School of Interpreters, and utilise all existing linguistic material regarding that region.

I will conclude with the words which, on a kindred subject, I addressed a quarter of a century ago, alas, in vain, to a meeting at the College of Preceptors. I hope that everything I have said to-night will not share the same fate; it was as regards Turkey I then said:—"It is almost too late, as France and Russia have a great start; but 'better late than never.' The character of the English inspires more respect, it seems, in Orientals, than that of almost any other nation. . . . . Yet we carelessly forego the national advantages of character, and sacrifice our commercial interests. In a higher point of view, it seems but fair that we should carry back to the East some of the enlightenment to which it gave the first inspiration; and that there, if anywhere, our Societies, as well as our Government, should not shirk the duty; the former of increasing the usefulness of their appliances, and the latter of appointing competent representatives of British policy, and of the cause of education."

The CHAIRMAN said he regretted that, owing to the length of the lecture, there was no time for discussion, but he was sure the meeting would all agree in a cordial vote of thanks to Dr. Leitner for his most valuable and interesting lecture.

The motion was carried unanimously, and the meeting separated.

Mr. FREDERIC PINCOTT writes as follows:—

"The inevitable tendency of an Education Department is towards extravagance; and this arises from the desire to show good results, and from the absence of personal interest in the ultimate cost. When unlimited funds are not available, as in India, an expensive system can be maintained only by limiting the area of its operation. This accounts for the fact that the Indian Education Department has tried to give a high education to a limited number, rather than to the task of giving an elementary education to the masses. It is clearly impossible, with the funds available, to extend the operation of the costly Department beyond its present limits, without the imposition of oppressive taxation. This elementary fact shows that education can never attain national expansion, except through the agency of the inexpensive indigenous schools. The great value of native agency can easily be demonstrated by the following comparison. The Anglicising Departmental system is in operation throughout Bombay, North-West Provinces, Punjab, Central Provinces, Coory, and the assigned districts of Haidarabad, and thus attends to the educational wants of 99,000,000 of people. Throughout Madras, Bengal, and Assam, however, another system prevails, which, although to an extent departmental, is based on a recognition and encouragement of indigenous schools. The united populations of these three latter places is 105,000,000; thus we find that about half the people of India are under the Anglicising system, and half under a modified indigenous system. But mark the difference in the result. In Bombay, and its associated districts, with a population of 99,000,000, the total number of children under instruction amounts to 807,801; while in Madras, &c., with a population of 105,000,000, there are no less than 1,476,807 children under instruction. We thus see that in populations almost equal in numbers, the indigenous school method reaches nearly twice the number of children as the departmental methods. These figures may be taken as trustworthy, for they are given in the recent report of the Indian Education Commission, and in themselves constitute a thorough condemnation of the departmental system. It is simply amazing that, after establishing such a fact, the Commissioners should actually recommend an extension of the Department's influence."

Mr. Hyde Clarke writes:—

"It is very much to be regretted that there was no discussion on Dr. Leitner's most valuable paper, for we did not hear Sir Lepel Griffin, Sir W. Robinson, or others well acquainted with the subject. From the very diffusion Dr. Leitner was in some cases misunderstood, and in discussion many points would have been cleared up, and many important subjects would have received explanation.

"It was certainly not clear to many whether Dr. Leitner preferred Arabic and Persian as instruments for the diffusion of higher civilisation, or whether he advocated the study of English. In following him, I believe I correctly understood him to recommend to Englishmen the study of Arabic and Persian, as means of intercourse with the higher classes of Mussulmans, and that he relied on the extended cultivation by natives of English for their full advancement in the teachings of modern knowledge and thought. Indeed, to stint natives in the study of English, is to stint their intellectual and political growth. After all, Arabic and Persian are available only with a portion of the vast population of India.

"Indeed, the advocacy by Dr. Leitner, of vernacular education, implies the cultivation of the vernaculars, Dravidian, Kolarian, Burmese, Prakrit, or other; and, consequently, the diminished ascendancy of Persian, Arabic, and Sanscrit, which have been most stimulated, of late years, by the patronage of English officials awakening native effort.

"It was the more necessary to have some explanation, as while the doctrines of Dr. Leitner applied to vernacular education, throughout India, his illustrations referred to the schools of the Punjab and North-West, and were not applicable to Madras and the South. There we have vernaculars neo-Aryan, the whole body of Dravidian languages, derived in uninterrupted tradition from ages long anterior to the introduction of Sanscrit. It is when we concentrate our attention on particular regions only, where some foreign influence has attained pre-eminence, that we forget the general conditions, and that all such languages have been introduced into India as English has. Those who wish to exclude English as foreign, and to promote Persian, forget that Sanscrit, Arabic, and Persian are not indigenous to India, and have all been imported.

"Arabic and Persian, to all intents and purposes, are foreign to India, and they only obtain in degree a higher antiquity than the three centuries of English. Foreign conquest and foreign influence have ever dominated in India. Race has followed race, dynasty dynasty. The English are expected to enforce Persian as a public language, and yet are expected not to employ English, or to allow the natives the privilege of acquiring the greatest of European languages, the tongue of one hundred millions of English-speaking people.

"Dr. Leitner had only one word at the end for a most important subject, his effort to endow London with a high school of the Oriental languages, which may enable us to vie with other countries. No one knows the value of this better than Dr. Leitner; no one is better able to accomplish this than the Professor at King's College, who formed pupils in Arabic and Turkish, whose distinction, it must be said with regret, was more marked than their number. We want for success something more than the scholastic method hitherto in force, or the attempt to confine Oriental studies to schoolboy colleges.

"If once Oriental studies were put on their proper footing in London, they would obtain the same cultivation as is awarded to other branches of knowledge, and it may be that the energetic efforts of men of independent means and position will enable us here also to compete with the professional students of the Continental countries."

APPLIED CHEMISTRY & PHYSICS SECTION.

Thursday, May 22, 1884; W. H. Perkin, F.R.S., in the chair. The paper read was "Economic Applications of Seaweed," by Edward C. Stanford, F.C.S.

The paper will be printed in next week's *Journal*.

TWENTY-THIRD ORDINARY MEETING.

Wednesday, May 28, 1884; W. H. PREECE, F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Burroughs, Silas Manville, Snow-hill-buildings, Holborn-viaduct, E.C.
Fremersdorff, William Frederick, Roseneath-villa, Castle-road, Cardiff.
Hodgson, Christopher, 144, Blake-street, Barrow-in-Furness.
Kilburn, Charles Conning, 3, Cannon-place, Hampstead, N.W.
Sandford, Henry, 31, Ferndale-road, Clapham, S.W., and 36, King-street, E.C.
Wellcome, Henry S., Snow-hill-buildings, Holborn-viaduct, E.C.

The following candidates were balloted for and duly elected members of the Society:—

Atkins, Richard Day, 3, Sidney-place, Cork.
Chapman, Spencer, 84, Eccleston-square, S.W.
Clarke, Stewart, M.P., Bailey's Hotel, South Kensington, S.W.
Kendrew, John Anthony, The Ollands, Reepham, Norfolk.
Paget, Sir James, Bart., F.R.S , 1, Harewood-place, Hanover-square, W.
Pearson, Rev. Henry Daniel, M.A., St. James's Vicarage, Clapton, E.
Phillips, Henry Dominic, J.P., The Maples, Hampton-wick.
Stotherd, Colonel Richard Hugh, R.E., Ordnance-house, Southampton.

The paper read was—

PRIMARY BATTERIES FOR ELECTRIC LIGHTING.

By ISAAC PROBERT.

It has been said that "history repeats itself," and this quotation was never more appropriate than to the subject that will engage our attention this evening.

All of us probably know that it was by a primary battery that the electric light was first produced. So far back as 1802, Sir Humphry Davy, using a battery consisting of plates of copper and zinc dipping into dilute acid, obtained the electric arc between poles of carbon. In the *Journal of the Royal Institution* for that year, Davy, in describing some experiments on the spark yielded by the newly-invented galvanic battery, uses these words:—"When, instead of the metals, pieces of well-burned charcoal were employed, the spark was still larger, and of a vivid whiteness." He also pictures an apparatus for, as he says, "taking the galvanic electrical spark in fluids and aëriform substances." It consisted of a glass tube, open at the top, and having a tubular outlet at the side through which a wire tipped with charcoal was introduced, another wire, also tipped with charcoal, being cemented in a vertical position through the bottom.

In the same year, the electric light, sustained by voltaic action, was publicly shown in Paris by the citizen Robertson. Professor Silvanus P. Thompson, in an interesting communication to *Nature*, has quoted a passage in the *Paris Journal* of March, 1802, from which it appears that the experimenter used a voltaic pile of 120 elements of zinc and silver, to each pole of which he attached a carbon. On bringing the carbons into contact, a brilliant spark was obtained of extreme whiteness.

A few years later, Davy, with the large battery of 2,000 cells, which the munificence of some members of the Royal Institution placed at his disposal, obtained an electric light of a power that has rarely been surpassed, even in our own day.

Thanks to the kind efforts of our Chairman, one of Davy's original battery cells is on the table to-night. The complete battery, to use Davy's own words, consisted "of 200 instruments connected together in regular order, each composed of 10 double plates arranged in cells of porcelain, and containing in each plate 32 square inches. The battery, when the cells were filled with 60 parts of water, mixed with one part of nitric acid, and one part of sulphuric acid, afforded a series of brilliant and impressive effects. When pieces of charcoal about an inch long and one-sixth of an inch in diameter, were brought near each other (within the thirtieth or fortieth part of an inch), a bright spark was produced, and more than half the volume of the charcoal became ignited to whiteness, and by withdrawing the points from each other, a constant discharge took place through the heated air, in a space equal to at least four inches, producing a most brilliant ascending arch of light, broad and conical in form in the middle."

The electrician, Children, constructed a battery of twenty cells having huge double plates four feet by two, of which the whole surfaces were exposed, in a wooden trough, in cells covered with cement, to the action of diluted acids. It was the grandest combination ever then constructed for exhibiting the effects of extensive surface. To quote Davy's words:—"Points of charcoal ignited by it produced a light so vivid, that even the sunshine, compared with it, appeared feeble."

The light obtained by these experimenters was beautiful in the extreme, and naturally excited the admiration and the hopes of the public, or at least of that educated section of the public to whom the advances of science are not unknown; but it was in no way a practical light. The copper-zinc battery used in the experiments was crude, and quite incapable of sustaining a constant current, the carbon points employed for the arc to play between were mere sticks of wood charcoal, which gave an unsteady light and rapidly consumed, and the beautiful regulators with which we are familiar, for keeping the length of the arc constant, were then quite unknown.

It has just been said that the current obtained by the battery employed in those early experiments was not constant. This want of constancy is due to what is called the polarisation of the battery—that is, the deposition of hydrogen gas upon the copper plate. In the working of the battery, the zinc plate is oxidised and transformed into sulphate of zinc by the sulphuric acid in which the plates are immersed. At the same time, hydrogen gas is liberated on the surface of the copper-plate, where it collects and forms a layer of appreciable thickness, which offers considerable resistance to the transmission of the electric current. It also gives rise to an electromotive force opposed in direction to that of the copper zinc couple. The effect of the polarisation of the battery is then to considerably reduce the current flowing, and worse than this, the amount of deposited gas varies with time and other circumstances, and the current likewise varies. Such a battery, when used to produce the electric light, furnishes a light of constantly varying intensity which is extremely painful to use, and possesses other drawbacks also.

It is evident then that a battery, to be of any use for practical electric lighting, must be capable of generating a constant current. It should also possess these other qualifications, viz., a high and constant electromotive force and a small and constant internal resistance. It should consume inexpensive materials, and should consume nothing when it is producing no current. It should be capable of being easily cleaned, and of being supplied with fresh materials. It should require no skilled attendance. Unfortunately, no battery hitherto invented possesses all the required qualifications.

So long as constant batteries were unknown, the electric light remained a scientific curiosity, but the invention, by Grove, in 1836, of his nitric acid battery, gave a fresh impetus to the subject. Of all the points enumerated, the power to furnish a constant current is the most important. As the want of constancy of a battery is due very largely, although not exclusively, to the deposition of hydrogen gas upon the copper plate, inventors naturally turn their attention to the devising of methods of ridding the battery of this objectionable feature. Mr. Alfred Smee was very early in the field; he found that by roughening the copper plate, the disengagement of the bubbles of hydrogen from its surface was greatly facilitated. The gas, instead of forming a smooth layer upon the copper, collected upon the rough portions, and was discharged upwards through the liquid in streams.

On further investigating the subject, Smee found that it was not necessary that these roughenings of the surface should have appreciable size. In fact better results were obtained with a multitude of small points, from which the gas could be disengaged as quickly as it was liberated by the electrolytic action of the battery, than with a few points of large size, which, although capable of releasing big bubbles, yet permitted the gas to remain on the plate until the big bubbles had been formed by the aggregation of the tiny particles of gas which first appear. He therefore abandoned the copper plate, roughened mechanically, with which his earlier experiments were performed, in favour of a platinum plate, coated with a deposit of very finely divided platinum, obtained by exposing the plate to the action of solution of chloride of the metal, under the influence of the galvanic current. In our own day, platinised silver is often, through a false idea of economy, substituted for the platinised platinum.

This was a very great advance. The Smee battery was justly esteemed at the time for its great constancy as compared with the batteries previously in use. But its constancy, although great in comparison with that of the other batteries then known, was still very far from perfect.

Smee's method of eliminating the ill-effects of the layer of hydrogen was but a method of removal, and the question naturally presented itself to the minds of inventors whether a method of prevention could not be devised. An answer in the affirmative was given by Professor J. F. Daniell, of King's College, who invented a battery which remains to this day unequalled in constancy. You may be interested to hear the description of this first constant battery worthy of the name, in its first form, in the inventor's own words. They are these:—

"A cell of this battery consists of a cylinder of copper three and a-half inches in diameter, which experience has proved to afford the most advantageous distance between the generating (that is the zinc) and conducting (that is the copper) surfaces, but which may vary in height according to the power which it is wished to obtain. A membranous tube, formed of the gullet of an ox, is hung in the centre by a collar and circular copper plate, resting upon a rim placed near the top of the cylinder, and in this is suspended, by a wooden cross bar, a cylindrical rod of amalgamated zinc, half an inch in diameter. The cell is charged with a mixture of eight parts of water and one of oil of vitriol, which has been saturated with sulphate of copper; and portions of the solid salt are placed upon the upper copper plate, which is perforated like a colander, for the purpose of keeping the solution always in a state of saturation. The internal tube is filled with the same acid mixture without the copper. A tube of porous earthenware may be substituted for the membrane with some little loss of power. A number of such cells admit of being connected together very readily into a compound circuit, and will sustain a perfectly equal and steady current for many hours together, with a power far beyond that which can be produced by any other arrangement of a similar quantity of the same metals.

"The surface of the conducting metal is thus perpetually renewed by the deposition of pure copper, and the counter-action of zinc or any other precipitated metal effectually prevented. The minor affinity of the copper for the acid, however, still remains, and such an opposition could only be effectually avoided by the employment of platinum plates, perpetually renewed by the decomposition in the circuit of chloride of platinum; such an arrangement would be perfect, but too costly for ordinary applications."

This battery, the prototype of all chemical depolarising batteries, is worthy of attentive study. In it the hydrogen, instead of being deposited upon the copper plate, is oxidised to water by the solution of copper sulphate, and metallic copper in place of hydrogen is thrown down upon the copper plate. Polarisation is thus entirely prevented.

If constancy of current were the sole requisite of a battery for electric lighting, the Daniell battery would be admirably suited to the purpose, but it will be remembered that a high electromotive force and a low internal resistance are also essential, and here the Daniell battery fails. The electromotive force of any copper zinc couple is low, and the internal resistance of the Daniell cell is high. The electromotive force might be raised by the device suggested by Daniell of employing platinum in place of copper, and solution of chloride of platinum in place of solution of sulphate of copper, but the expense would militate against the practical success of such an arrangement.

It was reserved for Grove—now the Hon. Sir W. R. Grove, one of her Majesty's Judges, but then Professor of Chemistry at the London Institution—to overcome this difficulty, and to produce a chemical depolarising battery of high electromotive force, low internal resistance, and employing a comparative cheap depolarising liquid. Daniell, as we have seen, had appreciated very clearly the advantage of a platinum plate, but his mind seemed so engrossed with his original idea of a metallic solution, as depolariser, which in decomposition deposit upon the plate dipping into it a layer of the same metal, that the possibility of finding a non-metallic depolariser does not appear to have suggested itself to him. Grove, however, saw this possibility, and by the substitution of strong nitric acid for the metallic solution, achieved the success which Daniell had vainly sought for. For the first time, the production of the electric light by the acid of a primary battery became possible on a practical scale; and the very year of Groves' invention, the electric light was used for theatrical purposes, at the Opera House, in Paris.

Suggestions by Cooper, Walker, Bunsen, and Archereau, quickly followed, and in the course of a few years the nitric acid battery had assumed its present convenient form.

It would be tedious to tell you of the many attempts to practically introduce the electric light which now rapidly succeeded one another. One of the most noteworthy instances of the employment of this battery is the electric lighting of the Cherbourg Docks, during their construction in 1858, whereby 1,800 men were enabled to work during the night, when work must otherwise have been suspended.

In 1831, Faraday made the important discovery that when a closed circuit of conducting material—a ring of copper, for example—is moved in the neighbourhood of a magnet, so that the conductor passes from a position of one magnetic intensity to a position of a different magnetic intensity, a current of electricity is generated in the conductor, and that when the conductor is moved, so that a current is generated in it, more mechanical work is done in producing the motion than when no current is generated. In effect, this great discovery was that, by the intervention of a magnet and a coil of wire, mechanical energy—the energy of the arm or of the steam-engine—can be transferred into electric energy. Out of this discovery have grown the huge dynamo-electric machines of to-day, which, as generators of electricity for lighting purposes, have almost driven voltaic batteries from the field of competition.

Why is this? Why is it that a dynamo-electric machine should be almost universally preferred to a voltaic battery for the production of the electric light? It is a question of cost—of the relative cost of the two methods of producing an electric current. Let us examine this point a little in detail.

Both in a voltaic battery and in a dynamo-electric machine, the electric energy is ultimately referable to combustion, or, more strictly, to chemical combustion. In each there is a combustible substance, oxygen or an equivalent substance, to sustain the combustion, and the means wherewith to collect and utilise the energy liberated. In a voltaic battery, the combustible substance is usually zinc, and the oxygenous substance sulphuric acid. In a dynamo-electric machine—or rather in the furnace of the engine that drives it—the combustible substance is coal, and the oxygenous substance air. The question, therefore, as ordinarily presented, resolves itself into this:—Required a certain quantity of electric energy; can it be more economically produced by burning zinc in sulphuric acid in a voltaic battery, or by burning coal in air in the furnace of the engine of a dynamo-electric machine. In answering this question, we must consider the relative cost of zinc and coal, their thermal equivalents—that is, the amounts of heat obtainable by the combustion of equal weights of the two materials; the efficiency of the battery and the engine and machine—that is, the proportion of useful work obtained to the total energy generated; the cost of the oxidant of the zinc-air—the oxidant of the coal costing nothing; the relative cost, both original and for maintenance of the battery and the dynamo and engine; and the relative cost of attendance. In the case of the battery, there is also the possibility of the utilisation of the bye-products to be considered.

To make the matter quite clear, let a practical illustration be taken. Let it be supposed that a house has to be lighted by a hundred incandescence lamps, each requiring a current of ·75 of an ampère urged by an electromotive force of 100 volts. The rate at which energy is expended in each lamp, expressed in volt-ampères or watts, of which 746 were equal to a horse-power, will be ·75 × 100, that is 75. The energy expended in the 100 lamps will be at the rate of 7,500 watts, which are equal to 10·05 horse-power. But this, it must be remembered, is the actual rate at which energy is expended in the lamps. The energy that has to be developed by the engine is greater, for no dynamo-electric machine is perfectly efficient, no dynamo machine gives out as electrical energy the exact equivalent of the mechanical energy expended upon it. Let it be supposed that the machine used in our installation has a "commercial" efficiency of 80 per cent., that is, that 80 per cent. of the mechanical energy put into the machine reappears in the external or lamp circuit as electrical energy, the balance being wasted in heating the armature coils, and the friction of axles, slipping of belts, and other mechanical sources of loss. Then the rate at which energy is generated by the steam-engine must be 10·05 + 1·25, that is 12·55 horse-power. This mechanical energy is to be produced by the combustion of coal, and if all the heat liberated in the combustion of the coal could be collected and utilised, the supply of coal required to generate energy at the rate of 12·55 horse-power would be very small; but, unfortunately, steam-engines, even of the best make, have but low efficiency, and a horse-power-hour of energy requires in practice somewhere about 4½ lbs. of coal for its production; 12·55 horse-power-hours will therefore require about 56½ lbs. of coal—say, roughly, half a-hundredweight, the cost of which is not more than 6d. Assuming that the lamps were required to burn for 1,800 hours a year—that is on an average nearly five hours a day—the annual cost for coal would be £45. The prime cost of a suitable dynamo-machine and engine (with boiler) would be, say, £300, the interest on which, at 4 per cent., would be £12, and the annual depreciation, at 10 per cent., £30; the cost of attendance would be about £60, so that the prime cost would be £300, and the total annual cost £147, or £1 9s. 5d. per lamp.

If a galvanic battery is used to supply the current to the lamps, the energy will require to be produced at a rate of somewhere between 10·05 and 20·1 horse-power, for the efficiency of a galvanic battery depends upon the relation subsisting between the resistance of the battery itself and the resistance of the external circuit. When the greater resistance is reduced until it exactly equals the smaller, the greatest possible current is obtained from the battery, but exactly one-half of the energy liberated is wasted in heating the battery. When the external resistance is high, as compared with the internal, the current is less, but the per centage loss of energy is also less. As a matter of practice, therefore, it becomes advisable to arrange the resistances so that the external is greater than the internal, whereby the efficiency of the latter is made to as nearly approach a hundred per cent. as we wish. Let it be supposed that in our installation the efficiency is, as in the dynamo just considered, 80 per cent. To liberate a horse-power-hour of energy, a quantity of zinc must be oxidised equal to 2·022 lbs. divided by the electromotive force of the galvanic couple in use. It is calculable that the highest electromotive force obtainable in any zinc sulphuric acid battery is 2·248 volts, from which, however, a deduction must be made on account of the energy absorbed in the chemical action of depolarization. The amount of the deduction will depend upon the nature of the depolarizer: with nitrate of soda and sulphuric acid it is ·708 volt, with bichromate of potash it is ·343 volt, and with fuming nitric acid ·284 volt. In order to do fullest justice to batteries, let it be assumed that strong nitric acid is the depolariser used in our installation. The deduction to be made from the total electromotive force of the battery is, therefore, ·284 volt, and the net electromotive of the battery is 1·964 volt, which corresponds to a consumption of 1·03 lb. of zinc per horse-power-hour of energy. To liberate 12·55 horse-power-hours, 12·93 lbs. —say 13 lbs.—of zinc must be used. If the price of zinc be taken at 2½d. per lb., the zinc used per hour costs 2s. 8¼d. But the expense does not end here. Air, the oxidant of coal, costs nothing; whereas sulphuric acid, the usual oxidant of zinc, is of considerable value, costing, even on the commercial scale, ¾d. per lb.

To oxidise a pound of zinc, 1½ lb. of sulphuric acid is required, as is shown by the equation, $Zn + H_2SO_4 = ZnSO_4 + H_2$. To oxidise 13 lbs. of zinc, 19½ lbs. of acid are therefore required, which costs 1s. 2⅝d.; this, added to the cost of the zinc, makes about 3s. 11d. But we cannot stop even here. In order that the zinc may give the greatest possible return of energy, the electromotive force of the voltaic arrangement must, as has been stated, be high, and this—as a net result, at least—can only be obtained by the aid of a good depolarising liquid. We assumed ourselves to be using strong nitric acid, and if we suppose that the average effect of nascent hydrogen upon this substance is to produce nitric oxide (N_2O_2), the amount of acid required will be shown by the equation, $2\,HNO_3 + 3H_2$ (equivalent to 3 Zn) $= N_2O_2 + 4\,H_2O$. It follows, therefore, that the solution of every pound of Zn is accompanied by the deoxidation of ⅔ lb. of nitric acid. In the production of 12·55 horse-power-hours of energy, 8⅔ lbs. of nitric acid will therefore be deoxidised, the cost of which, at 6d. per lb., is 4s. 4d. This, added to the cost of zinc and sulphuric acid, gives 8s. 3d. as the total cost of materials.

But we have not yet done. A battery cannot be charged, and then kept in action until every grain of zinc, and every drop of acid have been consumed. It has been found by experience that no more than about 20 per cent. of the acid can be utilised. When this proportion has been used, the battery begins to flag, and is soon of no further use for electric lighting until the solution has been changed. The greater part of the acid is thus removed as spent solution. But neglecting this source of waste for the moment, and assuming that by a careful process of "refreshing" it is possible to completely exhaust the acid solution, let us see what the cost of our 10·05 horse-power is when generated by a galvanic battery. We have seen that the cost of materials per hour is 8s. 3d., and assuming, as before, that the light will be required for 1,800 hours a year, the annual cost for materials only is £742 10s. od. The prime cost of the battery may be taken at £120, the interest, at 4 per cent., on which is, say, £5, and the annual depreciation, at 10 per cent., is £12. The cost of attendance is very difficult to determine. Primary batteries have as yet been used for electric lighting to such a small extent, that there are, practically, no records of experience whereon to base an opinion. It is claimed by the inventors of batteries that the cost is very small; they say that no skilled attendance is required, and this seems reasonable; and that there is nothing further to do than might be done by a domestic servant in the ordinary course of his duties. Let us assume that this is so, and that the cost of attendance is so small as to be negligible.

If we divide the total annual cost (that is £759 10s.) by the number of lamps, the annual cost per lamp is found to be £7 11s. 8d., as against £1 9s. 5d., when a dynamo machine is used. The difference is great, but it becomes even greater when we remember that it is never possible to completely use the acid solution.

From what has been said, it will be gathered that, in a comparatively large installation such as has been sketched, primary batteries have little chance of success; but for smaller installations, of, say, ten to twenty lamps, there may, perhaps, be a field of action open to them. Few people occupying a house requiring so few lamps as this would incur the trouble of a dynamo and engine, although for health's sake they might not object to the cost of the light as produced by a battery.

In what way is it possible to reduce the cost of electric lighting by galvanic batteries? It is evident that there are four ways open; and invention has been active in all. In the first place, a cheaper oxidisable substance than zinc may be employed; and in the second, possibly a cheaper oxidant than sulphuric acid. Next, contrivances may be adopted by which the solutions are more completely exhausted; and lastly, the bye-products—the substances formed during the action of battery—may be utilised in the arts.

In the first place, as to the oxidisable substance:—Zinc is almost universally employed, but lead and iron have been suggested, and a battery using the latter substance is now before the public.

Next, as to the oxidant, or, speaking more generally, the solvent of the positive element of the cell:—Sulphuric acid has been replaced, among other substances, by hydrochloric acid, and the battery employing this liquid has been introduced by Mr. Ross.

As to the bye-products, little can be said, except that the less said the better. Some promoters of patent batteries make a great point of the value of the bye-products of their batteries, but, as a matter of fact, their statements on this point will seldom bear investigation. A zinc residue contains a certain percentage of the metal in a state of chemical combination, from which it has to be recovered by a somewhat costly process, and one hardly likely to afford any profit to the person using the battery.

It may be interesting to notice that, in the Telegraph Department of the Post-office, no residues are thought worth preserving, except the "black mud" (technically so-called) from the Daniells, which contains a very large percentage of pure copper in the metallic state. Last year, there were 69,323 Daniell cells in use, and the sum realised by the sale of the year's "black mud" was £167 14s., or rather more than a halfpenny per cell per year. An idea may be formed from these figures of the magnitude of the sum likely to result from the sale of the zinc residues—which in the Post-office are thrown away as worthless—in the case of an ordinary householder using some ten or twenty cells.

During the past few years, several batteries especially designed for use in electric lighting have been devised, and the inventors of the more important have been good enough to bring their batteries here to-night, or to furnish descriptions of them. These batteries may be divided into two classes; those in which the liquids are kept in motion, and those in which they are allowed to remain in a state of quiesence. Of the latter, one of the most important is that devised by Messrs. Holmes and Burke. A description which these gentlemen have been good enough to furnish reads thus:—

"Each battery of eight cells can be charged or discharged at two operations, by means of a system of syphons formed partly in the substance of the outside cells. In order to charge the battery it is only necessary to fill a wooden measuring vessel with the exact quantity of fluid necessary to run into the battery, to connect this vessel with the long leg of one of the syphon systems, and to raise the vessel to a certain height, when the liquid immediately distributes itself amongst the cells, and is bound to attain a uniform height in each of them. To discharge the battery, it is only necessary to reverse the process.

"The fumes are collected and suppressed. The porous pots are sealed into wooden covers, which contain passages for the escape of fumes. The passages communicate with one main pipe formed in the substance of the cells, and the fumes can thence be led away to the fume box, where they are either dissolved or chemically absorbed, according to circumstances.

"The connections between the cells are so simple that they can never be coupled up wrongly, and they are placed beyond the reach of injury by acids or fumes. They never require disconnection when the battery is discharged or re-charged. They require partial disconnection when the plates have to be amalgamated, but the latter, when once thoroughly amalgamated, hardly ever requires re-touching. Plates have been run for two months without re-amalgamation.

"The depolarizing liquid is cheap and easily handled. It is made of nitrate of soda dissolved in solution of sulphuric acid of a particular strength. It depends for its action on the formation by the current of nitric acid in the porous pot. The hydrogen entering decomposes the nitrate of soda by the aid of the acid, forming sulphate of soda and nitric acid. The liquid is of very good conductivity, and as the nitric acid is only formed as it is wanted, the inconvenience of handling this very disagreeable acid is avoided.

"The cost of the liquid is only 5½d. to 6d. a gallon. Each gallon furnishes from 750 to 800 ampère-hours of electricity at an electromotive force of 1·92 volt—*i.e.*, about 1,536 watts, or very nearly two hour horse-power.

"The internal resistance of the battery is very low for a primary cell, and equals ·02 ohm. as nearly as possible."

It may be added that, like the generality of electric lighting batteries, the batteries of Messrs. Holmes and Bourke employ carbon and zinc as the elements.

The battery which next claims attention is that of Mr. O. C. D. Ross, of which a model is on the table. The chief point of novelty distinguishing it is the ingenious arrangement for charging and discharging the depolarising liquid.

The battery itself is enclosed in a box, about 1 ft. square by 7 ft. long, which contains thirteen double cells, the plates in each of which weigh about 10 lbs; the whole box when charged weighs about 2 cwt. Each cell contains two carbon plates (formed of ½ in. carbon rods placed side by side) which are immersed in dilute hydrochloric acid mixed with one-sixth of its bulk of a mysterious compound, called by Mr. Ross "Eureka," but which might doubtless be replaced, without materially affecting the action or the cost of the battery, by nitric acid. The zinc plates dip into a solution of common salt, the liquids being kept apart by porous partitions. The mechanical arrangement by which the carbon cells are filled and emptied is very simple; a horizontal pipe connected by flexible tubes to the bottom of each inner cell is raised or lowered; one end is attached by a flexible tube to a cask of acid, and the other end is led to a waste tank. When the horizontal pipe is raised, and communication with the waste tank cut off, the acid flows, on turning the tap of the acid cask, into the inner cells. When spent liquid is required to be removed, the horizontal pipe is lowered, and the liquid flows from the cells to the waste tank. The outer cells are filled with solution of salt, in one operation, by pouring the solution into a groove extending the whole length of the box, and connected by side passages with the cells.

The Ross battery has been examined by Dr. Hopkinson, who reports that:—

"Comparing this battery with others, a great deal may be said in its favour.

"Its constancy with a large current is remarkably good.

"The liquids used in the cells are less expensive than in any battery having any pretence to constancy.

"Mr. Ross's method of drawing off and replenishing the liquid is very convenient."

The electromotive force per cell is stated to be 1·82 volt, and the resistance 0·06 ohm.

Another battery, introduced some time back, is that known as the "Edeo" or "Heap" battery. It is a carbon-zinc couple using bichromate of potash as the depolariser, and dilute sulphuric acid as the excitant. The cells are lined with lead, and hold each 1½ gallon of the bichromate mixture (which can be purchased ready prepared at 1s. per gallon). The zinc plates are 10 × 6 inches, and so offer a total surface of 120 square inches to the action of the acid; they weigh 3 lbs. each. The electromotive force is stated to be 2 volts per cell, and the resistance 0·2 ohm. The point of novelty is claimed to lie in the preparation of the bichromatie solution, the description.of which is best given in the manufacturers' own words. They are as follows:—

"In each lead cell pour six pints of water, and in each repeat the following operation:—

"Fill the colander (which is supplied with the battery) with bichromate of potash, and hang it in the cell so that the crystals are just immersed in the water. Pour about one-fourth of three pounds of sulphuric acid over the crystals in the colander slowly, stopping occasionally when the liquid boils. As fast as the bichromate of potash gets dissolved, add more, and continue pouring in sulphuric acid as before, until there are used up for each cell all of one and a-half pounds of bichromate of potash, and three pounds of sulphuric acid. When the liquid is entirely cool, it is ready for use. . . . . This fluid will last twice as long as the . . . fluid ordinarily supplied."

Mr. Heap is good enough to exhibit a three-cell battery in action to-night.

In the other or circulating class of batteries, there is one deserving of notice. It is the invention of Messrs. Oliphant, Burr, and Gowan. It is a two fluid bichromate battery, having zincs coated with an extremely thin film of gold before amalgamation. The exciting liquid is a solution of salts of mercury. The liquids for the outer jars and inner porous pots are pumped out of separate tanks into distinct pipes communicating with the first jar and the first porous pot. They then rise up syphon pipes into the adjoining cell, and flow onwards in this way through the whole series. To avoid any possible stoppage through friction in the pipes, it is advisable to have the first cell half-an-inch higher than the second, and so on. Thus, in a series of six cells, the last cell will be three inches lower than the first. The last jar and porous pot are connected to their respective tanks. The tank holding the bichromate solution is fitted as a cell, and works a Griscom or other motor, which causes two small pumps to keep the liquids in constant circulation. The pumps raise two cubic inches of liquid per stroke, and work at the rate of thirty strokes per minute. The pumps are constantly at work day and night, whether the battery is in use or not.

The effect of gilding the zincs before amalgamation is, it is stated, to materially decrease local action.

Many other batteries might be described, and it may be interesting to note that, during the past three years, about 150 patents for improvements in primary batteries have been applied for in Great Britain alone.

A question which presents itself in connection with the problem of economical lighting by primary batteries is this :—Is it not possible to effect economy in the lamps—to so improve the lamps that a given expenditure of energy on the part of the battery will develop more light in the lamps than is now obtained? Yes; it is possible. It would be troubling you too much to enter here into a lengthy account of the scientific principles which should guide the designer of the luminous conductors of incandescence lamps. It must suffice to say, that the ideally perfect conductor would assume a spherical form; its mass would be very small, and its surface also, and the material of which it was composed would possess the power, possessed unfortunately by no known substance, of enduring without change for an unlimited time the passage of a very powerful electric current. Of all substances hitherto used for incandescing conductors, carbon obtained by the intense heating of a pure hydro-carbon is the best. It will give a greater returning light for a given expenditure of energy, and will withstand the action of the conductor longer than any other substance. It will become possible, therefore, by its aid to approach more nearly to the ideally perfect form of luminous conductor than we should otherwise be able to. If also we can so fashion the intimate structure of the carbon, that the particles already have that arrangement which they tend to assume under the action of the current, the type of perfection can be approached even more nearly. This has been done. In a patent obtained in November, 1882, by Messrs. Boullon and Soward, in conjunction with myself, a method was described by which luminous conductors can be obtained of pure deposited carbon formed under the influence of the electric current. By suitable means, these conductors can be obtained of any required degree of approximation to the theoretically perfect form. What thickness they will ultimately assume it is impossible yet to say. The shorter and finer they are made, the greater is the economy, but the shorter is their life. The thickness at which the economy in action is just balanced by the increased cost of renewal of lamps is the practical working thickness, but this can only be determined by lengthy experiments, which are still in progress.

It may be noted in passing that high resistance luminous conductors—and they can be made without difficulty with a resistance of 1,000 ohms and upwards to the inch—have the great advantage that they work with a small current, although they necessarily require a somewhat high electromotive force. This enables the copper leads to be much thinner, and therefore less expensive, than in the case of a low resistance luminous conductor, worked by a large current, which is an important point worth bearing in mind. Messrs. Woodhouse and Rawson have quite recently introduced a new lamp, which they call their "hair filament lamp." These lamps have an extremely thin, hair-like filament, whence their name. No particulars of the method of manufacturing these filaments have been published, but it appears that, like the filaments of my colleagues and myself, they are made of deposited carbon. The method of their preparation is carefully kept secret, doubtless for fear of piratical imitations, which although generally easily detected, are yet often hard to prove in a court of law. These filaments are stated to be very efficient. It is said that they will furnish a given amount of light with less than half the expenditure of energy necessary to furnish the same amount in an ordinary thick filament. This is doubtless true: the experiments of my colleagues and myself with our own filaments perfectly support this statement, and we have had the opportunity of experimenting with filaments of much greater length, and therefore light-giving power, than Messrs. Woodhouse and Rawson seem to have had, if a conclusion may be formed from the lamps before the public.

It is hoped that the many inventors of primary batteries, who are doubtless present, will favour us with a fuller description of their inventions than the limits of this paper have permitted, and that an interesting and valuable discussion will ensue.

DISCUSSION.

The CHAIRMAN said, when it was remembered that during the last three years no less than 150 patents had been taken out for new primary batteries, no one could wonder that Mr. Probert had only been able to refer to three or four of the number; but he was somewhat surprised that he had omitted all reference to one which had created as much interest as any he had named, one devised by an extremely clever Russian officer, who had unfortunately succumbed to the English climate—Mr. Skriwènoff. This battery was very remarkable for its compactness and power; when visiting Vienna lately he carried one in his waistcoat pocket, and had a small lamp in his scarf, and he now had one concealed about him connected to a little lamp in a flower in his button-hole, and by simply bringing the two wires together it was put into a state of incandescence.

Mr. HOLMES then exhibited a model of his battery, and described its construction and mode of operation. The fumes from the nitric acid were conveyed to a box, where they were either absorbed by a solution of sulphate of iron, or converted by a solution of sulphate of ammonia into nitrate of ammonia. The cost of the nitrate of soda which formed the polarising liquid, was only £10 a ton, or a little over 1d. per lb., and the total cost of the sulphuric acid solution was from 5½d. to 6d. a gallon, each gallon giving from 700 to 800 ampère hours of electricity.

Mr. ROSS next exhibited a model of his battery, and described its mode of action. There was no attention required beyond removing about one-seventh of the liquid each day, and replacing it by fresh acid, which was effected by lowering and raising a tube at the side. For a battery lighting 50 lamps of 20 candle power, the quantity of liquid required to be drained off each day was about 10 gallons, and smaller batteries in proportion; any domestic servant could manage it without difficulty, and the battery would work for two or three weeks without anything else being done to it; but he arranged for an inspector to go round once a fortnight, and attend to the zinc plates. The liquid was very cheap, being principally water; the outside cells were filled with salt water, and the inside with water and acid, mostly hydrochloric acid, the cheapest in existence, being, even in London, only ⅓d. per lb. In Newcastle it was only 3s. 6d. per cwt., and, in fact, large quantities were taken out to sea in barges, and thrown away; to this was added a very small portion of a solution, the nature of which was a secret. He had made a calculation showing the relative cost of electric lighting by batteries, as compared with gas, and though he did not pretend that the battery could compete with gas, yet the expense of the zinc in the battery was less than the price of gas. The product of a ton of coals—say, 10,000 cubic feet of gas—when burned in Argand burners, would give a light of 30,000 candles for an hour, which, at 3s. per 1,000, would be 30s. Now one ton of zinc would give 1,280 horse-power, which, at the rate of 333 candles per horse-power, would be 426,240 per hour, or more than fourteen times as much light as was obtained from a ton of coal; while the cost of zinc at £18 a ton was only twelve times as much as the 30s. which the gas cost. That was a strong argument against the popular belief that the cost of zinc was absolutely prohibitory of its use in lighting. He did not for a moment suppose that galvanic batteries as now made could compete with dynamos when used on a large scale, because the economy of the dynamo was shown to be very great when used for large installations; but a dynamo could not be put into a cellar, and a battery could. Central stations would not exist in many parts of London, at any rate, for many years to come, and meanwhile there were many persons who would willingly introduce the electric light. Its wholesomeness was one very great point, and it was innocuous to books and gilding, so that there was a large field for it where wax candles or lamps were now used, the former of which cost fifteen times, and the latter five times as much as they would, even when supplied by a battery.

Mr. BURR next explained the battery made by his firm, which he said had three peculiarities. In the first place, they endeavoured to minimise the destruction of the zinc, by coating it with gold previous to amalgamating with mercury. They had great difficulty in obtaining patents in America and Germany for that process, but ultimately succeeded. Secondly, in place of mercury they employed chloride of mercury, a small portion of which had the same effect, and avoided the bad effects of mercury fumes being given off. The third improvement was due to the late Mr.

Spottiswoode, the object of which was to prevent the polarisation of the carbon by the formation of hydrogen bubbles. This was effected by keeping up a circulation in the liquid; Mr. Spottiswoode's suggestion only went to circulating the liquid in the carbon cells, but they found the results so excellent that they applied it to both sets; the circulation being effected by means of syphons, and small pumps worked by a dynamo, as described in the paper. The solution they found to act best in the carbon cells was $3\frac{1}{2}$ parts, by weight of bichromate of potash, to 1 of sulphuric acid, and 10 of water. For the zinc cells, water only with the addition of about $\frac{1}{2}$ oz. of chloride of mercury was used. This cost 2s. 6d. per lb., and a pound would supply 30 cells for three months. It was necessary to add to the zinc cells about a pint of water every three days, for the water appeared to be consumed far more rapidly than would be accounted for by evaporation. In the carbon cistern was hung a small colander filled with bichromate of potash, and when that got empty you simply had to refill it, and, provided the circulation was kept up, there would be no formation of chrome alum crystals. The cost of the zinc was hardly worth considering. They had worked a battery constantly day and night for 100 hours, and the consumption of bichromate of potash was about 1 lb. per week, while the amount of chloride used was hardly worth mentioning. When they commenced, the bichromate of potash cost 7d. per lb., but it was now reduced to $3\frac{1}{2}$d., and no doubt it would come down still further.

Prof. GEORGE FORBES said Mr. Probert had giveu a very impartial view of the relative merits of dynamos and batteries, and of course the enormous economy of the former, on a large scale, was obvious to all. The merits of the different batteries had also been well brought out. He had examined one or two of these batteries, and certainly some had great advantages, but he must say that claims were sometimes put forward by inventors which were not borne out; for instance, the economy which was promised in the consumption of zinc and so forth, had not been found to exist. He would not go into particulars on this point, as some of the information he had obtained was confidential, but he must admit that all who had tested this class of primary batteries found that great improvements had been made in the depolarising agent, and especially in the economy of it. The nitric acid which had generally been used was an expensive material, and great economy had been introduced in this respect by more than one inventor. Still more advance was shown in the mechanical improvements which had been made, by which the process of charging and discharging the batteries from day to day had been rendered very simple, and thus a very important obstacle to their use had been removed. He regretted the reader of the paper had not gone more fully into some other batteries introduced, not only in this country, but also on the Continent. For instance, there was the interesting battery of Lalande, in which oxide of copper was used as the depolariser, from which it was hoped considerable results might come. Again, Mr. Probert told them that the substitution of some other material for zinc was a possible line of economy, but up to the present he had no advance to announce. It would have been interesting if he had given some information about the attempts to use carbon as the positive plate. These experiments had been chiefly made in France, and some in America. He believed some of the first experiments were made by himself in 1879, when he thought he saw a twofold advantage from the consumption of carbon. Since you must consume carbon in a furnace in order to produce steam, and then afterwards convert steam-power into electricity, it seemed much simpler to produce the electricity from the consumption of carbon direct. Secondly, if you could consume carbon to give a fair amount of electromotive force in combination with any other material, the atomic weight of carbon being so small, the weight required to be used would also be very small. Again, considering that in the Bessemer furnace, the carbon consumed the oxygen of the air which was blown in, and the iron did not, it seemed probable that in that case the carbon would be positive to the iron. The first experiment, therefore, was made with black oxide of iron in Professor Crum Brown's laboratory in Edinburgh. The oxide of iron was melted, and a plate of iron and a plate of carbon were immersed in it, and the carbon was found to act as a positive plate. The intense heat required, of course rendered that method useless practically, and he then tried litharge, but found that that melted the vessel in which it was put. Then they passed to the use of melted salts, in which the chemical action appeared to be the consumption of oxygen in red-hot water; but that was rather trenching on Professor Guthrie's subject of cryhydrates. These experiments had been carried farther on the Continent, and he thought it would be in this direction that they must look for the next advance, for the consumption of zinc must always be an expensive way of getting electricity. When he heard the figures given of the amount received by the Post-office for the bye-products of their batteries, he could not help asking the Chairman whether those products were utilised as well as they might be, and whether they did not get much more for them in Germany. The value of these bye-products was another point on which more information would be welcome, as they were accustomed to hear statements which, if true, would lead one to believe that electricity could be had for nothing, and the bye-products into the bargain.

Mr. SHOOLBRED asked the size of the battery which had worked continuously for 600 hours.

Mr. BURR said it was a 12-cell battery, and the same cells were on the platform and could be examined, only the porous cells were round instead of square.

Mr. WHARTON said he had had a fair amount of experience with one of Mr. Holmes's batteries. No doubt dynamos were more practical things and he would far sooner use them than batteries, where the installation was of a size of from 100 to 1,000 lights; but if they could approach anything like the economy claimed by Mr. Burr, where water was oxidised, there might be more to be said for the batteries, or if they could succeed in oxidising coal in a battery, and getting a better proportion of the theoretical heat value out of it. With any combination of a steam or gas-engine to a dynamo they only got about 4 or 5 per cent., whilst in Mr. Holmes's battery about 60 per cent. of the theoretical efficiency of the zinc was obtained. He had used a battery on many occasions for real practical work, and had found it useful, and far superior to accummulators. On one occasion, he lit 48 lamps 8 hours a-day for 6 days consecutively, under a contract; the current was uniform, 65 ampères; the external resistance was constant because he kept the same number of lamps on the whole time, and the fall of potential between the mains was *nil*. That was about as large a practical use of a primary battery as had ever been made, and was for lighting a bazaar in a building underground. If he had used accumulators, he should have had much greater difficulty, more weight to carry, and would have had to bring them back each day to be re-charged. The cost was, perhaps, more than that of a large dynamo and steam-engine, but the convenience was very great. Again, for small installations in houses, where one or two rooms only had to be lit, it was quite out of the question to use a dynamo and steam or gas-engine, and for such purposes these batteries might be very useful. There was also a great improvement going on in the lamps; a short time ago, 3 watts per candle was considered very good, but the lamps on the table were running at 1·7 watts per lamp.

Mr. FERGUSON said he had been using the Lalande and Chaperon battery, to which Professor Forbes referred, for electric lighting; he had one in his office, at 31, Lombard-street, which had been at work without being touched at all for four or five weeks, giving light for about six hours a day. He had sent down a couple of the cells, which were on the table, and if a little more attention were turned to the use of alkalies for these batteries, they would be much improved. The acids made a horrible smell, and there was some trouble in getting rid of the fumes, but by the use of caustic soda or potash, he thought that might be avoided. He should be glad to show the battery to any one who would call at his office.

Mr. PROBERT, in reply, said he had not forgotten the Lalande and Chaperon battery, but it only came under his notice the previous day, and he had not had much time to examine it. He could not say anything about the carbon theory; his feeling was that thermopiles would ultimately become the most efficient generators of electricity for domestic lighting. There you certainly had heat transformed directly into electricity, and it seemed to him a much neglected subject which deserved more attention. He would also drew attention to a table lamp of 3-candle power lent by Mr. Smith (Elliott Brothers). The base box contained five small Skrivanow cells of the kind alluded to by the Chairman. This form of battery is a costly luxury, being chiefly used for buttonhole or necktie pin lamps on special occasions. The compounds and elements are chloride of silver, caustic potash, silver and zinc. In conclusion, he desired to mention the fact that the forty-five Swan 10- and 12-candle lamps, so artistically arranged by Messrs. Wharton and Down, and so efficiently worked during the evening, derived their energy from thirty-three Holmes and Burke cells, the area occupied by each cell being 4 in. by 13 in.

The CHAIRMAN, in moving a vote of thanks to Mr. Probert, having drawn attention to one of Messrs. Woodhouse and Rawson's small lamps attached to a laryngscope, said he must first refer to the question of the waste products in the Post-office. Mr. Probert had referred to 69,000 Daniell cells, but that was but a small part of the total battery power employed; altogether it would be more like 200,000 cells. But the consumption of material in each cell, per annum, was quite insignificant. Taking the maximum current employed for telegraphic purposes, he made out the resulting product for twelve months was only equivalent to that resulting from the production of 30 ampères in one hour; so that the whole product from one cell in a year in the telegraphic service was only half that of one of Mr. Holmes's batteries working for an hour. But the real point was that the cost of collecting the waste far exceeded the amount realised by selling it. In Germany they might do better, because there the railways were practically in the hands of the Government, and carriage was free. He did not take such a pessimist view as some people of the future of primary batteries; there was plenty of room for them, not only where dynamos and secondary batteries were out of the question, but even in economy, as compared with other modes of producing electricity. On the other hand, he could not go so far in their favour as some ardent inventors. One of his duties was to examine inventions, and as he had to inquire into about three a day on an average, it might easily be imagined that he got rather sick of inventions, especially when the same thing was brought forward again and again. The gist of what many of these inventors claimed was to this effect, that their new battery cost nothing; it never required charging; its electromotive force was infinite, and the residuals were of great value; its internal resistance was nothing, and its current absolutely constant; in fact, if Mr. Chamberlain and the Chancellor of the Exchequer availed themselves of the invention, they would very soon pay off the National Debt. It was a pity inventors should go so far as that, but there were some exceptions, and certainly some of the instruments brought forward that evening were really doing very good work. He had seen Messrs. Oliphant, Burr, and Gowan's battery at work after it had been at work for some hundreds of hours; and he had seen one of Mr. Holmes', lighting up a train on the London and South-Western Railway very successfully, and was informed that another was employed on the Midland line. Mr. Probert had brought out the cost of 100 lamps for 1,800 hours, but no one wanted to use a battery for 100 lamps; they wanted a small battery to give a light in a dining-room or library, where the consumption was very small; or in City offices, where it got dark at 4 o'clock, and they wanted to remain an hour longer. How pleasant it would be to turn on a battery to give that hour's light, instead of having to submit as at present to the poisonous fumes of gas. Mr. Ross had given a curious calculation as to the cost of zinc, as compared with gas, which he should be interested in verifying when he saw the figures in print, but that was not the proper way of estimating the cost of a battery. You must take into account the capital charges, depreciation and renewals, and above all the cost of supervision and attendance; and when all these were examined carefully, it would be found that batteries, though they were very nice fore some purposes, were expensive luxuries. Experience was the only test, and he should strongly urge inventors to apply it to their batteries, and bring forward the actual results, showing how they behaved. One of the most important points in connection with this question was the efficiency of the lamps. Edison lamps were used in that hall, and though one would occasionally give in, he believed nine-tenths of those now in use were the same which were originally put up. The efficiency was indicated by the number of watts consumed to produce one candle power; the Edison required four; some Swan lamps exhibited that evening required three-and-a-half, and he had recently been experimenting with some of Woodhouse and Rawson's, which only required two, so that in less than two years the efficiency of incandescent lamps had been doubled, and probably, before they met again, some one else would have made a still further improvement.

The vote of thanks was carried unanimously, and the proceedings terminated.

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION.

A Conference, arranged by the Mansion-house Council on the Dwellings of the Poor, will take place on June 4th, 5th, 6th, at 2 p.m. The chairman, on June 4th, will be the Lord Mayor, M.P., and the papers to be read, "The Population of London and its Migrations," by G. B. Longstaff, M.A., M.B., F.S.S.; "The Treatment of the London Poor," by Miss Gertrude Toynbee; "Overcrowding," by Rev. A. Mearns. On June 5th, chairman, the Archbishop of Canterbury; papers, "Suburban Dwellings and Cheap Railway Fares," by James Hole; "The Treatment of the London Poor," by Miss Lidgett; "On the Creation of a Building Fund," by H. D. Harrod. On June 6th, chairman, Cardinal Manning; papers, "Some Difficulties of Sanitary Legislation in the Metropolis," by Shirley F. Murphy, M.R.C.S., and B. C. Whitelegge, M.D.; "Suggestions to the Royal Commissioners," by C. M. Sawell.

Further conferences, the dates of which are not yet fixed, are as follows:—

Society of Medical Officers of Health; Parkes Museum of Hygiene; Sanitary Institute of Great Britain (these three institutions are amalgamated for the purpose of a conference)—"Domestic Sanitation in the Urban and Rural Districts; Industrial Diseases; How Infectious Diseases are spread; Notification of Infectious Diseases; Disposal of the Dead, Cremation."

Central Chamber of Agriculture—"Meat Supply."

Society of Arts—"Water Supply and Distribution."

Royal Institute of British Architects—"Construction of Houses with regard to Sanitary Arrangements."

Association for the Oral Instruction of the Deaf and Dumb—"Oral Instruction of the Deaf and Dumb."

Society of Telegraph Engineers and Electricians—"Electric Lighting—Municipal and Domestic," or on other subjects connected with application of Electrical Science.

Institute of Chemistry—"Food Adulteration and Analysis."

Social Science Association—"Sanitary Legislation."

National Health Society—Some subject cognate to the work of the Society.

Medical Society of London—"The Effect on the Health of Teachers and Children of Overwork in Schools."

St. John's Ambulance Association; National Society for Aid to Sick and Wounded in War—"Ambulance Work in Peace and War."

British Bee-keepers' Association—"Bee-keeping generally."

Epidemiological Society—"Tropical Sanitation."

The following lectures will be given during June, July, and August:—Mattieu W. Williams, F.C.S., "Science of Cookery;" Prof. Charles Graham, D.Sc., "Chemistry of Bread-making;" Edmund Owen, "Rearing of Hand-fed Infants;" R. W. Wigner, "Pure Milk;" Miss M. Smithard, "Dairy Management;" Prof. de Chaumont, M.D., F.R.S., "Practical Dietetics, especially in relation to Preserved and Condensed Food;" Professor T. Spencer Cobbold, M.D., F.R.S. (two lectures), "Parasites which infest Meat and Food generally;" Hon. S. Lewis Wingfield, "History of English Dress;" Wm. Morris, "Textiles Generally," and "Artistic Furniture;" Caspar Purdon Clarke, C.I.E., "Oriental Dress;" T. Pridgin Teale, "Healthy Houses;" Thomas W. Cutler, "Sanitary Furniture;" Malcolm Morris, "Ethics of the Skin;" S. D. Darbishire, M.D., "Recreation;" Henry Carr, "Our Domestic Poisons;" Harold B. Dixon, "Domestic Use of Gas;" W. H. Preece, F.R.S., "Domestic Use of Electric Light;" Leopold Field, "Candles;" Charles F. Cross, "Soap;" Ernest Hart, "How to Burn Coal."

INTERNATIONAL INVENTIONS EXHIBITION, 1885.

His Royal Highness the Prince of Wales, the President, has nominated the following Executive Council for the International Exhibition of New Inventions and of Musical Instruments, to be held next year:—Sir Frederick Bramwell, F.R.S., Chairman; The Marquis of Hamilton, Vice-Chairman; Sir Frederick Abel, C.B., D.C.L., F.R.S.; Mr. Edward Birkbeck, M.P., Hon. Treasurer; Mr. J. Lowthian Bell, F.R.S.; Colonel Sir Francis Bolton; Sir Philip Cunliffe-Owen, K.C.M.G., C.B., C.I.E.; Professor Dewar, F.R.S.; Mr. Joseph Dickenson; Sir B. T. Brandreth Gibbs; Sir George Grove; Mr. Edward W. Hamilton; Mr. Harry Jones; Mr. W. H. Preece, F.R.S.; Sir Edward James Reed, K.C.B., M.P., F.R.S.; Prof. W. Chandler Roberts, F.R.S.; Mr. John Robinson; Dr. John Stainer, M.A., Mus. Doc.; Mr. Richard Webster, Q.C.; with Mr. Edward Cunliffe-Owen as Secretary.

The first division of the Exhibition will comprise apparatus, appliances, processes, and products, invented or brought into use since 1862; the second division will be devoted to music since 1800.

Correspondence.

TELEGRAPH RATES.

Mr. John Ruscoe writes respecting Colonel Webber's paper:—

"It is evident that by the use of some code or regulation, whether it be by adopting time or urgent messages at 1s. each per twenty words, and messages of the same number of words at 6d. each, to be sent as soon as the wires are freed from pressure of urgent or 1s. messages, or what in a vast number of cases would amount to the same thing, 20 words for 1s., and 10 words for 6d., the Department will be kept in more regular and continuous operation, for should the introduction of 6d. telegrams, on the base of the paper, or some other similar basis, become a matter of fact, the State will reap substantial financial benefit, not only from the increased messages which will be sent, but by the more regular and continuous employment of their staff. There can be no doubt that urgent and delayed messages will both be appreciated by the commercial community. I could enumerate cases where a speeded telegram, at an increased price to an ordinary message, would be frequently adopted. To reduce all to one level would, in my humble opinion, be a great mistake. The offices now in busy centres from 11 to 3 are fairly engaged; to double their labour by a uniform telegram rate of 6d. each would choke those offices in the best and most business part of the day, with the result that the general telegraphing public would bitterly, and very justly, complain; but by express and secondary messages, all such complaints would be avoided.

"Dr. Cameron, M.P., in his advocacy of this scheme, deserves to be, as I feel sure he will be, supported in his efforts in this matter."

General Notes.

Telpherage.—Professor Fleeming Jenkin, LL.D., F.R.S., wishes it to be known that the model of the telpher railway can be seen in action at No. 18, Fitzroy-street, W., on Friday afternoons, by members of the Society of Arts and others, on presentation of their visiting cards.

Grocers' Company's Research Scholarships.—At a Court of Assistants of the Worshipful Company of Grocers, held on Wednesday, May 21st, 1884, the following candidates were elected to the Company's Scholarships for Research, into the causes of important diseases, viz.:—1. W. North, subject, "Ætiology of Ague." 2. Leonard C. Wooldridge, D.Sc., M.B., subject, "Hœmorrhagic Disease, Pernicious Anæmia, and Blood Clotting." 3. Alfred Lingard, M.R.C.S., subject, "Intimate Ætiology of Enteric Fever."

Oranges in New South Wales.—The orange-tree was first introduced into Sydney, New South Wales, from Brazil, in 1788. Captain Hunter says, in his "Journal of Transactions at Port Jackson and Norfolk Island," that they took on board at Rio de Janeiro, among other seeds and plants, "orange, lime, and lemon trees," and further states, that at Sydney "vines, orange, and lemon trees are in a very thriving state." These were introduced from Sydney into Norfolk Island, when Lieut. King observes in his Journal of 1788, at that island, "Two orange-trees, which I brought with me (from

Sydney) were kept in tubs until I should find a sheltered situation to plant them in." He afterwards says they were planted in the vale; and in March, 1790, observes, "Vines, orange, and lemon trees are in a very thriving state." Thus we find that they appeared to be well established in Norfolk Island; and at this time they were also thriving at Sydney, as we learn from "Phillips's New South Wales in 1790," from which date we may consider the cultivation of the orange-tree as permanent in the Colony. Orange cultivation is now a leading industry in New South Wales, its head-quarters being at Paramatta, near Sydney, where millions of oranges are annually grown, both for home consumption and for export. The orange is also largely grown in other parts of the Colony, being in some measure to the colonists what the apple and pear are to residents in the United Kingdom.

Antwerp International Exhibition.—This Exhibition will be held next year, under the patronage of the King of the Belgians. Failing any vote from the British Government, in order to facilitate English exhibitors, the Local Committee propose defraying all the expenses of decorating the British section, London offices, staff, and advertising, bringing in and taking out goods, and storing cases, so that exhibitors will have only a fixed charge for space to pay. Mr. P. L. Simmonds has been appointed British Commissioner, and has already formed an Honorary Committee, which comprises the Lord Mayor and Sheriffs, many of the leading Aldermen, the Provincial Mayors, the Agents-General for the Colonies, and Members of the Council of the Royal Colonial Institute, the Marquis of Hamilton, Lord Thurlow, Lord Claud Hamilton, Lord Alfred Churchill, Sir Lyon Playfair, K.C.B., M.P.; Sir Drummond Wolff, K.C.M.G.; Sir Philip Cunliffe-Owen, K.C.M.G.; Sir George Birdwood, C.S.I.; Sir Daniel Cooper, Bart, K.C.M.G.; Sir Francis R. Sandford, K.C.B. Our imports from Belgium has increased in value by 3½ millions in the past three years, and our exports of British produce and manufactures have increased in value from a total of 5 millions sterling in 1879, to over 8 millions in 1882, to say nothing of the foreign and colonial merchandise shipped there to the value of 7 millions. Our cotton and woollen manufactures sent there have doubled very lately, and the Board of Trade returns for 1882 show the following figures:—Exports of cotton manufactures, £2,260,808; wool, woollens, and woollen yarn, £1,713,226; total, £3,974,034.

MEETINGS OF THE SOCIETY.

Indian Section.

Friday evenings:—

May 30.—"Street Architecture in India." By C. Purdon Clarke, C.I.E. This paper will be illustrated by means of the Oxy-Hydrogen Light.

Health Exhibition Season Tickets.

The Executive Council of the International Health Exhibition have consented to allow members of the Society of Arts the privilege of purchasing season tickets for the Exhibition at half price (10s. 6d.) Each member can purchase a single ticket only on the reduced terms, and these tickets can only be obtained through the Secretary of the Society of Arts. For further particulars see notice in the *Journal* for May 2, p. 575.

MEETINGS FOR THE ENSUING WEEK.

Monday, June 2...Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Tuesday, June 3 ...Royal Institution, Albemarle-street, W., 3 p.m Prof. Gamgee, "The Anatomy and Physiology of Nerve and Muscle." (Lecture V.)
Zoological, 11, Hanover-square, W., 8½ p.m. 1. The Secretary, "Additions to the Society's Menagerie in May." 2. Mr. F. E. Beddard, "Some Points in the Structure of *Hapalemur griseus*." 3. Mr. A. D. Bartlett, "Some Hybrids of Bovine Animals bred in the Society's Gardens."

Wednesday, June 4...Entomological, 11, Chandos-street, W., 7 p m.
Archæological Association, 32, Sackville-street, W., 8. p.m. 1. Mr. C. Roach Smith, "The British Oppidum at Old Winchester." 2. E. P. Loftus Brock, "Ancient Chapel at Dover." 3. G. Grover, "Mount Nod, Clapham."
Obstetrical, 53, Berners-street, W., 8 p.m.
Shorthand, 55, Chancery-lane, W.C., 8 p.m.

Thursday, June 5...Linnean, Burlington-house, W., 8 p.m. 1. Mr. A. R. Hunt, "Influence of Wave Currents on Fauna inhabiting Shallow Seas." 2. Mr C. B. Clarke, "The Flora of Parnsnath, North-West Bengal." 3. Mr. H. W. Bates, "Longicorn Beetles of Japan." 4. Mr. P. H. Carpenter, "Remarkable Forms of *Metacrinus*."
Chemical, Burlington-house, W., 8 p.m.
Royal Institution, Albemarle-street, W., 3 p.m. Prof. Dewar, "Flame and Oxidation." (Lecture VII.)
Archæological Institution, 16, New Burlington-street, W, 4 p.m.

Friday, June 6...Royal Institution, Albemarle-street, W., 8 p.m. Mr. Willoughby Smith, "Electric Induction Experiments."
Geologists' Association, University College, W.C., 8 p m. Mr. T. V. Holmes, "Some Curious Excavations in the Isle of Portland." Mr. Charles E. De Rance, "The Underground Waters of England and Wales."
Philological, University College, W.C., 8 p.m. Prince L. L. Bonaparte, "Modern Basque and Old Basque Tenses."

Saturday, June 7...Royal Institution, Albemarle street, W., 3 p.m. Prof. Bonney, "The Bearing of Microscopical Research upon some large Geological Problems." (Lecture IV.)
Actuaries, The Quadrangle, King's College, W.C., 3 p m. Annual Meeting.

Journal of the Society of Arts.

No. 1,646. Vol. XXXII.

FRIDAY, JUNE 6, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CONVERSAZIONE.

A Conversazione will be given at the International Health Exhibition by the Council of the Society of Arts, in conjunction with the Executive Council of the Exhibition, on Wednesday evening, 9th of July.

It has been found necessary to change the date of the Conversazione from the 2nd of July, as announced in the last number of the *Journal*, in consequence of that being the day fixed for the evening *fête* of the Royal Botanic Society.

Further particulars will be duly announced.

Proceedings of the Society.

APPLIED CHEMISTRY & PHYSICS SECTION.

Thursday, May 22, 1884; W. H. Perkin, F.R.S., Vice-President of the Society, President of the Chemical Society, in the chair.

The paper read was—

ON THE ECONOMIC APPLICATIONS OF SEAWEED.

By Edward C. C. Stanford, F.C.S.

In 1862, twenty-two years ago, I had the honour of reading a paper before the Society of Arts, on this subject, in this room. The Council marked their appreciation of that paper by awarding me a silver medal, and I cannot forget that the honours of that year were shared by another chemist, my friend, Dr. Crace Calvert, once so well known here, but who has since passed away. When, therefore, I was again invited a little while ago to read a second paper, I felt that some apology was due for not returning to report progress before. I am bound to admit that, like some wanderers through space, the period has been long and the orbit eccentric. For the former, I must plead the difficulty of the subject; for the latter I must remind you that any one who follows seaweed must go to the wildest and most inaccessible shores.

It is extremely interesting to me, and I trust it may be made somewhat entertaining to you, to look back on that paper, with the light of over twenty years' experience, and see how far the views then put forward were right, and how far they were wrong, premising that even failures are excellent lessons. "Many things have happened since then," and new and better sources have been discovered of many of the products then brought forward for the first time. As, however, it may be advisable to follow the lines of that paper, I shall first briefly allude to the uses of seaweed for food and for manure, and then speak more at length on the important application of these in the manufacture of kelp, and the production of iodine.

Seaweed as Food.

In this country, little advance has been made in the use of the algæ as food. The algæ generally contain important nitrogenous constituents, and form nutritious articles of diet, but they have not been popular. We all like a "sniff of the briny," but we do not cultivate a taste for the internal consumption of our marine vegetables. We are equally guilty, however, in rejecting the majority of the fungi, so largely consumed as an important article of food on the Continent. The algæ are closely allied to these, but have the advantage of containing, as far as is known, no poisonous species. The algæ also contain a large proportion of salts which, however, are easily removed, if desirable.

Ulva latissima, or green laver, and *Porphyra laciniata*, or pink laver, are occasionally used in soups. *Rhodomenia palmata*, or dulse, is still sold in the streets of Edinburgh and Glasgow. *Aliara esculenta*, or murlins, is also eaten in Ireland; some others are occasionally used, but, as a general food, the algæ are almost unknown. The sweetest species is the *Laminaria saccharina*, which is usually covered, when dry, with an efflorescence of mannite; a large quantity of this plant yielded me 7·47 per cent. of mannite. It appears to be a product of fermentation, and does not exist in the fresh plant. This plant is found only on sandy or gravelly shores.

The best known British species of the edible algæ is the *Chondrus crispus*, or Irish moss; this grows far down on the rocks, and is only uncovered at low spring tides. It is obtained mostly from the west coast of Ireland, and after being bleached by exposure to sun and rain, is largely exported to this country and to Germany. It is a gelatinous species, containing a principle known as carragheenin; it yielded me 63·7 per cent. of this substance.

The only other gelatinous British species is the *Gelideum corneum*; this is not very common, but it furnishes the import known as Japanese isinglass, of which it contains 50 per cent. This substance, known also as gelose, was first imported into France, from China, in 1856; it has great gelatinising power, much higher than any other material. It is not nitrogenous, and contains carbon 42.8, hydrogen 5·8, oxygen 51·4.

The following table shows the value of these species in making jelly. The melting point of the jelly is also appended.

1,000 parts of water require of—

	Parts.	Proportion.	Melting point.
Gelose	4	1	90° Fahr.
Gelideum corneum	8	2	90° ,,
Irish moss (*Chondrus crispus*)	30	75	80° ,,
Isinglass	32	8	70° ,,
Gelatine	32	8	60° ,,
Carragheenin	36	9	70° ,,
Agar-agar (*Euchemia spinosa*)	60	15	90° ,,

It will be seen that gelose has eight times the gelatinising power of isinglass and gelatine; but the melting point of the jelly is too high to melt quickly in the mouth, hence gelatine is still the favourite.

The carragheenin has evidently become altered by evaporation. Gelose jelly keeps well, the others soon get mouldy. Although not fit for jelly, gelose may be valuable in the arts as a substitute for gelatine, which it so much exceeds in gelatinising power. I would specially suggest its use as a substitute for gelatine in the production of instantaneous photographs.

The *Euchemia spinosa*, or agar agar, is an Australian alga, and another important gelatinous species. The algæ form a large article of food consumption in China and Japan; some years ago I procured some of these samples, one was a dark green frond, and the other two were cut up from it, about the size of vermicelli; I append the analyses of there and of a sample of our own laminaria from Loch Eport in North Uist.

EDIBLE SEAWEEDS.—JAPAN.

	I.	II.	III.	IV.

Iodine	0·3171	...	...	0 2946

No. I.—"This is a good average sample, worth to-day, in this market, 11 taels, which at 6s. 6d., the average value of the tael, is 71s. 6d. per picul of 133 lbs.; therefore one ton (16·75 piculs) would cost, in Shanghai, £57 4s. It can be cut finer, and then the price, if it is of the deep green which this is when it leaves me, would be about 14 taels per picul, or £72 10s. per ton."—*Extract from letters.*

The sample is green, and evenly cut about as fine as vermicelli.

No. II.—"This is the worst sample I can find, worth 2 taels, which is £11 8s. per ton. The uncut leaf would be more valuable than this if of the colour of No. I. It would fetch £16 per ton."—*Extract from same letters.*

This sample looks like the former deteriorated.

No. III.—This was apparently the uncut weed. It much resembles in colour and appearance No. IV.

No. IV.—Laminaria, cut in Loch Eport, North Uist; colour, dark green. Quotations by Mr. Frazer, Yokohama, September 18, 1868:—Fine cut, £17 9s. 8d.; fine brown, £15 10s. 9d.; large green, £9 14s. 2d —per ton. Specimens of No. IV. were sent out to Yokohama, but they did not take the market. It is remarkable that so high a price as 72s. 6d. per cwt. (or nearly 8d. per lb.) should be realised there for this seaweed for dietetic purposes.

The taste for marine vegetables must be acquired, but those who have eaten them often are said to become very fond of them; and I have known some gentlemen in the Highlands, no mean judges of diet, who consider a dish of dulse, boiled in milk, the best of all vegetables. There is no doubt that a valuable food is lost in entirely neglecting the algæ; but I shall show, presently, how much of this may be recovered in an available form.

Seaweed as Manure.

This appears to me to be one of the worst applications of seaweed, and I do not think it has increased; farmers are beginning to find out that it seldom contains less than 80 per cent. of water, often more; and that for the actual manurial value in it, it may be very expensive if a long cartage is required. Four tons of water, at least, must be carted for every ton of dry manure, and when dried there is much additional expense, and it is very bulky. The dry weed contains an average of 2 per cent. of nitrogen, so that, as it is used, it contains less than ½ per cent. The chemical value is very little, except from the potash contained; but the mechanical value may be greater, as in covering root crops as a protection from frost, or where the soil is simply sand, and it binds it together. However, the cartage of water, and the manufacture of soil, are expensive amusements, and seaweed is not much used where there is high farming. It appears also, where continually used alone, to impoverish the soil; it is like feeding a dog on butter. The residue of seaweed ash, or kelp waste, one ton of which is equal to forty tons of wet seaweed, and contains all the phosphates, is quite unsaleable for manure in this country. It may be remarked, too, that in the wet climates of the west of Ireland, and of Scotland, where it is mostly used, the application of water is quite a superfluous operation for the farmer.

Another application of seaweed, which I mentioned before, was the manufacture of paper. As far as I know, this has only been carried out in France, on one plant, the *Zostera marina*, or grass wrack, a material largely used in this country for stuffing mattresses, and for packing light furniture. Some curious specimens of this plant, rolled up in little balls of fibre, were shown here at that meeting, as thrown up by the sea at Majorca and Minorca; and soon after it created a good deal of attention, having been proposed as a substitute for cotton; it contains litle fibre, however. It grows in enormous fields, on sand-banks, and is widely distributed, and is to be found in almost every ocean; it is a pure marine plant, with flowers, having nothing in common with the algæ except the habitat. It is often found on the shore perfectly bleached. All the algæ are cellular, and contain no fibre, but properly treated they make a tough transparent paper, to which I shall have to allude presently.

The Manufacture of Kelp.

This crude substance which, for many years, made the Highland estates so very valuable, was at first made as the principal source of carbonate of soda. At the beginning of this century it realised £20 to £22 per ton, and the Hebrides alone produced 20,000 tons per annum. The importation of barilla then began, and for the twenty-two years ending 1822, the average price was £10 10s. The duty was then taken off barilla, and the price of kelp fell to £8 10s.; and in 1823, on the removal of the salt duty, it fell to £3; and in 1831, to £2. It was used up to 1845 in the soap and glass factories of Glasgow, for the soda. Large chemical works were then existing in the island of Barra, built by General McNeill, for the manufacture of soap from kelp, and a very large sum of money was lost there. Two tall octagonal chimneys were still standing not long ago, but have now succumbed to the gales. In the meantime, soda was being largely made by the Le Blanc process, and superseded kelp, which was always a most expensive source, yielding only about 4 per cent., often less than 1 per cent.; it must have cost the soap-makers what would be equal to £100 per ton for soda ash, the present price of which is £6.

The manufacture of iodine and potash salts then began to assume some importance, but the kelp required was not the same; that which contained the most soda containing the least iodine and potash. Chloride of potassium, the principal salt, was at one time worth £25 per ton. The discovery of the Stassfurt mineral speedily reduced this price to about a third, and the further discovery of bromine in this mineral, also reduced the price of that element from 38s. per lb. to 1s. 3d., its present price. The amount of bromine in kelp is small, about a tenth of the iodine, and not now worth extracting. Large quantities are now produced in Germany and America. More recently, the manufacture of iodine from the caliche in Peru has attained large proportions, and has so far reduced the price of that article, as to make its manufacture from kelp unremunerative. In a paper, compiled for the British Association, published in 1877, I estimated the then total production of iodine in Great Britain and France, at 2,000 kegs of 1 cwt. each; and the future production of Peru at 6,000 kegs; an estimate which is now being rapidly realised.

In 1882, the amount of iodine exported from

Peru was 205,800 kilos, or 4,116 kegs, divided as follows:—

To London	120,900	kilos.
,, Hamburg	62,100	,,
,, New York	22,800	,,
	205,800	,,

The present annual output is estimated at 300,000 kilos, or 6,000 kegs.

On the other hand, the present manufacture of Great Britain and France is less than 1,000 kegs, the production of France being now reduced to almost nothing, and the kelp sold as manure.

I append an abstract of a table in that paper, showing the imports of kelp into Glasgow, to which city or its district the manufacture of British iodine has always been confined.

The prices given are the average prices for the year; higher than the maximum, but not lower than the minimum, have been reached. It is remarkable that we are now coming back to exactly the price of 1841, forty-three years ago, and also exactly to the price of twenty-two years ago, when my first paper was written. Potash salts, however, were then three times the present price.

IMPORTS OF KELP INTO CLYDE.

Five years, 1841 to 1845.

Tons of kelp, 1,887 in 1844 to 6,086 in 1845; average 3,133. Price of iodine per lb., 4s. 8d. in 1842 to 31s. 1d. in 1845; average 11s. 9d.

Ten years, 1846 to 1855.

Tons of kelp, 3,627 in 1846 to 11,421 in 1850; average 3,627. Price of iodine per lb., 8s. 8d. in 1851 to 21s. 3d. in 1846; average 12s. 11d.

Ten years, 1856 to 1865.

Tons of kelp, 6,349 in 1856 to 14,028 in 1863; average 9,730. Price of iodine per lb., 5s. in 1863 to 13s. 8d. in 1856; average 8s. 10d.

Ten years, 1866 to 1875.

Tons of kelp, 8,116 in 1868 to 10,923 in 1874; average 9,187. Price of iodine per lb., 10s. in 1866 to 34s. in 1872; average 15s. 11d.

Seven years, 1876 to 1883.

Tons of kelp, about 6,000 to 8,000; average about 7,000. Price of iodine, 5s. in 1883 to 15s. 6d. in 1879; average about 10s. 2d.

Total average kelp import, 1841 to 1883 (42 years) 6,750 tons. Average price of iodine per lb., 12s.

So that the present price is only about 40 per cent. of the average value. The great fluctuation in the price, and the small bulk of the article in proportion to its value, and the limited production, have led to great speculation, and I have no doubt a few kegs might still be found here and there in London which were bought some years ago at a pretty high price, and are still waiting the improbability of a turn in the market.

The amount of iodine in sea water is so minute, that it is extremely difficult to detect by ordinary tests; by evaporating down two portions of sea water filtered and unfiltered, each over 14 gallons, and by employing a delicate colour test, I have succeeded in estimating it. The sea water was collected carefully in the Atlantic, west of the island of Tyree. I found in 1,000,000 grs. measure (14·2857 gallons) of unfiltered sea water, ·003572 or 1 in 280,000,000; in 1,000,000 grs. measure of filtered sea water ·003442 or 1 in 291,000,000. The unfiltered water might be expected to contain more iodine from minute algæ in suspension, although it appeared clear. Kortstoffer, who estimated it in the Mediterranean, puts it at 1 part in 50,000,000. Bromine is easily detected; sea water generally contains about 6 parts in 100,000, and of chlorine about 2 per cent. Professor Dittmar, who has been working out the sea water samples of the *Challenger* expedition, has discovered a remarkable relation between this element and that of the chlorine which he has kindly communicated to me. He finds the relation in the great number of samples examined (77) to be constant in the proportion of ·340 bromine to 100 chlorine. He finds the average amount of chlorine to be 1·9 per cent., or 19,000 parts in 1,000,000, and of bromine ·00646 per cent., or 64·6 parts in 1,000,000, or 18,422 times as much as my mean result for the iodine. The Woodal Spa has been long known to be very rich in iodine and bromine; a recent analysis by Wright giving of chlorine 1113·73 parts per million, bromine 49·7 parts per million, iodine 5·21 parts per million. Here the relation of bromine to chlorine is ·44 to 100, and the iodine about a tenth of the bromine; in sea water the proportion of iodine is a very minute fraction of this. Examination of the brine and the mother liquor from the salt mines of Cheshire failed to detect iodine. The algæ possess the power of assimilating the iodine to about ten times the extent of the bromine. I append estimates of iodine in a number of algæ, those of the Laminaria and Fuci are the average of a great number of specimens collected at different times of the year, and all round Great Britain and Ireland, the Channel Islands, and the Isle of Man, and including Orkney and Shetland, Iceland, Denmark, and Norway. I append also estimates of the iodine in several of the giant algæ in the Falkland Islands, for which I am indebted to Governor Kerr, and Mr. F. G. Cobb, of the Falkland Islands Company.

These gigantic species are seen in this country for the first time in the fresh state, and little is known about them. The macrocystis is said to grow to a length of 1,500 ft., or over a quarter of a-mile in length. It grows in 10 fathoms water in Stanley harbour.

The *d' Urvillea* forms stems branched like trees 12 ft. or 14 ft. long, and a foot in diameter. All these weeds are thrown up in enormous quantities on the shores of the Falkland Islands, and along the Straits of Magellan, making it difficult for a boat to approach them.

In the foregoing table the Laminariæ and the Fuci are the kelp-producing species.

It is remarkable that the three gelatinous species, *Chondrus*, *Gelideun*, and *Euchemia* contain little or no iodine.

It is noticeable, too, that the *Enteromorpha*, or sea grass, a plant which retains, when dry, a very strong odour of the sea, contains no iodine.

It is also remarkable that the giant algæ contain so little iodine, growing outside the influence of the Gulf Stream, which, rightly or wrongly, has been supposed to be the iodine carrier. It is a curious fact that there are certain seeds, supposed by the natives to grow on the tangle, and called "tangle nuts." A specimen here from Tyree is evidently the seed of a leguminous American tree, brought over by the Gulf Stream.

It is probable that all animal substances from the sea contain iodine; its presence has been long known in cod-liver oil, a substance supposed to be rich in it, and to owe most of its valuable medicinal property to it, but I found, after investigating a good many various specimens of this oil, that the amount is infinitesimal. The liver itself contains double as much; oysters, especially the Portuguese variety, have also been said to contain a good deal. The following are my results:—

		Per cent.
Cod-liver oil, average of six specimens		·000322
Cod-liver, fresh		·000817

Scotch herring, brine		·000120
Oysters, Portuguese		·000040
Whale oil		·000100
Seal oil		·000050

There are two distinct and well-defined varieties of kelp. Cut weed or black-wrack kelp, and drift weed or red ware kelp. Cut weed kelp is the old soda-producing variety, and is made from the three *Fuci*, *Fucus vesiculosus*, *F. nodosus*, and *F. serratus*; these grow on the rocks in the order named, the latter being the most submerged and containing the most iodine, though all contain but little. The plants are cut at low tide, floated ashore, dried and burnt; the weed does not soften much by rain, and it can always be obtained in the fine natural harbours of the West of Scotland and Ireland. This kelp, burnt into a dense fused slag, contained the most carbonate of soda, and was that variety which employed so many poor crofters and cottars, and enriched so many highland lairds. It is now worthless, and the Fuci, which hang from the rocks at low water in luxurious festoons in these lochs, are now entirely unutilised. I have seen 10,000 tons of this weed cut in a single loch, in a few weeks of summer.

The drift kelp is made from two varieties of red weeds, or Laminaria, the *L. Digitala*, and the *L. Stenophylla*, the former known as tangle; both are always submerged, and are torn up by the violent gales, so common on the west coast; both are sometimes cut in Ireland with long hooks under water from boats. These plants, especially the latter, suffer very much from rain, and are often, after drying, almost valueless; but if well saved, contain ten times as much iodine as the Fuci.

This is the only kelp now used for making iodine, and it ought to be burnt into a loose ash; but although they employ a different material, we have to deal with the same people, and they still insist on raking it into a molten slag, with iron clauts, at great extra trouble, so much so that the men of the family are obliged to do this part of the work, under the erroneous impression that it will weigh heavier, thus mistaking specific gravity for weight; the fact being that they drive off more than half the iodine, and a great deal of the salts, spending several extra laborious hours in reducing the value to a half. It may be asked why we allow it? An incident which occurred to me may answer that question.

Some years ago, when I had to take a large quantity of black-wrack kelp in North Uist, it was made to enable the people to pay their rents, and could not then be given up, though it has been since. I tried hard to get some improvement made in the direction of burning the weed at a lower temperature. The people were assembled in great numbers, and the sheriff eloquently harangued them in Gaelic for me. Their objections were threefold: it would not yield so much, it would not be so good, and it would take too long. The late Sir John P. Orde, the proprietor, and his factor were present, and it was agreed at last that the most experienced kelper and myself should try the experiment, each to have a certain quantity of weed weighed out to him, and each to burn it his own way. As I expected, my lot was finished first. The yield was 25 per cent. greater, and the product was also, weight for weight, 25 per cent. more valuable. Any one can understand this double advantage of ash *versus* slag. The old man, my opponent, on the result being explained to him, made a remark in Gaelic, which was translated for me as follows:—"I have been making kelp for fifty years and more, and am I to be taught by a young Sassenach with no beard on his face to speak of?" That was the only result of the experiment. How could I explain to him, especially in Gaelic, the difference between specific gravity and weight, to say nothing of quality? As they would not improve the process, the work had to be stopped, and their evidence before the Royal Commission shows how much they have missed it. We took away their clauts, but it was no use; landing once in the middle of the night, I came upon a group hard at work with new irons, raking off the salts, and making themselves hideous, for so intense is the heat, that the soda volatised gives a strong monochromatic yellow flame which does not improve the beauty of the workers.

To show that this extraordinary idea still prevails, I quote the following from a daily paper, referring to the island of Tyree this year:—

"The men attending the kilns used to turn over the burning mass with iron 'clauts,' but about two years ago the company forbade the use of the 'clauts,' and the kelp is simply reduced to ashes instead of a hard substance. It may be better fitted for manufacture in this state, but it is also evident that it will take more of it to make a ton than by the old process."

It has one advantage for them, being on the sandy shore, or shingle, it enables them to rake in, and embody with the fused kelp a quantity of sand and stones. We sometimes get a block of granite thinly veneered with kelp from our Irish friends, to remind us, I presume, of their national wrongs, and take a slight revenge.

The great heat involves the additional disadvantage that the carbon reduces the sulphates to sulphides, which involve considerable expenditure of oil of vitriol to decompose them, so that sulphur thus deposited is one of the bye-products of the lixiviation of kelp. We are, therefore, compelled to reverse the ordinary process, and manufacture sulphur from sulphuric acid.

The usual yield of kelp from 100 tons of wet seaweed is 5 tons, and as only half of this is soluble, 2½ tons forms the total valuable product of the labour of cutting, carrying, drying, and burning 100 tons of wet seaweed; the burner, in many parts, does not receive more than £2 per ton, sometimes less, so that all this labour is done for 2s. per ton of weed. When it is also remembered that bad weather often reduces this payment to nothing, it is easy to understand that this occupation is soon given up where any other employment can be obtained. Moreover, the weed is dried in a climate where a native comes up to you with the rain pouring off his hat and nose, and outrages your sense of sight by informing you, if he knows "the English," that it is "a wee misty." The large mass of material to be dealt with, the stormy character of the coasts, the constant moisture of the climate, all tend to still further reduce the quantity obtained. Even with favourable conditions, the yield is only 5 per cent., which is quite inadequate to afford profit either to the maker or to the lixiviator.

These evils were fully pointed out in my former paper, and a method was then suggested by which several new products could be obtained, and the whole of the iodine secured. I proposed to submit the seaweed to destructive distillation in iron retorts, thus obtaining a loose, porous charcoal, which retains the salts and the iodine; ammonia, acetic acid, and tar were obtained from the distillate. In looking over the tables published in my former papers, some of the diagrams of which are once more on the wall, I notice that the amount of iodine lost in kelp was much underestimated; much too low a figure having been taken for the produce of iodine. The amount of kelp then made was 10,000 tons in this country, and 24,000 in France; and I estimated the loss of iodine, in this country alone, at 50,000 lbs. annually, it really was about three times that amount, or 150,000 lbs., worth, even at the present low price, £37,500, a sum in excess of the whole value of the additional new products proposed to be recovered.

The Duke of Argyll was the first to see the value of the improvement suggested, and the new process was first carried out in his island of Tyree, in 1863, where works were erected for the purpose; soon afterwards works were also erected in North Uist, under an arrangement with the late proprietor, Sir John P. Orde; and more recently in Ireland.

In some respects, Tyree was the best place that could have been selected, in others, the worst. The wildness of its shores, and its numerous outlying rocks, make it the deposit of much drift weed. The inaccessibility and the great difficulty of landing heavy machinery, &c., made the erection of works extremely difficult. The factor calculated that 30,000 tons were used annually for manure, and that four times that quantity was lost. Our calculations were based on recovering 16,000 tons of this, and if even that quantity could have been obtained, the works there would have had a very great success, and turned out more iodine than all the other Highland shores put together. It is impossible, however, to estimate the amount of seaweed thrown up in a storm, and the sea has an awkward habit of calling again, and removing a good deal of it, or covering it over with sand. This seaweed is also much injured by rain, which soon washes out the salts and iodine. It is a nitrogenous substance, and is quickly devoured by maggots, which become flies, and the material, like some other riches, speedily takes to itself wings and flies away, so that when once I carted a large quantity to the works for experiment, some knowing ones observed that the Sassenach had taken a great deal of trouble to put in the material, but it would not give him any kind of pains to put it out, as it would leave him of its own accord. I may add that it did not; there is nothing so offensive as rotten seaweed, but I had preserved the weed with chloride of calcium. In the winter the long sea rods are thrown up, and these when properly stacked bear a good deal of exposure. There was much difficulty in getting the people to collect these at first, for it was a new thing, and they did not believe in it. They soon found out, however, that it affords winter employment for what they call "a lairge sma' family," and which, to do them credit, most of them possess, as children can work at it. It consists simply in stacking the tangle out of reach of the tide. This work has been going on ever since 1863, and none is lost that can be secured. The works in Tyree and in North Uist are still continued, to the great advantage of the people. For the latter the tangle is also collected in South Uist and shipped to Loch Eport. Both these islands also yielded large quantities of black-wrack kelp, which is now entirely given up.

The works were lighted with the gas obtained by distillation, but after the gas has passed through all the purifiers, it still burns with a strong monochromatic yellow flame. The ammonia obtained is all used as manure for the farm; for whatever other business you follow in these outer islands, you must be a farmer, to feed your horses, &c. The tar is used for the roof of the works; and I may state here, that after great experience of large roofs, many of which have been blown away, I prefer a lattice girder low felt roof. No one who has not witnessed a winter gale in one of the Hebrides can form an idea of it. We find it advisable to raise the walls two feet above the girders on each side. I would also mention here that there is no building so efficient or suitable for the damp climate of these outer islands as concrete. The shingle of the shore is always there as the bulk of the material, and cement only has to be sent out. A vessel loaded with quick lime, anchored off one of these islands in a gale, is not a happy or a safe possession, and I know from experience that it does not contribute to the sweetness of sleep.

Iron retorts, heated by coal or peat, were at first used, but these were superseded by brick ovens, which are now employed without fuel. The tangle swells in the retort, and produces a charcoal of great porosity, from which the salts are easily washed out, and there are no sulphides. The residual charcoal is a very efficient decoloriser and deodoriser, but has never been largely used for these purposes. I shall mention presently an application of it.

The following analysis shows the comparison of this charcoal with that from bone. It does not in any way approach the composition of that from wood :—

	Seaweed.	Bone.
*Carbon	52·54	11·77
Phosphates	10·92	77·70
Calcium carbonate	15·56	8·43
Calcium sulphate	—	·35
Magnesium carbonate	11·34	—
Alkaline salt	5·70	1·09
Silica, &c.	3·94	·66
	100·00	100·00
*Containing nitrogen	1·75	1·5
Containing ammonia		

My experience in the use of peat may be worth recording. I found it give a very fair red heat; we cut and stacked about 600 tons a year of good quality in North Uist, it cost 2s. 6d. per ton, and I do not think it can be obtained for less. There was no royalty or rent, and the bog was close to the works. It required three times the quantity compared with coal, which greatly increases cost of firing. There is this peculiarity about peat that, where a large supply is required, its cost increases with the quantity collected, because a larger area must be worked.

The winter tangle forms but a small part of the seaweed used for kelp. In the spring and autumn large quantities of Bardarrig or tangle top come ashore, and this is the substance most difficult to deal with. It is ruined for kelp-making by rain, and it will not repay cartage to a long distance. Even washing about in the sea spoils it. To work it by my process would require a large number of small works, which is out of the question, so that it is still mostly made into kelp in the old way, with all its attendant evils. It is this substance which I propose now mainly to deal with. I am convinced that no process will deal effectually with it unless it will afford the means of removing it to central works, say at Glasgow, involving a cost for carriage equal probably to the cost of the weed, doubling in fact its first cost. There are two ways of removing it, either wet or air dry. I prefer the latter, although I have proved that it can be perfectly well kept in a silo, a specimen so kept for several months having reached me perfectly good, and still containing 83·8 per cent. moisture; and it has been also proved that such a covering of earth as that used for potatoes is an available silo. Most of this material can, however, be got air dry, if, as soon as obtained, it is put in a rick and thatched over, a good deal of it being lost at present while they are waiting for enough to burn into kelp, which cannot be made in a small quantity, and for a way they have of putting it in small stacks to get damp again, because they object to burning it too dry. Twenty thousand tons of this dry material could easily be got in Ireland alone. Four hundred thousand tons of the black wrack was the usual annual collection in the Hebrides in former years, now all unutilised, so that there is ample material if use can be found for it. It is a well known fact that the Fuci grow better when regularly cut.

We are not, of course, limited to Ireland and the Highlands, as any demand for the raw material would offer up new and very extensive sources of supply.

The difference between kelp-making and distillation in retorts is shown by the following actual experiment on eight tons of tangle. Four tons were burnt with great care into kelp, and four tons were carbonised in a retort with the following results :—

	Cwt.	Per cent.
Kelp produced	15	18·7
Char ,,	30	37·5

	Salts. cwt.	Iodine. lbs.
Produce of char	8·77	29·25
,, kelp	6·57	13·27
Loss in kelp	2·10	15·98
,, per ton of tangle	0·53	4·00

As a rule the kelp does not contain anything like this. The presence of sand particularly, adds much to the volatility of the iodine.

A rich sample of seaweed ash, exposed in a platinum capsule over an ordinary Bunsen burner for twenty-four hours, will not retain a trace of iodine.

The sand in kelp is either shell sand, which is mostly carbonate of lime, or flint sand, which is silica; both are highly prejudicial, as the following experiment shows—100 grains of a rich seaweed ash was in each case heated for ten hours over an ordinary Bunsen burner.

	Per cent.		lbs. per ton.
The ash contained of iodine....	·8930	..	20
The ash after heating ten hours	·4911	..	11
The ash with 50 per cent. limestone	·3572	..	8
The ash with 50 per cent. sand	·2235	..	5

NEW PROCESS.

The salts made from kelp at present are as follows, taking an average on 20,000 tons:—

	Per ton.	
Muriate (95 per cent. potassium chloride)	5	cwt.
Sulphate (75 ,, potassium sulphate)	1·8	,,
Kelp salt (sodium chloride, containing carbonate = 8 per cent. alkali............	3·8	,,
	10·6	

Iodine, 12½ lbs. per ton.

I found, in the first instance, that these salts could be easily extracted from the seaweed, by simple maceration in cold water; the amount so removed from air dry Laminaria is pretty regularly about one-third of the weight, or 33 per cent., of which 20 to 22 per cent. are mineral salts, and the balance consists of dextrine, mannite, and extractive matter; leaving two-thirds of the plant, or 66 per cent., for further treatment, apparently unaltered.

This residue contains a peculiar new substance, to which I have given the name of Algin; and the cellulose; the whole plant being thus utilised.

The comparison between the three processes will, therefore, be as follows, on 100 tons of air dry Laminaria:—

KELP PROCESS.

Per cent. utilised, 18.

Kelp, 18 tons.	Salts, 9 tons. Iodine, 270 lbs.	Residuals—Kelp waste, 18 tons, valueless.

CHAR PROCESS.

Per cent. utilised, 36.

Char, 36 tons.	Salts, 15 tons. Iodine, 600 lbs.	Residuals—Charcoal, 36 tons, tar, and ammonia.

WET PROCESS.

Per cent. utilised, 70.

Water extract, 33 tons.	Salts, 20 tons. Iodine, 600 lbs.	Residuals—Algin 20 tons, cellulose 15 tons, dextrine, &c.

Showing that the last process has the first advantage of taking out more salts and iodine from the weed than any other; and these, even at present prices, are sufficient to recoup all the expense of carriage and working. Moreover, in the two prior processes, the residuals are those of the first product, in the last these are from the weed itself.

The water extract is carbonised, and the salts extracted. I append analyses of these; they differ from the kelp in containing no sulphides, and in containing calcium and magnesium salts.

AIR DRY (LAMINARIA STENOPHYLLA).

21 per cent. salts.

	Per cent.
Calcium sulphate	1·93
Potassium sulphate............	9·72
Potassium chloride............	31·97

Sodium iodide.................	1·79
Sodium hydrate	0·13
Magnesium chloride	5·74
	99·95

RESIDUAL WEED (LAMINARIA STENOPHYLLYA).

2·32 per cent. salts.

	Per cent.
Potassium sulphate............	35·27
Potassium chloride............	6·72
Potassium carbonate	5·00
Sodium carbonate	49·97
Sodium iodide................	2·63
	99·49

It will be seen that 90 per cent. of all the salts are thus removed, and much of those that remain are products of decomposition. These salts are obtained by the carbonisation of the water extract. This is not necessary, and may not be advisable, the salts can be fished out during evaporation. I append analysis of a 2 cwt. sample so fished:—

Calcium sulphate	1·18
Potassium sulphate............	14·20
Potassium chloride............	27·81
Sodium chloride..............	55·11
Sodium iodide................	1·69
	99·99

Iodine 32 lbs. to per ton.

Also of the mother liquor 54° Twad. evaporated—

Potassium sulphate	16·35
Potassium chloride............	17·48
Sodium chloride..............	54·98
Sodium carbonate	5·13
Sodium iodide................	5·27
Water	·70
	99·91

Iodine 100 lbs. per ton.

We now come to the treatment of the residual weed. If the long fronds of the *Laminaria stenophylla* be observed after exposure to rain, a tumid appearance will be noticed, and sacs of fluid are formed from the endosmosis of the water through the membrane, dissolving a peculiar glutinous principle. If the sacs be cut, a neutral glairy colourless fluid escapes. It may often be seen partially evaporated on the frond as a colourless jelly. This substance, which is then insoluble in water, is the remarkable body to which I have given the name of Algin. The natural liquid itself is miscible with water, but coagulated by alcohol and by mineral acids. It contains calcium, magnesium, and sodium, in combination with a new acid which I call alginic acid. When this natural liquid is evaporated to dryness, it becomes insoluble in water, but it is very soluble in alkalies. This new substance is so abundant in the plant that, on maceration for twenty-four hours in sodium carbonate in the cold, the plant is completely disintegrated. The mass thus obtained is a glutinous mass of great viscosity, and difficult to deal with on that account. It consists of the cellulose of the plant mixed with sodium alginate. The cells are so small that they pass through many filters, but by cautiously heating it, the mass can be filtered through a rough linen filter bag, the cellulose being left behind, and after the algin is removed, this is easily pressed.

The solution contains dextrine and other extractive matter, and it is then precipitated by hydrochloric or sulphuric acid; the alginic acid precipitates in light grey albuminuous flocks, and is easily washed and pressed, in an ordinary wooden screw press. A filter press, made for me by Messrs. Johnson and Company, answers perfectly well for this operation, but not so well for the preceding. It forms a compact cake, resembling new cheese, and has only to be stored in an ordinary cool drying-room, where it can be kept any length of time. If desired, by adding a little bleach during the precipation, it can be obtained perfectly white. The algin can be sent out in this state, it is only necessary to dissolve it in sodium carbonate in the cold for use. If, however, it be sent out as sodium alginate, it must be dissolved to saturation in sodium carbonate, the carbonic acid is disengaged, and sodium alginate is formed. If potassium or ammonium carbonate be used, the alginates of potassium or ammonium are formed, which are similar to the soda-salt. The bi-carbonates of these alkalies may also be used; but the caustic alkalies are not such good solvents.

The sodium alginate forms a thick solution at 2 per cent., it cannot be made above 5 per cent., and will not pour at that strength. Its viscosity is extraordinary. It was compared with well-boiled wheat starch, and with gum arabic in an ordinary viscometer tube; the strengths employed were as follows; it was found impossible to make the algin run at all over the strength employed:—

			Seconds.
Gum arabic solution,	25 per cent.	took	75 = 1 in 3
Wheat starch ,,	1·5 ,,	,,	25 = 1 in 8
Algin ,,	1·25 ,,	,,	140 = 1 in 112

So that the algin has 14 times the viscosity of starch, and 37 times that of gum arabic.

I append analyses of two samples of commercial sodium alginate of average composition:—

	No. 1.		No. 2.	
Water	17·13		19·30	
Organic matter	59·97		58·125	
Carbonate soda	18·32	P.C. ash 22·90	17·78	P.C. ash 22·575
Neutral salts..	2·98		2·77	
Insoluble ash..	1·60		2·025	
	100·00		100·00	
Dry algin	67·58		65·50	
Soda (Na_2O)	10·71		10·40	
Per cent. of Na_2O	15·85		15·87	

Showing that, excluding the water, salts, and ash, the composition is uniform.

The solution may be alkaline, or neutral, or acid, according to the degree of saturation; if alkaline, it may be made distinctly acid by the addition of hydrochloric acid, but any excess at once coagulates it; a 2 per cent. solution becomes semi-solid on this addition.

The evaporation is effected in a similar manner to that of gelatine, in thin layers on trays or slate shelves, in a drying room with a current of air, or on revolving cylinders heated internally by steam; high temperature must be avoided. The solution keeps well. Thus obtained, the sodium alginate presents the form of thin, almost colourless, sheets, resembling gelatine but very flexible. It has several remarkable properties which distinguish it from all other known substances.

Algin, or sodium alginate in solution is precipitated or coagulated by alcohol, ethylic and methylic, acetone, and collodion (but not by ether) by acid hydrochloric, sulpho-indigotic, nitric, sulphuric, sulphurous, phosphoric, citric, tartaric, lactic, oxalic, and picric; salts of cobalt, copper, platinum, nickel, silver, bismuth, antimony, zinc, cadmium, aluminum, chromium, uranium, barium, calcium, strontium, and tin chloride and bichloride; mercury pernitrate, and protonitrate; iron sulphate (white), and iron perchloride (brown); lead acetate, and basic acetate; lime water, and baryta water.

The solution is not precipitated nor coagulated by alkalies and salts of alkalies, including lithium, alkaline silicates, potass bichromate, (not coagulated by boiling), and chromate; sodium stannate, succinate, biborate, and tungstate; magnesium and manganese salts, starch, glycerine, ether, cane sugar, amylic alcohol, boracic acid, acetic, carbolic, tannic, butyric, benzoic, gallic, pyrogallic, arsenious, and succinic acids; potass ferrocyanide, mercury iodide, ferricyanide, and permanganate; bromine, iodine, and chlorine water; molybdate ammonia, tartar emetic, and peroxide hydrogen. It does not precipitate the ordinary alkaloids.

It is distinguished from albumen, which it most resembles, by not coagulating on heating, and from gelose by not gelatinising on cooling, by containing nitrogen, and by dissolving in weak alkaline solution, and being insoluble in boiling water.

From gelatine, by giving no reaction with tannin; from starch, by giving no colour with iodine, from dextrine, gum arabic, tragacanth, and pectin, by its insolubility in dilute alcohol and dilute mineral acids.

It is remarkable that it precipitates the salts of the alkaline earths, with the exception of magnesium, and also most of the metals, but it gives no precipitate with mercury bi-chloride nor potassium silicate.

It has a strong rotary power on polarised light; Mr. Tatlock estimated it for me as having a specific rotary power of 86·5° on Laurent's polariscope. This again fixes its position amongst animal bodies, gelatine, and albumen, and not amongst such vegetable products as pectin, which is neutral.

Alginic acid is insoluble in cold water, very slightly in boiling. It is insoluble in alcohol, ether, and glycerine. The proportion of soda ash used is one-tenth of the weight of the weed, and the cake of alginic acid obtained, is usually about the same weight as the weed. The quantity of dry alginic acid is given below:—

	Laminaria Digitata. Stem.	Laminaria Digitata. Frond.
Water	37·04	44·0
Alginic acid	21·00	17·35
Cellulose	28·20	11·00

	Laminaria Stenophylla. Stem.	Laminaria Stenophylla. Frond.	Laminaria Bulbosa.	Fucus vesiculous.
Water	34·5	40·02	43·28	40·10
Alginic acid	25·7	24·06	17·95	12 22
Cellulose	11·27	15·06	11·15	..

FALKLAND ISLANDS GIANT ALGÆ.

Nos.	1	2	3	4	5
Alginic acid	11·21	10·09	5·56	7·44	3·34
Cellulose	8·13	7·25	3·50	12·95	9·68

The three gelatinous algœ, already referred to, contain no algin.

The cellulose in the tangle is higher than in any other weed, the outside of the stem being rather fibrous. I append also analyses of the ash of three varieties of cellulose dry, unbleached to show the trace of iodine still retained:—

	Laminaria Digitala.	Laminaria Stenophylla.	Fucus vesiculus.
Yield of char.	38·36	36·41	44·62
Soluble	11·08	5·27	11·06
Carbon	12·73	14·27	15·93
Ash	14·55	16·87	17·63
Iodine	·12	·06	·05
On air dry plant about	·012	·006	·005

The new process may be tabulated as follows:—

		Per cent.
Extracted by water—		
Salts	20	
Sugar, mucilage, &c.	10	
	—	30
Extracted by sodium carbonate—		
Algin	20	
Dextrine, &c.	10	
	—	30
Cellulose		10
Moisture		30
		100

Of these, I have accounted for the salts, the algin, and the cellulose, leaving the mucilage, dextrine, and sugar for further investigation.

It is not necessary to extract the salts first with water, it comes to the same thing to act on the seaweed at once with soda ash, and to recover the salts by evaporation of the solution, after the alginic acid has been precipitated. In this case chloride of calcium, or of aluminium may be employed, the alginate of calcium or aluminium being precipitated. With either salt the alginate is thrown down instead of rising to the surface of the liquid, and the cakes are more compact and easily pressed. In addition to the cheapness with which it can be procured in almost any quantity, as a bye-product in alkali works, now all thrown away, the calcium chloride has the advantage of throwing down the sulphates in the salts, and decomposing them into chlorides, so that the salts consist of chlorides of potassium and sodium, which are easily separated, and do not require the tedious and expensive processes necessary in the lixiviation of kelp. The same remark applies to aluminium chloride, which can be cheaply obtained by dissolving banxite in hydrochloric acid. Either salt can be decomposed by hydrochloric acid, and the calcium or aluminum chlorides recovered; or the salts can be decomposed by sodium carbonate. The calcium alginate, when dry, is very like bone, as the dry alginic acid is like horn. The aluminum alginate is soluble in caustic soda, forming a neutral solution, and giving, on evaporation, a substance like algin, but harder and making a stiffer finish; it is also soluble in ammonia, the salt becoming an insoluble varnish on evaporation. The alginates of copper (blue), nickel (green), cobalt (red), chromium (green), and zinc, are all soluble in ammonia, and form beautiful coloured insoluble films on evaporation. So also do the alginates of platinum, uranium, (yellow), and cadmium. The latter is exceedingly soluble in ammonia. The alginate of chromium is also soluble in cold water, and it is deposited on boiling the solution, becoming then insoluble.

With bichrome, algin acts as gelatine, the mixture becoming insoluble under the influence of light. The silver alginate darkens very rapidly under exposure to light, and suggests applications in photography. Algin forms a singular compound with shellac, both being soluble in ammonia; it is a tough sheet, which can be rendered quite insoluble by passing it through an acid bath.

Commercial Application of Algin, or Sodium Alginate.

For Sizing Fabrics.—A soluble gum of considerable elasticity and flexibility is a great desideratum; so also is a soluble substitute for albumen, which can be easily rendered insoluble and used as a mordant. As a finish, algin has the advantage over starch, that it fills the cloth better, that it is tougher and more elastic, that it is transparent when dry, and that it is not acted upon by acids. It imparts to the goods a thick clothy elastic feeling, without the stiffness imparted by starch. It has the additional advantage, which no other gum possesses, of becoming insoluble in the presence of a dilute acid, which decomposes starch or dextrine. No other gum has anything like the viscosity in solution, and therefore none will go as far in making up the solution or cover such a large surface. Lime-water, salts of calcium, barium, and various metallic salts can be employed for rendering the coating insoluble. If greater stiffness be required, the algin can be mixed with gum arabic, starch, dextrine, gelatine, albumen, or glue, in any proportion.

The alginate of alumina, in caustic soda, is a stiff dressing, and in the crude, unbleached state, will be a cheap dressing for dark materials; and in the colourless state for finer fabrics. The ammoniated alginate of alumina can be used to give a glossy surface, which is quite insoluble after drying.

As to its use as a mordant in dyeing, I quote from Mr. John Christie, of J. Orr Ewing and Co., to whom I am indebted for the fine specimens of Turkey red dyeing exhibited, some of which are finished and mordanted with this new substance instead of cow dung:—"There is another application of the alginate of soda that occurred to me might be of some interest, namely, in the fixing of mordants, such as alumina, or iron, upon cotton fibre. I find, so far as I have gone with the experiments, very encouraging results. I believe a very large application will be found for the alginate of soda as a dunging substitute. The mordants, when precipitated, seem to have full dyeing power, the results indicating that this substance is capable of taking the place of cow dung, as used in print and dye-works; also as a dunging substitute it will rank with arseniates, phosphate, and silicate of soda, and a number of other salts, which are now largely used for the precipitation of mordants previous to the dyeing of cotton fabrics and yarns."

As an Article of Food.

Algin contains—carbon, 44·39; hydrogen, 5·47; nitrogen, 3·77; oxygen, 46.37; or about the same amount of nitrogen found in Dutch cheese. It has a slight pleasant marine taste, easily overcome if objected to, and may form a useful addition to the kitchen for thickening soups and puddings. It appears specially adapted to replace gum arabic in the manufacture of jujubes and lozenges. To make it into jelly, requires addition of gelose or gelatine, or admixture of lemon juice.

It will be useful for some pharmaceutical purposes, as for emulsion of oils, as an excipient for pills, and for fining of spirits.

For Boiler Incrustation.

The sodium alginate has a remarkable effect in resolving and preventing the incrustation of boilers. My friend, Mr. Spiller, who introduced the first, and one of the best fluids for this purpose, first suggested this application. He found it to precipitate the lime in a state in which it could be easily blown off. Further experience has fully corroborated his opinion. The solution is pumped in with the feed water, in the proportion of 1 lb. to every 1,000 gallons. Where hard waters are a necessity, the saving of fuel is considerable.

For Covering Boilers.

The seaweed charcoal, in conjunction with algin, is used for this purpose, and has been largely applied under the name of "carbon cement." It is nearly all charcoal, 3 per cent. of the algin being sufficient to make it cohere. Charcoal is known to be the best solid non-conductor of heat, and in this way its application to steam boilers has been made practicable. It forms a cool, light, and efficient covering.

Algic Cellulose.

This substance bleaches easily, and under pressure becomes very hard, and can be turned and polished with facility. It also makes a good paper, tough and transparent, but with no fibre. Alone, or mixed with algin and linseed oil, or shellac, it may be used as a non-conductor of electricity, where a cheap material is required.

Although there is still a small portion of the plant not accounted for, which will, I hope, also soon be worked out, I think enough has been discovered to justify the following conclusions:—

1. The only way to effectually utilise seaweed is to import it in the raw state.

2. By following the wet process, the additional cost is fully made up by the greatly increased amount of iodine and salts obtained from the water solution, leaving two-thirds of the plant for further treatment.

3. That by extracting from this the algin and the cellulose we utilise the whole plant, and obtain two new products of considerable commercial importance.

4. That the process is extremely simple, and requires no extravagant plant; nor do operations on the large scale present any serious practical difficulties.

5. That the new substance, algin, has very remarkable properties, which may find many applications not yet known, when it can be put on the market.

6. That the demand for such a substance in fixing and mordanting fabrics alone is enormous.

Our annual export of textile manufactures and yarns is valued at £40,000,000, or more than half the value of our total exports; and a large portion of this requires some dressing material to fit it for the market. We import about £200,000 worth of gum arabic, a good deal of which is used for this purpose; and the war in the Soudan is raising its price, and making it scarce.

7. That the supply of raw material is almost unlimited. Seaweed damaged by rain is equally available for the manufacture of algin.

I will only add that I bring forward this process with some confidence, as the result of a quarter of a century's scientific work, and an almost equally long practical experience—an experience gained in a wide and wild school. I am satisfied, whether it may be given to me to carry it out or not to the extent it should be, it will become the process of the near future. It immediately possesses the advantage of obtaining known marketable products of considerable value, and it bids fair to open up a new industry which may become one of large extent, supplying, as it will, new products for which there is an absolute want. On the other hand, the importance of attaching a marketable value to seaweed can scarcely be overrated. No Royal Commission will give the crofters and cottars on the shores of the Hebrides and the West of Ireland anything like the satisfaction that the offer of £1 per ton for all the seaweed they could gather would. In all these places the sea quest might soon become more important than the land question. Moreover, a shipping trade in the raw material itself, is a great benefit to the out-lying islands where it is obtained, it necessitates cartage, it tends to the improvement of roads and harbours, it improves communication by bringing steamers, and necessarily brings the people closer to civilisation, and the great centres of industry. This is especially the case where the expenditure of every thousand pounds on the raw material means the expenditure of about as much on carriage. I have reason to know that the lairds of all these shores would not be entirely dissatisfied with such a result. We should all share in the satisfaction of knowing that one more waste product had been effectually utilised.

DISCUSSION.

Dr. REDWOOD had listened with great interest to this paper, and all the more so from his early associations with the author, and from a recollection of his previous paper on his improved method for obtaining iodine from seaweed. It was very satisfactory to find that Mr. Stanford had persevered in the subject he then took up, and had succeeded in obtaining from seaweed these new products he had described. It was, perhaps, to be regretted that, owing to other sources of iodine having been discovered, his process for its manufacture from kelp had been to a great extent superseded; but that being so, it was all the more satisfactory to find there was a probability of rendering this industry advantageous from the discovery of another and very valuable product. Mr. Stanford drew his attention to the product some months ago, and he had satisfied himself experimentally of the facility with which algin could be isolated, whilst the author had shown that evening how extensive was the field for its application.

Mr. E. M. HOLMES said the thanks of the whole country were due to Mr. Stanford, for suggesting what might prove a very extensive industry, and one which might benefit the poorer classes of the population in districts where at present many of them were nearly starving. He had recently, at Swanage, noticed cows and donkeys on the beach eating the seaweed thrown up on the shore, and it occurred to him that seaweed might perhaps be utilised as food for animals. When they considered the immense amount of seaweed sold in China and Japan, it was astonishing that so small a use was made of it as food in this country. Laver (*Porphyra vulgaris*) was used to some extent in Devonshire, and it was by no means disagreeable in taste. Mannite, which was another product mentioned by Mr. Stanford, was principally obtained from Italy; but some algæ contained it in considerable quantity, and he saw no reason why it should not be utilised. With regard to the use of seaweed as manure, he knew it was constantly so employed in the Channel Islands, and we certainly obtained our earliest vegetables from those islands. He thought it was an error to regard the manurial value of seaweed merely from the point of view of the salts which they contained. Gardeners distinguished between what they called live and dead soil, live soil being that in which the decomposition of either animal or vegetable matter was going on; and this process apparently had an influence in causing changes of a chemical nature in the soil which promoted the growth of plants; it could, therefore, be reasonably supposed that the algæ might be more beneficial in the fresh state than when dried. He understood Mr. Stanford to say that the algæ from deeper water contained more iodine than those which grew nearer the shore, but in the table given, the largest amount was from the *Laminaria stenophylla*, which always grew higher on the shore than the *Laminaria digitata*. Another interesting point was that some of the gigantic algæ contained less iodine than the common Laminarias of our own shores. In the "Flora antarctica," published by Dr. Hooker some years ago, it was stated that Dr. Stenhouse had analysed these algæ, and had found in them a large quantity of iodine, and in one of them a considerable quantity of mannite; but probably so much was not known at that time about iodine, and no doubt Mr. Stanford's analyses were the more correct. But the interesting questions remained, where the iodine came from, and whether, as he believed Mr. Stanford thought, it came from the warm waters of the Gulf of Mexico. He should like to ask Mr. Stanford to what he attributed the strong odour of sea water possessed by the *Enteromorpha*, as he stated that contained no iodine. To show the rapid growth of the Fuci, he might refer to a statement in Dr. Landsborough's little book on marine algæ, that at one place in Scotland, where the rocks had been scraped quite bare, the algæ grew to a length of 6 ft. in six months. The idea of keeping seaweeds in a silo seemed a very excellent one, because under certain circumstances, as in wet weather, it was almost impossible to keep it without losing the salts. With regard to the use of algin for pharmaceutical purposes, it had already been employed for emulsifying cod-liver oil, and was found very superior to other agents, especially as it contained a small quantity of iodine. Some time ago he read that some parts of the coast of Mauritius was covered at certain times with immense quantities of foam, caused by mucilage apparently derived from Laminaria; and it occurred to him that perhaps the algæ might be employed for producing a head on beer, in preference to quillaia bark, which he understood was now used for that purpose, and which must be of a somewhat irritating character, from containing saponin; whereas the algin would certainly be of a harmless character. It occurred to him, from the insolubility of the salts of alginic acid, that it might perhaps be useful for waterproofing purposes. He should also like to ask whether textile fabrics became less combustible from its use. With regard to its substitution for gum arabic, he might say that it was almost impossible of late years to obtain this gum of good quality. That which they now obtained made a mucilage more like that of white of egg than that from good gum. The bean found with the sea wrack was one which was found in the West Indies, commonly called the asses'-eye bean (*Mucuna urens*).

Mr. CROSS said it would be very interesting to see

Mr. Stanford's results correlated with the main principles of cellulose chemistry. Perhaps the most interesting feature of the algin was the presence of nitrogen, but he had not said anything about the products of decomposition of the algin, such as would throw light on the point whether the nitrogen was essentially connected with the carbon molecule which presided over the whole. It would be very interesting to have some information on these points. There was certainly some evidence of its having the general properties of an aldehyde, and, in some respects, it reminded one of the body recently described as oxycellulose. Whenever cellulose was oxidised, it yielded these peculiarly gelatinising bodies. It was impossible, in a few words, to even indicate the enormous field which was opened up for investigation by the discovery of this substance, and he hoped it would be thoroughly taken up.

Mr. T. Christy said he had brought with him some *Eucheuma speciosa* from the western shore of Australia; and amongst several seaweeds which he had put into commercial use, none gave such excellent results in dyeing and the preparation of mordants. He had had several requests from France to procure further supplies, but though he held out every inducement to the traders on the west coast of Australia to forward this seaweed, he had not succeeded in getting any more. Mr. Greth, in making some experiments with it, and also on some Japanese seaweed, found that it took up 500 times its weight of water, and as a sizing material there was nothing equal to it. He had also tried it in several preparations for damp walls, and found it most effectual, both with plaster, lime, and brick walls. Mr. Greth was still working at this subject in Berlin. The use of the algæ in combination with shellac was of great importance, as it prevented the extreme brittleness which arose from the use of shellac alone. It was largely used for this purpose in France, where they were very particular as to the class of seaweed, and next to that from Australia, the weed from Singapore met with most favour. He had lately, however, received some *E. Spinosa* from Borneo, which was even superior to that from Singapore. There was an immense field for the use of seaweed, if a regular supply could be depended upon of these qualities,

Mr. Lloyd said everyone who had passed a heap of seaweed must have noticed the disagreeable smell which came from it, showing that it was most liable to decomposition, and this was the root of the difficulty of dealing with it as food; besides which, few, if any people, knew how to cook it. In Wales it was largely used fried in oil, and he believed it was also used in London to some extent boiled like greens. He was much surprised to hear that seaweed had been kept in a silo, and retained 80 per cent. of moisture, knowing its liability to decompose, and the immense difficulty which farmers had found in keeping grass with only 75 per cent. of moisture; it would be interesting to know what changes had taken place, and whether the preservation was due to the formation of some acid, or to the presence of salt in considerable quantities. Looking to the precipitating power of one of the products Mr. Stanford had obtained, it occurred to him that possibly it might be useful in the purification of sewage, at any rate in the initial operation of throwing down the solid matter.

Mr. J. M. Thomson said he understood Mr. Stanford that this new substance might be used in photography, and would produce a harder film than gelatine, but he thought there might be a difficulty in easily softening it with water for the purpose of making an emulsion with salts of silver. One point mentioned in the early part of the paper, viz., the affording occupation to the crofters, was of great importance. He could speak from experience of the west coast of Scotland, and if by the aid of the system of telpherage, lately brought forward by Professor Fleeming Jenkin, this industry could be developed, it would be of immense advantage to the inhabitants. If there were more men like Mr. Stanford in that district, indicating, as he had done, the directions in which the crofters might make their work remunerative, less would be heard of crofters' commissions.

Mr. Stanford, in reply, said that algin had been tried in photography, but there was one disadvantage about it, that the silver coagulum was not such a strong one as any of the others. What he had suggested for photography was gelose; it made a good emulsion, and dry plates had been worked with it. With regard to the preservation in the silo, he could only say that the seaweed had been kept for six months, and it was of a kind very difficult to keep, containing, when dry, about 35 per cent. of salts, and very liable to rot. It was put into a well-built silo, and after six months was taken out apparently unaltered. He could not say what was the exact change which had taken place, nor did he think this was as yet ascertained in the case of hay or grass. He did not, however, think the salt had anything to do with it; it was a description of seaweed which, if air got to it at all became full of bacteria, and rotted very quickly. He might also say that it had been noticed years ago that when a large quantity of this substance was kept under pressure, that which was kept underneath kept very well. He understood Mr. Christy to be referring to the *agar agar* as the seaweed from Australia which had given so much satisfaction. He had always drawn the line between these three gelatine-producing species and any other seaweed. Some years ago he investigated all the species he could get hold of, and could not find gelatine in any but the *Gelideum corneum*, and the *Chondrus crispus*, and it was somewhat remarkable that neither those nor the Australian *agar agar* contained either iodine or algin. With regard to Mr. Cross's remarks, he thought that gentleman had already shown that cellulose was sufficiently difficult to investigate without going into any nitrogenous substances. He had placed algin amongst the albumens and gelatines, and though he had made a great number of experiments on the decomposition products of it, he had not yet arrived at any satisfactory conclusions such as he could lay before a scientific society. This substance had not been known quite so long as gelatine and albumen, and yet the chemistry of both those substances was in almost as unsatisfactory a state as that of algin. He had not tried whether textile fabrics treated with this material would be less combustible, but probably they would be, from its containing soda. As to the odour of the *Enteromorpha compressa*, he had not the slighest idea what it came from, any more than he had what caused the odour of the sea; which again would form an interesting subject for investigation to any young chemist who liked to devote his lifetime to it. As to the important question of the deep-sea algæ, and the *stenophylla* which he had given as containing more iodine than the deep-sea tangle, although it grew higher up, the reason was, that the *stenophylla* varied very much in composition; there was no plant he was acquainted with which varied so much in the amount of iodine it contained. In fact, all the seaweeds varied very much according to the time of year, the age of the plant, and other circumstances. The *Laminaria digitata*, both the stem and the frond, almost always contained a definite amount of iodine, and though in this case the *stenophylla* had come out with the largest per-centage, it might easily have been the other way. With regard to the use of seaweed as food, it was a remarkable fact that in Japan they were used with a large amount of salts in them—as much as 30 per cent. when they were sent into the market. He considered that in isolating the algin, we obtained the whole food value, and the whole of the nitrogen of the plant. He was much obliged to Mr. Holmes for the diagrams and specimens he had lent him, and would draw special attention to a specimen of giant algæ from the Falkland Islands, one of which was supposed to be the longest plant in the world, growing sometimes to the length of 1,500 feet.

The CHAIRMAN said this paper was a most interesting one, and there were many points in which it might be very profitably discussed if time allowed. He could but congratulate Mr. Stanford on his perseverance with this subject, for he must have had a great many things to damp his ardour. Some years ago he (the Chairman) had an opportunity of going over the North British Chemical Works, where Mr. Stanford's process of distillation was going on, and he was much interested in seeing the way in which it was worked. He feared the discovery of new sources for iodine, and bromine which was now about the same price per lb. as it was formerly per oz., must have very much interfered with the success of the undertaking. He concluded by proposing a vote of thanks to Mr. Stanford, which was carried unanimously.

Miscellaneous.

THE COMMERCE OF COREA.

The United States Minister in Corea gives an interesting account of the people, trade, and industries of that peninsula. The territory is bounded on the north by the Shan-yan-alin mountains, and two large rivers, which take their rise in these mountains. The one known as Am-no-kan, flowing westward, empties itself into the Yellow Sea, and forms the natural boundary between Corea and China; the other, known as the Toman-kian, flowing eastward, empties itself into the Japan Sea, and divides Corea from Manchuria and the Russian territory. The kingdom is divided into eight departments, viz., Ham-Keung-to, Whang-hai-lo, Kang-wun-to, Keung-que-to, in which department is situated Seôul, the capital, and the open port of Inchun; Choong-chung-to, Chun-ra-to, and Keung-sang-to, which contains the open port of Poosan. Corea is a land of mountains, and in the central and western portions are several plains or plateaus called Maipo; these are extremely fertile, and for this reason Maipo is called the rice warehouse of Seôul. The country is well watered and fairly wooded, and the Government exercises much care in maintaining the forests. Many wild animals abound in the mountains, such as tigers, leopards, bears, wild boars, &c., and pheasants, water fowl, and other game are abundant. Among the domestic animals the horses are extremely small and inferior, and the swine are poor and ill-flavoured. Goats and sheep are rarely if ever seen. Corea produces apricots, nectarines, peaches, plums, apples, pears, and a variety of other fruits. The variety of vegetables is limited, and the quality poor. In spite of the severe restrictions, no inconsiderable amount of gold is extracted each year, and mines of gold, silver, copper, lead, and iron, are said to exist in the country. In the northern districts, wheat, barley, rye, cattle, ginseng — which is a Government monopoly—medicinal herbs, dried fish, honey, tiger and leopard skins, furs and hides are produced. The products of the central and southern districts are rice, silk, cotton, hemp, tobacco, wheat, corn, barley, beans, millet, dye woods, fruits, vegetables, cattle, and hides. Among the manufactures are silk, cotton, and linen cloths, iron and stoneware, pottery, hats, shoes, paper mats, fans, screens, combs, pipes, brushes, certain kinds of furniture, mechanical and agricultural implements, &c. Cloths are woven in hand looms, and pottery is made by the use of the wheel. The majority of the houses are simply hovels, with mud walls and floors, and thatched roofs. The better class of houses have stone foundations, intersected with flues for heating purposes. Upon this foundation is a wooden building with tile roofs, the floors, walls, and windows of which are lined with paper;

the number of houses is estimated at 1,700,000, and the population at 11,000,000. The clothing of the common people is made invariably of cotton or linen cloth, and in winter is wadded. They wear upon their feet straw or twine sandals, with soles of raw-hide, and upon their heads conical shaped hats made of horsehair. Their breeches are made very full, and are divided below the knee, and fastened at the ankles; over this a long loose robe is worn with flowing sleeves. The people are a hardy, vigorous, well-formed race, of medium stature, and while the yellow skin, almond-shaped eyes, and black hair of the Mongolian race prevail, men with light hair and beards and blue eyes are sometimes seen. The beard is allowed to grow, and the hair is never cut, but is tied in a knot on the top of the head. The wages paid to the labouring classes average about 7d. a day, and to the artisan 1s. Slavery is said to exist in a modified form, and is even sometimes voluntary, as thus the poor man escapes extortion and oppression. The artisans and many classes of labourers, however, belong to powerful organisations or guilds, by which means they maintain a degree of independence and enforce their rights. Crime is severely punished, and questions affecting civil rights are decided by the courts. The women, married and unmarried, are kept in great seclusion. Marriage is a matter of negotiation between the parents and friends of the parties, and is often concluded in childhood. Unmarried persons of the male sex can be distinguished by the method of wearing their hair, hanging down in Chinese fashion. The women adorn their heads with bands of false hair; their dress consists of the broad breeches divided below the knees and fastened at the ankles, over this a short skirt and jacket are worn. Persons in mourning eat no meat and pay no visits, they are dressed in robes of coarse grey cotton cloth, and wear immense straw hats, and when they go abroad, hide the lower part of the face with a mask. In conclusion, the United States Minister says:—"There are many industries here which might, by means of the cheap labour, be successfully promoted. There are mines of gold, silver, copper, lead, iron, and coal to be developed. In the north there are said to be large forests of timber, for which there should be a market near at hand. Agriculture, and cattle and sheep breeding, could be stimulated so as to produce a surplus for exportation, but there are difficulties to contend with; the extremes of heat and cold are great, there are no roads or means of transportation, and the policy of exclusion still has strong adherents."

AUSTRALIAN EXHIBITIONS, &c.

Mr. Samuel H. Roberts, honorary corresponding member of the Society, writes as follows:—

The closing of the Calcutta Exhibition, and the return of the Melbourne Commissioner (Mr. J. Bosisto), has attracted public attention here to the desirability of opening up a trade between Australasia and India; and already a Melbourne firm has laid on a line of steamers between this port and Calcutta; a large carrying and passenger trade is expected. The direct influence of an Exhibition on the industries of a country have seldom been so plainly manifested as in this prompt commencement of commercial relations between two important ports.

Our large Exhibition building (prepared for that of 1880-1) has just been opened with an Intercolonial Exhibition. The majority of the exhibitors, however, are Victorians. At the opening ceremony, the Marquis of Normanby congratulated the committee on their having made all the arrangements independently of Government aid. The Exhibition is worthy of the success that his Excellency wished it, as its main object is to bring the resources of the Colony under public notice, and it is promoted by private enterprise. Flower shows; fruit and grain shows; musical and other entertainments are also set before the visitors. The inmates of the Blind Asylum have their work-benches set up in the Exhibition, and practice basket-making, knitting, netting, brush-making, and other work, to the great interest of the public.

The treatment of boy prisoners has lately been attracting attention, the Hon. G. Coppin having advocated the re-establishment of reformatory training ships, and, with the Chief Secretary, Hon. G. Berry, has visited the prisons and reformatories with a view to their improvement. It is hoped that a vigorous effort will be made for their proper treatment and reclamation.

The discovery of coal in payable seams in Victoria will remove a very serious drawback to our industrial supremacy in these seas. Hitherto we have been dependent upon New South Wales for supplies of coal. Now we have found coal in several parts of the colony, and one company is delivering coal of a good quality from the mine at Kilcunda.

A new method or system of ventilation has just been designed by Mr. Lloyd Tayler, one of our leading architects. It has been put into practical use at one of the banks. The fresh air is supplied by a simple and interesting process. A stream of fresh air is forced down from the roof (by a small fan-blower) into an air-tight reservoir in the vaults under the ground floor, and distributed through smaller pipes to the various chambers of the bank, where it is delivered above the heads of the *employés*. The escape of the vitiated air has also been managed in an equally skilful manner.

The schools of art and design in the colony now number thirty-two, and are progressing satisfactorily. Several new schools are projected in different towns and boroughs of the colony. The Hon. William K. Vale, Chairman of the Commission for Promoting Technological and Industrial Instruction in Victoria (with the members of the Commission) takes an active part in the establishment and maintenance of the schools. There are now 2,700 pupils on the roll.

The sister colony of New South Wales is about taking up the question of technical education in earnest. Parliament has voted £20,000 towards it. A technical college has been commenced under the presidency of Mr. Coombs, M.P.

The study of the Australian flora has lent an attraction to the Art Department of our Exhibition, in the work of Miss Foster, who has gathered her examples on the beautiful slopes of the May-day-hills at Buckworth. The students of the Art Gallery at the Public Library, lately held an Exhibition of their own; and very handsome prizes were given by the trustees and others.

KITOOL FIBRE.

The palm, *Caryota urens* (Linn.), is a native of Ceylon, Malabar, Bengal, Assam, and various parts of India. Amongst natives of Ceylon, it is known as Kitool, Kitoo, Kittul, Jaffery, and Bynee. In India, it is called Bastard Sago, Coonda pauna (Tamil); Erimpana, or Schundra-pana (Mal.); Teeroogoo (Tel.), &c.

It is a beautiful and lofty palm, with a trunk more than a foot in diameter, and 40 ft. high. The large bipinnatisect leaves measures 18 ft. to 20 ft. in length, and 10 ft. to 12 ft. across. The fruit is of the size of a plum, with a thin yellow rind, and is very burning and acrid in taste. From the flower stem, an enormous amount of sweet juice can be obtained; as much as 100 pints in 24 hours. From this juice Jaggery sugar, well known in our markets, is prepared, although it is not the only source, other palm trees yielding it in commercial quantities. The caste who prepare this sugar in Ceylon, are known as Jaggeros. The juice is also pleasant to drink when fresh, and an intoxicating spirit known variously as toddy, arrack, pauna, or pawnee, is obtained by fermentation, and largely used.

The pith of the stem contains a large amount of farinaceous matter equal to sago in quality. The natives use this largely for food in the shape of gruel or a kind of bread. Like its relative, the Coco-nut, Kitool palm is a source of food and profit to its owner. Elephants make of the leaves their favourite food, and the "heart" or expanded leaves can be made into a capital cabbage, or pickled, or candied. The woolly substance at the base of the leaves is used in caulking ships.

The fibres or veins of the leaves furnishes the Kitool fibre, and it is largely used by the natives for the making of ropes, fishing-lines, bow-strings, brushes, brooms, baskets, caps, &c. Its great strength has earned for it the name of "Elephant fibre," and ropes made of Kitool are used to tether and secure wild elephants.

The fibre has long been known in this country, and under the name of "Indian gut," has long been used for fishing-lines. When made into brushes, it is found to be most durable, and some firms will not use brushes made of any other material. It seems to be the best substitute for bristles, as the fibre is strong, tough, and impervious to water. It is, however, rather brittle, and a sudden knot may break it. It can be woven together with cotton for petticoat stuffs, and forms a cheap and flexible fabric for dress-improvers, &c. Steamed and curled, it can be used for stuffing purposes in upholstery, and the refuse may be used instead of hair to mix with mortar for building purposes. When dipped in oil, it turns from a dull brown to a beautiful black colour, and the oiliness may be removed.*

The process of making brushes from this fibre, adopted at the works of Messrs. Horsey and Company, is such that no pitch or glue is required, and each knot is independent. The fibre and wire are driven down into the hole in the stock by means of a punch, which consists of two parts like two fingers. This doubles up the fibre with the wire on top, but as soon as it has reached the bottom of the stockhole, the fingers separate and force tho wire into the solid wood. The wire now flattened and secure, the arms of the punch close together, and ascend.

Correspondence.

MINERAL DEPOSITS IN THE SOUTHERN STATES OF AMERICA.

In the number of the *Journal* for December 28th, No. 1,623, was a "note" on the "Mineral Wealth of Colorado." It has since occurred to me that it might be suitable to bring to the notice of your readers another field of mineral wealth in the United States, much nearer to us than is the far South-West, but one that is comparatively neglected—mainly because of the noise made by the large yields some years ago at Leadville, Denver, and in other of the far western provinces. The paper recently read before the the Society, communicated by Mr. W. H. Penning, on "Transvaal Gold Fields," again reminded me that many readers might welcome a few particulars regarding the remarkable mineral deposits on the eastern slopes and upland valleys of the Appalachian range, chiefly in North Carolina, to which chance circumstances, some time ago, drew my attention.

These deposits, which exist chiefly in North Carolina, but also in parts of Virginia, and further south-east in Georgia, have long been known to scientific men, but are comparatively little known to working mineralogists. The Geological Survey Reports of the United States Government long since indicated the abundance and rich variety of mineral

* See Mr. Rowbottom's remarks, *Jour. Soc. Arts*, Dec. 22, 1882, p. 113.

formation in those regions, more especially in North Carolina. At the Boston Exposition of 1882 the prevalence and accessibility of these deposits were demonstrated by the exhibition of ores of every description from that field, those of argentiferous galena and copper being peculiarly rich, while gold nuggets with gold-bearing quartz and gems were also shown. These "exhibits" were more than sufficient to vindicate the prognostications of the official scientific surveyors. That the English public has not become familiar with the remarkable characteristics of the mineral region in the south-eastern States, may partly be due to the rule-of-thumb methods generally adopted by the unscientific pioneers, to whom our capitalists are content to leave the opening out of new or neglected fields of production. Certain local circumstances special to North Carolina, into which it is not needful to enter here, have also deterred both New England capitalists and British "prospectors" from any systematic examination of those districts, which, there fore, still await the operations of well-directed enterprise. Sufficient mining work has been already done in these fields to bring the subject within the scope of such direct and serious notice as many members of the Society of Arts are well qualified to bestow thereon. It is to Davidson County, in North Carolina, that attention should be specially drawn, as at the Boston Exposition the abundance of valuable ores, already "in sight" in that particular locality, was most manifest. The "Cid" copper mine in that country is very well known, it having been worked on somewhat better methods since ores from it were exhibited two years ago. The "Ore Knob" mine, and two or three others in or near the Blue Wing Mountain, are also tolerably well known; but, as yet, are worked under many disadvantages for want of sufficient capital and more experienced direction. In spite of the lack of efficient smelting and "reducing" works, the "Ore Knob" mine has produced over ten million pounds of copper; and, two years ago, It had paid $210,000 in dividends. In the year 1882–3 it produced $1,600,000 worth of pig copper. The "Conrad" mine, also in the Davidson county, is known as yielding gold in paying quantities; but its chief product is sulphuret of copper. The richness of the copper ores throughout North Carolina is quite beyond all usual averages; the other day I was shown a specimen that must have contained over 70 per cent. of copper. Then, in the "Silver Hill" mining district, also in Davidson county, lead and coppers ore are found in close proximity and great abundance. Mica also is present in bulk and quantity remarkably adapted for manufacturing purposes.

The ores and mineral products of these North Carolina districts have recently been brought under the notice of Mr. J. K. Hallewell, a well-known geologist of Denver, Colorado. He speaks of "the chalcopyrite and black oxide of copper from the Cid mines giving values of 47 per cent. copper, $7½ in gold, and 16 ozs. silver." Also from another district in North Carolina Mr. Hallewell reports on ore "giving value, gangue and all, 20 per cent. copper, and value in silver besides;" also much larger percentage by selection. Professor G. B. Hanna, assayer of the United States Mint, at Charlotte, North Carolina, gives assays as follows:—

"Specimen from Farris mine, $506·41 gold and $6·52 silver, per ton; specimen from Rudisil mine, $204·97 gold and $·53 silver, per ton; specimen from Black's mine, $485·75 gold and $2·37 silver, per ton; specimen from Eureks mine, $46·51 gold $2·78 per cent. copper."

One excuse for the neglect of these districts by British mineralogists and capitalists may be the imperfect state of common road communication in North Carolina; but the Richmond and Danville Railway runs within easy distance of some of the most promising of these mineral tracts. It belies our reputation as practical people, that so much British capital and enterprise have been risked and lost in the remote States of the far south-west; while, here in the eastern States, on the very seaboard, these scarcely worked, but practically inexhaustible, stores of copper and lead, so essential to our electrical and other industries, are disregarded as yet. Though the gold-fields of the Transvaal are tempting, there is far less of political and commercial risk to be encountered in the South-eastern States than in South Africa.

W. MARTIN WOOD.

West Kensington, May 21, 1884.

Obituary.

SIR BARTLE FRERE.—The Right Hon. Sir Henry Bartle Edward Frere, Bart., G.C.B., G.C.S.I., D.C.L., LL.D., F.R.S., died on the 29th ult., at Wressil-lodge, Wimbledon, after a long and painful illness. Born on March 29, 1815, he began his distinguished career in India as early as 1834. After the Indian Mutiny he twice received the thanks of Parliament, and in 1862 he was appointed Governor of Bombay. In 1872 he went as Special Commissioner to East Africa, to inquire into the slave trade, and subsequently he accompanied H.R.H. the Prince of Wales to India. In 1877 he was appointed Governor and Commander-in-Chief of her Majesty's Possessions at the Cape of Good Hope, and her Majesty's Commissioner for the settlement of Native Affairs in South Africa. This list represents a portion only of Sir Bartle Frere's employments during his long public life, but his achievements are fully recorded elsewhere; and in this plaee his interest in the proceedings of the Society of Arts should be more particularly recorded. He frequently took the chair at the evening meetings, and at the first meeting of the Indian Section, in 1873, which grew out of the Indian Conferences of previous years, he delivered an address on "The threatened famine in Bengal, and the means of preventing or alleviating famines in India," which formed the groundwork of his published volume on the same subject. He also gave an address at the opening of the African Section in 1874. In 1881 the Society's Silver Medal was presented to him, for his paper on "The Industrial Products of South Africa."

General Notes.

METAL INDUSTRY OF GREECE.—Since the year 1862, considerable attention has been paid to the above industry, which had been brought to a high degree of progress in Ancient Greece. More than 1,000 workpeople are now engaged in connection with the metal trade, and the capital employed is about £3,000,000 sterling. Saurium, the most important seat of the industry, has only commenced its existence as a populated centre since 1863, and it numbers at present 16,000 inhabitants. There are also, throughout Greece, mines of argentiferous lead, zinc, and iron; quarries of ochre and carbonate of magnesia likewise exist, but are not being worked on account of the necessary capital not being available for the purpose.

HEALTH EXHIBITION SEASON TICKETS.

The Executive Council of the International Health Exhibition have consented to allow members of the Society of Arts the privilege of purchasing season tickets for the Exhibition at half price (10s. 6d.) Each member can purchase a single ticket only on the reduced terms, and these tickets can only be obtained through the Secretary of the Society of Arts. For further particulars see notice in the *Journal* for May 2, p. 575.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 9...Engineers, Westminster Town-hall, S.W., 7½ p.m. Mr. J. C. Fell, "Soft *v.* Hard Water for Manufacturing Purposes."
Chemical Industry (London Section), Burlington-gardens, W., 8 p.m. Mr. W. S. Squire, "Th Processes Concerned in the Conversion of Starch into Alcohol, and their Relation to Brewing and Distilling." (Illustrated.)
Geographical, University of London, Burlington-gardens, W., 8½ p.m. Mr. W. W. Graham, "Travel and Ascents in the Himalaya."
British Architects, 9, Conduit-street, W., 8 p.m. Mr. J. T. Wood, "The Temple of Diana at Ephesus."

TUESDAY, JUNE 10...Medical and Chirurgical, 53, Berners-street, Oxford-street, W., 8½ p.m.
Gas Institute, 25, Great George-street, S.W., 10 a.m. Annual General Meeting. Inaugural Address by the President. Reading of papers and discussions.
Photographic, 5A, Pall-mall East, S.W., 8 p.m.
Anthropological, 3, Hanover-square, W., 8 p.m. 1. Mr. A. W. Howitt and Rev. L. Fison, "The Deme and the Horde" 2. Mr. C. A. Gollmer, "Africian Symbolic Language." 3. Dr. S. M. Curl, "Phœnician Intercourse with Polynesia."
Colonial Institute, St. James's Banqueting-hall (Regent-street Entrance), W., 8 p m. Governor Sir Frederick A. Weld, "The Straits Settlements and British Malaya."

WEDNESDAY, JUNE 11...Gas Institute, 25, Great George-street, S.W., 10 a.m. Reading of papers and discussions, continued.
Geological, Burlington-house, W., 8 p.m.
Microscopical, King's College, W.C., 8 p m. 1. Dr. J. Anthony, "The Camera Lucida." 2. Mr. G. F. Dowdeswell, "Some Phenomena of the Red Blood Corpuscles of Vertebrates, with reference to the occurrence of Bacteria normally in Living Animals." 3. Mr. C. D. Ahrens, "A New Polarising Prism." 4. Mr. G. F. Dowdeswell, "The Constancy of Specific Morphological Characters in the Bacteria."
Royal Literary Fund, 10, John-street, Adelphi, W.C., 3 p.m.

THURSDAY, JUNE 12...Royal, Burlington-house, W., 4½ p.m.
Antiquaries, Burlington-house, W., 8½ p.m.
Society for the Encouragement of Fine Arts, 9, Conduit-street, W., 8 p.m. Mr. C. M. Campbell, "What Health owes to Art."
Gas Institute, 25, Great George-street, S.W., 10 a.m. Reading of papers and discussions, continued.
Inventors' Institute, 27, Chancery-lane, W.C., 8 p.m. Mr. S. J. Mackie, "Some Recent Inventions."
Mathematical, 22, Albemarle-street, W., 8 p.m.

FRIDAY, JUNE 13 ... United Service Inst., Whitehall-yard, 3 p.m. Admiral Sir Alfred Ryder, "Fog Collisions."
Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting, 9 p.m. Prof. Dewar, "Researches on Liquefied Gases"
Astronomical, Burlington-house, W., 8 p.m.
Gas Institute. Visit to Hatfield-house. St. Albans.
Quekett Microscopical Club, University College, W.C., 8 p.m.
New Shakspere, University College, W.C., 8 p.m. Mr. Thomas Tyler, "Shakspere's Sonnets."

SATURDAY, JUNE 24...Physical, Science Schools, South Kensington, S.W., 3 p.m. 1. Mr. D. J. Blaikley, "The Velocity of Sound in Tubes." 2. Mr. H. H. Hoffert, "A new Apparatus for Colour Combinations."
Botanic, Inner Circle, Regent s-park, N.W., 3¾ p.m.

CORRECTION.—Page 710, col. 1, line 14, *for* half an inch *read* one-twelfth of an inch; line 15, *for* six cells, *read* thirty-six cells. Page 712, col. 1, line 8, *for* worked by a dynamo, *read* worked by a motor, actuated by the first cell of the series; line 25, *for* 100, *read* 600.

Journal of the Society of Arts.

No. 1,647. Vol. XXXII.

FRIDAY, JUNE 13, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

ALBERT MEDAL.

The Council of the Society of Arts have (with the approval of the President, H.R.H. the Prince of Wales) awarded the Albert Medal of the Society for the present year to Captain James Buchanan Eads, "the distinguished American engineer, whose works have been of such great service in improving the water communications of North America, and have thereby rendered valuable aid to the commerce of the world."

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Thirtieth Annual General Meeting, for the purpose of receiving the Council's Report and the Treasurer's statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new members, will be held, in accordance with the Bye-laws, on Wednesday, the 25th June, at 4 p.m.

(By order of the Council)
H. Trueman Wood,
Secretary.

CONVERSAZIONE.

A Conversazione will be given at the International Health Exhibition by the Council of the Society of Arts, in conjunction with the Executive Council of the Exhibition, on Wednesday evening, 9th of July.

Further particulars will be duly announced.

Proceedings of the Society.

APPLIED CHEMISTRY & PHYSICS SECTION.

Thursday, May 22, 1884; B. Francis Cobb, Vice-President of the Society, in the chair.

The paper read was—

SOME ECONOMICAL PROCESSES CONNECTED WITH THE CLOTHWORKING INDUSTRY.

By Dr. William Ramsay,
Professor of Chemistry at University College, Bristol.

In this present age of scientific and technical activity, there is one branch which has, I think, been the subject of an article in the *Quarterly Journal of Science*. It is one which deserves attention. It was there termed "The Investigation of Residual Phenomena," and I can conceive no better title to express the idea. The investigator who first explores an unknown region is content if he can in some measure delineate its grand features—its rivers, its mountain chains, its plains; if he be a geologist, he attempts no more than broadly to observe its most important rock formations; if a botanist, its more striking forms of vegetation. So with the scientific investigator. The chemist or physicist who discovers a new law seldom succeeds in doing more than testing its general accuracy by experiments; it is reserved for his successors to note the divergence between his broad and sweeping generalisation and particular instances which do not quite accord with it. So it was with Boyle's law that the volume of a gas varies in inverse ratio to the pressure to which it is exposed; so it is with the Darwinian theory, inasmuch as deterioration and degeneration play a part which was, perhaps, at first overlooked; and similar instances may be found in almost all pure sciences.

I conceive that the parallel from the technical point of view is a double one. For just as every technical process cannot be considered to be beyond improvement, there is always scope for technical investigation; but the true residual phenomena of which I would speak to-night are waste products. There is, I imagine, no manufacture in which every substance produced meets with a market. Some products are always allowed to run to waste, yet it is evident that every effort consistent with economy should be made to prevent such waste; and it has been frequently found that an attempt in this direction, though at first unsuccessful, has finally been worked into such a form as to remunerate the manufacturer.

It is my purpose to-night to bring under your notice methods by which saving can be effected in the cloth industry. I am aware that these methods have not much claim to novelty; but I also know that there are, unfortunately, few works where they are practised.

The first of these relates to the saving and utilisation of the soap used in wool scouring and milling. It is, perhaps, hardly necessary to explain that woollen goods are scoured by being run between rollers, after passing through a bath of soap, and this is continued for several hours, the cloth being repeatedly moistened with the ley, and repeatedly wrung out by the rollers. The process is analogous to ordinary washing; the soap dissolves the greasy film adhering to the fibres, and the "dirt" mechanically retained is thus loosened, and washed away. Now, in order to dissolve this greasy matter, a considerable amount of soap must be employed; and in the course of purification of the fabric, not merely what may be characterised as "dirt" is removed, but also short fibres, and various dye-stuffs with which the fabric has been dyed, many of which are partially soluble in alkaline water; moreover, it invariably happens that some dye does not combine with the fibre and mordant, thus becoming fixed, but merely encrusts the fibre; hence this portion is washed off when the retaining film of grease is removed from the fibre. The suds, therefore, after fulfilling this purpose, are no longer a pure solution of soap, but contain many foreign matters; and the problem is so to treat these suds as to recover the fat in some condition available for re-conversion into soap.

For this purpose wooden runnels are placed beneath the rollers, through which the cloth passes in the scouring machine, so as to collect the suds after they have been spent. These runnels lead to a wooden pipe or runnel, which receives the spent suds from all the scouring machines, and the whole of the waste, instead of being let off into the stream, polluting it, delivers into a tank or trough, which may also be constructed of wood, but, as it has to withstand the action of acid, is better lined with lead. This tank is necessarily proportioned in size to the number of scouring machines, and the quantity of spent suds to be treated. When a sufficient quantity has collected, oil of vitriol, diluted with twice its bulk of water, is added, one workman pouring it in gradually, while another stirs the contents of the tank vigorously. At short intervals, the liquid is tested by means of litmus paper, and when it shows a faint acid reaction, by turning the blue paper red, the addition of acid is stopped. The acid has then combined with the alkali of the soap, while the fatty acids formerly in combination with the alkali are liberated, and float to the surface of the liquid, carrying with them the impurities, in the shape of short fibres and dye stuffs; the sand and heavier impurity, should any be present, sinks to the bottom.

After standing for some hours, the separation is complete. In order to separate the two layers, the tank is provided with an exit in the side, near the bottom, closed by a sluice or valve. This valve is opened, and the watery portion is allowed to escape into a sand filter-bed. The filter serves to retain any solid impurities which may still remain suspended in the water; but it will be found that the escaping water is nearly pure.

The dark brown fatty acid is mixed with a large amount of impurity, such as short wool fibres, burrs, sand, and dye stuffs washed from the wool. To remove water more completely, the semi-fluid mass is pumped from the tank, and delivered into hair-cloth filters; the liquid which drains from these bags finds its way to the sand filters, joining the drainage which formerly passed out from the tank through the sluice. After being turned over in the filter several times, the residue is transferred to canvas sacks. These sacks are placed in a filter press, where they are exposed to pressure while heated to a temperature sufficient to melt the fat. The solid impurities remain in the bags, while the fatty acids escape, and are received in a barrel or tank for the purpose. The fatty acids, when cold, are of a deep brown colour, and of the consistency of butter. The residue is kept, and the method of treating it for the recovery of indigo will afterwards be described.

The fatty acids are now ready for conversion into soap. It may here be remarked that, on distillation, they yield a nearly white fatty mass, which, when treated with soda-ley, is capable of yielding a perfectly white soap. But, for the clothworkers' purpose, this purification is unnecessary.

The conversion into soap is a very simple matter. As the fats are acids—a mixture of palmitic, oleic, and stearic acids—and not the glycerine salts of these acids, like ordinary fats, soap is made by causing them directly to unite with caustic soda. The fats are melted in a copper, by means of a steam-jacket, or coil of steam-pipe in the copper, and the soda-ley is run in until complete union has taken place. The exact point of neutralisation can easily be found by taking out a small sample after stirring, and dissolving it in some methylated spirits. A few drops of alcoholic tincture of phenol-phthaleïn are then added, and as soon as a faint red colour appears, addition of soda is stopped. This shows that the fatty acids have been over-saturated. Addition of a little more fat renders them perfectly neutral, and the soap is then ladled out into wooden moulds, lined with loose sheets of zinc.

The resulting soap is of a brown colour, but is perfectly adapted for the purpose of wool-scouring. It should here be mentioned that, in practice, the soap is always made somewhat alkaline; in point of fact, it contains about 2 per cent. of free alkali. This is found to assist in scouring; I presume that the free alkali forms a soap with the oil added to the wool during spinning, and if no free alkali be present, this oil would not be so thoroughly removed.

It will be noticed that in this simple method of soap-making, there is no salting out to separate the true soap from the watery solution of glycerine, for no glycerine is present. The apparatus may be of the simplest nature, and on any required scale, proportionate to the size of the mill. It is a process which requires no specially skilled labour; in any works some hand may be told off to conduct the process as occasion requires; and as a very large proportion of the fatty matter is recovered, the soap-bill is reduced to a very small fraction of the amount which would be paid were recovery not practised. And lastly, the streams are not polluted; the only waste is a little sulphate of soda, which can hardly be regarded as a nuisance, inasmuch as it is a not unfrequent constituent of many natural waters.

Let us now return to the solid matter from which the fatty acids have been removed by pressure. This brown earthy-looking cake consists of vegetable impurity washed off from the cloth, of short fibres, and of various dye-stuffs. It is divided into two lots:—That which contains indigo, and that which contains none, or which contains too small a quantity for profitable extraction. And it may here be remarked, that it is advisable to collect the suds from cloth dyed with indigo separate from that to dye which no indigo has been employed. The residue from indigo-dyed cloth has always a more or less blue shade, and if much indigo is present, the well-known copper-colour is evident. Of course, the amount of indigo must greatly vary, but it may rise to 8 or 10 per cent. of the total weight of the refuse.

To recover the indigo from this refuse, the somewhat hard cakes are broken up, placed in a tank, and allowed to steep in water. When quite disintegrated, they are transferred to another tank—a barrel may be used for small quantities—and thus this refuse is exposed to the reducing action of copperas and lime. The indigo is converted into indigo-white, and is rendered soluble, and it oxidises on the surface, forming a layer of blue froth on the top of the liquid, while the remainder of the impurities sinks. This process of reduction may last for twenty-four hours, and is helped by frequent stirring.

The indigo scum is preserved, and placed in filter cloths, where it is thoroughly washed with water two or three times. The residue which has sunk to the bottom is removed, dried, and forms a valuable manure, owing to the amount of the nitrogen which it contains. Its value may be increased by addition of weak vitriol, which exercises a decomposing action on the nitrogenous matter forming with it sulphate of ammonia. The original residue from the filter-press, if it does not contain indigo, may be at once put to similar use.

In large works, which dye their own goods, it is well known that the "fermentation-vat" is in general use for indigo-dyeing. But this vat requires constant superintendence, and must be kept in continual action; besides, it is successful only on a comparatively large scale. And, moreover, it requires skilled labour. Small works, or works in which dyeing is only occasionally practised, find it more convenient to use Schützenberger and Lalande's process. Although this process is well-known, a short description of it may not here be out of place.

The process depends on the reduction of indigo to indigo white, or soluble indigo, by means of hyposulphite, or, as it is generally termed to avoid confusion with antichlore, rightly named thiosulphate of soda, hydrosulphite of soda. The formula of this substance is $NaHSO_2$, as distinguished from what is commonly known as hyposulphite of soda, $Na_2S_2O_3$. It is produced by the action of zinc-dust on the acid sulphite of soda. The zinc may be supposed to remove oxygen from the acid sulphite, $NaHSO_3$, giving hyposulphite, $NaHSO_2$. The reduction of the acid sulphite is best performed in a cask, which can be closed at the top, so as to avoid entrance of air. The acid sulphite of soda, at a strength of 50 or 60 Twaddell (specific gravity 1·26 to 1·3), is placed in the cask, and zinc dust is added, with frequent stirring. The liquid is then mixed with milk of lime, and after again thoroughly stirring, the liquid is allowed to settle, and the clear is decanted into the dyeing-copper. The indigo, in the frothy state in which it is skimmed from the purifying barrels or tanks, is then added, with sufficient lime to dissolve it when it has been reduced. It is heated gently by a steam coil, to about 90° Fahr., and the goods are dyed in it. The colours obtained by means of this indigo are light in shade, and the goods must be dipped several times if dark shades are required. But it is found better in practice not to attempt to dye dark shades by this process; the ordinary indigo-vat is better adapted for such work. The object of not wasting indigo is sufficiently attained by employing it for the purpose to which it is best adapted. Of course the recovered indigo may be used in the ordinary manner. I merely mention the most convenient way of disposing of it in works where only a small quantity is recovered, and which do not practice dyeing on an extensive scale.

I have now to ask you to turn to a different subject, namely, the scouring of wool, not by the usual agent, water, but by a liquid, bisulphide of carbon, made by the action of sulphur vapour on red hot coke or charcoal.

This, again, is not wholly a new process, for various attempts have been made to dissolve out the yolk, or *suint*, or greasy matter from unwashed wool, as it comes from the back of the sheep. Fusel oil has been patented for this purpose. Carbon disulphide has also been patented, but, as will afterwards be shown, the old method of removing it from the wool injured the colour and quality of the fibre, so as to make the application of this scouring agent a failure.

Wool in its unwashed state contains a considerable proportion of what is termed *suint*. This consists of the fatty matter exuded as perspiration from the sheep, along with, or in some form of combination with, potash derived from the grass on which the sheep feed. *Suint* was first investigated by Vauquelin. He obtained it by evaporating, after filtration, the water in which raw fleeces had been washed. The residue is of a brown colour, and has a saline, bitter taste. On addition of an acid to its solution in water, it coagulates, and a fatty matter rises to the surface. It is, in fact, a potash soap, to a great extent containing carbonate and acetate of potash, along with chloride of potassium and lime, probably in combination also with fatty acids. It is usually mixed with sand and carbonate of lime.

In 1828, M. Chevreul, who is still alive in Paris, although nearly a century old, published an analysis of merino wool. It consisted of:—

	Per cent.
Pure wool	31·23
Soluble *suint*	32·74
Insoluble ,,	8·57
Earthy matter	27·46
	100·00

It is easily seen that *suint* forms a very important constituent of raw wool. Its proportion varies, of course, according the nature of the pasture on which the sheep are fed, the climate, &c. Wool from Buenos Ayres, for example, contains much less than that analysed by M. Chevreul; its amount is only 12 per cent. of the weight of the raw wool.

This *suint* contains always about 52 per cent. of residue when ignited. The composition of this residue is:—

	Per cent.
Carbonate of potash	86·78
Chloride of potassium	6·18
Sulphate of potash	2·83
Silica, alumina, &c.	4·21
	100·00

In 1859, MM. Maumené and Rogelet patented the use of the water in which wool has been washed as a source of potash, and at present the extraction of potash from *suint* is practised in France on a large scale. The wool is washed in a systematic manner, in casks, with cold water, which runs out of the last cask with specific gravity 1·1. These washings are evaporated to dryness, and the residue is calcined in iron retorts, the gas evolved being used for illuminating purposes. The remaining cinder, consisting of a mixture of charcoal and carbonate of potash, is treated with water, whereby the latter is dissolved out. The residue left on evaporation of this water consists largely—almost entirely—of white carbonate of potash. At present there are works at Rheims, Elboeuf, Fourmier, and Vervier, which yield about 1,000 tons of carbonate of potash annually. Now, only 15,000 tons are made per annum by Leblanc's process. In 1868, 62,000 tons of wool were imported into Britain from Australia alone, and from this 7,000 to 8,000 tons of carbonate of potash might have been recovered, the value of which is £260,000. Yet it was all wasted! And this this estimate does not include the fats of the *suint*, which are worth an even greater sum.

Now, it is evident that there is here a profitable source of economy. So far as I am aware, no work in this country saves its washings. The water all goes to pollute the nearest river.

The use of carbon disulphide has again been introduced, and it is to be hoped with better success, for methods have been devised whereby the wool is not injured by it, but is even rendered better than when scoured by the old process of washing with carbonate of soda and water, or by soap. The process is due to Mr. Thomas J. Mullings. Briefly described, it consists in exposing the wool, placed in a hydro-extractor, to the action of bisulphide of carbon; the machine is then made to revolve, and the excess of solvent is expelled, carrying with it the fatty matters; the solvent finds its way into a tank, from which it flows into a still, heated with steam; the carbon disulphide, which boils at a very low temperature, distils over, and is again ready for use, while the residue in the still consists of *suint* washed from the wool. To remove the last trace of carbon disulphide from the wool in the hydro-extractor, cold water is admitted, and when the wool is soaked, the machine again revolves. On expulsion of the water, the wool is ready for washing in the ordinary machines, but with cold water only instead of hot soapsuds.

The distinguishing features of Mr. Mullings's process are, the method by which loss of carbon disulphide is avoided, and the extraction of that solvent by means of cold water. The apparatus consists of a hydro-extractor or centrifugal machine of special construction, fitted with a bell-shaped cover, which can be lifted into and out of position by means of a weighted lever. The rim of this cover fits into an annular cup filled with water, which surrounds the top of the machine, forming an effective seal or joint. Upon the spindle of this machine is suspended, as in ordinary forms of the hydro-extractor, a perforated basket, and in this basket is placed the wool to be treated. The cover being closed, the carbon disulphide is admitted, and passing through the wool, the greasy matter is dissolved, and along with the solvent, enters a reservoir. The machine is now set in motion, and the bulk of the solvent is drawn off. Cold water is then admitted, and the machine being again caused to rotate, the whole of the bisulphide is expelled. It is a curious fact that, although wool soaks remarkably easily with carbon disulphide, and at once becomes wet, cold water expels and replaces almost all that liquid. This operation takes about twenty minutes, and at one operation about 1½ cwt. of raw wool may be treated. The wool is then washed in suitable washing-machines of the ordinary type, but with cold water, no soap or alkali being employed. The bisulphide of carbon, mixed with water, flows into a reservoir, provided with diaphragms to prevent splashing, and consequent loss by evaporation. From its gravity it sinks, forming a layer below the water; it is then separated and recovered by distillation, and may be used in subsequent operations.

The point in which this process differs from the old and unsuccessful ones formerly tried, is in the expulsion of the carbon disulphide. It was imagined that it was necessary to expel it by means of heat or steam. Now, when wool moist with bisulphide is heated, it invariably turns yellow. No heat must, therefore, be employed. As already remarked, the solvent is expelled with cold water.

The residue, after distillation of the carbon disulphide, is a greyish-coloured very viscous oily matter, still retaining a little bisulphide, as may be perceived from the smell. It has not the composition of ordinary *suint*, inasmuch as it contains no carbonate of potash, and indeed little mineral matter of any kind. A sample which I analysed lost in drying 36·2 per cent., the loss consisting of water and carbon disulphide. It gave a residue on ignition amounting only to 1·6 per cent. of the original fatty matter, or 2·5 per cent of the dried fat. The oil appears, from some experiments which I made, to be a mixture of a glycerine salt and a cholesterine salt of fatty acids. It distils without much decomposition, giving a brown yellow oil, which fluoresces strongly, and has a somewhat pungent smell. The molecular weight was determined by saponification with alcoholic potash, and subsequent titration of the excess of potash employed. This was found to equal 546·3. This would correspond to a mixture of 18·7 parts of stearate, palmitate, and oleate of glycerine, with 81·3 parts of the same acids combined with cholesteryl. But this is largely conjecture. The boiling point of the oil is high, much above the range of a mercurial thermometer, so that it is difficult to gain an insight into its composition.

An objection which has been raised to this process is that the use of such an easily in-inflammable substance as bisulphide of carbon is attended by great risk of fire. Were the bisulphide to be exposed to free air, there might be force in this objection; but there is no reason why it should ever be removed from under a layer of water. The apparatus, to make all safe, should not be under the same roof as the mill; and no open fire need be used in the building set apart for it. It is easy to rotate the centrifugal machine by a belt from the mill, but better by a small engine attached, the power for which can be conducted by a small steam-pipe, and the distillation of the bisulphide can also be conducted without danger by the use of steam, as its boiling point is a very low one. The question may be naturally asked, "How do the wool and fabric made from the wool scoured by this process, compare with that scoured in the usual way?" To answer this question I may refer to a test made by Messrs. Isaac Holden and Co., at their works at Roubaix. A sample of wool was divided into two portions, one of which was scoured by the usual method, and the other by the turbine or Mullings's process. Skilled workers then span each sample to as fine a thread as possible. Now the thinness to which a wool can be spun is evidence of its power of cohesion—in other words, its strength. The weight of 1,000 metres of the wool cleaned by the new process bore to that scoured by the old process the proportion of 1,015 to 1,085, showing that a considerably finer thread had been produced. And in total quantity, 67·53 kilos. of the former corresponded to 71·77 kilos. of the latter, showing a proportionately less waste. Such fine yarn had never before been obtained from similar wool. The yarn of the soap-washed wool could not be spun, for it could not withstand the strain; whereas, that scoured by the new process gave an admirable thread.

Another test to which it was subjected may be cited. It is the custom in France, before the wool is scoured, to put it through a sorting process, by which all the short lengths are weeded out. On a quantity exceeding 11,000 kilograms, half of which was scoured by the turbine process, and half by the ordinary process, the former in scouring lost in weight 2 per cent. less than the latter, although the short length extracted from the moiety thus treated weighed only 10 kilograms, while that taken from the other weighed over 150 kilograms. This saving, even with the unequal treatment, amounted in value to from 30 to 40 centimes per kilogramme.

In order that the importance of this application may be realised, I shall conclude with some figures:—

The raw wool imported into England, in the year 1882, amounted to 1,487,169 bales, its total value being about £22,000,000. The cost of washing this wool by the old process, with carbonate of soda, amounts to about ½d. per lb. of the raw material. The cost for the total quantity of wool imported, is at least £1,214,000. But it is customary to wash wool with soap, especially for the combing trade, and the cost is then about 1d. per lb. The cost of scouring by the new process is about £1 5s. per ton, or 0·13d. per lb. Taking the least favourable comparison, were all the imported wool (home-grown wool is here left out of the calculation, for want of sufficient returns) cleansed by the turbine process, the actual saving would be £1,214,500 *minus* £315,700, or nearly £900,000 per annum.

It is thus seen that there is room for a very important economy in the treatment of wool. I have endeavoured to show how economy may be practised in scouring by the old process with soap, and how one dye-stuff may be profitably recovered. It is to be hoped that means of extracting other dyes from the residue may soon follow. Unless the process were too costly to repay the trouble of extraction, it would be well worth practising; for it would not merely be a solution of the problem of how to avoid waste, but would at the same time prevent the pollution of our streams, now, unfortunately, only too rarely pellucid; and were the last process to have as successful a future as I hope it may have, a very important saving of expense would result, and a large quantity of valuable fatty matter would no longer be thrown away.

DISCUSSION.

Earl CATHCART said it was only due to express the great sense of obligation which he felt to Dr. Ramsay for his most interesting paper. He attended that evening, because he had been informed that Mr. Mullings's process, which had been referred to, was in some way the result of a paper which he wrote some years ago for the "Journal of the Royal Agricultural Society of England;" not that he meant to suggest that he had anything to do with this discovery, but that the reading of his paper had suggested the idea which was afterwards carried out as had been described. Wool was not a profitable business just now in agriculture, but with regard to what Dr. Ramsay had said about the difficulty of obtaining statistics of the home produce of wool, having written upon that subject, he did not think there was any practical difficulty in arriving at a conclusion, seeing that the exact number of sheep in the country was recorded, and knowing what was the average fleece in different districts, a calculation could easily be made. If the learned professor would do him the favour to look at his paper, he would see that in 1875 a fairly correct approximation was made of the home produce of wool. It was perfectly well known that the imports into this country did not represent the manufacture of wool in this country, because London was the great emporium of the wool trade; the material was all brought here, and afterwards exported to different parts of Europe. He was very much surprised, as an agriculturist, to find that Dr. Ramsay did not know the term yolk, because that was the only term known in agriculture, throughout the whole of Great Britain, for what he had termed *suint*. The chemical composition of this substance was also very well known, and if Dr. Ramsay would refer to his paper, he would find there a letter from his friend Dr. Voelcker, which gave extracts from some learned German works, in which the chemical composition of the yolk was thoroughly explained. With regard to the quality of wool, that depended in a great measure, in England at any rate, on the geological formation on which it was produced. In his own immediate neighbourhood round Ripon and Thirsk, in the North Riding of Yorkshire, good wool was produced, owing, no doubt, to the geological formation. In another part of the country with which he was connected, Staffordshire and Derbyshire, the wool was very good, and it was quite common to hear one farmer say, you must give more money for my wool, for my wool is grit and my neighbour's wool is limestone, showing practically how thoroughly well understood was the influence which the geological formation had on the quality of the wool. He should like to ask what was the value of the residue cake after scouring, as far as its nitrogenous constituents were concerned.

Dr. RAMSAY said he thought it would rank along with many other high class manures, blood, for instance. He could not say the actual per-centage of nitrogen.

Lord CATHCART asked what was the value per ton?

Dr. RAMSAY said he could not say, as it was not produced commercially, but these woolly matters were worked into blood manures in large quantities.

The CHAIRMAN, in moving a vote of thanks to the reader of the paper, remarked that Dr. Ramsay did not come before them as a practical agriculturist, but rather as a chemist who wished to bring to their notice the peculiar action of bisulphide of carbon in cleaning and scouring of wool. No doubt this process would be very valuable, wherever it could be used, as a means of cheapening wool, and they all knew that where manufacturers were pushed so close, and profits were so small, anything in the shape of economy such as was now proposed, both in the working of the soap and the scouring, must be very much to the advantage of the country. It was quite true that on different geological formations you got different characteristics of wool, which required different treatment to a certain extent; but still there were the same general features throughout, so also in the case of Australian wools, though amongst them there were even greater variations than in English. The imports of wool, as Lord Cathcart had said, unfortunately, did not all stay in this country, but went to other parts of the world; but he hoped that the publishing of such a paper as the one they had just heard would tend to prevent that export of wool from England. The great competition of our continental neighbours made it desirable that every possible means for economising cost should be adopted. The exports from the Australian colonies were now going to such an extent to European ports direct by foreign ships, sailing under the bounties given them by foreign Governments, and with every facility given them to compete successfully with our own, that it became doubly important that every opportunity should be taken to diffuse valuable information of this kind for the benefit of our manufacturers.

Mr. J. BLAMIRES seconded the resolution, and begged leave to ask Dr. Ramsay if he could explain the reason why the same quality of wool could be spun to finer counts when cleaned by this new process than when the ordinary method was adopted. It occurred to him, having had some experience with wool in various processes, and having found that its power of spinning was much deteriorated when it had been scoured with too strong an alkali, whether soap, ash, or soda, that the crisp, hard, handling of the wool was caused by the absence of the yolk or fatty matter. They all knew that if they washed their heads thoroughly with soap, the hair became harsh and rough, and that the application of a little oil would render it soft and pliable again; and when the fibres of wool were in a similar state, the spinning or drawing process could be carried on better. He therefore came to the conclusion that it was desirable to leave a little fatty matter in the wool. It was well known that when wool had been scoured they used oil, in former times to the extent of two gallons per cwt., but at that time the wool was not scoured so clean as it was now, so a great deal of the oil put on was absorbed by the grit or earthy matter. Within the last twelve or twenty years there had been a great improvement in the scouring of wool, and the fibre being so much cleaner, received fatty matter and became softer and more pliable. He understood Dr. Ramsay to say that it cost ½d. per lb. to scour by the ordinary process, but that it cost more than that to scour for combing, but he did not catch exactly what was the difference.

Dr. RAMSAY said it cost 1d. per lb. for combing; by the new process it was one-eighth of a penny. He was not prepared to give a definite answer to the question why the wool spun finer, but he might say that he had tried the breaking strain of wool under the influence of various scouring agents, including ammonia, carbonate of soda, and carbonate of potash. He used the ordinary worsted, and took the same sample for each, and repeated the experiment a great many times, so as to get a fair average. He did not remember the exact numbers, but he did the order in which the result stood. An old scouring process had the least deleterious action on the wool, though ammonia was equally harmless; that material, however, was too expensive to be used. Soap came next, and very weak soap did a little harm, especially potash soap; it had less action than soda soap; next came carbonate of potash; next carbonate of soda, and lastly he tried the effect of caustic alkalis, which was, perhaps, rather a waste of time, because they were never used, they made the wool much more brittle than any scouring agents. He then examined the fibre under the microscope, and from that examination the fibre appeared to have scales upon it, which in the natural state lay down flat, and did not project at the edge of the fibre; but after treatment with alkalis the scales seemed to be loosened, and to cause the edge of the fibre to have a rough appearance, from the scales being raised. In the case of scouring by bisulphide of carbon, these scales did not appear to be raised, but to lie flat. There was no doubt that all these alkalis dissolved wool; if you used them strong enough, the wool would go into solution; even strong carbonate of soda soon made it into a gluey sort of mass; if the alkali was strong, it penetrated the fibre and disintegrated it to some extent, but if used weak it only attacked the outside. He believed bisulphide did not attack the fibre in any way or loosen the scales, but merely removed the grease; it was always possible to add grease again for the purpose of spinning. If you could remove the grease without injuring the fibre, it was quite possible to add it again, if necessary, which would remove all difficulty. The samples shown were spun from the same wool, and that cleaned by sulphide were stronger than the other. The surface had been less attacked, and so the wool fibre was actually stronger. There was little doubt that in milling cloth, what took place was that these scales were considerably loosened, and then they interlocked with each other, so as to bind two consecutive fibres together.

Lord CATHCART said that was really the felt process, which was the most difficult of all questions. He understood Dr. Ramsay to suggest that the cause of these feltings was the splitting out of these fish-hook like things which stuck out from the wool.

Dr. RAMSAY said that was so, but it was very desirable to keep the fibres down until the felting process was required to be carried out.

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION.

The conference arranged by the Mansion-house Council on Dwellings of the Poor was held at the Health Exhibition, on Wednesday, Thursday, and Friday, June 4, 5, and 6, when papers were read by Dr. Longstaff, Miss Gertrude Toynbee, the Rev. A. Mearns, Mr. James Hole, Miss Lidgett, Mr. H. D. Harrod, Mr. Shirley F. Murphy, Dr. Whitelegge, and Mr. C. M. Sawell. The chairmen were the Lord Mayor, the Archbishop of Canterbury, and Cardinal Manning.

On Monday, June 9th, the joint conference of the Society of Medical Officers of Health, the Sanitary Institute of Great Britain, and the Parkes Museum of Hygiene, was commenced. The subjects of the papers read were the sanitary and insanitary conditions in the dwellings of the poor, and improvements which might be made in existing homes, or be introduced in the construction of new buildings. The papers read were on "The Domestic Sanitary Arrangements of the Metropolitan Poor," by Dr. John W. Tripe, and on "The Improvement of the Sanitary Arrangements of Metropolitan Houses," by Mr. Ernest Turner. The chair was taken by Dr. T. O. Dudfield, President of the Society of Medical Officers of Health, and among the speakers were Mr. Rogers Field, Dr. Corfield, Dr. Alfred Carpenter, and Captain Galton.

On Tuesday, Capt. Douglas Galton, C.B., F.R.S., Chairman of the Council of the Parkes Museum, took the chair. The papers read were on "Domestic Sanitation in Rural Districts," by Dr. George Wilson, and on "Sanitary Homes for the Working Classes in Urban Districts," by Mr. H. Percy Boulnois. Among the speakers in the discussion were Sir Henry Acland, F.R.S., Sir Robert Rawlinson, Dr. Thursfield, Dr. Woodford, Dr. Alfred Carpenter, Sir T. Dyke Acland, &c.

KEW REPORT FOR 1882 AND 1883.

From the "Report on the Progress and Condition of the Royal Gardens at Kew during the year 1882," which has lately been issued, the following notes on economic plants have been taken. This document, which is an epitome of work done at the Kew establishment during the year in all branches of botany, not the least being that which concerns itself with the development or extension of the uses of plants, is, in reality, a great deal more than its title would seem to imply. The present report is dated November 1st instead of January 1st, 1883; the delay in its preparation is explained as being due to pressure of work and other unavoidable circumstances; but though dated in November last, it has only just come into the hands of the public. The report gives detailed accounts of the purely horticultural and scientific works carried on at Kew, but the following notes on economic plants are those of most general interest.

Argan Tree *(Argania sideroxylon)*.—Seeds of this tree, a native of Morocco, have been distributed to the Botanic Gardens of Adelaide, Brisbane, Cape Town, Fiji, Hong Kong, Jamaica, Grahamstown, Melbourne, Natal, Saharanpore, and Washington. From the Botanic Gardens, Natal, the Director says that he has failed in raising the plants, but that in Quanda, 2,000 feet above the sea, the plants had been more successful, and several of them were progressing satisfactorily, so that Mr. J. M. Wood says he hopes for success in acclimatising the plant.

Of the Arracacha *(Arracacia esculenta)*, a valuable tuberous rooted umbelliferous esculent, Mr. Duthie reports from Saharanpore as follows:—"Of this valuable South American vegetable there are a few plants still left, and they are in a fairly healthy condition. They do not, however, appear to have formed to any extent the characteristic tubers which constitute the edible portion of the plants so highly valued in its native country. M. Decandolle, in his recently published work on the origin of cultivated plants, observes that this vegetable bears comparison with the potato, and yields a starch which is lighter and more agreeable. It has been tried in England and in several parts of Europe, but without success, the climate being evidently too damp for it. I intend to give it a trial at Arnigádh, where it will at any rate have a better chance of being looked after than it had at Chajuri."

Mr. Morris, the director of public gardens and plantations, Jamaica, writing on the Arracacha, says that it was introduced into the island in 1882 by Dr. Bancroft; it flourishes best in the Blue Mountain districts, at elevations between 2,500 and 5,000, with mean annual temperatures of 72° and 65° Fahr. respectively, and a mean annual rainfall of 100 inches. Mr. Morris adds—"I believe the Arracacha is a most valuable food plant; and for my own part I not only like it, but find that it becomes more palatable and desirable the longer it is used. If the natives of India take to it as an article of food, I can conceive nothing more likely to flourish in the hill districts, and to afford with little labour, the means of sustaining life under adverse circumstances."

Under the head of Cacao, an extract is given of a letter from a resident in Fiji, who says that the plants sent him from Kew in 1881 are all doing well, and that plants introduced from Java three years since are bearing fruit in several places. Altogether about 1,500 trees are established in various parts of the colony, irrespective of a few finer sorts from Trinidad, of which the variety known as yellow criollo are described as "looking splendid."

As might be supposed, considering the importance of the subject, a great deal of space is given to the consideration of the different species and varieties of Cinchona barks, certain forms proving more suitable for cultivation in the soil and climate of some parts of the world than of others.

The East African Copal tree (*Trachylobium Hornemannianum*) seems to have made itself a home in Natal, the trees in the Botanic Garden there having produced some pods. Though the soil in which they grow is stated to be only a poor sand, the plants are reported as growing luxuriantly.

The elephant sugar-cane, which was introduced to the Jamaica Botanic Garden in 1880, is reported to be well established at the Hope Plantation. Of it, Mr. Morris says:—"It is now well established at the Hope Plantation, and is of a most promising character, more especially for moist districts. As showing what may be done in propagating plants of this character, it may be mentioned that this cane, of which only two small plants were received twelve months ago, is now being distributed amongst planters by thousands at a time. As it has been taken up by the most intelligent and enterprising planters, its value as a cultivated cane in Jamaica will soon be known. For eating purposes it is already a favourite among the peasantry; and I have no doubt that its yield under cultivation will prove to be, for certain districts, of a valuable character. A block established at the Hope in June last, in ordinary soil, had canes in October eight feet long, with joints seven inches in length, and with a circumference of six inches." At a later period Mr. Morris again writes:—"The elephant cane, the history of which has already been given in former reports, continues to be in great demand, and is much liked in certain districts. It is evidently best suited for warm, humid climates. In dry districts, even with irrigation, it is not so successful as the Salangore. With such varying conditions of soil and climate as exist on sugar estates in Jamaica, it may naturally be expected that numerous varieties of canes are required to enable the planter to obtain the best results with the means at his command. Hence, I look upon the greater interest which is taken in cultivating new varieties of sugar-canes, and the establishment of nurseries on estates, as most hopeful signs of awakening in the staple industry of Jamaica."

The important question of the acclimatisation of fodder-yielding plants has for some years past occupied the attention of the Kew authorities, and further light is thrown upon these in the present report. The mesquit bean, for instance (*Prosopis glandulosa*), is reported from Lucknow as flourishing most satisfactorily. The superintendent of the Horticultural Gardens at that place says, "It would seem the plants get more prolific with age, as they are bearing an unprecedently heavy crop of pods this year (1883). No water is given, yet the trees make new growth, and produce their crop of pods at the hottest and dryest season of the year. For clothing dry or broken raviny ground, where little else would grow, it would, I believe, prove a success, and is worthy of that on account of the grazing it would afford for goats and cattle at a season, and in places where scarcely any green food exists."

Another plant useful for fodder, and known as the Salt Bush (*Ariplex nummularia*), has attracted some attention. On this head Sir Joseph Hooker says "The desirability of finding any useful plants which will grow on salt in crusted lands in North-West India is a constant topic in Indian correspondence." Mr. Duthie says that the progress which the plant has made at Saharanpore within the last year is decidedly encouraging. Some of the plants raised from seed received at Saharanpore from Australia, in 1881, have now grown into compact healthy looking shrubs, a few of which were coming into flower at the time Mr. Duthie wrote in May last. Should the plants produce flowers and seed annually, large stocks of young plants will be raised for distribution. Other reports likewise speak favourably of this plant.

The Sheep Bush, also a fodder plant, native of the Cape of Good Hope, has been introduced into South Australia as well as into North West India. It is a composite plant, known to botanists as *Pentzia virgata*. It is described by Mr. Duthie as a small bush, something like an *Artemisia*, to which genus it is closely allied. It has been strongly recommended as a suitable plant to introduce into dessert countries, for besides being able to stand long continued drought, it, spreads rapidly by means of its trailing stems, which takes root as soon as they touch the ground. The plant has been tried in Australia for several years, and is highly spoken of as a fodder plant.

The Tagasaste (*Cytisus proliferus*) is still highly spoken of in Australia; Dr. Schomburgk considers that the plant has found a most genial climate in South Australia, the dry season showing not the slightest effect on the plants. He says, "if the seed were sown on the runs, it would soon become acclimatised, and would stock them with a profitable shrub, capable of withstanding the severest drought." As an illustration of the difficulty of introducing new articles of culture, may be mentioned the fact as stated by Dr. Schomburgk, for he says although he offered seed of the tagasaste for distribution, only a few applications have been made in South Australia, but a large number were received from the neighbouring colonies.

From numerous notes on india-rubber, the following are gathered as characteristic of the varied sources and wide distribution of this very important article. First with regard to the Central American rubber (*Castilloa elastica*), Dr. Trimen reports from Ceylon that they have raised some sturdy little seedlings from seeds produced in Ceylon, and he considers that the rubber from this plant is the most satisfactory of all the sorts grown in Ceylon, "the proportion of caoutchouc in the milk being larger than in any of the others." A sample of rubber obtained from plants grown in the experimental garden at Heneratgoda, Ceylon, was submitted to Mr. S. W. Silver for examination and report, which was as follows:—"On working and drying a portion of this sample, the loss is 12·3 per cent.; it is necessary to use warm water in washing this rubber; it becomes, on drying, much darker and shorter than Para rubber. It has a bitter taste, which is not removed on washing. The unwashed sample yields 1·9 per cent. ash, the washed sample gives 1·2 per cent. The shortness of this rubber would restrict its use to some extent, where tensile strength or tenacity is required." It was valued, December 8, 1882, as worth 2s. 9d. to 3s. a pound. The *Castilloa* has also been introduced to Jamaica, and promises well.

With regard to Ceara rubber (*Manihot Glaziovii*) a sample was received at Kew obtained from trees grown at Peradeniya, Ceylon; this was submitted to Mr. S. W. Silver, and reported upon to the following effect:—"Has a dry and compact appearance, is free from extraneous impurities, and from its tolerably uniform condition has been collected with care. It agrees in all respects with Ceara rubber of good and sound quality; when washed and dried gives a loss of 8 per cent. This loss is much less than is met with in Ceara rubber of the finest quality, and may probably be accounted for by the small bulk and facilities offered by time, mode of packing and transit, to the escape of the natural moisture of the product. On incineration it yields 4·13 per cent. mineral ash, which agrees in it chemical composition very closely with the ash obtained from Ceara rubber, the ash from which amounts to 4 or 5 per cent." The value put upon this sample was, in June, 1882, from 2s. 9d. to 3s. per pound. In consequence of this report, Dr. Trimen wrote later on:—"Some planters here are going in for vast quantities of Ceara, as a result of the price put upon the best sort by Messrs. Silver. If it should prove profitable, it will be a great help, as it grows anywhere up to almost 2,500 feet."

In Jamaica, the Ceara rubber tree promises in every way to be suitable for cultivation. The largest tree in the Botanic Gardens is said to be about twenty-five feet high, with a circumference, at two feet from the ground, of thirty inches.

The following interesting account of the plant in Southern India is quoted from the *Madras Mail* of

October 24th last:—"About six months ago some gentlemen imported Ceara rubber seed from Ceylon. The produce of these trees may now be seen flourishing in a wonderful manner at the foot of the Neilgherry Hills, by any one curious enough to look out of the tonga, just before reaching Kallar. Being much interested in the introduction of this comparatively new, but very valuable product, I gladly availed myself of an invitation to inspect these trees more closely. The rapid growth of the Ceara rubber tree is marvellous; some, measured six months old from seed, were fully eight feet high, and a cutting, that I was told had been put down scarcely six months ago, was quite eight feet high, and in blossom. Being of such wonderfully rapid growth, the tree is naturally very susceptible of wind, and liable to be blown over, until it gets firm hold of the ground; consequently a sheltered position is most necessary. It seems to thrive on poor soil, requires no shade, and very little rain. With such moderate requirements, we may expect to hear, before long, that this valuable tree, the demand for the produce of which seems to be unlimited, is being largely planted in India, where there is so much land likely to suit it. I was informed that a considerable quantity of seed has been sent to the S. E. Wynaad, where it is to be tried on some of the unprofitable coffee lands of the various companies. Unfortunately, the unusually heavy monsoon has been rather against the experiment. From what I could gather, it seems that it would be better to plant out the young Cearas after the first heavy burst of the monsoon, say in the months of August or October when the ground is thoroughly saturated, and the showers only occasional, with burst of sunshine between. The germination of seed seems a very simple process, and generally occurs in ten days, and sometimes less, from the time the seed is placed in the damp sand. The seed coat, being extremely hard, requires very careful filing, so as to enable it to burst more easily; if this is not done the seed may take months to germinate."

With regard to *Hevea brasiliensis*, the plant which yields the best Para rubber. Mr. Silver has also furnished a report on a sample of rubber obtained from plants grown in the Experimental Garden at Heneratgoda, Ceylon, which is as follows:—"As far as chemical examination goes, this rubber differs in no respect from the better descriptions of Para bottle rubber, except, perhaps, in having a little more water imprisoned in it than is usual with well-seasoned Para. A portion of this rubber, well washed and dried, gave a loss of 18·7 per cent. The amount of ash obtained on incinerating a portion of the unwashed sample is 0·7 per cent., which is about one-half that from the Brazilian product. There is a great similarity in the composition of the ash of the Hevea and the Para bottle rubber. The ash from the washed and dried Hevea is 0·6 per cent. The sample is almost entirely free from extraneous matter. On digestion in alcohol it yields a slight colouration. Like Para rubber, its fresh-cut surfaces show a slight acid reaction, easily removed by washing. The washed product is free from taste and smell, and turns a dark colour on drying, similar to ordinary Para rubber. As far as can be determined on so small a sample, there is reason to believe that as regards strength and elasticity, it would be fully equal to Para india-rubber." It was valued December 8th, as worth about 4s. a lb.

The other sources of rubber, namely species of of *Landolphia* and *Hancornia speciosa* have continued to receive attention at Kew, and plants have been distributed to various parts of the world. The foregoing are the principal economic plants treated of, but many other of considerable importance, in a commercial point of view, have occupied the attention of the Kew staff during the year and ten months of which its treats.

BOLIVIAN CINCHONA FORESTS.

The great progress made in the acclimatisation of cinchona trees in India, Ceylon, and elsewhere, has awakened the Governments of countries where the plants are indigenous to the necessity of conserving from reckless destruction, and re-planting denuded forests, so as to be able to keep up the supply of this valuable product.

In Bolivia, since 1878, according to the report of the Netherlands Consul, private individuals and land owners have taken up the question with great earnestness, and at the present time on the banks of the Mapiri, in the department of La Paz, there are over a million of young trees growing.

New plantations have also sprung up in various other localities, either on private ground or that owned by Government. The competition of India and Ceylon in supplying the markets, has had also the effect of inducing more care in collecting and also of revisiting old spots, often with the result of a rich harvest of bark which had been left on partly denuded trunks, and the opening up of new localities. The new shoots springing up from the old stumps have yielded much quill bark, and the root bark of the old stumps has also been utilised.

The re-planting entails very little expense. The Indian tenant on an estate has a house and land from the owner (hacienda) of the estate. For this he binds himself to work for two to four days a week, at from 28 to 36 cents per day, women and children obtaining 16 to 21 cents. per day. Thus the planting, weeding, &c., during the first two years, is but nominal in expense; after this period the trees may be left to themselves.

On Government land the expense is greater, as after an application being made, the land is put up to public auction, and may fetch a very low or a higher price, according to the bidding. The land secured, contracts are made with natives of the lower class to clear the forest and plant cinchona. The contracts are often sublet to Indians. The young plants are planted from five to six feet apart, with banana trees between, on account of their rapid growth and the shade the latter afford. From March to June, after the wet season is over, is the best time for planting, and the contractor keeps the plantation free from weeds and in good order for twelve months, when it is handed over to the owner. The following is given as the cost of the Mapiri river plantation of an area from 60 or more miles in extent :—

Ground	$1,200
300,000 plants at $ 0·14	42,000
Superintendent, buildings, &c.	4,400
Interest	4,800
Total	$52,400

Till the plants are above two years of age, they are liable to die from drought or the attacks of ants, and during 1878 many thousands died from these causes. At the end of the fourth year some proprietors begin to collect the quill bark by the method of coppicing.

It is feared by some that should this new venture be successful, it will prove a dangerous rival to the plantations of India, Ceylon, and Java, and lower the price of bark considerably.

General Notes.

PHILADELPHIA ELECTRICAL EXHIBITION.—In connection with the International Electrical Exhibition to be held under the auspices of the Franklin Institute, from September 2nd, to October 11th, it is proposed to form a Memorial Library. The Franklin Institute has appointed a Committee on Bibliography, to collect and arrange the library for exhibition. After the Exhibition is closed, the collection will be placed in the library of the Franklin Institute for permanent reference, as a suitable memorial of the state of electrical science at the time of the Exhibition. The committee ask for the presentation of a copy of all publications, papers, reprints of articles, or notes on or relating to electricity, which should be sent direct, addressed to the Committee of Bibliography, Franklin Institute, Philadelphia, U.S.A. ; or to the care of Mr. Frederick Ransom, Rushmere-lodge, Lower Norwood, Surrey.

HEALTH EXHIBITION SEASON TICKETS.

The Executive Council of the International Health Exhibition have consented to allow members of the Society of Arts the privilege of purchasing season tickets for the Exhibition at half price (10s. 6d.) Each member can purchase a single ticket only on the reduced terms, and these tickets can only be obtained through the Secretary of the Society of Arts. For further particulars see notice in the *Journal* for May 2, p. 575.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 16...Asiatic, 22, Albemarle-street, W., 4 p.m. 1. Prof. Lacouperie, "Three Embassies from Indo-China to the Middle Kingdom, about B.C 1110, and the way thither." 2. Dr. Duka, "The Tibetan MSS. of Csoma de Körös, given by Dr. S. C. Malan to the Hungarian Academy of Sciences."

Victoria Institute, 7, Adelphi-terrace, W.C., 8 p.m. Annual General Meeting.

TUESDAY, JUNE 17...Central Chamber of Agriculture (at the HOUSE OF THE SOCIETY OF ARTS), 11 a.m.

Statistical, School of Mines, Jermyn-street, S.W., 7¾ p.m.

Zoological, 11, Hanover-square, W., 8½ p.m. 1. Mr. Frederick Holmwood, "The Employment of the Remora by Native Fishermen on the East Coast of Africa." 2. Mr. R. Bowdler Sharpe, "Further Notes on Whitehead's Nuthatch." 3. Mr. Oldfield Thomas, "The Muridæ collected in Central Peru by M. Constantin Jelski." 4. Colonel C. Swinhoe, "New Asiatic Butterflies of the Genus *Teracolus*."

WEDNESDAY, JUNE 18...Meteorological, 25, Great George-street, S.W., 7 p.m. Mr. Robert H. Scott, "The Equinoctial Gales—Do they occur in the British Isles?" 2. Hon. Ralph Abercromby, "The Physical Significance of Concave and Convex Barographic and Thermographic Traces." 3. Mr. Charles Harding, "Maritime Losses and Casualties for 1883, considered in connection with the Weather." 4. Rev. Joseph Brunskill, "The Helm Wind." 5. Mr. W. T. Black, "Climate of the Delta of Egypt in 1798-1802, during the French and British Campaigns."

Hospitals Association, 11, Chandos-street, Cavendish-square, W., 8 p.m. Rev. Canon Erskine Clarke, "Is it desirable that Hospitals should be made self-supporting, and, if so, to what extent?"

Botanic, Inner Circle, Regent's-park, N.W., 2 p.m. Second Summer Exhibition of Plants, Flowers, and Fruits.

United Service Inst., Whitehall-yard, S.W., 3 p.m. Captain Claude E. Buckle, "Sir William Thomson's Sounding Machine, and its advantages both in Peace and War."

THURSDAY, JUNE 19...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. J. G. Baker, "Flora of Madagascar." 2. Mr. J. W. Davis, "Species of *Cœlacanthus* from the Yorkshire Cannel Coal." 3. Mr. C. T. Druery, "Development of the Lady Fern." 4. Mr. A. G. Bourne, "Remarks on Marine Fauna of Naples."

Chemical, Burlington-house, W., 8 p.m. 1. Dr. Perkin, "The Magnetic Rotation of Chemical Bodies in Relation to their Composition and Constitution." 2. Drs. Armstrong and Miller, "The Effect of High Temperatures on Petroleum Hydrocarbons." 3. Mr. R. Warington, "Nitrification." (Part III.)

Historical, 11, Chandos-street, W., 8 p.m. Mr James Heywood, "The Origin nnd History of the New England Company, London."

Numismatic, 4, St. Martin's-place, W.C., 7 p.m. Annual General Meeting.

FRIDAY, JUNE 20...United Service Institute, Whitehall-yard, 3 p.m. Colonel E. Maitland, "The Heavy Guns of 1884."

Philological, University College, W.C., 8 p.m. Mr. James Lecky, "Modern Irish."

Journal of the Society of Arts.

No. 1,648. Vol. XXXII.

FRIDAY, JUNE 20, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Thirtieth Annual General Meeting, for the purpose of receiving the Council's Report and the Treasurer's statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new members, will be held, in accordance with the Bye-laws, on Wednesday, the 25th June, at 4 p.m.

(By order of the Council)

H. Trueman Wood,
Secretary.

CONVERSAZIONE.

A Conversazione will be held at the International Health Exhibition by the Council of the Society of Arts, in conjunction with the Executive Council of the Exhibition, on Wednesday evening, 9th of July.

The whole of the buildings will be open, and the gardens will be illuminpted.

Each member will receive tickets for himself and a lady. These will probably be issued in the latter part of next week.

MEDALS.

The Council have awarded the Society's Silver Medals to the following readers of papers during the Session, 1883-4:—

To The Most Hon. The Marquis of Lorne, K.T., for his paper on "Canada and its Products."

To Rev. J. A. Rivington, for his paper on a "New Process of Permanent Mural Painting, invented by Joseph Keim."

To C. V. Boys, for his paper on "Bicycles and Tricycles."

To Professor Fleeming Jenkin, F.R.S., for his paper on "Telpherage."

To I. Probert, for his paper on "Primary Batteries for Electric Lighting."

To H. H. Johnston, for his paper on "The Portuguese Colonies of West Africa."

To Professor Silvanus P. Thompson, for his paper on "Recent Progress in Dynamo-Electric Machinery."

To Edward C. Stanford, F.C.S., for his paper on "Economic Applications of Seaweed."

To W. Seton-Karr, for his paper on "The New Bengal Rent Bill."

To C. Purdon Clarke, C.I.E, for his paper on "Street Architecture in India."

Thanks were voted to the following members of Council for the papers read by them:—

To W. H. Preece, F.R.S., Vice-President of the Society, for his paper on "The Progress of Electric Lighting."

To B. W. Richardson, M.D., F.R.S., Vice-President of the Society, for his paper on "Vital Steps in Sanitary Progress."

To Col. Webber, R.E., C.B., Member of Council, for his paper on "Telegraph Tariffs."

To B. Francis Cobb, Vice-President of the Society, for his paper on "Borneo."

To J. M. Maclean, Member of Council, for his paper on "State Monopoly of Railways in India."

To W. G. Pedder, Member of Council, foi his paper on "The Existing Law of Landlord and Tenant in India."

PRACTICAL EXAMINATIONS IN MUSIC.

The Examinations for London were conducted last week at the Society's House, by W. Alexander Barrett, Mus. Bac. (Oxon), and occupied five days. The numbers showed a considerable increase over former years. 198 candidates presented themselves, many of them taking the vocal as well as the instrumental portion of the examination. Of these 179 passed and 19 failed. The number of practical examinations was 226, resulting in the award of 41 first class, and 160 second class certificates, with 25 failures. Of these entries 176 were for the piano, 10 for the organ, 2 for the violin, 1 for the harmonium, and 37 for singing. In addition to these, there were three examinations for Honours, two second class certificates being awarded in this division.

In addition to the above, two provincial examinations were held by the Society in May; one in Glasgow (75 candidates), and the other at Liverpool (29 candidates).

FINANCIAL STATEMENT.

The following statement is published in this week's *Journal*, in accordance with sec. 40 of the Society's Bye-laws:—

TREASURERS' STATEMENT OF RECEIPTS, PAYMENTS, AND EXPENDITURE FOR THE YEAR ENDING MAY 31ST, 1884.

Miscellaneous.

*NATIONAL HEALTH AND WORK.**

It was very difficult to select, from the vast number of subjects relating to health and to education, one of which I could fitly speak to-day. On general education I could not venture to speak; and, believing that I should have to address a large and various audience, I thought it would be best to choose a subject by which I might urge one of the chief objects of this Exhibition, and one which I know that you, sir, have always had in view, namely, that the public themselves should consider, much more than they do, the utility and the means of maintaining their own health. I have, therefore, chosen the relation between the national health and work; especially as it may be shown in a few of the many examples of the quantity of work which is lost to the nation, either through sickness or through deaths occurring before the close of what may fairly be reckoned as the working time of life. I think it may be made clear that this loss is so great, that the consideration of it should add largely to the motives by which all people may be urged to the remedy of whatever unwholesome conditions they may live in. It is a subject which is often in the minds of the real students of the public health, but the public itself is far too little occupied with it.

I shall speak only of national health. In consideration of his own self, a man may be deemed healthy who lives idle, comfortably and long; who enjoys every day of his life, and satisfies every natural appetite without consequent distress. And when such a one dies of old age, with a timely, uniform and painless decay of every part, he may be deemed to have been completely healthy. And yet it is possible that he may have enjoyed his own health in the midst of a poor, unhealthy, and unhappy nation, to which he has done no good whatever.

If we could find a nation composed of people such as this man, we might be bound to speak of them as healthy; but we should be right in calling the whole nation utterly unsound, and might safely prophesy its complete stagnation, or its qnick decline and fall.

It is not health such as this—idle, selfish, unproductive—that we want to promote either in the individual or in the multitude. Comfortable idleness, such as that of some vagrants and fine gentlemen, is a despicable result of good health; it is what no thorough man would ever wish for. In view of the national health and welfare, the pattern healthy man is one who lives long and vigorously; who in every part of his life, wherever and whatever it may be, does the largest amount of the best work that he can, and, when he dies, leaves healthy offspring. And we may regard that as the healthiest nation which produces, for the longest time, and in proportion to its population, the largest number of such men as this, and which, in proportion to its natural and accumulated resources, can show the largest amount and greatest variety of good work.

Here let me insert, as an interpretation clause, that in all this and what is to follow the word "man" means also "woman," and "he" means also "she;" and that when I speak of work, I mean not only manual or other muscular work, but work of whatever kind that can be regarded as a healthy part of the whole economy of the national life. And I shall take it for granted that a large portion of all national welfare is dependent on the work which the population can constantly be doing; or, if I may so express it, that the greater part of the national wealth is the income from the work which is the outcome of the national health.

It is a common expression that we do not know the value of a thing till we have lost it; and this may be applied to the losses of work which are due to losses of national health. There are very few cases in which these can be estimated with any appearance of accuracy; but I am helped to the best within our present reach by Mr. Sutton, the actuary to the Registry of Friendly Societies. In his office are the returns, for many years past, of the sickness and mortality among the members of a very large number of these societies; and, among other things, there is recorded the number of days which each member, when "off work" on account of sickness, receives money from his society. Hence Mr. Sutton can estimate, and this he has been so good as to do for me, the average number of days' sickness and consequent loss of work among several hundred thousands of the workmen and others who are members of these societies. From the entire mass of these returns, he deduces that the average number of days' sickness, per member per annum, is very

* Address delivered by Sir James Paget, Bart., F.R.S., at the International Health Exhibition, 17th June, 1884. H R.H. the Prince of Wales, K.G., in the chair.

nearly 1½ weeks; and this agrees, generally, with the estimates made in other societies by Mr. Neison and others. But the averages thus obtained include the cases of members of all ages, and among them many cases of chronic sickness and inability to work during old age. In order, therefore, to get a better idea of the actual annual loss of work through sickness, he has calculated the average annual number of days' sickness of each person during what may be deemed the normal working time of life; that is, between 15 and 65 years of age. This he has done among the members of the large group of friendly societies known as the Manchester Unity of Odd Fellows; and then, on the fair assumption that the rates of sickness of the whole population during the working years of life would not be far different, he has calculated the following tables, showing the average annual rates of sickness of each person enumerated in the Census of 1881 as living between the ages of 15 and 65.

Ages.	Number of males: Census of 1881 (England and Wales).	Weeks' sickness per annum, according to the experience of the Manchester Unity.	Average sickness per individual per annum (in weeks).
15—20	1,268,269	844,428	·666
20—25	1,112,354	820,183	·737
25—45	3,239,432	3,224,134	·995
45—65	1,755,819	4,803,760	2·736
All ages from 15—65	7,375,874	9,692,505	1·314

Ages.	Number of Females: Census of 1881.	Weeks' sickness per annum, according to the experience of the Manchester Unity.	Average sickness per individual per annum (in weeks).
15—20	1,278,963	851,701	·666
20—25	1,215,872	896,685	·737
25—45	3,494,782	3,476,146	·995
45—65	1,951,713	5,368,229	2·751
All ages from 15—65	7,941,330	10,592,761	1·334

Briefly, it appears from these tables that the average time of sickness among males during the working years is 1·314 weeks—that is, a small fraction more than nine days in each year—and that among females it is a small fraction more. The result is that among males there is a loss of 9,692,505 weeks' work in every year, and among females a loss of 10,592,761 weeks. Thus we may believe that our whole population between 15 and 65 years old do, in each year, 20,000,000 weeks' work less than they might do if it were not for sickness. The estimate is so large that it must, on first thoughts, seem improbable; but on fair consideration I believe it will not seem so. For the members of the Manchester Unity who are in the working time of life, the reckoning is certainly true, and it is founded on the experience of between 300,000 and 400,000 members. In respect of health they may represent the whole population, at least, as well as any group that could be taken. They are not very strictly selected—they are not picked lives; yet they are such as are able, when they are in health, to earn good wages or good salaries, and, as their prudence in joining this association shows, they are comparatively thrifty and careful persons. They do not, at all events, include many of the habitual drunkards, the cripples or utterly invalids, or those who, through natural feebleness or early disease, or mere profligacy, cannot earn enough to become members or maintain themself in membership. Neither do they include many of the insane, or imbecile and idiotic, of whom there are, in our population, nearly 70,000, doing no work, and losing not less than 3½ millions of weeks' work in the year.

It would be tedious to tell the grounds on which the estimate may be deemed too high, for just as many and as good could be told on which it might be deemed too low. And it is rather more than confirmed by some estimates of the annual sickness in other and very different groups of persons.

In the Army, at home, the average number of days' sickness in each year is, for each soldier, about 17; and, as the number of the troops in the United Kingdom is more than 80,000, we have here a loss of about 200,000 weeks' service in each year.

In the Navy, on the home stations, the average number of days' sickness in each year has been in the last five years for each man nearly 16; so that for the total of about 20,000 men there is a loss of 45,000 weeks' service in each year.

The amount of sickness in the services thus appears much higher than in the friendly societies. This is due, in great part, to the fact that a soldier or a sailor is often put off duty a day or two for much less illness than that for which a civilian would "go on his club." Still, the one estimate may confirm the other; for the sickness in the Army and Navy is that of picked men, who were selected for the services as being of sound constitution, and who are in what should be the best working years of life: and if it includes many cases of sickness for only a day or two, it excludes nearly all cases of more than a few months, such as make up a heavy proportion of the average sickness in the friendly societies and in the general population.

And I may add that the estimate from these societies, that nine days in the year may justly be thought a fair estimate of the working time lost by sickness, is confirmed by the records of sickness among the 10,000 members of the metropolitan police force; for among these, including cases of long illness such as are also in the societies, the average is more than nine days in the year.

I think, then, that we cannot escape from the reasons to believe that we lose in England and Wales, every year, in consequence of sickness, 20,000,000 of weeks' work; or, say, as much work as 20,000,000 of healthy people would do in a week.

The number is not easily grasped by the mind. It is equal to about 1-40th part of the work done in each year by the whole population between 15 and 65 years old. Or, try to think of it in money. Rather more than half of it is lost by those whom the Register-General names the domestic, the agricultural, and the industrial classes. These are more than 7,500,000 in number, and they lose about 11,000,000 of weeks; say, for easy reckoning, at £1 a week; and here is a loss of £11,000,000 sterling from what should be the annual wealth of the country. For the other classes, who are estimated as losing the other 9,000,000 weeks' work, it would be hard and unfair to make a guess in any known coin; for these include our great merchants, our judges and lawyers, and medical men, our statesmen and chief legislators; they include our poets and writers of all kinds, musicians, painters, and philosophers; and our Princes, who certainly do more for the wealth and welfare of the country than can be told in money.

Before I speak of any other losses of work or of wealth due to sickness, permit me, as in parenthesis, to point out to you how very imperfectly these losses are told, or even suggested by our bills of mortality. These, on which almost alone we have to rely for knowing the national health, these tell the losses of life, and more than misery enough they tell of; but to estimate rightly the misery of sickness, and the losses of all but life that are due to it, we need a far more complete record than these can give.

Take, for example, such a disease as typhoid fever—that which Mr. Huxley has rightly called the scourge and the disgrace of our country. It has of late destroyed, in England and Wales, among persons in the working time of life, nearly 4,000 in the year. Its mortality is about 15 per cent., so that if in any year 4,000 die of it, about 23,000 recover from it. Of these, the average length of illness is, on the authority of Dr. Broadbent, about ten weeks. Here, therefore, from one disease alone, and that preventible, we have an annual loss of 230,000 weeks' work, without reckoning what is lost with those who die. And the same may be said of nearly all the diseases that are most prominent in the bills of mortality. The record of deaths, sad as it is, tells but a small part of the losses of happiness and welfare that are due to sickness. It is as if in a great war we should have a regular return of the numbers killed, but none of the numbers wounded, though these, more than the killed, may determine the issue of the war.

Let me now tell of another loss of work and of money through sickness and early death. In all the estimates I have yet referred to, no account is taken of those who are ill or die before they are 15 years old. They are not reckoned as in the working-time of life, though in some classes many thousands of them are. [In the domestic, agricultural and industrial classes of the Registrar-General nearly half-a-million of them are included.] And yet the losses of work due to sickness among children must be very large. Consider the time which might be spent in good productive work, if it were not spent in taking care of them while they are ill. Consider, too, the number of those who, through disease in childhood, are made more susceptible of disease in later life, or are crippled, or in some way permanently damaged; such as those who become deaf in scarlet fever, or deformed in scrofula or rickets, or feeble and constantly invalid, so that they are never fit for more than half work, or for work which is only half well done. These losses cannot be counted, but they must be large;

and there are others more nearly within reckoning; the losses, namely, which are due to the deaths of those who die young. If they had lived to work, their earnings would have been more than sufficient to repay it; but they have died, and their cost is gone without return. The mortality of children under 15 in 1882 was nearly a quarter of a million; what have they cost? If you say only £8 a piece, there are more than £2,000,000 sterling thus lost every year. But they have cost much more than this, and much more still is lost by the loss of the work they might have lived to do.

It is, indeed, held, I believe, by some that these things should not be counted as losses; that we have a surplus of population, and that really the deaths of children, though they may be the subjects of a sentimental sorrow, cannot reasonably be regretted. I cannot bring myself to admit that such a thing should even be argued. I have lived long in the work of a profession which holds that wherever there is human life it must be preserved; made happy, if that can be; but, in any case, if possible, preserved; and no argument of expediency shall ever make me believe that this is wrong. Indeed, I am rather ashamed—even for the purpose I have in view—to use so low an argument as that of expediency in favour of the saving of health and of life. I am ashamed of making money appear as a motive for doing things for which sufficient motives might be found in charity and sympathy, and the happiness of using useful knowledge; but it seems certain that these are not yet enough for all that should be done for the promotion of the national health; therefore, it seems well to add to them any motives that are not dishonourable; and so I add this, that we lose largely not only in happiness but in wealth by the deaths of these poor children.

I will add only one more illustration of these losses, which is always suggested by looking at tables of mortatity. The deaths of persons between 25 and 45 years old, that is during what may be deemed the 20 best working years of life, are annually between 60,000 and 70,000; in 1882 they were 66,000. Think, now, of the work lost by these deaths; and of how much of it might have been saved by better sanitary provisions. If one looks at the causes of their deaths, it is certain that many might have been prevented, or, at least, deferred. Say that they might have lived an average of two years more; and we should have had in this year and last an increase of work equivalent to that of at least 6,000,000 weeks; as much, in other words, as 6,000,000 people could do in one week.

More instances of losses of work by sickness and premature death might easily be given, but not easily listened to in this huge hall. Let these suffice to show something of our enormous annual loss, not only of personal and domestic happiness—that is past imagining—but of national power and wealth. Surely we ought to strive more against it.

But, some may ask, can these things be prevented? are they not inevitable consequences of the manner of life in which we choose or are compelled to live? No; certainly they are not. No one who lives among the sick can doubt that a very large proportion of the sickness and the loss of work which he sees might have been prevented; or can doubt that, in every succeeding generation, a larger proportion still may be averted, if only all men will strive that it may be so.

Let me enumerate some of the chief sources of the waste as they appear to oneself in practice.

Of the infectious fevers, small-pox might be rendered nearly harmless by complete and careful vaccination. Typhus and typhoid, scarlet fever and measles might, with proper guards against infection, be confined within very narrow limits. So, probably, might whooping cough and diphtheria.

Of the special diseases of artisans there are very few of which the causes might not be almost wholly set aside. Of the accidents to which they are especially liable the greater part, by far, are due to carelessness.

Of the diseases due to bad food and mere filth; to intemperance; to immorality; in so far as these are self-induced, they might, by self-control and virtue, be excluded. And with these, scrofula, rickets, scurvy, and all the wide-spread defects related to them, these might be greatly diminished.

It can only be a guess, but I am sure it is not a reckless one, if I say, that of all the losses of work of which I have spoken, of all the millions of weeks sadly spent and sadly wasted, a fourth part might have been saved, and that, henceforth, if people, will have it so, a still larger proportion may be saved.

We may become the more sure of what may be done by looking at what has been done already. Let me show some of it; it will be a relief to see something of the brighter side of this picture.

In a remarkable paper lately read before the Statistical Society, Dr. Longstaff says:—"One of the most striking facts of the day, from the statistician's point of view, is the remarkably low death-rate that has prevailed in this country during the last eight years." In these years the annual death-rate has been less than in the previous eight years, in the proportion of two deaths to every 1,000 persons living. The average number of deaths has been 50,000 less in the last than in the previous eight years. Doubtless many things have contributed to this grand result, and it is not possible to say how much is due to each of them; but it would be unreasonable to doubt that the chief good influence has been in all the improved means for the care of health which recent years have produced. This is made nearly certain by the fact that the largest gains of life have been in the diminution of the deaths from fever, and of the deaths in children under 15 years old; for these are the very classes on which good sanitary measures would have most influence.

The annual number of deaths from typhus, typhoid, and the unnamed fevers, has been about 11,000 less than it was about twenty years ago. The annual number of deaths of children under 5 years old has been about 22,000 less than it was; and that of children between 5 and 15 has been upwards of 8,000 less.

These are large results, and though they tell only of deaths, yet they bear on the chief subject I have brought before you—the working power of the nation; for, however much we might assign to improved methods of medical treatment of fever, yet the diminished number of deaths means a very large diminution in the total number of cases. The deaths during the working years of life were 6,500 less; and, this being so, we may hold that, if the average mortality was, say, 25 per cent., the diminution in the total number of cases must have been at least 25,000; and if we may believe, as before, that each of these involved ten weeks of sickness, we have, in these fevers alone, a clear saving of 185,000 weeks' work in every year.

And so with the diminution of the mortality among children, there must have been a greater diminution in the number of costly and work-wasting illnesses, and a large saving of money that would otherwise have been sunk. And not only so: but many of the children saved in the last eight years will become bread-winners or care-keepers; and who can tell what some of them will become? or what the world would have lost if it had lost all of them.

Let me add only one more reckoning. In a paper last year, at the Statistical Society, Mr. Noel Humphreys showed "that if the English death-rate should continue at the low average of the five years 1876-80, the mean duration of male life in this country would be increased by two years, and that of female life by no less than 3·4 years as compared with the English life-table." And he showed further that "among males 70 per cent. and among females 65 per cent. of this increased life would be lived between the ages of 20 and 60 years, or during the most useful period."

I should like to be able to tell the value in working power of such an addition to our lives. It is equal to an addition of more than 4 per cent. to the annual value of all the industry, mental and material, of the country.

But some will say,—admitting that it is desirable, seeing how keen the struggle for maintenance already is, can more than this be done? and the answer may be and must be, much more. In this, as in every case of the kind, every fruit of knowledge brings us within reach of something better. While men are exercising the knowledge they possess, they may be always gaining more. This Exhibition has scores of things which are better helps to national health than those of the same kind which we had twenty years ago, and with which the gains already made were won. If I were not in near official relation with the jurors, I would name some of them: there are truly splendid works among them.

But do not let me seem to disparage the past in praising the present. It is difficult to speak with gratitude enough of what has been done, even though we may see, now, ways to the yet better.

Anyone who has studied the sources of disease during the last thirty years, can tell how and where it has been diminished. There is less from intemperance, less from immorality; we have better, cheaper, and more various food; far more and cheaper clothing; far more and healthier recreations. We have, on the whole, better houses, and better drains; better water and air; and better ways of using them. The care and skill with which the sick are treated in hospitals, infirmaries, and even in private houses, are far greater than they were; the improvement and extension of nursing are more than can be described; the care which the rich bestow on the poor, whom they visit in their own homes, is every day saving health and life; and, even more effectual than any of these, is the work done by the medical officers of health, and all the sanitary authorities now active and influential in every part of the kingdom.

Good as all this work has been, we may be sure it may become better. The forces which have impelled it may still be relied on. We need not fear that charity will become cool, or philanthropy inactive, or that the hatred of evil will become indifference. Science will not cease to search for knowledge, or to make it useful when she can ; we shall not see less than we do now, and here, of the good results of enterprise and rivalry, and of the sense of duty and the sorrow of shame that there should be evil in the land.

What more, then, it may be asked, is wanted? I answer, that which I have tried to stir; a larger and more practical recognition of the value and happiness of good national health ; a wider study and practice of all the methods of promoting it; or, at least, a more ready and liberal help to those who are striving to promote it. In one sentence, we want the complete fulfilment of the design of this Exhibition, with all the means towards health and knowledge that are shown in it, and with its handbooks, lectures, conferences, and the verdicts of its juries.

We want more ambition for health. I should like to see a personal ambition for renown in health as keen as is that for bravery, or for beauty, or for success in our athletic games and field-sports. I wish there were such an ambition for the most perfect national health, as there is for national renown for war, or in art or commerce. And let me end soon by briefly saying what I think such health should be.

I spoke of the pattern healthy man as one who can do his work vigorously wherever and whatever it may be. It is this union of strength with a comparative indifference to the external conditions of life, and a ready self-adjustment to their changes, which is a distinctive characteristic of the best health. He should not be deemed thoroughly healthy who is made better or worse, more or less fit for work, by every change of weather or of food; nor he who, in order that he may do his work, is bound to exact rules of living. It is good to observe rules, and to some they are absolutely necessary, but it is better to need none but those of moderation, and observing these, to be able and willing to live and work hard in the widest variations of food, air, clothing, and all the other sustenances of life.

And this, which is a sign of the best personal health, is essential to the best national health. For in a great nation, distributed among its people, there should be powers suited to the greatest possible variety of work. No form or depth of knowledge should be beyond the attainment of some among them; no art should be beyond its reach; it should be excellent in every form of work. And, that its various powers may have free exercise and influence in the world, it must have, besides, distributed among its people, abilities to live healthily wherever work must be or can be done.

Herein is the essential bond between health and education; herein is one of the motives for the combination of the two within the purpose of this Exhibition; I do not know whether health or knowledge contributes most to the prosperity of a nation; but no nation can prosper which does not equally promote both; they should be deemed twin forces, for either of them without the other has only half the power for good that it should have.

It is said, whether as fact or fable, that the pursuit of science and of all the higher learning followed on the first exercise of the humanity which spared the lives of sick and weakly children; for that these children being allowed to live, though unfit for war and self-maintenance, became thinkers and inventors. But learning is not now dependent on invalids; minds are not the better now for having to work in feeble bodies; each nation needs, for its full international influence, both health and knowledge, and such various and variable health, that there should be few places on earth or water in which some of its people cannot live, and multiply, and be prosperous.

If, therefore, we or any other people are to continue ambitious for the extension of that higher mental power of which we boast, or for the success of the bold spirit of enterprise with which we seek to replenish the earth and subdue it; if we desire that the lessons of Christianity and of true civilisation should be spread over the world, we must strive for an abundance of this national health—tough, pliant, and elastic—ready and fit for any good work anywhere.

INTERNATIONAL HEALTH EXHIBITION.

The joint Conference of the Society of Medical Officers of Health, the Sanitary Institute of Great Britain, and the Parkes Museum of Hygiene, noticed in last week's *Journal*, was continued during the whole of the week.

On Tuesday, 17th inst., the work of the International Juries was formally inaugurated by his Royal Highness the Prince of Wales, President of the Exhibition, in the Royal Albert Hall. After the delivery of an address by Sir James Paget, Bart., F.R.S. (see *ante*, p. 752), the foreign Commissioners, the chairmen of juries, and the foreign jurors were presented to the Prince by Lord Reay.

On Wednesday, 18th inst., a conference on "The Meat Supply of this Country," organised by the Central Chamber of Agriculture, was held.

General Notes.

TELPHERAGE.—The telpher line may be seen in action any day next week at Weston. This village is reached by a drive of five or six miles from Hitchin, or by a somewhat shorter drive from Stevenage. The telpher train will be kept running for the greater part of each day, and no notice need be given by intending visitors, but those who wish to be certain that the line is running on a particular day can make inquiries at 12, Fitzroy-square.

METRICAL CONGRESS.—The following contractions have been adopted by the International Metrical Congress at Paris, and are recommended for general use: — 1. Length — Kilomètre, *km*; mètre, *m*; decimètre, *dm*; centimètre, *cm*; millimètre, *mm*. 2. Surface—Square kilomètre, km^2; square mètre, m^2; square decimètre, dm^2; square centimètre, cm^2; square millimetre, mm^2; hectare, *ha*; are, *a*. 3. Cubic Measure—Cubic kilomètre, km^3; cubic mètre, m^3; cubic decimètre, dm^3; cubic centimètre, cm^3; cubic millimètre, mm^3. 4. Hollow Measure—Hectolitre, *hl*; litre, *l*; decilitre, *dl*; centilitre, *cl*. 5. Weight—Ton (1,000 kilogrammes), *t*; metric hundredweight (100 kilogrammes), *q*; kilogramme, *kg*; decagramme, *dkg*; gramme, *g*; decigramme, *dg*; centigramme, *cg*; milligramme, *mg*. Italic letters are used for these contractions, and no stop is to be used at the right of them. The contractions succeed the figures to which they refer, on the same line, and after the last decimal placed when figures are used which contain decimal fractions.

ARGENTINE EXHIBITION AT BREMEN.—This Exhibition, opened May 25, has been organised by the Bremen Geographical Society, with the assistance of the Argentine Government. It contains a complete representation of the natural products and manufactures of the great South American Republic, with which Germany has extensive commercial relations, both as regards imports and exports. A collection exhibited by Professor Brackebusch, of Cordoba, illustrates the considerable and but little developed mineral wealth of the mountainous regions. A systematic display is made of various kinds of hides and wool. In the agricultural division are numerous specimens of plants being used in dyeing, medicine, and industry. A full collection of woods represents the timber of the northern provinces. The life of the inhabitants of the Pampas and of the Indian tribes is illustrated by numerous implements, weapons, tissues, &c. In a separate department are works of literature and art bearing on the object of the Exhibition.

HEALTH EXHIBITION SEASON TICKETS.

The Executive Council of the International Health Exhibition have consented to allow members of the Society of Arts the privilege of purchasing season tickets for the Exhibition at half price (10s. 6d.) Each member can purchase a single ticket only on the reduced terms, and these tickets can only be obtained through the Secretary of the Society of Arts. For further particulars see notice in the *Journal* for May 2, p. 575.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 23...Geographical, University of London, Burlington-gardens, W., 8½ p.m. Rev. W. P. Johnson, "Seven Years' Travels in the Region East of Lake Nyassa."

TUESDAY, JUNE 24...Statistical, School of Mines, Jermyn-street, S.W., 4 p.m. Annual Meeting.
Anthropological, 3, Hanover-square, W., 8 p.m. 1. Prof. Flower, "The Size of the Teeth as a Character of Race." 2. Mr. A. O. Shrubsole, "Flint Implements found at Reading." 3. Dr. S. M. Curl, "Phœnician Intercourse with Polynesia." 4. Mr. M. J. Walhouse, "A Hindu Prophetess." 5. Mr. J E. Greenhill, "Exhibition of Palæolithic Implements recently found in the north-east of London."

WEDNESDAY, JUNE 25...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4 p.m. Annual General Meeting.
Geological, Burlington-house, W., 8 p.m. Papers will be read by Prof. Judd, Dr. Hinde, Prof. Rupert Jones, Mr. G. R. Vine, Mr. T. Roberts, Mr. A. W. Waters, Lieut.-Col. Godwin Austen, Capt. F. W. Hutton, Mr. Teall, Mr. Tomes, Dr. Forsyth Major, Dr. G. W. Parker.
United Service Inst., Whitehall-yard, S.W., 3 p m. Lieut.-Colonel Moody, "Recruiting for Her Majesty's Service."
Royal Society of Literature, 4, St. Martin's-place, W.C., 8 p.m.

THURSDAY, JUNE 26...Society for the Encouragement of Fine Arts, 9, Conduit-street, W. A Morning Meeting.
Antiquaries, Burlington-house, W., 8½ p.m.

FRIDAY, JUNE 27...United Service Institute, Whitehall-yard, 3 p.m. Lieut.-General Sir Henry Daly, "The Punjaub Frontier Force."
Inventors' Institute, Lonsdale-chambers. 27, Chancery-lane, W.C., 8 p.m.
Quekett Microscopical Club, University College, W.C., 8 p.m.
New Shakspere, University College, W.C., 8 p.m. Annual Entertainment, Music and Recitations.

SATURDAY, JUNE 28...Physical, Science Schools, South Kensington, S.W., 3 p.m.
Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.

Journal of the Society of Arts.

No. 1,649. Vol. XXXII.

FRIDAY, JUNE 27, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CONVERSAZIONE.

A Conversazione will be held at the International Health Exhibition by the Council of the Society of Arts, in conjunction with the Executive Council of the Exhibition, on Wednesday evening, 9th of July.

The visitors will be received by his Grace the Duke of Buckingham and Chandos, K.G., Chairman of the Executive Council of the International Health Exhibition, and by Sir Frederick Abel, C.B., D.C.L., F.R.S., Chairman of the Council of the Society of Arts, near the principal entrance to the Exhibition in Exhibition-road. The reception will commence at 8.30 p.m.

The military bands of the following regiments will perform either in the buildings or in the gardens, according to the weather—the Grenadier Guards, the Coldstream Guards, the First Regiment of French Engineers (from Versailles), and the 7th German (Magdeburg) Cuirassiers. A vocal and instrumental concert, consisting of glees, &c., will also be given.

The gardens, as well as the Exhibition buildings, will be lighted by the electric light, and the gardens will also be illuminated with variegated lamps and Japanese lanterns.

The Exhibition will be closed on this evening to the general public, and there will be no admission by payment.

Each Member will receive tickets for himself and a lady. These will be issued early next week.

Proceedings of the Society.

ANNUAL GENERAL MEETING.

The Annual General Meeting for receiving the report from the Council, and the Treasurers' Statement of Receipts, Payments, and Expenditure during the past year, and also for the Election of Officers, was held, in accordance with the Bye-laws, on Wednesday last, the 25th instant, at four p.m., Sir FREDERICK ABEL, C.B., D.C.L , F.R.S., Chairman of the Council, in the chair.

The SECRETARY read the notice convening the meeting, and the minutes of the previous annual general meeting.

The following candidates were proposed, balloted for, and duly elected members of the Society :—

Anderson, William Adam, 4, Gladstone - street, London-road, S.E.

Angell, A. Torrington, 18, Redcliffe-road, S.W.

Ashworth, Edward, J.P., Staghills, near Waterfoot, Lancashire.

Atchison, William, 24, Finsbury-circus, E.C.

Bate, Lieut. Charles McGuire, R.E., 128, Westmoreland-road, Elswick, Newcastle-on-Tyne.

Bedford, James, Woodhouse Cliff, Leeds.

Bide, Augustus, 26, North Audley-street, W.

Brooke, George Freeman, Leadenhall Market, E.C., and Rotherfield-hall, Sussex.

Buller, Miss Mary Alice, 7, Holland-villas-road, Kensington, W.

Bullman, Edward Kenyon, 8, New Cavendish-street, W.

Burroughs, Silas Manville, Snow-hill-buildings, Holborn-viaduct, E.C.

Cameron, Charles, LL.D., M.P., 80, St. George's-square, S.W.

Collins, Joseph Henry, F.G.S., 64, Bickerton-road, Highgate New-town, N.

Cranley-Boevey, Arthur William, M.A., Balliol College, Oxford.

Davids, Richard Gore Brabazon, Campinas Sao Paulo, Brazil.

De Salis, Rodolph Fane, B.A., 1, Westminster-chambers, S.W.

Dowling, James, Leadenhall-market, E.C., and the Hawthorns, Upton, E.

Down, Frederick Jonathan, 13, Victoria-road, Old Charlton.

Dyer, Henry James, 21, Wendell-road, Shepherd's-bush, W.

Fremersdorff, William Frederick, Roseneath-villa, Castle-road, Card ff.

Gadesden, James Philip, Long Ditton, Surrey.

Glanville, George, 106, The Grove, Camberwell, S.E.

Gordon, Colonel Edward Charles Acheson, R.E., Commandant's-house, Brompton, Chatham.

Goolden, Walter T., M.A., 28, Westbourne-park, W.
Hodgson, Christopher, 144, Blake-street, Barrow-in-Furness.
Holt, Thomas, Sydney, New South Wales, and Grosvenor-hotel, Belgravia, S.W.
Jeffreys, Edward H., 7, Queen Anne's-gate, S.W., and 5, Westminster-chambers, Victoria-street, S.W.
Kilburn, Charles Conning, 3, Cannon-place, Hampstead, N.W.
McGregor, Duncan, 45, Clyde-place, Glasgow.
Mason, Alfred Henry, 178, Mance-street, Montreal, Canada.
Parnell, George Thomas, Mortimer-house, 45, Mortimer-road, Kingsland, N.
Record, J. C., Prescott-house, Eaton-rise, Ealing, W.
Rudler, Frederick William, 6, Regent's-park-villas, N.W.
Sandford, Henry, 31, Ferndale-road, Clapham, S.W., and 36, King-street, E.C.
Talbot, Colonel Hon. Wellington Patrick M. C., 15, Cromwell-road, S.W.
Theobald, John Wilson, 1, Macaulay-road, Clapham-common, S.W.
Watson, John Cecil, The Rhyddings, Church, Accrington.
Wellcome, Henry S., Snow-hill-buildings, Holborn-viaduct, E.C.
Wells, J. B., Cambridge-wharf, Grosvenor-road, Pimlico, S.W.
West, Rev. William De Lancy, D.D., Royal Medical Benevolent College, Epsom.
Wilkins, Lieut.-General H. St. Clair, 7, Nevern-square, Earl's-court, S.W.
Wilson, William, 3, Newman's-court, Cornhill, E.C.

The CHAIRMAN nominated Mr. Henry Maudslay and Mr. Henry Liggins scrutineers, and declared the ballot open.

The SECRETARY then read the following—

REPORT OF THE COUNCIL.

I.—ORDINARY MEETINGS.

For the first time since the appointment of a Chairman of Council, the bye-law of the Society which provides that every Session should be opened by an address from the Chairman was not carried out. Sir William Siemens, who was Chairman of Council for the previous year, and had been elected to the office a second time, was, as the members will well remember, engaged in the preparation of his opening address when his sudden and lamented death occurred. When he was first attacked by his illness it was hoped that the delivery of the address, which was then half written, need only be postponed, and arrangements were made for supplying the place of the Chairman at the Opening Meeting; but the illness which it was thought might be temporary, ended fatally two days before the date of the Meeting, and it was felt that, under such circumstances, the only course to pursue was to abandon the idea of commencing the Session in the usual formal manner, and to hold no meeting on the Wednesday evening on which the business ought to have begun. The first actual meeting of the Society was therefore held on November 28, on which evening a paper was read by Mr. A. J. R. Trendell upon the Fisheries Exhibition then just closed. Mr. Trendell, it will be remembered, had acted as Literary Superintendent of that Exhibition.

Looking at the meetings as a whole, the same remark may be applied to them that was made in the Annual Report last year, for it will be noted that amongst those dealing with applications of science, the most numerous and some of the most interesting were those which dealt with one or other of the applications of electricity to practical uses. Taking these in the order in which they were read, we come first to a paper by Mr. A. Reckenzaun, on "Electrical Launches," which was read at the first meeting after Christmas. Mr. Reckenzaun gave an account of the manner in which storage batteries are applied for the purpose of propelling small vessels or launches, and described the most complete of these vessels, the one which had been made by the Electrical Power Storage Company for the Vienna Exhibition. It will be remembered that the earliest attempt in this direction was due to Mr. Reckenzaun, whose boat, the *Electricity*, made her first run on the Thames in 1882. About six weeks after the reading of this paper, Mr. W. H. Preece, to whom the Society is indebted for so many admirable lectures and papers, gave a comprehensive account of the progress of electric lighting. In this paper Mr Preece maintained that electric lighting was a practical success, though he was unable to express an opinion as to the economy of the light. In the discussion which followed, Mr. Preece's views were vigorously supported by Mr. Crompton, Mr. Hammond, and others. At this meeting some very ingenious fittings were shown, devised by Mr. Tayler Smith, for the purpose of enabling the lamps to be moved from room to room, and fitted in any place where they might be required for a time.

At the end of the Session a number of electrical papers came together, the last three ordinary meetings having, in fact, been devoted to them. On the 14th of May, Professor Fleeming Jenkin gave his first public account of the very beautiful system of electric railways he has devised under the name of "Telpherage." At last year's meeting of the British Association at Southport, Prof. Fleeming Jenkin described the principles on which he was working, but at the meeting here he was able to give the results of a year's practical trials on an experimental line, together with full details of the improved machinery he had had constructed for the purpose. So complete was the form in which the invention was presented to the meeting, that the many electrical engineers who were present found but little to criticise, and on the whole the meeting seemed to be of opinion that there was a useful future before this novel system of applying electricity to the purpose of transport. At the following meeting, Col. Webber, in his paper on "Telegraph Tariffs," advocated his proposal for delayed telegraph messages; that is to say, for two classes of messages, one at a higher rate and to be expedited as much as possible, the other at a cheaper rate, to be sent after the first class and at times when the wires would otherwise be out of employment. At the last meeting of the Session, Mr. Probert gave an account of the different primary batteries which it is proposed to use for electric lighting, and stated very clearly the advantages and disadvantages of such batteries. Mr. Probert's general account was supplemented by descriptions, from several inventors present, of their particular batteries.

The important question of sanitation, with which the Society has so frequently dealt in recent years, received due attenion at the ordinary meetings. Dr. Richardson treated generally the question of sanitary improvement, pointing to the directions in which he thought it was most important that the attention of the Society and other kindred organisations should be directed. Mr. Elijah Hoole, who had much practical experience in the construction of dwellings for the poorer classes, read a useful paper on "The Dwellings for the Poor in Large Towns." The meeting at which this paper was read had the advantage of being presided over by Cardinal Manning. Mr. Westgarth, whose very liberal offer of Prizes for Essays is referred to in another portion of this report, brought before the attention of the Society the extensive scheme he proposes for the improvement of communication in the City of London. Mr. Westgarth's views are such as to claim the sympathy of all sanitary reformers, but whether it will be possible to carry them into effect upon so large a scale as he proposes, is a matter which remains to be seen. Another paper, dealing not indeed with sanitary matters but with another question of very great importance, the London communication across the river from north to south, was that read by Mr. Redman, on "Thames Communications;" while another, dealing both with one of the chief of sanitary questions, the supply of water, and also with the important topic of communication, was General Rundall's on "Water Regulation." General Rundall's views on the construction of storage reservoirs for the prevention of floods were combated by some English engineers of wide experience, but were equally strongly supported by engineers who have had experience in India.

Among other papers of an important industrial character, as dealing with various applications of science to manufactures, may be mentioned Mr. Bruce Warren's on "Mineral Waters;" Dr. Forbes Watson's on "Rhea Fibre;" Mr. Thomas Fletcher's on "Coal Gas as a Labour-saving Agent in Mechanical Trades;" and Mr. Swinburn King's on "Internal Corrosion and Scale in Steam-boilers." The paper read just before Christmas by the Marquis of Lorne on "Canada and its Products," was one of considerable value, and gained additional importance from the authority with which Lord Lorne, who had just then returned from the Governor-Generalship of Canada, was able to put forward his views. Mr. Lant Carpenter, in his paper on "Science Teaching in Elementary Schools," dealt with a branch of education which has always attracted much interest amongst members of the Society. The Rev. J. S. Rivington gave an account of the very promising process for permanent mural painting invented by Keim, of Munich. Mr. G. P. Sanderson, whose practical knowledge of the elephant, acquired during the performance of his duties as superintendent of elephant-catching operations in Bengal, makes him one of the greatest authorities on the subject, gave an account of the means now in use for obtaining a proper supply of these useful animals in India. But one more paper remains to be mentioned, the one in which Mr. C. V. Boys dealt in a very able and scientific fashion with a subject which is now attracting great popular attention, the construction of bicycles and tricycles.

II.—Indian Section.

The six evenings allotted as usual to the Indian Section were satisfactorily filled up, the attendances on each occasion were good, and the discussions animated and interesting. The first paper in the Section this Session was by Mr. J. M. Maclean, who ably treated the subject of the "State Monopoly of Railways in India," a subject of growing importance with especial reference to the enormously increased exportation of wheat, and consequent necessity for increased facilities of transport to the coast. The second paper, by Mr. Seton-Karr, on the "New Bengal Rent Bill," treated the Bill not from any party view, but its scope and object were clearly explained with judicial impartiality, and the reasonableness and necessity for some such measure pointed out. The third paper was on the "Routes through Afghanistan," by Mr. Griffin W. Vyse, who having been employed in carrying out actual surveys on the Afghan frontiers, had exceptional knowledge of that little known country, and was able fairly to surprise his audience by his descriptions. The fourth paper was on "The Law of Landlord and Tenant in India," by Mr. W. G. Pedder, who gave it as a sort of complement to the able paper read last Session, on "The Historical Development of the Different Scttlement Systems of India." These two papers by Mr. Pedder, with the two by Mr. Seton-Karr, one this Session, and one last Session, on "Agriculture in Lower Bengal," contain an amount of information, in a very readable form, on the somewhat difficult subject of land tenure in India, which could not be attained elsewhere without considerable expenditure of time and trouble, and combine to constitute a really valuable manual on the subject. The fifth paper was a valuable statement of facts and opinions on the past and present condition of indigenous education in India, by Dr. Leitner, who, as Principal of the University of Lahore, and an accomplished Orientalist, was especially qualified to treat a question of such great importance to the present and rising generation of our Indian fellow subjects. The sixth paper was a most interesting descriptive account of "Street Architecture of India," by Mr. Purdon Clarke, who last Session gave us a similar account of the domestic architecture of India. This paper derived additional interest and attraction from the very beautiful illustrations by means of the oxy-hydrogen light provided by Mr. Clarke.

III.—Foreign and Colonial Section.

At the first meeting of the Foreign and Colonial Section, Mr. J. J. Colmer, the Secretary to the High Commissioner for Canada, took the opportunity of the approaching visit of the British Association for the Advancement of Science to the Dominion, to give an account of the present condition of the country as it will be presented to the notice of the members of the Association. The interest of this meeting was considerably increased by the presence in the chair of the Marquis of Lorne, the late Governor-General of the Dominion. At the next meeting Mr. H. H. Johnston contributed a sketch, drawn from personal acquaintance, of the Portuguese Colonies of South Africa. The third communication to the Section was a paper by Mr. Demetrius C. Boulger on "Chinese History," in which the pertinacity and enduring vitality of the race were insisted upon. Following this, Mr. B. Francis Cobb gave an interesting account of the Island of Borneo, which led to a discussion of the value of North Borneo as a possible trade depôt for the commerce passing between China and Australia. Next, Mr. Robert Capper, Lloyd's agent for the West Coast of Africa, based upon his personal experiences in the district an earnest advocacy of the employment of the water-ways of the Congo and Niger as entrances for the introduction of the civilising agencies of commerce into the densely peopled regions of Mid-Africa, a view in which he was supported by Commander Cameron, who maintained that these two rivers must ultimately become the great arteries of the country. The last meeting of the Section was occupied by a communication from Mr. W. H. Penning, late of H.M. Geological Survey in England, upon the present state and future prospects of the Transvaal Gold Fields, which Mr. Penning, from the evidence of personal investigation, finds to be of very high promise, even in comparison with the older, and more thoroughly tested, gold.yielding districts of Australia. This testimony was practically verified and enforced by the exhibition of gold nuggets, recently brought by Mr. Barrett from the De Kaap Mines, and weighing respectively eleven, fourteen, and thirty-two ounces.

IV.—Applied Chemistry and Physics Section.

The first meeting of this Section took place at the end of January, when Prof. Wanklyn read a paper on "The Manufacture of Gas from Limed Coal." In the next paper, Prof. Silvanus Thompson continued the subject he so ably brought before the Society in his recent course of Cantor Lectures, "Recent Progress in Dynamo-Electric Machinery." The following paper, by Dr. Percy Frankland, on "The Upper Thames as a Source of Water Supply," gave rise to considerable discussion. The adjourned discussion extended over two nights, and was taken part in by many authorities on the subject. Dr. Alder Wright, in his paper on "Cupro-Ammonium Solutions," gave a description of the manufacture of the material known as Willesden paper. Mr. Stanford's paper on "Economic Applications of Seaweed," gave an acount of the progress of researches which have been carried on by Mr. Stanford for the past twenty years, and the earlier stages of which were described in a paper read by him in 1862. The last paper read before this Section was by Dr. William Ramsay, and dealt with the recovery of waste products obtained in the treatment of wool.

V.—Cantor Lectures.

During the present Session there have been six courses of Cantor Lectures. In the first course, which was delivered before Christmas, and attracted much attention, Mr. Mattieu Williams gave a useful popular account of the scientific principles which are, or ought to be, considered in the various operations of cookery. In the first course after Christmas, Mr. Bolas, whose course delivered here six years ago, on "Photo-typography" has practically become the standard work on this subject, brought the information thereon up to date in a course of three lectures on "Recent Improvements in Photo-mechanical Printing Methods." A great advance has been made since Mr. Bolas's first course, many of the processes, then only immature, having been since completed and brought into practical use. Mr. Bolas was followed by Mr. R. W. Edis, who dealt with the sanitary construction of London houses in the same interesting way as he had dealt two years ago with their decoration and furniture. In the fourth course, Professor Chandler Roberts, the well-known chemist of the Mint, under the title of "The Alloys Used for Coining," gave a lucid account of the various metals employed for the purpose, of the way of dealing with them, and the arrangements for coining and for testing our coinage. The next course was by Mr. Norman Lockyer, on "New Optical Instruments and Arrangements." In the two lectures on this subject, Mr. Lockyer described the advance which has been made both in the construction and the fitting of astronomical telescopes, and of the progress which has been made in photographing celestral objects. Mr. Lockyer laid great stress upon the want of proper arrangements for the manufacture of optical glass, and expressed his hope that the Society of Arts would take action in the matter. The concluding course of the session was by Prof. W. N. Hartley on "Fermentation and Distillation," the scientific principles on which the various manufacturing proceses are based being very clearly and graphically described in a course of three lectures.

VI.—Juvenile Lectures.

The subject of the usual short course of Juvenile Lectures, delivered for the benefit of children of members during the Christmas holidays, was "Crystals and Crystallisation," the lecturer being Mr. J. M. Thomson, the lecturer on chemistry at King's College. The chief feature of Mr. Thomson's lectures was the very beautiful experiments in crystallisation with which he illustrated them, experiments which had never been shown before on so large a scale to an audience in London.

VII.—International Health Exhibition.

In closing the International Fisheries Exhibition in October last, H.R.H. the Prince of Wales announced that he proposed to hold in the buildings at South Kensington, during the next three years, the following International Exhibitions :—

1884. A Sanitary and Educational Exhibition, comprising Health as applied to Food and Drink, the Dwelling, and Dress ; also General and Technica Education.
1885. An Exhibition of Industrial Inventions, especially Labour-saving Machinery.
1886. An Indian and Colonial Exhibition.

This announcement was soon followed by the publication of the names of the Executive Council which his Royal Highness had appointed for the purpose of carrying into effect his intentions with regard to the first-named of these three Exhibitions, that devoted to Health and Education. An application to the Council of the Society, asking that the Exhibition Council and Committees might meet at the Society's House, met with ready assent, and the Council undertook to co-operate in any way which lay within their power with the Exhibition Executive. The Executive Council accordingly continued their meetings from the

7th November until the end of January, in the Society's house, when the progress of the arrangements rendered it necessary for the place of meeting to be transferred to the buildings at South Kensington. The numerous Special Committees which dealt with the different sections of the Exhibition, also held their meetings here till they too were obliged to migrate to the Exhibition itself.

The Council felt that in thus endeavouring to assist the Exhibition, they were acting in accordance with the traditions of the Society, which has been so long and so intimately associated with work of this sort, and that they were not only carrying out the intentions of H.R.H. their President, but also anticipating the wishes of the general body of members, who have for many years past assented to the employment of the Society's influence and of its funds in the advancement of Education and the promotion of Public Health.

The Society may fairly claim the credit of having taken a very leading part in drawing public attention to the unhealthy conditions of modern life, especially of modern town life; the Sanitary Conferences held by the Society, were, if not the cause, certainly the first indication, of a change in public sentiment as regards the needs of healthful life. To this change in public opinion, and to the attention thus drawn to sanitary matters, is due the very great improvements of a sanitary nature which have taken place during the past ten years; the latest and probably the most important outcome of the movement thus set on foot may be said to be the present Health Exhibition.

Nor is the other division of the Exhibition (Education) less closely connected with the Society. It is unnecessary to do more than refer to the Examinations which, established in 1856 almost as an experiment, to test the scheme of holding simultaneous local examinations from a single centre, still, despite the numerous rival agencies, hold a useful place in our educational system. Nor need more be said of the long-continued efforts of the Society on behalf of Technical Education, efforts which prepared the way for the important institution founded by the London City Companies, and now gradually getting into steady practical work. The only Educational Exhibition ever held in this country was that held in 1854 by the Society of Arts.

Seeing how closely akin to the objects of the Society were those for which the Exhibition was founded, the Council felt that whatever help they could render by placing at the disposal of its executive the resources and organisation of this Society, they were bound to afford. They also readily undertook to carry on a useful part of the work of the Exhibition by assuming the charge of the valuable series of hand-books issued under the direction of the Exhibition authorities. A list of these books has been given in the *Journal*, and it has been announced that their publication will be continued by the Society after the dissolution of the Exhibition Council. In recognition of the assistance rendered by the Society, the Executive Council of the Exhibition granted to members of the Society the privilege of purchasing season tickets at half prices. Of this privilege members have largely availed themselves, nearly 400 tickets having been sold.

VIII.—International Inventions Exhibition, 1885.

Carrying out the proposal of H.R.H. the Prince of Wales, the announcement has been made that it is intended to hold in the year 1885, an International Exhibition of Inventions, and of Musical Instruments. Division I. (Inventions) is to be devoted to illustrations of apparatus, appliances, processes, and products, invented or brought into use since 1862. Division II. (Music) will consist of examples of musical instruments of a date not earlier than the commencement of the present century, supplemented by historical collections of musical instruments and music, and of engravings and paintings illustrative of the history of music.

As was the case with the Health Exhibition, the Council have readily consented to render any assistance in their power, to promote the arrangements for carrying out this most interesting project. The Executive Council appointed by H.R.H. the Prince of Wales have already commenced their meetings here, under the presidency of Sir Frederick Bramwell, a late Chairman of Council of this Society, and so long as such accommodation is of service, the Council will continue to place the Society's committee rooms at their disposal.

IX.—International Health Exhibition Prizes.

Amongst the funds which had been left to the Society, at different times, for the purpose of providing premiums, the members will remember that there is included a sum of £100, presented to the Society by the late Sir

Walter Trevelyan for prizes. This sum has been frequently offered for a method of preserving fresh meat, that being an object in which it was known the donor was greatly interested. The prize, however, has never been awarded; but the fact that one of the groups of the present International Exhibition was specially devoted to food, seemed to the Committee to afford a good opportunity for renewing the offer in a somewhat different form. They, therefore, determined to offer five gold medals, or five sums of £20 each, for the best exhibit in each of certain classes of the Exhibition relating to food. They further considered that it would be consonant with the wishes of the donors for them to offer a gold medal, or money of equal value, under the North London Exhibition Trust, for the best set of specimens illustrating handicraft teaching in any school. The two medals which were not awarded last year under the John Stock and the Shaw trusts are now offered, the former for the best example of sanitary architectural construction, and the latter for the most deserving exhibit in the classes relating to Industrial Hygiene. Inasmuch as one of the special objects in the Fothergill trust was the prevention of fire, a subject included in one of the classes of the Exhibition, the Council thought it would be desirable to add an offer of two medals out of this fund, one in the class containing apparatus for the prevention of fire, and the other for the best exhibit in the lighting apparatus class. Announcements to this effect having being made, Lady Siemens expressed her wish to provide a prize of £20 which might bear the name of the late Sir William Siemens, and should be devoted to a subject in which he was interested, the best application of gas for heating and cooking in dwellings. A little later on, also, Mr. Stacy, a member of the Society, was good enough to place in the hands of the Council a similar sum, leaving to the Council to decide in what way the prize thus provided should be offered. Having regard to the character of the prizes which had already been announced, the Council determined to offer Mr. Stacy's prize for the best exhibit in that class of the Exhibition which deals with sanitary decoration. Full particulars of all these prizes have already appeared in the *Journal*.*

X.—Premiums.

In the last Report of the Council reference was made to the premiums which had been offered under the following trusts:—John Stock, Benjamin Shaw, Howard, Fothergill, and Mulready. The Council regret to have to report that the response to the offers they made has been far from satisfactory. Of the two gold medals offered under the Shaw trust, the Council were only able to award one, which was given to Mr. H. A. Fleuss, for his apparatus enabling persons to breathe in mines and other places filled with vitiated air or irrespirable gases. The medal offered under the Mulready trust was also awarded, the recipient being Mr. C. J. Adams; but nothing worthy reward was sent in for the prizes offered under the John Stock, the Howard, or the Fothergill trusts. That the offer of £100 under the Howard trust should not have attracted better essays than those which were sent in is, to the Council, a matter of some surprise as well as of regret; and they did not feel themselves justified in bestowing so large a sum upon any of the essays which were submitted.

XI.—Swiney Prize.

In January last the occasion for the award of this prize recurred, the 21st of that month having been the fortieth anniversary of the testator's death. As the award has to be made jointly by the Society of Arts and the College of Physicians (though the Society is sole trustee), it has been the practice of the adjudicators to give the prize alternately to general and to medical jurisprudence. On this occasion it was awarded to Professor Sheldon Amos, M.A., for his work entitled "A Systematic View of the Science of Jurisprudence." The award was made, as usual, on a recommendation from a joint Committee of the Society of Arts and the College of Physicians. By the terms of the testator's will the prize consists of a silver goblet of the value of £100, containing gold coin to the same amount. It has now been awarded eight times.*

XII.—Owen Jones' Prizes.

These prizes are provided by the interest on the sum of £400, presented to the Society of Arts by the Owen Jones Memorial Committee. They are awarded on the results of the annual competition of the Science and Art Department to students of the Schools of Art, who produce the best designs for household furni-

* See *Journal* for March 14, 1884.

* Fo a li o the recipients, see *Journal*, 7th September, 1883, p. 91

ture, &c., on the principles laid down by Owen Jones. Six prizes were offered for competition in the present year, each prize consisting of a bound copy of Owen Jones's "Principles of Design" and a Bronze Medal. A list of the successful candidates has appeared in the *Journal*.* A similar number of prizes will be offered for the coming year.

XIII.—Prize Essays.

By the liberality of Mr. William Westgarth, a member of the Society, the Council have had a sum of £1,200 placed at their disposal, to be awarded in prizes for essays on "Dwellings for the Poor," and on the "Reconstruction of Central London."

This amount, in accordance with Mr. Westgarth's wishes, will be divided into five prizes:—

A first prize of £250, for the best practical essay upon the re-housing of the poorer classes, and especially of the very poorest classes, of the metropolis.

A second prize of £500, for the best practical essay upon the whole subject of the sanitation, street re-alignment, and reconstruction of the central part of London.

Three prizes of £150 each:—1. For the best treatment of the engineering considerations. 2. For the best treatment of the architectural considerations. 3. For the best treatment of the sanitary considerations.

The essays in competition must be sent in to the Secretary not later than the 31st December in the present year. The precise conditions to be observed will be found in the *Journal*.†

The Council trust that this generous offer will meet with a fitting response, and that they may be able to award the prizes to essays worthy of it.

XIV.—Medals.

The Council have awarded ten medals for papers read at the ordinary meetings, and at the meetings of the three Sections. Of these five have been given for papers read at the Ordinary Meetings, one for a paper in the Foreign and Colonial Section, two for papers in the Section of Applied Chemistry and Physics, and two for papers in the Indian Section. Besides the papers thus marked, there have been several the merits of which, as they were the work of members of their own body, the Council are precluded from recognising otherwise than by a vote of thanks. These papers are "The Progress of Electric Lighting," by W. H. Preece; "Vital Steps in Sanitary Progress," by Dr. B. W. Richardson; "Telegraph Tariffs," by Colonel Webber; "Borneo," by Mr. B. Francis Cobb; "State Monopoly of Railways in India," by Mr. J. M. Maclean; and "The Existing Law of Landlord and Tenant in India," by Mr. W. G. Pedder. The following is the complete list of the awards:—

To The Most Hon. The Marquis of Lorne, K.T., for his paper on "Canada and its Products."

To Rev. J. A. Rivington, for his paper on a "New Process of Permanent Mural Painting, invented by Joseph Keim."

To C. V. Boys, for his paper on "Bicycles and Tricycles."

To Professor Fleeming Jenkin, F.R.S., for his paper on "Telpherage."

To I. Probert, for his paper on "Primary Batteries for Electric Lighting."

To H. H. Johnston, for his paper on "The Portuguese Colonies of West Africa."

To Professor Silvanus P. Thompson, for his paper on "Recent Progress in Dynamo-Electric Machinery."

To Edward C. C. Stanford, F.C.S., for his paper on "Economic Applications of Seaweed."

To W. Seton-Karr, for his paper on "The New Bengal Rent Bill."

To C. Purdon Clarke, C.I.E., for his paper on "Street Architecture in India."

XV.—Albert Medal.

The Albert Medal for the present year has been awarded to Captain James Buchanan Eads, "the distinguished American engineer, whose works have been of such great service in improving the water communication of North America, and have thereby rendered valuable aid to the commerce of the world."

The works of Captain Eads are well known to members of his profession, not only in his own country but in this, as is shown by the fact that in response to the invitation sent out to various learned bodies, the Institution of Civil Engineers recommended Captain Eads. The works carried out by him for deepening and improving the south-western entrance of the Mississippi may be said to stand alone as regards the largeness of the scale on which they have been constructed. He is also the constructor of the celebrated bridge over the Mississippi at St. Louis, an arched bridge with a central span of 520 feet, and with side spans of 502 feet each, all formed of steel tubes. In making this award, the Council have been glad, not only to recognise the talents of one who is so

* See *Journal*, vol. xxxii., p. 905.

† See *Journal*, January 25th, 1884, p. 153.

near the head of his great profession, but also to do honour to a citizen of the United States.

XVI.—Howard Lectures.

Under the Will of Thomas Howard (1868) the Society holds a sum of £500 for the purpose of "presenting periodically a prize or medal to the author of a treatise on the properties of steam generally, or any of them particularly, as applied to motive power, or it may be of air or permanent gases, or vapours, or other agents so applied, or to the inventor of some new and valuable process relating thereto."

The offer made last Session under this trust, of a prize of £100 for an essay on the utilisation of electricity for motive power, not having produced anything considered worthy of so valuable a prize, the Council came to the conclusion that the best way of carrying into effect the wishes of the testator would be to arrange for the delivery under this trust of a series of lectures on some subject dealing with motive power, which might, after their delivery, form a text-book on the subject, and they are now glad to be able to announce to the members that Mr. Wm. Anderson, whose lecture on "The Generation of Steam, and the Thermodynamic Problems Involved" attracted so much attention when it was delivered before the Institution of Civil Engineers, has consented to give to the members of the Society, during the coming Session, a course of lectures on some subject coming within the terms of the trust. The great value of the Cantor Lectures, and the interest which has always been taken in them by members, make the Council feel sure that this addition to the Society's courses of lectures will be fully appreciated.

XVII.—Patent-law.

At the time of the publication of the last Annual Report of the Council, it was uncertain whether the Bill brought in by the Government for the reform of the Patent-law would pass into law. The history of the measure after that time is, of course, well known to those members who take an interest in patent-law reform; but, as a matter of record, it may be as well to state that the Bill was soon after taken up by the Grand Committee on Trade, and underwent at the hands of that Committee alterations of an important character. The Society's Committee, acting in concert with the Committee of the British Association, did their best to induce the Government to accept certain amendments which would have rendered the Bill more like that introduced by the Society of Arts, and would have got rid of the objections indicated by many of the speakers at the Society's meetings. The fact, however, that the Bill was carried through its concluding stages near the close of the Session, was urged by the President of the Board of Trade as a reason for not admitting amendments, on the ground that their acceptance would be likely to imperil the passing of the measure. Some few alterations however, were effected, but the Act, as it was passed, did not assume so satisfactory a form as the Council believes it might have taken, had the Government been able or willing to accept some of the alterations suggested to them. The Act, as the members are aware, came into operation at the beginning of the present year, and it may be fairly stated that so far as it has yet gone, it seems to have given great satisfaction to inventors generally. The number of applications have been far in excess of the estimate made by Mr. Chamberlain on the introduction of the Bill. During the first month there were 2,499, and up to the present time,* that is to say, for practically the first half of the year, the total is 9,207. For purposes of comparison, it may be mentioned that the greatest number in any previous year was that in 1882, namely, 6,241.

The Patent Committee of this Society was reappointed by the Council for the purpose of watching the progress of the Act, but it has not been necessary to call it together. The results of the Act cannot very fairly be estimated until it has had at least a year's working, and the time of trial has yet to come. The first six months of provisional protection under the new Act have not expired, and the publication of the specifications on which letters-patent have been granted is only commencing. A crucial test of the working of the new Act will be the result of the proceedings in opposition, disclaimer, and amendment. The manner in which the new office proves itself able to deal with these questions will be watched with the closest attention by all who take an interest in the matter; and on the success or failure to deal satisfactorily with these important questions depends the success or failure of the Act.

XVIII.—Collisions at Sea.

It was stated in the last Annual Report

* The numbers are really down to the 19th of this month.

that a Committee had been appointed by the Council to consider and report upon the question of the best means of preventing collisions at sea. Soon after its formation, the Committee found it would be better for them to restrict their labours to the question of collisions in fogs, and to this point therefore alone their attention has been directed. In answer to an invitation published in the *Journal*, a great number of suggestions were sent in by inventors as to the best means of preventing such collisions. Most of these suggestions dealt with methods of signalling. A synopsis of them all has been prepared, and, as already stated in the *Journal*, will be furnished to anybody applying for a copy. The Committee also took a good deal of evidence on the subject, and their chairman, Admiral Sir Alfred Ryder, to whom the Council are much indebted for the time and thought he devoted to the work of the Committee, prepared a report, which, after being presented to the Council, has been published in the Society's *Journal*.*

XIX.—Paris Exhibition of Art Industries.

The Paris Union Centrale des Arts Decoratifs have been engaged since the year 1880 in holding a series of Exhibitions of Art Industries. The chief object of the Union, which has the sanction and approval of the French Government, though it is not actually a Government Department, is to establish in Paris a museum similar in character to the South Kensington Museum in London. The President of the Union asked for the assistance of the Society in drawing the attention of English manufacturers to the Exhibition of the present year, which relates specially to industries connected with stone, wood, pottery, and glass. The Council felt they were promoting a useful work by rendering such aid as was in their power, and they have consequently done their best to make the aims and objects of the Exhibition known in this country. Some particulars with regard to the Exhibition have already appeared in the *Journal*, and further information can be obtained on application to the Secretary of the Society.

XX.—Examinations.

As no changes were made in the programme for the present year, there is not much which calls for special remark in the results of the examinations. There was a satisfactory increase in the number of candidates, 991 having presented themselves at 38 centres; whereas last year there were 808 candidates and 35 centres. Of these 991 candidates 785 passed and 206 failed. The number of papers worked was 1,058; of these 121 took first class certificates, 363 second class, and 348 third class, while to 226 papers no certificate was awarded. It is noticeable that of the 226 failures, no less than 110 were in Shorthand, a subject taken up by 234 candidates. It is evident that, when nearly 50 per cent. of the candidates fail, a large number must enter who have not sufficiently considered the nature of the examination or their own chances of passing. It will be well that in future years, candidates in this subject should not present themselves until they are satisfied that there is a fair probability of their attaining the standard of proficiency necessary to obtain a certificate. Teachers also of this subject might wisely exercise some discretion in recommending their pupils not to compete unless they are likely to pass. The subject of Book-keeping shows a large increase—233 against 141 last year, and of these only 28 papers failed to satisfy the examiner. In the following subjects, Commercial Geography and History, German, Italian, Spanish, and Sanitary Knowledge, no examination was held, as the requisite number of candidates (25) did not present themselves. As regards Sanitary Knowledge, this may be accounted for by the fact that the subject of Hygiene has been added to the Science and Art Department's list, and teachers are naturally induced by the payments on results to send their pupils in for the Government Examinations. It is intended to keep this subject on for one more year, but should it fail next year to attract a sufficient number, it will be discontinued. With regard to the other subjects, the Council would draw the attention of the Managers of Institutions and others interested in the Examinations to the neglect with which these important subjects are treated. The Council have decided not to make any alterations of importance in the programme for 1885, which will be issued very shortly.

XXI.—Practical Music Examinations.

The number of provincial centres at which the practical examinations in Music have been held this year has not increased, there being, as in previous years, only two such centres,

* See *Journal* for May 2nd, 1884.

Liverpool and Glasgow. At Liverpool 29 candidates presented themselves, all of whom passed; 21 first class certificates were awarded, and 13 second. At Glasgow 75 candidates entered, all of whom passed, taking 34 first class, and 45 second, with two second class honours. At London, there were 198 candidates, of whom 179 passed, taking 41 first class, and 160 second class certificates, with two second class honours. It should be stated that many of the candidates were examined both in the pianoforte and singing, and consequently the number of the certificates awarded does not agree with the total number of candidates passing. A comparison with previous years shows that though there is an increase in the number of candidates presenting themselves, there is a slight falling off in quality, the per-centage of first class certificates being smaller.

XXII.—Water Supply Conference.

In March last, the Council received an invitation from the Executive Council of the Health Exhibition, asking them to organise a Conference on the subject of Water Supply, to form one of the series of Conferences which it was proposed should be held at the Exhibition. The Council readily undertook to carry out this suggestion, and H.R.H. the President of the Society graciously consented, in answer to a request from the Council, to take the chair. The arrangements were interrupted by the sudden death of H.R.H. the Duke of Albany, and it became necessary to defer to a later period than was originally intended the date for holding the Conference. The Council, however, have continued the preparations, and they are happy to say they have received promises of papers from several well-known engineers and others. They hope that these preparations may soon be completed, and that they may be able to give due notice of the exact date on which the Conference will be held. They trust that it may prove no less successful than the one held in 1878, on the suggestion of H.R.H. the Prince of Wales, in the Society's own rooms.

XXIII.—List of Members.

There can be no better proof of the prosperity of the Society than is afforded by the fact that its numbers continue steadily to increase. The total number of life members, subscribing members, and institutions in union which subscribe to the Society from their own funds, is now 3,551, or 106 more than at the corresponding period last year, when the number was 3,445. During the year 1883-4, 262 members have been removed from the list by death or resignation. During the same period, 368 have been elected.

XXIV.—Conversazione.

Notice has already been given in the *Journal* that the Society's Conversazione, this year, will be held at the International Health Exhibition. The Council are glad that they have been able to arrange with the Executive Council of the Exhibition for the holding of a joint Conversazione, to which Members of the Society of Arts will, as usual, receive an invitation.

XXV.—Chairman of Council.

The death of Sir William Siemens, who had been re-elected Chairman by the Council at their first meeting after the Annual General Meeting, rendered it necessary to supply his place. The Council consequently elected Sir Frederick Abel, who has been an active member of their body almost continuously since 1868.

XXVI.—New Council.

Since the election of the Council, by the last annual general meeting, there have occurred several vacancies, which the Council, acting under the bye-laws, have filled up. The death of Mr. Wm. Spottiswoode took place on the very day of election last year. The Duke of Marlborough, who had been on the Council since 1881, died very soon after this; and Admiral Sir Alfred Ryder, who was elected on the Council last year, found himself unable to accept the nomination. The three vacancies thus formed were filled up during the year by the election of Admiral Sir Edward Inglefield, Mr. W. G. Pedder, and Colonel Webber. The lamented death of H.R.H. the Duke of Albany did not render it needful for the Council to elect another Vice-President, since his Royal Highness was nominated by H.R.H. the President of the Society.

The Vice-Presidents retiring this year from the Council, by reason of their seniority, in accordance with the bye-laws, are Sir Rutherford Alcock, Sir Frederick Bramwell, Sir Frederick Leighton, and Mr. W. H. Perkin. Sir Frederick Bramwell has been Vice-President since 1879, having previously served on the Council, and the other three gentlemen named, since 1880. The ordinary members of Council retiring are Mr. Henry Doulton, Admiral Sir Edward Inglefield, Mr. George Matthey, and Mr. Loftus Perkins. In place of these the Council now put forward for election, as Vice-Presidents, the Marquis of Hamilton, Sir James Paget, Lord Reay, and Mr. Matthey; as ordinary members of Council, Professor James Dewar, Mr. Brudenell Carter, Mr. Edward Birkbeck, and Colonel Donnelly.

XXVII.—Death of H.R.H. the Duke of Albany.

The Council deeply regret to have to place on record in their report the loss the Society has sustained by the death of H.R.H. the Duke of Albany, who, since 1879, had been a Vice-President of the Society of Arts. Immediately after the death of His Royal Highness, a special meeting of the Council was held, at which votes of condolence were passed with Her Majesty, with H.R.H. the Prince of Wales, and with H.R.H. the Duchess of Albany.

XXVIII.—Obituary.

The heavy losses which the Council have sustained by death have been referred to above. Besides H.R.H. the Duke of Albany, one of their Vice-Presidents, the Council have lost their Chairman, Sir William Siemens, the Duke of Marlborough, and Mr. William Spottiswoode, during the past year. They have also to note the deaths of Mr. Cromwell Varley, Lord Overstone, Dr. Hullah, for many years the Society's Examiner in Music, Dr. Goodford, the late Provost of Eton, and several other members, notices of whom have already appeared in the *Journal*.

XXIX.—Finance.

The members have had before them the annual Financial Statement published in last week's *Journal*, and there are a few items in it about which some words of explanation may, as usual, be desirable. On the debtor side of the account it may be noticed that the annual subscriptions received show an excess of £156 over last year, the total amount, £6,284, being considerably higher than that taken in any year since 1876. On the other hand, the life compositions, though up to the average of recent years, fall short of the large sum taken last year by £116. The other receipts of the Society do not differ greatly in amount from the corresponding items in recent years. There are, however, a few entries which appear on this side which considerably swell the total of receipts, though they do not form part of the Society's regular revenue. These are, the liberal contribution by the late Sir William Siemens towards the cost of last year's Conversazione (£1,120), the amount received from Mr. Westgarth for his prizes (£1,200), and two smaller sums of £20 and £40 each, one representing Mr. Stacy's prize, the other the amount which the Council have undertaken to expend for the Paris Union Centrale des Arts Decoratifs.

On the credit side of the account the items of ordinary expenditure do not seem to call for very much remark. Against the £1,500 expended on last year's Conversazione is, of course, to be set Sir William Siemens's contribution of £1,120, leaving a charge of £425 which was met by the Society. The principal item in the total of £279 expended on prizes consists of the Swiney Prize, £200. This charge, it will be remembered, recurs every five years. In addition to the life compositions invested as usual, the Council have been enabled to repay to capital a sum of £500, the balance of an amount sold out in 1876, and then applied for current expenses of the Society. The first portion of this money was repaid to capital account in the Session 1881-2. This sum, like the former one, has been invested in Queensland 4 per cent. Bonds. It has also been considered wise that the accumulations of interest on trust funds should be taken out of the current account, and for this reason a sum of £300, representing these accumulations, has been placed on deposit with Messrs. Coutts and Co. The amount of Mr. Westgarth's prizes has also been placed on deposit with the Society's bankers. A sum of about £80 has been invested on account of the Aldred trust and the North London Exhibition trust, in accordance with the resolution arrived at last year, that the amount accumulated under these trusts should be added to the principals. The reasons for this were given in last year's annual report. The last item, cash in hand, shows an increase of a little more than £100 on the amount at the commencement of the financial year.

Under the head of liabilities, it will be seen that the total liabilities are apparently considerably in excess of last year, being £2,482, as against £954. This is principally due to the one item of Mr. Westgarth's prizes, and is of course balanced by corresponding entries amongst the assets. In consequence of the investment referred to above, the Society's invested funds show a most satisfactory increase, being £1,060 more than last year. These investments now amount to £6,562, and are of course entirely independent of the invested funds chargeable with various trusts. The other assets, consisting of uncollected subscriptions, and the property of the Society, are estimated at their usual value. The financial statement closes with a list of the investments standing in the name of the Society, and of the trust funds included in them. On them it may be noted that the securities in which the Society's funds were in past years invested, now stand without exception very high. The property is, therefore, really very much more valuable than it appears on the face of the statement. The Council think that a careful examination of the statement will show that the Society's finances are in a thoroughly sound condition, and afford evidence of steadily increasing prosperity.

The CHAIRMAN, in moving the adoption of the report, remarked that the past year of the Society's existence had been not less active and useful than previous ones, and he congratulated members on the very satisfactory financial position of the Society. He referred to the great loss the Society had suffered by the death of Sir William Siemens, and to the invaluable aid which he had rendered as chairman of its Council.

Lord ALFRED CHURCHILL, who seconded the motion for the adoption of the report, remarked that although the funds were so highly satisfactory that some members seemed to think that the Society was too prosperous, they must bear in mind the time when the lease of the Society's house would fall in, so that they might be prepared to meet this contingency.

Mr. LIGGINS expressed his hope that the Committee on Collisions at Sea would not consider its labours at an end, in consequence of the report already given, which only dealt with one part of the subject. He urged the necessity of a clearer international understanding as to the meaning of the words "starboard" and "port," as used in steering a vessel. These terms were practically used in one sense by English seamen, and in another by the sailors of France, and certain other countries. This was a point to which the attention of the committee might well be devoted.

After some remarks from Mr. KLENCK on the financial statement, the report was adopted.

The ballot having remained open for one hour, and the scrutineers having reported, the CHAIRMAN declared that the following had been elected to fill the several offices. The names in *italics* are those of members who have not, during the past year, filled the office to which they have been elected.

PRESIDENT.

H.R.H. the Prince of Wales, K.G.

VICE-PRESIDENTS.

H.R.H. the Duke of Edinburgh, K.G.	Sir John Lubbock, Bart., M.P., F.R.S.
Sir George Birdwood, M.D., C.S.I.	*George Matthey, F.R.S.*
Andrew Cassels.	*Sir James Paget, Bart., D.C.L., LL.D., F.R.S.*
B. Francis Cobb.	W. H. Preece, F.R.S.
Edwin Chadwick, C.B.	Sir Robert Rawlinson, C.B.
Lord Alfred Churchill.	*Lord Reay.*
Sir Philip Cunliffe-Owen, K.C.M.G., C.B., C.I.E.	B. W. Richardson, M.A., M.D., F.R.S.
Captain Douglas Galton, C.B., F.R.S., D.C.L.	Lord Sudeley.
Earl Granville, K.G., F.R.S.	Sir Richard Temple, Bart., G.S.C.I., C.I.E., D.C.L.
Marquis of Hamilton.	Duke of Westminster, K.G.
Sir John Hawkshaw, F.R.S.	

ORDINARY MEMBERS OF COUNCIL.

Sir Frederick Abel, D.C.L., C.B., F.R.S.	*Colonel J. F. D. Donnelly, R.E.*
Edward Birkbeck, M.P.	Thomas Villiers Lister.
Alfred Carpmael	J. M. Maclean.
R. Brudenell Carter, F.R.C.S.	W. G. Pedder.
Thomas Russell Crampton.	R. E. Webster, Q.C.
Prof. James Dewar, M.A., F.R.S.	Colonel C. E. Webber, R.E., C.B.

TREASURERS.

W. H. Malcolm.	Owen Roberts, M.A., F.S.A.

SECRETARY.

H. Trueman Wood, M.A.

A vote of thanks to the Scrutineers, moved by the CHAIRMAN, was carried unanimously.

Mr. HYDE CLARKE proposed, and Mr. LIGGINS seconded, a vote of thanks to the President, Vice-Presidents, and members of Council for their services during the past year, which was carried unanimously.

Sir FREDERICK ABEL replied on behalf of the Council. He said that the Council were fully employed, but it was a gratification to them to find their labours appreciated by the members, and the Society in so prosperous a condition. He also remarked on the valuable aid they received from the Secretary.

Mr. LIGGINS proposed a vote of thanks to the Secretary, to the Editor of the *Journal*, and to the other officers of the Society, which was acknowledged by the SECRETARY.

The meeting concluded with a vote of thanks to the Chairman, moved by Lord ALFRED CHURCHILL.

Miscellaneous.

NOTES ON THE BUILDING EXHIBITION.

As the notes of last year relating to this Exhibition at the Agricultural-hall bore upon the outside of the house, those of this year deal principally with the interior and fittings. Wood-working has a special feature, many machines showing that great progress has lately been made in this direction.

F. W. Reynolds and Co. exhibited their "Queen" hand-power combined circular and band sawing machine, the table of which is perfectly clear on both sides for cross-cutting to any length, no obstruction being caused by the fly-wheel. The main features of the "Briton" combination band and circular sawing machine, for steam power, is the patent arrangement of countershaft for driving, whereby two separate motions are obtained from a single countershaft, the attendant being able to work instantly either the band saw or the circular saw. The "No. 3," improved planing and trying-up machine, with rising and falling tables, will take timber "out of winding" (as the joiners' call it), to a length of 7 feet, and, by means of the "fence," or guide, will square up timber accurately. The panel planer will plane any thickness, either hard or soft wood, up to 5 inches thick and 30 inches wide, without leaving any perceptible ridge or unevenness; and the "comprehensive" general joiner has been designed to do a large variety of work, while occupying only a small space.

Lewis and Lewis showed a hand-feed planing machine which, it is claimed, will "take out of winding" any kind of timber, however warped it may be, and reduce it to an even face more quickly than can be done in a trying-up machine. C. J. Boyce and Co. showed in action Olley's self-feeding saw-bench, the peculiarity of which is that the circular saw revolves in the contrary direction to that usually adopted, and thus cuts upwards instead of downwards, with a considerable reduction of friction, and, therefore, of the power required to drive. As the speed at which the saw is driven by hand is constant, the speed of the feed is altered according to the thickness of cut, thus equalising the strain at the handle. This company also showed in action an ingenious machine, invented by Mr. Tushaw, for punching holes in iron hoopings, for binding packing cases, and also a modification of the same machine, which serves not only to set large saws, but even to make them from the steel plate, by punching out the spaces between the teeth. J. T. Syer exhibited his convenient bench knives for joiners, and also a handy machine for cutting mitre-joints perfectly true.

There was more than one example of poultry houses and conservatories, especially designed and constructed so as to be easily removeable by the tenant at the expiration of his lease. There were also several examples of glazing without putty, the joints being at the same time perfectly good, in particular, a conservatory, erected by Messenger and Co., had a sheet of water constantly poured over it to show the tightness of the joints. In Samuel Deards' patent "Victoria dry glazing," the bar for holding the panes is composed of two zinc tubes combined, resembling the letter X, in which the glass is placed, and upon which a zinc cap is afterwards made to slide, all being held firmly to the rafter by one screw.

Several firms manufacture prismoidal and other glass blocks for being inserted into gratings, and thus allowing daylight to enter basements by refraction. Among them, Hayward Bros. and Eckstein had on view several examples of their "semi-prism reflecting lens" pavement light. T. Hyatt combines his prism and lens lights with silvered reflectors, so contrived that they direct the rays of light on to any part of the basement. In his "safe-walking surface" grating, the iron is completely hidden by a combination of glass and tiles, which produce a pleasing effect. The stand of Hamilton and Co. was fitted to represent a basement, arranged with their various lights and coal-hole plates, showing the quantity of daylight which they allow to enter.

There were two notable exhibitors of wall-papers, both plain and embossed, viz., Jeffrey and Co., and W. Woollams and Co., both of whom guarantee the absence of arsenic. There were also several examples of non-poisonous paints, in which the base is zinc instead of lead. Rendle Brothers gave practical demonstrations of the efficacity of their "electric" paint remover, which supersedes the use of a fire or hot iron for this purpose. While tin is successfully employed for lining lead pipes, wrought iron piping is, by Chedgey's process, lined with glass, so that water, or various acids and chemicals, passing through them, remain absolutely pure. The pumps of this exhibitor, with bored glass barrels, have the same advantage; while, owing to their transparency, the valves are exposed to view, so that anything going wrong with them is readily noticed.

Sanitary appliances formed a large class. The representatives of the late George Jennings exhibited a convenient appliance for City offices, consisting of a combined lavatory, slop sink, &c. The "concealed" lavatory, which takes up very little space, resembles an ordinary cupboard, while a similar contrivance for billiard-rooms is masked by a cue-rack. The one inconvenience of the "tip-up" basin, the chance of a portion of the waste water being projected upwards, is now obviated by the addition of a "splash rim" to the casing. The West Central Engineering Company have an arrangement of w.c., in which all the wood casing may be lifted up together, for facility of inspection and repair.

Stoves, ranges, and fireplaces, were well represented, not only in the expensive but also in the ordinary varieties. The principle of the gas-roasting appliances of James Slater and Co., which resemble large iron safes, is that the whole of the oven is surrounded by a stream of air, which is conveyed by passages in the top, sides, back and doors, to the burner pipe in the bottom of the oven, taking up in its passage all the heat that would otherwise be radiated to waste in the kitchen. The incoming and outgoing currents nearly balance each other, permiting of the retention of the hot air in the oven as soon as possible, and therefore of the extraction from it of the greatest amount of caloric. Their gas-heated circulating boiler has, with 1,800 cubic feet of Dawson's gas, equal to 900 cubic feet of coal gas, boiled 600 gallons of water. The gas-cooking stoves of H. and C. Davis are double-cased and surrounded by a non-conducting substance. An arrangement has been made whereby they may be obtained from the gas companies at quarterly rentals; and it is asserted that they will cook an ordinary dinner for ten persons at a cost in gas of $1\frac{1}{4}$d.

The bars of S. Deards' "Princess Louise" coil grate consist of wrought iron tubes, in which a current of water is heated for baths, warming greenhouses, and other purposes.

AMERICAN FOREST TREES.

The following particulars respecting West American forest trees are taken from a communication of Mr. Thomas Meehan to the *Gardeners' Chronicle*:—

In going westward from Lake Superior the arborescent vegetation ceases near Brainerd, the last trees being white pine, banks' pine, the larch, white birch, white maple, and aspen. Thence to the Rocky Mountains a continuous sheet of herbaceous vegetation covers the surface, and no trees are seen except cottonwoods (*Populus monilifera*) along the Missouri. The first ranges of the Rocky Mountains on this route along the Yellowstone River and in the Park are covered sparsely or densely with trees, the higher summits and ridges with *Pinus flexilis* (James), *Abies grandis*, and *Pseudo-Tsuga Douglasii* (Carr.); while the foot-hills, and in some cases the levels, are thickly set with *Pinus contorta* (Douglas), var. Murrayana (Watson). The latter is regarded by some as a distinct species *P. Murrayana* (Murr.), but is only an upland form, which is larger and more spreading. Both varieties, however, grow in proximity in many parts of Oregon and Northern California. In the lowlands of the Park are dense thickets of dwarf willow, and here and there a tree of *Populus augustifolia* (James), and *Pinus ponderosa* (Douglas).

Between the last ranges of the Rocky Mountains, near Pend'Oreille Lake, and the Cascades, the prevailing and almost the only tree is *Pinus ponderosa* (Douglas). It scarcely forms forests here, but is scattered over the country in considerable abundance, and attains a large size.

Passing the gorge of the Columbia, we come into the dense forests of the Pacific coast proper, where the number and magnitude of the trees is greater than I have seen in any eastern or even tropical region. The trees of several kinds here reach an altitude of 300 feet, and often stand so near together that all undergrowth is absent, and the horseman makes his way through them with difficulty. On the lowlands the Douglas spruce and the western arbor-vitæ are the most abundant. Locally, the hemlock is common, and along the rivers the north-western cottonwood (*Populus trichocarpa*), stands thick and attains a large size. Along the smaller streams, and in swampy places, the Oregon ash (*Fraxinus Oregana*, Nutt.) and the arborescent alder (*Alnus rhombifolia*, Nutt.) occur in considerable numbers, and attain about equal size—*i.e.*, a diameter of 1 foot, and a height of 50 or 60 feet. Scattered through this lowland forest are the two common maples of the west (*Acer macrophyllum*, Pursh, and *A. circinatum*, Pursh). Of these, the first grows sometimes to the height of 80 feet, with a diameter of trunk of 12 to 15 inches, and on young plants the leaves sometimes attain a breadth of a foot or more. The vine maple is a peculiar feature in the forests of the Lower Columbia, Puget Sound, Vancouver's Island. It never becomes more than 6 inches in diameter, and several trunks usually spring from the same root. These are very slender, droop, and frequently reaching the ground, take root at the summit. Where these interlacing trees are numerous, they form a thicket which is almost impenetrable.

Among the great conifers of the Pacific coast two of the most gigantic and valuable, the sugar pine, *Pinus Lambertiana* (Douglas), and the redwood, *Sequoia sempervirens* (Endl.), approach, and the first reaches the line of the N. P. Railroad, though their habitat is more southern, and both are important elements in the resources of the country from which it will derive much of its business. Of these the sugar pine—nearly related to the eastern white pine by habit, foliage, cones, and wood—is the monarch of the genus, frequently reaching a height of 300 feet, with a diameter of from 10 to 15 feet. This grows chiefly in the Sierra Nevada and Cascade Mountains throughout Oregon and California. The redwood is even larger. It is found only along the coast and about Port Orford forms forests, which surpass in the average dimensions of the trees any others I have seen. The lumber furnished by both these great trees is excellent; and, like the white pine of the East, they are suffering such wholesale destruction as promises soon to exhaust the supply they furnish. The next in intrinsic value as timber trees, and, from their abundance, having even greater economic importance, are the Douglas and Menzies spruces, the white fire, *Abies grandis* (Lindl.), and the western white cedar, *Thuia gigantea* (Nutt.). These form the basis of the lumber industry of the Puget Sound region, and supply all the great saw-mills, some of which cut 250,000 feet per day. The timber furnished by these trees is good, but the lumber is inferior.

With the array of magnificent conifers which flourish in the moist and equable climate of the North Pacific coast, the poverty of the angiospermous flora is in striking contrast. Two maples, two poplars—one on the high and other on low grounds—one ash, and one alder, have been enumerated. To these should be added two arborescent willows (*Salix lasiandra*, Benth., and *S. longifolia*, Muhl.), one oak of little value, and two other hard-wood trees and the list is complete.

In the open grounds of the Villamette Valley, Puget Sound, and Vancouver's Island, Garry's oak (*Quercus Garryana*, Dougl.) is not uncommon. It is usually of moderate size, and of a peculiar straggling and peculiar misshapen growth; occasionally, trees of three or four feet in diameter are met with, but the shape is so irregular, and the wood so brittle, that it has little value as a timber tree. In the forests of both Oregon and Washington Territory two trees are sometimes seen that are sure to attract the attention of the Eastern botanist. One of these, which grows on the higher grounds, is the Oregon Chinquapin (*Castanopsis Chrysophylla*), generally a shrub, but sometimes reaching an altitude of fifty or sixty feet, and conspicuous from the golden pubescence of the underside of the leaf. The other tree is the Madroña (*Arbutus Menziesii*, Pursh.). This is a small tree, but one much admired; the foliage is persistent and rich, the leaves oblong or lanceolate, with serrated edges, and the fruit, which grows in clusters, is red, and somewhat resembles that of the mountain ash, but is less abundant, and grows in more open panicles.

WATCHMAKING IN SWITZERLAND.

Some interesting information respecting this industry, one of the most important of Switzerland, has lately appeared in the report by her Majesty's Secretary of Legation, at Berne. From this it appears that the business of watchmaking dates back from the year 1587, taking its rise in Geneva, and gradually spreading north and east to the neighbouring cantons of Neuchâtel, Berne, and Vaud. Within a century from its introduction 100 master watchmakers are said to have been established in the city, the total annual turn out being 5,000 watches. In Neuchâtel the manufacture was introduced a century later, owing, it is said, to the importation of an English watch into a mountain hamlet, where a blacksmith examined it and succeeded in constructing one in imitation. As regards the Canton de Vaud, the Jura valleys of the Lac de Joux and Sainte Croix, have long been the head-quarters of the same industry, which has appeared to flourish more in the mountain region than in the plain. The same peculiarity is observable in the Canton of Berne, where the principal watchmaking centres, counting from the foot of the Jura, and ranging upwards, are Bienne, St. Imier, Franches Montagnes, Tramelan, &c. Further than Berne this particular trade does not appear to have established itself to any extent in any part of the confederation. There are, however, various isolated manufactories in other cantons as Fribourg, Soleure, Bâle, and Schaffhausen. The Cantonal Governments have accorded the watch manufacture a support by fostering various institutions created in its behalf. Foremost among these are the horological schools, of which the earliest was founded at Geneva, in 1824, and became, in 1843, a municipal institution, directed by a committee of watchmakers. At this school it is competent for a student in the craft to attend classes for practical instruction, as well as a special theoretical course lasting four years. The fee for Swiss pupils is five francs a month. In the Canton of Neuchâtel there existed, in 1872, three such schools; a fourth has since been established at Fleurier. The theoretical course here is of three years' duration. In the Canton of Berne there are two of these schools at St. Imier and at Bienne. Various societies have also been, from time to time, formed more or less in connection with watchmaking. Among these may be mentioned the "Section d'Horlogerie," of the Société des Arts, at Geneva, founded in 1870, with a monthly newspaper entitled the *Journal Suisse d'Horlogerie*. Another active society is the "Société Intercantonale des Industries du Jura," founded in 1876, having ten sections, and engaging in all manner of operations for the advancement of the watch trade generally. It is, however, to the public observatories of Switzerland, and in particular to those of Geneva and Neuchâtel, that the Swiss watchmaker is, above all things, indebted for the degree of precision to which his art has been enabled to attain. That at Geneva was built in 1773, and restored in 1829, since which special arrangements have been made in it for testing and regulating the chronometers brought for inspection. It communicates, by electricity, the exact time to all the principal factories in the city. The one at Neuchâtel, which was founded in 1858, similarly regulates the time for the chief watchmaking centres and telegraph offices in the canton, and even beyond. In both these observatories there is held a yearly competition of chronometers, with prizes offered either by the Society of Arts or by Government. There appears to be an absence of reliable statistical information on the subject of watchmaking in Switzerland, but from calculations which were made in 1866, as to the number of workmen employed and the watches turned out, it appeared that in the Canton of Neuchâtel there were 13,706 workmen, turning out yearly nearly 1,000,000 watches, valued at 50,000,000 francs; in the Jura Vaudois, 2,700 workmen; in the rest of this canton there were 5,000 workmen engaged in this manufacture and in that of musical boxes; in Berne, about 1,300 artificers, producing watches valued at 30,000,000 francs. At the present day, it is estimated that the total annual production of watches in Switzerland exceeds 1,600,000, with an aggregate value of 88,000,000 francs, the total number of workmen employed averaging 40,000. Dr. Adolph Hirsch, the director of the Neuchâtel Observatory, in his report on the watches of the Vienna Exhibition, gave it as his opinion that, "so far as regards watches, properly so called, Switzerland might be said to occupy the first rank among the nations, and even in respect of chronometers to be fully the equal of England." The total exportation of watches in 1882 was 154,500 kilogrammes, or 25,300 more than in 1881, while 46,400 kilogrammes were imported; the latter, however, were chiefly articles in the rough, intended to be finished and re-exported. Mr. Thornton, in conclusion, says that a novel kind of watch has been recently invented by M. Paul Kramer, at Neuchâtel, but owing to the defective state of the law in Switzerland, the inventor has been obliged to patent it in France. This watch is called *à aiguilles universelles*, and indicates simultaneously the times of different countries; one, for example, shows the different times for Paris, Suez, Bombay and Hué, another for New York and San Francisco. Any such watch might be constructed to suit the wishes of the purchaser. The hands pointing to these different hours are painted upon a small movable dial placed in the centre of the principal face of the watch. Mr. Thornton says:—"What is perhaps more generally needed than anything else for the recovery and maintenance of the old Swiss reputation for solid excellence in watchmaking, is the passing of a law for the protection of industrial inventions, models, and designs. Such a law was proposed eighteen months ago, but was, unfortunately, rejected by the popular vote for reasons entirely disconnected with its intrinsic merits or demerits; there is, however, little doubt that its more important provisions will, before long, re-appear in a similar measure, which will this time meet with a better fate."

THE WHEAT-FIELDS OF MEXICO.

It is stated, in a report recently issued by Mr. Joseph Nimms, Chief of the United States Bureau of Statistics, on the trade between Mexico and the United States, that Mexico, as a grain-field, is becoming large enough to affect the supply and consumption of the world, and to enter into serious competition with the United States and Russia; the two leading wheat-exporting countries.

The physical formation of Mexico is simply an extension southward of the great Colorado mountain base plateau. Wheat grows on the plateau of Mexico at from 6,000 to 9,000 feet above sea level, and between the 18th and 24th parallels of latitude. Corn grows everywhere, except on certain waste districts along the northern frontier. The wheat-growing area of Mexico really extends from Puebla nearly as far as Colima, about 500 miles east and west, and from Southern Michoacan to Zacatecas, about 400 miles north and south. This plateau is broken by mountain ranges into a number of rich districts specially adapted for the growing of wheat, namely the Lerma Valley, roughly 200 by 16 miles; the Bajis (Northern Michoacan, Jalesco, and Southern Guanajuato), 200 by 200 miles; Agnascalientes, 50 by 50 miles; the San Louis Potosi and Queretaro district 150 by 30 miles; thus making a total of 52,000 square miles. Of this immense field of rich and arable land one-third it is believed could be readily put into wheat cultivation, with due regard to other agricultural interests of the country.

Under the Mexican plan of cultivation, three crops are taken off the land every two years—one crop of wheat and two crops of corn. The average wheat yield of Mexico now does not exceed twenty bushels to the acre. Corn on irrigated lands averages about fifty, on dry land about thirty bushels to the acre. The mode of cultivation is similar to that practised by the Egyptians thousands of years ago. Wooden beam ploughs are used, with a small iron shoe, which scratches a furrow five inches broad, and about five inches deep; and it is said that five men are employed, and five yoke of oxen, to do the work which would in other countries be performed by one. The wheat grown is of the very finest quality. At the Centennial Exhibition at Philadelphia, in 1876, Mexico took the first prize for wheat. Threshing is done by driving horses round over a circular tile or stone floor, and winnowing is performed by men tossing the grain and chaff into the air with scoop shovels. Transportation from the field to the farmhouse or railway station is on ponderous two-wheeled ox carts. Apart from the 52,000 square miles spoken of above, which is the choice wheat-producing area, there is sufficient outlying wheat, barley, and corn land now under actual cultivation to supply the present population of Mexico, 10,000,000 persons. These persons are at present fed on grain grown in the immediate vicinity of their domiciles, there having been up to this time no machinery for the transportation of products from one part of the country to the other. Mexico is essentially a corn-fed nation, seven-eighths or more of the people living habitually on *tortillas*. If the wheat area were cultivated to its full capacity, namely, 17,333 square miles, or about the third of the 52,000 square miles, it would yield, under present conditions, twenty bushels of wheat and forty bushels of corn per acre, or an average of 110,000,000 bushels of wheat and 440,000,000 bushels of corn every year. This immense yield will be all available for a foreign market, as the outlying lands will always produce sufficient for the home consumption of Mexico, as they do at present. It is expected that by the end of 1884 Mexico will enjoy a perfect railway system, as there will be two trunk lines from the capital to the United States, having also good branch lines to the gulf ports of Vera Cruz, Tampico, Matamoros, and Corpus Christi. The land of Mexico is largely held in huge estates, for instance, the Bustamente extends over portions of three states, and the line of the National railway runs through it for fifty miles. These vast estates, with the fact that in the central part of Mexico at least they are of cleared land, will enable the wheat-growing area to be put rapidly under cultivation when once the railways open up a market for wheat. The Mexican wheat grower appears to enter the markets under peculiarly favourable conditions. He owns his own land in large tracts, he works it with the cheapest labour, and he is frequently a man of large funded capital. There is, however, one serious difficulty with which the wheat grower has to contend, namely, the system of State taxes which prevails all over the Republic. In some States the production of wheat is taxed, in others the importation of it into, or through their borders. This tax is uncertain, varies with the State, and is very burdensome. It is said to be almost impossible to codify or keep any account of these State imposts, which are levied without system, or on any system of political economy. It is computed, however, that they can be roughly estimated at one per cent. on the value of nearly everything grown or brought into the State.

NEW HAND-LOOM.

M. de Lagreré, a French consular representative in Russia, has forwarded to his Government an account of a new description of loom, which (according to a French contemporary) is likely to accomplish an important reform in the weaving industry; restoring to weavers that independence which had disappeared under existing conditions. This loom is considered to be the realisation of an idea often spoken of in the technical press, viz., the construction of machinery suitable for small manufacturers, and for hand-weavers, which would allow them to compete advantageously with the largest factories.

The new loom has the advantage of being worked by a pedal and bar, which are set in motion by the foot and hand of the weaver. The facility with which it is worked, allows of children and girls producing goods free from defects, without having any special knowledge of weaving. Thus it is said that young weavers of fifteen can make eleven yards of taffetas per day, without their strength being unduly taxed. When such looms are in a weaving-shed, one foreman can supervise the working of fifty looms, and this facility of supervision is also an important advantage in domestic weaving. Each loom occupies a space of about 16 square feet, and this new invention is considered to have solved the problem of an automatic loom, which can work at the varying degrees of speed applicable to different tissues.

This loom is said to be so light that the finest silk goods may be woven upon it without any fear of the warp-thread breaking; the weaver being, therefore, only obliged to stop when he weft has to be renewed. The loom is entirely constructed of cast-iron or steel, and can be used for several years without being repaired. The cost has been roughly estimated at £16. It is capable of being used for all descriptions of rich plain goods and armures, as well as wool and silk materials, cotton and silk Roubaix goods, batistes, &c., being, in fact, a universal loom.

AUSTRALIAN MALACHITE.

Hitherto the principal supply of this beautiful marble, which is largely used in Europe for mantelpieces, pedestals, and similar decorative purposes, has been obtained from Russia, but it is equally rich and abundant in New South Wales, where its colour ranges from pale emerald to deep green, the various layers often possessing different shades of colour, and forming a most beautiful and valuable stone for ornamental and inlaying purposes. Crystals are occasionally met with, and sometimes of large size; those from the Cobar Mines are particularly beautiful. The silky lustre is often very remarkable, the capillary crystals being sometimes several inches long, and compacted together into fibrous bundles. It is found in most of the upper workings of New South Wales copper mines, as in the Bathurst district with chlorite, vitreous, yellow, and other copper ores; at Cambalong earthy and fibrous malachite is associated with barytes or heavy spar, and with yellow and peacock ore; at Cobar, county Robinson, with steatite; Mitchell's Creek, Wellington, county Wellington, mixed with other surface ores, and often containing large quantities of gold and silver. Reedy Creek and Bingera, county Murchison; Icely, Yass, county King; Nymagee, county Mouramba; Buckinbah, county Gordon, in granite, with the sulphides of copper; at Lucknow, county Wellington; Gundagai, county Clarendon; Cow Flat and Milburn Creek, county Bathurst; Belara, county Phillip; Gordon Brook, county Richmond; Clarence River, county Clarence; Kaizer Mine, Mitchell's Creek, often containing beautiful specimens of coarse gold, and Peelwood, county Roxburgh; Wiseman's Creek and Oberon, county Westmoreland; Courntoundra Range, 60 miles from Wilcannia; Condobolin, county Gipps; between the Cotta and Queanbeyan Rivers; county Cowley; Mount Hope, county Blaxland. At Capabella, county Goulburn; Barraba, county Darling; Burraga, county Wellington; Silver Dale, near Bowning, county King; and Parkes, county Ashburnham, with cuprite, redruthite, and other copper minerals.

APPLICATION OF HOT SPRINGS TO CULTIVATION.

Signor Francesco Cirio, the exporter of early grown vegetables, &c., from Italy, who is also the lessee of the establishment of the baths of Acqui, has recently turned his attention to the utilisation of the heat derived from hot natural springs, for forcing melons and other market garden produce.

In the centre of the town of Acqui there is a fountain, supplied from a spring called "La Bollente," the temperature of hot water being 75° Cent. (167° Fahr.). This hot water is conducted in stone pipes to a small experimental garden belonging to Signor Cirio, on the outskirts of the town, and then by a suitable arrangement of sluices, is caused to flow in channels made in cement concrete and covered with stone slabs, under long lines of forcing frames about 4 feet in width; the slabs of stone being covered with from 10 to 12 inches in depth of rich vegetable soil, in which the melon plants are grown. The frames are precisely similar to those in use generally for hot-bed cultivation, and are covered with glass. Early last April an abundant crop of melons were ready for market. Tomatoes, asparagus, salad and other crops are being successfully grown, and it is probable that before long this system of cultivation will be carried on, on a large scale, in Acqui, as the "Bollente" springs supplies a far larger quantity of water than can be ever required for the use of the new bathing establishment now in construction, which water, at the present time, runs to waste.

The melons grown in this experimental garden are sent to Turin and Milan, and even to Paris, where, at the present time, they fetch high prices.

Notes on Books.

International Health Exhibition Handbooks. London. W. Clowes and Sons. 1884.

A list of the Handbooks on subjects cognate to the Exhibition, which the Executive Council propose to publish, has already been given in the *Journal.* Several of these have now been issued, and the following short notices relate to them:—

Health in the Village. By Henry W. Acland, C.B., F.R.S. Illustrated.

The author points out the conditions of village life unfavourable to health and well-doing, and then presents a broad view of the circumstances most favourable to the good order and happiness of a rural population. The book is divided under the headings—(1) The tale told; (2) The need stated; and (3) The lesson learnt. To these divisions is added a list of books on the subject treated of by Sir Henry Acland.

Healthy Nurseries and Bedrooms, including the Lying-in Room. By Mrs. Gladstone.

In this handbook, the wife of the Prime Minster treats first of the nursery in health, and the arrangements necessary to keep it healthy, and then deals with the special necessities of the sick-room.

Health in the Workshop. By James B. Lakeman, Senior Metropolitan Inspector of Factories, Home-office.

The subject is divided into the following sections:—1. Progress of factory legislation, from the first Act in 1802, to the last Act in 1883. 2. Accidents, their causes and extent. 3. Sanitation. 4. Ventilation.

Legal Obligations in respect to Dwellings of the Poor. By Harry Duff, M.A.; with a Preface by Arthur Cohen, Q.C., M.P.

Mr. Duff shows what has been done on this important subject, and analyses the various Acts of Parliament that have been passed for the removal and prevention of nuisances, and for the improvement of labourers' and artisans' lodging-houses. Mr. Cohen, in his preface, alludes to the necessity for the establishment of some central authority to be entrusted with the duty of seeing that the powers given by the various Acts are properly enforced.

Diet in Relation to Health and Work. By Alexander Wynter Blyth, M.R.C.S.

The general principles of diet are here enunciated, and an exposition is given of the composition and nutritive powers of the chief foods, a series of tables being added.

Water and Water Supplies, and Unfermented Beverages. By John Attfield, Ph.D., F.R.S.

Water as the basis of all beverages is treated very fully, both in respect to its source and its supply. Subsequent chapters are devoted to mineral waters and artificially aërated waters. Then follow water purification and analysis, and chapters on tea, coffee, cocoa, chocolate, milk, &c.

Fires and Fire Brigades. By Captain Eyre M. Shaw. Illustrated.

Captain Shaw has given in this handbook some account of the practice in various countries, and a large amount of information from his own experience of the best means of protection against fire.

"Our Duty" in Regard to Health. By G. V. Poore, M.D.

Dr. Poore shows what "our duty" is in regard to the arrangements of the house, both external and internal, to the proper supply of water, the importance of fresh air, and the need for seeing that it is not contaminated, to the right use of refuse, and lastly as to the treatment of the dead, and the best mode of burial.

Food and Cookery for Infants and Invalids. By Catherine Jane Wood, with an Introductory Chapter by W. B. Cheadle, M.D.

The authoress gives the principles upon which a rational diet for the young and the sick must be arranged, and shows how they can be carried out in practice. She also also adds a selection of recipes.

Ambulance Organisation, Equipment, and Transport. By Surgeon-Major G. J. H. Evatt, M.D. Illustrated.

The author states that this is intended as a primer to give the visitor to the Exhibition who is ignorant of ambulance aims and objects, a general idea of the work. He describes the ambulance arrangements of an army in the field, and describes the volunteer war aid given by knightly orders and Red Cross societies. All the various appliances in use are fully illustrated.

Dress and its Relation to Health and Climate. By E. W. Godwin, F.S.A. Illustrated.

Mr. Godwin treats his subject chronologically, and traces the changes in costume from the earliest times to the 19th century. He divides the dress of civilised nations into the two great classes of loose and tight, the former favoured in warm climates, and the latter in cold.

General Notes.

Amsterdam Exhibition.—The medals awarded to British exhibitors at the late International Exhibition at Amsterdam, will be presented by the Lord Mayor at the Mansion-house, on Monday, 30th inst., at 3 p.m.

King of the Belgians' Prize.—The prize of 25,000 francs, or £1,000, offered annually by the King of the Belgians for some work on social science or progress, is this year open for competition by natives of other countries besides Belgium. The subject selected is, "The best work setting forth the means to be employed, and the measures to be taken for popularising the study of geography, and for developing its teaching in educational establishments of various degrees." Works intended for competion must be addressed to the Minister of the Interior, Brussels, before the 1st January, 1885.

Garden Flowers of New South Wales.—The geranium is in New South Wales a very different plant from what is found in England, often attaining the size of a gooseberry bush, covered during eight months out of the twelve with a profusion of large blossoms. Violets do not, as commonly supposed, lose their fragrance on Australian soil, but thrive to an extent unknown in English gardens. Sweet-williams, convolvuluses, daisies, stocks, wall-flowers, and other common English flowering plants grow in a most luxuriant manner even in the poorest soil, while in some districts the rapidity with which the sweet-briar overruns the land causes it to be regarded as a noxious weed, to be extirpated at any cost. It is the same as the cactus, better known as the prickly pear. Although grown with much difficulty in English green-houses, it has thriven to such an extent in New South Wales that the Government have had to take steps for its eradication. Roses, lilies, camellias, &c., flourish everywhere, the most tender kinds being grown with the greatest ease.

Vegetable Products in Switzerland.—From a report of the Horticultural Department of the recent Zurich Exhibition, by M. E. Mertens, we learn that the approximate annual value of the horticultural products in Switzerland is as follows:—

	Francs.
In 1,002 hotels—Preserved fruits and vegetables	1,025,000
Fresh fruits and vegetables	1,200,000
In 606,723 private houses—Preserved fruits and vegetables	60,672,000
Stove plants, flowers, fruit trees, seeds, bulbs, &c.	30,386,000
	93,283,000
Less the excess of imports over exports	3,077,400
	90,205,600

Industrial Art Prizes at Ghent.—The Chambre Syndicale Provinciale des Arts Industriels of Ghent has arranged a series of competitions for designs and executed works, for prizes consisting of diplomas and medals, in addition to sums of money varying from £16 to £8. The cabinet work to be executed, in addition to the drawing one-tenth actual size, is an oak washstand, the cost of which is not to exceed £12 without the fittings; and the committee reserve the right of purchasing at that price all that are sent in. The designs are for a wrought-iron gate for square; a decorative panel; an oak confessional for church of 13th century; a woven woollen fabric with not more than six colours for upholstery; and a frontispiece for a work entitled "History of Art in the Flanders." Competitors must either be Belgians by birth, or must have lived three years consecutively in Belgium, and must give notice of competing before the 1st August, while the works must be sent in by the 10th October. The designs, &c., are to bear a symbol or motto, to be repeated on a sealed envelope containing the name and address. The designs and executed works will be exhibited in the Ghent University from the 19th to the 26th October next. Further information may be obtained from the Secretary, M. Emile Varenbergh, Ghent, Belgium.

Journal of the Society of Arts.

No. 1,650. Vol. XXXII.

FRIDAY, JULY 4, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CONVERSAZIONE.

The Council of the Society of Arts and the Executive Council of the Health Exhibition have arranged for a Conversazione to be held in the buildings of the International Health Exhibition, South Kensington, on Wednesday evening, the 9th July next.

The visitors will be received by His Grace the Duke of Buckingham and Chandos, K.G., Chairman of the Executive Council of the International Health Exhibition, and by Sir Frederick Abel, C.B., D.C.L., F.R.S., Chairman of the Council of the Society of Arts, near the principal entrance to the Exhibition in Exhibition-road. The reception will commence at 8.30 p.m. The gardens, as well as the Exhibition buildings, will be lighted by the electric light; the gardens will also be illuminated with variegated lamps and Japanese lanterns, and the fountains will be lighted by the electric light.

The following bands will perform, either in the buildings or in the gardens, according to the weather:—the Band of the Grenadier Guards; the Band of the Coldstream Guards; the Band of the First Regiment of the French Engineers, from Versailles; and the Band of the Seventh German (Magdebourg) Cuirassiers. A vocal and instrumental concert, consisting of glees, &c., by the Royal Criterion Hand-bell Ringers will be given.

Most of the exhibitors have undertaken to keep their stalls open, and those of them who have machinery in motion have agreed to keep it running. Refreshments, including tea, coffee, ices, fruit, &c., will be provided at the buffets in different parts of the building; and many of the exhibitors of articles of food have kindly consented to supply the same free of charge. No refreshments of any kind will be allowed to be sold.

The only entrance to the Exhibition will be that in the Exhibition-road.

There will be no arrangements for receiving hats, coats, cloaks, &c., as part of the entertainment will be in the gardens.

The Exhibition will be closed on this evening to the general public, and there will be no admission by payment, or by sesson tickets.

Each member will receive tickets for himself and a lady. They are now in course of issue.

Proceedings of the Society.

INDIAN SECTION.

Friday, May 30, 1884; Andrew Cassels, Vice-President of the Society, in the chair.

The paper read was—

STREET ARCHITECTURE OF INDIA.

By C. Purdon Clarke, C.I.E.,

Keeper of the Indian Collection, South Kensington Museum.

Introduction.

Whatever may have been the aspect of a Hindu town in that Golden Age when every action in life was regulated by the sacred Shastras, at the present time, with very few exceptions, the cities of India owe their plans to the same influences which have determined the growth of streets and the position of public offices in most of the towns of the world.

For the greater number, it is impossible to formulate a general plan owing to local peculiarities of site, but if classified under such heads as royal cities, holy cities, and commercial towns, a general description can be attempted. One of the exceptions to any such classification is the royal city of Jeypore, of which it is enough to say that, built in a very short space of time upon a level plain, it possesses the advantage — or what many would consider the disadvantage—of a regular plan, being a parallelogram divided longitudinally by a single wide street, and transversely by two, making the whole town six large blocks of buildings, of which one is entirely occupied by the palace.

Again, it is necessary to except the Presidency capitals, where, naturally, the foreign rule has asserted itself by the erection of large public buildings in a diversity of styles, and the interference with native custom by the introduction of building acts more or less vexatious, and, lastly, that crowning source of litigation and ugly building—"light and air" regulations.

Royal Cities.

The aspect of an Indian royal city, whether still a capital or fallen to the head-quarters of a collectorate, is not to be surpassed in picturesqueness by any other style in the world; the area restricted by embattled walls and bastions—a towering fortress, palace, often a town in itself, occupying a fair portion—being often the nucleus upon which the city grew. The gates mark the terminations of the principal streets which stretch out a rich succession of façades, the houses of officers of State, and the no less ostentatious shops of the well-to-do burghers and handicraftsmen. These streets are seldom regular in their line of frontage, even when bounded by the open drain which, running close under the shelf-like projection of the shop floors, is often buried where an arcaded canopy is added to the shelf, and the shop front encroaches on the road.

These shops, though separated by party-walls, and their line of frontage broken by irregular verandahs and awnings, yet mix and blend into a vista of rich profusion, where bright coloured stuffs succeed the splendour of the brass-worker's shop, again to be followed by the burnished metal and gaudy decoration of the cook or spice seller. The jewellers and money brokers may occupy a whole street, and their somewhat plain shops—white-walled, and white cotton-carpeted—assert a dignity which enhances even the apparent value of their wares.

The banking business is generally carried on in the upper part of the house, and in such cities as Delhi, Amritzar, Lashkar and many towns in the Bombay Presidency, the wealth of the owners has been lavished upon the façades, and, what is more than wealth, the individuality of owner and builder (for these people are, in a way, their own architects) has found expression, without that incongruity which, with us, generally results where an attempt is made to depart from the common-place lines dictated by ground landlords and speculating builders.

Off the main streets, and often approached by gate and archway, are the quarters of the various classes, casts and sects. These are small towns within themselves, and here the labyrinth seems to be the model upon which their streets, or rather alleys, were planned. The gates of their quarters in the Bombay cities show the necessity of such precautions in the Mahratta days, and their loop-holes, machicolations, ironbound doors, and surprise proof wickets, are significant of those good old stirring times. These gates are now fast disappearing in the towns under our rule, but the people still congregate in their several quarters, where the chiefs of each community vie with each other in the magnificent exteriors of their dwellings.

The royal city of Ahmedabad probably stands first among those Indian towns where civil architecture rivals that of the regal and ecclesiastical buildings, and has a still greater interest to us by still possessing the art in undiminished vigour.

The 16th century house front erected last year in the South Kensington Museum* (though to us a marvel of richness), is but a fair average example of an Ahmedabad merchant's dwelling. It belongs to a good period, and differs from the modern houses more in form than in excellence of design. There are still many of these balconied houses left, and all seem to owe the peculiarities of the upper stories to the absence of the deep open portico which, in the more recent buildings, stretches across the whole of the ground floor. Amongst these it is very difficult to distinguish between houses built ten years and those of fifty or sixty years since; and, perhaps, one of the best façades in Ahmedabad was erected during the great cotton times of the last American war. Under the Moguls, the officers of State generally held their courts in their town dwellings, and thus a number of minor palaces, thronged with suitors, uniformed attendants, and guards, marked important centres in the city, and changed the character of the scene; again to be changed when, passing on, the Hindu temple with busy worshippers, or the solemn court-yard of the Jumma mosque broke the line of shops and markets, and prepared the traveller for the greater glories of the palace.

The palace often contributes the least to the picturesqueness of the adjacent streets; generally occupying an exterior area, bounded by high walls unpierced by windows, the

* Now removed, and in course of re-erection in the India Museum, Exhibition-road, South Kensington.

effect is rather that of a prison or fortress, and it is only when one of the great gates is reached this impression is changed for another, when a row of shops is seen within, and a multitude of every-day people coming and going, apparently on their own business, again recalls the town gate. This last is not far from the actual fact, for the palace is a town with a full complement of purveyors and artificers, and a population which can only be reckoned by the thousand. By passing other gates, the more private precincts are reached, and having left the horses at the gate beyond which no one but royalty rides, and crossed another court on foot, at last the spot is reached where further progress can only be made in the company of a chamberlain.

Where the palaces are actually moated forts, like Agra, Delhi, and Lahore, they cannot be considered as influencing the architecture of the streets, especially when a difference of style is well marked. In the case of Jeypore, however, the palace and town (built together) seem to belong to each other, and one of my illustrations—"The Tower of the Winds"—is a remarkable and beautiful addition to a street which otherwise would have had all the attractiveness on one side.

Holy Cities.

The next type of town is the holy city, where rival temples dispute the offerings of pilgrims, and offer to the variously inclined security in the next world, or indulgences in the present. Benares, in the north, and Madura in the south, may be taken as good examples of this class. Here the enclosure walls and bastioned gates are wanting, and, though palaces have sprung up in various places, the towns preserve the peculiar character of their early days, when a newly canonised shrine, attracting a number of pilgrims, became surrounded with the huts where their wants were catered for.

It may be that the knowledge of the transitory state of mundane affairs has had a sobering effect upon the minds of the burghers and their builders, or that they are content to devote their spare wealth to the adornment of the temples, or to add to the jewellery and plate which are preserved in the holy treasuries for the service of their gods. Whatever may be the reason, the fact remains that the streets of the holy cities depend for their effect on the contents of the shops rather than on the shops themselves; and in the south, where the temple enclosures house not only the functionaries and their families, but the shops and families of those who sell food, spices, and the necessary articles for worship, it is only natural that the splendour of the town-bazaar suffers from this competition.

The number of people living in these places is enormous, and almost rivals the communities within the precincts of the royal palaces. As an example, the number of individuals said to live within the temple of Seringam, near Trichinopoly, is 3,000. Whilst noting the plainness of the streets in such a city as Benares, no injustice should be done to the wonderful pictures produced by the temples, which are of all sizes, from votive models, scarcely a yard high, to cathedral-like masses, many, fortunately, unenclosed, except where shops and other buildings have grown against them.

It is here that Hindu architecture is seen at its best, and perhaps owing to the sharp contrast between the exquisite finish of the elaborately unpractical but solid-looking angle of a temple porch or base jutting out from between low lintelled shops—some bright with whitewash, others smoke begrimed, all plain and business-like—such dignity is accorded to the portion which would be lost were the whole building seen clear of the surroundings.

The peculiar feature of these cities is the bathing ghaut on the river side, or the tank, which might sometimes be more properly termed a lake. These, the crowning works of the Hindu architect, though closely connected with almost every thought and action in their daily life, distinctly belong to the spiritual part of their existence; and, perhaps, it is for this reason, and because here the last rites are administered to their dead, that such splendid sites are almost unused for the erection of palaces or residences of the wealthy, except when intended for purposes connected with their religion.

Rich with closely packed temples, and the stepped ways thronged with innumerable people going and coming from the water, there is, however, a want of human interest in the scene; and the same feeling is experienced when a busy mart or dock is encountered in our own country, where the bustle and confusion of the people, each intent on his own business, the hard and unsympathetic look of the surroundings, and absolute want of the appearance of domesticity on all sides, makes the whole mechanical, and we wonder whether these moving units have homes like other human beings, or are puppets in a great show, moving only in obedience to some hidden force.

Commercial Cities.

The last class of city I have to describe is the least interesting as a general rule. Scattered about all over the country are towns which, owing to the ebb and flow of commerce, become for the time being commercial centres, or the depôts of produce of various sorts. Such cities spring into existence rapidly, and as soon fade out; whilst others have been leading marts since the beginning of history. Our railways have done much to confirm the stability of many of these, whilst others, left at a distance from the iron road, are ruined beyond hope.

Of new cities, I do not know of a better example than Beawar in Rajputana. It is difficult, on approaching the picturesque gateway and lofty crenulated walls, to realise that this town was built in a desert, and filled with one of the busiest populations in Rajputana in a few years; and it is still more surprising to find that the reverenced name of the founder is not that of a native warrior or saint, but of an English gentleman*; and the principal shrine where Hindu and Moslem leave votive lamps, the tomb of that officer's wife. Some of the commercial and royal cities still occupy the same sites after an existence of 2,000 years, whilst others have been constantly on the move, either in obedience to some physical change—such as river encroachment—or to such causes as the pride, intrigues, and family quarrels of those dynasties of rulers who founded the successive cities which culminated in the present Delhi, after leaving detached groups of ruins over an area of over 100 square miles. Others have disappeared, like Gaur in Bengal, which, during 300 years, retreated before the shifting bed of the river, and having moved back twenty-one miles, only forsook the contest when the commerce which the river brought found another channel and mart.

Of the class of towns represented by the important city of Nagpore in the Central Provinces, are several which show how much can be done in India when native talent and love of display are well directed. A few years since they were remarkable only for the plainness and dull monotony of their shops and dwellings, even though the possessors of some extensive sacred buildings. Then suddenly the native communities (encouraged by the chief English officials) began to build as only princes did in the ages passed by. Four of these towns owe much of their present splendour to the energy of a gentleman* who was successively the chief administrative officer in each. Beginning with the Ghaut at Mizapore, then the museum and many buildings, both public and private, at Muttra; and since, the the market places at Bulandshahr and Khonja, with numerous private houses which have sprung up through the emulation of the leaders in various sects and castes: all these improvements have been happily carried out in native style, and designed by good native workmen, the only European influence exercised being Mr. Growse's criticism on any proposed departure from the canons of good taste, which, from his knowledge of the modern Mogul style, he is able to give with authority. I wish particularly to instance these towns, as the work accomplished there within the last few years fully illustrates the latent power for true art work which exists in even the most unpromising of Indian towns, and which is so often wrongly developed or crushed out when Government or over-zealous but ignorant officials attempt to do something to revive the native arts of India.

I show a model of one of the most modest of the new Bulandshahr buildings, representing a row of shops built on one side of the market place, which replaced a row of single-storied buildings of the meanest description. I have here, also, a lithograph fac-simile copy of the working drawings which, made by Mircha Mistri, were submitted to the collector for approval before a start was made. Built with trust money of the Court of Wards, the building may be considered as erected under the same conditions as public buildings are generally; but, having personally examined the quality of the work, I can but express wonder at the organisation or control which restricted the finished cost to 8,700 rupees, or about £725 sterling. Another copy of a drawing by Yusuf Mistri, represents a façade, designed specially for erection in the Indian Section of the South Kensington Museum. The order given to the Mistri was that he should make a drawing of a house front to occupy a frontage of 25 ft. by a height of 35 ft., the cost of the building not to exceed 3,000 rupees, or £260. After some days the sketch was ready, but accompanied by a note stating that to keep within the sum, the width and height must be slightly reduced. This was

* Colonel Dixon.

accepted, and the conditions have been faithfully adhered to. Respecting this Moghul art, it is strange how it has displaced the national column and lintel wooden style in parts of the country where the Hindus have held their own. The Meywar people, though ubiquitous, have their own city in the great Rajput desert, and it is from choice only that they did not follow the lines of Hindu construction and design, which even the Moslem conquerors of Ahmadabad adopted.

The power and adaptability of national Hindu architecture is shown in the old palace of Man Sing, in Gwalior fortress, but even there it is barbaric, and fails entirely in grace and refinement.

But in adopting the style of their Moslem rulers, they have in a way made it their own, and seldom in architecture can such a blending of different forms be found as in the Seth's house in Ajmere, of which I have a few illustrations. It is not that stone replacing wood in Central India has led the merchant classes to adopt the construction and ornament of the Agra and Delhi palaces, for the same people, when in the Punjab, in places where stone is rare and wood plentiful, copy in the lighter material the lithic forms of cusped arch and hollow cornice, but with such due regard to the quality of the material used, and with such admirable taste and knowledge in proportioning the members, that wood seems to dispute the parentage of this art with stone.

As most of my illustrations are taken from this class of design, I may be permitted to direct your attention to the vast area of the world's surface which has been embellished with buildings in the Saracenic style, of which the Mogul is a branch, differing from others only in the details of ornamentation and such changes of plan as are necessitated by the different conditions of living in India. Whether developed in Byzantium, or invented later in Persia (for it is no descendant of the architecture of the Arsaces or Chosroes), Saracenic art possessed a strong individual character, and, even when in Eastern Bengal the general form of the buildings became that of the haystack-topped native houses, with eaves bending under the weight of covering, the similarity of expression was sufficiently retained to allow of comparison with the work of the Moors in the far west. This likeness is the more marked in the Deccan, where the lighter features of the Mogul work in the north disappears, and the stone work approaching the lines of Persian ecclesiastical art, leaves a stucco covered class of buildings like the great archways at Hyderabad, with very little surface ornament but the strongly marked forms so characteristic of Morocco and the cities on the north-west African coast.

My illustrations begin with a street scene in Jeypore (Plate I.), where the remarkable building, which occupies nearly the whole extent of the picture, bears the name of "The Tower of the Winds." It is placed at one angle of the great palace, and almost entirely constructed of stone, has open lattice work in its multitude of projecting windows, affording, in the interior, the combined open air and shade so necessary in such a climate. The shops on either side are built against the palace wall, and where they and other buildings occur, the monotony is relieved. Similar shops extend along the whole front of the palace, which, except at the large gates, would otherwise present a frontage of bare walls, of great height.

The second view (Plate II.) is of another street corner in the same city, and illustrates a peculiarity of Jeypore which is not always detected by admiring visitors. Owing to the short space of time allowed by Jai Sing for the building of the city, it was only possible to run up the façades of many houses in the principal streets. This, in some cases, led to a style of building beyond the means or requirements of the owners, soon resulting in a stoppage of the internal works, or their completion on a somewhat reduced scale, often without reference to the lines of the front.

The next (Plate III.) will be recognised by all who know the Bombay Presidency. It is a house in one of the inner streets where the commercial classes dwell. Although from Ahmedabad, it may be taken as a representation of the older style of house in other towns on the northern Malabar coast.

Plate IV. shows a row of such dwellings, but much more modern, some of them being only ten years built; whilst the fifth illustration will appeal to all lovers of the picturesque, and stand as a protest against fussy and interfering laws which, by docking the projecting upper stories and roof, and widening the roads, would destroy the grateful shade which, even to natives, alone makes life bearable in hot countries. The house blocking the end of the street possibly commits every crime forbidden by the Building Act, but at the same time it protects the street from the glare, and to some extent the noise of the market place beyond;

and although it is bound to go down, sooner or later, before the fiat of some collector (upon town improvement bent), we may wish it to stand long enough to convince the unthinking that, whilst wide streets are essential as the main thoroughfares of commerce, the same rule can be relaxed when private dwellings and retail bazaars are being planned in a tropical climate.

Another offender against our rules and regulations is the next view (Plate VI.)—a shop within the Lahore gates; and this illustrates one of the advantages enjoyed under the old unwritten laws of the country. The owner of a small corner plot, just 8 ft. wide by 13 ft. deep, runs up as tall a house as such a base will carry, without any regard to the surrounding buildings, and having the road on two sides, his floors are balconied out so that his open terrace at the top attains a respectable area. No one on the opposite sides of the two streets is ever likely to complain, as this block affords shelter from the sun during some part of the day; and his immediate neighbour, should he wish to go as high, or project as far, or to block up any windows overlooking his ground, would have full liberty to do so at any time, no length of enjoyment being accepted as a plea for the right of view across another man's land by which he would be prevented from building thereon when he desired to.

Plate VII. shows the window of a mezzanine floor over a shop in Lahore, and shows the richness attained in ordinary carpenter's work in that city. This is also illustrated in the next view, (Plate VIII.) where the upper window of wood recalls the Mushrabeyeh windows of Cairo. The triple casements beneath are in wood, but the piers, with their pilasters and foliated arches, are in cut brickwork, coated with stucco. These are flanked by two small niches for lamps on illumination days; and two oriel windows for use in the cool of the evening.

The general view (Plate IX.) of one of the principal streets in Lahore will afford a good idea of the result of leaving people, unfettered by rules and regulations, to build as they like, but subject of course to those laws which good neighbourship and fellow feeling dictate; and although no two keep exactly to the same frontage or horizontal parallels of floor, window, or cornice, it must be admitted that this wholly irregular street can compare favourably with many of our own in this great city, where these niceties have been attended to.

The next two represent a brick street in Delhi. The first (Plate X.), the entrance from a court, and the next (Plate XI.) a *cul-de-sac* leading from it; both are rich in the projecting balconies, which Government is striving to curtail, and, with us, the bridge which here joins the houses of two brothers would represent a correspondence with the Board of Works horrible to contemplate.

Plate XI. can scarcely be classed under street architecture. It was a very old courtyard behind some very modern shops, and used as a store for Manchester goods. The original façade had been demolished or built up, so I secured this note of all that remains of what was once a very important building.

Leaving these old-established cities for one of the mushroom class, the three following views of Lashkar or New Gwalior show the Moghul style adopted by an essentially Hindu people, even though their ruler set an example by going off in another direction, and employing an Italian to design and build the palace. It is not necessary for me to say how that palace compares with the ordinary shops and dwellings of Lashkar, for few would congratulate the Maharajah upon the wisdom of his choice of style.

The last (Plate XVI.), and perhaps the best, represents a portion of the Seths or bankers' house at Ajmere, and there is little in the royal palaces of India to compare with this mansion for graceful richness and delicate treatment. In this no assistance was rendered by the material, which is a stone so coarse that whitewash has been liberally used to make a surface.

Conclusion.

In conclusion, I beg to add a few remarks upon our influence on the future of Indian street architecture, and having instanced several towns where the imperial style of Delhi has been used (without any attempt to blend it with our own) by the executive, I consider it unfair to leave without notice of the remarkable series of buildings designed and erected by the architect* to the Madras Presidency. These are happily not confined to that portion of India, and the opportunity afforded to Mr. Chisholm by the commission for the Baroda buildings has been well utilised. With great courage, the leading characteristics of Hindu and Moslem architecture have been worked into the construction of these buildings, and if ever an eclectic style based on sound principles becomes

* R. F. Chisholm, F.R.I.B.A.

adopted by Hindu and Moslem as the one national style, it will be to such work as Mr. Chisholm's that the first steps will be attributed.

[A series of illustrations to this paper, taken from the original photographs, is given in a separate sheet as a supplement to this number of the *Journal*.]

DISCUSSION.

Mr. MARTIN WOOD, after alluding to the melancholy news announced in the morning papers of the death of one who was familiar with the subject they were discussing (Sir Bartle Frere), said, with regard to what Mr. Purdon Clarke had remarked respecting Mr. Chisholm, that he (Mr. Wood) remembered when Lord Napier of Ettrick delivered an elaborate lecture on the architecture of India, he vindicated—it might be said finally established—Mr. Chisholm's position as an architect. With regard to building regulations, and their interference with the picturesque and convenient styles of building in India, he might mention that, in 1866 or 1867, when the draft of a Building Act was put before the new Corporation of Bombay, it was found to be an exact counterpart of the Building Act of the City of London, and anything more absurd than that could not be imagined. There was no doubt that domestic buildings in India would have to be erected more in accordance with the requirements of modern times; but many difficult problems had been carried out in that country, and they need not despair of ultimately arriving at a successful issue with regard to this one. He would like to add that he felt sure everyone present was grateful to Mr. Clarke for the treat which the splendid views displayed had afforded them.

Mr. FITZGERALD inquired if Mr. Clarke could tell them at what period the Saracenic style of architecture was introduced into India, and whether or not it was introduced through Persia.

Mr. CLARKE said that the best authorities differed on the point. Saracenic art could be traced as far back as the 12th century, in the Pathan buildings of Northern India. It was introduced through Persia, but did not originate there.

In reply to a further question by Mr. FITZGERALD as to whether it was possible to trace the differences between Indian and Saracenic architecture, and whether there were courtyards to the private houses in India as at Damascus,

Mr. PURDON CLARKE said that 2,000 years ago the courtyard was a common feature in many countries, and from the Roman remains which had been found in England, there was no doubt that they were very general even in this country. He did not know whether the courtyard was a more general feature at Damascus than in Spain. He remembered comparing the two places, and he noticed that whereas at Damascus small houses were built which could not afford the luxury of a courtyard, the houses in Spain must be very small indeed to be without a patio.

Mr. FITZGERALD said that in Hindoo China there were enormous buildings, and inquired if they were of the Saracenic type.

Mr. PURDON CLARKE said that he did not know the Burmese side at all, and could give no information on the subject; they had models of temples and public buildings in the India Museum, but not of private houses.

General ST. CLAIR WILKINS, R.E., said that one of the finest buildings, as everyone knew, was the Taj Mahal, at Agra; and he should like to know if Mr. Clarke could tell who was the architect of that building. The objection which had been put forward against the adoption of the indigenous architecture of India, was the enormous cost of construction, supposing buildings were made of stone. Most of the modern buildings in the style were, he believed, of stucco, which was not a material approved of by architects.

Mr. CLARKE replied that the Taj Mahal was partly due to the king, who was assisted, no doubt, by both Italians and Frenchmen, but he thought it was a mistake to give too much of the credit to Europeans. The question as to who was the architect was almost answered when they looked at other buildings of the same class. There were an immense number of them. The central dome, flanked by four towers, was common all over Asia. There was very little originality in the Taj Mahal, and though no doubt it was the finest building of its class, the form was invented several hundred years before its erection; just in the same way as Sir Cristopher Wren was credited with the design of St. Paul's Cathedral, whereas St. Peter's, at Rome, was built by Michael Angelo long before it. He thought that it would be best to foster the style of architecture peculiar to the country. In the north of India there were very few stucco buildings, it was more in the south that that material was used; but what was often mistaken for stucco was the thick coating of whitewash which was placed on stone buildings. From Agra and Delhi, and up some distance, the houses were nearly all built of stone, and the slender columns and slight lattices, which seemed to be made of wood from their lightness, were really made of the same stone, obtained from the quarries near Agra.

General ST. CLAIR WILKINS said that in the public buildings erected in India it would be almost impossible to adopt the Hindoo Saracenic style of architecture, owing to the immense cost of carving the ornamental work of that style in stone, that was supposing the buildings were to be built of stone. In a great part of India there was no stone at all, and in some districts, very little stone indeed which was at all workable, and many of the buildings now erected were of necessity built of basaltic stone, which was inconceivably hard, and which would not be looked at in England. There was in India an ancient city which he ventured to assert would be better known in the future than it had been in the past, and that was the city of Bejapoor. It was to some extent known, owing to the magnificent work which had been produced by Mr. Ferguson and Colonel Taylor, but that work was very difficult to obtain. He had endeavoured to procure it, and found that £30 was the price for which he might become the owner of a copy. It was a work limited in its publication to so few copies that scarcely any one possessed it. This city was founded in the 15th century, and although till lately in a deserted state, steps were being taken to resuscitate it, the British Government having resolved that it was now to be the centre and the capital of the country, as it was in ancient days; and they might hope that some of its most beautiful ruins would be preserved from the decay into which they had fallen. He had charge of this city for some time, and endeavoured to stop the decay which was overtaking the magnificent buildings there, but he found it was almost a hopeless task. The buildings were being destroyed by trees growing out of the tops of the domes, and indeed, out of almost every crevice, tearing the buildings to pieces. There was a dome in that city which covered, he believed, more ground than any other similar building in the world. It was built as a tomb, and the dome was the most wonderful thing he had ever seen. It was constructed of very large bricks, and was ten feet in thickness, and rather flat, but it had not a single buttress, being entirely supported by its pendentives hanging inside, constructed in the most scientific manner. A great deal was being said just now about local self-government in India, but he imagined it was not altogether an unalloyed blessing to the people. There was a certain rajah who, in the time of the mutinies, was unfortunate enough to make a mistake and cut the head off the political resident, and was hanged. He had no heirs, and his palace became a public building, which he (General Wilkins) used occasionally to visit, in order to admire the beautiful pictures with which the walls were decorated. Local self-government was introduced into the country, and on the next occasion of his visit to the palace he looked in vain for the pictures—they were nowhere to be found; and on making inquiry, he found that the local municipal engineer thought the house required a cleaning, and he had had the whole of them whitewashed over. The speaker thought that it would be a great misfortune if the English Building Acts were introduced into cities like Bombay. They had all seen and admired the views which had been placed before them, showing the projecting balconies and the windows which, though very small, were very beautiful, and he certainly thought it would be a thousand pities if the native talent were interfered with by any attempt to draw hard and fast lines as laid down in the Building Acts. Of course, in London, they were obliged to obey the Building Act, but he thought that with regard to India, the case was altogether different.

Mr. R. PHENE SPIERS said that he possessed no practical knowledge on the subject of street architecture in India, what he did know being derived principally from photographs. As to the question of the time of the introduction of the Saracenic style of architecture into India, he thought it would be better if all those styles which had been practised by the races who embraced the Mohammedan religion were called the Mohammedan styles, because it would be much better for the purpose of explaining the peculiar features. The peculiarity of the Mohammedan style was that it changed to a certain extent, so far as the form of building went, according to the place where the buildings were erected. For instance, Mohammedan style in Constantinople was different in its main forms to that at Cairo, and that at Cairo was different to that found in Spain, the fact being that in each country which was converted by the Mohammedans the buildings in them were adopted by them, and they made certain modifications and introduced such details as their own style required. They were all no doubt aware that one of the first rules and regulations of the Mohammedan style was that no human form, or even vegetable form, should be employed in ornamentation; and they would see at once what an immense range of ornamental detail that must have knocked off from the architectural styles, and how those who had to design the buildings found themselves curtailed in their powers of producing beautiful forms such as had existed previously in those countries which were taken possession of by the Mohammedans. It was, therefore, necessary to find other forms which would give that richness in ornamentation which the Oriental mind especially always desired, and the only way of getting out of this difficulty would seem to have been either to adopt for the surface of the buildings, or for windows, a series of geometrical patterns and beautiful designs; or, for features which required more development, or more relief, they played with what were called constructural features. The earliest type of the stalactite style was found to consist of very few features. It was necessary to place a circular dome over a square form, and then to have four angles to cover over; the Byzantine form was to cover it over with the pendant, a portion of the sphere being intersected by four vertical planes touching one another, and also a horizontal one. In buildings of large dimensions the Mohammedans found that it was very difficult to use the spherical form, and so they sub-divided it. The Saracenic style seemed to have been originated with Persia; at least that country seemed to have been the great centre from which all Oriental art spread in every direction. Of course, it was just possible that someone who knew India better might point out features in the buildings of that country which were of earlier date than those of Persia. With regard to the very important question as to the Buildings Act, he would observe that as to London, one of its objects was to prevent the spreading of fire, and he thought that was one of the first problems which would have to be solved with regard to India. The projecting balconies were, no doubt, beautiful, and if they were built of stone there would perhaps be little danger, but if they were of wood, it was evident that they must be most dangerous in case of fire. They knew perfectly well that whenever a fire occurred, for instance in Constantinople, it burnt down an enormous number of houses, and there was no possibility of stopping it, owing to the amount of wood which was used in the erection of houses. If London of to-day were built in the same way as the old street, which they could see at the International Health Exhibition, he was afraid that one of the fires which occurred now and then would consume it as it did in 1666; and he thought, therefore, that it was necessary that some rules and regulations should be laid down for the construction of buildings, as well in India as in this country. There was no doubt that in India, with the immense heat, there was a necessity for covering over the streets to a certain extent, but he thought some other means ought to be found for doing this by the architects in India There were various buildings in Kensington, designed by Mr. Norman Shaw and others, which with their projections and bow windows, seemed entirely forbidden by the Building Act, but it would be found on inquiry that these projections were made of cement and fire-proof material, and consequently were within the Act. If, therefore, the balconies of the houses in India could be made of stone, or brick and stucco, he thought it would be infinitely better that they should be allowed to exist, and no doubt the Building Act might be so framed as to allow of this. He thought that General Wilkins had made a great mistake in saying that stucco was a material which was not accepted by architects. As far as he (Mr. Spiers) could see, all those buildings (such magnificent illustrations of which had been given) could be constructed in brick, and covered in stucco, and no one would have a word to say against them. The Mohammedan style was a style which suited stucco, and no one could raise any objection to its use, because it was only objectionable when it was used to imitate a material which it really was not.

Mr. CLARKE, in reply, said that with regard to the cost of these buildings in India, though apparently an extravagant style, he was surprised to find, on working it out, that the sum expended in erecting one of these houses was much less than the cost of the plain buildings which were being put up. As to the Mohammedan style, although they wisely adapted themselves to the requirements of the different countries, it would be found that they everywhere introduced two forms in their sacred buildings. They always used a dome of some sort, flat in some countries and high-pointed in others, and secondly, the minarets, in some cases placed close to the dome, and in others, following the style of the courtyard at Mecca, at the angles. The Mohammedan mosques were all, more or less, copies of mosques at Mecca or Medina. As to stalactite vaulting it was an art of the past in India, but it was of every day use in Persia. As a rule, very ordinary Persian houses possessed this feature. One did not walk directly into the house, but passed through a vestibule, and turned a corner. This vestibule started in a square form, and then intersecting arches cut the angles off, and these angles were filled with stalactite. In that case they were ornamentation, rarely they were part of the actual construction. With regard to fires in wooden cities, the people in India had got on without our rules and regulations for centuries, and fires were almost unknown, but in London they were of almost daily occurrence, even with the Building Act in operation. He had seen all the great cities built by the Mohammedans in Egypt, India, Syria, and Spain, and he had never seen a burnt house, although he did not mean to say they had no fires. In Persia he was foolish enough to propose to bring out a fire-engine, and was laughed at during the remainder of his stay there. He thought the people, knowing the danger, were very careful, and the fact of their being without matches would, perhaps, in some way account for their immunity from fires; but, perhaps, now that the Germans were importing large quantities of matches, fires would be of more frequent occurrence. In answer to a remark by Mr. Fitzgerald as to the cost of ornamentation, the lecturer said that in England, where generally one man built a house and another was forced to live in it, a little money was certainly saved in making a plain building; but in that case a good deal more was spent in gilt mouldings, wall-papers, and so on, to make it passable. In England the architect made expensive drawings which were not always understood by workmen, but in India, when a man was going to build a house, he sent for a clever builder, and the builder, after ascertaining the size of the house required, set about building it, and the ornamentation was done naturally and as a matter of course. That was the reason why it was not costly. But the moment a native builder was dictated to on the subject of ornamentation, he began to spend a great deal of money, and especially if requested to copy on the front of a house some inappropriate ornament from a neighbouring temple.

The CHAIRMAN proposed a vote of thanks to Mr. Purdon Clarke for his able paper, which was carried unanimously.

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION.

The following Conferences have been held and lectures given at the Exhibition since those mentioned in the *Journal* for June 20th :—

On Tuesday, June 24th, a lecture on "The History of English Dress" was delivered by the Hon. Lewis S. Wingfield, George Augustus Sala in the chair; and a lecture on "Healthy Houses" was given by T. Pridgin Teale, F.R.C.S., Captain Douglas Galton, F.R.C.S., in the chair.

On Wednesday, June 25th, a second lecture on "Parasites of Meat and Food" was delivered by Dr. F. Spencer Cobbald, F.R.S., the Right Hon. Sir Lyon Playfair, K.C.B., M.P., F.R.S., in the chair.

On Thursday, June 26th, a lecture was delivered by Surgeon-Major Evatt, M.D., A.M.D., on "Ambulance Organisation in Peace and War," Sir William MacCormac, F.R.C.S., in the chair.

On Friday, June 27th, a conference on Sanitary Legislation was held by the Social Science Association; Sir Richard Temple, G.C.S.I., in the chair; also a lecture on "Anglo-Saxon Dress, Food, and Houses" was given by J. Frederick Hodgetts.

On Monday, June 30th, a lecture on "Domestic Poisons" was delivered by Henry Carr.

A conference of "The Association for the Oral Instruction of the Deaf and Dumb" was held the same day.

On Tuesday, July 1st, a lecture on "The Digestive Ferments and Chemical Processes of Digestion" was delivered by Prof. Arthur Gamgee, M.D., F.R.S., Professor Huxley, P.R.S , in the chair.

On Thursday, July 3rd, a lecture on "The Chemistry of Bread Making" was delivered by Prof. Charles Graham, D.Sc., Prof. Odling, M.B., F.R.S., in the chair; and a lecture on "Reform in Poor Relief" was given by Dr. Gibert, of Havre, Samuel Morley, M.P., in the chair.

CITY AND GUILDS OF LONDON INSTITUTE.

The new Central Buildings of the City and Guilds of London Institute for the Advancement of Technical Education, in Exhibition-road, were formally opened on Wednesday afternoon, 25th ult., by H.R.H. the Prince of Wales, President of the Institute. His Royal Highness, who was attended by Colonel Teesdale, V.C., was received by the Lord Chancellor, Sir Frederick Bramwell, and Sir Sydney Waterlow, M.P., Vice-Presidents of the Institute; Mr. John Watney and Mr. Owen Roberts, Hon. Secretaries, and Mr. Philip Magnus, Director and Secretary; Lord Carlingford, President, and the Right Hon. A. J. Mundella, M.P., Vice-President of the Committee of Council on Education; and, as representing the Council of the International Health Exhibition, by Sir James Paget, F.R.S., Vice-Chairman of the Executive Council, the Marquis of Hamilton, Lord Reay, Sir Philip Cunliffe-Owen, Mr. Birkbeck, M.P., and others.

The LORD CHANCELLOR said:—May it please your Royal Highness, I have to thank your Royal Highness, on behalf of the Council and of the Governors of the City and Guilds of London Institute, for having graciously consented to open this Central Institution, thereby showing your continued interest in the success of the great educational work which the Corporation and the principal Guilds of London have combined to promote. It is now very nearly three years since your Royal Highness, in July, 1881, accompanied on that occasion by her Royal Highness the Princess of Wales, set the first column on which this building rests, and we are glad to be able to state that, under the able superintendence of Mr. Alfred Waterhouse, the architect, the work has been satisfactorily executed within the time originally intended. It is estimated that the building, when fully equipped, will have cost nearly £100,000, and the Council confidently trust that the balance still needed for its completion will be supplied by the liberality of the City Guilds, on which they have hitherto so hopefully and so exclusively relied. Pending the completion of the fittings, your Royal Highness, as President of the International Health Exhibition, will be gratified to learn that the Council of this Institute have been able to lend a portion of this building, for the exhibition therein of educational and school appliances, to the Executive Council of the Health Exhibition, who, in compliance with our request, have courteously postponed the opening of that interesting section of their Exhibition until to-day. During the last three years, the progress of the work initiated by the City Guilds has been most gratifying. The Finsbury Technical College, the foundation of which was laid in May, 1881, by the late Duke of Albany, whose loss we, in common with all classes of her Majesty's subjects, deplore as a national calamity, was opened in February, 1883. It is now in full working order, affording a sound and complete technical education to youths from middle-class schools who are preparing to enter industrial careers at a comparatively early age, as well as to large numbers of artisans engaged in various trades. At South London, our Applied Art School is filled with students who are being trained as wood engravers, and as designers for different branches of industry. The affiliated classes in the provinces, in connection with our technological examinations, have increased in number far more rapidly than could have been anticipated, and have developed, in many cases, into excellent technical schools. In 1881, when I had the pleasure of addressing your Royal Highness on the ground on which we are now standing, I stated that the number of candidates for the technological examinations was 1,563, as compared with 816 in the previous year, and I am now able to state that the number recently examined was 3,628, as compared with 2,322 in 1883. A great impulse was undoubtedly afforded to the establishment of technical schools in this country by the appointment, in 1881, of a Royal Commission, presided over by Mr. Bernhard Samuelson, M.P., to inquire into the facilities for technical instruction enjoyed by the industrial classes abroad, and to compare them with the opportunities enjoyed by similar classes at home. After a laborious investigation, occupying nearly three years, in the course of which they visited all the principal technical schools in Central Europe and in the United Kingdom, the Commissioners presented to her Majesty a report, in which they were able to show that, owing greatly to the action of the Science and Art Department and of the City and Guilds of London Institute, the opportunities afforded to workmen and to foremen in this country to obtain, by means of evening classes, sound technical instruction, compared favourably with those enjoyed by the same classes abroad; and it is gratifying to learn from them that no organisation like that of the Science and Art Department, or of the City and Guilds of London Institute, exists in any Continental country, and that the absence of any such organisations has been lamented by many competent persons with whom they came in contact. It is, however, in the appreciation of, and in the facilities for, higher technical instruction that we in this country are most deficient, and it is to supply the want that this central institution has been established. This college has been established to meet a two-fold want. It is intended to give that higher instruction of which the leaders of our industries stand so much in need; and also, and principally, to train teachers for the several technical schools and classes which, owing greatly to the encouragement afforded by this institute, now constitute an important feature in our educational system.

The Prince of Wales, in reply, said:—My Lord Chancellor, my Lords, and Gentlemen,—I have listened with attention to your address, and I assure you it gives me great pleasure to be able to preside at the opening of this important institution, the first pillar of which, in company with her Royal Highness the Princess of Wales, I set nearly three years ago. I thank you for your very feeling reference to the severe loss which the Queen, and each member of her Majesty's family, has sustained by the untimely death of my late brother. His interest in every movement calculated to humanise and to elevate the people of this country will, I am quite sure, cause his loss to be felt far beyond the circle of his immediate friends. I have been gratified that the City and the Livery Companies of London have so generously responded to the letter which, as President of the Institute, I addressed some few months since to the Lord Mayor and to the Worshipful Masters of the Livery Companies of London. This institute, which owes its origin to the liberality of the City and of the Guilds of London, is an illustration of the excellent work that may be done by united action, which could not possibly be accomplished by individual efforts. Conformably with the traditions of these ancient guilds, there is, perhaps, no purpose to which they could more appropriately devote their surplus funds, and none which would be of more practical advantage to the country at large than the promotion of technical education. As president of the International Health Exhibition, I am glad that the Council of this Institute have been able to place at the disposal of the Council of the Health Exhibition a portion of this building for the exhibition of apparatus and appliances used in technical and other schools. It now only remains for me to declare the Central Institution of the City Guilds of London Institute to be open, aud to express the warmest hope that the important educational work to be carried on in this great national school of technical science and art will help to promote the development of our leading industries, and that the City and Guilds of London, which have so liberally subscribed funds for the erection and equipment of this institution, will maintain it with efficiency, and will at the same time continue their support to all other parts of the institute's operations.

The Company was then addressed by Lord Carlingford, Mr. Mundella, M.P., and the Lord Mayor, after which the gentlemen connected with the institute, and the architect (Mr. Waterhouse) were presented to His Royal Highness.

AGRICULTURE IN PARAGUAY.

Consul Baker, of Buenos Ayres, states that one of the most valuable crops of Paraguay is tobacco; in 1829, its production amounted to only 2,675,000 lbs., while in 1860, the crop amounted to 15,000,000 lbs.; but the war with the allies almost ruined this source of wealth. It has, however, somewhat recovered its importance, the exports alone last year amounting to 8,975,000 lbs. A large proportion of the crop is annually worked up into cigars, a branch of industry which is almost entirely in the hands of the women. The tobacco planted in Paraguay originally came from Havana, with the exception of a particular kind which is called in Paraguay, blue tobacco, *peti-hoby*, the origin of which is unknown. The favourite leaf is a yellow tobacco, *peti-para*, grown chiefly in Villa Rica, which possesses about 6 per cent. of nicotine. Sugar-cane is another of the important agricultural products of the country—a plantation of which sometimes lasts, without any care or necessity of replanting, for ten or twelve years. It is estimated that one acre of the cane will produce about 250 gallons of molasses. Rice also is extensively cultivated, and also Indian corn. Coffee is largely grown, and is regarded by some as the crop of the future. The crop which is most esteemed by the Paraguayans is the mandioca, it being with them an article of prime necessity, taking the place of wheat-flour in the family household; the tuber is also used as a vegetable. The quantity of land now under cultivation is very small compared with the amount before the war with the allies, the great scarcity of labourers in the country very seriously retarding the development of the agricultural interests. At the present time there are 450,650 acres of land under cultivation, of which 210,000 are under corn, and 126,000 under mandioca. In Paraguay the cotton plant grows spontaneously, growing very rapidly, and lasting for ten or twelve years. The orange groves are scattered indiscriminately all over the country, the plantations attaining an immense growth, and the forests are everywhere full of the orange trees from the casual dropping of the seed. The fruit has come to be not only an almost indispensable article of food, but its annual exports exceeds 10,000,000 of oranges, chiefly destined for Buenos Ayres and Montevideo. The most important production of the country is stated to be Paraguayan tea, or *yerba maté*, which in former years, by its preparation for market and exportation, yielded the greater portion of the national revenue. The exportation of this article has increased from 4,000,000 lbs. in 1861 to 11,375,000 lbs. in 1882.

General Notes.

Industrial Statistics of France.—According to a return issued by the French Minister of Commerce, the working population of France is distributed among the various branches of industry as follows:—

	Hands.
Collieries (342)	106,415
Peat works (1,035)	27,977
Iron mines (353)	8,468
Other metalliferous mines (60)	4,422
Iron works (359)	57,000
China and earthenware factories (412)	18,708
Glass houses (162)	23,421
Paper-mills and cardboard factories (536)	32,655
Gas works (619)	10,575
Candle manufactories (157)	8,603
Soap works (339)	3,509
Sugar works (512)	63,526
Textile factories (5,024)	353,383

Production of Zinc.—The following quantities (in tons) of zinc were produced between 1880 and 1883, inclusive:—

	1880.	1881.	1882.	1883.
The Rhine district and Belgium	98,830	110,989	119,193	123,891
Silesia	64,459	66,497	68,811	70,405
Great Britain	22,000	24,419	25 581	27,661
France and Spain	15,000	18,358	18,075	14 671
Poland	4,000	4,000	4,100	3,783
Austria	2,520	2 520	3,199	2,879
United States	23,239	30,000	33,765	32,790
Totals	230,048	256,783	272,724	276,080

Utilisation of Maize Husks.—The husks of maize, or Indian corn, after the grain has been extracted, serve only for manure, or, in some cases, as fuel for portable engines for agricultural purposes. But they contain starch, albumen, and other substances capable of being turned to account, and even afford an alcohol which is at least equal to potato spirit, leaving a pulp suitable for the food of various animals. Herr Holl, of Worms, has invented a process for utilising these husks, by which he exposes the husks for an hour or an hour and a-half to the action of steam, at a pressure of 35 to 45 lb. per square inch, in order to reduce them to powder, and thus open the starch cells, when distillation is proceeded with in the ordinary manner.

Royal Colonial Institute.—1. The Council of this Institute offer prizes of £20, £15, £10, and £5, respectively for the four best essays or papers on "The Dominion of Canada: its History and Present Position, Geographical, Political, and Commercial." This may include the colony of Newfoundland. 2. The prize of £20 is open to persons being members of any University in the United Kingdom, and who shall not, at the time fixed for sending in the essays, have been members for more than three years. 3. The prizes of £15, £10, and £5 are open to pupils of any school in the United Kingdom, who do not exceed the age of eighteen years at the time fixed for sending in the essays. 4. The competition is open to both sexes. 5. Certificates will be awarded to the prize winners, and to such other competitors as may appear deserving. 6. The length of the papers to be from thirty to fifty pages of post quarto of twenty lines to the page, written on one side of the paper only, with an inch and a half margin on the lefthand side. 7. The papers must be delivered at the Rooms of the Institute, No. 15, Strand, not later than 5 p.m. on the 10th November, 1884. 8. Not more than three papers to be sent in by any school. 9. Each envelope to be marked on the lefthand upper corner "Essay Competition," "University," or "School," as the case may be, and addressed to "The Secretary, Royal Colonial Institute, 15, Strand, London, W.C." Further particulars respecting the regulations for the prizes can be obtained from the Secretary.

Journal of the Society of Arts.

No. 1,651. Vol. XXXII.

FRIDAY, JULY 11, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CHAIRMANSHIP OF COUNCIL.

On Monday last, 7th inst., at their first meeting, the Council elected Sir Frederick Abel, C.B., D.C.L., F.R.S., as Chairman for the ensuing year. The various committees were also re-appointed.

NEW MEMBER OF COUNCIL.

The vacancy on the Council, caused by the inability of Colonel Donnelly to attend, has been filled up by the Council, in accordance with the bye-laws, by the election of Sir Frederick Bramwell, F.R.S.

CONFERENCE ON WATER SUPPLY.

The Conference on Water Supply, to be held at the International Health Exhibition, by the Society of Arts, is fixed for Thursday, July 24th, and Friday, July 25th. The meetings will take place each day at 3 p.m. Further particulars will be duly announced.

Proceedings of the Society.

CONVERSAZIONE.

The Conversazione given by the Council of the Society of Arts and the Executive Council of the Health Exhibition was held in the buildings of the International Health Exhibition, South Kensington, on Wednesday evening, the 9th of July.

The reception was held near the principal entrance by his Grace the Duke of Buckingham and Chandos, K.G., Chairman of the Executive Council of the International Health Exhibition, and by Sir Frederick Abel, C.B., D.C.L., F.R.S., Chairman of the Council of the Society of Arts, assisted by the following members of the respective councils:—The Lord Mayor, Mr. Alfred Carpmael, Mr. Cassels, Mr. E. Chadwick, C.B., Mr. B. F. Cobb, Mr. T. R. Crampton, Sir Philip Cunliffe-Owen, K.C.M.G., Sir Joseph Fayrer, Captain Douglas Galton, C.B., Ernest Hart, Mr. T. V. Lister, Mr. J. M. Maclean, Mr. G. Matthey, F.R.S., Sir James Paget, Bart., Dr. Poore, Mr. W. G. Pedder, Mr. W. H. Preece, F.R.S., Sir Robert Rawlinson, C.B., Owen Roberts, Sir John Rose, Lord Sudeley, Colonel Webber, R.E.

The Exhibition buildings were lighted by the electric lights; the gardens were also illuminated with variegated lamps and Japanese lanterns, and the fountains were lighted by the electric light.

The band of the Seventh German (Magdeburg) Cuirassiers, Conductor Herr Wilhelm Gruenert, performed in the Vestibule near the entrance.

The band of the Coldstream Guards, conducted by Mr. C. Thomas, performed in the Central Avenue.

The band of the First Regiment of the French Engineers (Genie de Versailles), conductor, Mons. Gustav Wettge, performed in the Eastern Kiosk.

The band of the Grenadier Guards, conducted by Mr. Dan Godfrey, performed in the Western Kiosk.

The Chinese band performed in the gardens by the Chinese Court.

A vocal and instrumental concert, consisting of glees, &c., was given by the Royal Criterion Handbell Ringers, under the direction of Mr. Harry Tipper, in the Old London street.

The number of ladies and gentlemen present at the Conversazione was 14,080. Among these were:—His Excellency the Chinese Ambassador, the Marchioness Tseng, and Lady Blossom Tseng, Count D. de Bylandt, Count Vitzthum, Baron A. de Stoeckl, the Rajah of Sarawak, the Maori King, Earl of Belmore, Earl of Bradford, Earl Brownlow, Duke of Buccleuch, Earl Cairns, Marquis of Carmarthen, Viscount Castlereagh, Lord Cremorne, Earl of Darnley, Earl Ducie, Earl of Dysart, Earl of Gosford, Lord Hastings, Earl of Ilchester, Earl of Kenmare, Earl of Longford, Earl of Mayo, Earl Fortescue, Lord Norreys, Marquis of Ormond, Viscount Portman, Viscount Powerscourt, Earl of Powis, Earl of Mount Edgcumbe, Earl of Normanton, Marquis of Northampton, Lord Northwick, Earl of Onslow, Earl of Romney, Earl of Rosse, Duke of Sutherland, Lord Tewkesbury, Lord Tennyson, Lord Thurlow, Lord Vaux of Harrowden, Lord Coleridge, Lord Justice Cotton, Sir James Hannen, Lord Ormathwaite, Mr. Justice Giffard, Mr. Baron Huddleston, Mr. Justice Denman, Mr. Justice Manisty, Mr. Justice Pearson, Mr. Justice Pollock, Count Münster, Count A. E. Gleichen, Right Hon. John Bright, Right Hon. H. C. E. Childers, Right Hon. C. P. Villiers, Right Hon. Joseph Chamberlain, Right Hon. T. Dyke Acland, Bishop of Lichfield, Bishop of Manchester, Bishop of Maritzburg, Dean of Westminster, Dean of Hereford, Dean of Lincoln, Lord Edward Churchill, Lord Esmé Gordon, Lord Douglas Gordon, Lord Charles Montague, Lord Clarence Paget, Lord John Scott, Lord William Seymour, Colonel Richardson Gardner, M.P., Mr. Hastings, M.P., Mr. George Howard, M.P., Mr. T. R. Hill, M.P., Mr. Andrew Grant, M.P., Mr. Justin McCarthy, M.P., Colonel Makins, M.P., Mr. Nevil Maskelyne, M.P., Mr. Southeron Estcourt, M.P., Mr. W. H. Willy, M.P., Sir Henry Acland, Sir Henry Barkly, Sir James Bazalgette, Sir Robert Bazley, Sir Michael Hicks Beech, Sir Risden Bennett, Sir F. Bolton, Sir William Bowman, Sir C. T. Bright, Sir George Campbell, Sir Robert Carden, Sir Orfeur Cavenagh, Sir William Charley, Sir Andrew Clarke, Sir W. J. Codrington, Sir Daniel Cooper, Sir E. Du Cane, Sir W. Hart Dyke, Sir Howard Elphinstone, Sir Frederick Evans, Sir Douglas Forsyth, Sir W. A. Fraser, Sir Alexander Galt, Sir Frederick Goldsmid, Sir Julian Goldsmid, Sir J. P. Grant, Sir William Gregory, Sir Lepel Griffin, Sir George Grove, Sir William Gull, Sir E. B. Hamley, Sir Charles Hartley, Sir J. C. D. Hay, Sir Bridges Henniker, Sir J. McGarell Hogg, Sir Joseph Hooker, Sir William Humphrey, Sir Selwyn Ibbetson, Sir E. Inglefield, Sir P. G. Julyan, Sir Astley Cooper Key, Sir W. Owen Lanyon, Sir John Lawes, Sir E. A. H. Lachmere, Sir Henry Lefroy, Sir R. R. W. Lingen, Sir Joseph Lister, Sir Leopold McClintock, Sir George Macfarren, Sir Henry Maine, Sir T. Erskine May, Sir Julian Pauncefote, Sir Lewis Pelly, Sir Dighton Probyn, Sir Henry Rawlinson, Sir Edward Reed, Sir Saul Samuel, Sir Bernhard Samuelson, Sir Alfred Slade, Sir John Strachey, Sir Edward Sullivan, Sir John Swinburne, Sir H. Hussey Vivian, Sir Edward Watkin, Sir R. Wallace, Sir Spencer Wells, Sir Sydney Waterlow, Sir Allen Young, Messrs. J. E. Boehm, P. H. Calderon, Vicat Cole, C. W. Cope, Lowes Dickenson, Frank Dicksee, C. L. Eastlake, L. Fildes, Frith, Carl Haag, F. Holl, J. C. Horsley, J. E. Hodgson, Holman Hunt, E. Long, McWhirter, W. Orchardson, E. J. Poynter, Val Prinsep, G. Richmond, Lumb Stocks, Waterhouse, J. Abernethy, Ayrton, George Bullen, Hyde Clarke, R. B. Clifton, Crookes, Boyd Dawkins, Doulton, A. Geikie, Hales, Hawkesley, Jeaffreson, J. Knowles, H. Labouchere, Ray Lankester, Norman Lockyer, Oliver Lodge, J. Marshall, H. Maudslay, Max Müller, Mylne, Nasmyth, James Payn, Prestwich, Redgrave, Herbert Spencer, L. de Rothschild, Sylvester, J. L. Toole, Hon. Lewis Wingfield, Doctors Cobbold, Diamond, Gamgee, Gladstone, Günther, Mann, J. H. Murray, Stainer, Voelcker, Rev. H. R. Haweis, Rev. A. H. Sayce, General Pitt Rivers, Admiral Mayne, Captain Shaw, Captain Cameron.

Miscellaneous.

SULPHUR: ITS OCCURRENCE AND EXTRACTION.

By C. G. Warnford Lock.

The following notes relate exclusively to native sulphur (brimstone). Though the amount of sulphur annually mined in the form of sulphides of various metals (*e.g.*, iron and copper pyrites, galena, blende, &c.), probably far exceeds that obtained in the uncombined state, still, the separation of the sulphur in an inoxidised condition from such compounds is never attempted, for the simple reasons that, in the processes for extracting the several metals from their ores, the first step necessary is the elimination of the combined sulphur, which is most easily effected by a roasting or oxidising operation, whereby the sulphur is at once converted into sulphurous acid, itself a valuable commodity, and, moreover, capable of being readily oxidised one step further to form sulphuric acid, the chief purpose for which sulphur is consumed.

Occurrence.

It will be most convenient to discuss the occurrence of sulphur deposits under geographical headings, leaving geological differences to be noted as they are met with.

Austro-Hungary.—There are two mines of sulphur worked in this empire, one not far from Cracow, and the other at Radoboi in Croatia; both deposits are of considerable extent, but the annual yield is insignificant. The whole district around Mount Büdös, in Transylvania, is rich in sulphur. The deposits are situated at the south and west of the mountain, the principal localities being Kis Soosmezö, Vontala feje Bálványos, and a little above the châlet Gál András; some thirty or more diggings have been undertaken in a circuit of eighteen miles, but the area covered by the deposits is more than three times this size. The sulphur occurs in unequal strata one to nine inches thick, beneath one to three feet of mould. The soil is everywhere saturated with sulphur, and in this permeated earth pieces of the pure mineral are found. The whole is the result of living solfataric action, and the accumulation will continue to grow as long as that action survives. Samples of the impregnated earth, taken over an area of 16,000,000 square fathoms, yielded from 41 to 64 per cent. of sulphur. Allowing for interruptions in the deposits, and taking these at an average thickness of three inches instead of nine, Boner estimates that 200 lb. of sulphur might be obtained from each square fathom, assuming 50 per cent. of sulphur in the deposit; continuing the calculation, he thinks, the district should afford over 700,000 tons. He reckons the probable cost at £10 per ton, including carriage from Büdös to Kronstadt; this, he says, is less than the prices paid in the places where it is produced in Poland, Slavonia, and Bohemia. The total sulphur output of the Austrian empire, in 1863, was 1,754 tons, at an average rate of £12 15s. per ton. The imports are about 5,000 tons per annum.

Banda Islands.—Large quantities of sulphur are found in and about the crater of Gunong Api, and attempts have been made to collect it for exportation. It is said, however, that the labour of ascending the mountain is too great to render the speculation profitable.

China.—Sulphur is one of the most important products of Formosa. When taken from the mine, the ore is boiled in iron pans till it assumes a treacly consistence. This is constantly stirred till every impurity is separated from the sulphur, which is then ladled out into wooden tubs, shaped like sugar-loaves. In these it is left to cool, and the conical cakes are freed from the tubs by the simple process of knocking out the bottoms of the latter.

Sulphur is procurable in saleable quantities from the mountains around Ta-chien-la, in Western China; the inhabitants of the ravines may often be seen engaged in the manufacture of matches of the Guy Fawkes pattern, which they split from a pine plank, with a spokeshave, and tip with sulphur. During his penniless residence at Na-erh-pa, Baber generally used these sulphur chips to procure a flame.

France.—Near the hamlet of Tappets, about three miles north-east of Apt, in the department of Vaucluse, is a bed of sulphur ore yielding about 20 to 25 per cent. It consists of a sulphur-impregnated marly limestone, and accompanies the lignite beds of the tertiary system. The deposit is neither very extensive, nor very thick.

Iceland.—The sulphur deposits of Krisuvík, in the south of Iceland, were the subject of a paper by C. W. Vincent, published in the *Journal* of Jan. 17, 1873 (No. 1,052, vol. xxi., pp. 137-144); and those situated in the north of the island were described by me in the *Journal* for April 30, 1880 (No. 1,432, vol. xxviii. pp. 508-9). The interested reader may refer to these for details; it will suffice here to give a general idea of the deposits as a whole. They belong to the recent solfataric group, and, though often compared with the Sicilian mines, bear very little analogy to them. The sulphur occurs in a fine state, intimately associated with earthy impurities, as a superficial layer of no great depth, but having recuperative powers that render them practically inexhaustible. They are now the property of an English company, and give promise of being worked to advantage in the future.

India.—The sulphur deposits of India, according to Professor V. Ball,* are unimportant, and inconveniently situated. Near a village called Sura-Sany-Yanam, between the mouths of the Godaveri in Madras, small heaps of sulphur are occasionally collected in the dried-up margin of a tidal swamp, where the mineral appears to result from a deoxidisation of gypsum by contact with organic matter. Another trifling deposit is reported to occur at Ghizri Bandar, near Karachi. A considerable mine, worked by adits and chambers, exists at Sunnee in Cutchi, Balochistan, and affords the chief supply for Candahar; petroleum is said to be mixed with the refuse of the workings to produce an inferior quality of sulphur, while the pure sulphur is boiled in oil to prepare it in the form of commercial brimstone. This practice recalls the method adopted in Iceland about 300 years ago, when the crude ore was boiled in train oil, to effect separation of the dross. Sulphur is obtained in some abundance from near a hot spring called Pir Zinda, in the Soree Pass of the Suleiman Hills, Afghanistan. The native Kusranis and Bozdars treat the crude ore, consisting of amorphous gypsum traversed by streaks of sulphur, by distilling it in a retort improvised out of two gharas, one on the fire and the other inverted as a condenser. A "vast quantity" of sulphur is said to occur at Hazara, North Afghanistan. On the southern flanks of the Gunjully Hills, in the Kohat district of the Punjab, a large amount of sulphur is constantly being deposited as a result of the decomposition of pyritiferous alum shales. As much as 1,000 tons a year is said to have been gathered. At Luni-ki-Kussi, on the west side of the Indus, sulphur is obtained by roasting the loose earth. The sulphur mines at Nakband (Kushalgarh), on the Indus, eight miles from the mouth of the Kohat, are 30 to 40 feet deep, and have yielded largely, the ore being sublimed as in

* "Economic Geology of India."

Balochistan. Other localities mentioned as affording sulphur in the Punjab are Gumbat and near Panoba, four miles from Shadipur, on the Indus; Jaba, fourteen miles from Kalabagh, in the Bannu district; and Jeura, near Simla. None of these seem to possess any industrial importance.

The sulphur at Puga, in Kashmir, occurs massive, and as a lining in the clefts and fissures of a sort of quartz schist, often accompanied by gypsum. The process of formation seems to be still at work, judging by hotsprings in the neighbourhood. The deposits are worked by pits about 8 feet deep, and adits of the same length; but the production is small. A trifling quantity of sulphur is deposited by hotsprings in the beds of the Ramgunga and Garjia rivers, in the Kumaun district of the north-west provinces; and a considerable amount is found in the galleries of the lead mines at Meywar, on the Tons river, in the Jaunsar district. Little is known of the Nepalese sulphur mines. In Upper Burma the chief localities are Mooda Myo, Tsein Goon, Kyoukhoo, Bawyine, Dybayen Myo, Pagan Myo, Toogthoo Einlay, and Bhamo district. The dormant volcano of Barren Island affords small quantities of sulphur, the result of solfataric action.

Italy.—The sulphur deposits of the Romagna are situated in the Miocene lacustrine formation, and lie amid the sub-apennine hills. The mines worked in the province of Forli, by the Cesena Sulphur Company, cover an area of about 260 square kilometres. Their average annual production for the seven years, 1873-79, was 27,780 tons. The cost of extraction, refining, and royalties come to about £4 per ton, according to Consul Colnaghi. The mineral is worked by blasting, each miner having to bore three holes in six hours, when all are fired simultaneously. At Pergola, some 60 kilometres distant from Ancona, is a sulphur mine worked by a German Company, which shipped 90 tons of refined sulphur to England in 1880. In Central Italy, near Bologna, a vein is worked which extends over 15 miles in length. The ore is poor, and has to be raised from a considerable depth.

Japan.—Sulphur is said to be abundant in the island of Yezo.

Philippines.—A good deal of sulphur is collected at Camiguin.

Sicily.—Some notes on the sulphur mines of Sicily has appeared in the *Journal* (see Feb. 17, 1882). They may be supplemented by the following. At the end of the Middle Miocene period, the sulphur-bearing area was raised, and lakes were formed in which occurred the deposition of the sulphur rock and its accompanying gypsum, tripoli, and silicious limestone. The sulphur rock is composed of sulphur and marly limestone, the sulphur being sometimes disseminated through the limestone, and at others forming thin alternate layers with it. These sulphur-bearing seams are often separated by layers of black marl, 20 inches to 6 feet thick, some seams attaining thickness of 28 feet. The total aggregate thickness of the sulphur seams reaches 100 feet in one case, but the average total is 10 to 12 feet only. All the seams are decomposed at their outcrop, and show only an accumulation of whitish friable earth, called *briscale* by the miners, and mainly composed of gypsum. This has resulted from the oxidation of the sulphur to sulphuric acid by atmospheric agency, the acid in turn attacking the lime carbonate, and forming sulphate (gypsum). The most plausible supposition as to the origin of the sulphur seams would appear to be that the lakes received streams of water containing calcium sulphide in solution, this calcium sulphide probably resulting from a reduction of the masses of calcium sulphate (gypsum) by the action of volcanic heat. Gradual decomposition of the calcium sulphide in the presence of water would finally result in a deposition of sulphur and of lime carbonate, in the relative proportions of 24 and 76 per cent. As a matter of fact, much of the Sicilian ore actually has this per-centage composition. Whatever the process has been, it is no longer in activity, and there is no growth nor renewal of the beds, in this respect differing essentially from recent deposits due to "living" solfataric action.

Almost all the Sicilian ore is carried to the surface on boys' backs, consequently it does not pay to work below about 400 feet, as it then becomes necessary to employ hauling machinery. Hence the deposits lying below that horizon are hardly touched, and as many of the beds are nearly vertical, and do not diminish in yield as they descend, the still untouched resources must be very great. Various estimates have been made as to the period for which the supply will last at the present rate of consumption; these range from 50 to 200 years. There are said to be about 250 mines in the island, and no less than 4,367 *calcaroni* were reported in operation 15 years ago. The average yield is stated not to exceed 14 per cent.

Spain.—In the province of Murcia, and at other places, the existence of fine beds of sulphur has been ascertained. One is worked by an English association, the Hellin Sulphur Company. The quality is very good.

Suez.—A sulphur deposit exists at Djemsa, in a perfectly rainless desert on the African coast, very near the sea, and constituting a hill 600 feet high, whose sides are blasted down as in quarrying stone. Some 200 Arabs, employed under French engineers, succeeded in mining ten tons a day. A similar deposit occurs at Ranga, 500 miles from Suez, also near the coast of the African continent, which differs only in being buried under other strata, so that mining is necessary.

Sunda Islands.—The Gunong Jollo, or sulphur mountain, lies south west of the village Prado, and south east of Dompo. The sulphur is dug from three places in an old crater now in the solfataric stage of its existence. Each spot is 100 to 120 roods long, and 50 to 60 broad. The sulphur collects between masses of white stone (perhaps decomposed trachyte), and sometimes covers a space of one to three roods square. On the liquid and warm sulphur a hard crust forms, two inches thick. Digging is only carried on at morning and evening, the heat being too great at mid-day. Round holes are made, eight to nine feet apart, two feet deep, and with an outlet from above of one foot, and from below of three or four feet. Sulphur is also found in the solfatara of Gunong Prewa, but in trifling quantity. A great deal exists on the sides of Tambora.

Tripoli possesses a sulphur deposit important both for extent and richness, but it is not worked.

Turkey.—Native sulphur is found in some quantity adjacent to the lead lodes at Devrent (Derbend), near Alashehr, Salyklœ, and Nymphi. A sulphur mine exists two days' ride from Arta, and four from Butrinto, Albania. Some Italians are said to have secured a concession of a "basalt vein containing sulphur" near the Dardanelles. This has a very doubtful look, and if the mine alluded to be the same as the one I examined in 1873, the formation is the exact counterpart of that met with in Sicily, and the neighbouring basalt has nothing to do with the sulphur. This mine exists at a place known as Komarla, and the mineral affords about 40 per cent. of sulphur. A similar mine occurs at Alahtan, about six hours from Kassaba.

United States.—Sulphur is found native in Nevada, California, Utah, Virginia, Louisiana, and other States, occurring in beds of considerable bulk in Unitah county, Wyoming, near Evanstown, where it is said to be quite pure; also in some quantity in the Yellowstone Park, Montana, and in various localities in New Mexico. It is only worked to any extent in Nevada and California, and even there not on a large scale, the total production in 1880 being stated at under 600 tons. Locally produced sulphur cannot compete in price with imported Sicilian, on account of the cost of land transport; it is, moreover, found to be often contaminated with arsenic, which greatly reduces its market value and limits its application. At the most important mine, called the Rabbit Hole, in Humboldt county, Nevada, the sulphur occurs as an impregnation in a white volcanic tuff or breccia, of Miocene age. The deposit is worked by regular mining, and the mineral, containing 15 to 40 per cent. of sulphur, is dealt with by the steam process, the production being sometimes six tons a day. At the Pluton mines, California, the sulphur is found as a crystalline body scattered through a confused mass of decomposed rocks, and intimately associated with cinnabar, apparently occupying an ancient crater. The mineral is removed altogether, and the sulphur is either recovered by steam process, or, if both sulphur and cinnabar are in paying quantities, the mass is put into a mercury distilling furnace, and the sulphur is separated from the mercury by passing superheated steam into a chamber situated in front of the mercury-condensing chamber.

Extraction.

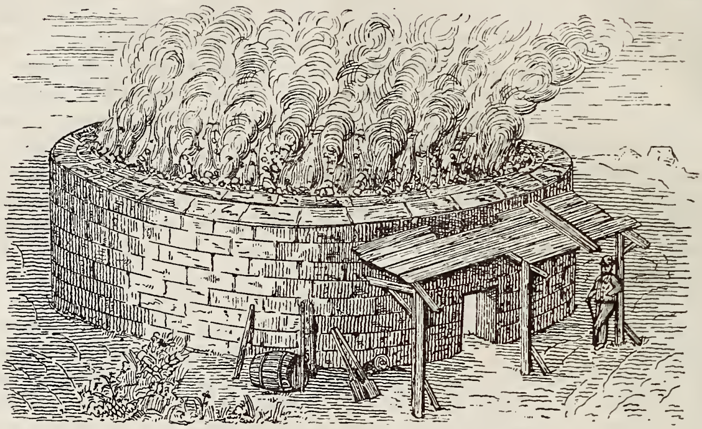
Sulphur is extracted from the earthy materials with which it is intimately associated in nature, by the following several means:—(1) Dry heat (roasting the ore in mass); (2) wet heat (melting out by the aid of aqueous solutions of salts, the salts being added to heighten the boiling point); (3) superheated steam; (4) chemical solvents. The great bulk of all the sulphur produced is extracted by apparatus belonging to the first class, and including the *calcarelle*, *calcarone*, and *doppione*.

Calcarelle.—The earliest system adopted in Sicily was the *calcarelle*. This consisted simply of a stack of ore, 6 to 15 feet square, built in a ditch 3 or 4 inches deep, and whose floor was beaten hard and sloped to a single point, permitting the molten sulphur to flow out by an opening termed the *morto*. In building the stack, care was taken to put the largest pieces of ore at the bottom, selecting lumps of gradually diminishing size as the top was approached. The mass was ignited at the summit. The construction of the stack usually occupied two days; on the third day the sulphur escaped by the *morto*, and on the fourth the *calcarelle* was pulled down. The air necessary for the combustion of a portion of the sulphur (to afford the heat required to smelt the remainder), was freely admitted at all sides; only the mineral in the centre of the heap was heated without actual contact with the air, so that its sulphur was melted out instead of being burned (oxidised). Consequently about 6,700 lb. of sulphur mineral were needed to afford 385 lb. of sulphur, or a yield of 5·7 per cent.; as the ore contained 35 per cent. of sulphur, the consumption of sulphur as fuel was 1,960 lb., in order to extract 385 lb. In addition, the immense volumes of sulphurous acid emitted from the stack caused a terrible destruction of the agricultural crops in the neighbourhood.

Calcarone.—Nearly all the sulphur prepared in Sicily is now extracted by the *calcarone* (or *calcherone*, as it may also be spelled). This, as is shown in Figs. 1 and 2 (p. 796), is formed by building a circular stone wall on an inclined sole. In front is the *morto* or outlet, having a height of 4 to 6 feet, and a width of 2 feet; over it is erected a wooden shelter for the workman in charge. *Calcaroni* may contain from 200 to 400 *casse* (each *casse* being equivalent to about 6 tons, and giving 12 to 16 cwt. of sulphur). The durability of the *calcarone* is governed by the care exercised in its construction; ten years is not an unusual period. The charging of the *calcarone* is a matter of primary importance, as on it depends the yield of sulphur. The largest pieces of ore are selected for the first layer, leaving interstices between them; the size of the lumps gradually diminishes as the height increases, care being taken to form the walls of the *morto* with calcareous stones, so as to ensure a passage being maintained for the escape of the liquefied sulphur. In adding the finest portions on the top, narrow channels, about two feet apart, are left for the draught to carry the heat down. The whole is covered with a layer of the refuse from previous operations. This layer is more or less thick, according to the state of the weather, because the *calcarone* being built in the open air, variations of temperature and wind influence the progress of the operation; consequently means have to be adopted to prevent an undue access of air rendering the combustion too rapid. For instance, during a sirocco (local hot wind) there is danger of the sulphur contained in the ore lying at the side facing the wind being completely converted into sulphurous acid, and thus lost. The employment of a roofed shed would prevent much of the waste occasioned by climatic causes.

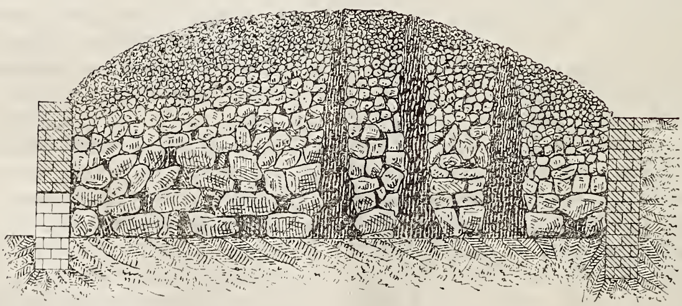
When the charging is completed, the *morto* is closed by a stone slab, and fire is communicated to the mass by means of little bunches of dried herbs, dipped in sulphur, which are thrust into the vertical channels before mentioned. Some six or eight days afterwards, a hole is pierced in the top of the *morto*,

FIG. 1.



by means of an iron rod; later, a second hole is made near the floor. By these two openings the sulphur escapes, and is collected in wooden buckets (*gravite*), shaped like a truncated cone, and holding about one hundredweight of sulphur. These buckets cost over 2s., and serve only for three or four castings without wanting repairs. The outflow of sulphur lasts for a fortnight or a month. Commonly, the *calcarone* is left to itself when once the mass has been ignited, but then the loss of sulphur is much more serious. To ensure good results many precautions have to be observed, mainly connected with the nice adjustment of the draught, so as to effect the maximum degree of fusion with a minimum of oxidation. When the operation is conducted during winter, the product is less abundant, and of inferior

FIG. 2.

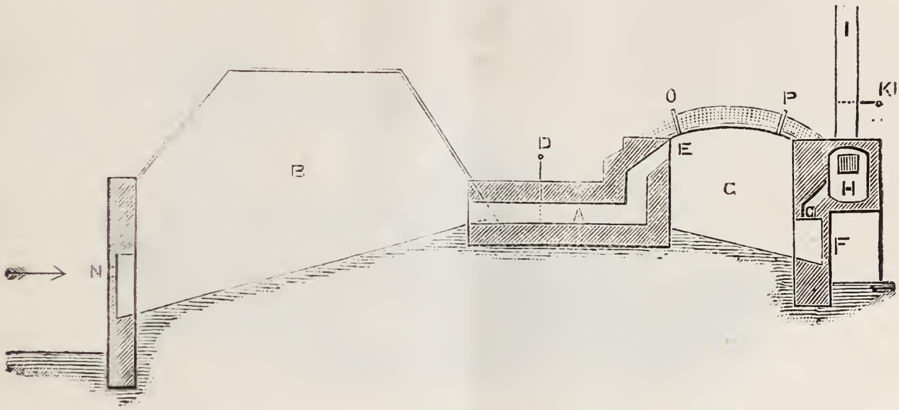


quality. After the charge is exhausted, a new one cannot be introduced till the mass has cooled down, occupying a period of ten days to a month, according to the size of the *calcarone*. The discharging has to be done slowly and cautiously, on account of the sulphurous fumes liberated. The consumption of sulphur (as fuel) in the heating is about 50 per cent. of the total amount contained in the ore. Thus, to obtain one ton of sulphur, there is consumed as fuel about another ton, worth, say, £5, and performing a duty which could be much more satisfactorily accomplished by two hundredweight of coal, costing, perhaps, 5s.

Calcarone, Foster's Improved.—A great improvement in the Sicilian *calcarone* has been introduced by P. Le Neve Foster, and worked with good results, showing an increase of yield of 30 per cent. above the ordinary plan. According to his description, the waste heat from an ordinary *calcarone*, after all the sulphur has been run off, is utilised to heat to the required temperature the charge of ore placed in his kiln, and as soon as the moisture has been driven off and the heat is great enough, the charge is fired from the top. The combustion, fed with hot air containing some sulphurous acid gas, is very slow, hence the loss of sulphur by burning is less than when, as in the ordinary *calcarone*, the ore has to be heated entirely by the combustion of the sulphur. The apparatus (shown in Fig. 3,* prepared from a drawing kindly furnished me by the inventor) consists essentially of three parts—(1) the flue, or conductor of heat; (2) the kiln, in which the ore is treated; (3) the chamber for the condensation of the sulphur that is volatilised during the fusion, and in which it is collected.

The kiln may be of any suitable form to contain two charges of ore, but a rectangular chamber is found to be most convenient, with floor sloping towards the front. The chamber consists of four walls, preferably not covered with an arch, as affording greater facility for charging and discharging. The kiln communicates, by means of a flue, A, with the back of an ordinary *calcarone*, B, which furnishes the heat necessary for melting the sulphur from the ore contained in the kiln, C. The upper portion of the *calcarone* should be covered with a layer of *genese* (spent ore), so as to prevent the dispersion of heat by any other channel than that offered by the flue, A, which is provided with a damper, D, so as to regulate the admission of heated air by openings, E, at the upper back part of the kiln. A rectangular opening, F, is left in the front wall of the kiln, from which the melted sulphur is run. This opening, if of sufficient size, may serve for discharging the spent ore at the termination of the fusion. From the upper part of the opening, and also in the front wall,

Fig. 3.



slightly above the level of the floor, flues, G, communicate with a horizontal passage, H, which is made large enough to serve as a condensation chamber, on the walls of which the sublimed sulphur collects. At one end of the chamber is a vertical chimney, I, provided with a damper, K.

The kiln is charged in the usual way by placing the large pieces of ore on the floor in such a manner as to leave passages for the flow of the liquid sulphur; the small pieces are next filled in, and the finer ore at the top. A few blocks of rough stone, or burnt ore, are placed at the opening in front in such a way as to leave a vacant place for the melted sulphur to collect before being run off. When charged, the ore is covered with bricks laid flat, and on these is put a layer of *genese*, well rammed and wetted, so as to form a nearly impermeable coating, with a slight slope towards the walls, in order that the rain water may run off. The opening, F, in the front wall should be closed with a thin wall of plaster of Paris The ore in the kiln, which is now ready for fusion, is put in communication with the spent *calcarone*, B, by opening the damper, D, and at the same a small hole, N, is made in the wall that closes the opening in front, from which the melted sulphur has been run off from the *calcarone*, B. The current of air entering by the hole, N, and passing through the incandescent mass of ore, is thus heated, and enters the kiln by the flue, N, at a sufficient temperature. In this manner the heated mass of spent ore in the *calcarone* becomes a regenerator of heat, to be utilised in the kiln for the fusion of the sulphur that it contains. In the upper covering, two or more tubes, O P, are placed, and serve not only for observing the internal temperature by a thermometer, but also for firing the mass.

The combustion of the sulphur supplied with hot air, mixed with a considerable proportion of sulphurous acid gas, proceeds slowly in the upper part of the kiln, and the liquid sulphur dropping to the floor,

* This block is kindly lent by the Editor of the *English Mechanic*.

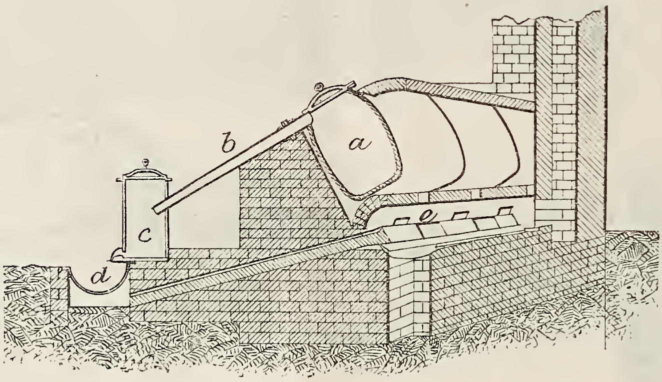
over the already heated ore, cannot solidify and choke the passages, and so prevent the circulation of the heated air and products of combustion of the sulphur to the chimney; in this manner the operation proceeds with regularity. The success of the kiln is principally due to the manner in which it is heated from the top and back towards the front and bottom, mitating, to a certain degree, the manner in which the heating of an ordinary *calcarone* proceeds, with this difference, that the heat is better utilised in the kiln, and, therefore, with less consumption of sulphur as fuel.

When the wall that closes the front opening, F, begins to heat, and the kiln is ready for running, a small hole is made with a pointed instrument, so as to allow the melted sulphur to flow off into wooden moulds. The horizontal flue or condensing chamber, H, should have a sloping floor, and when the temperature in it reaches the melting point of sulphur, the flowers that have been deposited on the sides are liquefied, and run off. Towards the end of the operation it will be found prudent to close all the dampers as well as the hole, N, to prevent the overheating of the kiln, in which case the sulphur would become thick, and difficult to run off, and the yield would consequently be lessened.

The first cost of the structure is slight, as the materials necessary are usually at hand. The yield too is much increased; but on the other hand the extra cost in charging, discharging, and attendance, as compared with the ordinary *calcarone*, make a large hole in the increased returns.

Doppione.—It will require little reflection to see that only a small quantity of the finely pulverised mineral, necessarily produced in the operations of mining and breaking down the ore, could be dealt with in the *calcarone;* consequently for a long time the bulk of this portion of the ore was simply thrown away, though it often assayed 70 per cent. of sulphur. The *doppione* was one of the earliest successful structures designed to remedy this state of things. As shown in Fig. 4, it consists of a set (generally six) of

Fig. 4.



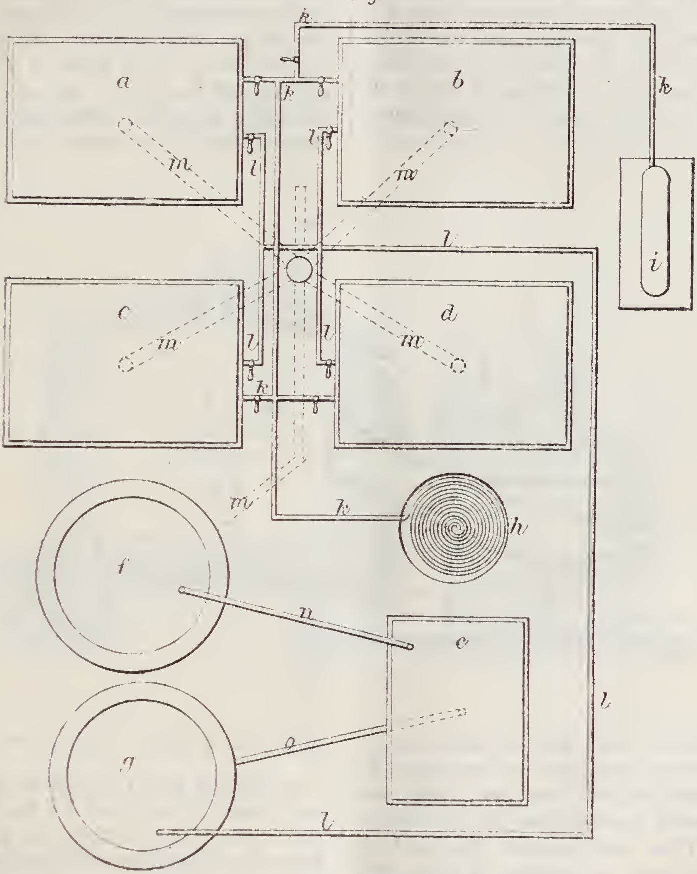
cast-iron pots, holding about 30 to 40 gallons each, arranged in a gallery furnace *e*, so as to be completely enveloped by the heated vapours from a fire beneath. Each pot, *a*, communicates by a long arm, *b*, with a cooling condenser, *c*, for the distilled sulphur, placed outside the furnace. The apparatus is generally employed on rich material, or on that obtained from the *calcaroni;* but it is also applicable to ores which are too poor to burn in the *calcaroni*, though the profit in that case must be small. The heat generated in the *doppione* is likely to encourage chemical action between the sulphur and any lime carbonate that may chance to be present in the mineral, creating a further loss of sulphur. The pots are charged and discharged by opening the lids, which are kept luted during the distillation. The volatilised sulphur is conducted by the cast-iron tub, *b*, into the receptacle, *c*, over which a small current of cold water constantly flows, reducing the sulphur to a fluid condition; it then escapes into the dish, *d*, beneath, whence it can be ladled into the moulds. The pots last for about 300 working days, and the furnace serves about the same time with a couple of repairings. The workman is expected to turn out 100 lb. of clean sulphur from every 109 lb. of *calcarone* sulphur.

Calcium chloride.—The principle underlying the use of calcium chloride is that, while raising the boiling point of water to about 239° F. (115° C.), the melting point of sulphur, it is cheap and inert in the presence of sulphur. The water to be used in the melting process is charged with 66 per cent. of the calcium chloride, and heated to boiling, in which state it is run into the vessel containing the sulphur to be melted. No doubt the sulphur is efficiently melted, but the very slight difference in specific gravity between the sulphur and the associated impurities from which it had been melted out practically precludes any real separation taking place. Consequently the process is virtually a failure, as I am assured by those who have worked it.

Steam.—At the Rabbit Hole mines, Humboldt county, Nevada, advantage is taken of the liquidity of sulphur at 232° F. (111° C.), to use steam at 60 to 70 lb. pressure for melting the sulphur out of the gangue. The apparatus employed consists of a cylindrical iron vessel, about 10½ ft. high, divided into an upper and a lower compartment, by means of a horizontal sheet iron diaphragm perforated with ¼-in. holes. As soon as the upper compartment is charged with ore (about 2 tons), steam is introduced for about half-an-hour, and the sulphur, liquefied by the heat, flows down through the diaphragm into the lower compartment, kept at the proper heat by injection of steam, and escapes by an outlet, opened at intervals into a receptacle placed outside. When water commences to flow out with the sulphur, steam is injected at full pressure for a few minutes, to clear out as much as will come, and the solid residue is afterwards removed through a door above the diaphragm. Each charge requires about three hours for its treatment. The process is adapted to ores which, for poverty and other reasons, cannot be economically worked by *calcaroni*, or other recognised methods.

Carbon Bisulphide.—Whilst hot water and steam have no solvent action upon sulphur, but merely

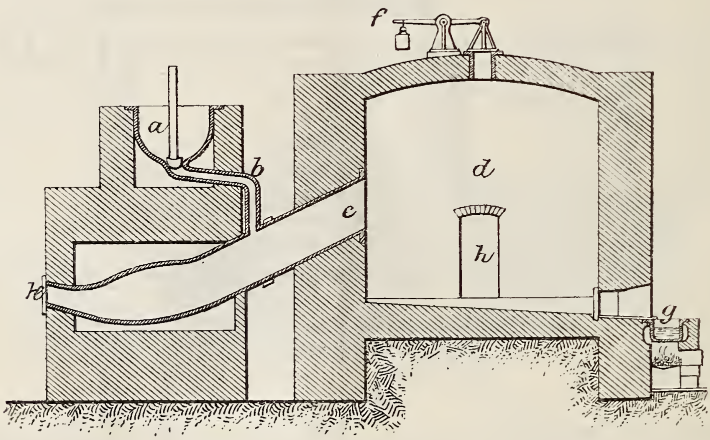
FIG. 5.



change it from a solid to a liquid state by the action of their heat, carbon bisulphide actually dissolves the sulphur and re-deposits it by evaporation. The plant necessary for carrying out this process is shown in Fig 5. It is designed of dimensions suitable for dealing with 20 tons of raw sulphur mineral per diem, yielding 50 per cent. of pure sulphur. The four extracting pans, *a*, *b*, *c*, *d*, have each a capacity of 5 tons, and are made of ⅜-in. wrought iron plate; they measure 6 ft. long, 4 ft. wide, and 4 ft. deep internally; and are fitted with a perforated bottom diaphragm, with connecting pipes, *m*, leading to the underground solution tank, *f*, with another set of pipes, *k*, for admitting steam from the boiler, *i*, and with a third set of pipes, *l*, communicating with the store tank, *g*. The still, *e*, is a steam jacketed "wrought jacket" pan, 6 ft. long, 4 ft. wide, and 4 ft. deep, with cast iron ("loam casting") oval-shaped bottom and ends, ½ in. thick, and provided with a dome-shaped lid, having an inlet pipe, *n*, and outlet pipe, *o*; its capacity is 3 tons. The store tank, *g*, measures 10 ft. in diameter, by 7 ft. deep, has a capacity of 10 tons, and is constructed of ½ in. wrought iron plates. The worm, *h*, is a coil of 2 in. pipe. The boiler, *i*, is of 20 horse-power nominal, and must be placed where it will be impossible for bisulphide vapours to find their way to the fire-hole. Force pumps are required to pump the bisulphide from the store tank, *g*, into the extracting vats, *a*, *b*, *c*, *d*, previously charged with the sulphur mineral. When the sulphur has been completely dissolved, the solution is run into the tank, *f*, and thence pumped into the still, *e*, where by the application of steam in the jacket, the bisulphide is evaporated, and passes into the store tank, *g*, for future use, while the sulphur forms a deposit in the still, and is collected therefrom. When the extracting pans have been emptied of solution, steam is let in so as to force any remaining bisulphide vapours into the worm for condensation and recovery, thus avoiding waste of bisulphide and consequent risk of fire and explosion by ignition of its dangerous vapours. The bisulphide is allowed to remain all night in contact with the charge. The diaphragm at the bottom of each extracting vat may advantageously be covered with bagging cloth to filter flocculent matters from the bisulphide.

Making Roll and Flowers of Brimstone.—For the preparation of "roll" and "flowers of" brimstone, the crude sulphur has to be again subjected to heat. The fusing apparatus, Fig. 6, generally consists of two cast-iron cylinders, *c*, measuring 3 ft. long, by 1 ft. in diameter, closed at one end by a door, *e*, and prolonged into a tube at the other, which leads into a brickwork condensing chamber, *d*. The retort, heated by a fire made immediately beneath, is completely surrounded by flues traversed by the heated vapours, which latter, before escaping to the chimney, heat a little pot, *a*, placed above the retort, and in direct communication with it by means of the pipe, *b*. Into the pot, *a*, is introduced the sulphur intended for distillation. It is raised to a temperature of 257° to 302° F. (125° to 150° C.), at which point the sulphur fuses, and flows, drop by drop, into the retort *c*, where it is vapourised, and whence it passes

Fig. 6.



into the chamber, *d*. The floor of this chamber is an inclined plane, converging to an aperture, *g*, by which the liquid sulphur flows out, while the "flowered" portion attaches itself to the walls of the chamber. These two forms (the liquid and the flowered) possess the same degree of purity, and their molecular difference depends only upon the varying grades of temperature under whose influence they are produced. An operation lasts about four hours. The door, *e*, facilitates the removal of spent refuse from the retort; the damper, *f*, regulates the draught and temperature in the chamber, *d*; and the door, *h*, gives access to the interior of the chamber, for the purpose of collecting the flowers of brimstone from the walls. The liquid sulphur, escaping at *g*, flows into a little pan, gently heated by a separate fire, and is thence ladled into wooden moulds suspended in a bath of cold water, to form the so-called "roll" or "stick" brimstone.

SCHOOL BOARD DRILL COMPETITION.

The Annual Drill Competition of Schools, under the London School Board, for the Challenge Banner given by the Society of Arts, took place on Saturday, July 5th, in Hyde-park, near Prince's-gate, in the presence of H.R.H. the Princess Louise, and the Marquis of Lorne, who acted as judge. Amongst the company present were the Duke of Buckingham and Chandos (chairman of the Executive Council of the International Health Exhibition), Mr. E. N. Buxton (chairman of the Board), Lord Reay, Lord Alfred S. Churchill, Captain Douglas Galton, C.B., F.R.S., Members of Council, and Mr. H. Trueman Wood, secretary of the Society of Arts, Sir Ughtred Kay-Shuttleworth, and Mr. S. Morley. The eleven schools represented were the Jessop-road, Brixton; Fairance-street, Limehouse; Harper-street, New Kent-road; Berwick-street, Soho; Lyndhurst-grove, Peckham; Bellenden-road, Peckham; Olga-street, Bethnal-green; Mina-road, Old Kent-road; Burrage-grove, Plumstead; Waterloo-street, Hammersmith; and the Gideon-road, Battersea. Each company was under the command of the masters of the respective schools, and the whole under that of Sergeant-Major Sheffield, drill instructor to the Board, while the music was supplied by the band of boys belonging to the training ship *Shaftesbury*. The drill commenced by the boys marching past in column, and then going through a serious of extension and flexion motions, after which each company was independently drilled. The whole of the boys, headed by the band, by invitation of the Executive Council of the Health Exhibition, marched to the Albert-hall, there to hear the award and witness the presentation of the banner by the Princess. Arrived in the hall, the Marquis of Lorne addressed the boys, and expressed the pleasure he and the Princess had felt in witnessing their proficiency in drill, which had been so good throughout that he had some difficulty in deciding which was the best company. The issue lay between the Gideon-street School (which held the banner for the past year) and the Berwick-street School; but a slight superiority in some of the minor evolutions had decided him and the committee to award the banner to the latter school. Two lads of the successful company then marched on to the platform and received the banner from the Princess, amid loud cheers. Mr. E. N. Buxton then thanked the Marquis and the Princess for their kindness in being present on the occasion, and added, as enhancing the value of their victory, that the winning boys laboured under the disadvantage of having no playground in which to drill at their school. The Marquis said the Princess wished to express the great importance she attached to physical exercise for boys and girls, and especially recommended the Swedish system for the latter as being particularly good. Besides its importance to health, drill, in a national sense, was by no means useless, as it made an excellent nursery both for our regular and auxiliary armies. The proceedings closed with three cheers for the Commissioners of the Health Exhibition, who had thrown it open to the boys for the remainder of the day.

PATENT-OFFICE REPORT.

The "First Report of the Comptroller-General of Patents, &c.," has just been printed, and is about to be issued to members of Parliament. By the Act of last year, the Comptroller is directed to submit to Parliament, before the 1st of June in every year, a report on the previous year; but inasmuch as the Act only came into force on the 1st of January, the only material available had to be sought in the first four months of the present year, and it is with that period that the document before us deals.

Under the Commissioners of Patents, whose rule was abolished by the Act, the practice was to report in August, by which time (the six months provisional protection of the applications sent in at the end of the previous year having expired) it was possible to give a twelvemonths' statistics in full, but the reason for this delay was not appreciated by the Grand Committee on Trade last year, and the earlier date was substituted.

The report, as far as it goes, seems satisfactory. It is obvious that it cannot go very far, since it only deals with a very short period during which there was little to do but receive the large number of applications attracted by the reduced cost of a patent under the new Act. That the office succeeded in dealing satisfactorily with the very large amount of work suddenly thrown upon it, is greatly to its credit. How sudden the pressure was, is shown by the fact that there were in January 2,499 applications, whereas the usual monthly average of recent years was about 500; and not only was the number increased fivefold, but the work in each case was much heavier. The provisional specifications were not merely pigeon-holed, as of old; they were all examined, and in a number of instances amendments were introduced at the suggestion of the examiners. As many as 2,484 communications of this nature were made by the Patent-office to applicants during the four months, the total number of applications being 7,060. Of the general character of the applications, the Comptroller does not express any opinion, but it may be remembered that a short time back it was officially stated that they were not apparently inferior to the average of former years. That 72 per cent. still pass through agents' hands, shows that the apprehensions of the patent agents of loss to their business from the passing of the Act were not well founded, but it is certainly remarkable that no larger proportion of inventors have availed themselves of the facilities thought to be offered for the obtaining of cheap patents directly from the office.

Of the 7,060 applications only 689 were accompanied by complete specifications, a proportion which seems to have surprised the Comptroller. As was pointed out in the *Times* last December, when the new patent rules were first issued, the drawback of immediate publication renders this method of proceeding less desirable than that by means of a provisional specification.

As the time has not yet arrived for the later stages of patents applied for during 1884, little appears about them in the report, reference being only made to some few which passed rapidly to the final proceedings, the applicants not having availed themselves of the full limit of time allowed. Nor have the cases been numerous in which existing patents have been affected by the new Act, since only a few applications for amendment of specifications have been received. It is, therefore, too soon to form any opinion as to the manner in which this part of the Act will work, or whether the plan of making the Comptroller sit as a sort of judge of first instance will answer.

The preparations for an illustrated journal of patented inventions are going on. The Comptroller has, as we anticipated last December, found that the descriptions given by inventors prove unsatisfactory, and announces that official descriptions will be prepared for the journal. It is stated that a few applicants have refused to furnish drawings for the journal, but no hint is given as to the fate awaiting these recalcitrant inventors.

An announcement is made that the indexes and abridgments published by the office are to be improved and completed. For a good many years a special staff has been engaged in preparing a full index of the "old law" specifications (from 1617 to 1852), and this is nearly completed. It is understood, though the report does not say so, that the completion of this work has been delayed in consequence of the special staff being employed in examining applications, and since the interest of the index is now almost wholly historical, the delay is, perhaps, no great matter. It is now intended to do what might well have been done before—to deal with the last 12 years or so (1870-1883) first, and work backwards to the historical periods. The subject-matter indexes are to be revised and consolidated, and the classified abridgments of specifications to be completed down to the end of last year. These are now sadly behindhand, none of the series going beyond 1876 and a large number stopping at 1866.

So far as can be judged from the financial statements appended, the office is working at a profit, notwithstanding the large reductions in fees; but the *data* for an accurate estimate are not given.

As regards designs and trade-marks, the alterations introduced by the Act appear, in the opinion of the Comptroller, to be working well; they are not of a very important character.—*The Times*.

OYSTER PRODUCTION AT ARCACHON.

The production of oysters in the Bay of Arcachon near Bordeaux, has, according to Consul Ward, become of late years a very important and lucrative branch of industry for the inhabitants, as well as the originators of the new method of breeding, which latter has had the result that the number of oysters now annually produced at Arcachon is greater than at any other place in Europe. During the year 1883, the number of oysters measuring at least 5 centimetres, or 1·95 inches in length and breadth, which were exported, is estimated to have reached about 173,000,000. The greater proportion of these were two or three years old, and were sold as "table" oysters, the remainder, though not inferior in size, were only one year and a-half old, and were forced by a peculiar process. This consists in placing the young oysters into so-called ambulances, that is, boxes with wooden sides and tops and bottoms, covered with galvanised wire, the boxes being fixed about a quarter of a yard above the ground. The oysters placed in these boxes grow about twice as rapidly as others which are merely placed in the beds. The chief reasons of the success of the Arcachon oyster beds are, on the one hand, the favourable condition of the water, which does not leave the beds dry for more than three hours at each tide, and thus causes the oysters to grow rapidly; and, on the other hand, the composition of the soil, a sort of blue clay, which is sufficiently hard to prevent the oysters from sinking down too deeply. The prolific production is also considered to be owing to the arrangement of tiles in the water along the sides of the oyster beds, the tiles having been previously dipped in a solution of lime; about 10,000 tiles are sufficient for a bed three acres in size, and after a short time from 50 to 1,200 oysters will collect upon each of the tiles. In consequence of the great productiveness of the Arcachon oyster beds, the French Government has lately prohibited oysters measuring less than 5 centimetres in length to be taken out of the bay for sale. The present price of oysters at Arcachon is considerably lower than 15 years ago, when only a few hundred thousand were exported annually; at the present date, oysters measuring over 7 centimetres fetch from 55 to 58 francs per 1,000, compared with 120 francs in 1870.

General Notes.

RAILWAYS BETWEEN FRANCE AND SPAIN.—According to the *Zeitschrift für Transportwesen und Strassenbau*, there are now three railways in contemplation, intended to augment the imperfect traffic facilities at present available between France and Spain, and regarding which Commissions appointed by the two countries will shortly make official reports. One line is intended to run from Pamplona in a north-easterly direction through the Roncal valley towards the French departments of Hautes Pyrenées and Haute Garonne. At the other end of the mountain chain there is intended to be a line built (without State help) from Lerida to the French departments of Ariège and Pyrenées Orientales, passing either through Arran or the more easterly valley of Noguera Pallares. The third project is favoured by the inhabitants of Arragon, and is a prolongation of the railway from Madrid to Saragossa and Huesca. At the Somport pass there will be a tunnel four miles in length, and the communication with the French railway system will be effected near Oloron on the Midi line. The French government has shown itself opposed to this last-named scheme, and even the Spanish government has manifested a preference for the Lerida-Arran line. Nevertheless, the works commenced in 1882 have so far been steadily proceeded with.

* Class 16. *Docks and Harbours.*—Models, plans, and designs for docks, harbours, piers, breakwaters, &c.; submarine constructions; diving apparatus; dredging machines; pile-drivers, screw piles; coffer-dams; graving docks, "patent" slips, caissons, pontoons, floating docks, hydraulic apparatus for working dock-gates, &c., gridirons. Buoys.

* ,, 17. *Lighthouses.*—Methods of construction; appliances used in lighthouses and in lightships, fixed and flashing light apparatus, lamps, sound signalling apparatus.

* ,, 18. *Rivers and Canals.*—Conservation and improvement of rivers; construction of canals; locks, lifts and inclines, weirs.

* ,, 19. *Water Supply and Sewerage.*—Methods of collecting, pumping, storing, filtering, and distributing water; appliances for detecting and preventing waste of water, water-meters; water fittings, filters; sewers, sewage disposal and utilisation.

,, 20. *Reclamation, Irrigation and Drainage of Land.*—Drainage (natural and artificial) of low-lying districts; embanking and warping land; irrigation works.

,, 21. *Testing Apparatus.*—Apparatus and instruments used in testing iron. stone, brick, concrete, cement, &c.

,, 22. *Military Engineering and Fortification.*—Military topography.

* ,, 23. *Materials used in Building.*—Bricks and tiles, machines for making them; concrete, artificial stone, cement, materials and appliances used in their production; asphalt; roofing felt, and other roofing materials; columns, girders, and other applications of metal in building; applications of terra cotta to buildings; preservative and fire-resisting materials, paints, &c., for application to stone, wood, iron, &c., methods of applying the same.

* ,, 24. *Building Construction.*—Models and plans showing methods of construction; non-combustible constructions; labour saving and other machines and appliances used in building, scaffolds, elevators; fittings and appliances used in buildings, shutters, blinds, lifts, bells, speaking-tubes, &c.

* ,, 25. *Heating, Ventilation, House-drainage, &c.*—Sanitary appliances; ventilators; cowls for chimneys, chimney-sweeping apparatus; apparatus for heating by steam, water, air, &c.; means of cooling air.

Group IV.—PRIME MOVERS, AND MEANS OF DISTRIBUTING THEIR POWER.

(For distribution of power by water, *see also* Group xi.; by electricity, *see* Group xiii.)

Class 26. *Steam-engines and Boilers.*—Stationary, portable, marine, locomotive; fireless locomotives; methods and means of preventing corrosion and incrustation; methods and appliances for preventing explosions, and for testing boilers; fire-grates, fire-feeders, smoke-consuming appliances; valves and valve gear, steam joints, governors, injectors, pumps; bearings, lubricators, anti-friction metals; indicators, gauges, manometers, tachometers, dynamometers.

,, 27. *Gas and Air-engines, &c.*—Gas-engines, hot-air engines, petroleum-engines, air-compressors, compressed air-engines; ammonia-engines, vapour-engines; accessories for the above.

,, 28. *Means of Utilising Natural Forces.*—Turbines, water-wheels, tide-mills; means of utilising wave-power; hydraulic rams, water-pressure engines; windmills, solar engines.

,, 29. *Means of Transmitting Power.*—Driving bands, shafts, pulleys, gearing, clutches, distribution of power by water or by air.

Group V.—RAILWAY PLANT.

(For construction of railways and tramways, *see* Group iii.; for locomotives, *see* Group iv.; for common road locomotives, *see* Group vi.; for signals *see also* Group xiii.)

Class 30. *Rolling Stock (excepting Locomotives)* —Carriages, trucks, waggons, vans; wheels, tyres, axles, springs, bearings, buffers, couplings.

„ 31. *Fixed and other Appliances.*—Switches, signals, crossings, turntables, switch-locks, communication with trains and in trains, water cranes and other modes of tender supply.

„ 32. *Brakes, Hand and Automatic.*—Screw, chain, compressed air, vacuum, steam, electrical.

„ 33. *Tramways.*—Rolling and fixed plant.

„ 34. *Atmospheric Railways, Portable Railways, &c.*—Rope railways, pneumatic dispatch.

Group VI.—COMMON ROAD CARRIAGES, &c.

(For farm wagons, &c., *see* Group i.)

Class 35. *Carriages for Common Roads.*—Steam, &c., carriages; pleasure and travelling carriages; cabs, omnibuses; hearses; trucks; carts; bath chairs; perambulators; ambulance carriages; machinery used in carriage, &c., construction; indicators; carriage lamps; carriage furniture and fittings; methods and means of propulsion.

„ 36. *Bicycles and Tricycles.*—" Cycles " of every description, and fittings for the same.

„ 37. *Saddlery and Harness.*—Horse clothing; whips; spurs; means and methods of breaking-in horses; disengaging runaway horses.

„ 38. *Farriery.*—Veterinary apparatus and material; medicines for horses, cattle, &c.; horse-shoes, machinery for making horse-shoes and horse-nails; methods of roughing horses; horse-clippers; grooming apparatus.

Group VII.—NAVAL ARCHITECTURE.

(For floating docks, and dredging apparatus, *see* Group iii.; for engines and marine engines, *see* Group iv.; for nautical instruments, *see* Group xxvii.)

*Class 39. *Ship and Boat Building.*—Construction and materials; sheathing, armour plating, launching; cleaning ships' bottoms, preventing fouling; raising sunken vessels, leak-stoppers, life-boats, life-rafts and fittings, life-saving apparatus; light-ships; submarine boats, torpedo boats; loading and discharging cargo.

* „ 40. *Ships' Fittings.*—Masts, sails, rigging, &c.; materials for sails, wire-rigging, self-reefing sails, use of steam power for working sails, anchors and chain cables, means for weighing anchor, steam winches, capstans, lowering ships' boats; pumping and ventilating arrangements.

„ 41. *Marine Propulsion (including Steering).* — Screw propellers, paddles, hydraulic propellers, river and canal propulsion, chain towing, hand, steam, and hydraulic steering gear.

Group VIII.—AERONAUTICS.

(For observing instruments, *see* Group xxviii.; for apparatus for balloon photography, *see* Group xxix.)

Class 42. *Balloons.*—Materials for balloons; methods of constructing and inflating; manufacture and transport of gas for the purpose; fittings; military and captive balloons; balloon equipment for field and siege purposes; fire-balloons; parachutes.

„ 43. *Aeronautic Apparatus.*—Flying machines; propelling and steering apparatus for such machines.

Group IX.—MANUFACTURE OF TEXTILE FABRICS.

(For dyes, mordants, &c., *see* Group xiv.)

Class 44. *Treating Raw Material.* — Cotton—picking, ginning, seed-cleaning, baleing, pressing, opening. Flax, jute, rheea, &c.—retting and its substitutes, breaking, scutching, heckling. Wool—clipping, sorting, washing, drying, heckling. Silk-rearing and feeding of silk-worms, reeling, winding, loading, conditioning.

" 45. *Preparing for Spinning.*—Combing and carding fibrous materials; manufacture of combs and cards.

" 46. *Spinning.*—Drawing, slubbing, roving, spinning, twisting, doubling, throwing, spooling, reeling, balling, &c. Making sewing and darning thread; reels, cops, and cop tubes.

" 47. *Preparing for Weaving.*—Sizing, warping, beaming, &c., yarns.

" 48. *Weaving.*—Weaving plain, figured, damask, and double fabrics, weaving carpets, velvets, and other pile and terry fabrics; weaving ribbons, tapes, &c., hose for water, sacks, sailcloth, hair; jacquards and apparatus for making jacquard cards, electrical and other substitutes; temples, pickers, including pneumatic and other modes of "handing" shuttles; harness, healds, and reeds, weft and other stoppers.

" 49. *Rug and Mat Making.*—Cocoa-nut and other fibre.

" 50. *Lace-making, &c.*—Manufacture of lace, knitted fabrics, hosiery, &c., net and meshed fabrics, nets, fringes, chenille, braid and plaited fabrics, elastic fabrics.

" 51. *Dressing and Finishing.*—Drying, stretching, ageing, dressing, finishing, singeing, shearing, folding, fulling, calendering, measuring, packing, and otherwise preparing for market.

" 52. *Felt-making.*—Manufacture of felted fabrics.

" 53. *Bleaching and Tissue Printing.*—Machines and appliances used in bleaching, dyeing, and printing fibres, yarns, and fabrics; mixtures used in bleaching and washing; dyeing patterns; resist and discharge printing; printing rollers and blocks. Dyeing materials and colours; thickeners.

" 54. *Rope-making.*—Manufacture of twine, cord, rope, safety fuses; materials used in the manufacture.

" 55. *Utilisation of Second-hand Materials and Waste Products.*—Mungo, shoddy, tow, oakum, waste silk, waste cotton.

Group X.—MACHINE TOOLS AND MACHINERY.

(For steam-hammers and forging machinery used in iron and steel making, *see* Group ii.; for machines for making horse-shoes and horse-nails, *see also* Group vi.)

Class 56. *Metal Working Machines.*—Lathes; planers; machines for punching, shearing, sawing, drilling, boring, slotting, shaping, milling, wheel-cutting, screw-cutting, rolling and bending, corrugating, stamping, coining, pressing, riveting, forging; emery wheels, grinding machines, rivet, nail, bolt, and screw-making machinery.

" 57. *Wood-working Machinery.*—Lathes (including lathes for ornamental turning), machines for sawing, planing, moulding, mortising, carving, veneering, cask-making. wheel-making, cork-cutting, &c.

" 58. *Stone-working Machinery.*—Machines for sawing, planing, turning, dressing, polishing, grinding, breaking and crushing stone and slate.;

Group XI.—HYDRAULIC MACHINES, PRESSES, MACHINES FOR RAISING HEAVY WEIGHTS, WEIGHING, &c.

(For hay and straw elevators, *see* Group i.; for elevators used in building, *see* Group iii.; for hydraulic rams, *see* Group iv.; for grain elevators, *see* Group xvii.; for chemical, &c., balances, *see* Group xxviii.)

Class 59. *Pumps, hand, steam, rotary, centrifugal.*—Ships' pumps, pumps for corrosive fluids; hydropults; syphons; methods of raising water; methods of obtaining, distributing, and equalising hydraulic power; accumulators.

* ,, 60. *Fire-engines.*—Fire-extinguishing apparatus; automatic apparatus for indicating and extinguishing fires; fire-escapes, ladders, fire-hose, accessory fittings and appliances; hydrants.

,, 61. *Cranes and other Lifting Apparatus.*—Hand, steam, and hydraulic cranes; travellers; elevators, jacks, capstans, windlasses, crabs, hoists, blocks, pulleys, derricks.

,, 62. *Hydraulic and other Presses.*

,, 63. *Weighing Machines (for commercial purposes).*—Steel-yards, platform weighing machines; commercial balances, scales, weights, &c., registering weighing machines, spring balances.

Group XII.—ELEMENTS OF MACHINES.

Class 64. *Mechanical Movements.*

,, 65. *Separate parts of Machines.*

Group XIII.—ELECTRICITY.

(For railway signals, *see* Group v.; for photometers, *see* Groups xv. and xxviii.; for scientific apparatus used in electrical research, *see* Group xxviii.)

Class 66. *Generators.*—Dynamos, primary and secondary batteries, thermo-electric batteries.

,, 67. *Conductors.*—Submarine cables and apparatus for laying them; aerial wires and underground cables; insulators and poles; insulating and coating materials; joints and connections; underground conduits; pipes, tubes, troughs, &c., electric light leads.

,, 68. *Testing and Measuring Apparatus.*—Galvanometers, magnetometers, dynamometers, volt-meters, current-meters, methods of testing.

,, 69. *Telegraphic and Telephonic Apparatus.*—Needle instruments, A.B.C. instruments, Morse instruments, type-printers, relays, duplex and quadruplex apparatus, keys, recording instruments, automatic transmitters, electric bells, indicators, telephones, microphones, lightning protectors.

,, 70. *Electric Lighting Apparatus.*—Lamps, resistance coils, cut-outs, safety catches, switches. Fittings for glow and other lamps.

,, 71. *Electro-metallurgy and Electro-chemistry.*—Methods of depositing and coating various metals. Electrotyping, galvano-plasty. Vats, cleaning and polishing apparatus, materials, tools, and appliances.

,, 72. *Distribution and Utilisation of Power.*—Electric railways, electric motors, electrically driven boats, tricycles, and other conveyances, systems of distribution.

,, 73. *Electric Signalling.*—Fire and burglar alarms, railway, ship, and time signals, water level and wind indicators, tell-tales, electric clocks, chronoscopes, &c.

CLASS 74. *Lightning conductors.*

" 75. *Electro-medical apparatus.*

" 76. *Electrolytic methods for extracting and purifying metals.*—Copper, zinc, lead, iron, refining the precious metals.

" 77. *Electro-Thermic Apparatus.*—Electrical apparatus for war, mining, blasting and other purposes.

GROUP XIV.—APPARATUS, PROCESSES, AND APPLIANCES CONNECTED WITH APPLIED CHEMISTRY AND PHYSICS.

(For chemical apparatus used in scientific research, *see* Group xxviii.)

CLASS 78. *Inorganic Products, and means used in obtaining them.*—Sulphuric and other acids, alkalies and ammonia, bleaching agents, dyes and dye-stuffs, salts, whitelead, pigments, and other paints, phosphorus, lucifer matches, disinfectants.

" 79. *Organic and Synthetical Products, and means used in obtaining them.*—Coal tar products, oils, soaps, and detergents, lubricating agents, candles, perfumery, paraffin, varnishes, manures.

" 80. *Apparatus and Appliances for Compressing and Liquefying Gases, and applications thereof.*

GROUP XV.—GAS AND OTHER ILLUMINANTS.

(For electric lighting, *see* Group xiii.; for gas-stoves, *see* Group xvi.; for photometrical apparatus, *see also* Group xxviii.)

CLASS 81. *Coal Gas.*—Manufacture, purification, storage, and distribution of gas; treatment of residues.

" 82. *Water Gas, Oil Gas, Carburetting Air, &c.*

" 83. *Tests and Photometrical Apparatus.*—Chemical tests; standards of light; measurement of light.

" 84. *Burners, and means of Utilising and Applying Gas.*—Gas fittings; burners for illuminating gas; devices for imparting luminosity to flame; gas-meters; methods of lighting gas; methods of increasing illuminating power of gas.

" 85. *Mineral and other Oils.*—Methods of obtaining; distilling and refining; testing.

" 86. *Candles, &c.*—Candles of wax, tallow, sperm, paraffin, &c.; night-lights, appliances used in the manufacture.

" 87. *Lamps for Oil and Spirits, Holders for Candles, &c.*

GROUP XVI.—FUEL, FURNACES, &c.

(For coke ovens and metallurgical furnaces, *see* Group ii.; for glass, &c., furnaces, *see* Group xxiii.)

CLASS 88. *Manufacture of Fuel.*—Materials and processes for the manufacture of artificial fuel; preparation and use of liquid fuel; preparation of peat; charcoal burning.

" 89. *Furnaces for Manufacturing Purposes.*—Furnaces for burning solid, pulverised, liquid and gaseous fuel.

* " 90. *Stoves for Coal, for Gas, for Oil, &c.*—Cooking stoves and kitchen ranges; domestic fire-places; gas cookers; gas burners for heating and cooking; petroleum and other stoves for heating and cooking.

Group XVII.—FOOD, COOKERY AND STIMULANTS.

(For the cooking of cattle food, *see* Group i.)

Class 91. *Machinery for Treating Grain and Flour.*—Machines for preparing and grinding corn and dressing flour, and other mill machinery; mill-stone dressers, roll turners, and similar machines; machines for milling and polishing rice; grain elevators; apparatus for drying grain; granary fittings.

* " 92. *Manufacturing Articles of Food.*—Apparatus for manufacturing and refining sugar; confectioners' machinery; machines and appliances for preparing mustard, spice, pepper, &c.; manufacture of salt.

* " 93. *Preserving Food.*—Methods, materials, and processes for preserving animal and vegetable food, machines for producing cold.

* " 94. *Bread and Biscuit Making.*—Kneading machines, biscuit and bread-making machines, ovens; processes for making bread.

* " 95. *Cooking Apparatus.*—Culinary utensils, chopping and mincing machines, apparatus for paring and slicing fruit and vegetables, cleaning fruit, washing and cleaning vegetables.

" 96. *Brewing, Distilling, and Wine-making.*—Machines and appliances connected with the manufacture and use of alcoholic drinks.

* " 97. *Manufacture of Aërated Waters.*—Machinery, materials, &c., used for the purpose. Stoppers and other appliances.

* " 98. *Infusions.*—Apparatus, &c., used in the preparation and use of tea, coffee, chocolate, &c.

* " 99. *Tobacco.*—Machinery, appliances, and processes for treating and using tobacco.

Group XVIII.—CLOTHING.

(For textile machinery, *see* Group ix.; for jewellery, &c., *see* Group xix.; for waterproof clothing *see* Group xxi.)

* Class 100. *Fabrics.*—Specimens of new materials, or materials recently applied to the manufacture of clothing.

* " 101. *Articles of Clothing.*—Specimens of clothing of novel construction.

* " 102. *Machinery and Apparatus.*—Machinery, &c., used in the production of articles of dress, sewing machines, knitting machines, machinery for the manufacture of boots, hats, gloves, &c., needles, and machinery employed in making them.

* " 103. *Cleaning Clothing.*—Washing and wringing machines, mangling, &c., machines; boot-cleaning machines; machines and processes for cleaning other articles of clothing.

* " 104. *Dress Fastenings, &c.*—Buttons, pins, hooks and eyes, machinery employed in their manufacture.

Group XIX.—JEWELLERY.

Class 105. *Jewellery and Personal Ornaments.*—Materials, apparatus for manufacture, &c.

Group XX.—LEATHER, &c.

(For saddlery, *see* Group vi.; for boots and shoes, *see* Group xviii.)

Class 106. *Manufacture of Leather.*—Materials, processes and appliances for cleaning, curing, preserving, unhairing, drying, tanning, dyeing, splitting, dressing, and otherwise preparing skins and hides. Specimens of leather prepared by new processes. Manufacture of parchment.

„ 107. *Treatment and Application of Leather (exclusive of saddlery and of boots and shoes).*—Methods of ornamenting, painting, polishing, staining, waterproofing, &c., leather.

„ 108. *Artificial Leather.*—Imitation leather, waterproof canvas, and tarpaulin.

Group XXI.—INDIA-RUBBER AND GUTTA-PERCHA, &c.

(For use of gutta-percha, &c., in electrical insulation, *see* Group xiii.; for artificial leather, *see* Group xx.; for kamptulicon, *see* Group xxi.)

Class 109. *Machinery for treating India-Rubber and Gutta-Percha.*—Washing machines, rasps, masticators, mixing machines, vulcanisers, spreading machines, thread-making machines, wire-covering machines; machines for manufacturing rubber goods, pressers, moulds, &c.; appliances for stereotyping in rubber.

„ 110. *Applications of India-Rubber and Gutta-Percha.*—Waterproof goods; elastic webbing; articles of unvulcanised and vulcanised rubber and gutta-percha, and fabrics prepared therewith; ebonite, vulcanite, and articles made therefrom; complex or insertion goods; kamptulicon, &c.; cements; grinding wheels; bottle-stoppers; printing rollers.

„ 111. *Substitutes for India-Rubber and Gutta-Percha, materials used in their treatment, &c.*—Natural substances available as substitutes; artificial substitutes; combinations of rubber or gutta-percha with other materials; rubber, &c., from new sources of supply; pigments, solvents, &c., used in the manufacture; celluloid and other preparations of nitrated cellulose.

Group XXII.—FURNITURE AND ACCESSORIES—FANCY GOODS.

(For bronzes and alloys, *see* Group ii.; for household fixtures, *see also* Group iii.; for manufacture of carpets, *see* Group ix.; for rug and mat making, *see also* Group ix.; for glass and china, *see* Group xxiii.; for paper hangings, *see* Group xxvi.)

* Class 112. *Furniture and Upholstery.*—Articles of furniture; machinery and processes used in their production; frames for pictures and mirrors; safes.

* „ 113. *Floor-coverings and wall-coverings (other than paper-hangings).*—Oilcloth; linoleum, kamptulicon; mats and matting; material, appliances, and processes used in their manufacture.

„ 114. *Artistic and ornamental metal work.*—Goldsmiths' and silversmiths' work; electro-plate; ornamental bronzes; appliances used in the manufacture.

„ 115. *Trunks, portmanteaux, &c.*—Dressing bags, cases, ivory horn and bone goods; travelling equipments.

„ 116. *Basket-work.*—Appliances for use in the manufacture.

„ 117. *Brushes.*—Materials; machines and appliances used in the manufacture; methods of brush-making.

„ 118. *Umbrellas, Parasols, and Walking Sticks.*—Machinery, &c., used in their manufacture.

Group XXIII.—POTTERY AND GLASS.

(For optical glass, *see* Group xxviii. : for glass apparatus, *see* Group xxviii.)

Class 119. *Kilns and Furnaces.*
,, 120. *Bricks, Tiles, Earthenware, &c.*—Terra cotta; architectural pottery; fire-clay goods; crucibles; drain-pipes; chemical and similar stoneware; materials, machinery, and apparatus.
,, 121. *Porcelain, Majolica, and Artistic Pottery.*—Biscuit ware, faience; Parian; materials, machinery, and apparatus.
,, 122. *Crown, Sheet, and Plate Glass.*—Window glass, mirrors, stained glass; glass mosaic; materials, machinery, and apparatus.
,, 123. *Bottles, Table Glass, Toughened Glass, &c.*—Materials, machinery, and apparatus.

Group. XXIV.—CUTLERY, IRONMONGERY, &c.

(For nail and screw-making machinery, *see* Section x.)

Class 124. *Cutlery and Tools.*—Engineers', carpenters', joiners' &c., tools.
,, 125. *Surgical Instruments and Appliances.*—
,, 126. *Files and Rasps.*—File-cutting machines.
,, 127. *Hardware.*—Hollow ware; ornamental castings; locks and bolts.
,, 128. *Screws, Nails, &c.*—Spikes, hinges; furniture fittings.

Group XXV.—FIRE-ARMS, MILITARY WEAPONS, AND EQUIPMENT; EXPLOSIVES.*

(For fortification, *see* Group iii.; for torpedo boats, *see* Group vii.; for special articles mentioned under "military equipment" *see also* respective classes.)

Class 129. *Ordnance.*—Heavy guns and means of working them; carriages and accessories; naval, siege, field, and mountain guns; machine guns; mitrailleuses; shells, and apparatus for their manufacture; apparatus used in testing, in measuring velocity, pressures, recoil, &c.
,, 130. *Fuses, Detonators.*—Appliances for firing guns, and for exploding shells, signal lights, war and signal rockets, life-saving rockets.
,, 131. *Guns, Rifles, Pistols.*—Military and sporting guns and rifles; revolvers; magazine guns; harpoon guns; air guns; machinery used in the manufacture of small arms; proving apparatus; targets.
,, 132. *Swords, Bayonets, Sappers' Tools, &c.*—Entrenching tools; shields; lances; dirks;
,, 133. *Gunpowder and Ammunition.*—Explosives generally, and apparatus used in their manufacture and testing; cartridges; cartridge cases.
,, 134. *Torpedoes.*—Submarine and subterranean torpedoes and mines, methods of laying, firing, and removing the same; naval torpedoes, means of carrying, projecting and firing the same.
,, 135. *Telemeters.*—Range-finders for artillery and submarine mine service.
,, 136. *Military Equipment.*—Photographic, telegraphic, pontoon, mining, signalling, hospital equipment; transport service.

* Explosive substances will under no circumstances be admitted. They must be represented by dummies or models.

Group XXVI.—PAPER, PRINTING, BOOKBINDING, STATIONERY, &c.

(For applications of photography to printing, *see also* Group xxix.)

Class 137. *Machines and Processes for the Manufacture of Paper, Paste-board and Papier-Mâché.*—Materials; manufacture of "half-stuff"; washing, beating, and bleaching engines; agitators, strainers, moulds; methods, &c., of glazing and planishing; methods of treating waste paper; appliances, &c., for treating and moulding papier-mâché; manufacture of artificial parchment; recovery of waste products, and preventing the pollution of streams.

" 138. *Machines, &c., for Cutting, Folding, and Ornamenting Paper.*—Stamping; embossing; envelope and bag making; manufacture of playing cards; chromo-lithography; paper box machines; marbling; perforating; ruling; waterproofing; enamelling.

" 139. *Paper-hangings.*—Printing machines; apparatus for engraving printing rollers; materials; tests for injurious materials.

" 140. *Letter-press and other Printing.*—Printing machines and presses; glazing and hot-pressing apparatus; apparatus, &c., for type-founding; lithographic machinery, materials, &c.; stereotyping apparatus, &c.; methods of anastatic printing; process blocks from autographic drawings; wood blocks; engraving machines; machines for cutting wood letter; type-setting machines, numbering machines, printers' furniture and locking-up appliances; production of printing surfaces; methods of printing cheques, bank-notes, &c.

" 141. *Bookbinding, Manufacture of Portfolios, &c., Applications of Papier-Mâché.*—Materials; bookbinding machines, wire-stitching machines, cutting presses, rounding machines, backing machines, arming presses; account books, desks, cases, &c., for stationery, &c.; purses.

" 142. *Artists' Implements and Materials.*—Pencils, brushes, colours and varnishes, easels, crayons, palettes, palette knives, drawing boards, drawing instruments, pencil sharpeners.

" 143. *Writing Materials and Appliances.*—Type-writers; manifold writers; copying presses and processes; processes for multiplying copies of MS.; pens; ink; penholders; inkstands; sealing-wax; stationery.

Group XXVII.—CLOCKS, WATCHES, AND OTHER TIME-KEEPERS.

(For electrical clocks, *see also* Group xiii.)

Class 144. *Clocks.*—Timepieces and other domestic clocks; regulators and astronomical clocks; watchman's, calendar, turret, electrical and pneumatic clocks; hour-glasses, sun-dials, water-clocks.

" 145. *Time Signals, &c.*—Methods of controlling and synchronising clocks; apparatus for the distribution and signalling of time; also for the determination of time by astronomical observations.

" 146. *Watches and Chronometers.*—Examples illustrative of stages of manufacture and of the different types of watches and of chronometers; keyless, chronograph, repeating, calendar, and other forms of watches.

" 147. *Tools, &c.*—Lathes and mandrils; wheel-cutting engines; machine tools for producing the several parts of watches on the "interchangeable" system; various hand-tools used in the manufacture and repair of clocks and watches; gauges and templates; appliances used in case-making.

Group XXVIII.—PHILOSOPHICAL INSTRUMENTS AND APPARATUS.

(For testing machinery, *see* Group iii.; for commercial weighing apparatus, *see* Group xi.; for practical applications of electrical apparatus, *see* Group xiii; for industrial applications of chemistry, *see* Group xiv.)

Class 148. *Optical.*—Lenses, prisms, telescopes, microscopes and accessories, spectroscopes, polariscopes, polarimeters, stereoscopes, photographic lenses, spectacles, eye-glasses, optical glass.

„ 149. *Astronomical.*—Telescopes (astronomical), transit instruments, equatorials, mural circles, driving clocks, siderostats, heliostats, altazimuths, methods of fitting observatories and mounting instruments.

„ 150. *Physical.*—Acoustic apparatus, tuning forks, sirens, phonautographs, phonographs; apparatus connected with molecular physics, air-pumps, manometers, radiometers; apparatus for measuring, &c., heat, thermometers, pyrometers, calorimeters; photometers; kinematic, static and dynamical apparatus, mechanics.

„ 151. *Electrical.*—Friction and induction machines, batteries and other sources of electricity, Leyden jars, condensers, electroscopes, electrometers, galvanometers, voltameters, dynamometers, magnetometers, rheostats, resistances, electrical units, induction coils, thermopiles, vacuum tubes.

„ 1 *Chemical.*—Thermometers, hydrometers, pyrometers, furnaces, blowpipe apparatus, assaying apparatus, apparatus for organic and inorganic analysis, for gas analysis, and for volumetric analysis, laboratory fittings and apparatus generally, balances, reagents.

„ 153. *Mathematical.*—Calculating machines, indicating and registering apparatus, pedometers, counting machines, slide rules, planimeters, drawing instruments, ellipsographs, straight-edges, gauges, surface planes, dividing engines, pantographs, eidographs.

* „ 154. *Meteorological.*—Barometers, thermometers, rain gauges, manometers, hygrometers, aneroids, anemometers, ozonometers, storm-signalling apparatus.

„ 155. *Geographical.*—Surveying apparatus, theodolites, chains, levels; underground surveying apparatus; apparatus for hydrographic surveying, and for marine investigations and observations; hypsometrical instruments, tide gauges; seismographical apparatus; projections, maps, charts, models, and globes.

* „ 156. *Nautical.*—Sextants, quadrants, sounding apparatus, logs, compasses.

„ 157. *Weighing and Measuring.*—Weights, scales, balances; measures of length, graduated scales, verniers, steel tapes; measures of capacity; instruments for angular measurement, clinometers, goniometers.

„ 158. *Biological.*—Apparatus for anatomical research; physiological apparatus; apparatus for collecting and preserving natural history specimens.

Group XXIX.—PHOTOGRAPHY.

(For applications of photography to printing, *see also* Group xxvi.; for photographic lenses, *see* Group xxviii.)

Class 159. *Processes and their results.*—Methods of gelatino-bromide plate-making, apparatus for making emulsion, apparatus for separating the sensitive constituent, coating, drying and packing machines; emulsion and other processes; printing processes, silver, carbon, Woodbury-type, platinotype, gelatino-bromide, collodio-chloride of silver, &c., apparatus for washing, &c., prints and negatives; methods for making photographic lantern slides.

CLASS 160. *Apparatus (excluding lenses).*—Cameras, shutters, changing-boxes, slides, tents, lamps; apparatus for making enlargements and for micro-photography.

" 161. *Application of Photography to various purposes, Typography, Ceramics, Relief-moulds, &c.*—Method of producing printing surfaces; photographic enamels, photographic printing on pottery; photographic reliefs. Use of photography in self-recording apparatus, in scientific observations, &c.

GROUP XXX.—EDUCATIONAL APPARATUS.

* CLASS 162. *Models and Apparatus.*—Appliances used in primary, scientific, technical, and artistic instruction.

GROUP XXXI.—TOYS, SPORTS, &c.

(For sporting guns, *see* Group xxv.)

CLASS 163. *Toys, Games, and Exercises.*—Outdoor games; gymnastic apparatus; skates, artificial skating surfaces; indoor games; billiard tables.

* " 164. *Field Sports.*—Apparatus used in hunting, fishing, shooting, &c.; traps for animals, birds, vermin, &c.

" 165. *Scenic and Dramatic Effects.*—Theatrical fittings and apparatus; optical (magic) lanterns and apparatus for illuminating them.

DIVISION II.—MUSIC.

GROUP XXXII.—INSTRUMENTS AND APPLIANCES CONSTRUCTED OR IN USE SINCE 1800.

CLASS 166. *Organs.*—Details of construction; machines for blowing, hydraulic or otherwise; details of mechanism and the construction of pipes; pneumatic apparatus for keyboards and couplers, electric appliances, designs for organs, designs for organ-cases.

" 167. *Harmoniums.*—American organ, vocalions, concertinas, accordions, varieties of reeds and air-channels, details of construction.

" 168. *Wind Orchestral Instruments.*—(*a*) Wood; (*b*) Brass.

" 169. *Pianofortes* (Grand, square, and upright).—Models of framings, castings, models of actions, pedal appliances, mechanical devices for tuning and transposing, wire and other material used in construction, designs for cases.

" 170. *Violins, and instruments of the Violin family; also Bows, strings;* and inventions connected with these instruments.

" 171. *Harps.*

" 172. *Automatic and Barrel Instruments.*

,, 173. *Drums, Cymbals, and other instruments of percussion.*
,, 174. *Bells and Carillons.*
,, 175. *National Instruments of all countries not ordinarily used in orchestras.*
,, 176. *Sirens, Tuning Forks, Pitch Pipes, Tonometers,* and appliances for the determination of pitch.
,, 177. *Miscellaneous Musical Appliances.*—Metronomes, desks, seats, appliances for forming the hand ; instruments for recording improvisation.

Group XXXIII.—MUSIC, ENGRAVING, AND PRINTING.

Class 178. *Printed and Engraved Music; and Machines and Appliances for its production.*

Group XXXIV.—HISTORIC COLLECTIONS.

Class 179. *Musical Instruments and Appliances.*
,, 180. *Pictures, Engravings, and Drawings of Musical Subjects.*

INTERNATIONAL INVENTIONS EXHIBITION, 1885.

CLASSIFICATION.

(UNDER REVISION).

NOTE.

The heads given below are not intended to be exhaustive, but are rather to be regarded as indicative of the proposed scope of each class.

Only under exceptional circumstances can applications be entertained for space for objects which have been shown in the Smoke Abatement Exhibition, 1881*; the Fisheries Exhibition,* 1883*; or the Exhibition of Health and Education,* 1884*; or for Agricultural Implements. The space allotted to those Classes marked with an asterisk, will therefore be very limited.*

DIVISION I.—APPARATUS, APPLIANCES, PROCESSES, AND PRODUCTS, INVENTED OR BROUGHT INTO USE SINCE 1862.

Group I.—AGRICULTURE, HORTICULTURE, AND ARBORICULTURE.

(For land drainage, reclamation, &c., *see* Group iii.; for agricultural engines, *see* Group iv.; for manure *see* Group xiv.; for milling machinery, *see* Group xvii.)

* Class 1. *Field Implements.*—Ploughs, drain-ploughs, cultivators, steam-diggers, harrows, drills, haymakers, horse-hoes, rakes, reapers, mowers, binders, anchors and rope porters, wagons, wagon-harness.

* ,, 2. *Barn and Farm-yard Implements.*—Thrashing machines, screens, winnowers, corn-cleaning machines, hay and straw elevators, hay and straw and fresh fodder compressors, turnip-cutters, chaff-cutters, grist mills, horse-gear, crop dryers.

* ,, 3. *Dairy and Poultry-Farm Appliances.*—Milking appliances, cream-separators, churns, cheese-making apparatus, apparatus for manufacturing butterine, incubators.

* ,, 4. *Agricultural Construction.*—Models, plans and designs for farm buildings, oast houses, siloes, rickstands, &c.

* ,, 5. *Cattle Food.*—Materials, processes, apparatus, seed mills, cake crushers, boilers, steamers and cooking apparatus; feeding appliances.

,, 6. *Horticultural Apparatus.*—Hot-houses, frames, greenhouses, orchard houses, graperies, boiler and heating apparatus, lawn mowers, watering apparatus, tools and implements, pots and plant boxes, garden wire work, chairs, &c., plant labels.

,, 7. *Arboriculture.*—Apparatus, &c., used in forestry; methods and material for the preservation from decay of trees and timber.

Group II.—MINING AND METALLURGY.

(For stone-working machinery and testing machines, *see* Group x.; for metal-working machinery, *see* Group x.; for slate sawing and dressing machines, *see also* Group x.; for electrolytic methods extracting, &c., metals, *see* Group xiii.; for furnaces in general, *see* Group xvi.; for manufacture of fuel, *see also* Group xvi.; for explosives, *see also* Group xxv.; for mine-surveying apparatus, *see also* Group xxviii.)

Class 8. *Machinery and Appliances used in Mines and Quarries.*—Prospecting searching, boring, shaft sinking, exploring, working, hauling, pumping, winding, hoisting; man engines, safety catches, safety hooks, hydraulic mining; tools, drills, cutters, getters, breakers, air compressors; blasting substitutes for explosives. Ventilating, lighting. Aids to respiration in mines. Life-saving appliances. Washing and dressing coal and other minerals, crushers, pulverisers, disintegrators, stamps, screens, riddles, separators, classifyers, jiggers, buddles, precipitators, sawing-machines. Utilisation of waste.

„ 9. *Production and Manufacture of Iron and Steel.*—Coke ovens, blast and other furnaces; Bessemer plant, Siemens plant, other processes for making iron and steel; blast engines; hot-blast stoves; steam and other hammers; rolling machines, hydraulic and other forging machines, squeezers and other shingling apparatus; production and use of malleable cast iron; wire-making apparatus; manufacture of tin plate, utilisation of gases and of slag; alloys and artificial compounds of iron with non-metallic elements.

„ 10. *Forging and Foundry Work.*—Cupolas, air furnaces, pot furnaces; moulding machines, plate-moulding; forges, forging machines; blowers, bellows, fans.

„ 11. *Metallurgy of Metals other than Iron, with the exception of the precious metals. Alloys.*—Furnaces and appliances used in the dry and wet methods of extracting and purifying copper; extraction of lead; metallurgy of zinc, tin, nickel, cobalt, bismuth, antimony, arsenic, mercury, aluminium; manufacture of sheet lead, lead pipe, Muntz's metal, sheet zinc, copper and brass tubes; bronzes, German silver and other nickel alloys; wires of copper and its alloys.

„ 12. *Metallurgy of the precious metals, Gold, Silver, and Platinum.*—Furnaces and appliances used in the dry and wet methods of extracting the precious metals; desilverisation of lead; amalgamation in all its forms, refining gold and silver; purification, melting and working of platinum and its alloys.

Group III.—ENGINEERING CONSTRUCTION AND ARCHITECTURE.

(For railway plant, *see* Group v.; for launching ships, *see* Group vii.; for surveying instruments, *see* Group xxviii.)

Class 13. *Roads.*—Methods and materials for constructing and paving roads; cleansing roads and pavements; road-sweeping machines; rollers; apparatus for the removal of mud, snow, &c.; water-carts and other means of watering.

„ 14. *Railways and Tramways.*—Construction; excavators and appliances used for earth-work and tunnelling. Permanent way; rails, chairs, sleepers.

„ 15. *Bridges and Viaducts.*—Models, plans, and designs for arched, girder, suspension, trestle, and other bridges; apparatus used in construction.

Journal of the Society of Arts.

No. 1,652. Vol. XXXII.

FRIDAY, JULY 18, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

THE ALBERT MEDAL.

The Council of the Society of Arts attended on the 16th inst., at Marlborough-house, when his Royal Highness the Prince of Wales presented to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S., the Albert Medal awarded to him in 1883, "for the eminent services which, as a botanist and scientific traveller, and a Director of the National Botanical Department, he has rendered to the Arts, Manufactures, and Commerce, by promoting an accurate knowledge of the floras and economic vegetable products of the several colonies and dependencies of the Empire," and to Captain James Buchanan Eads, the distinguished American engineer, the Albert Medal for the present year, awarded to him "for his works, which have been of such great service in improving the water communications of North America, and have thereby rendered valuable aid to the commerce of the world."

The members of Council present were Sir Frederick Abel, C.B., F.R.S., chairman, Sir George Birdwood, Sir Frederick Bramwell, Mr. Brudenell Carter, Mr. Andrew Cassels, Mr. Edwin Chadwick, C.B., Mr. T. R. Crampton, Professor Dewar, F.R.S., Capt. Douglas Galton, F.R.S., Sir John Lubbock, Bart., F.R.S., Mr. J. M. Maclean, Mr. W. G. Pedder, Mr. W. H. Preece, F.R.S., Sir Robert Rawlinson, C.B., Lord Reay, Mr. Owen Roberts, Lord Sudeley, Sir Richard Temple, Bart., G.C.S.I., Colonel Webber, C.B., with Mr. H. Trueman Wood, secretary, and Mr. H. B. Wheatley, assistant secretary.

WATER SUPPLY CONFERENCE.

The Conference on Water Supply by the Society of Arts, will be held at the Health Exhibition on the 24th and 25th inst. The Conference will meet each day at 11 a.m., and will sit till 1.30, then adjourn till 2, and sit again till 5 p.m. The proceedings will be opened on Thursday, at 11, by the Chairman. The papers and discussions will be arranged under the following heads:—1. Sources of Supply. 2. Quality of Water; Filtration and Softening. 3. Methods of Distribution; modes of giving pressure; house fittings; discovery and prevention of waste, &c., &c. The proceedings will be continued on Friday, and, if necessary, on Saturday. The readers of papers will be restricted to twenty-five minutes. Speakers will be restricted to ten minutes. The papers to be read will, in most instances, be printed and distributed in the room. Members desiring to attend the Conference will be furnished with tickets admitting to the Exhibition and to the Conference-room, on application to the Secretary of the Society of Arts, John-street, Adelphi.

INTERNATIONAL EXHIBITION OF INVENTIONS, 1885.

A supplement issued with the present number of the *Journal*, gives the full text of the Classification for the International Exhibition of Inventions to be held next year at South Kensington. As already announced, the Exhibition will consist of two Divisions, the first to consist of apparatus, appliances, processes, or products, invented or brought into use since 1862, and the second of examples of musical instruments of a date not earlier than the commencement of the present century. Division II. will also comprise machinery, apparatus, and appliances connected with music, and, in addition, historical collections of musical instruments, and paintings and engravings representing musical subjects.

The Executive Council, of which Sir Frederick Bramwell is chairman, have issued a series of regulations indicating the scope of the Exhibition, and the limitations which have been considered necessary in order to confine it within the available space. It is announced that the space devoted to those subjects which may be considered to have been sufficiently illustrated in recent exhibitions will be limited, and regulations have also been made as to the admission of large machines, or of models illustrating their working.

Applications from intending exhibitors are to be made not later than the 15th of September, and it is promised that the allotment of space will be completed by the beginning of December.

For further information, copies of the regulations, prospectuses, forms, &c., application should be made to the Secretary of the Exhibition, Mr. Edward Cunliffe-Owen, at the Exhibition-offices, South Kensington.

Proceedings of the Society.

CANTOR LECTURES.

ALLOYS USED FOR COINAGE.

By W. Chandler Roberts, F.R.S.
Chemist of the Royal Mint; Professor of Metallurgy, Royal School of Mines.

Lecture I.—Delivered Monday, Mar. 17, 1884.

At a very critical period of the history of the alloys used for coinage, one of the earliest of the English political economists, William Stafford, dedicated a little work to Queen Elizabeth, in which, under the form of a dialogue sustained by a knight, a doctor, and a merchant, he shows a keen appreciation of the conditions which a metallic currency has to meet.

The doctor complains of the base alloys circulated as coin in the previous reign, to which the knight (who tells us incidentally that he "was once in Parliament") replies:—"Forsooth, and such a dullard am I indeed, yt I cannot perceave what hinderance it should be to the realm to have this metal more than that for our coyne, seeing the coyne is but a token to goe from man to man when it is stricken with the prince's seale. . . . If ye prayse the gold for his weight and pliableness, led [lead] doth excel it in these pointes; if ye commend his colour, silver bye many men's judgement passeth him." The doctor then enters on an eloquent defence of the use of the precious metals for coinage, and sets forth what he calls "a briefe conceipte of English pollicye with regard to currency."*

* London, 1581.

At the present day, preference for one metal more than another, or for the simultaneous use of two metals, as standards of value, is widely and forcibly expressed; but although it is generally known that neither sovereigns nor shillings are made of pure gold or pure silver, few people have very definite ideas as to the composition of the alloys which are employed in coinage, and still fewer are aware that the amount of base metal added to the precious one is guarded with the most rigorous care. As showing the national importance of the subject, it may be mentioned that between 700 and 800 tons of the alloy of gold and copper constitute the gold coinage of this country.

There is a great difficulty in tracing, chronologically and in detail, the history of the mechanical side of the art of coining, because its progress has been by no means continuous. Certain types of machines have survived persistently in some countries, and have been abandoned in others often to be again introduced with or without modification. A good illustration of this difficulty is presented by the fact that the method of coinage practised in this country under the Plantagenet kings is still met with in native mints in India; and, conversely, a machine—the *mouton*—used for striking coins in France and Italy, and abandoned in the 13th century, is now employed in Birmingham, and in the Mint of this country, in the preparation of medal clasps. Again, the screw-press, invented in the 14th century, and long used for coining, is employed for striking medals in all mints in almost its primitive form; while a machine the action of which depends on a very different principle, is as universally adopted for striking coins.

It is safe, however, to conclude that while in civilised countries, at least since the 13th century, the designs of coins have always fairly represented the general artistic culture of the periods at which they were struck, the appliances used in their manufacture have, at times, been distinctly behind the mechanical science of their days, as indicated in other technical arts. For the last fifty years, until the year 1882, the Mint in this country presented a striking example of this, as its machinery was admitted to be antiquated, while the general progress of mechanical science, during the same period, was probably greater than at any other time.

Further, there can be no doubt that, viewed from a modern standpoint, there have been periods during which the work of the metallurgist—in the purification of precious metals, in alloying them, and in verifying their "standards"—has been greatly in advance of that of the artist who engraved the dies, or of the mechanician who struck the coins.

The historian of the coinage of Great Britain begins his great work* by stating that "in the most early stage of society, when the wants of man were confined to the absolute necessaries of life, barter may be sufficient for every purpose of exchange. But this is a point at which society cannot long remain fixed; and the first step towards civilisation introduces a train of wants that will require a more perfect medium of commerce; something which, by general consent, shall be received at a determinate value, in exchange for all other things." The problem is, however, by no means a simple one, and it is usual, in even the most elementary works, to give examples of articles, such as fruits, shells, and skins, which have been used in abortive attempts to find this common medium of exchange, under the adverse circumstances of imperfect civilisation.

M. Boucher de Perthes held that prehistoric stone implements were among the earliest mediums of exchange, a suggestion which Jevons considers not improbable. Metallic implements certainly would meet many of the necessary conditions of money. Even with regard to metals, I may remind you that Artemus Ward felt he must refuse the coffin-plates† and door-knockers offered him for admission to his lecture, for, although these were metallic, fairly portable, and may even have borne engraved devices, they did not meet the necessary condition of being universally acceptable.

The circulation of gold and silver by weight approached nearest to the convenience of coins; but even this method was open to the objection that the masses of metal bore no external evidence of their value, and, therefore, much time had to be devoted to weighing or assaying them, and these difficulties were not removed until coined money was devised, the stamp being an authoritative indication of its weight, standard, and value.

The commodity for exchange must be in such general use as to ensure the certainty of its being readily acceptable, and further, as Nicolas Oresme pointed out in the 14th century, it must be of value, *materia preciosa et cara*;* or as a later writer, Rice Vaughan, said in 1675, money should be made of a material which is not too common, "something not easy to be consumed with use, or spoiled for want of use." Further, it must be portable.† "I confesse" (said William Stafford), "precious stones do excell siluer, or yet golde as in value or lightness of carriage, but then, they may not be deuided without injury, nor yet put agayne together after they be once deuided." ‡

* "Annals of the Coinage," by the Rev. Rogers Ruding. 3rd edition, 1840.

† "Travels." English ed., p. 98.

The quality of being easily divided is very important. "The tailor," says Jevons, as we are reminded in several treatises on political economy, "may have a coat ready to exchange, but it much exceeds the value of the bread which he wishes to get from the baker. He cannot cut the coat up without destroying the value of his handiwork."

That is no reason, however, why articles of clothing most needed should not be represented by metallic symbols, as was actually done in a very early form of Chinese money, which was not struck but cast. These curious coins are said to go back four thousand one hundred years, and to have been made certainly in the time of Yaou B.C., 3256.§ The coin from the Mint collection (of which a drawing was provided), represents a Chinese shirt, and, in fact, pieces of cloth, or these metallic equivalents, were used, as Sir John Lubbock has pointed out, "in some measure, as a standard of value, almost as grey shirting is even now."||

Lenormant, speaking of Roman coins, considers that casting did not precede striking, and, quoting Mommsen, he points out that the Romans adopted the method of casting for the sake of cheapness and speed.¶ Information respecting the details of the method of casting will be found in papers published in the *Numismatic Chronicle*, from which it appears that, "under the reigns of the Cæsars, Constans, and Constantius, there were cast, in a mint established at Bibé, large quantities of money with the stamp of the emperors who had reigned from Caracalla to

|| *Nineteenth Century*, No. 33, p. 789, November, 1879.

¶ Lenormant, "La Monnaie dans l'antiquité," Paris 1878, t. 1., p. 274.

Postumus, and that this manufactory did not belong to forgers, but was for the imperial money, copper money being struck with the die of the reigning emperors, and the silver money of the ancient Cæsars, still more adulterated than the original pieces, being reproduced by founding."*

With reference to the casting of money, I may add that, until the close of the 15th century, the beautiful medals, such as those of Giulio Romano, were all cast in fine sand moulds, and not struck, and that the use of cast money was revived in Europe in the year 1791, when a coinage of bell metal was cast in France under the the following circumstances:—In that year the bells of certain churches, which had been suppressed by order of the National Assembly, were ordered to be converted into coin. M. l'Abbé Rochon suggested that these should be cast in sand and not struck, and he pointed out, in an official report, that a "skillful moulder could easily cast 2,400 pieces in a day.† M. Dumas states that this bell metal was of two kinds; one variety, containing 20 to 22 per cent. of white metals, was cast directly into coins in sand moulds; and the other, containing only 10 to 12 per cent. of metals other than copper, was cast into strips of metal of the right thickness for cutting into discs without rolling. Over 19,000,000 francs' worth of these bell metal coins were subsequently converted into the bronze coins now circulating in France.‡

The early Greek coins, from an artistic point of view, present but little evidence of mechanical skill other than that involved in engraving the dies; but I purpose, before dealing with the alloys used for coinage, to trace the gradual development of the mechanical processes of coining from these earliest types until the introduction of the machinery now in use. It will not be necessary to deal with the existing appliances, as they have recently been fully described,§ and because they can be seen in operation at any time in the Mint. I shall, however, subsequently allude to the balances by which the weight and fineness of the coins is ascertained.

To return to the older methods. Nuggets, either of electrum or gold, presented a more or less convenient shape for direct conversion of coin, but if the precious metal had first to be melted as a preliminary stage of its conversion, then some kind of moulding was necessary. In the early days, a globular forms seem to have been given to the precious metal, by allowing it to fall in a molten state, through orifices so as to produce globular shot. These were placed on an anvil, and received a blow which served to flatten them, and at the same time to impress a device from an engraved die on their surface. Unstruck globules of the kind described have been found, lying with finished coin, at Reculver, in Kent.

As soon as the stamping of irregularly shaped portions of metal gave place to coins of rough, but more or less regular form, certain mechanical devices had to be adopted. First, the portion of metal to be converted into coin had to be fashioned by moulding into shape either a disc or a hemispherical mass. When the latter form was adopted, the device appeared on one side in high relief, and on the other in low relief. In either case the metal was probably cast into a shape approximating to that of the finished coin, and the more prominent features of the relief were given to the disc by casting. The early dies were made of an alloy of copper and tin. Such alloys are capable of being made of great hardness, but there is abundant evidence to show that the blanks were often, if not always, struck hot; and mechanically speaking, coinage must have been a very imperfect art before the art of hardening steel was well understood.

The Roman dies were shaped liked a sugar-loaf, and the flat bases bearing the engraved devices were of the diameter of the pieces to be struck. Both the obverse and reverse dies were sunk in metallic cylinders, the diameters of which were considerably larger than the dies. The lower cylinder bore a kind of rim which did not in any way restrain the lateral spreading of the metal to be struck, but prevented its ejection if the blow was incorrectly imparted to the upper die.

We owe descriptions of these very early methods of coining to M. l'Abbé Barthelemy,* a well-known antiquary of the last century, and to M. Mongez†, who repeated what were believed to be the ancient methods of producing dies and striking coins, and showed that the entire process might be performed with great rapidity.

It is probable that the use of cast globules of metal was followed by that of cast cylindrical rods of approximately the diameter of the

coins; pieces cut transversely from these cylinders would, of course, be circular, and could be easily adjusted in weight. There is no reason to believe that this method long survived in the English Mints, but it is still practised in India, into which country it was probably introduced previous to its invasion by the Greeks. The beautiful coins of the Emperor Akbar were struck by this method*. That it is still retained in India is shown by the following description of the process, as conducted at the Cabul Mint.† "Silver, refined by cupellation, is melted with an equal amount of English rupees, and the mixture is ladled by hand into moulds, which give it the shape of flattened bars, twelve inches long. These bars are taken to a shed to be annealed by hammering, and given the form of slender round rods. These rods are drawn through a perforated iron plate, to give them a uniform circumference, after which they are cut by a chisel into short lengths or slices, of a size requisite to form the future rupee, each of which slices is carefully weighed. Those which are too light have a fragment of metal inserted in a notch, which is then closed up by hammering. The pieces are gently heated, and hammered into round blanks, which are pickled in a boiling solution of apricot juice and salt, then struck by the blow of a hammer from engraved dies."

The coins of Edward I. of England were produced by a similar process, but in this case the bars were probably square,‡ and the square fragments cut off were forged round with the tongs and hammer before being struck. This process was used from time to time in England, up to as late a period as 1561.

The primitive method of preparing "blanks" for coinage survived in Germany, even to the middle of the 18th century, and is thus described by Jars,§ who saw it in operation in the mint at Zellerfeld, in the Hartz, and I quote his description because the method of conducting the preliminary casting of the bars for coinage is interesting, as it differs essentially from the methods then in use elsewhere which involved casting the bars in moulds of sand or of iron.

"All the silver produced by the Communion district, even that from Upper Hartz, is brought to Zellerfeld to be converted into coins. An old coining method has been preserved in that town. The silver, after being melted in a crucible, is poured on a band (made of a kind of 'duck' or cross-woven tissue) fixed at each end, on a kind of bow, which can be stretched at will by means of a screw and nut. The tension of the stuff, and the mode of its attachment, form a rim on each side. The bands are more or less wide, according to the size of the coins; but only ingots destined to make coins from the smallest size, up to florin pieces, are poured on it; the two-florin pieces are cast in sand. Care is taken that all the ingots should be much narrower, and therefore thicker than the coins. A workman holds this kind of bow above a small vessel filled with water, in which he dips the band, whilst another workman pours on it the silver, the tissue being still damp. The former agitates it gently before the metal is set, in order that it should be equally spread in all directions. Afterwards, he dips the metal into the water, and causes it to drop to the bottom of the vessel, otherwise it would burn the band. Fresh silver is poured, and the operation is continued in the same manner." A variety of commercial copper, which was formerly highly esteemed, was cast in canvas furrows or moulds, under water, much in the way Jars describes in the case of the silver bars or ingots.

The cast metal is then cut into square pieces, and these are rounded into blanks by the hammer, and the coinage is effected by the obsolete hammer method already described.

After the abandonment of the method involving the use of cylindrical rods, the early coins that were prepared by purely mechanical means as distinguished from casting coins were cut into discs from sheets or strips of either pure metals or alloys, by means of shears. The metal or alloy was beaten into a sheet or strip by means of the hammer, as is shown in a well-known engraving of the 14th century; the method was retained in France as late even as the year 1553, when the system of rolling the metal into sheets, attributed to Antoine Brucher, was introduced.* The invention of rolls was, however, much more ancient, and although they do not appear to have been previously used in minting, they were probably employed in very early times for laminating metals and alloys; but little is known as to the exact forms given to rolls used in mints before the introduction of Briot's machines into the Scotch Mint. These, however, are described by Sir James Hope, in 1639, as being

"rollers of yrne for drawing of mettels into length and thinness, standing in the turneing loome,"* and in a marginal note he shows that they were of this form, Fig. 1. Horse-power

FIG. 1

was used for driving the rolls from a very early date, and it is perhaps worth noting that, in 1661, King Charles II. gave authority for the gold bars to be removed from the mint in the Tower to an adjacent building at St. Katherine's, in order that the "plates might be passed" through rolls attached to a water-mill.† With regard to the dimensions of the rolls, it may safely be stated that they were much smaller than those now in use.

Boizard describes the laminating mill used in the Paris Mint in 1692,‡ as consisting of two cylinders about four inches in diameter, keyed on to a driving rod of square iron, and turned by the wheels of a mill driven by horses, and he adds that the distance between the rolls could be adjusted by nuts and screws.

Probably but little change was made for a century after the above was written, for a description by Mr. Alchorne,§ Assay Master of the Mint in this country, in the reign o King George III., shows the general arrangement of the rolling-room in the Paris Mint towards the end of the last century, and incidentally indicates the nature of the London rolling mill. He says, "the bars are brought to a proper thickness by being passed several times between steel rollers, as in England. The rollers are turned by millwork, with horses as in London; viz., one large pair of rollers in the centre, and four smaller pairs at the four corners, if they may be called so. The central rollers are turned by the axes of secondary wheels, as in England; the rest by other wheels which are turned by these secondaries. The middle rollers both turn on the same level, so that the bars pass between them in a perpendicular direction, the other rollers turn one above the other as in England, so that the bars pass between them horizontally. The central rollers are considerably stronger and larger than the rest, and these are used for bringing the bars to a moderate thickness; after which they are properly reduced by the smaller rolls. The same mills are employed for both gold and silver, and four sets of them are placed in one range. Each set is worked by four horses, when the five pairs of rollers are used at the same time, and thus sixteen horses may work together under the same roof." I will only add that in the Mint, as re-organised in 1882, there are twelve pairs of rolls, the diameters of which vary from ten to fourteen inches, and that these are driven by an engine of sixty nominal horse-power.

It will be evident that the weight of the finished coin depends upon the thickness of the fillets; and to show how accurately the rolling must be performed in modern mints, it may be pointed out that, in the case of the half-sovereign, a variation of $\frac{1}{20000}$th of an inch above or below the accurate thickness, or a range of $\frac{1}{10000}$th of an inch, throws the coin out of the limits of weight within which its issue to the public could be permitted.

We may now pass to the preparation of the discs or blanks, and it is certain that whether the sheets of metal were prepared by hammering or by rolling, discs were originally cut from them by means of shears.

Lenormant,* quoting Hennin, considers that there is evidence of the use of circular cutters in early Egyptian times, but the adoption, in more modern times, of a cutter producing circular discs has been attributed to Aubin Olivier, who effected considerable improvements in the Paris Mint in 1553. Recent investigations have shown that the origin of the disc cutter was somewhat earlier, as its use was undoubtedly suggested by Leonardo da Vinci, the grandeur of whose genius has long been recognised, and the recent publication of whose literary works† has placed at our disposal a store of facts from which an estimate may be formed of his labours in specific branches of science. He is supposed to have designed the coins of Louis XII., King of France and Duke of Milan‡ in the time of Pope Leo X. He must, as Dr. Richter shows, have spent at least a year (1513-15) in the Roman Mint, where he cannot fail to have been struck with the crude ap-

pliances and methods of coinage then in use. In a note-book that can be proved to have been used in Rome, he says:—"All coins which do not have the rim complete are not to be accepted as good; and to secure the perfection of their rim it is requisite that, in the first place, all the coins should be a perfect circle; and to do this, a coin must, before all, be made perfect in weight, size, and thickness. Therefore, have several plates of metal made of the same size and thickness, all drawn through the same guage so as to come out in strips, and out of these strips you will stamp the coins [*i.e.*, cut the blanks] quite round as sieves are made for sorting chestnuts; and these coins [*i.e.* blanks] can then be stamped. The hollow of the die [cutter] must be uniformly wider than the lower, but imperceptibly. This cuts the coins perfectly round, and of the exact thickness and weight, and saves the man who cuts and weighs, and the man who makes the coins round. Hence it [the blank] passes only through the hands of the guager and the stamper, and the coins are very superior." *

The appliances devised by Da Vinci are shown in Fig. 2, and it is hardly necessary to

point out what a great advance upon the methods in use in the 16th century they indicated.

Fortunately, his countryman and contemporary, Biringuccio, the author of almost the earliest elaborate treatise on metallurgy we possess, devoted a chapter of his work to "a discourse, and advice on working a mint properly and profitably."† He distinctly says that the alloy of precious metals is to be cast, beaten out with the hammer, cut in square pieces and rounded.

Da Vinci's instrument for cutting blanks differed from that devised, or at least adopted, by Briot, and figured in a rough marginal sketch appended to Sir James Hope's account of the "Fyneing of Metalles," written in 1639.* It consisted of a vertical screw, worked by a lever, and terminating in a solid cylindrical cutter, which forced its way through the sheet or strip of metal, driving the blank before it, instead of allowing the latter to pass up into the interior of the hollow cutter as in Da Vinci's machine. It in no way differed from the cutter actually used in the Mint within the Tower of London, until its removal to the present site on Tower-hill; one of these old cutters is now before you.

The "blanks" may next be struck directly into coins, or they may just have their edges turned up by a special machine or marked with letters, lines, or geometrical devices. The earliest coins that have such marked edges are those with serrated edges called by Tacitus, *nummi serrati*, represented, among the specimens shown, by a silver coin of the Roman Republic which somewhat resembles, as regards its edge, a coarsely cut watch wheel.

M. Castaing was probably the inventor of the machine for edge-marking. It consisted of two strips of steel bearing letters or an engraved device, which were placed horizontally and parallel to each other at a distance somewhat less than the diameter of the blank One of the strips could be moved backwards and forwards by a rack and pinion, and when the blank was squeezed and rolled edgewise between the plates, the device was transferred to its edges. The instrument appears to have been in use in France in 1685.† The methods of imparting an impression to the edge of a coin, as part of the operation of striking in the coining press, will be noticed subsequently.

The operation of annealing the metal, either during the lamination or before the blanks are struck, is probably extremely ancient. "Blanching" also, or removing the alloying metal by the aid of dilute acid from the surface of the coins, has long been practised. The new money in the 18th year of Edward I. was "made white and refulgent by nealing or boiling," and the process remains in use until the present day.

* Hopetown papers.

† Boizard, "Traité des Monnoyes," p. 142.

The next process to be considered is that by which the disc has an impression imparted to it, and is thus actually converted into coin. I have already referred to the use of the hammer, and will now only add that the prejudice or interest of the craftsmen called moneyers delayed its entire abandonment in this country until the year 1662, although, as we shall see, better methods were well known more than a century earlier than this date.

The hammer was succeeded by a block of stone or metal, which, guided between two rods, fell vertically on the upper die, between which and a fixed lower die the disc was placed. The great antiquity of this appliance is referred to in a letter from M. L'Abbé Barthélemy, to M. Rochon, by whom it is quoted.*

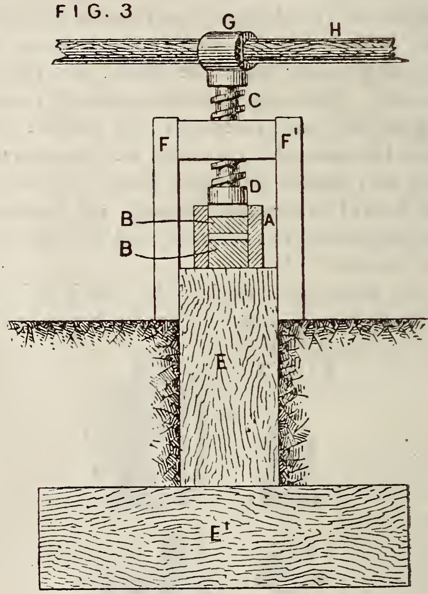
It is still extensively employed in the manufacture of buttons, and is used in the Royal Mint for making medal clasps. There is no evidence, as far as I am aware, that it was ever used in this country for striking coins, but it seems to have been employed for this purpose for a short period on the Continent.

The date of the invention of the screw-press is uncertain. It consisted of an iron frame, like an inverted U, in the bend of which a powerful screw fitted. The upper end of the screw was fixed to a cross arm furnished at its extremities, with heavy masses of metal; the lower end of the screw carried the upper die, the lower die being fixed in the bed of the machine.

Ruding,† quoting Le Blanc, says that the screw-press was introduced into this country in 1561, apparently by a Frenchman named Eloye Mestrell. It met with much opposition from the corporation of moneyers, and in 1572 Sir Richard Martyn, then Warden of the Mint, reported that, after repeated trials, it had been found defective. I am not aware that the exact form of Mestrell's press is known, but it cannot have differed much from the one in Italy at the same period, which is minutely described by Benvenuto Cellini,‡ who engraved coins for Pope Clement VII., and was perfectly familiar with this method of coining which he describes as *coniar a vite* in his treatise.§

A receptacle of iron (*staffa*, A, Fig. 3) is made of the size before mentioned (four fingers wide, two thick, and half a *bracchia* long), but so much longer as to admit, beside the dies (*tasselli*, B B'), on which is the intaglio of the medal, the female screw of bronze, which is forced into it on the male screw of iron (*mastio*). This *mastio* is in fact what is actually called the screw, the female being called *chiocciola*, D. The screw should be three fingers thick, and the worms of it should be made square, as they have more strength than those made in the old way. The *staffa* must be open at the top, and, since the dies will be placed in it, and between the dies the metal that is to be stamped, it is necessary that the size of the *chiocciola* is such that it does not move in the *staffa*. As the dies

FIG. 3



have to be somewhat smaller they are firmly fixed with wedges (*biette*) of iron, so that they do not move at all.

A beam of wood is prepared, E, two *bracchia* long, or more, which is buried so that only half a *bracchia* remains above ground, and that is planed smooth, the lower end is attached to a thick piece of timber, two *bracchia* long. In the upper end of the beam the *staffa* is placed in a notch into which it fits exactly.

Then certain wings (*aliette*, F F) are made of strong iron, which support the beam in which the screw is placed, so that it does not yield. The top of the screw is flattened (*stiacciata*), and in this flattened part is placed a great iron ring, G, having two ends which are open and fitted to a long pole (*corrente*, H) the length of which must not be less than six

‡ "Il Fiorino d'oro," p. 265. (Firenze, 1738.)

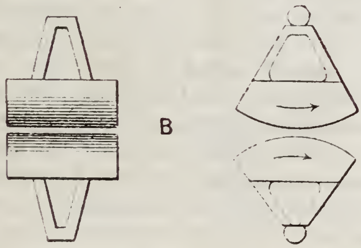
§ "Trattato dell' Oroficeria in Fiorenza, 1568," chap. x., p. 77. Ed. of 1731.

bracchia, and then the stamps and metal being dexterously kept straight, the medal is brought to perfection by the aid of four men.

The next invention of importance seems to have been made by Nicholas Briot, to whom reference has already been made. He proposed to substitute for the screw-press a machine invented or probably only improved by him, which consisted of two semi-cylinders, each bearing an engraved device, the distance between them being so adjusted as to admit of an oval blank, the minor axis of which being inserted between the cylinders, received the impression when the cylinders were moved on their axes through part of a revolution. The disc was, at the same time, extended laterally by the pressure, so that the oval disc became circular. This explains the description given by Sir James Hope, of Briot's machinery, which was actually used in the Scotch Mint in 1639. He says, the blanks that "wer cutt ovall did receave their impression successivlie, by the quhilk they were forced to the bread (broad) and so wer maid round....... The forme of thair stamp is the portione or sectione of a cylinder engraven on both syds,* and he fortunately gives a rough marginal sketch, reproduced in Fig. 4, which makes

FIG. 4

A B



A. Front view of the engraved cylinder. B. End View

the general nature of the appliance evident. He specially says "that the stamp [or die] of those that wer cut round was flat, and impress thairupon by one force lyke to the cutting out press, which in principle exactly resembled a screw coining press."

There has been much misconception as to the nature of Briot's machinery, and Rochon expresses surprise† at the absence of any allusion to the screw-press, in M. Poullain's description of the procès verbal of the trial of machinery, made in Paris, in 1617; but as the machine invented and claimed by Briot, coined by a squeeze and not by a blow, it is evident that it is quite distinct from the screw-press.

Dumas describes a similar machine in use at Geneva, in 1840, which consisted of two rolls, moving continuously, each roll being provided with four dies, capable of adjustment, so as to make each die on the upper roll correspond precisely with one on the lower roll. This arrangement enabled round blanks to be used instead of the oval blanks employed by Briot.

Briot's machinery does not appear to have had either a long or a widely extended use. It was soon abandoned in this country, and the method of striking by the hammer was resumed, and ultimately an improved form of screw-press was adopted.

I have dwelt on these appliances of Briot, because the lever-coining presses which have been definitively adopted in the newly organised Mint present some analogies to the above types; that is to say, they impart the impression by a squeeze, and against a definite resistance. Their analogy to Briot's machine will be made clear later on. But to return to the historical sequence. The hammer was still retained for coining in the Mint at the Tower of London, but the question of the adoption of the screw-press by the moneyers appears to have been revived in 1649, when the Council of State had it represented to them that the coins of the Government might be more perfectly and beautifully done, and made equal to any coins in Europe. It was proposed to send to France for Peter Blondeau, who had invented and improved a machine and method for making all coins "with the most beautiful polish and equality on the edge, or with any proper inscription or graining." He came on the 3rd of September, and although a committee of the Mint reported in favour of his method of coining, the Company of Moneyers, who appear to have boasted of the success of their predecessors in opposing the introduction of the mill and screw-press in Queen Elizabeth's reign,* prevented the introduction of the machinery, and consequently he did not produce pattern pieces until 1653.

Early in the reign of Charles II. the consideration of the question was resumed, and Mr. Pepys states, in his diary under the year 1660-61, February 18th, that he "met with Mr. Slingsby, Master of the Mint, who showed me the stamps for the King's coyne, which is

* Hopetown papers, 19th January, 1639, quoted by Mr. R. W. Cochran-Patrick, "Records of the Coinage of Scotland," vol. i., p. lx. 1876.

† Rochon, "Essai sur les Monnoies," pp. 62 et 89. Paris: 1792.

* "Simon's Medals," by Virtue, p. 23, 1780.

strange to see how good they are on the stamp, and bad on the money for lack of skill to make them. But, he says, Blondeau will shortly come over, and then we shall have it better, and the best in the world," and a year later, March 9th, 1662-3, he says, "Mr. Slingsby showed me examples of all the new pieces, both of gold and silver, that were made for the King by Blondeau's way."

It is certain that Blondeau did not invent, but only improved the method of coining by the screw-press, and I believe his improvements related chiefly to a method for "rounding the pieces before they are sized, and in marking the edges of the moneys with letters and grainings," which he undertook to reveal to the King. Special stress is laid on the engines wherewith the rims were marked, "which might be kept secret among few men."*

I cannot find that there is any record in the Paris Mint of Blondeau's employment there, and the only reference to his invention in the mint records of this country refers to the "collars" or perforated discs of metal surrounding the "blank" while it was struck into a coin.† There is, however, in the British Museum a MS., believed to be in Blondeau's hand, in which he claims his process "as a new invention, to make a handsomer coyne, than can be found in all the world besides, viz., that shall not only be stamped on both flat sides, but shall even be marked with letters on the thickness of the brim."‡ The letters were raised.

The press Blondeau used was, I believe, the ordinary screw-press, and I suppose that the presses drawn in Akerman's well-known plate of the coining-room of the Mint in the Tower, published in 1803,§ if not actually the same machines, were similar to those erected in 1661-2, by Sir William Parkhurst and Sir Anthony St. Leger, wardens of the Mint, at a cost of £1,400.||

Each press is served by four men, who set the cross-arm attached to the screw in motion by the aid of subsidiary jointed levers, which evidently allowed a certain amount of "play." Jars states¶ that the "balanciers" used in the Cremnitz Mint, one hundred years ago, required eight men at each press, when two florin pieces were struck, and as the men worked for only a quarter of a hour at a time, they had to be replaced by another set of eight men, making in all sixteen men to each press.

The blanks seem to be placed between the dies by the hand of an attendant, but a system of mechanical "laying on," as it is called, had been suggested in 1727, by M. du Buisson;* and in 1807, Phillipe Gengembre† devised and introduced a simple and ingenious "layer on" which permitted blanks to be struck surrounded by a plain perforated disc of metal called the "collar," the removal of the finished coin and its replacement by a fresh blank, being performed automatically.

The screw-press of Boulton marks a great advance in mint machinery for the "cutting-out," and coining presses continued to be worked by manual labour until he claimed the "application of motive power to stamping and coining" in 1790, when a patent‡ was granted to him "for certain new methods of applying the powers of water mills, cattle mills, and steam-engines, either simply or combined with the pressure of the atmosphere" for the purpose of coining. He employed a screw-press in which the blow is imparted by the intervention of a vacuum chamber; that is, instead of workmen operating directly on cross arms, a lever at right angles to the screw is connected with a piston of a chamber rendered vacuous during the upward motion of the screw, which is effected, not by manual labour, but by a projection on a revolving wheel or, in later forms, by a lever. When the screw has been raised to the utmost limit of its path it is released, and the pressure of the atmosphere on the upper part of the vacuum chamber forces it down, and brings down the screw which bears the upper die.§

This press was finally abandoned in the re-organisation of the Mint machinery, effected in 1882, when the lever-press invented by Uhlhorn in 1829 was adopted. Some of these lever-presses had been in use in the Mint since 1872. A sketch of the portion of the lever machine (Fig. 5, p. 813) which bears the dies will be all that is necessary to make clear the principle by which it works. The blanks are placed at B, between the dies, D D, and the pressure is imparted by the toggle joint, E, and bent lever,

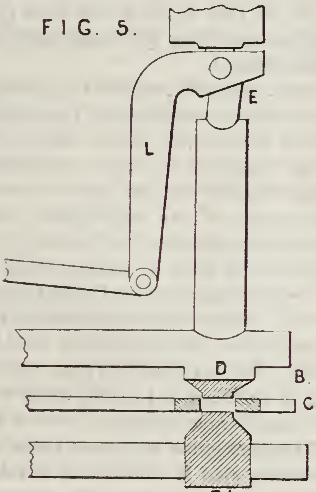
L, and not by the partial revolution of a cylinder, as in Briot's machine. The edges of the coin may, at the same time, be marked with lines, or with a device, by means of a collar in the plate, C.

It is strange that the method of striking in a collar was not adopted earlier. The earliest reference I have been able to find, to a coin marked with letters on the edge, is a gold piece of Henry II. of France, dated 1555,* but the drawings of Leonardo da Vinci, published by Dr. Richter, clearly show that Da Vinci suggested the use not only of a collar fitting tightly round the blank, but of one capable of being divided into two portions, upon which a device might have been engraved, although he does not appear to have used such an engraved collar.

FIG. 5.



Simon's celebrated "petition crown," which bore an elaborate inscription on its edge, was probably not struck in a segmental collar, but in a plain one, the device being engraved on a steel spring, which was coiled inside the collar. A very slight pressure would remove the coin from the collar, and then the elasticity of the spring would remove it from the coin.

In conclusion, I would offer a few remarks with reference to the artistic side of the subject, in which the Society has always taken the deepest interest.

With regard to the substitution of the screw-press for the hammer in coining, M. Lenormant observes, "mais l'art y a perdu, comme il perd presque toujours à l'emploi des machines," and this is the complaint of a distinguished school in this country, whose view is probably based on the undoubted inferiority of modern work. But did art lose by the introduction of machinery? Such was not the opinion of Cellini, who advocated the use of the screw-press, nor of Da Vinci, who insisted that the discs should be cut with mathematical accuracy, and struck so as to ensure their being circular. It is not a little remarkable that the artists of the mints, the engravers, appear to have been the very people to urge the adoption of mechanical improvements. For instance, Nicholas Briot, "graver general of the monies," an excellent artist, quitted France in disgust because the introduction of his machinery was so bitterly opposed in that country. Jean Varin, Briot's successor in France, secured the definitive adoption of the screw-press in 1645, and Simon, Briot's pupil, and the greatest engraver England has ever had, aided Blondeau, who effected the great changes in the appliances of the Mint in the reign of Charles II., by secretly engraving the dies for him.

Speaking with no claims to artistic culture, I would venture to submit that no hand-struck Greek coins can be finer, as works of art, than certain machine-struck Renaissance coins, with designs in low relief, examples of which are now before you. The dies for striking them were either drawn or engraved by Francia, Da Vinci, Cellini, Hameranus, and Simon,* and the coins were struck from carefully rounded blanks. All these coins are surely marked by what Mr. Ruskin has called the "sign of the highest art," which "parts voluntarily with its greatness ...... so to exalt and set forth its theme that you may be fain to see the theme instead of it."† But in order to meet your obvious objection that these artistic questions are not in the province of the metallurgist, permit me to appeal to the words of Biringuccio, who, in 1540, in his advice to a Mint Master, reminded him that if he coined strictly according to the letter of the law, he would make but very small profits; if, on the other hand, he introduced too much base metal into the alloys, the execrations of the people would follow; but he specially urges that a good workman should

SUGAR.

By G. Buchanan.

The sugar crop or supply of the world is estimated at five millions of tons. Of this quantity one million tons may be put down to India and China. The cane is grown throughout India, and a small enhancement of value in the export market is soon followed by a large accession of sugar in the bazaar. The export from India is stated in the Statistical Abstract to be 644,531 cwts. But of the real production of the one or the other country very little is known. Omitting them from the calculation, the supply would be four million tons. It consists of cane and beet sugar in nearly equal parts, the figures for the year 1882 being:—

Cane sugar	2,060,565 tons.
Beet sugar	1,860,994 ,,
