JOURNAL

OF THE

SOCIETY OF ARTS.

VOLUME XXXII.

FROM NOVEMBER 23, 1883, TO NOVEMBER 14, 1884.

ROYAL SOCIETY OF EDINBURGH

LONDON:
PUBLISHED FOR THE SOCIETY BY GEORGE BELL AND SONS,
4, 5, & 6, YORK STREET, COVENT GARDEN.

1884.

JOURNAL OF THE SOCIETY OF ARTS.

No. 1,618.] *FRIDAY, NOVEMBER* 23, 1883. [*Vol. XXXII.*

ONE-HUNDRED-AND-THIRTIETH SESSION, 1883-84.

COUNCIL.

H.R.H. THE PRINCE OF WALES, K.G., *President of the Society.*

H.R.H. the Duke of Edinburgh, K.G., *Vice-Pres.*
H.R.H. Duke of Albany, K.G., *Vice-Pres.*
Sir Frederick Abel, C.B., D.C.L., F.R.S.
Sir Rutherford Alcock, K.C.B., *Vice-Pres.*
Sir George Birdwood, M.D., C.S.I., *Vice-Pres.*
Sir Frederick Bramwell, F.R.S., *Vice-Pres.*
Alfred Carpmael.
Andrew Cassels, *Vice-Press.*
Edwin Chadwick, C.B., *Vice-Pres.*
Lord Alfred S. Churchill, *Vice-Pres.*
B. Francis Cobb, *Vice-Pres.*
Thomas Russell Crampton.
Sir Philip Cunliffe-Owen, K.C.M.G., C.B., C.I.E., *Vice-Pres.*
Henry Doulton.
Captain Douglas Galton, C.B., D.C.L., F.R.S., *Vice-Pres.*
Earl Granville, K.G., F.R.S., *Vice-Pres.*
Sir John Hawkshaw, F.R.S., *Vice-Pres.*
Admiral Sir Edward A. Inglefield, C.B., F.R.S.
Sir Frederick Leighton, P.R.A., *Vice-Pres.*
Thomas Villiers Lister.
Sir John Lubbock, Bart., M.P., F.R.S., *Vice-Pres.*
J. M. Maclean.
W. R. Malcolm, *Treasurer.*
George Matthey, F.R.S.
W. G. Pedder.
W. H. Perkin, F.R.S., *Vice-Pres.*
Loftus Perkins.
W. H. Preece, F.R.S.
Sir Robert Rawlinson, C.B., *Vice-Pres.*
B. W. Richardson, M.A., M.D., F.R.S., *Vice-Pres.*
Owen Roberts, M.A., F.S.A., *Treasurer.*
Lord Sudeley, *Vice-Pres.*
Sir Richard Temple, Bart., G.C.S.I., C.I.E., D.C.L., *Vice-Pres.*
R. E. Webster, Q.C.
Duke of Westminster, K.G., *Vice-Pres.*

SECRETARY.

H. Trueman Wood, B.A.

ASSISTANT SECRETARY.	*ACCOUNTANT.*	*AUDITOR.*
Henry B. Wheatley, F.S.A.	Howard H. Room.	J. Oldfield Chadwick.

SESSIONAL ARRANGEMENTS.

The Second Meeting of the One Hundred and Thirtieth Session of the Society will be held on Wednesday, the 28th November. Previous to Christmas there will be Four Ordinary Meetings, in addition to the Opening Meeting.

The following arrangements have been made:—

November 28.—A. J. R. Trendell, of the Inner Temple, Barrister-at-Law, "The International Fisheries Exhibition of 1883."

December 5.—Thomas T. P. Bruce Warren, "The Manufacture of Mineral Waters."

" 12.—Thomas Fletcher, F.C.S., "Coal Gas as a Labour-saving Agent in Mechanical Trades."

" 19.—The Most Hon. The Marquis of Lorne, K.T., late Governor-General of Canada, "Canada and its Products."

For Meetings after Christmas:—

B. W. RICHARDSON, M.D., F.R.S., "Sanitary Progress."
W. H. PREECE, F.R.S., "The Progress of Electric Lighting."
DR. BRANDIS, F.R.S., "Forest Administration in India."
A. RECKENZAUN, "Electric Launches."
WILLIAM LANT CARPENTER, B.A., B.Sc., "Science Teaching in Elementary Schools."
C. R. ALDER WRIGHT, F.R.S., D.Sc., "Cupro-Ammonium Solution and its Use in Waterproofing Paper and Vegetable Tissues."
DR. PERCY F. FRANKLAND, "The Upper Thames as a Source of Water Supply."
W. G. PEDDER, "Historical Development of the Different Settlement Systems of British India." (Second communication.)
JOSEPH G. COLMER, Secretary to the High Commissioner for Canada, "Canada as it will be seen by the British Association in 1884."
PROFESSOR FLEEMING JENKIN, F.R.S., "Telpherage."
GENERAL RUNDALL, "Water Regulation in England."
EDWARD C. STANFORD, F.C.S., "Economic Applications of Seaweed."
J. M. MACLEAN, "State Monopoly of Railways in India."
B. FRANCIS COBB, "North Borneo."
DR. LEITNER, "Indigenous Education in India."
PROFESSOR WANKLYN and W. J. COOPER, "Manufacture of Gas from Limed Coal."

FOREIGN AND COLONIAL SECTION.

The meetings of this Section will take place on the following Tuesday evenings, at Eight o'clock:—
January 29; February 26; March 18; April 1, 29; May 20.

APPLIED CHEMISTRY AND PHYSICS SECTION.

The meetings of this Section will take place on the following Thursday evenings, at Eight o'clock:—
January 24; February 21; March 27; April 24; May 8, 29.

INDIAN SECTION.

The meetings of this Section will take place on the following Friday evenings, at Eight o'clock:—
February 15; March 7, 28; April 25; May 9, 30.

CANTOR LECTURES.

Monday evenings at eight o'clock:—

The First Course will be on "The Scientific Basis of Cookery." By W. MATTIEU WILLIAMS, F.C.S.

Lecture I. Dec. 3.—The Kitchen a Chemical Laboratory. Modes of applying Heat. Radiation, Conduction, and Convection. Roasting, Grilling, Baking, Boiling, and Stewing.

Lecture II. Dec. 10.—The Constituents of Flesh. The action of Heat on Albumen, Gelatine, Fibrin, &c. The Juices of Flesh and their nutritive value. Exosmosis and Endosmosis as operating in the Kitchen. Maceration. Caseine. The cookery of Cheese and its nutritive value. Milk, Butter, and "Bosch."

Lecture III. Dec. 17.—The nutritive constituents of Vegetables. The changes effected by cookery on Vegetable Substances. Ensilage of Human Food. May the use of Flesh Food be superseded by the scientific preparation of selected Vegetables?

The Second Course will be on "Recent Improvements in Photo-Mechanical Printing Methods." By THOMAS BOLAS, F.C.S.

Lecture I. Jan. 28.—New Developments of the Woodbury-Type Process.

Lecture II. Feb. 4.—Type Blocks from Line Drawings and Half Tone subjects.

Lecture III. Feb. 11.—Intaglio Plates. Collotypes. Photo-Mechanical Methods, as applied to the Decoration of Pottery. Miscellaneous Processes.

The Third Course will be on the "Building of Town Houses." By ROBERT W. EDIS, F.S.A.

Lecture I. Feb. 18.—Their Arrangements, Aspect, Design, and General Planning.

Lecture II. Feb. 25.—Sanitation, Lighting, Heating, and Ventilation.

Lecture III. Mar. 3.—Fittings, Planned Furniture, Constructive Decoration.

The Fourth Course will be on "The Alloys used for Coinage." By Professor W. CHANDLER ROBERTS, F.R.S., Chemist of the Royal Mint:—

March 17, 24, 31; April 7.

Lectures I. and II.—Gradual Development of the Processes of Coining. The Composition and "Standards of Fineness" of the Alloys used for Coinage in Ancient and Modern Times.

Lecture III.—Methods by which Accuracy of Weight and "Fineness" of the Alloys is ensured.

Lecture IV.—Questions connected with the liability to Reduction in Weight of various Coins by Wear during Circulation.

The Fifth Course will be on "Some New Optical Instruments and Arrangements." By J. NORMAN LOCKYER, F.R.S., F.R.A.S.:—

April 28; May 5.

The Sixth Course will be on "Fermentation and Distillation," by Prof. W. NOEL HARTLEY, F.C.S.:—

May 12, 19, 26.

JUVENILE LECTURES.

The two Juvenile Lectures will be by J. MILLAR THOMSON, F.R.S.E., F.C.S., Lecturer on Chemistry at King's College, London, on "Crystals and Crystallisation." The dates for these lectures are Wednesday evenings, the 2nd and 9th January, at seven o'clock.

PROCEEDINGS OF THE SOCIETY.

CHARTER.—THE SOCIETY OF ARTS was founded in 1754, and incorporated by Royal Charter in 1847, for "The Encouragement of the Arts, Manufactures, and Commerce of the Country, by bestowing rewards for such productions, inventions, or improvements as tend to the employment of the poor, to the increase of trade, and to the riches and honour of the kingdom; and for meritorious works in the various departments of the Fine Arts; for Discoveries, Inventions, and Improvements in Agriculture, Chemistry, Mechanics, Manufactures, and other useful Arts; for the application of such natural and artificial products, whether of Home, Colonial, or Foreign growth and manufacture, as may appear likely to afford fresh objects of industry, and to increase the trade of the realm by extending the sphere of British commerce; and generally to assist in the advancement, development, and practical application of every department of science in connection with the Arts, Manufactures, and Commerce of this country"

THE SESSION.—The Session commences in November, and ends in June. The number of Meetings held during the Session amounts to between 70 and 80.

ORDINARY MEETINGS.—At the Wednesday Evening Meetings during the Session papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed.

INDIAN SECTION.—This Section was established in 1869, for the discussion of subjects connected with our Indian Empire. Six or more Meetings are held during the Session.

FOREIGN AND COLONIAL SECTION.—This Section was formed in 1874, under the title of the African Section, for the discussion of subjects connected with the Continent of Africa. It was enlarged in 1879, so as to include the consideration of subjects connected with our Colonies and Dependencies, and with Foreign Countries. Six or more Meetings are held during the Session.

APPLIED CHEMISTRY AND PHYSICS SECTION.—This Section was formed in 1874, for the discussion of subjects connected with Practical Chemistry and its applications to the Arts and Manufactures. It was enlarged in 1879, so as to include the consideration of subjects connected also with the Applications of Physical Science to the Arts. Six or more Meetings are held during the Session.

CANTOR LECTURES.—These Lectures originated in 1863, with a bequest by the late Dr. Cantor. There are several Courses every Session, and each course consists generally of from Three to Six Lectures.

ADDITIONAL LECTURES.—Special Courses of Lectures are occasionally given.

JUVENILE LECTURES.—A short Course of Lectures, suited for a Juvenile audience, is delivered to the Children of Members during the Christmas Holidays.

ADMISSION TO MEETINGS.—Members have the right of attending the above Meetings and Lectures. They require no tickets, but are admitted on signing their names. Every Member can admit *two* friends to the Ordinary and Sectional Meetings, and *one* friend to the Cantor and other Lectures. Books of tickets for the purpose are supplied to the Members, but admission can be obtained on the personal introduction of a Member. For the Juvenile Lectures special tickets are issued.

JOURNAL OF THE SOCIETY OF ARTS.—The *Journal*, which is sent free to Members, is published weekly, and contains full Reports of all the Society's Proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce.

EXAMINATIONS.—Examinations are held annually by the Society, through the agency of Local Committees, at various centres in the country. They are open to any person The subjects include the principal divisions of a Commercial Education, Sanitary Knowledge, Political and Domestic Economy, and Music. A Programme, containing detailed information about the Examinations, can be had on application to the Secretary.

LIBRARY AND READING-ROOM.—The Library and Reading-room are open to Members, who are also entitled to borrow books.

CONVERSAZIONI are held, to which the Members are invited, each Member receiving a card for himself and a Lady.

MEMBERSHIP.

The Society numbers at present between three and four thousand Members. The Annual Subscription is Two Guineas, or a Life Subscription of Twenty Guineas may be paid.

Every Member whose subscription is not in arrear is entitled :—

To be present at the Evening Meetings of the Society, and to introduce two visitors at such meetings, subject to such special arrangements as the Council may deem necessary to be made from time to time.

To be present and vote at all General Meetings of the Society.

To be present at the Cantor and other Lectures, and to introduce one visitor.

To have personal free admissions to all Exhibitions held by the Society at its house in the Adelphi,

To be present at all the Society's *Conversazioni*.

To receive a copy of the Weekly *Journal* published by the Society.

To the use of the Library and Reading-room.

Candidates for Membership are proposed by three Members, one of whom, at least, must sign on personal knowledge; or are nominated by the Council. The Annual Subscription is Two Guineas, payable in advance, and dates from the quarter-day immediately preceding election; or a sum of Twenty Guineas in lieu of all further contributions, may be paid.

All subscriptions should be paid to the Secretary, H. T. Wood, and all Cheques or Post-office Orders should be crossed "Coutts and Company," and forwarded to him at the Society's House, John-street, Adelphi, London, W.C.

NOTICES.

DEATH OF SIR WILLIAM SIEMENS.

It is with feelings of the very deepest regret that the Council have to record the loss which the Society of Arts has sustained by the death of the Chairman of Council, Sir William Siemens. Their appreciation of the services which he has rendered to the Society of Arts, will, it is hoped, find fitting expression in a resolution which will be passed as soon as a meeting of the Council can be formally held for the purpose. A short sketch of his life and scientific labours will be found at page 7.

INDIAN SECTION COMMITTEE.

A meeting of the Committee of the Indian Section was held on Friday, November 16th, at 4 p.m. Present—Mr. Andrew Cassels (in the chair), Sir George Birdwood, M.D., C.S.I., Mr. J. M. Maclean, Sir W. Rose Robinson, K.C.S.I., with Mr. H. Trueman Wood, Secretary, and Colonel Hardy, Secretary of the Section. The programme of papers to be read during the present session was discussed.

Proceedings of the Society

FIRST ORDINARY MEETING.

The First Ordinary Meeting of the Session was announced for Wednesday last, the 21st inst. As stated in last week's *Journal*, arrangements had been made for the holding of the meeting, and it was then hoped that Sir William Siemens's health would have permitted his delivering the address at a later period of the Session. When his sudden and quite unexpected death occurred on Monday last, the Council felt that, under the circumstances, they had no other course to pursue than to adjourn the meeting entirely, and notices to this effect were inserted in the newspapers.

With regard to the arrangements for the Session, the Council think it well to lay before the members the following brief sketch of the work with which it is probable the Society will be engaged. It was prepared with a view of submitting it to the members at the Opening Meeting:—

Ordinary Meetings.

The papers which have already been arranged for the Ordinary Meetings of the Society, have been announced in the *Journal*. Before Christmas there will be four meetings. At the first of these Mr. Trendell, who has been intimately associated with the conduct of the Fisheries Exhibition, has undertaken to bring before the Society a summary of its results. At the second meeting Mr. Bruce Warren, who has had considerable experience as a chemist in the subject, will deal with the manufacture of mineral waters, a manufacture which has been, during the past few years, of growing importance. At the next meeting after this Mr. Thomas Fletcher, to whom the Society were indebted three years ago for a paper on appliances for the combustion of coal-gas, will describe recent advances in the same direction. At the last Ordinary Meeting before Christmas a paper, which the Council anticipate with much interest, will be read by the Marquis of Lorne, upon the great Dominion, of which he has just ceased to be the Governor-General. Lord Lorne has, as the members are aware, not long since made a most interesting journey into the North-West Provinces of Canada, and will be able to speak with a personal as well as an official knowledge of the resources of the colony. Several important papers are also down for the meetings after Christmas. Amongst these may be noticed one by Dr. Richardson, a Vice-President of the Society, on Sanitary Progress. The value of Dr. Richardson's communications is too well known to make it necessary to say much about this, but it will doubtless gain additional interest from the fact that it will be delivered before the opening of the great Health Exhibition now in progress of arrangement.

Indian Section.

The Indian Section of late years has been specially fortunate in the character of the papers which the Committee of the Section have been able to secure. There seems every hope that the papers for the present Session will equal in interest and value those previously read before this Section. Mr, W. G. Pedder has promised a paper in continuation of that read last Session on the "Land Settlement of India." Mr. Maclean has promised to read a paper on the "State Monopoly of Railways in India," a subject of considerable interest at the present time. Dr. Leitner, who is now in England, will contribute a paper on "Indigenous Education in India," and it is hoped that arrangements may be made for a paper on the "Trade Routes to Afghanistan," by Mr. Griffin Vyse. Arrangements are also in progress for papers which will fill up the remaining evenings of the Session.

Foreign and Colonial Section.

The arrangements for the meetings of this Section are not yet entirely complete. As soon as they are, the usual announcements will be made in the *Journal*. Amongst the papers already promised, is one by Mr. Colmer, the Secretary to the High Commissioners of Canada, which will have for its special object the giving of those who join the meeting of the British Association at Montreal next year, some knowledge of the points of interests to which their attention may be specially directed. Mr. B. Francis Cobb has undertaken to prepare a paper on "North Borneo," and the Committee of this Section will have before them suggestions for papers on New Guinea, the Congo River, China, and New Zealand.

Applied Chemistry and Physics Section.

The papers anticipated for this Section include one by Dr. Alder Wright on the application of ammoniacal solutions of copper to the waterproofing of paper, &c., this being the process employed in the manufacture of the new waterproof paper which attracted a good deal of notice, as a material for building and other purposes, at the recent Fisheries Exhibition. Dr. Percy Frankland has promised a paper on "The Upper Thames as a Source of Water Supply." Messrs. Wanklyn and Cooper will bring their method of gas manufacture by the use of lime in combination with coal, before this Section, and there will also be a paper on the economic application of sea-weed, by Mr. E. C. Stanford. In 1862, Mr. Stanford received a medal from the Society for a paper on the same subject, and his promised communication will deal with the progress made since that date in this important though little known industry.

Cantor Lectures.

The first course of Cantor lectures, which will be delivered before Christmas, will be by Mr. Mattieu Williams, who is well known to the members for the interesting courses he has before delivered to the Society, especially the valuable course on the "Manufacture of Iron and Steel," in 1876. Mr. Williams' subject will be the "The Scientific Basis of Cookery." The lectures will be of a practical character, and the Council think they will be of general interest to the members of the Society. After Christmas Mr. Bolas will give a course which will be a continuation of the course delivered in 1878, on "Photo-Mechanical Printing Processes." Mr. Edis, who will give a course of lectures on the construction of London houses, is, like his two predecessors, no stranger to the Society. Professor Chandler Roberts, who has promised a course on the "Alloys used for Coinage," has not before lectured here, but the Council think the members are fortunate in having the opportunity of hearing so great an authority on this special subject. The same remark may be applied to Mr. Norman Lockyer's promised course on "Optical Instruments." This series, again, will, to some extent, be a continuation of previous courses of Mr. Lockyer's. The last course of the Session will be by Professor Hartley, on "Fermentation and Distillation."

Juvenile Lectures.

The two juvenile lectures of the present year will be delivered by Mr. J. Millar Thomson, the Lecturer on Chemistry at King's-college. Mr. Thomson has, for some years, been engaged in researches into certain points connected with the theory of crystallisation, and the subject is one which the Council think will lend itself with peculiar readiness to our juvenile lectures, admitting as it does of so many and such beautiful illustrations. The arrangements for the lectures will be the same as usual, and any member who applies will be furnished with a ticket admitting one adult and two children. The dates for the lectures are the 2nd and 9th of January.

Committees.

Besides the ordinary Standing Committee of the Council, there are now at work only two Committees, that on Patent Law, and that on Collisions at Sea. Though the work of the Patent Committee may be said to have been finished when the Patent Act of last Session was passed, the Council thought it well to reappoint them, with a view of watching the effect of the Act and the method of its administration. It is obvious that the whole value of the patent laws will depend upon the way in which the Act is administered. If it be administered in such a way as to consult the best interests of the inventor, and, therefore, the best interests of the country, the results of last Session's legislation cannot fail to be beneficial; but if on the contrary, it is administered in a purely official fashion, there is little hope of any good to the inventor, or to anybody else, arising from it. Should opportunities occur for the useful exercise of the Society's influence in this matter, the Council will be as ready to use their best efforts in procuring a good administration of the law as they were last Session in endeavouring to secure the passing of a satisfactory Act.

With regard to the Committee on Collisions at Sea, they hope soon to be able to present a report on the subject. They have had the advantage of the advice of many competent authorities; and they have also had before them a large mass of information which inventors, and others interested in the question, have been good enough to send in. All the information has been carefully digested, and will, it is believed, prove a valuable appendix to their report.

Premiums.

As stated in the Council report last Session, premiums have been offered from the funds provided from the following trusts:—John Stock, Benjamin Shaw, Howard, Fothergill, Mulready, and Owen Jones. In answer to the announcements put out, competing models, designs, drawings, essays, &c., have been received in the following numbers:—John Stock, 3; Benjamin Shaw, coal-mining, 8—manufacture, &c., of explosives, 3; Howard, 2; Fothergill, 17; Mulready, 8. The Council regret that offers which they certainly regard as liberal, have not produced larger results, and that a greater number of competitors have not offered themselves. The awards in each case will very soon be made known, as soon as the Council are furnished with the reports of the different Committees to whom the adjudication has been referred. As next January will be the 40th anniversary of Dr. Swiney's death, the prize founded under his will will have to be awarded in that month. The award is made jointly by the Society of Arts and the College of Physicians; the prize being offered to the author of the best published work on jurisprudence. Members who wish to bring any suitable work under the notice of the Council, are requested to send in notice at once. Besides the above prizes, the prizes offered by Mr. Wilson and Mr. Loder for plant labels are still under adjudication. A selected number of the labels sent in are now undergoing practical trial. The award will be made as soon as the trial has been continued for a sufficient period.

Examinations.

With regard to the Examinations, the Council have no alteration to announce on last year's programme. The examinations in practical music will be held in London in July, and probably at Liverpool on dates to be hereafter announced.

International Health Exhibition.

The members are aware, from the announcement made by H.R.H. the Prince of Wales, at the closing of the Fisheries Exhibition, that it has been decided to hold, on the grounds of the Horticultural Society, a series of Annual Exhibitions, the first of which will be devoted to Health and Education. As regards Health, His Royal Highness, the President of this Society, may be said to be carrying out, on a larger scale, work with the commencement of which he was closely associated in the Society of Arts. The Sanitary Conferences of the Society, held from 1876 to 1880, and the Conferences on Domestic Economy, with both of which series the name of the late Sir Henry Cole was so intimately connected, were held under the approval of the Prince of Wales, and it was at his initiation that the important Conference on Water Supply, in 1878, was held. What part the Society of Arts can take in carrying out His Royal Highness's wishes in regard to the South Kensington Exhibition yet remains to be seen. It may, however, be stated that the Council, in answer to a communication from the Executive Council of the Exhibition, have expressed their readiness to render any services which may be in the power of the Society to offer. The Society is represented on the Executive Council by their President.

Obituary.

SIR WILLIAM SIEMENS, D.C.L., F.R.S.

The Society of Arts has suffered a severe loss in the death of Sir William Siemens, its Vice-President and Chairman of Council, who has been struck down in the very midst of his active work. The loss the world has sustained by the death of one of its foremost men is widely and keenly felt, but nowhere will this loss be more deplored than among the members of that Society with which he was connected during the greater part of his active life. Although, as the members know by the announcement in the *Journal*, Sir William Siemens had been ill for a short time, no fatal consequences were anticipated by those around him. About a fortnight ago, he stumbled while crossing Hamilton-place, on his way home to Bayswater-hill, and a day or two afterwards it was found that some injury had been caused to the heart, but it was hoped that rest would in time bring about a restoration to health. On Monday last, however, he was taken with more alarming symptoms, and at nine o'clock at night he expired at his residence, 3, Palace-houses. At the *post-mortem* examination it was found that the cause of death was ossification of the heart, which might at any time have brought about a fatal issue. How strong was Sir William Siemens's feeling of interest in the Society over whose proceedings he presided with such assiduous attention, courtesy, and judgment, he himself expressed on the very last occasion when he took the chair, which was at the annual meeting held on the 27th June. When acknowledging the vote of thanks accorded to him, he said "that the Society of Arts had a very old claim upon him; it was, he might say, the first society with which he became acquainted, and the first which recognised his labours, by awarding him in 1850 its gold medal." He was elected a member on 21st November, 1849, and this medal was awarded in the following year, for his Regenerative Condenser. On April 21st, 1858, he read a paper before the Society, "On the Progress of the Electric Telegraph." The Albert Medal was awarded to him in 1874, "for his researches in connection with the laws of heat, and the practical applications of them to furnaces used in the arts; and for his improvements in the manufacture of iron, and generally for the services rendered by him in connection with economisation of fuel in its various applications to manufactures and the arts." He has been continuously on the Council from 1874 until the present time, having been elected a Member of Council in that year; a Vice-President in 1870, and Chairman in 1882, and again in the present year.

In consequence of the postponement of the Conversazione to a later date than usual, the annual meeting was not the last occasion upon which he appeared as Chairman of the Council, and his munificence in connection with that Conversazione will long be remembered by all associated with the Society.

The announcement that Sir William Siemens would be unable to deliver the usual Chairman's address on the opening meeting of the new session was naturally received with great regret. The remembrance of the important address of last year caused large expectations to be raised respecting the one for the present year; but the disappointment experienced was tempered by the further announcement that the address would, it was hoped, be only postponed to a date to be hereafter fixed. A portion of the address had been written when Sir William was taken ill, and it was his intention to treat of measurement generally, and of that of electricity in particular, so that there is little doubt but that this year's address would have equalled that of last year in the originality of its conception and the interest of its contents.

Charles William Siemens was born at Lenthe, in Hanover, on the 4th of April, 1823. He was educated at the Gymnasium at Lübeck, afterwards at the Polytechnic School at Magdeburg, and finally at the University of Göttingen, where he studied under the distinguished Professors, Wöhler and Himly. In 1842 he became a pupil in the engine works of Count Stolberg, and here he laid the foundation of his engineering knowledge. It was to introduce to the English public a joint invention of his own and his brother Werner in electro-gilding that William Siemens first came to England. This was in 1843. Speaking, two years ago, to the members of the Birmingham and Midland Institute, Dr. Siemens, as he was then, gave an interesting account of the difficulties which not unnaturally beset the young foreign inventor, so ignorant of the language of the country that his first visit was to an "undertaker," under the impression that he was a suitable person to take up and bring out his invention. He was able to dispose of his invention so far successfully to Messrs. Elkington and Mason, of Birmingham, that he was induced in the following year to come back again on a similar errand. This time it was his "chronometric governor," an apparatus which, though not very successful commercially, introduced him into the engineering world, and was really the cause of his settling in this country. The chief use of this apparatus, intended originally for steam-engines, has been found in its application to regulate the movement of the great transit instrument at Greenwich.

The process of "anastatic printing," a process only superseded by recent advances in the application of photography to the same purpose, was due to William and Werner Siemens, and it was made the subject of a lecture at the Royal Institution, in 1845, by Faraday, whose last lecture there was on the advantages of the Siemens furnace. When, in 1874, Sir William Siemens designed his remarkable vessel, intended for the laying of the Direct United States cable, he named it, in remembrance of the famous philosopher, *The Faraday*.

His studies in the dynamical theory of heat, led him to pay special attention to methods of recovering the heat generally allowed to run to waste in various engineering and manufacturing processes. The first application of these researches was in the regenerative steam-engine which he set up, in 1847, in the factory of Mr. Hicks, at Bolton. In this, superheated steam was employed, but its use was attended with certain difficulties, which have prevented the commercial introduction of the invention.

The direction in which he was then working was stated in a paper he read before the Institution of Civil Engineers in 1853, on the conversion of heat into mechanical effect. This paper gained him the Telford Premium and medal of the Institution; and only last week the same Institution voted him their Howard prize, which is given quinquennially to the inventor of an improved process connected with iron-making, and has only been once awarded before—to Sir Henry Bessemer. In 1857, William Siemens, in connection with his younger brother and then pupil, Frederick, turned his attention to regenerative furnaces for metallurgical purposes. The regenerative gas furnace, as it is certainly the greatest invention due to the Siemenses, is the one in which William Siemens is believed to have had the largest share. The first successful application of these furnaces was in 1861. The earlier application of the principle of the regenerative furnace to steel and glass-making have been followed by its extension to many other industrial purposes in which great heat is required, the powers of the furnace being only limited in practice by the nature of the materials of which it can be constructed.

The application of the furnace to the making of iron and steel naturally led the attention of its inventor to other improvements in the same manufacture. In 1862, he endeavoured to reduce to practice the result of Reaumur's experiments in making steel by fusing malleable iron with cast steel. After some years experimenting, the Siemens process of steel making was perfected, and a little later still the Siemens-Martin process. In the latter, scrap iron is melted in a bath of pig iron on the hearth of the furnace; in the former, ore is reduced. The production of steel in this country, under Sir William Siemens's processes, was 340,000 tons in 1881.

It is, however, with the electric light that the name of Siemens is, at the present time, most closely associated in the popular mind. It was on the 4th February, 1867, that his paper on the conversion of dynamic into electrical force, without the use of permanent magnetism, was received by the Royal Society. Strangely enough, at the meeting of 14th February, when it was read, another paper in which the same discovery was enunciated by Sir Charles Wheatstone was read; while there is yet a third claimant, in the person of the late Mr. Cromwell Varley, who had previously applied for a patent in which the idea was embodied. As regards the Siemens discovery, the originator of the idea was Dr. Werner Siemens, who, on being shown an electrical motor constructed without permanent magnets, immediately saw that a generator without permanent magnets was equally possible. The details, however, of the construction of the Siemens machine, and the various improvements by which it has been brought to its present form—or, rather, forms, for there are, of course, several varieties—are due alike to the younger and the elder brother; generally of all the various inventions which emanated from the great firm of Siemens Brothers the same may be said.

In the installation of the electric light, the firm was among the foremost. At the Paris Exhibibition they were *facile principes;* at Munich, at Vienna, and at the Crystal Palace, they were alike conspicuous. Visitors to the lately-closed Fisheries Exhibition will remember how large a share of lighting there was effected by Messrs. Siemens. As regards the electrical transmission and conveyance of power, this is a field they have made peculiarly their own. The Berlin electric railway and that at Portrush, are alike the work of one or other branch of the firm. Working at the subject of the electric light had of late led Sir William Siemens to considerations of the nature of the light itself. The tendency of some of these thoughts is shown by certain of his recent communications to the Royal Society, including his last paper of all, in April last, "On the Dependence of Radiation on Temperature," and these, again, influenced by his earlier studies on the conservation of energy, led him to one of the most recent of his researches—that which produced his theory of the conservation of solar energy. Sir William Siemens was not so voluminous a writer as some of his contemporaries, but thirty-five papers are registered in the Royal Society "Catalogue of Scientific Papers" as due to his labours, and, since that work closes in 1873, several others might be added to the list. When it is remembered that each of these papers represents a discovery, or at all events a large amount of experiments, the great labours of his life become evident.

Honours were freely awarded to Sir William Siemens. The medals of the Society of Arts and the Institution of Civil Engineers have already been mentioned. He was elected a Fellow of the Royal Society in 1862, and he served on Councils of that Society in 1869-71, and in 1878-80. At the Exhibitions of 1851 and 1862 he received prize medals, and in 1867 he was awarded a *grand prix* at the Paris Exhibition for his regenerative gas furnace and steel process. In 1875 the Iron and Steel Institute gave him the Bessemer medal, and last April he was knighted, in recognition of his scientific services. He was honorary member of various foreign scientific societies, and possessed several foreign orders, among them that of the Legion of Honour. In 1870, the University of Oxford conferred upon him honorary degree of D.C.L., and some years later the University of Dublin and Glasgow followed with the degree of LL.D., and the University of Würzburg with that of Ph.D. He was the first President of the Society of Telegraph Engineers, and served a second time in that capacity. He had been President of the Institution of Mechanical Engineers, of the Iron and Steel Institute, and of the British Association, and he served some years on the Council of the Institution of Civil Engineers.

In addition to a full account of the life and labours of Sir William Siemens, the *Times* of Wednesday, the 21st inst., contained an appreciative leading article upon his career, the greater portion of which is here reprinted:—

"The death of Sir William Siemens, at the comparatively early age of 61, deprives the world of the services of a singularly powerful and fertile mind. Had he been spared, as but for an accident it is reasonable to believe he might have been for many years to come, he would, beyond doubt, have yet further enriched the world with discoveries in the realms of speculative or applied science. * * * * For nearly forty years he has been an English citizen, and has devoted a large portion of his time and ingenuity to the perfecting of processes for the improvement of a staple English industry. His name recurs upon every page of the history of iron manufacture since he came among us; and although some of his inventions have not proved entirely suitable to English ores and English wants, it is impossible to exaggerate the importance of others, whether directly or through the stimulus they gave to the minds of English manufacturers. It has been thought fitting that one who has thus identified himself with us, and has achieved great things, not merely in that important department, but in chemistry, in engineering, and in electrical researches, should now be honoured with such public and formal recognition as it is in our power to give. It will be admitted by all that if we are to have a national pantheon, none can more justly claim a place therein than a man who has attained the highest eminence in the subjects which it is the boast of the present day to have carried to a perfection unknown before. Science now claims the services of the most powerful and highly-trained intellects; hence it is natural and proper that we should announce our belief in the worth and greatness of our chosen pursuits by doing honour to the men who enlarge the scope of scientific speculation, and add to the solid results of practical effort. Unfortunately, every claim of this kind raises questions which derive their relevancy and importance only from the poverty of our resources. We have no adequate means of doing honour to departed greatness, and the Abbey which we have converted to the uses of a pantheon has retained so much of its original character as to create a perpetual conflict between different orders of ideas. We have modernised it so far that it is difficult to resist the further demands of the modern spirit, yet so much of its original character remains as to give room for continual resistance. The question whether a man deserves national honour and commemoration, which in the case of Sir William Siemens would cause no difference of opinion, is complicated with the totally different question whether the means actually at our command are sufficient to satisfy an admitted claim.

"Sir William Siemens was essentially an inventor. In whatever direction he turned, his thoughts seemed to perceive new methods of working out old problems, or to discover new problems which it immediately became his province to solve. There is an abundance of most meritorious inventors who proceed upon one line of thought only, and show no aptitude for creative work in any other direction. But the inventor proper is one who, like Sir William Siemens, is continually throwing out original ideas in spheres where others find it sufficiently difficult to master what has already been done. His patents were numerous and various, but he invented many things which he never patented, and conceived many ideas which can never become the subjects of a patent. His improvements in the manufacture of steel have probably produced larger results than any of his other discoveries, but that is rather because the field of their operation is of great extent and importance, than because they are intrinsically greater than his achievements in other directions. Electricity is in its infancy, hence the most remarkable discoveries must, as yet, have comparatively restricted pecuniary results, but the vigorous growth of the new science is very greatly due to his early appreciation of the possibilities opened up by a method of converting force directly into electricity. He showed his usual versatility in perceiving the numerous ways in which the new and copious supplies of electrical energy can be utilised. His electric furnace, intended to melt considerable quantities of refractory substances hitherto fused only in minute beads, or by means of enormous and costly furnaces, is only an example of the readiness with which he applied new forces and new ideas. Whenever machinery was required for the carrying out of his aims, he seemed to invent new arrangements with the same facility. He found serious defects in the mode of insulating telegraph wires, and forthwith devised a machine for covering them effectively and cheaply with India-rubber. Ordinary ships were unsuitable in various ways, even after much ingenious adjustment, for the work of laying telegraph cables, so Sir William Siemens designed the *Faraday*, a vessel crowded with special provisions for her peculiar work, and capable of being turned, by a novel arrangement of her screws, upon her own axis. Some new construction of hydraulic presses and receptacles for compressed air had become desirable, and again Sir William Siemens produced the thing required. The measurement of high degrees of heat has always presented serious difficulties, but he invented a method of electrical measurement which gives any temperature, from that of the sea bottom to that of the interior of a blast furnace. These extremely diverse inventions, which are merely samples of his restless activity, may serve to convey some idea of the fecundity and originality of his mind.

"His practical labours, great and manifold as they were, left him time and energy for the most abstruse speculation. While astronomers quietly accepted the conclusion that the sun is cooling down, and will become at some distant and calculable epoch a mere cinder hung in space, he endeavoured to show that energy can no more be lost in the solar system than in the laboratory. The ingenious theory he advanced to show that force returns to the sun is based upon the assumption that aqeuous vapour and carbon compounds are present in interstellar space, and that the solar energy which is sometimes assumed to be lost in the empty void really acts upon these substances, and converts the universe into a kind of vast regenerative furnace. In some recent observations of the luminous extensions from the body of the sun, he found corroboration of his views. They were, of course, severely criticised, and may be admitted to amount to nothing more than an ingenious theory; but then there is nothing to set up against them except other views equally incapable of proof and considerably less ingenious. It must have happened to many men to feel the profoundly visionary character of many statements confidently put forth concerning the constitution of the universe, and they will at least be grateful to Sir William Siemens for rebelling against the tyranny of an induction founded upon extremely meagre knowledge. It is more scientific to believe, with him, that there is some restorative and conservative agency at work, than to suppose that the universe is gradually cooling down into balls of slag, were it only because his theory does not require an effort of creation at once tremendous and futile. It leaves us free to avoid contemplating a time when the solar system was not, and another when it will cease to be. In another and very different direction we find Sir William Siemens seeking relaxation in the less sternly practical applications of science. It occurred to him to try the effect of the electric light upon the growth of plants, and he succeeded in considerably accelerating their development. It has not been proved either that continual light is incompatible with plant sleep, or that it could be applied to successive generations without pernicious effects. But his experiments remain extremely curious, and form another illustration of the extraordinary originality and resource of the intelligence now prematurely quenched in death."

Miscellaneous.

PISCICULTURE.

By J. J. Manley, M.A.

Pisciculture, as applied to both salt and fresh-water fish, was well illustrated at the recent Fisheries Exhibition; and it is expected that an impetus will be given to its pursuit in this country, which has hitherto been somewhat backward in this matter, except as regards the artificial propagation of the *Salmonidæ* family. The culture and acclimatisation of salt-water fish has made little progress among us, and foreign countries have left us far behind. The Romans, in the time of the Empire, paid great attention to salt-water fish farming, rich men having extensive and elaborate vivaria for amusement sake and gastronomic pleasure, while others cultivated fish for profit. Arrangements were made for the fish to run into the vivaria from the sea and deposit their ova in them, and spawn was collected in the sea itself and brought into the vivaria to hatch. Exotic fish also were brought from long distances. But the artificial propagation of fish does not appear to have been practised till the fifteenth century, and in this country not till within the last fifty years; and we are still without any recognised establishment or enterprise for the culture of sea fish. The United States Government are thus far ahead of our own, and the shad has been artificially disseminated in many districts, to say nothing of the success in other branches of pisciculture. Other Governments are following the example of the United States; and in England it is hoped that the establishment of a marine biological station, or stations, will lead before long to an extensive system of marine pisciculture and the acclimatisation of foreign fish. The recent news from America, that the spat of the oyster has been successfully impregnated by artificial means, will give a further impetus to marine pisciculture.

In the matter of pisciculture in fresh water, other countries, notably France with its famous Huningue establishment, and Germany, are also in advance of us, notwithstanding many admirable private enterprises, such as those at Stormontfield, on the Tay, and of Sir J. Gibson Maitland, at Howietown. But there is no fear now that the culture of salmon and trout, and their allies, will not make continued progress, and it is already an established and remunerative industry. The culture of other and commoner kinds of fresh-water fish is another matter, and this, too, has, directly and indirectly, had fresh attention called to it by the Fisheries Exhibition; and it is to this branch of pisciculture the following remarks are directed.

The question seems to present three chief heads for consideration; the first, whether pisciculture applied to fresh water could be so carried out in this country as to supply an amount of food which would be a sensible addition to our resources; the second, whether the fish food thus produced would be acceptable to our tastes; the third, whether pisciculture would pay commercially. As to the first point, there can be little doubt but that the supply of fresh-water fish of the ordinary kinds might be immensely increased by proper culture. By ordinary kinds are meant jack, carp, tench, roach, dace, perch, chub, gudgeon, bream, and eels; but the culture of the *Salmonidæ* family is not included, as it forms a distinct branch of this question, and may be considered as an established and remunerative industry. Pisciculture, as applied to the common fresh-water fish of different countries, is a very ancient art. It was successfully practised by the Greeks and Romans, and probably by the Egyptians before them. It has been a branch of public industry among the Chinese for many centuries, and at the present time fresh-water fish form the cheapest and most plentiful food in that country. This is the case also to a very great extent in Japan, where, by the way, it is said that most fish are preferred in a raw to a cooked state. For many centuries the abbeys and monasteries in this country produced a large supply of fish food from their ponds and stews; and during the Church fasts, which were many and often of long duration, a large proportion of the population lived mainly on a diet of fresh-water fish. The monks, and country gentlemen too, in those days, must have had tolerably good ideas of pisciculture, as the different old books on the formation and management of fish ponds indicate; and it is certain that fish formed a very considerable portion of the food supply of the kingdom. With our improved knowledge of natural history, and especially of the method of expressing the ova from fish and artificially hatching them, whereby the increase of production is extended a thousand-fold, we could, doubtless, raise a very large stock of fish in our ponds and rivers; but, considering the great increase in the population, it is more than doubtful whether the supply thus obtained would be any very appreciable addition to our food resources.

But though the supply of "coarse" or common fresh-water fish, could be greatly increased, the acceptability of such fish as food to the mass of the population is very uncertain; indeed, the popular verdict seems decidedly against them, with few exceptions. They have all, more or less, a palpably muddy taste, and where this is not predominant, they have but little more flavour than stewed blotting paper. Even trout, from many streams that could be named, are either insipid, or partake to a great extent of the characteristic flavour of other fresh-water fish. Persons may be found, indeed, who will go into raptures over jack stuffed with the appropriate "pudding," or over carp and tench stewed *secundum artem*. Even roach, dace, barbel, and bream, find advocates; but in this matter, the *vox populi* is probably right; and it is more often the sauce or the stuffing which gains admirers than the fish themselves. It may be admitted that there is a vast difference in fresh-water fish, and much depends on the way of cooking them. Thames fish have a decided superiority over most others; and the wives of Thames puntsmen, and cooks at Thames-side hostelries, seem to excel in the art of serving up the fish from their river. The secret chiefly lies in cleaning the fish as soon as possible after they are caught, and thoroughly drying them when split open, in the sun and wind before cooking. Thames gudgeon, when properly cooked, are by no means bad eating, and are fairly entitled to the name of "fresh-water smelt." Thames perch also, and jack, are certainly eatable; and a Thames trout is undeniably excellent, but he is a *rarissima avis*. Thames fish, are however, an exception. Those from other rivers are mostly inferior; while it is no exaggeration to say that fish from stagnant water, or from ponds and lakes which have only a slight stream running through them, can hardly be considered as coming within the category of acceptable food. Even enthusiastic anglers can hardly dare to advocate the culinary merits of fish from the Norfolk Broads. As a rule, the poor will not eat fresh-water fish, even when they can get them for nothing, or when *paterfamilias* brings home a basket of "coarse" fish of his own catching, pretends to like them himself, and his family eat them out of compliment to the catcher.

When a pond or river is dragged, the owner, as a rule, can hardly find persons to carry away the carp, tench, and other such fish captured. As an instance of this, I once saw large heaps of fine roach, which had been netted out of the trout water round Wilton, lying on the banks, and no one caring to come for them, though a general invitation to help themselves had been given to all the country side. There is little or no market for coarse fish in London, except at particular seasons, when the Jews will buy them, following some "tradition of the elders." But this is a poor testimony to their goodness, when we find that barbel is the most favourite fish among the Jews, whereas most Christians would agree that this fish is the most unpalatable one our waters produce. It may be said that this popular estimate of fresh-water fish is all prejudice. Perhaps it is, to some slight extent. We know how prejudice militates against the use of Australian tinned meat. We know that a true Celt will not taste an eel; or a true Englishman a snail or a French edible frog. It would take many years of "raniculture" to make the latter an acceptable article of food. But it is not all prejudice in the matter of fresh-water fish. With the exception of trout, to which may be added gudgeon and perch from the Thames and some other rivers, and eels, which, like salmon, almost stand apart by themselves in this question, fresh-water fish have either a muddy or unpleasant flavour, or are simply tasteless; add to which, the abundance of large and small bones throughout them renders them still more unacceptable. Again, it might be alleged as a proof of present prejudice, that our forefathers, not only of the lower, but the higher classes, ate and appreciated these fish. True, but this was partly because of the cheapness of this poor food, and the scarcity of better, and partly owing to their want of good taste. This is not begging the question. The tastes of a nation travel forwards, so to speak, not backwards, and food which previous generations accepted is refused by those that follow them. This is a fact, however much as in certain respects it may be a subject of regret. Jack and carp can hardly be considered as generous dishes at modern, civic, or regal banquets, as they were of old, though I believe the latter fish is still served at Windsor Castle. But the Virginia water carp do not appear at the royal table till they have spent a considerable time in clear, sharply running water, arranged for the purpose, in which they, to some extent, are freed of their muddy flavour. And after all, this serving of the old Elizabethan stew must be more a matter of form and of keeping up old traditions, than based on any real appreciation it meets with. Of course scientific pisciculture might improve the quality of our pond and river fish; and proper feeding, due cleansing of the ponds, a proper regulation of the number of fish in any given space, and a cleansing of those about to be used as food in stews of swiftly running water, according to the old custom, might do much to make the fish more palatable; but I cannot imagine that the time will ever recur when the old saying recorded by Isaac Walton, "He that hath bream in his pond hath always a welcome for his guest," will be true either in reference to the poor-eating fish named, or to the other ordinary inhabitants of our waters. We cannot expect, by scientifie culture, to improve their breed as we have that of our flocks and herds. The salmon family and eels seem to be the only products of our fresh waters really worth cultivating from a food supply point of view, or as ministering to the pleasures of gastronomists.

If pisciculture is destined to supply us with any appreciable increase of palatable fresh-water fish food, it must be by the introduction of new species from other countries, and their acclimatisation in our waters. Several such have been proposed as most suitable, and some have actually been introduced by way of experiment. For instance, the *Silurus glanis*, or "sheat fish" of Central Europe, is thought by some as a very likely kind to thrive in our waters. It is excellent food, and grows rapidly, and to a great size. It was in reference to the enormous weight which this fish attains that a humorous contemporary suggested that, if naturalised in our rivers, it would show excellent sport when played with a chain cable attached to a crane, which should move on a tramway along the river's bank. The great lake trout of Switzerland has been successfully introduced into some of our waters, and so has the *Salmo fontinalis*, or American "brook trout." The black bass *(Grystes nigricans)* from the northern districts of America, and that from the southern and western known by the name of *Grystes salmoides*, have also been found likely to suit our waters. The Marquis of Exeter has been very successful in the acclimatisation of some species of black bass at Burleigh-house, and it is a fish which would probably thrive well in some of the waters of the East Anglian Broads and rivers, as suggested by Mr. Wilmot, the Canadian Commissioner at South Kensington, on the occasion of a visit some few weeks ago to the Norfolk Broads by gentlemen connected with the Fisheries Exhibition. The black bass is a fine sporting fish, and gastronomically to be commended. To these we may add, as suitable to some of our waters, the white fish *(Coregonus albus)* of Canada, which is very prolific, and most excellent eating.

The third point for consideration is—Would pisciculture pay? Even if our ordinary fresh-water fish were acceptable to consumers, it is doubtful whether the culture of them would commercially be successful. Under no circumstances could it be expected that they would be able to compete with salt-water fish in cheapness. The cost of cultivation would, probably, be greater than the advocates of pisciculture anticipate. Letting the water off ponds in succession, and cropping them with corn or vegetables, as proposed by the late Mr. Frank Buckland, and the after removal of the soil, would involve great labour and expense. Fish are but slowly growing creatures, unless supplied with abundance of food, and this represents a further outlay. During the summer months, Mr. Buckland suggested that putrefying flesh hung over the ponds would supply maggots, and that lob-worms might be gathered in the meadows after dark. But suitable flesh is not always obtainable, and for weeks in a drought not a lob-worm will show itself. The latter are often worth from a shilling to half-a-crown a quart for fishing, in dry weather, along the Thames side; and are actually imported by thousands from Nottingham, where "vermiculture," or rather worm gathering, is a recognised industry. The difficulty and expense of feeding the fish in the winter would be still greater. It certainly would not pay to supply them, as Mr. Buckland did his small fry of various kinds at South Kensington, with "chopped beef-steak and biscuits." Whether the quicker growth of foreign fish proposed for naturalisation would cover the expenses attached to their culture, is a matter on which it is almost impossible to give an opinion. It would be satisfactory to think that careful calculations as to the whole matter would give good grounds for expecting that any system of pisciculture in fresh water would answer the expectations formed of it by its advocates. At all events they will be benefactors who can make two fish to live where only one lived before, and will, by the introduction of new species, develop the capacities of our now generally ill-stocked waters. As an encouragement to such, it may be noted that in Germany the scientific culture of carp in ponds is found to be remunerative, as in that country, and in some other districts on the Continent, this fish is still specially popular as an article of food.

Perhaps the recent establishment of the National Fish-culture Association of Great Britain and Ireland, the honorary secretaries of which are Mr. R. B. Marston and Mr. W. Oldham Chambers, will do much towards the solution of the question. It is certainly one which may fairly be taken up by scientific and philanthropic members of the community; and perhaps many of the general, and especially the angling, public will supply funds for the acquisition of some suitable water or waters, for experiments in the way of pisciculture, not so much in the hopes of receiving a pecuniary return, at least for the present, as for the purpose of practically testing the possibility of improving our own fresh-water fish supply by cultivating the species already in our rivers, ponds, and lakes, or naturalising new ones. Such an attempt would have the sympathy of a considerable public interested in the subject, and could not fail to elicit valuable information. It is hoped that the remarks here made will not be considered as discouraging to such an inquiry. Even apart from the question of fresh-water fish as contributing to our food supply, their multiplication for the sport of the angling fraternity is a matter well worth attention, as the facilities for rational and wholesome recreation are no mean elements towards the well-being of a nation, and especially of its poorer classes.

REMARKS ON BALATA AND OTHER PSEUDO-GUTTAS.

By James Collins.

The great value of gutta-percha, the fear of the supplies, in time, not equalling the demand, has led to the recommending of various substances as substitutes, or as supplementary, to the present supplies of gutta-percha. The following notes may be taken as a short *resumé* of the subject, and indications are given as to the way in which these substances may possibly be utilised. For convenience, these various substances are grouped geographically:—.

I.—American Sources of Supply.

Natural Order, *Sapotaceæ.*

Balata Gum* (*Mimusops Balata*, Gærtner), known also as paardenvleesch (horseflesh), bullet tree, boerowé, bolletrie, &c., is found in Demerara, Berbice, British Guiana, Antilles, Jamaica, and Surinam.

Professor Bleekrod was one of the first writers on the subject, his communication being addressed to the Society of Arts, in 1857,† and the tree described and named by him as *Sapota Mulleri.* In 1860, Mr. Walker‡ communicated samples, &c., received by him from Dr. Van Holst, of Berbice; and, in 1864, Sir William Holmes§ also drew the Society's attention to the same subject.

The tree is a large one, with a trunk of about 6 feet in diameter, and furnishes a wood much liked for building purposes. The Dutch name, "paardenvleesch," is given on account of the wood being of the colour of horseflesh. The bark is thick and rough, and the fruit is of the size of a coffee-berry, sweet like a plum, and with a hard white kernel, which yields a bitter oil. The leaves are glossy, oval, and acuminated. The milk is drunk by the natives, and when diluted with water is used as a substitute for cows' milk. The tree grows in groups, and in alluvial soil.

The "Balata" gum is of a character somewhat between caoutchouc and gutta-percha, combining in some degree the elasticity of the one with the ductility of the other, freely softening and becoming plastic, and easily moulded if plunged in hot water. What small parcels were sent to this country met with a ready sale, and were remarkably pure and free from adulteration. But, unfortunately, through the difficulty of collection, the undertaking being dangerous and unhealthy, the supply of this excellent article has fallen off.

The Balata is collected by making incisions in the bark, about 7 feet from the ground, and a ring of clay placed round the tree to catch the milk as it exudes. The yield is said to be in profusion, especially at the time of the full moon, and the operation can

* The term "gum" is here used in its colloquial, not in its scientific sense.

† *Journal of the Society of Arts*, London, Oct. 8, 1857.

‡ *Ib.* Aug. 24, 1860.

§ *Ib.* Mar. 4, 1864.

be repeated every two months in the rainy season. It takes six hours to bring about coalesence by simple atmospheric influence, but very quickly by boiling in water. A large tree is said to yield as much as 45 lb. of "dry gum."*

II.—Indian Sources of Supply.

Natural Order, *Sapotaceæ.*

Pauchontee, or Indian gutta tree (*Dichopsis elliptica*), is the *Bassia elliptica*† of Dalzell, and the *Isonandra acuminata* of Cleghorn‡, and is found distributed through the Wynaad, Coorg, Travancore, Anamally, and Neilgherry Hills, Sholah Forest, Cochin, and the Sichars. According to General Cullen, it "appears to be common in all the forest tracts at all within the influences of the south-west rains."

This tree, which is now placed in the same genus as the true Malayan gutta-percha, is a large one, attaining a height of from 80 to 100 feet. The gum is obtained by tapping, a pound and a-half being obtained from one tree, by five or six incisions, a large tree yielding from 20 to 40 lb. of sap. Many experiments have been tried with the raw milk, and General Cullen and Dr. Cleghorn used every exertion to bring the substance prominently forward. The simply dried milk was found wanting in several essential qualities for telegraphic purposes, but has been recommended as a sub-aqueous cement or glue. When dissolved in ordinary gutta-percha solvents, it, after the evaporation of the solvent, remains some time soft and viscid, and partaking somewhat of the characteristics of bird lime. When cold it is hard and brittle.

Natural Order, *Euphorbiaceæ.*

Cattimandoo (*Euphorbia Cattimandoo*, W. Elliot), is found in Vizagapatum, and was first brought to notice by the Hon. W. Elliot, who was awarded a prize medal by the jurors of the 1851 Exhibition. This spiny euphorb grows to the size of a shrub or small tree, and the milk flows out freely when a branch is cut. The natives use the milk as a cement to fasten knives in handles, &c. Under the influence of heat it becomes soft and viscid, becoming very brittle on drying.

The Milk Hedge, Indian Tree Spurge, or Tirucalli (*Euphorbia tirucalli*, Linn), common in the Coromandel, Malabar, Bengal, &c., is a succulent unarmed plant attaining a height of about 20 feet. Its inspissated juice is used for various, chiefly medicinal, purposes in India, but has a very acrid character, rendering its collection a very dangerous operation to the eyes.

Natural Order, *Apocynaceæ.*

Alstonia, or Pala Gum (*Alstonia scholaris*, R. Br.).—This tree is found distributed through Travancore, Coromandel, Assam, and in Ceylon. It attains a height of fifty feet, and its wood and bark are much valued in India for their medicinal qualities. To Mr. Ondaartjee is due the credit of recommending Pala gum as a substitute for gutta-percha.* It readily softens in water, and retains, when cold, good impressions of any objects. Good specimens, properly prepared are, however, much wanted.

Natural Order, *Asclepiadaceæ.*

Mudar Gum (*Calotropis gigantea*, R. Br.).—This shrub is found distributed throughout the Peninsula and Southern Provinces of India, in waste places, and grows to a height of 6 to 10 feet. Ten average trees are said to yield about one pound of gutta-like substance, which is plastic in hot water, and in other ways behaves like gutta-percha. *Calotropis procera* is said to furnish a like product.

III.—Ceylon Sources of Supply.

Natural Order, *Sapotaceæ.*

Ceylon has many species of *Dichopsis*, *Isonandra*, and other closely allied genera, which are likely to yield a gutta-like substance. The late Dr. Thwaites, the talented director of the Government gardens at Peradenia, informed me that the natives did not collect any gutta, and one sample sent to the late Sir W. J. Hooker was unfavourably reported on. In some parts of Ceylon, the climate is similar, if not identical, with the Malayan Archipelago, the home of the true gutta-percha.†

IV.—African Sources of Supply.

At the Cape of Good Hope there are many species of euphorbias which yield a substance very similar to cattimando, but like the *Euphorbia officinalis*, Berg, the juice is so acrid as to give intense pain and irritation to any part of the body with which it may come into contact, especially the nostrils. The Rev. J. C. Brown, whilst botanist to the Cape Government, paid much attention to the subject, and the juice has been recommended as an anti-fouling dressing for ships' bottoms.

Mr. Barter, whilst on the Niger expedition, collected a specimen from a species of *Chrysophyllum*, which was said to resemble gutta-percha. Tropical Africa should undoubtedly yield some such substance.

With regard to these various substances, it may be said that Balata gum has an assured value of its own, and efforts should be made by cultivation or acclimatisation to utilise this valuable substance. With regard to the others, the consideration of some of the aspects of the gutta-percha question may throw some light on the subject.

The utilisable products existing in plants is a most important question in phyto-chemistry. As to their use and characteristics whilst in the plant we know little, and that little is almost entirely inferred from the characteristics of the products after they are extracted from the plant. Thus, indigo does not

exist as indigo (as we know it) in the plant itself, but is the result of fermentation after the juice is extracted from the plant. Sugar-cane juice too, furnishes us with an illustration as to how quickly products change after taken from the plant. The juice whilst in the cut cane even does not change, but as soon as it is expressed it speedily ferments, and uncrystallisable sugar is the result—a result which is retarded at least by the addition of lime. Thus with these and many other substances, exposure to atmospheric influences, induces change, and a new set of chemical combinations are inaugurated. Some products, such as alkaloids, acids, resinous matters, &c., are not used, so far as is known, in the economy of the plant, and are accordingly removed from young and active portions of the plant to store cells or reservoirs; whilst others, such as gums, starches, &c., undergo many changes, are changed from starch to gum and to sugar, and are freely used up in the sustentation and growth of the plant. In cinchonas it has been proved by analysis that those growing in hot valleys have a greater development of bark and a lesser elaboration of alkaloidal contents, whilst in the mountains the reverse is the case. This may arise from the alkaloid, or its primal constituents, being used up in the elaboration of tissue, or its larger formation being at the expense of tissue, or it may be from simple translocation, that is, a process of removing products from the active part of a plant to store cells or reservoirs.

With regard to gutta-percha, these facts have a very important significance, and are worthy of all attention, bearing as they do also on pseudo-guttas. Gutta-percha, as it flows from the tree, is a viscid fluid, acquiring milkiness and concreteness on exposure to the atmosphere, and unless arrested, the change results in two resins, *albine* and *fluavile*. Thus, according to M. Payen, the analysis of commercial gutta-percha gives—

	Per cent.
(a) Pure gutta (an hydrocarbon, milk-white in colour and fusible)	75 to 82
(b) Resins soluble in boiling alcohol, and consisting of two parts :—	
(1) Crystalbine or albine, a white crystallisable resin, crystallising out of the alcohol as it cools	16 to 14
(2) Fluavile, a yellow amorphous resin, falling in a powder on the cooling of the hot alcohol in which it is soluble	6 to 14

It is thus apparent that the change of pure gutta into a resinous-like mass takes place naturally, if means are not taken to stop it. This resinification I have often witnessed. If two bottles of equally pure and identical gutta be taken, and the one bottle hermetically sealed, and the other left exposed to the atmosphere, the first will retain its goodness, and the other will become resinified, and as brittle as shellac. Again, from experiments extending over years, both at home and in the East, I have found "getah muntah," or raw or "uncooked" gutta, soon become a resinous mass, being, in fact, in character like so much kowrie gum or cutch.

This change, I have proved experimentally, can be lessened, retarded, or altogether obviated, by thoroughly well boiling the product immediately after collection.

There is also another fact to bear in mind, with regard to this proneness to chemical activity in gutta-percha. In cutting through the bark to arrive at the laticiferous, or milk-bearing vessels, many other vessels and cells become ruptured, containing tannic, gallic, and other proximate principles, and the presence of these no doubt initiate and accelerate oxidation. In opening bottles of milky juices, a turbidity and effervescence is often noticed, owing to the formation of a brownish liquid, the colour of which is probably due to the presence of gallic acid, and gallic acid has been found to exist naturally in parenchymal cells and milk-ducts. In blocks of gutta-percha which have not been properly prepared, these foreign substances induce the presence of a brown, fermented, and putrid liquid, which decomposes the internal mass. Now, most of these foreign substances are soluble in water, and in the process of boiling the gutta would be eliminated.

These considerations seem to prove that some, at least, of these pseudo-guttas are worthy of, and indeed require, fresh trials before their utility can be certified, or otherwise.

To those who have the opportunity, I would recommend that samples should be collected in the manner I have already pointed out in the *Journal* of this Society.*

These samples and results, if submitted to competent authorities, would enable the question of these substances being utilisable as substitutes, or rather as supplementary sources of supply, to be set at rest.

PIURI OR "INDIAN YELLOW."

The following communication has been received from the India-office :—

Piuri is a yellow dye, used chiefly in painting walls of houses, doors, and railings. It is seldom used for dyeing cloth, owing to its bad smell. It is derived from two sources—(1) of mineral origin, imported from London; (2) of animal origin, manufactured at Monghyr, a town in Bengal. Sir Joseph Hooker has asked for information about the latter.

By inquiries in Calcutta, I found that piuri is made at Monghyr from the urine of cows fed with mango leaves. To substantiate the truth of this statement, I went to Monghyr, and there found that a sect of

* *Vide* "Africa," &c. Letter by James Collins, *Journal of the Society of Arts*, April 25th, 1879, p. 467. See also "Report on the Caoutchouc of Commerce," to Her Majesty's Secretary of State for India, p. 46, iv., 1872.

gwalas (milkmen), residing at a place called Mirzapur in the suburbs of the town, are the only people who manufacture the substance. They feed the cows solely with mango leaves and water, which increases the bile pigment, and imparts to the urine a bright yellow colour. It is said that the cows thus fed die within two years, but the piuri manufacturers assured me that this statement is wrong; and, indeed, I myself saw cows six or seven years old from which piuri has been obtained during the last four years. The cows, however, looked very unhealthy, and the manufacturers of piuri told me that, to keep up the strength of the animal, they now and then allow her grass and other fodder besides the mango leaf, but a mixed food reduces the proportion of the colouring principle in the urine. Owing to the injurious effect which the treatment necessary for the manufacture of piuri has on the cows, the occupation of making piuri is confied to a very small number of people, who for this reason are looked down upon by their fellow caste-men. I am told that in no other part of the country is the manufacture of piuri carried on. The cows treated with mango leaves are made to pass urine three or four times a day by having the urinary organ slightly rubbed with the hand, and they are so habituated to this process that they have become incapable of passing water of their own accord. The urine is collected during the whole day in small earthen pots, and in the evening put over a fire in an earthen vessel. The heat causes the yellow principle to precipitate, separating it from the watery portion. It is then strained with a small piece of cloth; the sediment is made into a ball, and dried first on charcoal fire and then in the sun, when it is ready for the market. The merchants (chiefly Marwaries), who advance money to the milkmen for the purpose, purchase the stuff at R. 1 (1s. 8d.) per lb., and export it to Calcutta on the one side and Patna on the other. The price of the imported (mineral) piuri is only 4d. per lb. The animal piuri is of an exceedingly bright colour, and is therefore considered very superior to the mineral piuri. The high price of the animal piuri is probably owing to the deterioration of the live stock consequent on the manufacture of the article, and the cost of procuring mango leaves, which are sold at the rate of Rs. 2 for the produce of a middle-sized tree, say 30 feet high. An average cow passes about three quarts of urine per day, which yields about 2 ozs. of piuri. The animal supply is said to be about 100 to 150 cwts.; but this seems to be an over-estimate, considering the small number of cows employed for this purpose.

I myself saw mango leaves lying before the cows, the collection of urine, and the manufacture of piuri. So the real source of this kind of piuri is now beyond any doubt whatever.

I have sent to Sir Joseph Hooker direct—(1) The mineral piuri brought to Calcutta from London; (2) Monghyr piuri purchased at Calcutta; (3) Monghyr piuri purchased from the manufactures; (4) a bottle of urine from which the piuri is obtained; (5) an earthen pot in which the urine is collected; (6) quantity of mango leaves.

SOUR BEER.

In your last issue "Hampshire Brewer" invites suggestions for means of utilising, in some outside industry, the sour beer which he considers renders any fresh beers to which it is added unpalatable to the modern beer drinker.

Now, it is very difficult to conceive of any use to which "returns" could be put, without incurring serious loss to the brewer; for, although the beer is sour, still it approximates very closely to the sound article; and one may safely say, that no manufacturer could utilise, to their real value, all the various constituents of the sour beer which the brewer has been at so much trouble and expense to produce in their right proportions.

It therefore seems that steps should be taken rather to render sour beer suitable for mixing with fresh without the mixture appreciably differing in flavour from ordinary beers; and, in considering this matter, I wish to point out that there are two classes of sour beers:—Firstly, those that are more than normally acid, and are in course of undergoing the acid fermentation; secondly, those that are abnormally acid, but in which the acid fermentation has ceased; and a rough distinguishing test between the two is that, while the former are turbid, the latter are bright. But the microscope should be used to detect the presence of the acid ferment.

Naturally, the addition of the first class of sour beers, as such, would be fatal in every case, for the acid fermentation would attack the fresh beer, and additional loss to the brewer would be incurred. In the second class there is a difference. In the first place, there is no chance of a communication of the acid fermentation; and secondly, the following remarks will show that an intermixture in due proportions will not appreciably affect palatability. A very acid beer, in which acid fermentation has ceased, would not, as a rule, contain above 0·7 per cent. total acidity (estimated as acetic acid). New beer would contain 0·1 per cent. The addition of three gallons of the sour beer to thirty-three of the new, would yield a barrel containing 0·15 per cent. acidity, and this 0·05 per cent. acidity above the normal amount could not be detected by experienced beer drinkers. And there is no necessity to wait till the acid fermentation has ceased, thereby raising the acidity percentage above what it need be. Take a beer undergoing the acid fermentation, as specified above, in Class I., containing, say, 0·4 per cent. acid, destroy the acid ferment, and remove the other matters in suspension; now mix it off with fresh beer in the same proportions as above, and we have a barrel containing under 0·13 per cent. of acid.

The treatment of the sour ales of Class I., before intermixture, is too technical a subject to be properly dealt with in a letter; moreover, each individual case of beer restoration requires special treatment; but I may add that seldom, in my experience, has an exception been proved to the rule that, by proper manipulation, the ordinary sour beers may be utilised as above, without appreciable loss to the brewer.

General Notes.

EXHIBITION AT ROUEN.—The *Moniteur des Fils et Tissus* states that a national and district exhibition will be opened at Rouen on 1st January, 1884. This exhibition will comprise all the industries of the following departments:—Aisne, Calvados, Eure, Eure-et-Loire, Marche, Mayenne, Nord, Oise, Orne, Pas-de-Calais, Sarthe, Seine-Inferieure, and Somme. This portion of the display will include a scholastic group and an annexe devoted to retrospective art. The exhibition will, however, extend to the whole of France, as far as the woollen and cotton industries are concerned, and also with respect to the application of electricity as a source of light and power.

NEWCASTLE SCHOOL OF ART.—The prizes awarded to the students of this School of Art during the past year were presented to them by Earl Percy, M.P., on November 6th, in the Lecture-hall of the Newcastle Literary and Philosophical Society. The students who attended the school during the year have numbered 186, and two bronze medals and six Queen's prizes were awarded in the national competition, and twenty-one third or lower grade prizes. In the second grade examinations, conducted by the local committee in the month of May last, fifty-two candidates presented themselves for examination, of whom twenty-five were successful. In the science department, for building construction, four candidates presented themselves, of whom one obtained a first-class in the advanced stage, two a second-class in the advanced stage, and one a second in the elementary class. In the technological examinations for carriage building, one passed in honours, second-class; and in plumbers' work also, one passed in honours, second-class.

MARINE EXHIBITION AT TYNEMOUTH, 1882.—The concluding general meeting of the promoters and guarantors in connection with the North-East Coast Marine Exhibition, which was held at Tynemouth in the autumn of 1882, has just been held in the Wood Memorial-hall, Newcastle. The report of the executive committee stated that upwards of 250,000 persons had visited the Exhibition. There were about 630 exhibitors, from all parts of the kingdom, and the committee, upon the report of competent judges, had awarded 135 silver medals, 76 bronze medals, and 80 diplomas of merit. The total receipts had been £15,261 2s. 5d., and the expenditure £14,844 19s. 4d., leaving £1,116 3s. 1d. in hand available for distribution. They recommended that £750 be invested in trustees to form a nucleus of a fund for the foundation of a chair of Engineering and Naval Architecture in the Durham College of Physical Science at Newcastle, with power to establish scholarships until such time as the arrangements for founding a chair are completed. The available balance they recommended should be divided amongst local and national maritime charities and life-saving institutions. In the discussion which followed, Mr. F. C. Marshall announced that a local shipbuilder had sent him a letter to say that he would willingly subscribe £500 towards the proposed fund for establishing a chair of engineering and naval architecture. The endowment should not be less than £500 per annum, so that the chair should be worth at least £1,000 a year; and it would take £12,500 to do that.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, Nov. 26...Royal Geographical, University of London, Burlington-gardens, W., 8½ p.m. Mr. Charles M. Doughty, "Travels in North-Western Arabia and Nejd."
Institute of Actuaries, the Quadrangle, King's College, W.C., 7 p.m. 1. Address by the President (Mr. T. B. Sprague). 2. Mr. D. J. McKenzie, "An Easy Method of forming Logarithms and Anti-Logarithms, correct to ten or eleven places, with the aid of Mr. Peter Gray's Tables for the Formation of Logarithms and Anti-Logarithms to twelve places."
Medical, 11, Chandos-street, W., 8½ p.m.

TUESDAY, Nov. 27...Civil Engineers, 25, Great George-street, Westminster, S.W., 8 p.m. Mr. W. T. Douglass, "The New Eddystone Lighthouse."
Medical and Chirurgical, 53, Berners-street, Oxford-street, W., 8½ p.m.
Anthropological Inst., 4, St. Martin's-place, W.C., 8 p.m. 1. Dr. J. G. Garson, "The Cranial Characters of the Inhabitants of Timor-laut." Mr. H. O. Forbes, "Some of the Tribes of Timor." 3. Dr. G. B. Barron, "A Human Skull found at Southport."

WEDNESDAY, Nov. 28...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. A. J. R. Trendell, "The International Fisheries Exhibition of 1883."
Royal Society of Literature, 4, St. Martin's-place, W.C., 8 p.m.

THURSDAY, Nov. 29...Antiquaries, Burlington-house, W., 8½ p.m.
Parkes Museum, 74A, Margaret-street, W., 8 p.m. Dr. Charles Kelly, "Diseases Caused by Sanitary Defects in Houses."
East India Association, Exeter-hall, Strand, W.C., 3 p.m. Edmund Kimber, "The Indian Railway Policy."

FRIDAY, Nov. 30...Royal, Burlington-house, W., 4 p.m. Annual Meeting.

Journal of the Society of Arts.

No. 1,619. Vol. XXXII.

FRIDAY, NOVEMBER 30, 1883.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

SIR WILLIAM SIEMENS, F.R.S., D.C.L., LL.D.

Extract from Minutes of the Council of the Society of Arts, November 26th, 1883.

The Council of the Society of Arts desire to record their sense of the very heavy loss which the Society has sustained by the sudden death of their Chairman, Sir William Siemens.

Pre-eminent among those who have successfully devoted themselves to the advancement of knowledge, it was his peculiar merit to have applied the results of scientific research to industrial progress, and to the improvement of many of the conditions of human life.

From the versatility of his genius, and from the direction of his more important labours, he was singularly well fitted to lead the work of a Society which, devoted to many and very various objects, has for its special province the application of science to practical purposes.

This Society which, thirty-three years ago, honoured itself by the award of its gold medal in recognition of talents not then evident to the world, now mourns the loss of one who was long closely associated with its work, and who for some time back took an important share in the administration of its affairs.

His talents were the admiration of his contemporaries, but his rare personal merits could be known to those only who were fortunate enough to share his friendship. The facility with which he applied his powers to the solution of the most difficult scientific problems was equalled by the modesty with which he presented the successful results of his efforts.

While thus recording their sense of their loss, the Council desire further to express their deep sympathy with Lady Siemens and with Sir William Siemens's distinguished brothers, Werner, Carl, and Friedrich, who were so closely associated with his labours.

Funeral in Westminster Abbey.

The funeral service took place at Westminster Abbey, on Monday, 26th instant, at twelve o'clock, and was performed by the Dean and clergy of the Chapter, and the full choir.

The pall-bearers were Professor Huxley, President of the Royal Society; Sir Frederick Bramwell, Vice-President of the Society of Arts; Mr. Brunlees, President of the Institution of Civil Engineers; Mr. Percy Westmacott, President of the Institution of Mechanical Engineers; Sir William Thomson, representative of the British Association; Professor Tyndall, representative of the Royal Institution; Mr. Willoughby Smith, President of the Society of Telegraph Engineers and Electricians; and Sir James Ramsden, representative of the Iron and Steel Institute.

His Royal Highness the Prince of Wales, President of the Society of Arts, was represented by Mr. Andrew Cockerell, Groom-in-Waiting; and the Society by a large attendance of the Council, consisting of Sir Frederick Abel, C.B., F.R.S.; Sir Frederick Bramwell, F.R.S. (pall-bearer); Mr. Alfred Carpmael; Mr. Andrew Cassels; Lord Alfred Churchill; Mr. B. Francis Cobb; Mr. T. R. Crampton; Sir Philip Cunliffe-Owen, K.C.M.G., C.B.; Mr. Henry Doulton; Captain Douglas Galton, C.B., F.R.S.; Sir John Hawkshaw, F.R.S.; Admiral Sir Edward A. Inglefield, C.B., F.R.S.; Mr. T. V. Lister; Mr. W. H. Perkin, F.R.S.; Sir Robert Rawlinson, C.B.; Mr. Owen Roberts, and Lord Sudeley; with Mr. H. Trueman Wood (Secretary), Mr. H. B. Wheatley (Assistant Secretary), and Mr. H. H. Room (Accountant).

The Royal Society was further represented by the Treasurer, Mr. John Evans; the Secretaries Professor G. G. Stokes and Professor Michael Foster, and a large number of Fellows.

The Institution of Civil Engineers, and the numerous other societies with which Sir William Siemens was connected, were represented by the members of their councils and their secretaries.

At the conclusion of the service in the Abbey, the funeral procession proceeded to Kensal-green cemetery, where the body was interred.

COOKERY EXHIBITION.

An Exhibition of gas and other stoves, and the various apparatus and appliances used for cooking purposes, in connection with Mr. Mattieu Williams's Cantor Lectures on "The Scientific Basis of Cookery," will be opened on Monday evening, December 3rd, and will remain open, until December 17th, daily, from 10 a.m. to 4 p.m. (with the exception of Saturday, when it will close at 2 p.m.), and on the evenings of the lectures.

Members of the Society can admit their friends by use of the tickets supplied for the evening meetings and lectures. Persons not members of the Society may obtain tickets on application to the Secretary.

THE MARQUIS OF LORNE ON CANADA.

To enable a greater number of members than can be accommodated in the Society's own Room to hear the paper on "Canada and its Resources," by the Marquis of Lorne, on the 19th December, the Council have arranged for the meeting to be held at Exeter-hall, Strand (in the smaller hall). Members will be admitted as usual on signing their names, but the privilege of admitting friends will be restricted. Each member will be entitled to admit *one* friend only, either personally or by the usual ticket.

Proceedings of the Society.

SECOND ORDINARY MEETING.

Wednesday, November 28th 1883; Admiral Sir Edward Inglefield, C.B., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Anderson, Christopher, Hunslet Shed, Leeds.
Anderson, William, Lesney-house, Erith, Kent, and 3, Whitehall-place, S.W.
Andrews, John Joseph Frederick, 10, Cedar-terrace, Old Charlton.
Babb, Harry R., 21, Portland-square, Plymouth.
Banker, Stewart Melville, Avon-villa, Pellatt-grove, Wood-green, N.
Barber, Charles Albert, Bristol-house, Brighton, and 5, Furnival's-inn, E.C.
Barge, Samuel, Great Yarmouth.
Barker, John, Devonshire Villa, Grove-pk., Chiswick.
Barnett, Francis Thomas, Nyton-house, Chichester.
Barrow, Robert Philipson, 26, Old Broad-street, E.C.
Batchelor, Allan Edward, B.A., 73, Jermyn-st., S.W.
Beauchamp, Major Clayton Scudamore, R.E., 4, Mount-street, Berkeley-square, W.
Beeman, George Beaumont, 182, Earl's-court-road, S.W.
Blakey, James W., 46, Hyde-park-road, Leeds.
Bloomfield, John Caldwell, J.P., Castle Caldwell, Co. Fermanagh.
Brady, Thomas F., 11, Percy-place, Dublin.
Brereton, William Henry, 52, Nevern-square, South Kensington, S.W.
Broadbent, Thomas Oliver, 14, Cross-street, Manchester.
Brough, William Spooner, 71, New Bond-street, W.
Burnard, Robert, Cattedown, Plymouth.
Cameron, Duncan Grant, Quilon, Travancore, Southern India.
Casella, C. F., The Lawns, Highgate, N.
Clifford, Henry Charles, 1, Lansdowne-place, Blackheath, S.E.
Colmer, Joseph G., 9, Victoria-chambers, S.W.
Cook, John Mason, Ludgate-circus, E.C.
Cory, Edward, 5, Church-rd., Castelnau, Barnes, S.W.
Cosser, Frederick Chas., 97, York-rd., Lambeth, S.E.
Craven, George Pople, 14, Roland-gardens, S.W., and City Carlton Club, St. Swithin's-lane, E.C.
Crockford, William, 2, St. Peter's-road, Mile-end, E.
Cross, Charles Frederick, Brentford.
Crossley, Atkinson, Moor-end-house, Adwalton, near Bradford.
Dabbs, W. M., 11, Amhurst-park, Stamford-hill, N.
Dampier, Henry Ludwell, Frindsbury, Rochester, Kent.
Davis, Joseph, 6, Kennington-park-road, S.E.
Dawson, Charles Royal, Westbury, Grange-park, Ealing, W.
Day, Charles Aubrey, 321, High Holborn, W.C.
Donkin, R. S., Camp-villa, North Shields.
Dowler, Frederick, jun., 25, Frederick-road, Aston, Birmingham.
Drinkwater, Thomas William, M.D., F.R.C.P., 41, Chambers-street, Edinburgh.
Duff, William Pirie, 2, Champion-park, Denmark-hill, S.E.
Duncan, William Aver, Redhill, Surrey.
Durrant, Frederick William, Holland-lodge, Addison-road, Kensington, W.
Elwell, Paul Bedford, Wolverhampton.
Eno, James Crossley, Wood-hall, Dulwich, S.E.
Ernst, Emil, 80, Charlotte-street, Fitzroy-square, W.
Eskholme, George, J.P., Brass Works, Rotherham, Yorks.
Ettinger, Joseph, 30, Lawrence-lane, E.C.
Farmer, William Mortimer, 1, Collingham-rd., S.W., and Maynard-ville, Cape Town, South Africa.
Finch-Hatton, Hon. M., Haverholme Priory, Sleaford, Lincolnshire, and 6, Prince's-gardens, S.W.
Fleming, James, 136, Glebe-street, Glasgow.
Fowler, Captain Francis Hayman, The Lodge, Brixton-oval, S.W., & 9, Serjeant's-inn, Fleet-st., E.C.

Fry, Samuel, Sherington-house, Kingston-on-Thames.
Galbraith, Robert, jun., 21, Notting-hill-square, W.
Gardiner, Charles Lawrence Weare, The Temple, Goring, Oxon.
Glover, Arthur, Galley Hill-house, Swanscombe.
Gray, James, The Shrubberies, near Whitby.
Greig, Henry A., The Eaves, Belvedere, Kent.
Hamilton, Marquis of, 2, Belgrave-square, S.W.
Hammersley, William Archibald Leslie, Bath-street, Leek, Staffordshire.
Harrison, Hugh Erat, 2, Red Lion-square, W.C.
Hartmann, William, 18, Billiter-street, E.C.
Hawker, Thomas H. Seymour, Birmingham and Warwickshire (Brush) Electric Light Company, 110, Cannon-street, E.C.
Hawkins, Miss J. E., 5, Walpole-street, S.W.
Henderson, Charles J., 6, Drumsheugh-gardens, Edinburgh.
Hill, George Charles Singleton, Bedminster Mill, Bristol.
Humphrey, James Charlton, 22, High-road, Knightsbridge, S.W.
Imray, Oliver, 4, Dane's-inn, Strand, W.C.
Jackson, John Evans, The Hermitage, Carleton, near Horsforth, Yorks.
Jenkins, Thomas M., 5, Tavistock-street, Covent-garden, W.C.
Jetley, Victor, 8, North Audley-street, W.
Jeyes, Frederick Leslie, 32, Sussex-street, South Belgravia, S.W.
Johnson, Henry, jun., Dartmouth-terrace, West Bromwich.
Jones, Edward, 2, Westhill-terrace, Chapel Allerton, Leeds.
Jones, Walter William, Lambeth Savings Bank, Hercules-buildings, S.E.
Jupe, John, Lloyds', E.C.
Leon, John Temple, 26, Belsize-park-gardens, N.W.
Leverson, James, 72, Cornwall-gardens, S.W.
Lupton, Sydney, M.A., Harrow-on-the-Hill.
Macalister, James, 95, Bishopsgate-street Within, E.C.
Macdermott, Martin, Scott's-chambers, 25, Pudding-lane, E.C.
Markham, Thomas Thornhill, 102, Fetter-lane, E.C.
Marsden, R., 117, Acomb-street, Manchester.
Maxim, Hiram Stevens, 47, Cannon-street, E.C., and 59, Liebertz-street, New York.
Meihé, John Rudolph, 15, Abchurch-lane, E.C.
Morison, Robert Joseph, Arundel-lodge, Cathnor-road, W.
Morison, W. C., 18, Cromwell-grove, Shepherd's-bush, W.
Morris, Richard, Doncaster.
Morton, Mrs., 10, The Grove, Highgate, N.
Neale, Captain Melville T., 1, Southwick-crescent, Hyde-park, W.
Nurthen, Frederick Richard, 390, Strand, W.C.
Oakley, Richard, 235, High Holborn, W.C.
Orton, Charles James, Ferry-house, Twickenham.
Pemberton, Colonel Robert Charles Boileau, R.E., Lucknow, East India.
Phillips, F. C., The Hammond Electric Light Company, 110, Cannon-street, E.C.
Piper, John Townend, Vernon-house, Willesden-lane, Kilburn, N.W.
Pullman, Arthur, Westbrook, Godalming.
Quincey, Richard de Quincey, 76, Avenue-road, Regent's-park, N.W.
Ramm, Charles W., 9, Newgate-street, E.C.
Ravenhill, Charles, Bushey-house, Streatham-hill, S.W.
Richardson, Edmund, 24, New Bond-street, W.
Rocke, Colonel James Harwood, C.B., 10, Clarendon-road, Kensington, W.
Rumball, Thomas, 8, Queen Anne's-gate, S.W.
Ryle, John, 213, Brompton-road, S.W.
Santos, Flavis A., 88, Palmerston-buildings, E.C.
Sarkies, Martin, 1, Pump-court, Temple, E.C., and Wanderers' Club, S.W.
Schweder, Percy, 133, Gloucester-road, S.W.
Shepherd, William, 101, Bermondsey New-road, S.E.
Spence, Frank, Manchester Alum Works, Manchester.
Spence, William Heather, 40, Kyverdale-road, Stoke Newington-common, N., and 8, Quality-court, Chancery-lane, W.C.
Stanesby, Arthur John, 3, Kingsdown-villas, Wandsworth-common, S.W.
Staples, Sir Nathaniel Alexander, Bart., 4, Savile-row, W., and Lissan, Cookstown, Ireland.
Stenning, Charles, 3, Upper Hamilton-terrace, N.W.
Stevens, Charles Richard, 8, Woodstock-terrace, Burnt Ash-road, Lee.
Stevens, Leicester, Darlington Works, Southwark-bridge-road, S.E.
Stodart, Rev. George Earle, M.A., St. John's-vicarage, Leamington.
Stott, Alfred, Brighouse, Yorkshire.
Strangman, John Pim, Sarno, Province of Salerno, Italy.
Stuart, Charles, Bletchley Ironworks, Fenny Stratford.
Sutton, Francis, Norwich.
Sutton, John Edmond, 1, Shenley-road, Peckham-road, S.E.
Tebbs, C. Harding, M.A., St. Margaret's, Mitcham, Surrey.
Thomas, Edward Croft Greenway, 11, Harrington-road, South Kensington, S.W.
Thompson, Alfred, 3, Fenchurch-avenue, E.C.
Thomson, Alec, Preparatory School, 173, Union-street, Aberdeen.
Thornton, Alfred, LL.B., 7, Walbrook, E.C.
Turner, Henry Gribble, 14, St. James's-square, S.W.
Vaughan, James Henry, Spencer-house, Streatham-common, S.W.

Wright, Edward Mounsteven, 91, St. James's-road, Brixton, S.W.
Younger, Robert, B.A., Brackenbury Hall, Magdalen-street, Oxford.

The CHAIRMAN, in opening the proceedings, said he was sure the subject uppermost in every one's mind must be the recent death of the Chairman of the Council, Sir William Siemens. It was not competent for him on that occasion to propose any resolution with reference to the matter, expressing the natural sympathy of the members with the relatives; but he would simply ask them to listen to the minute which was written at the Council meeting held on the same afternoon that Sir W. Siemens was committed to the grave. The resolution would be sent to Lady Siemens, as a token of what was felt by the Council of the Society with reference to the loss of their Chairman.

The SECRETARY read the minute of the Council (see p. 19).

The paper read was—

THE TEACHINGS OF THE FISHERIES EXHIBITION.

By A. J. TRENDELL.

One of the most singular phenomena incidental to social progress is the impatience of society for results. In regard to the operations of nature a certain amount of common sense prevails. Men do not expect to find a full-grown oak where a week before they had planted an acorn. Even in political affairs some recognition is occasionally made of the action of time, and a generation or two may be allowed to elapse before the full effect of some constitutional change is considered ripe for appraisement. But no sooner does it become a question of society—the least elastic and most conservative of human organisations—than everything is expected to undergo variation with the ease and rapidity of a kaleidoscope. Yet take, for instance, these very fisher-folk who are my subject to-night, and note with what limpet tenacity they cling to the rocks of wasteful, toilsome ignorance. For century after century, these poor toilers of the sea have adhered to the traditions of their caste with almost Oriental fanaticism, and have persisted in using their ancient instruments of hook, and net, and line, each generation treading precisely in the steps of their fathers, and their fathers' fathers before them; but at last—within, indeed, the last fifty years—that much praised, much abused instrument, the trawl, was introduced, and the wonderful changes for the better that the present generation have witnessed gradually recognised. But no sooner does an International Fisheries Exhibition take place, than markets are to be erected, fisheries to be opened, prices to be reduced, almost before the echo of the steps of the last visitor has died away. How long was a respite granted before practical results were expected to appear? A decade? A year? A month? Nothing of the kind. While the long vista of nets was still festooning the vast galleries, before the strains of the band had died out in the gardens, while expectant crowds were yet besieging the doors of the sixpenny fish dinner, voices were not wanting to clamour already for results, and to advertise their disappointment at not being able to see anything of what they are pleased to call practical effects. And now that all is over they are doubly importunate. What has the Exhibition effected, they say, and who will show us any good thing which has come out of it?

To commence then, I would maintain that there have not only been great social benefits already conferred, but that the lessons taught by the Exhibition show us how to secure immense practical advantages in the future. Among the social benefits already conferred none is more noteworthy than the discovery of the immense attraction for the British public of those simple open-air amusements that are such admirable features of continental cities. I read the other day that a recent number of a foreign magazine stated that, as a nation, we were incapable of combining for such forms of enjoyment, and that an English crowd required horse-play and music-hall singing to be really happy. We were told that we could not, like the French or Spanish, Belgians, Swiss or Germans, meet for reciprocal amusement without expanding, collectively, into a modified rowdyism. We, on the other hand, have seen day by day, for six months, an unprecedented congregation of our countrymen, of every possible class, enjoying themselves as heartily, as innocently, and as quietly as ever did any people on the Continent. From the eager morning to languid evening the masses of human beings have moved to and fro, thoroughly pleased, and entirely without misdemeanour. The guardians of peace and property soon discovered that stringent vigilance was uncalled for, and the vast collections of the Exhibition and the beautiful grounds have, therefore, been virtually confided to the common sense and the good feeling of the nation. And that confidence has been most honourably justified.

As for the indirect results, they must have been very far-reaching, multiform, and admirable, and we get a glimpse as it were of unsuspected spheres of influence in the pathetic exclamation of one of the Irish fishermen, brought over for a visit by the kindness of the indefatigable Mr. Brady. "Ah," said he, "if our poor people could only see England, they would know where to go for a friend!" But it is not in regard to the past that I have the honour to address you this evening, except in so far as it forms the basis for considerations of the future My task is to treat of what has been done, only in order to show what may be done; to aim at collecting some at least of the many valuable suggestions preferred by the experts who graced our conferences, to foreshadow in some sort the potentialities of development arising from this mighty undertaking—and, in a word, to elicit in a clear and succinct form the teachings of the Fisheries Exhibition.

In dealing with this subject, there are two distinct objects to be attained—the discomfort of the fish and the comfort of the fishermen. Alike for fisherman and fish, we need to know the habits, the haunts, the environment of every description. We trace the fish, as best we can, into their most secret hiding places in the depths of the sea, in order that we may lay snares for them with the greater efficiency; we search out the homes of the fishermen, that their households may become happier and their dwellings better, and in every way more worthy of them. We watch the habits of the fish, that we may the more easily compass their destruction; we desire to know the habits of our fishermen, that their industries may the more easily assume that importance with which the increasing demands of commerce and requirements of society invest them. We give our attention to the breeding of fish, that we may thereby obtain more food for our population; we desire to cultivate the welfare of our fisher lads, that they themselves may help to maintain those traditions of courage and endurance with which, for generation after generation, their race has adorned the State.

And for both these objects we require increase of knowledge, which is necessary for improvement of practice. To a certain extent, indeed, these two methods may be regarded as one, for growth in knowledge were but an idle thing unless it led to improvement in action; and, on the other hand, any attempt to innovate in practice were worse than useless, unless it were based on a more perfect knowledge. How much damage may be done to a fishery by an injudicious clause in an Act of Parliament, let the history of the salmon declare; how much benefit may be effected by judicious legislation, let the crabs and lobsters put in their word. Professor Lankester, in his admirable diagnosis of the scientific results of the Exhibition, points out the fallacy of conceiving any antagonism to exist between the scientific and the practical. "The contrast," he observes, "insisted on between the scientific and practical man becomes simply the contrast between the man who knows and the man who does not know, but acts in ignorance. As a matter of fact, there is no such antithesis. Your man of science is, or should be from the nature of his pursuits, more thoroughly practical than any one who affects to despise scientific knowledge, for he is accustomed to insure success in his experiments and investigations, by taking every means in his power to that end; above all, and chiefly, by guiding himself by reasonings based on the most accurate and extensive knowledge. So, too, indeed, every so-called practical man who is not a mere adventurer—a happy-go-lucky tempter of Fortune—makes use of accurate knowledge to aid him in his commercial ventures and speculations; so far as he can get it, he makes use of science, though he often calls it by some other name as soon as it becomes useful knowledge." The Professor then goes on to draw attention to the fact, though it gives us little cause for pride, that while the Governments of many foreign countries, notably of France and the United States, Norway, Sweden, Holland, Prussia, and Saxony, have enlisted the skilled services of zoologists in developing and managing the resources of their respective fisheries, Great Britain exhibited at South Kensington scarcely anything under the head of zoological science at all, that is to say, of science which illustrates the results of exact inquiry into the natural history of the fishes and other animals which form so great a part of our national wealth. The first grand teaching of our International Exhibition, therefore, I hold to be this, that zoological study must be made the basis for all improvement in practice, whether in regard to the preservation, the extension, or the working of our fisheries.

Knowledge, it is rather wisely said, is only an exchange of ignorance, but it must not be forgotten that at every exchange the world gains a little, inasmuch as ignorance is shifted on step by step to deeper problems, and nearer to the hidden roots of science. And an Exhibition like the Fisheries teaches us that it is only by the comparison of ideas, and a mutual bartering of experiences between individuals, companies, powers, and nations, that the standard of public knowledge can be raised to a uniform level of practical intelligence. Take, for example, what Mr. Cornish, of Penzance, tells us about the deep shoal seine. "Mackerel," he says, "shoal in deep water as well as in shallow. Our desideratum for a long time past, has been a seine which can capture the deep-water shoals. A gentleman named Cox, a Cornishman, has invented a seine, of which a model was shown in the middle of the Cornwall stall. He said that this seine could be worked at deep-sea shoals of fish; and, curiously enough, a model of a second seine on the same principle, but differing a little in detail, was exhibited on the same stall by Mr. Moses Dunn, of Fowey, and a third by Mr. Barron, of Mevagissy. Practical men saw these models, both before they came to the Exhibition and since, and pronounced them very pretty little toys, which might succeed in a fish-pond, but utterly unfit for use at sea. Now, a full-sized seine costs a large sum of money, and no hard-headed capitalist is likely to lay it out on a speculation which these practical men told him must inevitably fail. But mark what happened—the models came to South Kensington, the nets came here, and to them came an American expert, who said, 'You have the precise principle on which we are working deep-sea seines in America, and they succeed admirably.'"

A certain, at least a possible, advantage is the Greenway Breakwater, the merits of which I do not pretend to judge, but which have been certified, I see, by a bronze medal from the jury. Whether, therefore, the fishermen of Penzance will find in it the protection which they so earnestly desire, is a point which they must decide for themselves; but at least the Exhibition has been the means of showing them a device by which, if successful, all they desire may be accomplished at a cost which, as compared with a solid breakwater, is little more than nominal. Or, take another suggestion, as to that terrible problem bequeathed to us by the carelessness of our population, and the feebleness of our local administrations, namely, the cleansing of our rivers from the abominations of town sewage and other pollutions. The Exhibition has brought out, thanks to the admirable essay of Mr. Barrington Kennett, and the enterprise of competing companies, the difficulties which lie in the way of manufacturers and of local authorities, the means of surmounting them, and the utilisation—securing an actual profit to manufacturers—of waste substances. Let us take but one more example, not relating, however, to the fish, either for their preservation or destruction, but to the economy and domestic habits of the fishermen. One of the most remarkable contributions, in every way, to the literature of the Exhibition (as has been so truly urged by the Press), was the first of the series of conference papers, written by H.R.H. the Duke of Edinburgh, and read by H.R.H. the Prince of Wales on his brother's behalf. In it His Royal Highness advocates, with unanswerable argument, the institution of a mode of insurance amongst fishermen, similar to that which exists among the coastguard and other communities, enabling all—even the very poorest — to make some provision for his family, in the event of accident or death. Here, again, we see the immense advantage that results from comprehensive comparison of the social features of differing and distant communities—comparison that, but for the focussing of many interests within one exhibition, would have been impossible. And here I may be permitted to refer to this most important paper by His Royal Highness, as replete with the most valuable information, and fertile with the most practical suggestions.

I come now to the means by which that most important object, accuracy of zoological knowledge, may be obtained:—an increase of our acquaintance with the habits and natural foods of the fish, the bait which attracts them, the seasons in which they are found on different parts of the coasts, the course which they pursue in the ocean, the periods of spawning, the drifting of the fry into the estuaries, and all the other thousand points on which we may flatter ourselves as still possessing all the exterior decencies of ignorance. For such national purposes as these, there is no more reason why private enterprise should conduct the necessary inquiries than why it should collect the income tax. It is to the State, and the State alone, that we can look for an adequate biological survey of the resources of our ocean waters, similar in intent and purpose to the Geological Survey, which was undertaken by the State without question, as a natural function of the executive administration of the country. And it will be at once seen that this is a project which admits of a twofold form of execution—one by land and one by sea.

The proposal to erect a laboratory for carrying on investigations with regard to fishes and fishery animals is one which, though brought forward in England for the first time by Professor Lankester, with the support of the Duke of Argyll, during the late Exhibition, is already familiar to the Government and zoological students of more than one country in Europe. Naples boasts such an observatory, fitted with aquaria, glass apparatus, and all other necessaries for carrying on these fascinating and remunerative inquiries. Austria possesses a similar institution at Trieste; and France has no less than five—at Concarneau, Roscoff, Villefranche, Havre and Banyuls—besides a school for fishermen at Dieppe. As a matter of fact, our English Universities, and likewise the Committee of the British Association, subsidise the zoological station at Naples, for the privilege of permitting Englishmen to gain knowledge concerning fish and other marine animals, which they might at much less cost, and with far more completeness, acquire at their own doors. The establishment of such an observatory would not only be a worthy memorial of the popular Fisheries Exhibition, but would be a national gain of the highest order.

Thus far the land—now for the more kindred element, the sea. For many years, it might almost be said ever since a Fisheries Board has existed in any part of the kingdom, one persistent cry has gone up from the inspectors, time after time—and time after time in vain—for Government vessels to make thorough researches into the nature and number of the inhabitants which swarm the seas surrounding our islands. So familiar is the idea—far more familiar than that of a zoological observatory—that there is little need to dilate upon its advantages, or to illustrate the benefits which might be expected both for fisheries and fishermen. For certainly it would be to the last degree undesirable that such a survey should be conducted without direct reference to those on whose behalf it would be primarily instituted. Fishermen and fisher lads might be taken from time to time on board such vessels, and there habituate themselves, not only to habits of obedience and familiarity with improved apparatus and the best modes of capture, but also acquire elements of scientific training, and so prepare themselves for utilising the opportunities of accurate observation which their calling so abundantly affords. For who have better opportunities for observing the phenomena of the heavens and of the sea than those whose calling compels them to frequent the desolate ocean, out of sight for the most part, not merely of the dwellers upon the shore, but even of the passing ships which traverse the watery wastes.

Nor does there seem to be much difficulty in pointing out the spot where a beginning should be made; for, after all, if anything is to be done, a beginning must be made somewhere. I say nothing now of the political and social regeneration which could hardly fail to attend the resuscitation of certain energies of our kith and kin, too long dormant and undeveloped; but one thing I do say and urge, with all the energy I may be permitted to put forth, and that is that, if any reliance can be placed on the averments of fishermen or reports of inspectors, if any indications suffice to denote the presence of the shoals of fish short of the actual establishment of a fleet of fishing vessels, if the conformation of the coast, the evidence of men well acquainted with those seas, the general consensus of universal testimony, nay, if the result of experiment itself is to have any weight, then I say that the magnificent success attendant on the example set by that illustrious lady, the Baroness Burdett Coutts, at Baltimore, on the Irish coast, will not be allowed to remain unfruitful, and that the loan of a revenue cutter will be granted by the Government to make a biological survey, not only of the fisheries of the west coast of Ireland, but of other sections of the teeming acreage of waters, with a view to the logical development of those great repositories of a prolific food-supply for our population.

An endeavour, I understand, has already been made to obtain the loan of a Government vessel for the purpose of making biological researches off the coasts of Mayo and Donegal, on the condition that a committee is prepared to form a company for thoroughly working those fisheries, if the results of the investigation should give fair promise of success; and I hear also that the steps which have been taken have received the warm support of one of the most experienced of the Irish inspectors. Of the boon which would be conferred, should success attend the movement, upon the fishermen of the locality, upon the industries of Ireland, and even, one may say, upon the nation at large, it is needless for me to speak.

And here I may be permitted to quote from the *Times* of Monday last, a most interesting paragraph, showing what is being done in respect to fish exploration and culture in the deep seas, by our acute and far-seeing brethren across the Atlantic:—

"It is stated that the Fish Commission which has been issued in the United States has a threefold object; a study of pisciculture on the coasts, improved methods of fishing, and the introduction and multiplication of food fishes. America will be a long time before she makes the most of her splendid lakes and rivers for fish purposes. New England is the scene of the most active operations. A temporary laboratory has been constructed every summer, and naturalists have been busy collecting upon the shore, clearing out the beaches, or using dredge and trawl at as great depths as can be reached by a steamer in a trip of three days. The fishermen of Cape Ann are enthusiastic in their assistance, and during the last few years have vied with each other in their efforts to procure the rarer forms of life, which they have every opportunity of doing, since every halibut vessel sets, twice daily, lines from ten to fourteen miles in length, with hooks upon them 6 ft. apart, in water from 1,200 feet to 1,800 feet in depth. Fifty to sixty thousand specimens have been obtained in this way, comprising some thirty species of fishes not before known to inhabit American waters, besides about fifty other forms of life new to American fauna. No dredging has been done south of Long Island by the Commission itself, but agents are working in various localities."

Bearing in mind the laxity on our own part to which I have directed your attention, is not the teaching of this, that incalculable good would result to the British nation from the appointment by the State of a Fish Commission very similar to that which is doing such important work in the United States? I will only say that I conceive this to be the third great lesson taught by the Fisheries Exhibition.

Once more I must hasten onwards, conscious that indeed I ought already to have brought my remarks to a close; but there is a point which I cannot pass over in silence, and I may lay claim to the greater indulgence because it is connected with my own special department, and associated with the pleasantest privilege which I have enjoyed during the last six months, that of familiar intercourse with some of the highest intellects and most refined thinkers of our own and of foreign countries. If it be permitted for the book-cover to call attention to the book, if the bouquet-holder may be allowed to illustrate the beauty of the nosegay, then may I call attention to the literature of our Fisheries. To observe fresh facts, to investigate more deeply the causes of well-known phenomena, are not the only points, it may be that they are not the most important points, in regard to the development of our knowledge. Vital as is the acquisition of fresh knowledge, it may be questioned whether the diffusion of correct information is not of almost equal moment with its attainment, even as the sun itself would give us no heat if it never rose above our horizon. To this end our literary department has been framed. Under the modest title of "Prefaces to the Exhibits of the Different Countries," there appears in the catalogue what forms in reality a unique and almost complete system of State papers on the fish traffic of the world; and of the many acts of courtesy and usefulness by which the foreign Governments of the different countries represented have rendered us their debtors, none perhaps was more courteous or more useful than their graceful concession to the request of the Executive Committee that they would invite, each for its own territory, some person of authority and experience to draw up in brief a conspectus of their condition in respect to their fisheries and fishermen. It is proposed to re-issue these State papers in a separate volume, independently of the catalogue, as I conceive them to be among the most valuable of the literary contributions which passed through my hands. For such an epitome Mr. Brown Goode, the distinguished Chief Commissioner to the Fisheries Exhibition from the United States, told me, only the other day, that he had long experienced a desire, and certainly there is no one better qualified to appreciate its value, or whose writings in it give greater lustre to its pages. The same earnest desire to supply original information in a condensed form was kept in view, in relation both to the Conference papers and to the series of handbooks in which so many men of eminence have favoured us with their assistance.

As an illustration of the foregoing remarks, I may notice some of the points brought out with regard to the important science of fish culture, taking that as one of the most important of the subjects with which the literature of the Exhibition has dealt. It is now pretty generally admitted that, were it not for the exertions of the late Mr. Frank Buckland, the stock of salmonidæ in our rivers would by this time have been almost or altogether exhausted, and it is in a great measure due to his untiring energy, and absolute devotion to his self-appointed task, that we owe the comparatively flourishing condition of our salmon fisheries. Among the literature, the principal portions relating to salmon culture in our own country (for the limits of this paper do not allow me to touch on others) are: — "The Salmon Fisheries," by Mr. C. E. Fryer, of the Home-office; "The Culture of Salmonidæ and Acclimatisation of Fish," by Sir James Maitland; "Fish Diseases," by Professor Huxley; the admirable and exhaustive "Handbook of Fish Culture in general," by Dr. Francis Day. These four volumes form in themselves a *vade mecum* for all interested in this particular pursuit, and the subject is treated from all points of view. Mr. Fryer, as an assistant to the distinguished Government Inspector of Fisheries, can speak from the practical and quasi-official side. Sir James Maitland is probably the greatest proprietor of hatching stations in the three kingdoms. Professor Huxley's qualifications will nowhere be gainsaid, nor will those of Dr. Day.

But salmon culture is not an occupation for the delectation of all men, the royal fish patronising only lordly rivers, free from the pollution of factories, while riparian owners keep a sharp look-out for persons wanting to get a too near view of his ascent; and the ordinary angler, whose purse is not equal to his enthusiasm, must depend on what are ignominiously termed "coarse fish" for his particular benefit. For the advantage of this latter class, Mr. R. B. Marston, the accomplished editor of the *Fishing Gazette*, read, during the course of the Conferences, a most valuable paper on "Coarse Fish Culture." This paper was very well received, and I have no doubt has already widely commended itself to the class it more immediately concerns.

What may be called a new departure in fish culture (for we will treat crustaceans, &c., as fish for the purposes of this evening) is a paper by Mr. Saville Kent, on the "Artificial Culture of Lobsters," in which that gentleman gives his experiences on this head, and argues that lobsters can be reared as easily as the salmonidæ, and far more economically; their well-known habits of living near where they were hatched being a very important feature in the cultivation which renders the returns, like those of oyster and mussel culture, much more certain than can be the case with any species of fish the movements of which when turned out are, of course, beyond prediction. I have here but touched the fringe of the Fishery Literature, which, besides its more practical side, nowhere more marked with scholarship than in the many papers from the pens of the Foreign and Colonial Commissioners, is not wanting in charm and romance—witness the graceful essays of Mr. Philip Robinson and Mr. William Senior. There are also two works of special interest not yet completed, but which we trust soon to have ready for publication. The first of these is the enlarged edition of the Fisheries Map of the British Islands, which was announced in the first edition of the Official Catalogue. This production will not merely show the trawling and other fixed fishing grounds round our coast, but will also give particulars as to the seasons of the greatest catch for some five or six and twenty of the principal kinds of fish at different parts of the coast, the various spawning times, the fishing grounds frequented by the men of the different ports, and other particulars never before ascertained, but which have been collected from experienced men in the different localities, by Mr. W. Marsham Adams. As certain portions of the coast yet remain to be visited, I will only say that we are greatly indebted to the numerous fishermen, to the railway companies, and to the other public bodies and private individuals who have assisted his researches in every way, and that we trust, by means of this map, to combine in an accessible and attractive form those aspects of science, of practice, and of commerce which have been too long dissociated, and to forward at once the acquisition and the diffusion of fresh knowledge concerning our fisheries and fishermen. The other work to which I have alluded is one which I trust will combine in a collected whole the entire vast field of thought which has been generated by the Fisheries Exhibition. The official Report, with statistical tables, the Handbooks, the Conference Papers, the Prefaces, the Essays, the Map, the Jury Reports, the Catalogues, Guides, and miscellaneous papers, are all being carefully revised and re-edited, and will be published in a convenient form, constituting a series of about twelve volumes of records of suggestion and execution; and to the entire course I propose to append an index-digest, showing the place in which each several topic has been treated in any literary contribution, no matter of what kind. Such a digest will, I trust, tend to bring out the great value of the literary contributions with which we have been favoured by so many eminent writers, and will aid in the general diffusion of icthyological knowledge, wherein we shall find the most certain guarantee for judicious policy in legislation, for improved methods in practice, and for carrying out the teachings of the Fisheries Exhibition.

And now, how shall I conclude, and with what words shall I take leave of the subject? If, indeed, I were merely speaking in our private capacity, or if this were a common occasion, there would be no room for further words: but it seems to me as if the echoes of the familiar "Fisheries" were still sounding in our ears, and that I had the privilege of being the bearer to the public of a message from an honoured friend whose latest word is now being spoken. What, then, is the message? I have already endeavoured to state it at some length, but I will try to put it into a few words. It is that we should cultivate a better knowledge of our fish, and a more practical sympathy with the calling of our fishermen. For our fish, "the harvest of the sea," let us have observatories, Government vessels, and whatever other physical appliances are necessary for their investigation, preservation, and capture. For the fishermen, let us see how, by considerate and respectful sympathy, aid may best be offered without offence, as in the admirable institution, the Society for the Relief of Shipwrecked Mariners and Fishermen; and how, by systematic insurance, by labour-saving apparatus, by better homes, by more attractive systems of education for fisher-lads, and by all other kinds of moral inducement, we may alleviate the toil and enhance the condition of those patient toilers in a hard, and not very remunerative industry. For although, as I have already earnestly said, in another place, it is much to defend the natural wealth of our rivers and seas from the rapacity of greed and the recklessness of pollution; to provide improved harbour accommodation, and greater facilities for transport and commerce; to render the meals of the million more palatable, more wholesome, and, at the same time, more economical; yet all these things are comparatively less important than the safe-guarding of our fishermen's lives and the improvement of our fishermen's homes. These are objects in which all nations can cordially co-operate, because all mankind is interested in the result; and in no way can our island kingdom more gracefully or beneficially exercise the historic pre-eminence conceded to her upon the seas, than by promoting these interests in connection with such an enterprise as that of the International Fisheries Exhibition. And this, I think, is the last, though not the least, of the "Teachings" of that great Exhibition.

DISCUSSION.

The CHAIRMAN said among the many valuable points contained in the paper, he would particularly refer to the great improvement which had taken place in the implements used in fishing. When he first went to sea, whales were caught with harpoons thrown by men, but the harpoons were now projected by gunpowder, and of course the whales were caught with greater facility and certainty. Reference had also been made to the deep sea seine, which experience on the other side of the world had shown to be successful, though this was doubted by our own fishermen. Another useful suggestion was with regard to zoological observatories, and he hoped this would be carried out. He had known the late Mr. Frank Buckand for many years, and he knew how long that zealous naturalist exerted himself to obtain protection for salmon ova, which was formerly destroyed in immense quantities. The various handbooks published in connection with the Exhibition were of great value, and he had no doubt that the result would be to improve the condition of the fishermen as a whole.

Mr. P. L. SIMMONDS expressed the pleasure he had felt in listening to the paper, and regretted that he had not been able to visit the Exhibition, having been engaged at the time in connection with another international exhibition in Holland, where the prosperity of the capital was said to be founded upon fish bones. He had long taken an interest in, and had written upon the subject of fisheries and other industries connected with the sea, such as the sponge pearl, mother-o'-pearl, and other fisheries, and on the utilisation of seaweed, an article which was largely used for food in Japan and China. Fish had hitherto been chiefly a luxury of the rich, but much might be done, by facilitating transport, to popularise it as a cheap and useful diet for the people.

Mr. WILLIS-BUND said there was one point in the teaching of the Exhibition which had hardly been brought out so strongly as it might be, perhaps because Mr. Trendell held a different view upon it to his own, and that was with regard to State aid. Anyone who had compared the exhibits from the United Kingdom with those from other countries must have felt very proud of the fishermen of this country, unaided by a single penny of State money. It was all very well to talk of what had been done in France, Germany, and elsewhere, but our exhibits were not only equal, but superior to almost all of them. They had heard of the enormous fishing and breeding establishments in America and so on, but he thought that if the size of our English rivers was taken into account, it would be found that proportionately more was done in this country by private enterprise than was done in America by State aid; and that being so, they should pause before asking for State assistance in the fisheries. It was all right enough to establish an observatory, but anything in the nature of a subsidy, he hoped, would not be attempted. It would have to be accompanied by inspection, and of that he had a horror, though he was a Government inspector himself. He had been one of the Severn Commissioners since 1865, and he could only say that during all that time his experience had been that if anything went wrong the blame was thrown on the Commissioners, whilst if anything succeeded, someone else took the credit. He, therefore, thought one important lesson to be drawn from the Fisheries Exhibition was, that private enterprise should not be checked by Government aid and inspection. Let the State encourage the study of natural history by all means, but with regard to the fisheries themselves, the best thing it could do was to let them alone.

Captain J. D. CURTIS, R.N. remarked that, in the event of a war, the fishermen would form a most important and valuable portion of our naval reserve. He had been much amused by watching a discussion in the *Field* and *Land and Water* as to whether fishermen called fry spawn, or spawn fry; and on asking a practical fisherman about it, the reply he got was that eggs were eggs, and chickens were chickens. He thought that fishermen had fair cause of complaint with regard to the destruction of spawn by steam trawlers near the coast, and hoped that full inquiry would be made into the matter, and at any rate, the experiment might be tried of affording some protection at the particular season when the spawn was maturing into fry. Another important point was the utilisation of fish refuse for manure, an experiment in which he was much interested, from his father having manufactured fish guano in this way by mixing it with charred peat; and the manufacture was now being carried on on a large scale, though in a different manner, by Messrs. Johnson, at Belvedere, the refuse being taken down in iron tanks, and dried by superheated steam, the product fetching from £8 to £11 a ton. He might add that the workmen employed were particularly healthy. The refuse from Billingsgate would be very valuable if treated in this way, but at present it was useless, through being mixed with straw and other rubbish.

Mr. WILMOT (Canadian Commissioner to the Fisheries Exhibition) said he had listened with great pleasure to the able paper but he regretted to find that no mention whatever was made of Canada. That colony had taken a high plaee in the competition, and with regard to fish culture, he might say she set an example to all the world. He regretted that a stronger feeling had not been shown in favour of the protection of fish, for some objected to this altogether, and others said that, in order to be effectual, there must be international legislation. He thought this was unnecessary; it would be quite sufficient to protect the fish within the three mile territorial limit, and if they waited for international legislation, it would never come at all.

Mr. LIGGINS said the remarks already made proved the wisdom of those who organised the Exhibition, though he could not agree with what was said by Mr. Willis Bund. They were thinking of the ocean, not of the rivers, of the fish which swam all round the coast, which form a large portion of the food of the people, and not simply of the salmon which formed the sport and luxury of the rich. Having visited the Exhibition many times, he came to the conclusion that Canada was the queen of the whole in the excellence and simplicity of her boats and apparatus. It was very desirable that there should be a scientific head to some department which should have the care of the fisheries, for an immense deal of ignorance existed on the subject. Some years ago, when visiting the West India islands, he was much struck by finding that a large whaling industry was carried on there by the Americans, which he believed very few Englishmen were aware of, though the West Indies were English colonies. In the Canadian lakes, which were inland seas, there was any quantity of fish which might be canned and sent all over the world. He did not think scientific research would be of much practical use without State aid. There ought to be inspections, and the collection of information, which would often be very useful. Gunboats were already placed on certain stations in order to prevent quarrels amongst the fishermen of different countries, and their services might also be rendered available in a scientific way. Some of the most interesting conversations he had ever had were with sailors, on the various rigs adopted by fishing boats in different localities. One of the most important elements of safety was to have a stably constructed vessel with a rig, handy and suitable for the duty she had to perform. There had been much controversy as to the merits of the sprit sail, the lug sail, and other rigs, and within his recollection the Boulogne fleet, and also the Yarmouth, had entirely altered their rig. Of late years, too, the whole model of the Scotch herring boats had been altered and improved, much larger and safer boats being now used, and the result had been a great saving of life in proportion to the number of men employed. Fishing boats very seldom went down in a gale of wind except from a collision; and from inquiries he had made of men from different parts as to what caused loss of life, he found they all agreed that it was mainly from collisions in dark or foggy weather, not from what might be strictly called the perils of the sea. Some of the fishermen present at the last Conference, suggested that further meetings should be held at a time of the year when it would be convenient for them to attend, and he would venture to hope that this idea would be carried out.

The CHAIRMAN said he should have made some remarks himself with regard to Canada, but he preferred leaving more opportunity for other speakers, for he had a note before him that when there he had bought lobsters at two shillings a dozen. If they could be sold at such a price, in a climate so like our own, it seemed to him that something might be done here by cultivation. As Commander-in-Chief on that station, it was his duty to keep a certain number of gunboats on the coast of Newfoundland, to protect the fisheries, there being men there of different nationalities, and it was only the presence of the gunboats which prevented quarrels, and perhaps fighting. While he was there, a quarrel took place between the English and the Americans; the English had made a rule that they would never fish on Sundays, but the Americans had no such regulation, and when a fine school presented itself one Sunday afternoon, the Americans launched their boats and went to catch them. This aggravated the English, who cut their nets, and a regular fight ensued, which led to a great deal of correspondence between the two Governments. This showed the necessity of gunboats being present.

Mr. WILMOT said he had known lobsters caught in such vast numbers that they were sold at 4s. a hundred, or at ½d. to 1d. a piece singly, but in some places where they were so numerous two years ago they were not now to be found at all. The protective laws, in the case of lobsters, had to a certain extent failed, owing to the Government having been misled by the fishermen as to the proper time for enforcing the close season.

Mr. MARTIN WOOD, referring to the statement made in the paper with respect to the advantages of the loan of a revenue cutter, for the purpose of investigations into the fisheries on the west coast of Ireland, said it seemed very desirable that such aid should be afforded by Government, and there was no quarter where it was more needed, or would be more welcomed, than on the west coast of Ireland.

Captain CURTIS said he commanded the Coast Guard near Londonderry, from 1867 to 1870, when the Irish Society spent £48,000 in trying to develop the fisheries thereabouts, but he believed the mistake made was in paying the men regular wages, in lieu of shares.

Mr. CROSSMAN said that the purpose of the paper, which was conceived in a broad spirit, was to ascertain the practical teaching to be derived from the Exhibition. There was one thing characteristic of Englishmen, that when they began anything new, they did it in a confused kind of way, but as they went on they gradually evolved order out of chaos; and there is no doubt that it did seem to gentlemen like Mr. Wilmot, that the important fisheries round our coast had been utterly neglected, when he found that in some cases the bait ground had been utterly destroyed through the exercise of that individual liberty which one gentleman had so earnestly advocated. As a member of the Executive of the late Exhibition, he considered that the whole work would prove entirely evanescent, unless some permanent body were created to study and watch over everything connected with the fisheries. He did not see why there should not be a Fisheries Society, composed of scientific and practical men, who would be able to invite to their consultations eminent men from every country in the world. The papers which had been referred to were distributed, and no doubt diffused a certain amount of information, but that would soon be lost or forgotten, unless some steps were taken to establish a permanent centre. The Exhibition had been successful, and there would be a certain surplus after paying expenses; and he was glad to hear the Prince of Wales announce that whatever surplus there was should be devoted to the furtherance of the fisheries of the United Kingdom. If part of it were used to found such a society as had been mentioned, other minor societies having a similar object would merge into it, and something might really be done to protect the fisheries, and further the interests of the fishermen.

Mr. DIOSY said Mr. Trendell had seemed to doubt the propriety of the book-cover speaking of the merits of the book; but at any rate the reader might be permitted to praise the book-cover which had held the book together, and he would therefore say that he had never met with a more efficient book-cover than Mr. Trendell. Until this Exhibition took place, there was no such thing as a popular literature of fisheries. There was a scientific literature which was read by experts, and there were popular works on natural history dealing incidentally with fishes, and some popular books dealing with the various toils and pleasures of a fisherman's life; but at this Exhibition he believed the first attempt had been made to collect all the available information, and put it into such a form that it would not be necessary to go through a course of training at the proposed biological observatory before undertaking their reading—in fact, to produce such books as the million could understand. It might be said that the million were not concerned with the fisheries, but if they were to take the interest in the matter which, in his opinion, they ought to take, they really were concerned. This Exhibition had awakened an enormous amount of interest; and all who were interested in the fisheries of the world should see that this interest was not allowed to die out. He would ask whether it would not be well to hold international fishery congresses every year at different places where there were great fishing interests located. He was quite certain that it would be considered a great honour in Austro-Hungary to receive such a congress in Trieste or Fiume, and he believed all his foreign colleagues would say the same for their respective countries.

The CHAIRMAN, having proposed a vote of thanks to Mr. Trendell, which was carried unanimously,

Mr. TRENDELL, in reply, said he could only hope that he had thrown out some ideas which might lead to the consideration of important questions intimately connected with the welfare of the State. He had endeavoured to deal with these subjects in the broadest and most general manner, and had endeavoured carefully to avoid anything like putting one country in antagonism to another. He had referred to the State Commission, on the other side of the Atlantic, as suggestive of what might be done here. As to the Conferences to which Mr. Liggins had referred, and which were really models of what such meetings should be, he might say that they had not ceased to exist. At the close of the last one it was understood that they would be continued, it was hoped, under the auspices of the Fishmongers' Company, in January or February next, when practical fishermen would be again invited, and the subjects not yet dealt with thoroughly discussed. He had taken notes of the various remarks and suggestions which had been made, and hoped to be able to make good use of them.

Miscellaneous.

TELPHERAGE.

The following, which is taken from *Engineering*, refers to a subject upon which Professor Fleeming Jenkin, F.R.S., has promised to read a paper before the Society of Arts, in the course of the present Session.

The transmission of vehicles to a distance by electricity, independently of any control exercised from the vehicle, is called "Telpherage" by Prof. Fleeming Jenkin, and was the subject of the address he delivered at the commencement of the present session, to his class of engineering in the University of Edinburgh. He stated that in adapting electric motors to the old form of railways, inventors had not gone far enough back. George Stephenson said that the railway and the locomotive were two parts of one machine, and the inference seemed to follow that when electric motors were to be employed, a new form of road, and a new type of train would be desirable. The ease with which electricity can be transmitted and controlled, led him to conclude that upon electric railways the load might be advantageously distributed among many light vehicles following each other in an almost continuous stream, and that by this arrangement a cheap, light form of road, such as rods or metal ropes, carried on posts, might be possible, and this would require no bridges or earthworks. He had consequently elaborated a scheme in connection with Professor Ayrton, and a company had been formed who were now erecting an experimental line at Weston. It consisted of a series of posts 60 ft. apart, with two lines of rods or ropes, supported by crossheads. Each of these lines carried a train, and was divided into sections of 120 ft., each section being insulated from its neighbour. The rope or rod was supported at the post by cast-iron saddles curved in a vertical plane, so as to facilitate the passage of the wheels over the point of support. Each alternate section was insulated from the ground; all the insulated sections were in electrical connection with one another, and so were all the uninsulated sections. The train was 120 ft. long, and consisted of seven buckets and a locomotive, evenly spaced with ash distance pieces. The skeps hung below the line from V wheels, and the dynamo on the locomotive was also below the line. It was supported on two broad flat wheels, and was driven by two horizontal gripping wheels connected with the motor by nest gearing. The motor weighed 99 lb., and would give a maximum of 1½ horse-power. A wire connected one pole of the motor with the leading wheel of the train, and a second wire connected the other pole with the trailing wheel; the remaining wheels were insulated from each other. Thus the train, wherever it stood, bridged a gap separating the insulated from the uninsulated sections. The insulated sections were supplied with electricity from a dynamo driven by a stationary engine, and the current passing from the insulated section to the uninsulated section, drove the locomotive. The line would carry 15 cwt. on every alternate span of 120 ft., or 16½ tons per mile, which, with a speed of five miles per hour, would convey 92½ tons of goods per hour. It would require a station every ten miles.

MANUFACTURE OF CAMPHOR IN JAPAN.

It appears from a recent report by Consul Jones, of Nagasaki, that the manufacture of camphor is an mportant industry on the island of Kin Shin. From the port of Nagasaki there were exported in the year 1882, 15,186 piculs, the picul being equivalent to 133⅓ pounds, with a total value of £58,000. From other ports of the island not yet open to foreign trade, a large quantity was shipped by native merchants in native vessels to Shanghai and Hong Kong, whence it finds its way to India and England. The camphor tree grows abundantly all over the district of Kin Shin, and is found alike on high elevations and in the valleys and lowlands. It is a hardy, vigorous, long-lived tree, and flourishes in all situations. Many of the trees attain an enormous size. There are a number in the vicinity of Nagasaki, which measure ten and twelve feet in diameter. The ancient temple of Osuwa at Nagasaki is situated in a magnificent grove of many hundred grand old camphor trees, which are of great age and size, and are still beautiful and vigorous. It is said that there are trees at other places in Kin Shin, measuring as much as twenty feet in diameter. The body or trunk of the tree usually attains a height of twenty to thirty feet without limbs. It then branches out in all directions, forming a well-proportioned beautiful tree, ever green, and very ornamental. The leaf is small, elliptical in shape, slightly serrated, and of a vivid dark green colour all the year round, except for a week or two in early spring, when the young leaves are of a delicate tender green. The seed or berry grows in clusters, and resembles a black currant in shape and appearance. The wood is used for many purposes, its fine grain rendering it especially valuable for cabinet work, while it is used also for ship-building. In the manufacture of camphor, the tree is necessarily destroyed, but by a stringent law of the land, another is planted in its stead. The simple method of manufacture employed by the natives is as follows:—The tree is felled to the earth and cut into small pieces, or more properly speaking, into chips. A large metal pot is partially filled with water and placed over a slow fire. A wooden tub is fitted to the top of the pot, and the chips of camphor wood are placed in it, the bottom of the tub being perforated so as to permit the steam to pass up among the chips. A steam-tight cover is fitted on this tub, and from the tub a bamboo pipe leads to another tub, through which the enclosed steam, the generated camphor and oil flow. This second tub is connected in like manner with a third. The third tub is divided into two compartments, one above the other, the dividing floor being perforated with small holes, to allow the water and oil to pass to the lower compartment. The upper compartment is supplied with a layer of straw which catches and holds the camphor in crystal in deposit as it passes to the cooling process. The camphor is then separated from the straw, packed in wooden tubs containing 133⅓ pounds each, and is ready for market. After each boiling, the water runs off through a faucet, leaving the oil, which is used by the natives for illuminating and other purposes.

VEGETABLE WOOL OR SILK-COTTON.

By James Collins.

In the *Journal* for September 28, 1883, p. 972, there is a note, taken from the *Moniteur des fils et tissus*, respecting a description of "Vegetable wool" from Java, exhibited at the Amsterdam Exhibition, under the name of *Kapoc.*

Kapoc, or kapok, as it is more usually rendered, is a Malayan word, signifying cotton or a cotton-like substance, *i.e.*, silk-cotton; real silk being known as *sutra*. *Kapas* is also used in Malay for cotton or silk-cotton, the same vernacular name obtaining in Bengalee and other dialects; but in this latter case the term is restricted to true cotton plants (*Gossypium eps*).

Kapok silk-cotton is furnished by the *Eriodendron anfractuosum* DC., the *Bombax pentandrum* of Linnæus. The plant has been placed in various natural orders, some giving it a place in Bombaceæ, others in Sterculiaceæ, or in Malvaceæ.

The tree is from 50 to 60 feet in height, the trunk being prickly at the base, and the branches growing out horizontally. There are five to eight leaflets, lanceolate in shape, and either entire in their margins or serrated towards the apex. The capsule, or fruit, is five-celled and five-valved; the cells contain many seeds, covered with silky or cottony hairs, which form the kapok or vegetable-silk. The gum furnished by the tree, when mixed with spices, is used in India in bowel complaints, and the seeds yield a dark-coloured oil. The tree is of rapid growth, and is lofty and imposing in appearance. It is found in India, the Malayan Archipelago, and in Africa and other countries. In the East generally, Kapok is used for stuffing pillows, &c., and for tinder, but it has been found that the smoothness of the fibre prevents cohesion or "felting," so necessary and important for spinning purposes. In Africa the tree is looked on with veneration, and is termed the "god-tree," in some districts it being looked upon as a sacrilege to cut the tree down. Still the trunk is used for forming canoes, and although the wood is soft and liable to the attacks of insects, if soaked in lime-water it becomes much more durable. The silk-cotton, either alone or mixed with cotton, is largely utilised in Africa. The young leaves are used as food, and form not a bad substitute for "Ochro" (*Hibiscus esculentus*).

Another tree yielding silk-cotton in India is the *Cochlospermum gossypium*, DC., the *Bombax gossipinum* of Linnæus; a member of the tea order (Terustrœmiaceæ). It is a tree attaining a height of 50 ft., and the soft silky hairs surrounding the seeds are used for stuffing purposes. The tree has large conspicuous yellow flowers, and is not uncommon in Southern India, Travancore, and Coromandel. The *Calotropis gigantea*, or Mudah tree (Nat. Ord. Asclepiadaceæ), also yields a like substance.

In America, both north and south, various so-called "milk-weeds," as *Asclepias verticillata*, and other plants, such as species of *Bombax*, &c., yield silk-cottons, whilst the *Asclepias syriaca* obtained the attention of European agriculturists as early as 1785, and paper has been made from the cortical fibres of this plant. The young shoots of the plant too are said to equal asparagus in flavour.

These are only a few of the plants yielding silk-cotton, which might be mentioned. Silk-cotton has made its appearance in the markets from time to time, and in 1851, the jurors of the Great Exhibition recommended this substance for stuffing purposes, and in mixed fabrics, and notices respecting it have occasionally appeared in this *Journal*. For the lining of quilts, quilted petticoats, &c., silk-cotton seems to answer admirably, but its want of cohesion, or non-felting qualities, renders it of no use for spinning purposes, except as a mixture to impart a silky gloss to the fabric so mixed. The price is low, it is light in weight, elastic and soft, and is said to resist the attacks of insects.

Obituary.

LORD OVERSTONE.—This distinguished financier, who died on Saturday, 17th instant, in his eighty-eighth year, was elected a member of the Society of Arts in 1848. The Right Hon. Samuel Jones Lloyd, 1st Baron Overstone, the only son of Mr. Lewis Lloyd by Sarah, daughter of Mr. John Jones, was born on September 25th, 1796. He was educated at Eton and Cambridge, and graduated M.A. in 1817. He was the last representative of a Parliament of George III., having been elected for Hythe in 1819, for which town he sat till 1826. Several pamphlets on currency were written by him, and he was an ardent advocate of the principles which Sir Robert Peel subsequently embodied in the Bank Charter Act. The University of Oxford conferred upon him the degree of D.C.L. in 1850. When raised to the peerage he terminated his connection with the banking firm of Jones, Lloyd, and Co. In 1862, he was appointed one of the Commissioners to inquire into the working of the Patent Laws. Several volumes of early tracts on political economy were privately printed by his Lordship, and at the death of Mr. McCulloch he purchased the entire library of that famous political economist.

MR. JOHN ELIOT HOWARD, F.R.S., died at his residence, Lord's Meade, Tottenham, on the 22nd of November, at the age of 76. Although Mr. Howard was not a member of the Society, he occasionally attended the meetings and joined in the discussions. His scientific work with regard to the Cinchonas, and his many important publications thereon, are monuments to his memory of patient industry and scientific acumen, and these labours have met with recognition and honours from all parts of the world. He was the son of Luke Howard, F.R.S., one of the founders of the modern science of meteorology, and a descendant of the more famous John Howard, the philanthropist.

Correspondence.

SOUR BEER.

In reply to Mr. Moritz's letter, I hope the following facts may pave the way to the accomplishment of my object, viz., how the quality of beer might be improved, by giving information to brewers as to the disposal of the waste product, sour beer, otherwise than by blending it with new beer. Early in my long experience, I pursued the plan Mr. Moritz advises, but I have given it up for at least twenty years, and as my ale has improved thereby, so has my trade increased.

I found that the addition of three gallons to thirty-three of the new (the proportion that Mr. Moritz states) was disapproved by my customers, and so was even half that quantity.

I also at that period of my career neutralised the acidity of the sour beer, by the addition of whiting, and drew off the compound bright, after sufficient settling; but my impression is to blend this mixture with new beer is about "as sensible a thing as to add three gallons of water to thirty-three of beer." I am no chemist, and therefore I cannot say what constituents of beer would be remaining in sour beer "after destroying the acid ferment and removing the other matters in suspension." Would it be of more value than water? I can only say that I prefer to supply my customers without such an addition, and I feel, too, that in studying their interests in this respect I am not unmindful of my own, and if this applies to myself so does it to every brewer.

HAMPSHIRE BREWER.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

The following arrangements for the Wednesday evenings before Christmas have been made:—

DEC. 5.—"The Manufacture of Mineral Waters." By THOMAS T. P. BRUCE WARREN. Dr. B. W. RICHARDSON, F.R.S., Vice-President, will preside.

DEC. 12.—"Rheea Grass." By Dr. FORBES WATSON. Major-General HYDE, R.E., will preside.

DEC. 19.—"Canada and its Products." By the MOST HON. THE MARQUIS OF LORNE, K.T., late Governor-General of Canada.

CANTOR LECTURES.

The First Course will be on "The Scientific

Basis of Cookery." By W. MATTIEU WILLIAMS, F.C.S.

LECTURE I. DEC. 3.—The Kitchen a Chemical Laboratory. Modes of applying Heat. Radiation, Conduction, and Convection. Roasting, Grilling, Baking, Boiling, and Stewing.

LECTURE II. DEC. 10.—The Constituents of Flesh. The action of Heat on Albumen, Gelatine, Fibrin, &c. The Juices of Flesh and their nutritive value. Exosmosis and Endosmosis as operating in the Kitchen. Maceration. Caseine. The cookery of Cheese and its nutritive value. Milk, Butter, and "Bosch."

LECTURE III. DEC. 17.—The nutritive constituents of Vegetables. The changes effected by cookery on Vegetable Substances. Ensilage of Human Food. May the use of Flesh Food be superseded by the scientific preparation of selected Vegetables?

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 3...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. W. Mattieu Williams, "The Scientific Basis of Cookery." (Lecture I.)

Farmers' Club, Inns of Court Hotel, Holborn, W.C., 6 p.m. Mr. George Street, "The Decrease of Live Stock in Great Britain."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Institute of Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. J. W. Willis Bund, "The Agricultural Holdings Act, 1883."

British Architects, 9, Conduit-street, W., 8 p.m. Discussion on Mr. E. C. Robins's paper, "Fittings for Applied Science Instruction Buildings."

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 7, Adelphi-terrace, W.C., 8 p.m. Rev. H. G. Tomkins, "Recent Discoveries in Egypt in their relation to the Bible."

London Institution, Finsbury-circus, E.C., 5 p.m. Prof. G. J. Romanes, "Instinct."

Society of Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Mr. H. L. Greville, "A New Residual Product from Coal Gas." 2. Mr. C. N. Hake, "Further Notes on the Stassfurt Industry." 3. Mr. A. Zimmerman will exhibit Drs. Raydt and Kunheim's Liquid Carbonic Acid Apparatus.

TUESDAY, DEC. 4...Civil Engineers, 25, Great George-street, Westminster, S.W., 8 p.m. 1. Mr. W. T. Douglass, "The New Eddystone Lighthouse." 1. Mr. W. H. Preece, "Electrical Conductors."

Pathological, 53, Berners-street, Oxford-street, W., 8½ p.m.

Biblical Archæology, 9, Conduit-street, W., 8 p.m. 1. Mr. H. Rassam, "Biblical Nationalities in their Primitiveness, and as they exist at present." 2. Dr. J. Peters, "The Babylonian Origin of the Phœnician Alphabet."

Zoological, 11, Hanover-square, W., 8½ p.m. 1. Mr. R. Bowdler Sharpe, "Notes on the *Diceidæ*." 2. Mr. J. B. Sutton, "The Diseases of Monkeys dying in the Society's Gardens." 3. Mr. H. O. Forbes, "The Habits of *Thomisus decipiens*, Forbes, a Spider from Sumatra."

WEDNESDAY, DEC. 5...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Thomas T. P. Bruce Warren, "The Manufacture of Mineral Waters."

Geological, Burlington-house, W., 8 p.m. 1. Dr. Henry Hicks, "The Cambrian Conglomerates Resting upon and in the Vicinity of some Pre-Cambrian Rocks (the so-called intrusive masses) in Anglesey and Caernarvonshire." 2. Prof. T. G. Bonney, "Some Rock Specimens collected by Dr. Hicks in Anglesey and N.W. Caernarvonshire." 3. Mr. A. J. Jukes-Browne, "Some Post-Glacial Ravines in the Chalk Wolds of Lincolnshire."

Entomological, 11, Chandos-street, W., 7 p.m.

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m. Messrs. Wyndham R. Dunstan, and F. W. Short, Report upon the Pharmaceutical Preparations of Nux Vomica (continued). II. "Notes and Suggestions upon Tincture of Nux Vomica." III. "Extract of Nux Vomica." 2. Mr. Edward Grindle Hogg, "Tincture of Cinchona." 3. Mr. Harold Senier, "The Purgative Principle of Croton Oil." 4. Mr. Harold Senier, "The Vesicating Principle of Croton Oil."

Archæological Association, 32, Sackville-street, W., 8 p.m. 1. Mr. C. H. Compton, "Brambletye House, East Grinstead." 2. Mr. Thomas Morgan, "Report on the recent Congress at Dover."

Obstetrical, 53, Berners-st., Oxford-st., W., 8 p.m.

Civil and Mechanical Engineers, 7, Westminster-chambers, S.W., 7 p.m. Mr. B. Haughton, "The Suez Canal choked at last."

THURSDAY, DEC. 6...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. Mr. Charles Darwin, "Posthumous Essay on Instinct." A discussion to follow.

Chemical, Burlington-house, W., 8 p.m. Ballot for the election of Fellows. 1. Dr. E. Divers and M. Rawakita, "The Constitution of the Fulminates;" "Liebig's Production of Fulminating Silver without the use of Nitric Acid." 2. Dr. H. E. Armstrong, "Note on the Constitution of the Fulminates." 3. A. B. Griffiths, "Experimental Investigations on the Value of Iron Sulphate as a Manure for Certain Crops."

London Institution, Finsbury-circus, E.C., 7 p.m. Rev. W. Green, "The High Alps of New Zealand."

South London Photographic (at the HOUSE OF THE SOCIETY OF ARTS), 8 p.m.

Civil Engineers, 25, Great George-street, Westminster, S.W. Special Meeting. Mr. W. Anderson, "The Generation of Steam, and the Thermodynamic Problems involved." (Second Heat Lecture.)

Royal Society's Club, Willis's-rooms, St. James's, S.W., 6 p.m.

Parkes Museum, 74A, Margaret-street, W., 8 p.m. Dr. G. V. Poore, "Coffee and Tea."

Philological, University College, W.C., 8 p.m.

Archæological Institution, 16, New Burlington street, W., 4 p.m.

FRIDAY, DEC. 7...Geologists' Association, University College, W.C., 8 p.m.

SATURDAY, DEC. 8...Physical Science Schools, South Kensington, S.W., 3 p.m. 1. Prof. S. P. Thompson, "The Static Telephone as an Instrument of Research," "A New Insulating Support," and "The First Law of Electrostatics." 2. Prof. J. Monckman, "Experiments illustrating the Attraction and Repulsion of Bodies in Motion." 3. Mr. Walter Baily, "An Integrating Anemometer."

Royal Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.

Journal of the Society of Arts.

No. 1,620. Vol. XXXII.

FRIDAY, DECEMBER 7, 1883.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

THE MARQUIS OF LORNE ON CANADA.

To enable a greater number of members than can be accommodated in the Society's own Room to hear the paper on "Canada and its Resources," by the Marquis of Lorne, on the 19th December, the Council have arranged for the meeting to be held at Exeter-hall, Strand (in the smaller hall). Members will be admitted as usual on signing their names, but the privilege of admitting friends will be restricted. Each member will be entitled to admit *one* friend only, either personally or by the usual ticket.

JUVENILE LECTURES.

The usual short course of lectures, adapted for a juvenile audience, will be given on Wednesday evenings, January 2nd and 9th, by J. Millar Thomson, F.R.S.E., F.C.S., on "Crystals and Crystallisation." The lectures will commence at seven o'clock. A sufficient number of tickets to fill the room will be issued to members in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each member is entitled to a ticket admitting two children and one adult. Tickets are now in course of distribution, and members requiring them should apply at once.

CANTOR LECTURES.

On Monday evening, the 3rd inst., Mr. W. Mattieu Williams delivered the first lecture of his course on "The Scientific Basis of Cookery," in which he likened the kitchen to a chemical laboratory, and dwelt on the necessity for a knowledge of certain chemical principles amongst those who had to conduct, or at least to direct, the processes of cooking. He described the different modes of applying heat by radiation, conduction, and convection; explained the difference between boiling, stewing, roasting, &c., and using, as an illustration, the effect of various degrees of temperature on albumen, showed how important it was that the precise heat required for each process should be attained and maintained. For instance, as boiling water never rises above 212 degrees Fahr., it is an obvious mistake on the part of the cook to attempt, by increasing the fire, to make water boil faster.

EXHIBITION OF COOKING APPLIANCES.

An Exhibition of gas and other stoves, and the various apparatus and appliances used for cooking purposes, was opened, in connection with Mr. Mattieu Williams's Cantor Lectures on "The Scientific Basis of Cookery," on Monday evening last, and will remain open until December 17th. It will be open daily, from 10 a.m. to 4 p.m. (with the exception of Saturdays, when it will close at 2 p.m.), and on the evenings of the lectures.

Members of the Society can admit their friends by use of the tickets supplied for the evening meetings and lectures. Persons not members of the Society may obtain tickets on application to the Secretary.

Proceedings of the Society.

THIRD ORDINARY MEETING.

Wednesday, December 5th, 1883, B. W. Richardson, M.A., M.D., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Crow, John Kent, D.Sc., 2, Colham-villas, West Drayton, Middlesex.
Cunliffe-Owen, Edward, 64, Inverness-terrace, W.
Henderson, Richard, The Grange, Kirkcudbright, N.B.
Latchford, Edward, 50, Penywern-road, South Kensington, S.W.

The paper read was—

THE MANUFACTURE OF MINERAL WATERS.

By Thomas T. P. Bruce Warren,

In this paper I have intentionally omitted to deal with the historical part of the subject. I mention this because I know that there are many firms in the metropolis who are very proud of their time-honoured connection with this business, and who may perhaps feel that I have acted with some discourtesy towards them on that point. The fact is, I found that so much time would be occupied in travelling over the historical part of this matter, that it would be better to leave it for another occasion. With these remarks, I feel confident that those firms which we regard as the founders of this important and interesting manufacture, will be assured that no unkindness is meant by the omission.

There is, however, an important link in the manufacture which cannot be overlooked. We cannot fail to be struck with the elegant and smart appearance of some of these bottled beverages, when we consider what they were a few years ago. It must have been the work of a man with a very strong nerve who first ventured to depart from the old-fashioned form of bottles. There is no doubt that these beverages have become much more fashionable from the fact that a dinner table can be laid out and decorated with them, especially when bottled in syphons. Why an untidy finish, until only a few years ago, was almost considered a necessary accompaniment to mineral waters, I have never been able to understand. Fig. 1 shows how the contents of a syphon should be allowed to fall into a glass.

Fig. 1.—Mode of Opening a Syphon.

Another fact, which deserves more than an incidental reference, is that the term "mineral water manufacturer" no longer defines the nature of the products which are now turned out from the "soda water works." Not many years ago, ginger, lemons, citric and tartaric acid and sugar were the only representatives derived from the vegetable kingdom; these, together with about half-a-dozen inorganic salts, constituted what we may call the *materia medica* of the mineral water manufacturer. A glance at this interesting collection of specimens which have been kindly sent here by Messrs. Stevenson and Howell, Bush and Co., Lichtenstein and Co., and others, will give you some idea of the present stock-in-trade belonging to a mineral water manufacturer As a very few of these materials are derived from the mineral kingdom, it is evident that the word mineral is inappropriate to a large majority of the beverages generally so classified.

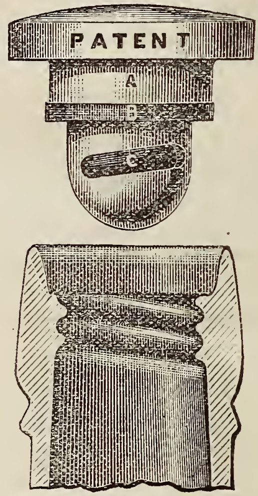

Fig 2.—Barnett and Foster's Stopper.

When people were content to drink these mineral waters principally as medicinal agents, or as media for diluting brandy, &c., there was no room for the development of that artistic skill which may be fairly said promises now to alter the taste of mankind in the matter of drinks.

The frequent disclosures which have now and then been made of the manœuvres carried on in the champagne trade, ought more strongly to reconcile us to the aërated fruit-flavoured beverages, which we know are wholesome and refreshing, and which I believe were first introduced by Messrs. Barnett and Foster.

FIG. 3.—BARNETT AND FOSTER'S MACHINE WITH NIAGARA MIXER.

It has been unfairly represented that these beverages are made of chemicals of a very doubtful character, as regards their harmlessness, and an attempt has been made to support this charge by selecting from a general trade-list a few seemingly obnoxious compounds, as though they constituted the sole ingredients employed in this business. The increasing demand for these beverages, and the fact that they form so important an element in the dietaries of the educated classes of this country, prove, to my mind, that Bacchus is becoming uneasy at the great stride which temperance has made, through the introduction of artistic skill in compounding non-intoxicating beverages which are alike palatable and captivating. Messrs. Bush have given a great deal of attention to the preparation of syrups and fruit essences for preparing these beverages.

In the manufacture of aërated waters, the matter of greatest importance is the purity of the water itself which is employed. Consumers of these waters, which are sent out by our largest and well known manufacturers, can rest perfectly contented that the most scrupulous care will be taken to secure a thoroughly wholesome water supply. From the results of an inquiry into the general London trade, I am able to state that manufacturers, as a rule, are fully alive to the importance of keeping their natural supply of water above suspicion. Few manufacturers, however, apply chemical tests themselves, but rely upon the water companies delivering the article as pure as circumstances will permit. There is, no doubt, a great difference in the suitability of he water supplied by the different metropolitan water companies for the requirements of a mineral water factory. The same remark applies, but with greater significance, to the water supplies of our different towns.

The recent alarm of cholera reaching our shores threatened to invest mineral waters bottled in this country with an unenviable character, somewhat to the advantage of the enterprising foreigners.

Without wishing to raise an unnecessary alarm, I think it would be to the advantage of the trade, as well as to the consumer, if some legislative enactment could be carried so as to prevent this trade being carried on either by ignorant or unskilled persons, or by those to whom notions of profit are of greater importance than the sanitary considerations necessary for conducting a manufacture which is so intimately associated with our daily wants as aërated waters.

With a view of assisting mineral water manufacturers, brewers, and others interested in the matter of water impurities, &c., I have designed a chemical cabinet containing all the requisites for such an inquiry, and for the general examination of trade products. One of these cabinets, fitted up for a mineral water manufacturer, is exhibited by Messrs. How and Co., Farringdon-street, and contains all that is necessary for the examination of water and the purity of the materials more generally employed in the manufacture. Mr. Cetti has sent a collection of apparatus for examining water, including the Bischoff evaporating arrangement (Fig. 16, page 49).

Cases are known where a damaged water pipe inside a factory has led to serious pollution of the water, although, as supplied by the water company, it was perfectly good when drawn from their mains. Frozen pipes, and the subsidence of newly-made ground, are not unfrequent sources of such accidents. Water drawn from a well may become contaminated by the infiltration of surface water through the upper part of the casing of the well being defective. Fortunately, a defect in a water pipe laid in the ground becomes too evident to be overlooked; well water, however, may become contaminated without the fact becoming evident; it is therefore safer to apply a few tests as frequently as possible, especially after heavy rains, and following upon long drought. Deep wells, if lined to a sufficient depth, are quite safe, provided the supply is drawn up through a pipe carried some distance down below the casing, instead of being drawn too near the top of the bore.

The considerations which should guide a manufacturer in sinking a well can scarcely be given here; but in a town supplied with good water, as regards freedom from organic matter, better waters may probably be made from the town supply than may be expected from a well, even if sunk to a considerable depth; for we must not lose sight of the fact that we are generally more liable to infiltration of surface water unless we put down a very costly and perfect lining. Faults from fissures are not unfrequent in very deep wells.

Most people have an idea that filtering will render any water fit to drink. There is nothing to be said against using a good and properly constructed filter; a water of ordinary quality may be improved, and even if free from organic impurities, may leave the filter no worse than when it went in; but the unfortunate thing about filters is, that people think that they last almost for ever without being looked to, or that any amount of water may be passed through them. In removing organic impurities by filtration we trust partly to mechanical separation and partly to oxidation Baker's high pressure filter is the best form for obtaining a large supply of good filtered water rapidly.

Other methods of removing or destroying organic impurities are distillation and boiling. The main difficulty in carrying out these operations on an extensive scale is the subsequent cooling, and in the case of distilling, the cost of condensing.

Boiled water is of great importance, as not only does boiling tend to remove or destroy organic impurities, but by subsidence a great number of inorganic compounds are removed, such as oxides of iron and manganese, lime, magnesia, and silica. The presence of oxygen is objectionable in the case of waters flavoured with essential oils or other principles liable to change by oxidation. Waters containing ferrous compounds can only be prepared successfully by the careful exclusion of oxygen in every stage of the manufacture.

There are two or three methods in use for bottling waters containing ferrous compounds; one consists in first filling the bottles with water highly charged with CO_2, and then emptying them so as to retain a quantity of the gas in the bottles. A fact of great importance is that most ordinary waters, under general conditions, contain considerably more oxygen than is contained in the same volume of atmospheric air. It is found by experiment, when the gases are obtained from ordinary water by boiling, that the air which is evolved is much richer in oxygen than atmospheric air is. This has led to the discovery of what is known in chemical physics as the law of partial pressures. We learn from this that in a mixture of gases, the co-efficient for the solubility of each gas in water has to be multiplied into the number expressing their relative volume pressures, in order to obtain the actual volume of each gas absorbed.

Under ordinary circumstances, a litre of good river water may contain about 7 c.c. oxygen and 13 c.c. nitrogen; the same volume of atmospheric air will contain 4·2 c.c. oxygen, and 15·8 c.c. nitrogen.

From certain experiments which I have made, and am still carrying out, it would appear as if this oxygen contained in the water acquires an enhanced chemical activity under certain circumstances, and although I am not able to prove that it becomes ozonised, I am certainly of opinion that the oxidation of oil of lemon in lemonade is in a great measure the cause of deterioration where sound and genuine ingredients have been used. Other substances liable to change by oxidation may, of course, alter in the same way.

In the ordinary manufacture of aërated waters belonging to the saline class, oxygen gas is not likely to do any harm, but it is impossible to regard its presence with indifference where essential oils or other easily oxidised materials are employed.

The examination of the gases contained in ordinary water is a tedious operation. On the table are two arrangements for conducting this; one of these, proposed by the late Dr. Miller, is, in my opinion, the most trustworthy.

The objections to air-impregnated water have not escaped the attention of manufacturers, and a system of bottling water free from atmospheric air has been recently perfected by Mr. F. Barrett, Messrs. Barnett and Foster, and Messrs. Hayward Tyler and Co. for patent stoppers.

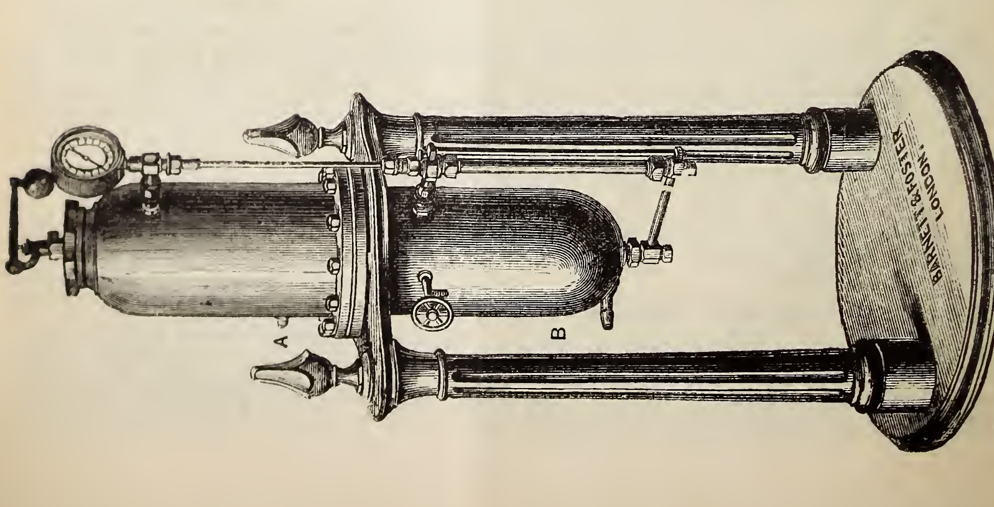
When a bottle of aërated water contains air, a portion of the contents are ejected with violence when the bottle is opened; it also prevents good aëration with the gas. By the more usual method of bottling, this cannot be avoided. The bottle to be filled is placed under a nipple, and the aërated water forced in. When the pressure in the bottle prevents any more liquid flowing in, the tap is closed, and the accumulated air and gas allowed to rush out; it is then re-placed securely under the nipple and filled up. In this way the water is bound to contain a very great deal of air.

By the new system, the liquid is poured or forced through a tube reaching to the bottom of the bottle, the bottle being inverted, so that on filling, the air is completely forced out, just as we would collect a jar of the gas by downward displacement, driving out the lighter air before it. Diffusion between the air of the bottle and the gas is avoided completely by the upward pressure of the gas.

Messrs. Pitt and Co., who use this system of filling, have sent a variety of their waters, which are not only very highly charged with the gas, but retain an active effervescence for a long time, and on opening, none of the liquid is ejected over the side of the bottle.

If we open a bottle filled by both methods, you will be able to see the remarkable advantage of what is now known as the "apneumatic" system. Before opening, it would be

Fig. 4.—Niagara Mixer.



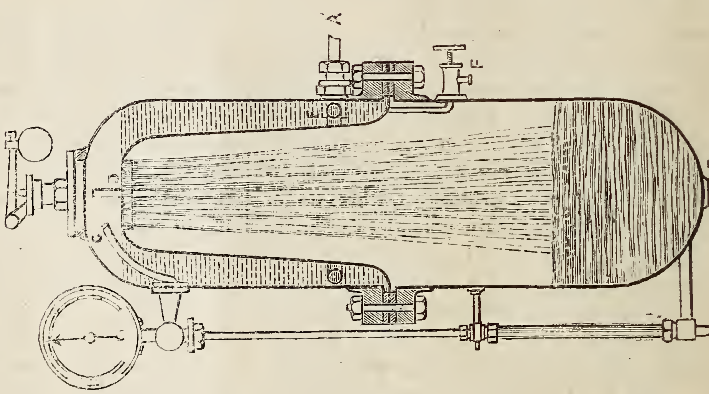


Fig. 5.—Niagara Mixer (Section).

Fig. 6.—Knee-bottling.

interesting to compare the pressure in each bottle.

By this method, and by excluding air from the water, and its ingress in any part of the operation, it is possible to obtain in solution ferrous compounds, which are among the most difficult materials to bottle up without depositing. With this method, we may be said to have attained perfection in making aërated beverages.

Mr. James Packham, of the firm of Packham and Co., Limited, of Croydon, has given a great deal of attention to the purification of water by distillation, and informs me that he

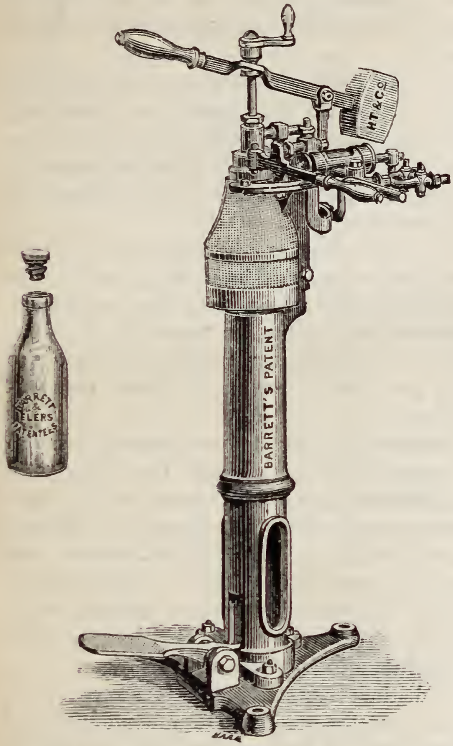

FIG. 7.—BARRETT'S BOTTLER FOR SCREW STOPPERS.

has no difficulty in distilling all the water required for their extensive trade. There is a fine display of the various waters made by this firm, and I have very great pleasure in stating that these waters have not only a high character, both in purity and general qualities, but are as near perfection as possible. I consider the fine flavours of these sweet beverages are preserved by the non-presence of oxygen gas or air in the water used in preparing them. After the air has been expelled from water by boiling or distilling, care should be taken to keep it closed up in tanks; it would even be better to impregnate the water slightly with carbonic acid gas, which would not only give a greater security against the absorption of air, but would, in a great measure, counteract the tendency to contamination when in contact with metals, &c.

As pure water has a much greater solvent action than ordinary water, extra precaution

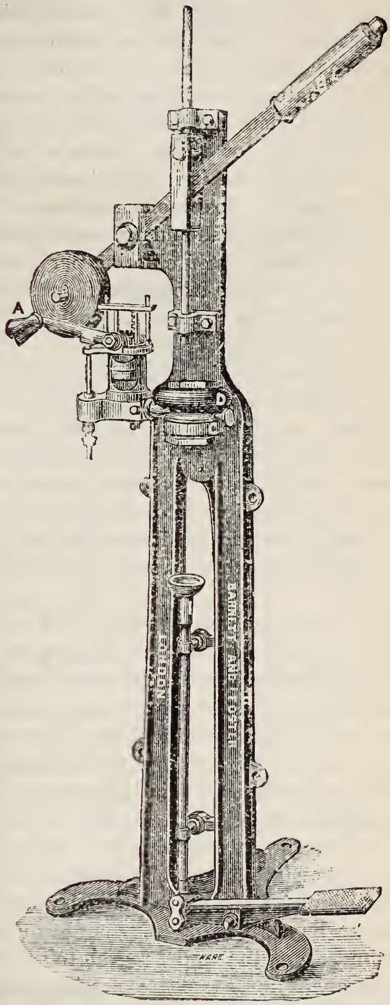

FIG. 8.—BOTTLER FOR CORKED WATERS WITH SYRUP PUMP.

is necessary to avoid contamination; Mr. Packham uses pure tin pipes, and when other metals are necessary, they are protected by a heavy coating of silver.

Another method of purifying water consists in removing its carbonic acid gas, whereby the carbonates of lime, iron, and magnesia are precipitated, together with silica and organic matters. This is effected by the addition of lime water. This method has been rendered more practicable by the application of the filter press, as carried out under the well-known Porter-Clark process. The presence of an abnormally large amount of earthy carbonates in a natural water is very undesirable. These can be removed by adding a little soda to the water, where such addition is not likely to be objectionable; after standing for a time, the earthy salts will be precipitated.

A good natural water for manufacturing aërated beverages should be free from organic impurities as near as can be, for very few waters, in a natural condition, are absolutely pure in this respect; it should not contain more than twenty or thirty grains of solid matter per gallon, and if it contain over this amount, it should be capable of being removed by a softening process. It should not contain much air; and the quantity of chlorine per gallon must not exceed one to two grains for ordinary water, although this quantity is considerably exceeded by deep well water.

A little experience is required in order to decide on the merits of a water from the results of analysis. An impure water would unhesitatingly be condemned, but a very pure water may involve us in trouble almost as serious; so that, without going into this part of the subject fully, it would be impossible to give much information which would be generally applicable.

We are tolerably well supplied with works on water analysis, from a sanitary point of view. A mineral water manufacturer requires much more than this, he requires to know how to find out the composition of a naturally occurring mineral water, and the details and methods of analysis far in advance of the works at present in print. I hope shortly to do something towards supplying this want.

It is of equal importance that a manufacturer should be able to tell whether the articles he buys are what they ought to be in purity and strength; and I regret to say that no work, as far as I am aware of, will give him much assistance in this direction. Although this business has advanced at such a pace that there are now over 2,000 manufacturers in this country, and we have some good trade journals, such as the *Mineral Water Trade Review*, and a few beside, we have nothing in the way of scientific literature; this I attribute to the transitional condition of the business. A new state of things is created, which involves more scientific knowledge than is possible for a manufacturer to keep up with.

The general plan [and] arrangement of a mineral water factory must be such that ventitation and cleanliness can always be secured; bad smells from any cause must be an impossibility; all water ways, drains, &c., should communicate with the outlets to sewers outside the buildings, and be well trapped; any drains in the factory should be closed with moveable coverings, so as to admit of their being well cleaned and swept out. Wood flooring, or anything likely to hold moisture or dampness, is unfit. No dust nor mildew should be allowed to accumulate on the walls or floors; and a current of fresh air should always pass through the parts of the building devoted to the more important parts of the work. Fig. 11 (page 45) shows the general plan of a factory plant.

The machinery should be so fixed as to be easily accessible for repairs or cleaning. Whiting should be well dried, and kept away from damp and dust. A plentiful supply of water for rinsing bottles and washing, is indispensable.

I have had the pleasure of going over several of the larger factories in London, and I could not help being struck with the scrupulous attention paid even to the minor details of the work; in this respect the contrast between what prevailed a few years ago is very encouraging.

Probably nothing has contributed more to the popularising of aërated beverages than the different kinds of stoppers, which have been so successfully developed by Messrs. Barrett and Elers, Mr. Codd, and others. As may be expected, this system of corking or stoppering has undergone some changes which pertain, however, more to the design of the stopper than to anything else.

A distinct feature which is an enormous advance on the preceding form of stopper, and which, from the fact of their being forced into the bottle in order to get at its contents, have been called "internal stoppers," is the patent screw stopper of Barrett and Elers, and the intermittent screw stopper of Barnett and Foster. Barrett's stoppers are made of ebonite tube, the thread being made by moulding the tube when softened by heat; the stoppering is rendered tight by an india-rubber washer. Mr. Barrett has kindly sent a variety of beverages bottled and corked according to his system, and also a variety of bottles and stoppers showing the growth of the new method of corking. We have, first, the somewhat barbarous looking "Jersey wood stopper," which, however convenient in use, can lay no claim to elegance or neatness; secondly, we have the ebonite stopper, which in turn was substituted for the glass ball stopper; lastly, we come to the screw stopper, which, although it was originally introduced for bottled beers, bids fair to supersede every other form of this kind of stopper for aërated waters.

There is a great difference of opinion respecting the merits of the old and familiar method of corking, and the use of the patent stoppers. I have no hesitation in saying that the driving of the stopper into the contents of the bottle is very objectionable, it promotes a rapid evolution of gas, and what is still worse, any dust or particles of straw contained in the neck of the bottle find their way into the tumbler when the contents are poured out. A metal capsule would remove the last objection.

This system of corking has, in spite of all that can be urged against it, been the means of developing a taste for these beverages among our artisans and the less wealthy of the middle class, and has no doubt stimulated the demand for waters where cork is used.

I am indebted to Messrs. Hayward Tyler and Co. for this display of bottles, designed by Lamont, and others, for their well-known system of corking. Messrs. Barnett and Foster have also sent Codd's patent bottles.

The fact that the screw stopper can be quickly replaced when a portion of the contents of the bottle has been poured out, adds very materially to its merit, the water retaining enough gas to bear opening a second time in a satisfactory state of aëration.

Messrs. Hayward Tyler and Co. have kindly sent a machine here, and my friend, Mr. H. Dowell, their engineer, has promised to have the same in operation. This machine is a perfect representation of the type involving the well-known Bramah hydraulic process, and is a unique specimen of workmanship and finish (Fig. 21, page 53).

The process of making unsweetened aërated waters consists of three distinct operations. The generating and washing the carbonic acid, the saturation of the water with the gas, and the bottling; with sweetened waters, the syrups and flavouring ingredients are added by a separate process, continuous with the bottling. K is the generator for obtaining the carbonic acid, as will be explained further on; the gas is passed through a washer or purifier, and thence into the holder, C, which is made of copper lined with tin, and which works in an oak tub or cistern, O. The combination of the gas with the water is effected by pumping into a stout copper vessel, D, called the condenser, under a very high pressure. This is the system almost universally used in this country. In this machine, the pump and condenser are placed on one frame for convenience and compactness. The pump is an inverted plunger pump, with valves at the top; gas is drawn in one side, and water at the other. G is the pump, H the valves, M the vessel from which the water or solutions are drawn. From the pump the water and the gas pass together into the condenser, D, which is lined inside with pure tin or silver; an agitator or fan, actuated by the cogwheels, F, works in the condenser; by a recent improvement this agitator is dispensed with by passing the gas and water together from the pumps into a perforated pipe, which gives the needful agitation in the condenser.

Messrs. Barnett and Foster exhibit a machine in which they effect the mixing of the gas and water by lifting the water and letting it fall through a series of fine perforations. Fig. 3 (page 37) shows the complete machine, with the generator and holder. Figs. 4 and 5 (page 40) show their Niagara mixer, in detail and section.

The condensers are sometimes fixed on separate frames from the pumps, and are generally worked in pairs. The pressure maintained in the condenser varies according to the water or beverage which is being made, and to the practice of the maker. Some makers work with a pressure as high as 200 lbs. per square inch in the condenser; from recent experience, however, a pressure of from 80 to 120 lbs. is found to be practically the best. From the condenser the water which is now aërated can be drawn off at the cock and nipple, E, as in the old process of knee bottling. (Fig. 6, page 40).

For machine bottling, a pipe leads from E to the machine. The bottling machine varies in its details, according to the form of bottle used and the means of closing it, whether by cork, patent stopper, or syphon. The various systems are well illustrated in the machines now exhibited, but the system of steam bottling, which is now rapidly taking the place of the older method, cannot be shown without steam-power. Fig. 7 (page 41) is Barrett's bottler for his patent screw bottle. Fig. 8 (page 41) is used for ordinary bottles. Syphons are filled as in Fig. 9 (page 44). A special form of bottler is shown in Fig. 10 (page 44) which fills any form of patent bottle.

The contamination of the water by contact with metals, has been a source of considerable anxiety to the manufacturers of waters, and also to the machines. Contact with lead or any easily oxidised metal must be avoided. There is no difficulty in securing this object by a coating of tin or silver, but when particles of metal

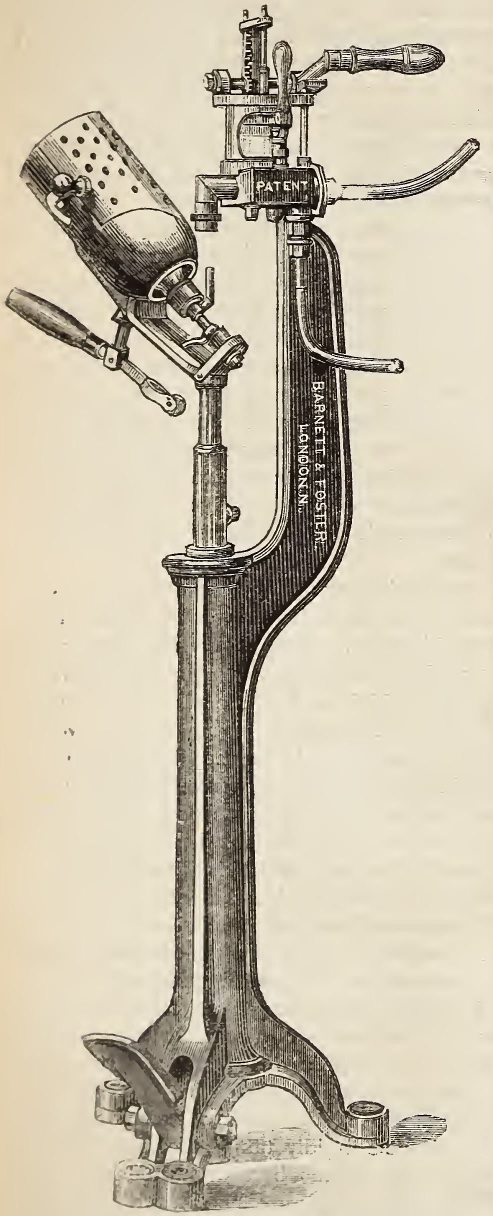

FIG. 9.—SYPHON FILLER.

are introduced by attrition, it is not so easy to suggest a remedy; this is completely avoided by the perforated tube introduced by Messrs. Hayward Tyler and Co., and already alluded to, or by the Niagara system of Barnett and Foster.

We occasionally hear of metallic impregnations in water, especially water containing citric or tartaric acid, and I would just suggest that, before we attribute this to defects in the mechanical appliances, it will be better to see if the materials are free from fault. These

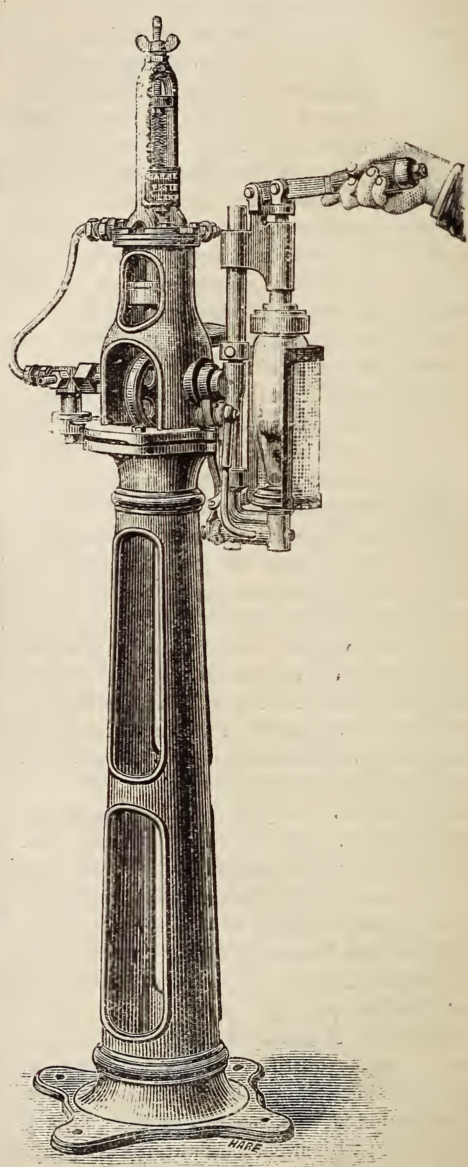

FIG. 10.—FILLER FOR ANY PATENT STOPPER.

acids are usually crystallised in lead-lined vessels, and are more frequently impregnated with this metal than most people are aware of. Cheap acids should be avoided. Messrs. Stevenson and Howell are directing their

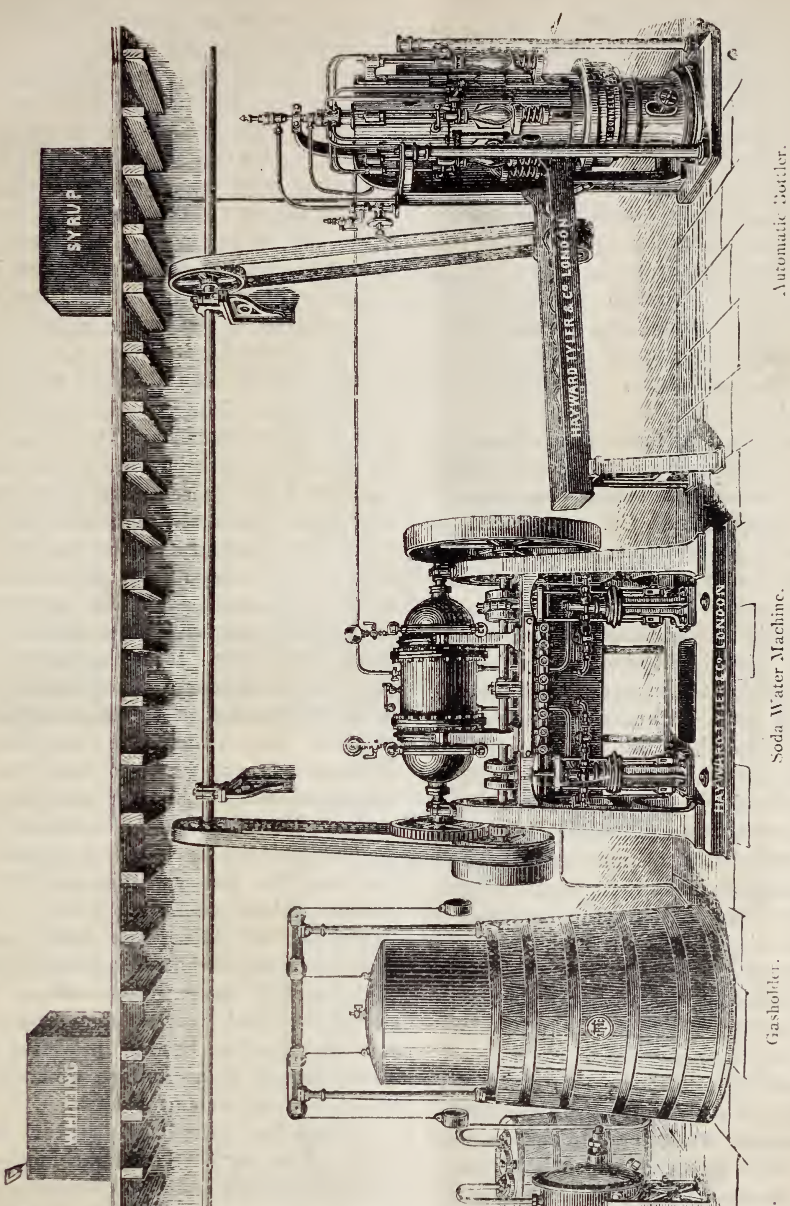

Fig. 11—Plan of Machinery capable of producing from 1,500 to 2,000 Dozen Bottles of Aerated Waters daily.

attention to this important matter, which has not only been overlooked by wholesale dealers generally in these articles, but has escaped the notice of our active analysts.

The manufacturers of machinery, used in the different parts of this business, must have had a severe task to keep pace with the march of improvement, and the rapidly increasing wants of the mineral water manufacturer. A few years ago the only mechanical arrangement in most factories was the agitating and forcing of the gas into the condenser, everyshing else being done by hand.

Bottles are now washed and rinsed by machinery, filled, corked, and wired, and the required quantity of syrups added, in the case of sweetened beverages, by mechanical arrangements.

The most important mechanical alterations have been in the process of filling, corking, and wiring the bottles. About 1840, Messrs. Hayward Tyler and Co. introduced a machine which in its simpler form constitutes what is now known as the bottling rack; this has become almost universally used, and is now supplied in various forms by the different makers of this description of machinery. Fresh demands have been made on the bottling rack, and in some instances it has been so ingeniously adapted, that its ancestral kinship is almost disclaimed. In its latest and most highly-developed form, it appears almost as if it were an automatic soda water maker; all that is necessary with this machine is to place the bottle and cork in their proper places, when the measured quantity of syrup is added; if required, the air is forced out by the ingenious process of filling, and the cork driven in; the completed bottle of water being delivered to the attendant for wiring, at the rate of from twelve to thirty-six per minute.

It is found by experience that the waters produced by this machine are superior in all respects to those obtained by the more general methods. This machine, which is known as Mr. Allen Macdonell's automatic bottling and corking machine, is becoming very extensively adopted. Fig. 18 (page 52) shews the machine.

The machine occupies a space of about three feet square, and stands on a cast-iron foundation, easily fastened down by bolts to the floor. The principal working part is an upright cylinder, revolving on a central pillar. The outer part of this cylinder is provided with six mouthpieces, very similar to those on an ordinary bottling rack, only that all the operations of syruping and bottling are performed automatically, by means of cams, &c., as the cylinder revolves. One attendant is all that is required to place the bottles and corks in their place, as each mouthpiece in turn comes round to the front. As the bottle passes round it first receives its charge of syrup from a glass pump; it then receives the aërated water, and allows the atmospheric air to escape in a manner similar to that accomplished by hand, but with all the accuracy and regularity of well-fitted machinery. The cork is then driven down—all by automatic action—and by the time the bottle has nearly completed its revolution round the cylinder it is ready to be delivered, by a self-acting guard, on to an endless band, which carries it to the wirers. It will thus be seen that the whole process of syruping, filling, and corking is reduced, as far as labour goes, to putting the bottle and the cork into suitable rests in the machine as it passes round. The speed of working is practically limited by the rate at which the attendant can supply the bottles and corks. In practice it is found that with a day or two's experience a youth can put in from 120 to 140 dozen an hour, and the machine is regulated accordingly. It is easy, however, to adjust the machine to turn out any smaller quantity, by throwing one or more of the mouthpieces out of work. This is often done when there are not wirers enough at hand to wire the whole out-put of the machine, or when the pumps will not supply the aërated water fast enough. The whole of the machine is driven by a single belt, and the power required is very small, probably about half-horse power. From the experience of those who have given the machine a somewhat lengthened trial, it is plain that it is easily understood by the attendants, and very seldom requires any special attention, beyond providing for the wear and tear of a machine which is getting through a vast amount of work.

It was first introduced to the trade, in England, in 1878. Some machines, made at Mr. Macdonell's works, at Newry, were set to work in one or two important factories, and soon afterwards the manufacture was placed in the hands of Hayward Tyler and Co., 84, Whitecross-street, London, E.C. The advantages of the system were evidently so great, that although it was brought out at first in an incomplete form, it was speedily adopted by the most intelligent and enterprising among the larger manufacturers. The machines can be depended on with entire confidence, both for simplicity and safety of working, and for the quality of their product, as may be seen by the reports of the distinguished firms who habitually use them.

The Macdonell Bottlers were at first only made in a form suited for large factories—each machine being capable of filling 160 dozen bottles in an hour. The success of these machines, of which a large number are at work, induced Hayward, Tyler, and Co. to bring out a size to fill 120 dozen an hour, and later, in order that the advantages of the system might be available for all classes of factories, they have introduced a machine, at very moderate price, to fill any quantity up to 60 or 70 dozen an hour, worked by one boy or girl.

In the larger machines, the bottles, as they are being filled, revolve around a central cylinder, several bottles being filled at the same time. In the smaller machines, the bottle is stationary as in an ordinary rack. It requires only to be put into its place by the operator, and is passed to the wirer by the machine itself without further trouble. These machines are all of great strength; they work perfectly steadily, and almost noiselessly; they occupy little room, and will run for years without repairs.

For the benefit of those who have not seen the machine at work, I will explain what the process is.

The attendant sits or stands in front, with the empty bottles at hand on one side and the corks on the other. With one hand he places the bottle on the bottle-rest, and with the other he places the cork in the mouth-piece. This is all he has to do; the bottle is held in its place by the machine itself, the cork-plunger descends and drives the cork into the tube. The bottle is then partly filled, then snifted, then completely filled, finally snifted, and the cork driven home. The bottle is released, and gently pushed off down a shoot to the wirer, all by the machine itself, without any further attention of the attendant, who has only to get his next bottle and cork ready to be put into place.

If syrup goods are being filled, the syruping process is also performed by the machine at the same time, so that the bottle is delivered, filled, and corked without any trouble at all.

With the May Davis Bottling Machine the above object is accomplished by hand. Soda water, of uniform aëration and superior to that to be obtained by any other method, is said to be produced with a pressure of from 65 to 80 lbs. in the cylinder, and all other aërated waters and beverages at proportionate reductions from the old standards. Beers, wines, or any sweetened or frothy liquors, may be passed through the cylinder, and bottled with facility.

The principle of the machine will be readily understood. The neck of the bottle being placed in the india-rubber cup, ready for filling, as in the ordinary rack-bottling machine, a tube is pulled down, by a lever, to the bottom of the bottle, a little additional pressure opening a valve admitting the liquid to the tube, and thence to the bottle. An automatic adjustable valve allows the escape of the air and superfluous gas from the bottle. By a simple lever movement the bottle is shifted from the filling to the corking position. Being filled from the bottom, the atmospheric air which the bottle contains is at once lifted to the top or neck, and is the first to be expelled, instead of being mixed up with the gas and water as hitherto. The whole process is quicker than that by the ordinary rack, as the bottle fills very rapidly and quietly. The machine is adapted for bottles of any size.

A prominent objection to rack-bottling, namely, the presence of cork dust driven into the bottle at the time of corking, is removed by an arrangement for washing the cork-cone or thimble, and the bottom of the incoming cork. The figure of this machine will be found at p. 53.

The process of wiring, by which the corks are secured, has hitherto been done by manual labour. Generally the wire, which is tinned iron, to prevent rusting, is cut into suitable lengths of about 10 or 12 inches. As these waters are bottled under a pressure of from 30 to 50 lbs. per square inch, the cork, when secured by wiring, is forced outwards, causing the wire to cut into the corks; to prevent this, which is not only unsightly, but frequently leads to leakages, some manufacturers place a piece of hard wood on the top of the cork, through which the wire cannot be forced. Some bottles are on the table with and without this addition, so that you may judge for yourselves of the superior appearance of the bottles where the wood disc is used. I am surprised that this is not more generally used; the pressure on the cork is uniform, and the non-yielding of the cork prevents leakage.

Mr. Howard, of the firm of Hayward Tyler and Co., has produced a machine by which the wiring can be accomplished by mechanical means entirely. Instead of using a single wire cut into lengths, as usual, he uses four parallel wires, each of which is continuous, one passes on each side of the neck, and the other two pass over the cork. They are

twisted at each side, and cut off by a mechanical arrangement, leaving the necessary loop for untwisting by hand when the bottle is to be opened. Specimens of bottling wire are here, and also a few bottles wired by the old and more usual method, and by the exquisite arrangement of Mr. Howard.

A simple form of mechanical arrangement for holding the bottle whilst wiring, has been some time in use. The illustration will explain itself. Formerly, the workman held the bottle between his knees, without any means being adopted for securing the cork in its place during the operation. I will ask my friend Mr. Dowell if he will kindly show us the operation of wiring.

Carbonic Acid.—Fig. 12 (page 48) shows the generator and washer. The usual source of this gas is whiting, or marble, which are well known forms of calcic carbonate. The carbonates of the alkalies, or other alkaline earths, are not so suitable, partly from their greater cost, as in the case of soda, potash, and magnesia, and the poisonous qualities of the resulting salts where strontia, baryta, &c., are used. However carefully a manufacturer may carry out the various operations of his business, his labour will be in vain for the production of good palatable waters, unless particular attention is paid to the condition of his whiting, or other source of carbonic acid.

The native forms of calcic carbonate do not yield pure carbonic acid; the gas is liable to contamination from the organic matter present in the carbonates, which is much greater in whiting and chalk than the harder forms, such as marble; it is generally considered that by washing these impurities can be removed. When the gas is generated from an impure carbonate, it is by no means so easy to remove the impurities carried over with the gas into the holder or purifier.

Whiting should be kept in a dry, airy shed, protected from dust, and beyond the reach of gaseous emanations or odours; however good the whiting may be when received, it will rapidly deteriorate if stored in a damp, musty corner of the factory.

The quality of a water depends so much on the purity of the gas, that I cannot help expressing surprise at the little attention which has been directed to this part of the manufacture, until quite recently. By allowing the gas generated in the ordinary way to bubble slowly through a solution of potassic permanganate, or any other powerful oxidising agent, these impurities can be most effectually removed without in any way deteriorating the gas by exchange of contaminations.

The impurities which pass over with the gas from the generator, when sulphuric acid is employed, are sulphurous acid, sulphuretted hydrogen, carburetted hydrogen, nitrogen and sulphur compounds, together with the usual impurities given off by commercial sulphuric acid. It is generally considered that by washing the gas twice the impurities can be removed; if a saturated solution of sodic carbonate be used in the second washing, no doubt many of the volatile acid products can be removed, by their uniting with the soda, and liberating their equivalents of CO_2.

From repeated experiments, I am convinced that the only method for effectually removing these products is by the use of oxidising agents, for when the impurities are taken up by the wash-water, we simply drive them out again when fresh gas is passed through.

A perfectly pure whiting can be obtained by exposing freshly burnt and recently slaked lime to the air for a few days, or until its causticity is removed, care being taken that the air is fairly good. With pure sulphuric acid, the gas thus obtained is exceptionally pure.

We must not lose sight of the fact that the acids employed to decompose our carbonates also contribute to the list of impurities met with in the gas.

I may note here a few improvements which have been made in preparing and purifying the gas. A simple precaution which prevents air getting mixed with the gas is always to keep the generator, and connections with the washer and gas holder, full of the gas. In attempting to get rid of admixed air, manufacturers generally incur a large and needless waste of gas, without securing the desired object.

After charging the generator, the gas should be liberated very slowly, and a little collected into a gas pipette, which is transferred to a gas jar containing strong caustic potash solution. As soon as the sample of gas examined is entirely absorbed, we may rest contented that no air is present. A simpler plan would be to attach a flexible tube to the generator or gas holder, and to allow the gas to pass into an inverted test tube filled with mercury, standing in a mercurial trough; a few drops of a strong solution of caustic potash are passed up the tube and agitated; a minute bubble of unabsorbed gas will show when the gas may be considered sufficiently pure.

Instead of allowing the gas to rush in and out of the washer in a stream, arrangements are now in use for breaking the current of gas, and making it pass through a series of perforated diaphragms. The lower part of the washer contains cooled well-boiled water; the upper part is packed with granulated marble, or, preferably, with crystals of sodic carbonate. The gas thus washed is sufficiently pure for almost any purpose.

Carbonic acid is readily soluble in water, and if present in sufficient quantity, imparts to it a refreshing and slightly exhilarating effect. A very large quantity of water, simply aërated with the gas, is now consumed as a refreshing beverage, and with some people is regarded as an indispensable article for the dinner table. As a beverage for children in warm weather it is eminently appropriate, and is very much appreciated when mixed with a little syrup of lemon or ginger. Fig. 13 (page 48) shows a form of carbonating machine on the American system. These cylinders are now charged from an ordinary machine.

The solubility of the gas in water is effected by a great variety of circumstances, those of which we have the greatest experience being temperature and pressure ; others, which are now beginning to assert their importance, are the presence of other gases and liquids, and mineral salts, sugar, &c.

The principal thing to guard against in purchasing whiting is an abnormal amount of strongly moisture. It ought not to blacken when heated, nor destroy the colour of a dilute solution of permanganate of potash too rapidly.

To a manufacturer it is a matter of importance to know how to estimate the quantity of carbonic acid in a sample of water. Generally, the little arrangement known as the testing gauge, is used. We must not forget that pressure alone is no proof of the quality of the water. By means of a kind of hollow corkscrew, which has a hole a little way from the bottom, we allow the gas when the tap is opened to act upon an ordinary but delicate Bourdon gauge, the pressure being shown on the dial plate. The action of the arrangement can be easily shown. It may be used as a check against the bottlers, or to compare the products of different manufacturers. (Fig. 17, page 49).

The carbonic acid in a bottle of mineral water, such as soda, potash, seltzer, &c., is partly combined and partly free; we may estimate each portion separately. A large flask containing about 250 c.c. of strong solution of ammonia is fitted with a cork having two perforations; through one of these is passed a bent tube, reaching nearly to the bottom, and to the bent end is attached a flexible tube, connected to a cork borer, with a few holes drilled a little distance from the end. A tube containing fragments of glass, moistened with ammonia, is inserted into the other perforation, so as to catch every trace of carbonic acid. The borer should be inserted so that the holes are just below the cork ; the gas passes into the ammonia, its evolution is assisted by shaking the bottle, and, towards the end, by heating in a water bath until no more gas passes over. The contents of the flask and absorption tube are precipitated with calcic chloride, from which the amount of CO_2 can be estimated.

The combined carbonic acid is best obtained by evaporating to dryness the contents of the bottle, and decomposing the residue in one of the little forms of apparatus used for this purpose. Messrs. How and Co. have kindly sent a variety of these. The calcinimeter is an arrangement for measuring instead of weighing the gas. We are indebted to Mr. Cetti for the loan of this apparatus. A slight modification of this instrument, so as to measure larger volumes of gas, ought to be invaluable to a manufacturerer of aërated waters.

To make a complete examination of the gases contained in a bottle of aërated water, necessitates the use of eudiometric methods. The apparatus designed by Dr. Frankland for the analysis of water residues by the combustion process is eminently adapted for this purpose. (Fig. 14, page 49.)

The gas is allowed to escape into the laboratory tube, which contains a little saturated solution of caustic potash ; more gas is passed up as the absorption goes on. Any gases remaining unabsorbed can be passed over into the measuring tube, and again transferred to the laboratory tube; a few drops of a strong solution of pyrogallic are passed up, and the tube slightly shaken ; a dark coloration being produced, shows the presence of oxygen ; the gas remaining unabsorbed may be taken as nitrogen, which may be again passed over into the measuring tube, its volume noted, that of the oxygen being obtained by difference.

A good description of this apparatus, and the details necessary to be carried out, can be found in Frankland's "Water Analysis," or Sutton's "Volumetric Analysis." Mr. Cetti has shown us a convenient form of Sprengel pump for use with this apparatus (Fig. 15, page 49).

A word or two may be necessary respecting sulphuric acid ; on no account should any other

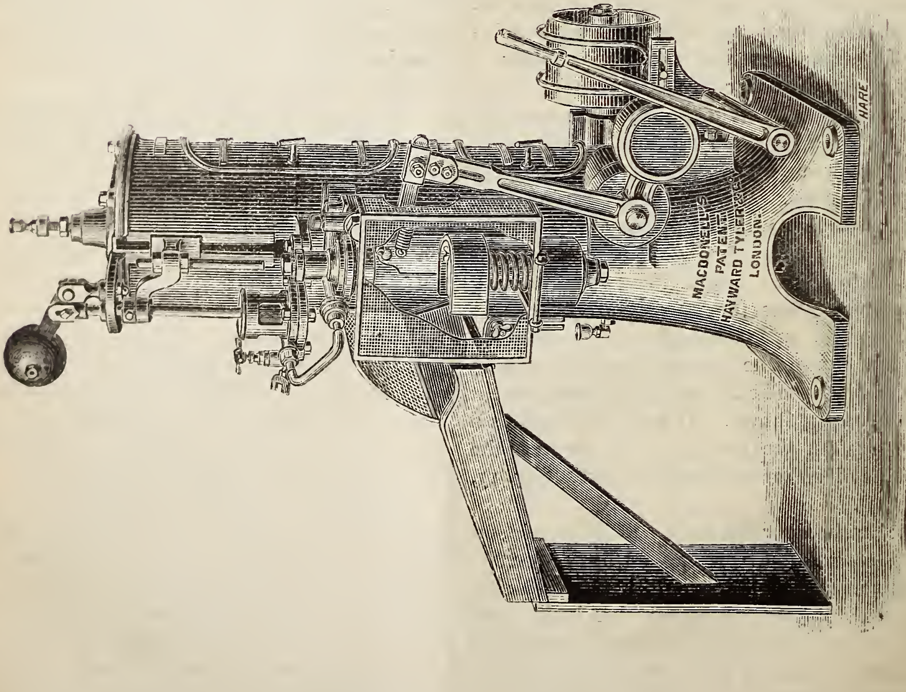

FIG. 18.—MACDONNELL MACHINE.

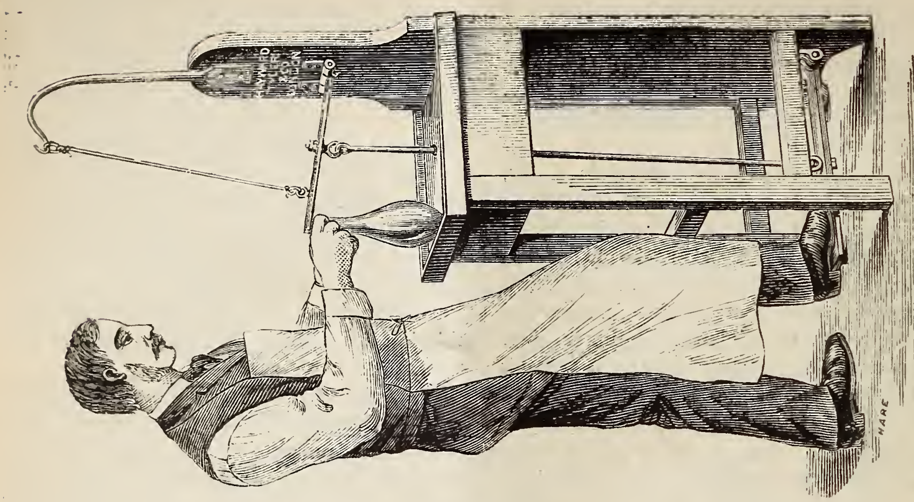

FIG. 19.—WIRING MACHINE.

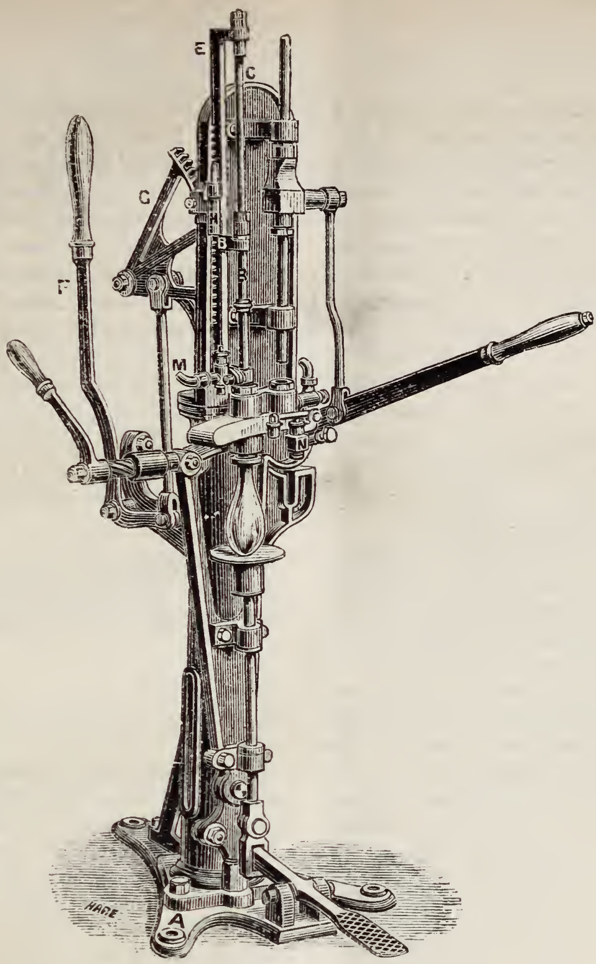

Fig. 20.—The May-Davis Bottler.

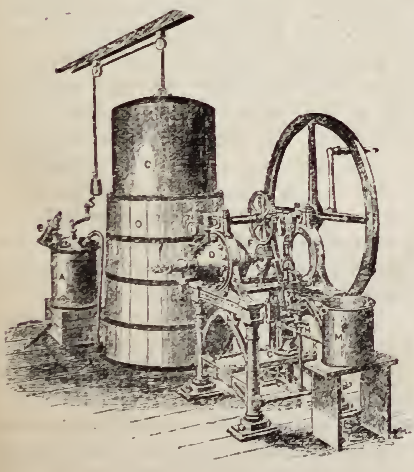

Fig. 21.—Improved Bramah Machine.

acid be employed but the white or colourless acid. If purchased according to density, care should be taken that we are not purchasing a dilute acid, containing fixed sulphates to give it the appearance of being what it is not. A few drops heated on a piece of platinum foil should leave no residuum.

Care should be taken to prevent pieces of straw, cork, &c., falling into the acid; this can hardly be avoided in pouring from a carboy, but a luxury unknown a few years ago is now in use in most factories for decanting the acid, thus avoiding contamination, waste, and danger from spilling. The American syphon pump is the best for this purpose.

The solubility of salts, preparation of syrups, tinctures, &c., are most important subjects to the manufacturer of waters, but are beyond the scope of the paper, as regards time. These subjects may be dealt with on a future occasion, and also the method of compounding artificial mineral waters from the result of analysis. No one has given so much attention to this branch of the business as the late Mr. William Hooper, of Pall-mall East; the waters manufactured by the present firm have earned a well deserved distinction. It is no exaggeration to state that we have at present no scientific mineral water maker; this has been accounted for by stating that the demand for this class of waters has given place to others. I believe it is due to the fact that we want an enterprising spirit to take up the manufacture of the new mineral waters which have been more recently introduced, in the same way as Mr. Hooper took up the manufacture of the numerous German spas, and which, in nearly every case, he successfully accomplished.

The manufacture of lithia water is a striking illustration to the point. An eminent physician, I believe Dr. Garrod, had written a book on gout, and suggested lithia as a remedy, to be administered as an effervescent beverage. I was sent by Mr. Hooper to inform Dr. Garrod that he would be very pleased to prepare this, and to gain any information I could on the subject. There was absolutely nothing to start upon; carbonate of lithia could only be had in small quantities, and at the price of about 24s. per ounce, and was scarcely known. In spite of these obstacles, lithia water was manufactured, and introduced to the medical profession within four days after the publication of Dr. Garrod's book. The demand for lithia water is now very great, and the carbonate can be had, at the present time, for about 8s. per pound. Our worthy chairman can inform you that this is not to be taken as an indication of our becoming more gouty as a race, but that the water is found to be a very beneficial beverage. A great variety of mineral waters are exhibited by Hooper and Co., the excellence of whose manufacture, especially that of seltzer water, is too well known to require any further remarks from me.

In conclusion, I wish to express my obligation to those firms who have so liberally supplied the information which has been sought for. As manufacturers of waters, I would especially mention Messrs. Hooper and Co., Mr. James Packham, Messrs. Barrett and Elers, and Messrs. Pitt and Co. As manufacturers of machinery I am particularly indebted to Messrs. Hayward Tyler and Co., and to Messrs. Barnett and Foster, Messrs. Dows, Clark, and Co., Mr. Davenport, and Mr. H. Favarger.

Mr. Favarger had promised to send for exhibition the well known and ingenious system known as Mondollet's system, but in a letter which I received from him, a week or so ago, he expressed his regret that, through having to leave England for some time, he would be unable to exhibit his machine.

I am perfectly conscious of many omissions in reference to several other useful appliances. I have endeavoured in this paper to intoodnce technical details, only where improvements have been made, and to generalise the information so as to represent the progress which has been made in appliances and processes, in order to keep pace with this rapidly increasing and very important branch of industry.

[Messrs. Hayward Tyler and Co., and Messrs. Barnett and Foster, have kindly lent the blocks which have been used to illustrate this paper.]

DISCUSSION.

The CHAIRMAN said this was quite a model paper, from the great care and conscientiousness with which it was constructed; and to all who, like himself, were interested in the cause of temperance, it must be singularly interesting, inasmuch as it showed that there was an important rivalry with those drinks which they regarded as injurious to mankind, and a strong movement in favour of those which they considered simple in their character, useful, and free from all danger. It occurred to him that the whole of the paper and the apparatus in the room showed that the quantity of aërated drinks consumed must be very large; he had no conception of the number of patents which had been mentioned in connection with these beverages, and the way in which they were preserved; and was altogether surprised at the extent of the business which was being done. The public ought to be grateful to those who were engaged in this manufacture, not only for their skill, but for the attention which they paid to the purity of the water they used. He recollected quite well having tasted some bottled water, which was strongly impregnated with paraffin, and being quite unable to account for it, since he was sure it could not have been introduced intentionally. They had now heard that it might have been introduced by the chalk from which the carbonic acid was produced having come in contact with the vapour of paraffin in the shop, a very shrewd observation, which did Mr. Warren great credit. He was also pleased to find that care was being used with regard to the sulphuric acid, for physicians knew long ago that this was a common source of impurity in these waters. With regard to mineral waters proper, no doubt they could be made in this country in great perfection, and it would be quite unnecessary to import the foreign mineral waters. All that was required could be attained by artificial means, and the more so as doctors were now coming to the view that perhaps these foreign mineral waters were not of so much benefit as the journey which the patient had to take in order to get them. Perhaps they had heard of the famous letter which Dr. Arbuthnot wrote to Dean Swift when he was talking of going abroad to take the waters. He advised Swift to take the Geronster waters, because they could not be carried; by which he no doubt meant to convey that the journey to the waters which would do the Dean more good than what he drank. There were, however, some mineral waters which were considered very good, and to be of real service, and they might be manufactured in this country. It would be a great boon to members of his profession if they could feel that there was a firm of thoroughly scientific mineral water manufacturers to whom they could look for what was correct chemically in those mineral waters which they considered serviceable. It was very usual now to prescribe mineral water to be taken at table, and thus to make medicine an article of diet rather than to give drugs in a less pleasant form. Mr. Warren had refrained from going into the history of the subject, but it would be very interesting if he had done so; it dated, however, further back than the time he had named; for they were indebted for aërated waters to the illustrious discoverer of oxygen, Dr. Priestley. Priestley first manufactured waters with gas under pressure, and the possibility of doing so was first publicly demonstrated by him before a meeting of the College of Physicians in London. At the time, it was thought that the discovery would have very important results in the cure of disease; and what was called the antiphlogistic treatment—giving effervescing drinks in fevers, sprang from that demonstration of Dr. Priestley's. The administration of effervescing medicines in the sick room had now almost passed away, as it was found much more convenient to give them in the form of drink. He was sure all men of science who were present would join with him in thanking Mr. Warren for his valuable and interesting paper.

Mr. Maignen said Mr. Warren had referred to the mistake people made with regard to filters, in not taking care to cleanse them, and one particular filter had been selected for praise. He hoped he might be allowed to say that his invention, the *filtre rapide*, which obtained the gold medal at the Fisheries Exhibition, was in use in several soda-water manufactories. One difficulty with regard to sweetened and flavoured water, was that the syrups were not always bright, and he had devised a filter for the especial purpose of removing this difficulty.

Mr. William Botly said it was very fortunate they had Dr. Richardson in the chair on this occasion, as he was an authority on the subject. Very few of the aërated waters now made seemed to possess the delicate flavour which he remembered when simpler materials were used. He agreed with the Chairman that it was very desirable that the manufacture should be carried out on thoroughly scientific principles, and also with what he said about the beneficial effects of travel. He thought it very likely that in the case of Bath, Cheltenham, Harrogate, Tunbridge Wells, and other places, artificially prepared waters would not have the same effect as the natural springs, because the patient would not have the benefit of the change of scene, society, and travel.

Mr. Lloyd (of Messrs. Hayward Tyler and Co.) said it might be interesting to give some figures showing the enormous increase in the aërated water trade. In 1815, his firm made the first machine, which would produce about 150 dozen per day of ten hours. At the present time, or last year, say, the aggregate machines sold would produce three million bottles of soda water per day; and the large machines now made, instead of producing 150 dozen per day, would produce 3,000 dozen. He knew one firm which turned out 17,000 dozen per day. One remark of Mr. Warren's might perhaps be misunderstood, when he said that the Macdonnel machine was cumbersome, and only suited for a large manufactory. The largest machines might be so described, but machines were made suitable for the smallest manufactory, and the user of these small machines would find that water bottled by it would contain a greater pressure in proportion to the pressure in his cylinder than that bottled by hand; it would be all of uniform quality, and the corks would be all driven to the same level.

Mr. Bush thought it was a pity that Mr. Warren had not given some sketch of the history of this trade; and mentioned one or two facts, showing the enormous increase which had taken place. Since the Great Exhibition of 1851, great improvements had been made in the machinery employed, and also in the introduction of essences which made the drinks more palatable, and gave a greater variety than when there was nothing but soda-water and lemonade. In 1851, his firm first got the idea of introducing these essences, and he contended they had conferred a great boon on the temperance body in giving them some hing more palatable than tea, coffee, or soda-water.

Mr. Forster said the great object to be aimed at was purity in the product, and that could only be attained by perfection in the machinery. The true test of perfection was the amount of carbonic acid they could get the water to take up. Several means had been devised for this purpose. Some used distilled water, and others boiled the water, whilst others again filtered it; and he might say that so much was the trade developed that there was as much competition amongst the makers of apparatus as amongst the manufacturers of aërated waters themselves. His firm had a machine for extracting the air from water, thus allowing more room for the carbonic acid, and they watched most narrowly every way by which metallic contamination was possible, and endeavoured to avoid it. For this purpose they had done away with the mechanical agitator, and introduced the perforated pipe. The gas and water were not forced through the perforations, which would mean work and friction, but it was raised to a sufficient height, and then falling by gravitation was broken up into spray, thus effecting the necessary admixture. His screw-necked stopper was not developed for the purpose of aërated waters, though it was applicable to them, but for malt liquors, but he might inform the Chairman that by his process for removing the air he could produce a malt liquor without alcohol, but still retaining its beneficial properties. He found that when the atmospheric air was removed from malt liquor, the alcohol, being mixed with air, came away with it to a great extent, and the beer was rendered non-intoxicating. Having done that, he charged it with carbonic acid, which made the beer fit for immediate consumption, and prevented after fermentation. The reader of the paper had perhaps hardly done justice to the revolution in the trade caused by the patent stoppers, and also by the introduction of "splits," which enabled manufacfacturers to work all the year round, whereas formerly they were almost stopped in the winter. He could only hope that publicans would see it to their interest to reduce the price which they charged to the public. He did not suppose there was any trade so heavily handicapped as the aërated water trade; manufacturers only got a fair living profit, but the publicans, hotel keepers, and chemists who retailed the waters made 400 or 500 per cent.; 1s. 3d. per dozen was considered a fair price for the maker to charge the publican, but the seller put a price of 4d. or 6d. a bottle upon it; and while that was the case, there was no wonder that the respectable working man preferred a glass of beer, or a "split," with a dash of bitter in it. If the retail prices were reduced, it would do more than anything else to assist the temperance movement, and at the same time both aërated water makers and machinists would benefit by it.

Mr. H. Trueman Wood, the Secretary, read a letter received from Messrs. Pitt, of 28, Wharf-road, City-road, saying that on Tuesday, Wednesday, and Friday, in next week, between the hours 3 and 4 p.m., they would be happy to show any member of the Society, or any one interested in the subject (not connected with the trade) over their factory. (The factory is about five minutes' walk from the Agricultural-hall.) He also wished to draw the attention of aërated water machinery manufacturers to the Exhibition to be held next year, at South Kensington, of matters connected with Health, Food, and Drink. There would be a special section for aërated waters, and it struck him that it would be very desirable for some of the large makers of machinery to make early application, and set up a complete plant there, so that the public might have an opportunity of seeing the process and trying the results.

The Chairman then formally moved a vote of thanks to Mr. Warren, which was carried unanimously, and the proceedings concluded by a general examination of the machinery exhibited, and the sampling of the various beverages.

CATALOGUE OF THE EXHIBITION OF COOKING APPARATUS AND APPLIANCES.

1. Anglo-American Tin-stamping Company, Stourport.
   Enamelled iron ware, plain and printed in colours.

2. Billing & Co, Smart's - buildings, W.C. :—
   "Sun Dial" gas cooking stoves, with movable copper reflector for use as a combined heating and cooking stove.
   Cooking utensils for use with stove.

3. Brown & Green, Limited, 69-71, Finsbury-pavement, E.C :—
   Patent smoke-consuming kitchener, with self-acting damper, and an arrangement for supplying fuel at the bottom of the fire.
   "Gem" portable cooking stove.
   Patent smoke.consuming cottage kitchener.
   Special cooking utensils for kitcheners.

4. W. S. Burton, 88, Oxford-street, W :—
   Oven for roasting fish, as recommended by Sir Henry Thompson.
   Egg cooker, hot-water cooking pan.
   Fish saucepans and strainers, &c.

5. Charles Churchill & Company, 21, Cross-street, Finsbury, E.C. : —
   American cake mixer.
   Combined sausage stuffer, fruit and jelly press.
   "Enterprise" and "Gem" cherry-stoners.
   American ice chisel.
   "Eureka" and "Triumph" egg-beaters.
   Improved potato parer.

"Gold Medal" and "Lightning" apple parers.
"Climax" apple corer and slicer.
Smith's patent nutmeg grater.
Houchin's patent revolving grater.
"Enterprise" meat chopper.
Various forms of lemon squeezers, &c.

6. T. and C. CLARK & COMPANY, Shakespeare Foundry, Wolverhampton :—

Cooking utensils of various kinds, tinned inside, or lined with patent non-poisonous enamel.
Patent enamelled wrought iron ware.
Patent "Digester" cooking pot, with valve in the lid for the escape of steam.

7. T. J. CONSTANTINE, 61, Fleet-street, E.C. :—

Patent "Treasure" cooking range.
Patent "Treasure" cooking pots.

8. H. & C. DAVIS & COMPANY, 200, Camberwell-road, S.E. :—

"Combination" metropolitan family gas kitchener, fitted with boiler for self-supply, and adapted for heating with either coals or asbestos fire.
Metropolitan gas kitchener.

9. DEAN & COMPANY, 46, King William-street, E.C. :—

Fletcher's patent asbestos stove for heating or roasting.
Fletcher's patent gas cooking range, with reversible burners for grilling.
Fletcher's patent gas oven.
Fletcher's patent gas attachment for fire ovens.
Fletcher's patent quick grill.
Fletcher's patent quick coffee roaster.
Fletcher's patent ventilated hot-air oven, with radial burners.
Newport's patent "Gem" mixer or egg beater.
Dolby's beef tea extractor.
Captain Warren's cooking pot.
Parisian potato masher.
Brawn press, &c.

10. GENERAL GAS-HEATING & LIGHTING APPARATUS COMPANY, 74, Strand, W.C. :—

Leoni's "Nonpareil" gas kitcheners, coated by an inoxidation process, to prevent rust.
Patent incandescent radiant gas fire, for heating or cooking purposes.

11. GRIFFITHS & BROWETT, Bradford-street, Birmingham. :—

Loysel's patent hydrostatic urn, for the table.
Bevan and Fleming's patent thermoterion or nursery heat retainer, for keeping milk, &c., warm.
Carey's patent "Hecla" coffee pot.
Steam egg boiler, for table use.
Dolby's beef-tea extractor.
Muller's patent domestic coffee roaster.

12. GROOM & COMPANY, Liquorpond-street, E.C. :—

Registered milk saucepan.
Bower's patent potato steamer, and fish or poultry steamer.

13. G. KENT, 199, High Holborn, W.C. :—

Kent's patent cooking appliances.
Patent cabinet ice safe.
No. 3 filter.
Beef-tea cooker.
Universal press.
Thermoterion.
Masticator.
No. 2 mincer, with R. Hopper's egg beater and bowl.
No. 2 whisk.
Miniature ice preserver.
Miniature ice maker.
Four-quart salt extractor.
Lemon squeezer.
Apple parer.
Lemon parer.
Potato parer.
Coffee roaster
Coffee-mill.
Wheat-mill.
Cocoa-mill.
Milk saver.
No. 06 minute churn.
No. 1 soup strainer.
Jelly strainer.
Marble bread cutter.
Pudding mixer.
No. 1 potato masher.
Marmalade cutter.
Bean cutter.
Horizontal freezer (2 quarts).
Patent rotary knife cleaner.

14. J. F. LOVELOCK, Broadway Works, George-street, Hackney, E. :—

Improved coffee-mill.

Improved sausage-making and general mincing machine.

15. NEWTON, CHAMBERS & COMPANY, Thorncliffe Ironworks, near Sheffield :—

Improved "Thorncliffe" patent close and open fire cooking range.
The "Economist" patent portable open and close fire range.

16. NYE & COMPANY, 143, Oxford-street, W :—

Improved press for brawn, tongue, &c.
Improved bread-making machine for household use.
Grating-mill for bread crumbs, &c.
Bread-slicing machine.
Egg-beating and mixing machine.
Patent domestic wheat-mill.
Vegetable-slicing machine.
Patent mill for grinding cocoa nibs, &c.
Patent small mincer or masticator.
Patent coffee-mill, sausage machine, &c.

17. PAUL PFLEIDERER, 37, Farringdon-street, E.C.:—

Patent "Universal" kneading and mixing machine.
Vermicelli and macaroni press for household use.

18. PISTON FREEZING MACHINE & ICE COMPANY, 314, Oxford-street, W.:—

"Self-Feeding" Cabinet Refrigerator or Ice Safe, for use with block or rough ice.
Ash's kaffee-kanne, or table urn for making coffee.
Patent Norwegian self-acting cooking apparatus, or travellers' kitchen.
Ash's patent "Piston" freezing machine.

19. H. RIOTTE, 14½, Swallow-street, W. :—

Lager beer cabinet and cooler, with aërating pump.

20. SELIG, SONNENTHAL & COMPANY, 85, Queen Victoria-street, E.C. :—

Patent "Victoria" mincing machine.
Patent chopping machine.

21. SIDDAWAY & SONS, West Bromwich: —

"The Paragon" gas cooking stove, double-cased and lined with non-conductor.

22. SILBER LIGHT COMPANY, 47, Lower Whitecross-street, E.C. :—

Silber's patent "Miratus" petroleum cooking stove, with fittings.

23. SPONG & COMPANY, 226, High Holborn, W.C :—

Mincing and slicing machines.
Apple corer and cutting machine.
Grinding mills.
Bread and cake slicing machine.
"Lightning" egg cutter.
Lemon squeezer, toasting fork, &c.

24. A. TOZER, 53, Rupert-street, Haymarket, S.W :—

Universal "Muller," lined with earthenware, for keeping tea and coffee pure and free from any metallic flavour.

25. WOODCOCK & HARDY, Eldon-place, Sheffield :—

Tea pot and tea urn fitted with registered strainers

26. JOHN WRIGHT & COMPANY, 155A, Upper Thames-street, E.C. :—

The "Eureka" and other gas cooking stoves.
Improved steamer cooking pot.

Miscellaneous.

TURIN EXHIBITION, 1884.

The preparations for the National Industrial Exhibition, to be held in Turin next spring, are proceeding fast. A large number of intending exhibitors have sent in applications, and it is anticipated that the show will prove how great has been the national progress since the first Italian Exhibition held in Florence in 1861. As might have been expected, there are many exhibitors of furniture, some of them extensive producers.

After the lapse of 22 years, a remarkable development it is expected will be observed, not only in the chemical, and textile, and other manufactures, but in the mechanical and engineering industries, then in their infancy, but which have since increased beyond all recognition. Machinery of various kinds is said to be rapidly approaching in excellence that of Northern Europe; railway carriages and plant will assume an important position; telegraphy and electrical apparatus of various kinds will be likewise conspicuous. Food products will be largely represented, one-third of the

1,900 exhibits being devoted to wine. Next in order will be oil, butter and cheese, but apparently the produce of the soil has attracted comparatively few exhibitors; and under the heads of horses, cattle, and poultry, the numbers amount only to about 55. The hope has been expressed that Italy will improve the natural advantages of climate she possesses in so high a degree by paying more attention to her agricultural interests, and reforming the very absolute institution of the *Mezzadria*, which regulates the relation between the owner of the soil and the actual cultivator, so as to render it possible for the scientific farmer to control and direct the latter; for large farms, it is argued, must in our times be far preferable and more profitable than the infinitesimal subdivision of property in the hands of uneducated country people.

The most novel, and one of the most attractive features of the Exhibition will, it is said, be the Mediæval Piedmontese castle, erected on the banks of the Po, in the splendid grounds, which embrace a panorama of some 200 miles of the most glorious Alpine scenery, from the Monte Rosa to the confines of the ancient territory of Nice. In this castle and its precincts everything will be in keeping with the feudal times—the furniture, the costumes and the arms. All around are grouped the huts and humble cottages of the serfs, constituting a village of the fourteenth century, each dwelling fitted up so as to be inhabitable. The hostelry, the various artisans' and peasants' dwellings will be recognised, nor will the inhabitants themselves be wanting to give life and reality to a fairy scene, which is intended to show the manners and customs of by-gone days. Another portion of the Exhibition which is expected to be a success, is that of educational books and appliances, in which 565 exhibitors are already inscribed; scientific and literary productions have attracted other 138 exhibitors; while provident institutions and appliances, with all which is connected with public health, comfort, and security, embrace some 700 more exhibitors. When the kingdom of Italy first came into existence, excepting in the north the lower classes were uninstructed, and the rural population never dreamt of schools, and only one-third of the inhabitants were able to read.

RICE-PLANTING IN THE STRAITS SETTLEMENTS.

Consul Studer, of Singapore, says that the chief agricultural implement used by planters in the Straits Settlements is the hoe, termed in the Malay language "chankoli," and the system of planting by Europeans and natives is a very primitive one, namely, a number of coolies furnished with as many hoes. The hoes are all of the same shape, about six inches wide and eight or nine inches in length, and are nearly all made by Chinese blacksmiths, and purchased at the rate of about one shilling each. With these common hoes, the coolies do all the planting, dig ditches, make excavations, and fill the baskets that serve in lieu of wheelbarrows for removing earth, *débris*, or stones. They carry two baskets at a time, suspended from either end of a pliable stick or bar, carried across their shoulders. An effort has been made to induce the coolies to use wheelbarrows, but hitherto without success. For the removal, however, of objects too heavy for one or two men to carry any great distance, they use two-wheeled hand carts, which are large unwieldy vehicles, and on which they pull and push very heavy loads. The rice-planting natives, when planting lowland rice, have an article resembling a plough, made of very hard wood, and drawn by buffaloes. It consists of a beam, into which a sharpened broad stick of wood is inserted, the beam having simple arrangements at either end for guiding and drawing the implement. With this, after the rice field is covered and watered, they stir and loosen the mud, then women come with bundles of rice settings, grown in seed-beds near their houses, and, armed with a sharp stick, plant a few settings to a hill, the hills being about one foot apart each way. When the crop is ripe, they do not use scythes, but with a very small sickle they cut it about two-thirds the length of the stalk up from the ground, and carry it to a shed under cover. The Chinese and Siamese, instead of threshing it, tread it with buffaloes on hard clay ground. This process separates the unhulled rice, called "paddy," from the stacks. To remove the hulls from the rice, and polish the kernels, the paddy is taken to mills or hand-machines, the latter being clumsy, hard to work, and very primitive in their construction. The Malays, not having buffaloes, separate the paddy from the stalks by hand, and, as a rule, they plant no more than they need for their own use. For the cultivation of upland rice the natives use the common hoe, breaking the soil as deeply as possible, and they transplant their settings when the rainy season commences. This species of rice is not so yielding, the kernels being smaller than is found in marsh paddy. The hill rice is of excellent quality, but only sufficient for home consumption is planted. Consul Studer says, that there appears to be a rooted objection on the part of the planters to use ploughs, as they incline to the belief that it would be impossible to break up with them land which was covered with stumps and lubricate masses of large and small roots, and that they would be useless in "lallang fields," "lallang," in Malay, meaning a species of long and very tough grass, growing very thickly and luxuriantly, used chiefly for thatching roofs. Tracts of "lallang" are met with in many provinces, and each tract indicates an abandoned rice field, or a gambier or pepper plantation. Soon after cultivated land has been abandoned, "lalling" grass, especially on heavy clay soil, will spring up, and so thickly that seeds blown from trees in the jungle, or carried by birds, wil find no chance to take root.

Correspondence.

INTERNATIONAL FISHERIES EXHIBITION.

I beg leave to make a few remarks upon Mr. Trendell's admirable paper anent the "Teachings of the Fisheries Exhibition," contained in the last issue of the *Journal*. With respect to his proposed exhaustive biological survey of our territorial waters, much all but voluntary assistance might be obtained from the fishermen independently, who, for a very small consideration, would willingly save and deliver, or forward to some district station, samples, with a note as to local habitat, of the innumerable marine organisms gathered in their daily dredging and trawling operations, and which they have hitherto been accustomed to throw overboard as rubbish. Before, however, we can look to the fishermen for mportant aid in this direction, it is requisite that they should, to a certain extent, be educated in the rudiments of marine zoology. Now, the readiest means of imparting to this industrious, but relatively uneducated class, the necessary amount of zoological knowledge, is undoubtedly through the sense of sight. In this connection, I would suggest that, under Government auspices, a series of charts should be prepared for distribution among the fishermen, illustrative of every class of marine animals, and in which should be included a characteristic, though rough figure, of every known British representative of its respective class, be it fish, mollusk, worm, or crustacean.

Printed matter might be added to these charts, indicating those species of animals about which we chiefly require accurate information, concerning their distribution, spawning seasons, and other habits. Brief instructions might likewise be added as to the method in which the various species should be preserved. Fitting rewards might furthermore be offered as an encouragement to those fishermen who, in the course of the year, shall have contributed the most important collections or information to the central depôt. Through the enlistment of aid of this description from the fishing community, the Government of the United States, as Mr. Trendell has already told us, have derived much of their most important material and information concerning the habits and distribution of their own ocean fauna. The coastguard might also be advantageously ememployed as receivers and storers in the practical working of this biological survey.

The investigation of the life-histories and possible means of artificially propagating certain of the more important of our marine food fishes, is another important object of research. Already in this direction a most valuable initial experiment has been carried out during the past autumn, at the instance of the Fishery Board for Scotland, with relation to the herring. The attempts then made for the first time, to artifically fecundate and develop the eggs of the fish, were attended with the most signal success, insomuch so that the committee engaged in these experiments arrived at the opinion that the artificial hatching and turning into the sea, at a single station, of many millions of herring-fry, would be a perfectly easy task, and might, moreover, be accomplished, reckoning from the time of fecundation of the eggs until they were hatched, within so short a space as a single fortnight. As a matter of fact, the number of eggs produced by a single herring varies from 30,000 to 50,000, and these eggs are so minute that 20,000 may be deposited in a single layer upon a sheet of glass having an area of but one square foot. Whether the artificial propagation of herrings, mackerel, pilchards, and other pelagic or migratory fish, would be of practical use beyond supplying abundance of bait for attracting shorewards shoals of larger fish, is at the present moment an open question, but in the case of other sedentary or non-migratory species, which are undoubtedly becoming scarce on our own shores through over-fishing, too much importance cannot be attached to the success that has been achieved in the case of the herring. In the opinion of the committee just referred to, soles, turbot, and other valuable fish might be artificially propagated under similar conditions, and our waters restocked with their fry, if we only knew more concerning their habits; a recommendation is made by the Board for further means wherewith to carry on the work of investigations in this most desirable direction. A *sine qua non* of success in these propagating operations is the possession, close at hand, of a marine laboratory or hatchery, wherein the eggs after fecundation may be successfully developed. Fortunately one such building, belonging to the Edinburgh University, was placed temporarily at the disposal of the Scottish Fishery Board, in connection with their experiments upon the herring. If, however, these propagating operations are to be carried out on a sufficiently extensive scale as to be of practical good, it will be found desirable to establish hatching stations on every available point of our coast line. Such hatcheries, having tanks suited for the reception and development of the eggs, might be constructed at small cost, and so arranged that the water might circulate through them with the rise and fall of the tide, thus obviating the expense of machinery. Fitting custodians of these hatcheries might here again be enlisted from among the ranks of the coastguard; members of which, moreover, might be instructed in the simply mechanical process of manipulating and fecundating the eggs of the fish brought in by the fishermen.

The question of these hatcheries necessarily leads to that of zoological stations or marine observatories, for the more purely scientific investigation of marine organisms. Where these stations are to be set up, is a matter that awaits determination. The coasts of Devonshire or Cornwall, or the Channel Islands, with its from 40 to 50 feet alternations in the rise and fall of the tide, exposing at low ebb literally miles of rock-pools replete with every form of marine life, might be severally named in connection with the southern district. In Wales, the neighbourhood of Bangor, adjacent to the exceedingly rich fauna of the Menai Straits, might invite the authorities of the newly-founded North Wales University to co-operate in the establishment of a station in the above-named township subject to their control. An observatory, however small, might doubtless be found of immense importance in connection with the migration of our food fishes, and for the observation of deep-water forms, if established in that most northerly point of our jurisdiction, the Shetland Islands.

It might be suggested that the proprietors of the various aquaria about the country, greatly to their own advantage and to that of the nation, might be invited to lease or loan their tanks to the Government, or to a responsible society, for the purpose of scientifically cultivating and studying the habits of fish, and all other aquatic animals, and for conducting experiments in the direction of this artificial propagation. If to the custody of such tanks, space for fitting up an efficient laboratory was likewise conceded, the problem concerning the establishment of our zoological stations would be solved at a very little cost. The fine aquarium at Brighton, within an hour's journey from London, would be eminently suited for such a station, while those of Great Yarmouth and Scarborough might become most valuable observatories for the eastern coast line.

Valuable scientific observations respecting the habits and life-histories of marine oganisms need not, however, be exclusively conducted at zoological stations, nor even at the seaside. The following facts, among many others, that have fallen within my observation among my several years' connection as naturalist with certain of the larger public aquaria of this country, some situated at the seaside and some inland, may be cited in demonstration of the great utility in the fisheries interest to which, under intelligent control, these institutions might be made subservient. Thus, various species of the smaller oviparous and viviparous sharks and rays, have been bred at the aquaria of Brighton, Manchester, and Southport; providing the material for the recent very important monograph, by Professor Parker, on the embryology of these fishes. The remarkable developmental phases of certain flat fishes, *pleuronectidæ*, have likewise been supplied for scientific investigation from examples cultivated at the Southport Aquarium. Herring spawn has been hatched out at the Brighton Aquarium, while herring in that more advanced condition of growth known as whitebait, was successfully conveyed by myself to the Manchester Aquarium in the year 1875, and cultivated to the adult state; these hitherto supposed distinct species of fish being then, for the first time, practically demonstrated to be identical. At the same inland aquarium I also succeeded in rearing lobsters from the egg, through their numerous metamorphoses, to the ambulatory form of the adult. The success attained in this direction convinced me that, conducted upon an extended scale, the artificial culture of lobsters might be developed into a highly profitable industry. This subject was referred to, for the first time, in a paper upon the construction, management, and utility of aquaria, I had the honour of reading before the Society of Arts in March, 1876. The further details of these experiments, embodied by me in one of the Conference papers of the recent International Fisheries Exhibition, has already brought forth fruit to the extent that arrangements are now being made for initiating the artificial culture of lobsters, as a commercial undertaking, next season on the coast of Ireland. Through the conduct of similar operations on all suitable portions of our coasts, there is no doubt that our well-nigh exhausted inshore lobster fisheries might, in the course of a few years, be completely recuscitated.

Many kindred facts might be recorded, but enough has been said to illustrate the direction in which our public aquaria, even as they now exist, might be utilised for the advancement of marine biological knowledge. More especially, however, I would wish to emphasise, in this communication, the very important and valuable assistance to State-aided research in the department of pisciculture that has been afforded by the Executive Committee of the International Fisheries Exhibition through their generously placing at the disposal o the Government the series of tanks and fittings belonging to the Exhibition aquarium, wherein kindred experiments may be conducted, and in connection with which will doubtless be hereafter associated some of the most important "teachings" of the bygone eminently successful Fisheries Exhibition.

W. Saville Kent.

SOUR BEER.

From "Hampshire Brewer's" remarks on my last letter on this subject, I gather that, not even in the early part of his career did he pursue the plan of treating sour beer as suggested by me a fortnight ago; and, as regards the neutralisation of acidity by addition of whiting, I quite endorse his opinion that such a course would lead to unpalatability of the beer treated, and a consequent loss of trade. In answer to his query:—Would sour beer, after destruction of the acid ferment and removal of suspended matters, be of more value than water? I beg to state that a comparison between the two is quite out of the question; for the beer treated in this manner would possess a gravity only a very little lower than when it was sent out fresh from the brewery. Moreover, most of its constituents would be practically unaltered both as to quantity and quality.

"Hampshire Brewer's" arguments have failed to convince me that returns should be used for purposes other than blending; for, firstly, the value of such returns in any industry outside brewing would bear no comparison to their worth; secondly, he has not gone beyond the application of whiting in treating his beer before blending, such neutralisation by alkaline substances not having formed a part of the manipulation suggested.

EDWARD R. MORITZ.

72, Chancery-lane, W.C.,
December 4th, 1883.

General Note.

THE LATE SIR WILLIAM SIEMENS.—Mr. Meyerstein, a member of the Society, has undertaken to prepare a steel plate engraving from a portrait of the late Sir William Siemens. The engraving will be printed in 4to. Imperial size ($10\frac{1}{2} \times 14\frac{1}{2}$ inches). As soon as the plate is finished, proofs will be placed on view in the Society's library, but members and others desiring to procure copies must communicate with Mr. Meyerstein direct, at the offices of the Universal Printing Company, 280, High Holborn.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

The following arrangements for the Wednesday evenings before Christmas have been made:—

DEC. 12.—"The Preparation and Use of Rheea Fibre." By Dr. FORBES WATSON. Major-General HYDE, R.E., will preside.

DEC. 19.—"Canada and its Products." By the MOST HON. THE MARQUIS OF LORNE, K.T., late Governor-General of Canada. Sir ALEXANDER GALT, G.C.M.G., will preside.

CANTOR LECTURES.

The First Course will be on "The Scientific Basis of Cookery." By W. MATTIEU WILLIAMS, F.C.S.

LECTURE II. DEC. 10.—The Constituents of Flesh. The action of Heat on Albumen, Gelatine, Fibrin, &c. The Juices of Flesh and their nutritive value. Exosmosis and Endosmosis as operating in the Kitchen. Maceration. Caseine. The cookery of Cheese and its nutritive value. Milk, Butter, and "Bosch."

LECTURE III. DEC. 17.—The nutritive constituents of Vegetables. The changes effected by cookery on Vegetable Substances. Ensilage of Human Food. May the use of Flesh Food be superseded by the scientific preparation of selected Vegetables?

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 10...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. W. Mattieu Williams, "The Scientific Basis of Cookery." (Lecture II.)

Royal Geographical, University of London, Burlington-gardens, W., $8\frac{1}{2}$ p.m. Mr. W. W. McNair, "A Visit to Kafiristan."

Institute of Actuaries, The Quadrangle, King's College, W.C., 7 p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Sir William Wedderburn, "The Indian Ryot."

TUESDAY, DEC. 11...Civil Engineers, 25, Great George-street, Westminster, S.W., 8 p.m. Discussion on Mr. William Henry Preece's paper, "Electrical Conductors."

Medical and Chirurgical, 53, Berners-street, Oxford-street, W., $8\frac{1}{2}$ p.m.

Photographic, 5a, Pall-mall East, S.W., 8 p.m. Discussion on Mr. Jabez Hughes's paper, "Thirty Years of Photographic Progress."

Anthropological Inst., 4, St. Martin's-place, W.C., 8 p.m. 1. Mr. A. W. Howitt, "Some Australian Ceremonies of Initiation." 2. Dr. R. G. Latham, "The Use of the terms Celt and German."

Royal Colonial, Prince's Hall, Piccadilly, W., 8 p.m., The Right Hon. the Marquis of Lorne, "Our Relation with Canada, and Great Colonies."

WEDNESDAY, DEC. 12...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Dr. J. Forbes Watson "The Preparation and Use of Rheea Fibre."

Graphic, University College, W.C., 8 p.m.

Microscopical, King's College, W.C., 8 p.m. Dr. J. H. T. Flögel, "Sections of Diatoms."

Royal Literary Fund, 10, John-street, Adelphi, W.C., 3 p.m.

Central Chamber of Agriculture (at the HOUSE OF THE SOCIETY OF ARTS), 1 p.m. Annual Meeting.

THURSDAY, DEC. 13...Royal, Burlington-house, W., $4\frac{1}{2}$ p.m.

Antiquaries, Burlington-house, W., $8\frac{1}{2}$ p.m.

London Institution, Finsbury-circus, E.C., 7 p.m. Prof. G. W. Henslow, "The Glaciers of the Alps."

Telegraph - Engineers and Electricians. Annual General Meeting. J. E. H. Gordon, 1. "An Instrument for Measuring the Strength of a Magnetic Field." 2. "A Method of Calculating the Total Horse-power Expended in a Network of Conductors (such for instance as a system of street mains)."

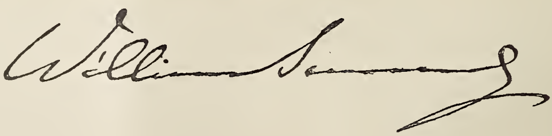
Philosophical Club, Willis's-rooms, St. James's, S.W., $6\frac{1}{2}$ p.m.

Mathematical, 22, Albemarle-street, W., 8 p.m. 1. Lord Rayleigh, "The Form of Standing Waves on the Surface of Running Water." 2. Mr. W. J. C. Sharpe, "A Method of Finding the Plane Sections of a Surface, and some Considerations as to its Extension to Space of more than Three Dimensions."

FRIDAY, DEC. 14...Astronomical, Burlington-house, W., 8 p.m.

Quekett Microscopical Club, University College, W.C., 8 p.m.

Clinical, 53, Berners-street, W., $8\frac{1}{2}$ p.m.



Journal of the Society of Arts.

No. 1,621. Vol. XXXII.

FRIDAY, DECEMBER 14, 1883.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

THE LATE SIR WILLIAM SIEMENS.

The portrait of the late Sir William Siemens, D.C.L., LL.D., F.R.S., Chairman of Council, which accompanies the present number of the *Journal*, is from a photograph taken by Mr. Van der Weyde, on the 12th June, 1882. The reproduction is the work of the American and Continental Engraving Company, Munich. Any member wishing for an uncreased copy of the portrait, for binding with the volume of the *Journal*, can have one on application to the Secretary.

CHAIRMAN OF COUNCIL.

On Monday last, 10th inst., the Council elected Sir Frederick Abel, C.B., F.R.S., as Chairman, in place of the late Sir William Siemens.

SHAW PRIZE.

The gold medal, or twenty pounds, offered under the terms of this prize for the best plan for obviating or diminishing risk to life in the operations of coal-mining, has been awarded by the Council to Mr. H. A. Fleuss for his apparatus, enabling persons to breathe in mines and other places filled with vitiated air or irrespirable gases.

The Council regret that they are not able to award the second Shaw prize, which was offered for the best plan of obviating or diminishing risk to life in the manufacture, storage, and transport of explosives, nothing having been submitted which, in the opinion of the judges, deserved a medal.

THE MARQUIS OF LORNE ON CANADA.

The attention of members is drawn to fact that the Ordinary Meeting, on Wednesday, 19th December, when the Marquis of Lorne, late Governor-General of Canada, will read a paper on "Canada and its Products," will be held at Exeter-hall, Strand (in the smaller hall).

As a large attendance is expected, the Council have found it necessary to restrict the members' privilege of admitting friends. Each member will be entitled to admit *one* friend only, either personally or by the usual ticket. Members will be admitted as usual on signing their names.

JUVENILE LECTURES.

The usual short course of lectures, adapted for a juvenile audience, will be given on Wednesday evenings, January 2nd and 9th, by J. Millar Thomson, F.R.S.E., F.C.S., on "Crystals and Crystallisation." The lectures will commence at seven o'clock. Nearly all the tickets having now been disposed of, the issue will be stopped on Monday next, December 17. As all the available accommodation will be required for those members who have applied for tickets, it will be understood that no member can be admitted without a ticket.

CANTOR LECTURES.

On Monday evening, the 10th inst., Mr. W. Mattieu Williams delivered the second lecture of his course on "The Scientific Basis of Cookery." The lecturer described the chief constituents of flesh, and explained the action of heat upon albumen, gelatine, fibrin, &c. He alluded specially to the important investigations of the Gelatine Commission of the French Academy, and pointed out the source of the fallacy which vitiated the conclusions they came to adverse to the nutritive value of gelatine. Further investigations had replaced gelatine in its former high position. It was not capable of sustaining life alone, but taken with other nutritive substances, it was of the greatest value. Mr. Williams then proceeded to treat of various processes of cooking, directing special attention to the frying of fish, and to the need of supplanting the ordinary frying pan, for this purpose, by a pan deep enough to hold sufficient fat to cover the fish completely. He explained the reason why fish fried in plenty of fat is less greasy than when a small amount only is used. In conclusion, he detailed the philosophy of browning, as obtained by cooking.

EXHIBITION OF COOKING APPLIANCES.

The Exhibition of gas and other stoves, and the various apparatus and appliances used for cooking purposes, in connection with Mr. Mattieu Williams's Cantor Lectures on "The Scientific Basis of Cookery," will be closed on Monday evening, December 17, after the conclusion of the third lecture.

Proceedings of the Society.

FOURTH ORDINARY MEETING.

Wednesday, December 10th, 1883, Major-General HENRY HYDE, R.E., in the chair.

The following candidates were proposed for election as members of the Society:—

Bennett, John William, Carisbrooke, Bromley-common, Kent.
Chaytor, Edward Clerevaux, Elstree School, Herts.
Coleman, Thomas Henry, Regent-street, Wrexham.
Ellis, George Henry, Knighton Hayes, Leicester.
Fielden, John Ashton, Cruton-vale, Todmorden.
Lovelock, James Frederick, Rokeby-house, Bishop's-road, Highgate.
Smith, William, Sundown-house, Clifton-down, Bristol.
Willis, William H., Ochhorn-house, Culverden-road, Balham.

The following candidates were balloted for and duly elected members of the Society:—

Anderson, Christopher, Hunslet Shed, Leeds.
Anderson, William, Lesney-house, Erith, Kent, and 3, Whitehall-place, S.W.
Andrews, John Joseph Frederick, 10, Cedar-terrace, Old Charlton.
Babb, Harry R., 21, Portland-square, Plymouth.
Banker, Stewart Melville, Avon-villa, Pellatt-grove, Wood-green, N.
Barber, Charles Albert, Bristol-house, Brighton, and 5, Furnival's-inn, E.C.
Barge, Samuel, Great Yarmouth.
Barker, John, Devonshire Villa, Grove-pk., Chiswick.
Barnett, Francis Thomas, Nyton-house, Chichester.
Barrow, Robert Philipson, 26, Old Broad-street, E.C.
Batchelor, Allan Edward, B.A., 73, Jermyn-st., S.W.
Beauchamp, Major Clayton Scudamore, R.E., 4, Mount-street, Berkeley-square, W.
Beeman, George Beaumont, 182, Earl's-court-road, S.W.
Blakey, James W., 46, Hyde-park-road, Leeds.
Bloomfield, John Caldwell, J.P., 7, Nightingale-terrace, Willesden, N.W.
Brady, Thomas F., 11, Percy-place, Dublin.
Brereton, William Henry, 52, Nevern-square, South Kensington, S.W.
Broadbent, Thomas Oliver, 14, Cross-street, Manchester.
Brough, William Spooner, 71, New Bond-street, W.
Burnard, Robert, Cattedown, Plymouth.
Cameron, Duncan Grant, Quilon, Travancore, Southern India.
Casella, C. F., The Lawns, Highgate, N.
Clifford, Henry Charles, 1, Lansdowne-place, Blackheath, S.E.
Colmer, Joseph G., 9, Victoria-chambers, S.W.
Cook, John Mason, Ludgate-circus, E.C.
Cory, Edward, 5, Church-rd., Castelnau, Barnes, S.W.
Cosser, Frederick Chas., 97, York-rd., Lambeth, S.E.
Craven, George Pople, 14, Roland-gardens, S.W., and City Carlton Club, St. Swithin's-lane, E.C.
Crockford, William, 2, St. Peter's-road, Mile-end, E.
Cross, Charles Frederick, Brentford.
Crossley, Atkinson, Moor-end-house, Adwalton, near Bradford.
Dabbs, W. M., 11, Amhurst-park, Stamford-hill, N.
Dampier, Henry Ludwell, Frindsbury, Rochester, Kent.
Davis, Joseph, 6, Kennington-park-road, S.E.
Dawson, Charles Royal, Westbury, Grange-park, Ealing, W.
Day, Charles Aubrey, 321, High Holborn, W.C.
Donkin, R. S., Camp-villa, North Shields.
Dowler, Frederick, jun., 25, Frederick-road, Aston, Birmingham.
Drinkwater, Thomas William, Ph.D., F.R.C.P., 41, Chambers-street, Edinburgh.
Duff, William Pirie, 2, Champion-park, Denmark-hill, S.E.
Duncan, William Aver, Redhill, Surrey.
Durrant, Frederick William, Holland-lodge, Addison-road, Kensington, W.
Elwell, Paul Bedford, Wolverhampton.
Eno, James Crossley, Wood-hall, Dulwich, S.E.
Ernst, Emil, 80, Charlotte-street, Fitzroy-square, W.
Eskholme, George, J.P., Brass Works, Rotherham, Yorks.
Ettlinger, Joseph, 30, Lawrence-lane, E.C.
Farmer, William Mortimer, 56, Stanhope gardens, S.W., & Maynard-ville, Cape Town, South Africa.
Finch-Hatton, Hon. M., Haverholme Priory, Sleaford, Lincolnshire, and 6, Prince's-gardens, S.W.
Fleming, James, 136, Glebe-street, Glasgow.
Fowler, Captain Francis Hayman, The Lodge, Brixton-oval, S.W., & 9, Serjeant's-inn, Fleet-st., E.C.
Fry, Samuel, Sherington-house, Kingston-on-Thames.

Galbraith, Robert, jun., 21, Notting-hill-square, W.
Gardiner, Charles Lawrence Weare, The Temple, Goring, Oxon.
Glover, Arthur, Galley Hill-house, Swanscombe.
Gray, James, The Shrubberies, near Whitby.
Greig, Henry A., The Eaves, Belvedere, Kent.
Hamilton, Marquis of, 2, Belgrave-square, S.W.
Hammersley, William Archibald Leslie, Bath-street, Leek, Staffordshire.
Harrison, Hugh Erat, 2, Red Lion-square, W.C.
Hartmann, William, 18, Billiter-street, E.C.
Hawker, Thomas H. Seymour, Birmingham and Warwickshire (Brush) Electric Light Company, 110, Cannon-street, E.C.
Hawkins, Miss J. E., 5, Walpole-street, S.W.
Henderson, Charles J., 6, Drumsheugh-gardens, Edinburgh.
Hill, George Charles Singleton, Bedminster Mill, Bristol.
Humphrey, James Charlton, 22, High-road, Knightsbridge, S.W.
Imray, Oliver, 4, Dane's-inn, Strand, W.C.
Jackson, John Evans, The Headlands, Carleton, near Horsforth, Yorks.
Jenkins, Thomas M., 5, Tavistock-street, Covent-garden, W.C.
Jetley, Victor, 8, North Audley-street, W.
Jeyes, Frederick Leslie, 32, Sussex-street, South Belgravia, S.W.
Johnson, Henry, jun., Dartmouth-terrace, West Bromwich.
Jones, Edward, 2, Westhill-terrace, Chapel Allerton, Leeds.
Jones, Walter William, Lambeth Savings Bank, Hercules-buildings, S.E.
Jupe, John, Lloyds', E.C.
Leon, John Temple, 26, Belsize-park-gardens, N.W.
Leverson, James, 72, Cornwall-gardens, S.W.
Lupton, Sydney, M.A., Harrow-on-the-Hill.
Macalister, James, 95, Bishopsgate-st., Within, E.C.
Macdermott, Martin, Scott's-chambers, 25, Pudding-lane, E.C.
Markham, Thomas Thornhill, 102, Fetter-lane, E.C.
Marsden, R., 117, Acomb-street, Manchester.
Maxim, Hiram Stevens, 47, Cannon-street, E.C., and 59, Liebertz-street, New York.
Meihé, John Rudolph, 15, Abchurch-lane, E.C.
Morison, Robert Joseph, Arundel-lodge, Cathnor-road, W.
Morison, W. C., 18, Cromwell-grove, Shepherd's-bush, W.
Morris, Richard, Doncaster.
Morton, Mrs., 10, The Grove, Highgate, N.
Neale, Captain Melville T., 1, Southwick-crescent, Hyde-park, W.
Nurthen, Frederick Richard, 390, Strand, W.C.
Oakley, Richard, 235, High Holborn, W.C.
Orton, Charles James, Ferry-house, Twickenham.
Pemberton, Colonel Robert Charles Boileau, R.E., Lucknow, East India.
Phillips, F. C., The Hammond Electric Light Company, 110, Cannon-street, E.C.

Wright, Edward Mounsteven, 91, St. James's-road, Brixton, S.W.
Younger, Robert, B.A., Brackenbury Hall, Magdalen-street, Oxford.

*** This list contains 138 names, and it may be interesting to members to know that it is the longest list of elections into the Society since the meeting of December 3, 1862, the year of the International Exhibition, when 218 members were elected.

The paper was on—

THE PREPARATION AND USE OF RHEEA FIBRE.

By Dr. Forbes Watson.

What is rheea? This is a specimen of rheea of one length. This is another specimen of rheea of a different length, and here is a specimen of rheea in the dry, semi-succulent state. When green and fresh, these specimens are of course different to what they appear now, and they have characteristics which I shall notice farther on. Unfortunately, I am not in a position, at this season of the year, to present you with more than this solitary green specimen, for the illustration of one or two points which I should like to lay before you before proceeding with my subject, which, instead of being in the form of a written paper, will consist of remarks which I shall endeavour to make as clear as I can. You will observe, on breaking this sample of green rheea, I succeed in getting off a certain quantity of green fibre, tearing it down in this manner. I wish to refer, in the first place, to the composition of the component parts of this bark. The outside portion consists of a film to which a very distinguished chemist has applied the term cutose. Below that there is a bark which contains the green colouring matter of the plant, that is called vasculose, and next to that comes the fibre itself. That fibre, and the bark attached to it, is united to the stem by another principle, which is called pectose. Now, the problem of getting the bark separated from the fibre constitutes the great difficulty which has hitherto impeded the use of this fibre. In China they succeed in removing the bark and otber matters, to a certain extent, by means of scraping. They scrape off the whole of the bark substance as far as possible, and they produce it in the condition of what is called China grass, of which this is a sample. You will observe from the appearance of the plant itself, that it has nothing of the character of a true grass, and belongs to the exogenous class of plants. Now, up to the present time, the whole of this fibre, as it has appeared in the market, has been prepared by hand. There has been a certain quantity prepared in the dry state by applications which I will afterwards refer to, but so far, in China, the whole of the China grass which has been introduced into the market has been prepared by hand, with the result that the cost of the fibre has never yet been reduced to an extent to make it pay, and you never can have the fibre at a less cost than from £49 to £50 per ton. It is this which has impeded the introduction of the rheea fibre and so-called "China grass," and their extended use in this country. During the last twenty or twenty-five years, many attempts have been made to manufacture this, and as far back as the year 1860, when I had the honour of reading a paper in this room upon the plants of India, I showed then a number of most interesting samples, sixty in number, which had been prepared in Bradford from this fibre. At that time, and subsequent to that, a large amount of capital had been expended upon the manufacture of the China grass, and the various fibres; and a great deal of money has been lost within my own knowledge. I should say I could add up £150,000 of capital which have been sunk in this fibre since that time, all arising from the difficulty of getting it sufficiently cheap. The moment you excited a demand for the fibre, the price rose; it has even gone up as high as £85 a ton; and this killed the trade. What we have to do to-night is to see whether there are any elements which would lead us to suppose that we can now get it cheaper—that is really the object of my story to-night. The Government of India has for a great number of years—going back to the days of the East India Company, which took a warm interest in this matter, I may say for the last eighty years, at least—devoted very considerable attention to the question of the introduction of this fibre. The East India Company directed attention to it by importing regularly, year by year, considerable quantities. About five tons, if I remember rightly, was annually sent to this market to afford an opportunity of trying it. It was considered, after a time, that we had a sufficient knowledge of the fibre and its properties to warrant the authorities in discontinuing the importation. However, in 1869, Lord Mayo, who took an active interest in all agricultural matters in India, offered a prize of £5,000 for a machine which would extract this fibre from the green rheea; and our Chairman superintended those experiments, which were afterwards carried out in 1870 with this object, and his report, I must say, is a model of what a report should be on such a subject. The result of these trials were negative, in the sense that only one machine presented itself for trial, and after examining the whole of the evidence about it, General (then Colonel) Hyde reported that it was not sufficiently good as regarded both the quality and the out-turn. It did not fulfil the conditions which the Government indicated should be fulfilled, and only a small prize, £1,500, was awarded to the machine. After that the matter was referred to the India-office, and various attempts were made, with which I had somewhat to do, to see what could be done in order to have a test of machines in this country; and at one time I was in hopes that we might obtain a sufficient quantity of green material to have a practical trial here on the spot, and that we should have at least one opportunity of testing the fibre in its green condition. Those hopes were not fulfilled. A certain gentleman kindly promised to let me have the whole of his crop of fibre, which he expected to cover something like twenty-five acres; but his imagination had been such that, on my sending to a district not far from Marseilles, and making arrangements with the railway companies to have the whole of the crop conveyed *grande vitesse*, there was only about two or three acres planted with rheea, and the crop was very inferior, not to say "scrubby," throughout; consequently, I only got 1½ tons instead of 25 tons; therefore, that attempt failed. A good many experiments were made to see whether it would be possible to extract the fibre from the stalks in their dry state, and these experiments showed that it was quite possible to prepare satisfactorily the fibre, which was worth about £15 a ton less than China grass, but was still sufficiently good to give hopes that, if you got the rheea dried, it might be a matter of consideration whether something might not be done. The Government of India, however, saw the difficulty of extracting the fibre from the dry stems; inasmuch as you cannot get them dried except during certain seasons in India; it would require artificial means to dry the stems properly, which would be much too expensive a plan. Hence the method of preparing the fibre from dry stems had to be given up, and the Government of India, after a certain time, resolved to re-offer this prize; and two or three years ago another competition took place, but with the same result as at the first one. No machine at this second competition was considered worthy of a prize on that occasion, and I believe that no portion of one was awarded. The samples which were sent for examination to this country were examined by my colleague, Mr. Collyer, and other brokers, and declared to be very far inferior from what it should be if it were to be comparable in quality with China grass. That represented the position of matters up to very recently. About two months ago, I was asked to go to Paris for the purpose of examining a process by which one could succeed in stripping the stems very readily, subjecting them to chemical treatment afterwards. I had a double object, in addition to finding out and seeing what could be done by this process—it was a *dernier ressort* if we could not get a machine to do the work, and said, "Let us get the next best thing;" and, accordingly, I went to Paris for the purpose of examining this process, and I will describe the results which I saw, which were very interesting. The method is a conjoint one, and is known as the "Favier-Fremy" process. It consists, in the first place, in facilitating the removal of the bark, with all its adherent fibre, by the action of steam. Immediately after it is cut, it is not difficult to remove the bark, and almost all the fibre attached to it, leaving a very little fibre behind. If the plant is allowed to lie a certain time after cutting, a few hours will make a great difference, the quantity of fibre left on is largely increased. I find it goes up in this way to nearly as much as 15 per cent. in stems which were several days old before they were peeled. When cut fresh, you get off, by the hand, nearly the whole of the fibre—it peels off—there is a little fine fibre remaining, but very little; this, however, must be done immediately the plant is gathered. The process of steaming—putting the stems into a box with a false bottom, and letting steam in below, so facilitates the separation of the bark, that you get everything, and this dark rough fibre is the result of the steaming upon some of the rheea stems, grown in

Hampshire, which I took from this country to Paris with me for experiment. I may mention that I found the rheea which I got here was very much longer and better grown in some respects than that which I got in Paris. That process facilitates the getting off of the bark, but having got this off, the question is what to do with it. Now, M. Fremy, the distinguished French chemist, and his able assistant, M. Urbain, made a number of experiments, with a view of determining the best way of getting rid of all this black bark—I will call it black bark; I am not using scientific language—and they came to the conclusion that it was necessary to employ a high-pressure boiler, in addition to a solution of caustic soda, for that purpose; and, in testing this process, I found the pressure was very considerable indeed, the temperature in the boiler, as I ascertained by experiment, being 295 degrees of Fahrenheit; and at the end of the operation, which extended over four hours' time, the fibre was taken out of the boiler, still in a black condition. But the theory was, that the high pressure had aided the caustic soda in dissolving the whole of the gums, including the bark, which is the difficult thing to get rid of. Now this bark and fibre, as removed from the boiler, was then placed in a solution of hydrochloric acid, and almost at the moment it touches the acid, that which looked a black, dark mass, speedily clears, and you see the beautiful fibre making its appearance. I felt that this settled the question of getting the fibre in a very nice condition. When I came to examine it more minutely, however, I found this alteration was one of appearance only; the bark to a large extent was simply in a changed condition, not dissolved by the alkali; it still remained there, and continued to do so throughout the greater portion of the subsequent operations. I can only now give you some of the general features of the case, but shall be happy to enter more minutely into the matter at any time at Mr. Collyer's office, No. 141, Fenchurch-street. I found that this process did produce a certain effect upon the material. This sample is a dried sample of the fibre as it leaves the Fremy boiler, and it contains a very considerable proportion of gum undissolved; it contains very nearly as much as China grass, which is prepared in the other way. It is true it is looser, and more easily dissolved out, but there it is. Here is a sample of fibre from the acid solution, which is the same as that which was afterwards in this state placed in a chlorine solution of some strength, and I find this loses a very considerable per-centage of its weight. However, the point I am coming to is this; after leaving Paris I made experiments to see whether it was necessary to have this high-pressure boiler at all. It is anything but a simple operation; when you come to operate upon many tons of material it is difficult to manage, and a high-pressure boiler always means expense. Thus came the question, was it necessary? and I was desirous to find out (whilst I was very pleased with the Favier portion of the process, as it got the fibre off the stems very readily), since no machine was available, whether a future, so to speak, might not be opened up by adopting this process. I was anxious to get rid of the high-pressure boiler, and my experiments—made in my own laboratory—show clearly enough that it is not necessary. I have here samples (I have them in a fresh condition) which are in a sticky-looking mass. They have been simply boiled in the Fremy solution, and I find all my barkh ere is just as readily removed as that from the boiler. It is, perhaps, a little more adherent together, but in after operations that can be got rid of as readily as possible. Therefore I had to come to the conclusion that the high-pressure boiler was not required—that we could get all these results without it—and that would be one great gain. That is a very important consideration. This represents the position, so far, of the matter when I returned from carrying out these experiments in Paris.

I now come to what happened next. Fortunately, I had asked the nobleman who, year after year in times past, had allowed me to have, for the use of my Department, all the rheea stems which grew in his garden, and he has been good enough to allow a certain proportion of the stems to be left standing for experiment on my return, and I had thus the materials for carrying out some experiments, the results of which will appear at the end of my paper. I had heard, when recently in India, of Messrs. Death and Ellwood's machine, the invention of Mr. H. C. Smith, as a very ingenious machine, which had been successfully used for extracting the fibre from leaves of the Agave plant, similar to those now before you. For instance, here is a specimen of the sort of leaf with which that machine would deal. Here is another kind, and here are several other leaves to which I shall have occasion to refer presently. I knew it had dealt with these successfully, but I had no idea that it would do for rheea. In fact, I had come to the conclusion (though I never put it in writing, by-the-bye) that we should never get a machine that would do for the rheea. I could not conceive of any machine which we could apply without crushing rollers in some way or other. I saw no difficulty in getting a machine which would extract the fibre, but the point was to get one which would do this, and leave it in a good condition as regards quality. When asked to test this machine, I did so very willingly, and my test was this: I had in stock at the time a considerable quantity of rheea stalks nearly five feet long, and some of very much shorter lengths. That is to say, I had rheea stalks as thick as my thumb, and nearly five feet long, and others smaller than my little finger. With these I tested the machine, and was surprised for the moment to find that the large and small sticks were operated upon with equal readiness. Here is an actual portion of the fibre prepared on that occasion, from these very stems. The secret of the success of this machine lies in this, that one-half of it is, so to speak, water. Now, I will explain what I mean by this, as it seems a somewhat out-of-the-way remark. Imagine this tumbler that I hold in my hand to be the cylinder of the machine, 18 inches in diameter. It is provided with what are called beaters, that is to say, a certain number of projecting ribs, and it revolves in front of a feeding table at a great rate. It is worked at 600 revolutions a minute. This operation goes on in front of the feeding table, as it is called, and this constitutes the whole machine, as regards the mechanical portion, with the exception of the water. Below, and at an angle of about 45°, a strong flattened jet of water passes, and I will tell you what the effect of that is. The cylinder, remember, is rapidly revolving; you feed in at the side here, the beaters catch and break up the sticks into very small pieces, and the jet of water, coming from below, meets the fibre, and keeps it up against the beaters, so that it is really beaten in a stream of water. The result of this is, you not only get the fibre cleared of a large portion of its gum, but you have next to no waste, and what little there is, is excellent for many purposes—it can be made use of, as most other waste products can. Thus is explained the secret of the success of the invention, and how it solves the problem of a machine for cleaning rheea.

I may mention, with regard to this rheea which I experimented upon, that it was three days old. In order to obtain the full success, the rheea cannot be too freshly cut. I should say that it ought to be operated upon within six hours, and that it should be kept in the shade until operated upon. I took some stems, which looked to me perfectly fresh, but when I broke them I found that the colouring matters and the gums had sunk into the fibre, which, if it had been quite fresh, you would have been able, after scraping, to blow through, but you could no longer do so, thus showing the necessity of having the stalks quite fresh to operate upon. I again made a series of experiments to try this machine in preparing other fibres, and I have here to-night a large number of specimens. For instance, there was one very interesting series of experiments which I made with the Moorva (*Sanseviera zeylanica*). This plant grows as a weed in Madras and other parts of India. In fact, it is such a nuisance that the people sometimes do not know what to do with it; but this machine tells us what to do with it. The sample which I hold in my hand was prepared upon the occasion to which I have alluded, Here is a sample which is prepared on the commercial scale in India by this machine, and, I may say, with regard to that particular fibre, that it has been proved that it will compete fairly with Manilla hemp, which occupies a very important place in this market. Here is a sample of cord made from it, and you can all see how beautiful and white it is. This cord is made by one of the principal makers in the kingdom, and his report is that it is 7·4 stronger than Manilla, and over 4 per cent. lighter. This machine has been the means, already, of bringing this new and important fibre to notice, and it operates upon the plant which produces it with great facility. Then I had some large aloe leaves, some of the leaves being as thick as my arm. Here is a specimen of New Zealand flax which was prepared by the machine. I am indebted to Mr. Christie for this sample, which, I believe, has come from Africa. The surprising thing is the ease with which the machine operates upon all sizes of leaves and stalks, taking them all, little and large indiscriminately, without any special adjustment or setting whatever; this fact, therefore, shows that the character of the action was a very simple and effective one. With regard to the question of setting, I may just mention that the beaters were adjusted at a quarter of an inch away from the table, so that it was clear the New Zealand flax which I have just shown you was not struck by them. All these stalks and the others received rapid blows from the beaters, but this could not have got any, because the leaf is not one-tenth of an inch thick; therefore, the total action arose from the beating of the water, the leaves being held up by the current, and the beaters coming round and round, worked the whole of the refuse out of it, and produced the fibre which I have shown you. In short, this machine is what I venture to call a universal fibre cleaner. It cleans every fibre, and it will extract the fibre from every plant into which nature has put one.

There is one other question, namely, will it extract the fibre from jute? I reason in this way. Jute is a plant very succulent in its nature, and something like China grass. The stem is about the same thickness, and in many other respects it is the same, so that I think the inference I draw is a fair one, and that this machine will clean jute, and thus be the means of introducing a superior class of this important fibre into the market. Jute is now prepared by a retting process. If done, as one gentleman whom I see here has prepared it, in a running stream, you get rid of the rotting or retting, and obtain the fibre in the best possible condition; but if it is prepared in a stagnant pool, with lumps of mud to keep it down, it becomes partially decomposed, and you will necessarily get weak fibre. Jute prepared by this machine—as I said before, is likely to supply a new class of jute, one taking a high place in the market. In the same way the machine will settle one or two other moot points. It will afford, I believe, the means of cleaning another fibre which has attracted a great deal of attention, namely, *mudar*, or *Calotropus gigantea*, which grows as a weed all over India. The juices of this plant are more difficult to deal with than even those of the rhea, being of a gutta-percha character; and if, as anticipated, it is found possible to clean it by this machine, it may be the means of introducing another new fibre to commerce.

Let us now look at the character of the machine. It is a very simple machine; I have described it to you, and there are photographs of it here, and arrangements can be made for those who are really practically interested in it, seeing the machine at work. It is easily worked. The power it requires is small; 1 horse-power being sufficient. Of course the question of the supply of water is an important one. Now, there are two ways of doing this, the first being from a height. In a hilly country you can have a tank some sixty feet up, which will give you the pressure required, which is only thirty pounds; or you may use the pump which is attached to each pair of machines to give the necessary pressure. The pump is specially adapted for working the machine, and is not liable to get out of order, not being a valve pump; and it will be found, I believe, to be admirably adapted for the purpose. The quantity of water required for working the machine amounts to about 400 gallons an hour. That is a good deal, perhaps, but you can use the same water three or four times over, if you let the refuse sink away from it, and draw it back by means of a hose, so that 1,000 gallons a day will represent the quantity of water necessary to work with. With regard to the question of water, there is this to be borne in mind—that it is very desirable that the water should be secured and turned to account for helping the plants to grow; that is to say, it should be used for irrigation, for it contains a great deal of the nutriment of the plants. We all know that if you wish to grow crop after crop of any plant, it is necessary to restore the constituents in the form of artificial manure, where in this case, if the water is put upon the land, the soil will repossess itself of what has been taken out of it. In the same way the broken up stalks should be collected, and used for manure or fuel. I may say this, that with regard to the question of the number of crops that you expect of China grass or rheea fibre, some people will tell you that there will be as many as four or five, and I have met enthusiasts who spoke of six or seven. No plant can be grown on the same soil, time after time, unless great care is taken to restore the elements to the soil which have been taken out, and that is the case particularly with regard to rheea. In China they manure and till the ground very carefully.

Now, one word more about the machine, with regard to the important question of out-turn. The experiments which have been made here are very interesting as regards the quality of the fibre, but they are no guide as to the quantity of out-turn, and, therefore, I have to depend for this upon the evidence which has been laid before me, and which has led me to the conclusion that a pair of machines will turn out from 140 to 250 pounds of clean fibre in a day, according to the assiduity and skill with which the machines are worked. If a man dawdles over his work, he will not turn out so much as the man who goes to work with a will. There are other elements which should be considered. The other day a complaint was received from a gentleman to the effect that the machine worked capitally, but he could only get forty pounds out of it in a day's working. The next mail brought a letter to say that he had been thinking of making a suggestion with regard to the working of the machine —namely, that they should take off the roots from the plants, because he found that the earth which was attached to them rather interfered with the working of the machine! This gentleman had been putting in roots and all, and then complained that the out-turn was not so good as might be expected.

Returning to rheea, what are its prospects *now?* I have indicated that, for the last 25 years, or more, the great search has been for some machine to clean it. That machine we have now got, or, at least, I believe so. I think the facts which I have mentioned point clearly in this direction. I started by pointing out that it was not possible to sell China grass in this country under £49 to £50 a ton, that is to say, the cost of preparing it by hand prevented its being sold at a cheaper rate. To clean one ton of China grass, it would take upwards of a thousand Chinamen one day, that is to say, each pair of hands can clean only from one to two pounds. In experiments which were carried out by Mr. Thompson and Mr. Mylne at Baheea, they found that only a few ounces could be cleaned by one person—nothing, in fact, at all approaching the two pounds which the Chinaman cleans, which is a considerable quantity, and the result of great practice. If, however, we get a machine which will do it, as I believe we now have, it will reduce the price very considerably.

With regard to the cost of working, I will mention to you what appears to me to be a fair estimate, after making every allowance, including the cost of labour, the carriage and cutting of the material, the cost connected with the engine, and of fuel, &c., and this estimate shows that it is possible to clean fibre with it at a cost of from about £7 to £1 a ton calculated on 100 lbs. of fibre for the working day per machine. Suppose it is only 50 lbs., which is dependent, as I said before, on the assiduity with which the machine is worked, it will only come to probably between £10 and £12. Such being the case, the result will be that China grass may be introduced at a much cheaper price than hitherto. What that price will be, I cannot say, but I think it will be possible to sell at £30 to £35 a ton—possibly less; still it will always be an expensive cultivation. I am satisfied that those who think they are going to grow this plant at a very cheap rate, are mistaken. Great care must be taken in its cultivation, but in any case it will still always command a good price. The demand for it is likely to be very large, and it will, in consequence, continue to fetch a good price; those who grow it need, I believe, have no fear upon that point.

As to the yield per acre of rheea, there are no fresh facts since I went into the question for my report in the year 1875. I am aware that there are some notable facts which have been founded upon experiments made in Algiers. Estimates have been made, showing that you could get forty tons per acre, but I think these will require to be verified before we can accept them. Any way, I do not see that we can conclude at the present—I hope I shall be mistaken—that each crop will yield more than 250 lbs. per acre. You may, however, obtain three crops, or even four in the year, which would bring it to 1,000 lbs. per acre.

The question of cutting and storing of the plant are practical questions which will have to be considered hereafter. One of my objects, in the experiments which I carried out in Paris, was to determine, as far as I could, the height to which the plants should be grown in order to give the largest yield of fibre. Some people say that the plant should be grown to the height of 6 feet; some say they should not be more than 3 feet; but the results of my experiments, as you will find from the table at the end of my paper, point to the fact that 3½ to 4 feet is about the right height to grow them. If the length is not more than 2 feet, the fibre is very fine, but the chances are you get more waste, and not such a good per-centage of fibre. In the long stems the fibre is not so fine as in the medium ones; in short, the medium stems from 3 ft. to 4 ft. are about the right length to cut. This has an important bearing upon the question of the number of crops which can be obtained. It is clear that if you allow the plant to grow 6 or 8 ft. high, you cannot expect to get as many crops as when only 4 ft. Moreover, there is this characteristic; all these stalks which you see here are from the same plant, that is to say, the shoots have come from the same root. Having determined the proper length, the stems should be gathered accordingly, only those being cut which have attained the right height; in this way a continuous crop may possibly be secured.

We find that with China grass there is a great variety in quality. Here is a sample of short China grass, and here are others which are much longer. These variations in quality gives rise to the complaints which are frequently made. If you grow it, however, a certain standard length, it will be likely to produce it of a definite quality, and that is what is wanted for commercial purposes.

With regard to the comparison of the machine-prepared rheea fibre and ordinary China grass—here is a sample of the former, and those who have an opportunity of examining it will find the fibres are separate, and nearly fit for spinning. There is a very small amount of gum in these fibres, and if you take the China grass in your fingers, you will find that it is very stiff, owing to the large quantity of gum that is left in it. In the machine this gum is washed out; but by merely scraping, you leave it in. The amount of gummy matter in the machine-prepared sample is about 19 per cent., as compared with from 25 to 35 per cent. in China grass. I feel satisfied that in this sample, had the stems been operated upon when freshly cut, the proportion of gum would have been considerably less. If it is 19 per cent. in this, I should say that if it had been cut fresh it would have gone down to 15 per cent., or even less; but these are points upon which I hope to make experiments in India, where I shall have an opportunity of doing so on a larger scale.

Now, what is rheea good for? It is difficult to say what it is *not* good for. It is the strongest fibre in nature. According to the experiments made by Dr. Forbes Royle, it is two and a-half times as strong as the best Russian hemp. Compare it with flax. Many years ago, one of the largest flax spinners in the kingdom spent a considerable sum, £20,000, I believe, in trying to use China grass in the place of flax, but the experiment was given up, owing to the hairy character of the yarns produced. It is, however, quite possible to prepare rheea in a way which would enable it to be spun on flax machines; and we find table-cloths and beautiful fabrics of this material equal to anything that could be produced from flax. It is also an admirable substitute for wool, especially for mohair and other lustre wools. On the table are illustrations of what it is good for, and many of these specimens show what can be done with it in that respect. From what I hear, there is likely to be a run upon lustre wool shortly, as it appears likely dead surface wools will go out of fashion, and lustres come into vogue again, thus leading to an increased demand for rheea. Then, as to silk. Rheea is prepared in various ways, so as to leave the gloss upon it, giving it all the appearance of silk, and it is certainly far superior even for mixing with silk than jute. Many of the ladies present know that the silk dresses which they buy now are very inferior as compared with what they used to be some years ago, the difference arising from their being adulterated with jute. No doubt the ladies would like to see the persons who mix jute with silk locked up for life, and most men will agree that the scoundrel who dares to put jute into sailcloth deserves to be hanged, for that might often mean death on a lee shore.

I do not know that I have much more to say upon this subject. My story has been rather a long one, but I have done my best to give you some idea of the present position of the matter, and how it is likely to be altered by the existence of this machine, the result of the genius and intelligence of Mr. H. C. Smith. It is interesting just to think of how he came to invent it. What first suggested it to his mind was noticing the great aloes, the stems of which grow up to 30 or 40 ft. Mr. Smith observed during the monsoon in the Mauritius that where the inner leaves were dashed against these great stems, they were broken up, the result being that the pith got washed away, and the fibres were left hanging. This suggested, to his mind, the idea of a machine in which a rush of water would play the same part, and he was fortunate enough to find in Messrs. Death and Elwood a firm possessing the largest experience in the manufacture of fibre-cleaning machines for a similar object in South America and elsewhere. The result of this combination has been the production of the present simple and highly effective machine.

With regard to the exhibition of the machine previously referred to, it will not be possible to show it at work upon fresh rheea, but there is a supply of Agave and other leaves which will show its action upon them, and there is some rheea now on its way from Algiers, which may come in time for a trial on Tuesday next, although it will be far from fresh. The various samples now exhibited will be on view at Mr. Collyer's rooms, 141, Fenchurch-street, and I shall be happy to give any special information which it may be in my power to afford.

I — Observations.

1 Containing Bark = 16·85.
2 ,, ,, = 17·71.
3 The bark could not be separated with sufficient accuracy for the determination of its per-centage *per se*.
4 This sample was apparently not quite so fresh as the others.
5 Calculated upon Nos. 1, 2, and 4 only.

In conclusion, it is my duty to express my thanks to Messrs. Garnock, Bibby & Co.; A. Donisthorpe & Nephew; J. Glazebrook & Co.; J. Grathvohl; George Hall & Co.; Richard Harris & Sons; Herbert E. Hounsell, Limited; Charles Rhodes; F. Wilkinson; and very specially to Mr. W. Whitaker, for the interesting series of specimens exhibited on this occasion; as also to Mr. Howson and to Mr. Lascelles Scott,—to the former for assistance in connection with the trials of the machine, and to the latter for assistance in the investigation, a small portion of the results from which only appear in the Tables, pages 73 and 74.

Amongst the specimens exhibited in illustration of the foregoing paper were rheea and China grass in various stages of preparation, from the stalk to the finest bleached fibre, also many fabrics, including lace and other curtains, shawls, hosiery, handkerchiefs, muslins, sailcloth, &c., made entirely from rheea; also some ropes and twine spun from "Moorva," fibre produced by Messrs. Stains and Co., from the plants growing wild on their Madras Government concession in the Coimbatore district.

DISCUSSION.

Mr. Wm. Haworth said he could confirm what Dr. Forbes Watson had said with regard to rheea and all other such fibres of India, that the stem should be acted upon, if possible, immediately after it was cut from the ground. It was as easy to separate the fibre in that state as it was difficult to do so afterwards. In 1842, he grew rheea, just for a sample; he cut it, and placed it immediately in a running stream of hot water from a condensing engine, and by this means the bulk of the fibre was very easily separated by hand. All the gummy matter appeared to be separated, and a more beautiful sample he never saw. The moment the stem was taken from the water, and just held at the tip, you could draw the whole circumference of the bark and fibre away from one end of the plant to the other; then, drawing it through your hands again, you could separate the bark, and all that was required was to wash the fibre in hot water. He held that if this machine could be placed on a plantation where the plant could be cut immediately it was ready, especially if hot water were used with it, it would accomplish all that could be done by hand, and would give a very satisfactory result. Rheea would make the warps of the finest cotton goods, and the wefts could be made of Sea Island or other fine cotton. He had seen it used in Lyons for the warp of piece goods, and very beautiful goods they were. It could be used for the very finest materials up to the coarsest. He had seen plants growing near Calcutta from seven feet to ten feet in height; and the time to cut them was just when they were begining to flower. Next after it would come the mudar, the only trial of which yet made had been from plants growing wild, spreading out into a number of branches, and forming seed pods, like flax; but if this were sown more closely, it would grow much taller, nearly all stem, and would make even a more beautiful plant than rheea, though not so strong. He was quite sure there was a great future for all these Indian fibres, if they were looked after and treated in the way now described.

Mr. Martin Wood remarked that the large prize offered for the machine for cleaning rheea fibre was the first special effort made by Lord Mayo towards developing the special industries of India. His own impression was that Mr. Greig's machine scarcely had fair play. The time announced was 1st April, but the trial did not come on until the end of August. He believed Lord Northbrook, who witnessed the experiments, considered the machine a decided success. It turned out something like 150 lbs. per day, which came within the condition of costing less that £50 a ton. That, however, was now an old story. He was anxious to see the machine described succeed, because it seemed just what many had been wishing to have introduced for the purpose of developing the fibres of India. Dr. Watson was, no doubt, enamoured of the rheea plant, but for his own part, there were many reasons which made him take more interest in what he might call the Cinderella fibres—the aloes, the mudar, and others. However important and interesting these results were with regard to the rheea, it was a hundred times more important that these commoner fibres should be utilised. If this machine could be worked with 1 horse-power, it could perhaps be worked by hand, and if so, it was one of the most invaluable inventions India could have, for the great difficulty there was to get motive power. The cultivation of rheea was limited, because he believed it would not grow in the plains, but only at an elevation of some 2,000 feet, or in the hilly districts at any rate; and it would involve the outlay of considerable capital. These common fibres, however, cost nothing, they were within the reach of the mass of the people, and if they could be utilised by the aid of our wonderful mechanical appliances, they would be a most important adjunct to the food crops and coarse agriculture of the country.

Mr. Kahlert said his firm had had a sample of rheea grown in Sumatra, on the plains, near the northern coast.

Mr. W. Haworth said his experiments in growing rheea were made on plains near Calcutta, than which you could not find any place much lower. He had found it growing wild on the slopes of the Himalayas, at Darjeeling.

Dr. FORBES WATSON said the best sample he had seen was grown in Egypt.

Mr. LIGGINS would suggest that a drawing should be published, so that they might see the nature of the plant, and also information given as to how far apart the plants would grow best. Within his recollection the sugar-cane was planted 3 feet apart, but it was discovered in Barbadoes that they grew much better 5 feet apart, and, he believed, that on some of the most fertile lands they were planted from 7 to 8 feet apart. If a larger production of cane was produced in this simple way, at the same time decreasing the cost of planting, the same result might be produced in the case of this plant. He should also like to know whether it required a swampy soil, and whether it would stand the heat of the tropics without frequent rains. The esparto grass in the West Indies would not grow except on swampy soil, and possibly this would be the same. Between thirty and forty ago he was much interested in trying to get perfected in England similar machines to that now described, but it was found that nothing could be done without an amount of water in connection with the rollers, which rendered it impossible to work at a profit. The aloe, which grew in great profusion in the West Indies, was not utilised because of the difficulty of separating the gummy matters for want of a sufficient supply of water. He and his friends found that they could not get English manufacturers to alter their machinery to use a new material. About the same time, he imported a considerable quantity of a very beautiful substance called silk cotton, but no manufacturer in England or France would take the trouble to look at it. So it was, some years ago, with esparto; the difficulty always was, with a new material, to get manufacturers to alter machinery. He was much pleased with the specimens of cordage shown, and could speak from experience as to the importance of reducing both the weight and size of ropes used for rigging.

Mr. C. F. CROSS said Dr. Watson had spoken of the jute industry in connection with this machine, but he thought its application would revolutionise the present trade. He had pointed out, from an examination of the fibre, that the whole of the jute imported into the country represented degraded fibre, and he had satisfied himself, by chemical examination of the nature of a large number of bales of jute, that there was sometimes a considerable developed degradation of fibre in the centre, especially when it was packed with the least dampness, involving the passage of the constituents of the fibres into soluble matters, and consequently great depreciation in value. He inferred that not only were the portions to be examined degraded, but probably the whole bulk. He was far from wishing to say anything in depreciation of this new machine, but he should like to ask whether some of the lesser practical questions might not be lost sight of in view of the great theoretical triumph accomplished. He thought these might out-weigh, in the case of the Cinderella fibres which had been referred to, the advantages. In the first place, it would be very difficult to organise the jute industry into any concerted action for the adoption of a machine of this kind, the qualification being in the hands of a large number of small producers, each of whom worked his own fibre. Then, of course, the cost of production had been put from £7 to £10 a ton, and when they remembered that jute was retailed at about £18, it seemed to him the margin left was somewhat narrow. Dr. Watson called the machine a universal fibre cleaner, and it might prove to be so; but chemists still believed that there was a certain future for chemical manipulation in the case of fibres which it was impossible to treat mechanically. When you had simple bast, as in the case of rheea jute, the handling of the fibres was easy, but where you had the bast built up into internal stems, such as wood—where you had fibre to deal with like straw, where the bast elements were solidified into curiously complex substances—there was a great future for chemistry. There was no doubt that chemistry, and this remarkable machine, would have to run a considerable race until the functions of the two were properly adjusted on a chemical basis. He was interested in certain new processes, which had been worked at a considerable cost for the chemical treatment of fibres. With regard to rheea and other fibres which had been treated by this machine, he thought they were apt, in the face of new results, to over-estimate a little the value of the fibre. It must be remembered that affinity of rheea for colouring matters was very weak, and, therefore, he thought its substitution for silk was perhaps more than they could expect, or for other things where the property in taking a fast colour was desirable. In the Favier and Fremy process there was a conjunction of chemical and mechanical treatment, but this machine of Mr. Smith's did not seem to be worked in connection with any chemical treatment; very likely under previous chemical manipulation of a large number of these complex structures, the isolation of the fibres would be more easily accomplished, and the fibre produced would be of considerably higher order than would be produced by the machine alone. Lastly, he would ask if the inventors had any hopes of being able to apply it to the flax industry, which was a very important one, particularly in Ireland, where such a machine was greatly needed, for he did not think there was any product which came into the market in such varying quality as flax.

Mr. T. CHRISTY remarked, with regard to the price of rheea fibre coming down, it might not be known to many present that since it had come into the market, experiments had been made for turning it into a material closely resembling leather. Comparing the two, he might say that the value of leather bands was about 5s. a lb., and that of rheea fibre 1s. a lb. at the utmost. These bands had been tested, and a 3-inch rheea fibre band was found to do the work of a 9-inch leather band. That being so, there was not much fear of rheea going down. One other important fact, not mentioned by Dr. Watson or by Mr. Cross, was this, that if the fibre were wetted, it was most difficult afterwards to perform many of the chemical operations upon it. Mr. Ekman had had most excellent results in his process by treating the rheea after it had been worked in Mr. Smith's machine. That was a very great feature in this new process, and might be the means of enabling a dyer to bring up the colour of the fibre, which, at present, had been found very difficult.

Mr. Collyer said Dr. Forbes Watson had asked him to reply to the various points raised, as he, unfortunately, was not able to hear them. It was very evident that Mr. Martin Wood had but a very partial knowledge of the rheea plant and of its mode of cultivation. His own impression was that it grew more favourably in rich alluvial soil than on the hills; certainly, he had himself had samples both from high and low levels, and he thought that the lower ground plants were the best; at any rate, there was not much difference. As Dr. Watson had said, the finest he had seen was grown in Egypt. With regard to Mr. Liggins' questions, no doubt superior cultivation would give a better result than merely trusting to wild plants. It stood to reason that with rheea, like all other plants, cultivation improved the fibre, and a great result would be obtained, and probably a more economic result, if it were carefully attended to. With regard to close or open planting, he did not know that there were any facts yet ascertained, but his impression was, taken from analogy, that growing rheea for the sake of the fibre, it would be better to grow it rather closely together, because if it were grown far apart, you would get a wide bushy plant, which meant a great number of breaks in the fibre; the straighter you could have the stem, and the fewer leaves upon it, the better. He could hardly speak as to the nature of the soil, but he thought a rich alluvial soil was best. As to esparto growing in swamps, it struck him as being new, for he always thought it grew on stony, mountainous soil.

Mr. Routledge said the esparto grown in Jamaica was declared by authorities not to be really true esparto.

Mr. Collyer said with regard to the quantity of water required for the machine, he was told by the engineer that it required less than the quantity now used for washing the fibre when prepared by other processes. As to silk cotton, that hardly came within the range of the paper, but he might say the Dutch were far in advance of us, as he had noticed it in the Amsterdam Exhibition, and in Holland it could be sold for 8d. per pound, whereas in England you could not get 2d. The quality of it was better however. As to the rope, the makers told him the breaking strain was 7,705 pounds, which was something greater than a similar rope of best Manilla hemp. The smaller cord, which was made for fishing lines and net purposes, stood a strain of 80 pounds, and broke at 81, which gives 7·4 greater strength than the best quillot Manilla, and, at the same time, was 4·72 per cent. lighter, which was 12 per cent. in favour of the yarn made of this fibre. He could not say the cost, but if it weighed 5 per cent. less, and was 7 per cent. stronger, he should argue the cost would be much less than if made of Manilla.

Mr. Liggins asked if it was liable to rot.

Mr. Collyer said he could not answer that question, because until this machine appeared on the field none of this fibre ever came to England in commercial quantities, though he had known it in samples for twenty-five years; it was, practically, the creation of the machine. He had sent samples to various people, and none gave an unfavourable opinion; the worst was that it was at least equal to Manilla. It was a new fibre brought into the market for the first time, and was the first attempt of the natives to use the machine, so that it had not yet been practically tried. He agreed with Mr. Cross that jute was a degraded fibre, and one of the greatest merits claimed for this machine was that it would stop that degradation; that it would give all the fibre nature put into the plant in the purest and strongest condition, for this reason, that the action of the water was peculiar, and different to any other process. When the skin of the plant was broken, all the acids contained in it at once set up a deleterious action, and commenced to injure the plant, but the advantage of this machine was that the deleterious matter and strong acids, which tended to weaken and discolour the fibre, were at once swept away before they could act upon the fibre. Incidental to that was the fact that it did away with the necessity of retting. Wherever this machine went, retting would become a thing of the past. It would have the same effect on flax, if they took the flax young enough. He firmly believed it would do away with retting altogether as regards flax, hemp, and every other fibre, including jute. They had to deal with 800,000 tons of jute a-year, 50,000 or 60,000 tons of Manilla hemp, and a great many thousand tons of other fibres, which showed what an enormous product of fibre there was throughout the world. He personally claimed for the machine that it was the best for every fibre, always excepting bristle fibres. As to chemistry, it seemed to him the great advantage of this machine was that they did not want a chemist at all. According to their belief, rheea was not bast at all; jute was bast. As to the affinity of rheea for colouring matters, he had lately made a tour amongst the principal manufacturers of Europe, and they all told him of the difficulties that did exist in dyeing it;

fast colours had been, by recent improvements, effectually obtained. His information was that, at £30 a ton, there was no limit, practically, to the quantity which could be sold; at £40, it would go slowly; at £50, with the present price of wool, it was barred. One man said to him, "If you bring it down to £35, you will sell a lot; if you bring it down to £30, nobody knows the quantity we can use." In addition to all the present outlets, there were many new things constantly coming under notice, such as Mr. Christy had referred to. A new one sprang up only the other day, and he believed that in a short time felted carpets would be made of wood instead of wool. Of course, for a time the increased supply of fibre may have an inconvenient effect on the market, but the fittest would survive, and if any had to give way, it struck him it would be the old-fashioned people not those who had the best fibre, at the lowest price.

Mr. W. HAWORTH said jute was not so much bast as rheea, but neither was really bast. Bast was always taken from the interior of the bark of a forest tree. Jute was called "a lie," but how was it so much came into consumption? He remembered the first 35 bales shipped from Calcutta as a sample by the East India Company, and when it came home there was great difficulty in disposing of it, but now the consumption, in Great Britain, was about 2,200,000 bales of 400 lbs. each, and the whole quantity required to be produced in India was upwards of six million bales. If, therefore, it was an inferior article, there was nothing yet which would take its place, unless it was rheea. He believed the younger persons in the room would see a larger quantity of that come into use even than jute.

The CHAIRMAN, in proposing a vote of thanks to Dr. Forbes Watson, said he would say a few words drawn from his experience in India, where he had superintended the experiments instituted by the Government. With regard to this fibre, the rheea plant for these trials was cultivated in the Botanic Gardens at Serampore, which was practically on the plains; and Mr. Sandys also cultivated the plant at Baugulpore, which was in the delta of the Ganges. The Government also cultivated it in the Botanic Gardens at Calcutta, in order to enable machinists to obtain a supply to use in their endeavours to design a machine for preparing it. In Assam it grew wild, and with regard to its rotting, he might say it was used there for fishing lines, and he did not think any fibre which was liable to rot would be used for such a purpose. He had a fishing line from Assam which had been ten years in his possession. No doubt this plant required careful attention, and as far as he could ascertain from what was done in the Botanic Gardens, Serampore, the maximum amount of crops would be three in the year. But there was another question which had not been touched upon: it was a very quick growing plant, and in that part of India grew best in the rains, and in Calcutta during the hot stagnant atmosphere of the rainy season. For fourteen days he carried on the experiments, and he had found the crop was very different at the end of that time from what it was at the commencement, showing a considerable growth in the stems. It was quite certain that, to secure an excellence in fibre, the stems should be cut at a certain point, and therefore considerable care must be exercised in regulating the growth to enable the crops to be cut in proper succession. All this was a question for the future, because little attention had as yet been paid to the cultivation of the plant. There were two factories in India where the rheea was prepared, one began by Colonel Thelwall in the Deyrah Dhoon, the other in the Dhoons of Kangra. In these, some attempts to prepare the rheea by machinery was made, but the work was done mostly by hand, the method employed being to scrape the fibre after it had been stripped from the stalk on a table with a sensitive machine, namely, the hand and the knife. This machine of Mr. Smith's appeared to provide a substitute for the hand in the film of water which held the rheea up to the scraper, and it would probably be better prepared by that means, because the way in which it was held up was better; all previous attempts had been to scrape the fibre. Mr. Greig asserted that he adjusted the rollers of his machine so that the fibre was scraped between two knives, but as the fibre was only about $\frac{1}{1000}$ inch, it was obviously impossible to adjust two rollers to travel with that nicety. The result was that the machine did not scrape the fibre, and it was found that as the supply of water was increased, the condition of the fibres turned out improved. This was entirely confirmed by what Mr. Haworth said; he pointed out that they put the fibre into a stream of running water, which softened the gum and carried it away. This gum was of a remarkable character.* One Saturday in September, Mr. Greig had broken up in his machine a large quantity of fibre, there being a close murky atmosphere. The fibre was placed in a shed, and remained there until Monday morning, and on the Monday morning the mass, as high as that table, was like a large mass of isinglass glued up together with the fibre in it, nothing could be done with it, and it had to be thrown away. That showed the absolute necessity of attacking the stem the instant it was cut, with a running stream of water to carry the gum whilst it was in its natural state. It was then easily attacked, but let it wait or dry in any way, then

* When the experiments with Mr. Greig's machine were concluded, all the rollers, &c., were found to be thickly covered with a very hard varnish, so hard, that it could only be taken off by a chipping chisel. It had the appearance of lac. The analysis of this dry juice gave as follows:—"The juice contains 62 per cent., by weight, of oxalate of lime; and, besides this, some alumina, oxide of iron, and other mineral matters which dissolve in hydrochloric acid, the residue, insoluble in dilute hydrochloric acid, consists of colouring and resinous matter, and forms 2·5 per cent. by weight of the dry juice."—H. H.

the difficulty commenced and increased. The colour of the fibre also darkened in proportion with the delay in removing the juice. Mr. Greig's machine consisted of two rollers with scrapers, but there was another machine from America which was not tried, which broke the stems in a somewhat similar manner to this machine of Mr. Smith's, only there was no water employed, and hence it failed. The excellency of this machine was in its simplicity and in the application of water. The jet of water held up the mass of stems to the beaters; the instant the beater scraped off the bark, and all that adhered to keep the mass together, the fibres got separated, and they were so fine that they fell through, and into the film of water, leaving only the agglomerated portion to be worked upon by the beaters, thus the fibres are cleaned all round, while in the hand process they are only cleaned on upper and lower surfaces. That was a kind of self-adjusting sensitive cushion, and on its results the machine depended.

The vote of thanks having been carried unanimously, the proceedings terminated.

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION, LONDON, 1884.

It is proposed to hold, during the year 1884, an International Health Exhibition, which shall also illustrate certain branches of education, and which will occupy the buildings at South Kensington, erected for the International Fisheries Exhibition. (See Vol. xxxi, p. 1030).

The object of the Exhibition will be to illustrate, as vividly and in as practical a manner as possible, Food, Dress, the Dwelling, the School, and the Workshop, as affecting the condition of healthful life, and also to bring into public notice the most recent appliances for elementary school teaching and instruction in applied science, art, and handicrafts. The influence of modern sanitary knowledge and intellectual progress upon the welfare of the people of all classes and all nations, will thus be practically demonstrated, and an attempt will be made to display the most valuable and recent advances which have been attained in these important subjects.

The Exhibition will be divided into two main sections—Division I. Health; Division II. Education; and will be further sub-divided into six principal groups.

In the First Group, it is intended specially to illustrate the food resources of the world, and the best and most economic methods of utilising them. For the sake of comparison, not only will specimens of food from all countries be exhibited, but the various methods of preparing, cooking, and serving food will be practically shewn. The numerous processes of manufacture, connected with the preparation of articles of food and drink, will thus be exemplified; and, so far as the perishable nature of the articles will admit, full illustrations will be given of the various descriptions of foods themselves.

In the Second Group, dress, chiefly in its relation to health, will be displayed. Illustrations of the clothing of the principal peoples of the world may be expected; and a part of this Exhibition, which, it is anticipated, will be held in the galleries of the Royal Albert Hall, will be devoted to the history of costume.

In the Third, Fourth and Fifth Groups, will be comprised all that pertains to the healthful construction and fitting of the dwelling, the school, and the workshop; not only as respects the needful arrangements for sanitation, but also the fittings and furniture generally, in their effect on the inmates. The most improved methods of school construction will be shown, and the modes of combating and preventing the evils of unhealthy trades, occupations, and processes of manufacture, will form portions of the Exhibition.

The Sixth Group will comprise all that relates to primary, technical, and art education, and will include designs and models for school buildings; apparatus and appliances for teaching; diagrams, text-books, &c. Special attention will be directed to technical and art education, to the results of industrial teaching, and to the introduction of manual and handicraft work into schools.

It is proposed to arrange collective exhibits in connection with some of the above classes, illustrating, among other subjects, the dwellings of the poor, the care in the dwelling for the welfare of the children and of the sick, model nurseries, sleeping apartments, completely fitted kitchens, fully equipped gymnasia for adults and for the young, model laboratories and collections for health-teaching, model schools, workshops, &c., and also collections having reference to special trades.

It is also proposed to hold an International Congress in June or July next, on each of the main sections of the Exhibition—Health and Education.

Lectures will be given, and Conferences will be held, on the various subjects illustrated in or cognate with the Exhibition; they will be explained by practical demonstrations and experiments, and reports on each group will be issued.

Processes will be shown in actual operation, and practical tests will, from time to time, be made of the inventions submitted to the juries.

The Executive Council of the Exhibition was appointed by H.R.H. the Prince of Wales, President; and consists of the Duke of Buckingham and Chandos, G.C.S.I., Chairman; Sir James Paget, Bart., F.R.S., Vice-Chairman; Sir Frederick Abel, C.B., F.R.S.; Mr. Edward Birkbeck, M.P.; Dr.

George Buchanan, F.R.S.; Sir Philip Cunliffe-Owen, K.C.M.G., C.B., C.I.E.; Sir Joseph Fayrer, K.C.S.I., M.D., LL.D., F.R.S.; the Marquis of Hamilton; Mr. Ernest Hart; Sir John Lubbock, Bart, M.P., F.R.S.; the Right Hon. the Lord Mayor; Mr. Samuel Morley, M.P.; Dr. G. V. Poore; Lord Reay; and Sir John Rose, Bart., G.C.M.G. The Secretary is Mr. Edward Cunliffe-Owen, M.A.

This Council is now meeting regularly, twice a week, at the Society of Arts House, by permission of the Council of the Society. A large General Committee is also in course of formation. From among the members of the General Committee, the following Sub-Committees have been appointed:—1. The Dwelling; 2. Workshop and Factory Sanitation; 3. Food—raw materials; 4. Food and Cookery; 5. Heat; 6. School and Education; 7. Ambulance; 8. India; 9. Colonial. They will meet for the present at the Society of Arts, and will have under their superintendence the arrangements necessary for securing the efficient representation of the objects of the various sections of the Exhibition. It is announced that persons wishing to exhibit in any of the classes should apply to the Secretary, Mr. E. Cunliffe-Owen, at the offices of the Exhibition, South Kensington. These offices, it may be added, are in the buildings formerly occupied by the Fisheries Exhibition.

TROUT BREEDING IN OTAGO.

Although much attention has been paid to the artificial rearing of fish in England and in America, little has been done in the Australian colonies towards this object. The *Otago Daily Times*, however, gives a full account of a series of experiments carried out by Mr. W. S. Pillans, of Otago—who has raised some 6,000 trout—from which the following particulars are taken:—"This gentleman's property, known as Manuka Island Station, is situated a few miles from Balclutha, near the bank of the river. It boasts no natural advantages for pisciculture, and what has been done has been done by dint of hard and persevering work. The number quoted (6,000) does not, however, by any means sum up the extent of Mr. Pillans' operations so far. He has, it is said, given a quantity of fry to the Acclimatisation Society; and, exclusive of these, he has now at his nursery 57,000 ova in course of hatching, 6,000 yearlings, and nearly 250 two-year-old fish, all apparently thriving exceedingly well in the limited space at their disposal.

"The earliest process is 'stripping' the fish, and upon this it is unnecessary to dwell at any length. Most people are acquainted with the manner of obtaining spawn for artificial incubation, and are aware that it is a process requiring care and skill. Mr. Pillans is indebted, in this respect, to Mr. Steele, who has for some years past allowed him to take trout from a portion of the Wairuna River for the purpose of stripping. The process of hatching the ova, which commences from this time, occupies something like seventy-five days, and although it is not attended by all the difficulties met with in rearing young fish, it is nevertheless a trying time for the breeder. The ponds, hatching-troughs, &c., comprised in Mr. Pillans' establishment, are all situated in the immediate neighbourhood of his residence, as is necessary in view of the constant attention they require. The hatching-house is a small, barn-like structure, with thatched roof, and a very elaborate and ingenious arrangement of shallow wooden troughs. These are placed upon gradually-declining levels in such a way, that a running stream of clear water can pass on to each in turn. In those troughs, sometimes on a gravel bottom, sometimes in trays of wire netting, lie 50,000 odd of this year's ova in various stages of development—an array of small pinkish globules, the peaceful and insignificant appearance of which is wholly disproportionate to the anxiety and trouble they entail now and hereafter. The interior of Mr. Pillans' hatching-troughs is invariably carbonised, and this is to avoid the formation of fungus, which is, perhaps, the most fatal of the ills referred to. If it once fastens upon the woodwork, it spreads its invisible hold with immense rapidity, and the owner will be fortunate if the owner save a very small proportion of his ova. The sediment, which is carried in even the clearest water, is another source of danger, and this Mr. Pillans obviates by filtering his little stream very carefully, and further, by placing some of his ova on trays of galvanised iron wire, which allows them to be easily cleansed. The troughs have also to be kept carefully closed against the visits of living animals; and even then there is a second class of fungus (known as *Byssus*), for which a watch must be kept. This forms on the eggs themselves, and kills them rapidly in numbers. To prevent the spread of this, the troughs have to be examined daily, and the dead eggs, which may be detected by their change of colour, must be carefully removed. The newly-hatched fish are about half an inch long, darkly transparent, and rather resembling a splint of wood. They are still attached to the egg yolk (technically known as the 'sac'), and for a period of about five weeks they live by the gradual absorption of this. The younger of these trout, 'alevins,' display no sign of animation save an occasional wriggle if disturbed; but the older ones, which Mr. Pillans has separated into other troughs, are far more lively.

"Those who have consumed their sac, and therefore passed the 'alevin' stage, Mr. Pillans has transferred to what he terms his nursery-ponds. In this confined area they take their first artificial food, consisting of curds, which are sparingly scattered upon the water at regular intervals. In three larger ponds, Mr. Pillans has disposed the elder portion of his family. A trout, 14 inches in length, will eat one of seven inches, and it is inability and not fraternal feeling that prevents him attempting those of larger growth. Thus Mr. Pillans has found it necessary to distribute his yearlings in two small ponds (about 3,000 are contained in each), and a very marked difference in size is noticeable between these two assortments. Even with this precaution cannibalism exists among the youngsters. It was only recently that Mr. Pillans noticed a fish swimming placidly about with the tail of an undigested brother protruding from its jaws.

"The food upon which Mr. Pillans raises his trout is a kind readily procurable in the country—viz., rabbits' flesh. To the smaller yearlings is administered a diet of curds mixed with the liver of the rabbit very finely minced. The larger yearlings take the liver alone, and the more tender parts of the flesh, and the tougher portions are similarly minced and thrown into the pond of the two-year-olds. About 240 very fine trout are at present contained in this pond. They vary in weight from half a pound to a pound and a quarter, and appear to have thriven excellently upon the above-mentioned diet, to which has been sometimes added the larvæ of the bluebottle fly. There are at least half a dozen of these fish measuring some fifteen inches in length, and the average weight of the lot would probably be about three-quarters of a pound. They are all broad, well-developed fish; and if this year's hatching turns out as successful, Mr. Pillans will have a very valuable stock of trout upon his hands.

"A large additional pond, sixty feet or seventy feet in length, is in course of construction near the others, and this would be capable of containing enough fish to supply the Dunedin market when other sources failed."

Correspondence.

INTERNATIONAL FISHERIES EXHIBITION.

In my communication to last week's *Journal*, I inadvertently referred to the operations of the Fishery Board of Scotland, concerning the artificial fecundation and development of the egg of the herring as the "first attempt," accompanied by success, that has been accomplished in this connection. Writing direct from the published report, such impression was conveyed to my mind. I have, however, been since informed that similar operations, on a far more complete and extensive scale, were carried out many years since by the German Fishery Commission, and that the Scottish Fishery Board had, consequently, the advantage of such experiences for the conduct of their recent experiments. A full reference to these earlier achievements of the German Commission will be found in the lecture upon the herring delivered by Professor Huxley, at Norwich, in the year 1881.

W. SAVILLE KENT.

SOUR BEER.

Referring to the correspondence on "Sour Beer," which has taken place in the last two or three numbers of the *Journal*, may I be allowed to suggest that "prevention is better than cure," and that if a beer becomes acid, it is the result of either carelessness or ignorance.

As to what should be done, should some unfortunately turn sour, I quite agree with "Hampshire Brewer" that it is highly probable that it would spoil good beer if the two were mixed.

I can only suggest that it should be given to the pigs—if they will take it.

H. S. CARPENTER.

The Metropolitan Laboratory,
32, Holborn Viaduct, E.C.

General Notes.

PAPER has been made from cedar bark in Massachusetts, and the trials are considered so satisfactory that works have been started at New Bedford for manufacturing on a large scale. The paper is said to be specially suitable for laying under carpets, because it has the property of keeping away insects.

EXHIBITION AT LUCKNOW.—An Exhibition was opened at Lucknow, on the 6th November, called the Soldiers' Industrial Exhibition. The articles sent to the Exhibition, by 241 exhibitors of the various regiments on the station, are said to include many of excellent manufacture and novel design. They consist of carpenters', coopers', and joiners' work, turnery and fancy woodwork, ironsmiths' work, tin and wire-work, cutlery, jewellery, and highly-finished metal-work, leather work, machinery models, coach building, painting, photography, plans, maps, and designs, printing and lithography, needlework, lace-making, taxidermy and skin dressing.

CALCUTTA EXHIBITION.—The first International Exhibition ever held in India was opened on Tuesday, December 4th. The Viceregal party, with their Royal Highnesses the Duke and Duchess of Connaught and Sir James Ferguson, Governor of Bombay, arrived at 4.30, and took their seats on the daïs, Colonel Trevor, Vice-President of the Executive Committee, read an account of the rise and progress of the scheme, and in the absence of the Lieutenant-Governor, requested the Viceroy to declare the Exhibition opened. The total area of covered space is 400,000 square feet, independent of the little shops scattered about the enclosure, and this is considerably larger than the Exhibition of 1851. The open air occupied space is 40,000 feet, and the wall space 30,000 feet more. Great Britain has 837 exhibitors, the Australian Colonies 1,311; Foreign

Europe 347, and the Foreign East 700; making a total of 3,195 exhibitors.

Hungarian Exhibition.—A national exhibition s to be held at Budapest during the summer of 1885, and it is proposed to add to it an international section, to which the assistance of English manufacturers is asked. Hungary is an agricultural country, and it is suggested that makers of novel implements would find new outlets for their trade at this exhibition, while makers of engines and tools might open up a market, not only in Budapest, but in the neighbouring countries to the east and south. The objects to be exhibited are engines, machines for working wood, metals, and leather; textile machinery; machines and tools for hatters, brushmakers, potters, horn-workers, millers, bakers, printers, lithographers, and bookbinders. Application must be made before the last day of February, 1884.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

The following arrangements for the Wednesday evening before Christmas have been made:—

Dec. 19.—"Canada and its Products." By the Most Hon. the Marquis of Lorne, K.T., late Governor-General of Canada. Sir Alexander Galt, G.C.M.G., will preside.

Cantor Lectures.

The First Course will be on "The Scientific Basis of Cookery." By W. Mattieu Williams, F.C.S.

Lecture III. Dec. 17.—The nutritive constituents of Vegetables. The changes effected by cookery on Vegetable Substances. Ensilage of Human Food. May the use of Flesh Food be superseded by the scientific preparation of selected Vegetables?

MEETINGS FOR THE ENSUING WEEK.

Monday, Dec. 17...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. W. Mattieu Williams, "The Scientific Basis of Cookery." (Lecture III.)

Institute of Surveyors, 12, Great George-street, S.W., 8 p.m. The Discussion on Mr. J. W. Willis Bund's Paper, "The Agricultural Holdings Act, 1883."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. E. J. Tarver, "English Architecture and Monuments of the Sixteenth and Seventeenth Centuries."

Institute of Actuaries, The Quadrangle, King's College, W.C., 7 p.m. Mr. William Thomas Gray, "The Probable Effect of Withdrawals on the Rate of Mortality among Assured Lives."

Medical, 11, Chandos-street, W., 8½ p.m.

Asiatic, 22, Albemarle-street, W., 3 p.m. Mr. W. F. Sinclair, "The Fishes of Western India."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. C. Ambruster, "The Musical Dramas of Richard Wagner."

Tuesday, Dec. 18...Civil Engineers, 25, Great George-street Westminster, S.W. Annual General Meeting.

Statistical, Somerset-house-terrace, Strand, W.C., 7¾ p.m. Prof. Leone Levi, "Statistics of the Revenue of the United Kingdom from 1859-1882, in Relation to the Distribution of Taxation."

Pathological, 53, Berners-street, Oxford-street, W., 8½ p.m.

Zoological, 11, Hanover-square, W., 8½ p.m. 1. Mr. E. B. Poulton, "The Tongue of the Marsupials." 2. Mr. J. Wood-Mason, "Contribution to our Knowledge of Embidæ, a Family of Orthopterous Insects." 3. Dr. Franz Leuthner, "Monographic Revision of the Lucanoid Sub-family Odontolabini."

Wednesday, Dec. 19...SOCIETY OF ARTS (in the Lower Room, Exeter Hall, Strand), 8 p.m. The Most Hon. The Marquis of Lorne, "Canada and its Products."

Meteorological, 25, Great George-street, S.W., 7 p.m. 1. Hon. Ralph Abercromby, "The Explanation of certain Weather Prognostics." 2. Mr. G. M. Whipple, "Preliminary Inquiry into the Variations in the Reading of Black-bulb Thermometers in Vacuo." 3. "Report on the Phenological Observations for 1883." 8 p.m. Special General Meeting, to consider certain alterations in the Bye-Laws.

Geological, Burlington-house, W., 8 p.m. 1. Mr. J. W. Davis, "Some Remains of Fossil Fishes from the Yoredale Series at Leyburn, in Wensleydale." 2. Mr. J. J. H. Teall, "Petrological Notes on some North of England Dykes." 3. Mr. C. Parkinson, "The Droitwich Brine Springs and Saliferous Marls."

Royal Society of Literature, 4, St. Martin's-place, W.C., 8 p.m.

Civil and Mechanical Engineers, 7, Westminster-chambers, S.W., 7 p.m. Messrs. R. M. and F. J. Bancroft, "Chimney Construction, with Examples of Existing Shafts, in Brick, Stone, and Wrought Iron."

Thursday, Dec. 20...Royal, Burlington-house, W., 4½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. F. O Bower, "Structure Stem *Rhynchopetalum montanum*." 2. Mr. J. R. Greene, "Glands of Hypericaceæ." 3. Mr. Alban Doran, "Ear Bones of *Rhytina*." 4. Mr. C. Potter, "Starch Grains in Lacteal Cells of *Euphorbia*." 5. Mr. Walter Gardner, "Stipulated Glands of *Coprosma Baueriana*."

Chemical, Burlington-house, W., 8 p.m. 1. Mr. C. O. Sullivan, "Researches on the Constitution of the Gums of the Arabin Class." 2. Dr. W. Ramsay and Mr. Sydney Young, "The Decomposition of Ammonia by Heat." 3. Dr. W. Ramsay and Mr. Franklen P. Evans, "The Dissociation of the Halogen Compounds of Selenium."

London Institution, Finsbury-circus, E.C., 5 p.m. Professor W. H. Flower, "Whales."

Royal Historical, 11 Chandos-street, W. 8 p.m. Mr. Oscar Browning, "The Triple Alliance of 1788."

Numismatic, 4, St. Martin's-place, W., 7 p.m.

Friday, Dec. 21...Philological, University College, W.C., 8 p.m.

Folk-Lore Society, 22, Albemarle-street, W., 8 p.m. 1. Mr. E. Clodd, "The Philosophy of Punchkin." 2. Mr. W. G. Black, "An Additional Chapter in Folk-Lore Medicine."

Journal of the Society of Arts.

No. 1,622. Vol. XXXII.

FRIDAY, DECEMBER 21, 1883.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CANTOR LECTURES.

On Monday evening, the 17th inst., Mr. W. Mattieu Williams, F.C.S., delivered the third and last lecture of his course on "The Scientific Basis of Cookery." He drew special attention to the nutritive value of cheese, and described the various modes of cooking it, a subject which he said was much neglected in the kitchen. In his remarks on milk, butter, and "bosch," Mr. Williams said that the latter substance was a fair substitute for butter, if made of good material, but, of course, it should be sold for what it is. The nutritive constituents of vegetables were next described, and the lecturer hinted that in the future it might be possible, by scientific treatment, to obtain direct from vegetables that nutriment which now we obtain from flesh food, without the vegetables passing through the body of animals. A vote of thanks to Mr. Williams for his interesting course of lectures was moved by the chairman (Dr. Mann) and carried. The publication of these lectures will be commenced in the next number of the *Journal*.

JUVENILE LECTURES.

The usual short course of lectures, adapted for a juvenile audience, will be given on Wednesday evenings, January 2nd and 9th, by Mr. J. Millar Thomson, F.R.S.E., F.C.S., on "Crystals and Crystallisation." The lectures will commence at seven o'clock. All the tickets having been disposed of, the issue is stopped. As all the available accommodation will be required for those members who have applied for tickets, it will be understood that no member can be admitted without a ticket.

Proceedings of the Society.

FIFTH ORDINARY MEETING.

Wednesday, December 19th, 1883; the Hon. Sir Alexander Tilloch Galt, G.C.M.G., late High Commissioner for Canada, in the chair.

[The meeting was held in the lower hall, Exeter-hall, Strand.]

The following candidates were proposed for election as members of the Society:—

Appleton, R. H., Woodside-hall, Eaglescliff Junction, by Darlington.
Houston, Frederick H., Carlisle-terrace, Belfast.
Pott, Henry, 81, Cornwall-gardens, S.W.
Prosser, William Owen, 5, Trinity-place, Swansea.
Rea, Russell, 19, Primrose-hill-road, N.W.
Tomkins, Daniel, The College, Great Yarmouth.
Wildsmith, James H. S., 131, Upper Kennington-lane, S.E.

The following candidates were balloted for and duly elected members of the Society:—

Crow, John Kent, D.Sc., 2, Colham-villas, West Drayton, Middlesex.
Cunliffe-Owen, Edward, B.A., 64, Inverness-terrace, W.
Henderson, Richard, The Grange, Kirkcudbright, N.B.
Latchford, Edward, 50, Penywern-road, South Kensington, S.W

The Chairman, in commencing the proceedings, said it was not necessary to introduce the Marquis of Lorne with any lengthened remarks, but he could not help drawing attention to the distinguished services he had performed as Governor-General of Canada during the last five years. Those connected with that colony knew that during his administration there he had not only done his duty to his Queen, but had made himself most useful to the people over whom he presided. Canada had had, under Lord Lorne's administration, five years of unexampled prosperity; there had been no discontent, but loyalty had reigned through her wide borders, and his lordship had the satisfaction of knowing that he returned his government to the Queen in a state which all of her subjects must rejoice to see. Besides the political services which Lord Lorne performed in Canada, as head of the Government, he devoted himself to acquiring a perfect knowledge of its resources, from the

Atlantic to the Pacific; and he (the Chairman) trusted that the paper about to be read would contain some account of the Marquis's numerous journeyings. He hoped also that he would be able to say something on the Indian question of North America. They were proud to believe that the Indians of British North America had been contented, and free from those feuds and bloodshed which had distinguished them in the neighbouring republic. Under the Government of the Queen they had found good faith observed towards them, and they found that honesty and justice were characteristic of the British Government. He hoped also that they would hear something of British Columbia, which Lord Lorne visited in company with the Princess Louise; a country not very well known, but which was destined to become one of the brightest jewels in the crown. It was not necessary for him (the Chairman) to say much about the dominion of Canada, but no one in this country, seeing the social questions which were agitating the public mind, could doubt that it was of the utmost importance to have, within little more than a week's sail from our shores, abundance of good land, and a contented people, ruled over by the same sovereign, enjoying the same civil rights, and ready to receive those who from any cause were unable to get a livelihood at home. One point he must say a word upon, and that was the question of the Irish in Canada. He was proud to say that amongst the Roman Catholics of Canada, numbering nearly a million, the most loyal sentiments were entertained. It was a proud thing to be able to say that the same sovereign that ruled Ireland ruled Canada, and the Irishmen there, with scarcely an exception, were as happy and contented as those that came from England and Scotland.

The paper read was—

CANADA AND ITS PRODUCTS.

By the Most Hon. the Marquis of Lorne, K.T.

Late Governor-General of Canada.

With respect to the climate of Canada, so often held up as a terror, except upon the sea coast, there is but little moisture in the air; and although the thermometer goes down far below zero during some of the winter nights, men feel the cold far less than on the sea coasts of England and Scotland. I remember visiting a place in the plains of the central part of Canada, where perhaps the cold causes the mercury to fall to the lowest point it reaches in the Dominion. I was met by a number of the residents, who were good enough to come to tell me of their experiences in their new homes. With settlers from the Eastern Provinces were mingled others who hailed from England, Ireland, and Scotland. I had received satisfactory accounts of the year's excellent crops from all, and then put questions to them as to the advantage or disadvantage of the climate as compared with that of other places. Several had borne evidence of the healthfulness and purity of the air, and to their preference for it as compared to that of any region they had known, when up pushed a sturdy Irishman, who said :—"I want you to tell this to my people at home. I come from the County Armagh; and I was thatching my house last year in the cold weather, and I felt it far less than I did the last time I thatched my house in Armagh."

When agents of railway companies, and men interested in the South, try to persuade settlers to go down to the South and settle in some parts which are notorious for their cyclones, snakes, and centipedes, it is well to remember how healthy the conditions of life in the North are, to what a great age men usually live. Throughout old Canada and British Columbia, and to the north of the Great Plains, there is not any place where the settler can want for wood and fuel. People, indeed, get too much of the forest; but what a blessing it is that the stove can always be replenished with logs of any size at will, that a house as comfortable and as warm as any can be put up in a few days for so little money, and that, unless a man voluntarily exposes himself to the weather, he need never fear the consequences of the cold season; and where the pine woods fail on those great prairies, of which so much is now said, what is now happening? One great railway already traverses these plains throughout their entire breadth of 800 miles. Branch lines are being rapidly formed, and each train may carry firewood enough for the use of half a settlement for the winter. But these trains are now carrying more than wood, for under the shadow of the Rocky Mountains lies a province, recently named Alberta, where is a great zone lying for hundreds of miles north and south, and with a breadth from east to west of thirty or forty miles, the country is found to be rich in excellent coal. There is a fine specimen in the room from the mines of Sir A. Galt, who has taken land in several places, and the Canadian Pacific Railway regularly uses that procured from his works. As you approach the mountains, the coal seams become always of a better quality, until in the mountains anthracite itself is found. Comparatively nothing but mere surface scratchings have as yet been undertaken, and to judge from the coal lumps washed down by each of the streams near the hills, and the exposed sections often visible, there must be a vast quantity. Deep borings will no doubt now be undertaken. Already the railways carry the stuff for one and a-half cents. the mile, and the price of coal fuel will readily decrease as more works are opened, and more seams are worked. The quality hitherto found closely resembles what is procured from Vancouver Island, where mines are worked near the water's edge, and the produce taken to San Francisco, fetching a higher price than any at that port.

Away beyond the mountains, and down the Pacific Coast, we come upon a land whose climatic conditions are totally different, namely, a land called British Columbia—an immense land of mountain, forest, and flood, the Alpine ranges soaring in some of their peaks to the height of Mont Blanc—a land in the main so deeply and wonderfully forested that you may, on its sea coast, cut timber thirty and forty inches square, of a uniform size for one hundred feet—a country where the rivers rush impetuously through tremendous gorges, to run in shorter navigable reaches into harbours which are defended by a gigantic natural breakwater formed by the immense rocky island of Vancouver. Here, on this island, we have a climate like that of the south of England. All the shrubs which are familiar to you in the gardens about this city, and many more which would be too delicate to grow here, thrive in that favoured island. A great deal of it is mountainous, and practically unknown. To the north of it lie other great groups of islands and more mountainous coast, and the climate is again mild, but the rainfall is heavy. In the interior of this Canadian Switzerland you have strange variations of climatic condition within narrow areas; you may have a farm in a beautiful rich valley, surrounded by magnificent woods, and five miles off you may go and pay a visit to your friend who has another farm, and find that his place has such dryness that not only will it not support the heavy timber growth with which you are familiar on your own homestead, but your friend has even to bring water to irrigate his garden, which, with this provision, will produce even more richly than your own.

And now let us turn to the gigantic enterprise, the Canadian Pacific Railway, involving so much outlay and so much labour, and now being pushed with such energy and success.

You have heard how an American company, some years ago, constructed the railway which runs through the Mormon settlement of Salt Lake City; you may also have been told how another line now sweeps round by the south of California, and by the frontiers of Mexico, and across by the cactus-covered deserts, and wild torrid sands of Arizona and New Mexico, until it reaches the East and the connecting lines of the Atlantic companies on the Missouri and Mississippi. You may also have been told lately of the remarkable progress made by the Northern Pacific in the Northern States, thus giving the Republic three lines which cross from shore to shore, but in none of these cases have the lines been pushed with the speed, certainty, and thorough workmanship which has been exhibited on the Canadian line. The American Northern Pacific Railway Company was incorporated as long ago as 1865, nearly twenty years ago; whereas the Canadian company has been at work less than three years. Richly endowed with magnificent lands, the equal of which can only be found in the favoured American States of Illinois and Ohio, the British company has spared no expense to make the track so perfect that trains passed over it at great speed as soon as it was laid. In one week, during the last summer, no less than between twenty-five and thirty miles of railroad were laid and completely finished; and almost incredible as it may seem, it is yet a fact, that on the Saturday of that week over six miles of track were put down. It is a beautiful exhibition of perfect organisation to watch the manner in which this is done. First come the engineers with their levels; closely following them an army of spade men, who raise the embankment, or cut through the earth mounds, removing by blasting any obnoxious rock. Then, to the end of the completed track, and piled on vehicles drawn by well-equipped numerous teams, arrive the ties, or as they are in this country called, the sleepers, or wooden cross beams. Quickly these are scattered along, and laid by gangs in order. Instantly up comes a car laden with steel rails —steel rails, which, by-the-bye, have been imported all the way from the Old World. With iron hooks the men grapple these rails one after the other, and as each pair is laid upon the sleepers, boys place a couple of great nails along the line, and the sturdy hammermen with a few strokes drive these into the wood, fix the rails, and onward over the fresh joint of railway goes the car, until all its load of steel rails have been deposited. Imagine the perfection of the organisation which, in the prairie untrodden as yet by men, or still worse, in the rock-strewn and mountainous country, can on a single line of rail arrange for the accommodation of men, for the transport of material in wood, iron, and provisions, and can send on train after train to the end of the track, arranging the sidings as they proceed and accomplishing such feats as that recorded of the week of which I have spoken to you. You may ask how it is that such expenditure can be incurred, that work can be so quickly and so perfectly finished by such armies of workmen; for many thousands have been labouring during the last year, and are still labouring at this great national enterprise. The secret is in this, that the lands in the central portions of the Continent which have been granted to the company are of such excellence, that from their sale alone a certain remuneration can be expected. Emigration has poured into that region in a manner unexampled since the days of the settlement of the great western commonwealths whose chief and most remarkable city now is Chicago. In spite of opposition encountered from interested rivals, the fact of the excellence of the soil has become so patent that there was no difficulty in finding the money for the first great expenses, and the initial cost is always far the greatest. With the Americans, the Germans, the Russians, the Icelanders, and the English, Scotch, and Canadians, who are now flocking into the country, to the tune of 40,000 or 50,000 in each season, the traffic which must be developed to supply their wants in wood, coal, and the necessaries as well as the luxuries of life, must continually increase. It was only two years ago that the line left the suburbs of Winnipeg; it was only yesterday that it touched the mountains of the west, and already a vast increase in its traffic receipts are noticeable. It is not as though it started from no basis, and ended in no important terminus, or passed through barren lands on either side; it will rest upon two great oceans, and throughout the middle portion of the continent it has land, not only along its line, but also to the north and south of it, unrivalled on the continent of America. The branch lines, whereever they stretch towards the north, must feed its energy, and supply it with nutriment, for there is practically no limit to the vast area of wheat which may be created along the banks of the North Saskatchewan River, and the immense country lying towards that mighty stream, the Peace River. There is everything to attract settlement, and nothing to repel it. The man who desires to farm should have £100 to £500, according to his wish for a large or small farm; the labourer, the blacksmith, the bricklayer, and mason, may go with the assurance of finding work.

There is nothing so interesting as the first exploration of a new country destined to be a highway. Until this autumn, it was doubted if any good passes could be found through the Rocky Mountains, west of the Selkirk Range. Mr. Sandford Fleming, formerly chief engineer to the Canadian Government, was this year commissioned to accompany the present Canadian Pacific Railway engineer, Major Rogers, through these mountains, and to report. He had a hard time of it; but his account shows that although the passes are steep, involving heavy gradients, there is nothing that cannot easily be graded.

Let me give you a few extracts from his note-book, which I have only just received. The ground is all new, and he and his party went through country where no white man, and, probably, no Indian had before trod, in the transit across the central range, between the two great bends of the Columbia. You will see that the tourist and artist will have wondrous scenery on the Canadian Pacific Railway. In ascending from Morleyville "the valley is from three to eight miles wide, extending in a generally western direction between the foot hill of the Rockies. There are no sudden ascents, and the prairie country is gradually continued into the heart of the mountains by this valley. David Macdougall informed us that he has seen the valley black with buffalo, and from an eminence not far from Morley he has beheld at one view a herd estimated at not less than a million buffalo. As we advance, the prairie diminishes in extent, and we pass through park-like scenery. We find groups of trees at intervals, and the Bow River gleams in the sun at its various turns. A magnificent geological expanse presents itself. The mountain to the north of us is nearly perfectly bare, for 1,500 feet high nearly vertical, and possibly two miles in length, the lines of strata can be distinctly traced, all dipping in a westerly direction. Four miles above Padmore, we are completely in the mountains, the sound of hammer and drill echoing and re-echoing on every side. The Cascade Mountain has a small stream issuing from its side, possibly 1,000 feet high, and reaching the valley by a single leap. This is the most striking mountain we have yet seen in the valley. The engineers, whom we met a short way from the spot, had measured the height at 5,060 feet above the plain. We had a pleasant canter for twelve miles up the valley, between mountains of the grandest description; to the south of us two of great prominence present themselves. They command a valley leading to Vermillion Pass. They are of striking beauty, and one of them is crowned by a cubical mass covered with perpetual snow. The other is pyramidal in form. We proceed westwards, and we behold Castle Mountain to our right. The resemblance to Cyclopean masonry has doubtless suggested its name. This is very marked in its huge masses and tunnelled flanks.

"Our ride to-day is most agreeable, part of the way through Banksian pine, and occasionally by an immediate bank of the Bow River, which is still a large stream—larger a good deal in volume than the Thames at Richmond.

"The current is very strong, and it would prove a hard task to canoe up stream even with poles, as on the rivers of New Brunswick. At other points we ride through burnt wood, where fire has recently destroyed the groves of young timber. In consequence of the fires the air is smoky, and we cannot always see the mountains, but occasionally a snow-covered peak appears far above the dense smoke below. To the south of us we see what the map shows to be Mount Lefroy, but there are several lofty summits, any one of which is sufficiently remarkable to be named after the distinguished general. One of these is crested like the back of a huge camel. Another rose up to a sharp cone. Looking across the lake to the south, a vast mountain with snow-filled crevices stretches. This is a remarkable mountain, and makes a grand picture with its reflection in the bright lake. We cross the outlet of this lake by fording a clear, cold stream, some 40 feet wide and 16 inches deep. This is the commencement of Kicking Horse River, a stream which we have to follow for some days. It received its name, the Indians informed us, in Dr. Hector's time, who, it is said, was kicked by a horse not far from where we are now. The valley goes by the same name. The Indian name is something more euphonious —Shawatu Nowchata Wapta (Horse Kicking River). We are now entering, as our guide informs us, the worst five miles on the road to Columbia. It proves bad enough, and we move at a snail's pace. The poor horses have to scramble as best they can over rocks and other obstacles, in many places almost perpendicular. Three packs come off, and one horse rolls down the side hill, turning a complete somersault, but the pack being firmly secured to his back, probably saved him from injury. He is soon relieved by Wilson and Dave cutting the pack ropes, and lifting him to his feet again. We are seldom in the saddle, it being safer and pleasanter to drive the horses before us. The river comes in sight now and then, and passing over foaming rapids inclined at a general inclination of from 1 in 5 to 1 in 8, the water is soon churned into liquid. Before we reach our camp ground for the night, there opens up to our view a magnificent mountain spectacle. Looking up at an angle of probably 60 degrees, we see high in the heavens a great mural crown, variegated with the different coloured strata, nearly horizontal, and lighted with the bright sun. Separated from this mountain top by a great depression there is another equally lofty, and both are undoubtedly fully a vertical mile above our heads. On the mountain last referred to, some distance from the summit, we observed a great glacier overhanging a precipice below it, and presenting a vertical face of hundreds of feet in thickness.

"Our journey to-day proves exceedingly rough. We have to cross many gorges, some of them so narrow that a biscuit may be thrown from the last horse descending to the bell horse six hundred feet ahead. The fires have been running through the woods; they are still burning, many of the half burnt trees have been blown down, obstructing the way, and making it difficult to proceed. The delays are frequent, and ascending a long slope by a narrow path the footing of one horse gave way, and down he went, rolling over and over half a dozen times. Of course we thought he was killed, but Dave and George unfastened the load, and speedily got him on his feet from a depth of some fifty yards below the trail. As we proceed, our travelling does not improve. We have many miles through burnt woods. Fortunately the air is still, otherwise we would have the blackened trunks falling around or upon us and still more impeding our progress. Down and up gorges hundreds of feet deep, across rocky slides where the poor horses had to clamber, or between sharp points, running the risk of breaking their legs. The trail, to avoid a series of precipices, running sheer up from the boiling river, has been carried along a side hill to an elevation of some seven or eight hundred feet. The sloping ground is so steep that not a vestige of vegetation is to be seen on it for a long distance. The path we have to follow is exceedingly narrow, so narrow in places that there is scarcely a foothold. For five or six miles we have to travel over ground of this description, fitted only for the mountain goat or the chamois. We crossed clay slides and gravel slides at a giddy height. One cannot look down. Some three miles from the mouth of the Kicking Horse River, we met Major Rogers and Major Hurd, and secure our first glimpse in the distance of the Selkirk range. The sun beats down with great power. We are wet with perspiration. At last we reach the valley of the Columbia, where it is some twelve miles wide from peak to peak. We have travelled the whole length of the Kicking Horse River. From the summit to the flats of the Columbia the distance is nearly 50 miles, the descent about 2,700 feet, and the average fall about 57 feet per mile. Of this fall the first six miles gives a descent of 1,200 feet, or 200 feet per mile. The last ten miles the river falls on an average of 60 feet per mile, leaving for the intervening 32 miles an average fall of less than 30 feet per mile. We reached this point by a tributary from the east, the Kicking Horse River. This mountain torrent rises in the main crest of the Rocky Mountains, and flows for a great part of its course with tremendous impetuosity. For the first six miles from the summit, and the last ten miles, it passes through canyons. The descent in the upper canyon is violent, but the volume of water in the lower canyon makes the stream much more formidable before the Kicking Horse joins the Columbia."

Down the Columbia.

"*Saturday, September 1st.*—The Columbia River rises some seventy or eighty miles north of the International Boundary Line. It flows north-westerly 180 odd, or 200 miles, to a point on the 52nd parallel, known as the Boat Encampment. At the Boat Encampment it turns almost completely around, and flows nearly due south for more than 300 miles. Thence it takes a westerly course to the Pacific coast. Before crossing the International Boundary Line, it flows 400 miles through Canadian mountains. The second half of its course is through the United States. On Monday morning we will descend the Columbia in a canoe or boat, and overtake the horses a day's journey from here.

"*Sunday, September 2nd.*—This is a delightful Sunday morning in the valley of the Columbia, with the great Selkirk range in front of us. We see high peaks as far as the eye can scan, away to the east and north-west. We do not see the Rockies, as we are at their base, and they are concealed by a high terrace, but we can never lack company in presence of the mighty Selkirks. A great glacier is visible to the south, and huge snow fields lie between the peaks of the mountains generally. This is not fresh snow, as none has fallen for some time. This, therefore, has remained from former years. There are, in descending this river, long reaches of comparatively smooth water, then ravines which form simply a rapid portion of the river, where its waters pass through a somewhat contracted portion of the channel. There is nothing to prevent canoes or boats safely running these rapids. Indeed, a steamboat could go down, and it is less turbulent than the rapids of the St. Lawrence. There would, however, be difficulty in getting any kind of vessel up. The Indians in this country do not use canoes to any great extent. When they travel, they generally take horses with them, and follow trails where trails are possible. After leaving the canyon, we travel along the edge of the river, through flats, to our camping place for the night, opposite the mouth of the Beaver River, which falls in on the Selkirk side. We are now some thirty miles north-westerly from the mouth of the Kicking Horse River."

Crossing the Selkirks.

(Ascending from the East.)

"Leaving the River Columbia behind us, to be again seen and recrossed, we trust in about a week, after we have ascended and descended the Selkirks, we follow a roughly and recently made trail by the edge of the Beaver River. The Beaver River is quite a large stream, and, passing through an open canyon for some four or five miles, is quite unnavigable. There are few places where it could be forded. After passing the contracted valley near the mouth of the Beaver River, the hills recede, and we pass through a flat and well-timbered valley from a half to a mile or more in width. There is a dense growth of cedar, spruce, and cotton-wood. Cedar as much as four feet in diameter, and spruce three feet in diameter, are quite common. The undergrowth is now decidedly the flora of the Pacific slope. Everywhere the prickly auralia, or devil's club, ferns, skunk cabbage—all of rank growth—are to be seen on the low ground. There is no pasture for the horses. We followed Bear

Creek to the west for a short distance, passing through a tall forest until we reach a regular mountain defile leading up to the summit. The mountains are high above our heads, and although late in the forenoon, the sun is hidden by them. We cross many old avalanche slides. On the southerly side of the valley great scours in the mountains are seen filled with snow, some not more than two or three hundred feet above the bottom of the defile through which Bear Creek flows. To the north there is a great glacier, possibly fifty yards thick where it terminates. It comes from a point far back beyond our view. Underneath the glacier there are traces of a very heavy snow slide, where trees have been broken and crushed in all directions, and judging from the age of the timber, this slide must have occurred a considerable time back. It was caused probably by the breaking off of a large portion of the glacier. We are sitting on a rich meadow 4,600 feet above the sea, surrounded by great mountains of all forms, some pyramidal, some rounded and serrated with glaciers between them. Looking west there is an open valley with great peaks in the dim distance, and looking north in the direction from which we have come, there is certainly the grandest view of all. The valley is completely enclosed by what seems to be impenetrable mountains. The defile through which we have entered is not visible, and high up near the lofty peaks there is a series of glaciers stretching out a mile or two from north to south. The entrance through which we have come opens up faintly to view."

Descending the Western Slope.

"Leaving the grassy plain at the summit, we descended very rapidly, coming in sight within half-an-hour of a conical peak to the south-east, of great prominence. This cone was possibly a thousand or fifteen hundred feet above all the other mountains, and terminates in a sharp cone.

"Our journey this morning begins as it ended yesterday, along the edge of a rapidly descending stream, walled in by mountains thousands of feet high. Fourteen miles from here we find two large patches of snow or ice, one on each side of the river. This, we were informed, had been seen three years ago, but then they were much larger, and formed a bridge across the river. An avalanche had slid down from the mountains, but how long ago no one knows. All that we do know is that the remains of the avalanche was seen at this point three years ago, with a passage underneath for the water to flow. The walking is dreadful, climbing over and creeping under fallen trees of great size, the men soon feel the burdens they carry, and rests are frequent. It is hot work for all. The wet bushes make us wet from without, and the perspiration makes us wet from within. We meet with obstacles of every description, including millions of devil's clubs. We have to rest every fifteen or twenty minutes, and proceed again. The travelling, however, is varied from time to time in climbing up or down the rocky slops, to walk through alder swamps, treading down skunk cabbages, and fighting the prickly auralias. The toil continues hour by hour, with intervals of short rest, until half-past four in the afternoon, when, the men tired out, and unable to go further, a halt becomes necessary at the best spot which we can secure. We select a high bank, overlooking the Ille-celle-wate, and there rest for the night. The Ille-celle-wate here has increased from a tiny brook to a raging torrent more than forty yards wide. The colour of the water is much the same as that of the Thames in London. The valley we are in is very narrow. It is bounded by lofty mountains, wooded a long way up. Their summits are generally concealed from us by the forest, but occasionally during the day we have seen snow peaks peering over the lower elevations. In some portions of them never a stray sunbeam reaches them. The vegetation, in consequence, is peculiar, and mosses of every variety are found. The ferns, where the soil is rich, are as high as a man's head, and the auralias and skunk cabbages are as rank as possible. Here and there, on some rocky point above the deeper portions of the valley, we found many berry-bearing shrubs, the fruit of which was extremely palatable to us, although all were somewhat acid. We reached the lower canyon of the Ille-celle-wate, where we are compelled to clamber around from rock to rock, holding on to, or swinging ourselves by, the stunted trees and twigs which grow at intervals. At some places the men had to be unpacked, and they had to draw each other up by hand from one ledge of rock to another. At other points we had to climb along narrow ledges, creeping under a cascade, or over a point of a precipitous rock. But we at last reach camping ground. n about a half-a-mile from our starting point, we reach a jam of logs not far from the lower end of the canyon. Tree after tree has been piled here, for nobody knows the number of years, until a space of some hundreds of feet up and down stream is filled in inextricable confusion, to a height of at least thirty feet above the level of the water. Here is an accumulation of material which, if in London, would make a fortune for any man. We trudge along at a brisk rate through ground much the same as yesterday. Abundance of devil's club and fern, brush and logs, and every conceivable thing impeded our progress. We follow the same system of travelling as was found so excellent yesterday, resting five minutes every twenty minutes. We halted for lunch at noon, and it was suggested that we ought to be within the hearing of a gunshot on the Columbia. We expected a party from Kamloops with supplies to meet us, and they ought to be at the Columbia before this. Accordingly, I fired two rifle shots. In a short time we heard a gunshot. Our hopes were immediately raised. In reply, three more shots were fired in rapid succession, and in a little time we distinctly heard in reply one, two, and three shots. Our delight can well be imagined. Hurrah! hurrah!! hurrah!!! We have our connection with our party from Kamloops. Our lunch is soon over, and we are off, greatly excited, to get the first glimpse of the Columbia River. But we have a good way to travel still, and a five minutes' rest is called for. Here we fire another shot. Immediately we hear two shots in reply, more distinctly than before, and we are off in a bee line in the direction indicated by the shots. Soon we are out of the green woods, and in sight of the Columbia. We see smoke ascending from a camp on the opposite shore a mile away. It is undoubtedly our Kamloops friends. We see two canoes crossing the river, which is here known as the Great Eddy of the Columbia. We wait patiently on the high sandy bank in full view of the Eagle Pass directly opposite. Our hopes are soon dispelled, the canoes contain Indians who can speak no English, but, with the help of a little Chinook jargon, we learn, to our great disappointment, that no one has arrived from Kamloops. The Indians replied to our shots, and they belonged to a small hunting and fishing party who had been encamped at this place for some four weeks. They have seen no one whatever from Kamloops. Every joint ached. Our flesh was lacerated in places. Our hands were festering from the pricks of the devil's club. We knew we would have a great deal more of it before we could reach Shuswap Lake, and our food was very limited. We were short of men to carry it. We were terribly disappointed that the Kamloops party had not arrived. We were not ahead of time, but they were behind the time named. They were engaged by the Hudson Bay Company to meet us without fail. The head offices of the company were informed repeatedly that we would be absolutely depending upon them for food. True, we had one alternative. Providentially, the Indians were available, and we could possibly persuade them to paddle us down the Columbia to Fort Colville, and from this find our way to Victoria by the Northern Pacific Railway; but we could not entertain the idea of making a flank movement. We started to reach Kamloops on as direct a course as possible from Calgarry This is the work which we set out to do, and we have not yet done it.

"*Wednesday, September 12th.* — The much expected party from Kamloops has arrived. Five men issued from the woods on the flats of the Columbia a short distance from our camp. They have been sent with supplies to meet us at this point, and, on their first appearance, they were hailed with great joy. To-day we pass along a path used by the Indians for carrying carriboo and other game from the mountains. Near this the partridge berries were very large, almost like small grapes, and pleasant to the taste. We saw also abundance of large huckleberries and blackberries. Surely, when fruits grow here so luxuriantly, garden fruits might find a home in this sheltered valley. We are fast ascending towards the summit. The valley is probably a quarter of a mile wide, walled in by parallel mountains, for the most part wood to the top. As we proceed we pass through a fine grove of open wood, chiefly hemlock, suitable for railway construction. We cross the summit stream several times, and about five p.m. encamped on its western side, in a small spot which we find free from devil's club, and great cedars four feet in diameter rising like the columns of a temple around us. Within a circle of a hundred feet radius the eye may count forty of these large trunks. We are at the summit of the Eagle Pass, although scarcely yet in the heart of the Columbian range. We are only four hundred feet above the Columbia, and to-morrow we will be following a stream falling towards the west. Then through a series of lakes they pass down the Eagle river, which leads them to the British Columbian lakes, whose steamers take the lumber through beautiful wildernesses, and reach Kamloops, where the railway is all but completed, and then down the Thompson and Fraser gorges to the sea-coast, where we have no time to follow them, very interesting as hose regions are."

We can now return to the plains, and look at the Indian Nomad tribes. A law exists throughout our territories against the sale of whiskey, a law vigorously enforced. Whiskey is the bane which drives the savage wild, and is the fruitful cause of every crime amongst the white men in the American western villages; and the prohibition placed upon its use does much towards preserving order among the young communities of a British soil. You do not hear in villages in our land, as you do hear it said further South, that "shooting was pretty lively here last night." There is a story that, in a Colorado ball-room, it was necessary, on account of the manners and customs of the inhabitants, to write in large letters over the head of the unfortunate gentleman who had been detailed to perform music for the evening's amusement, "Please don't shoot the pianist, he is doing his best." If trouble occur in our Canadian West, it is promptly suppressed, and the guilty ruffian handed out. Ample provision is made, as the country settles up, for school purposes, nor are the spiritual wants of the people left unheeded. The Roman Catholics were early in the field, but Anglicans, Presbyterians, and other denominational bodies have quickly followed in their steps, and many a devoted servant of his church is at present labouring among the scattered population of every part of the territories. It is interesting to see how originally wild savage bands are becoming tame and half civilised.

It is only a few years ago that, near our line, a band of Sioux, under the leadership of a chief named Sitting Bull, achieved a victory over a civilised force which has no parallel in the annals of any recent war between civilised and savage troops, except the single case of Isandula. General Custer, one of the most gallant officers of that gallant Northern Army—a man distinguished for intrepidity and skill in the war against the Southern Confederacy—had been appointed to a command of cavalry not very far from our frontier line. As is too often the case, unnecessary quarrels had led to unnecessary fighting between Uncle Sam's boys and the braves under Sitting Bull. Custer, coming upon their camp in a place chosen with rare skill by the savages, impetuously ordered an attack. Accounts vary of the struggle which ensued, but the story must necessarily come chiefly from one side, because no American soldier lived to relate the tale. The Indians say that the white men advanced in two columns; that they had, to a certain extent, by twisting willow-growth and grass together, been able to make some defence, but the ground was favourable to the repelling of the assault; that the Indian women were sent out of camp, but that a child had been forgotten, and, just before the battle was joined, the chief's wife came riding up, and took the child up, and rode away with it, while already under range of the American carbines. As the troops came on they were greeted by a hot fire, and an impetuous charge of the red men, who, by this time, had partially surrounded the attacking troops. Something like a panic seems to have ensued, for the Americans broke and ran—several, as it is narrated, blowing out their own brains in order to avoid falling into the hands of the merciless foe who, mounted on swift ponies and armed in addition to their rifles with the terrible coupe-stick, or battle mace of stone, carefully carved into double points, and roughly fastened to a pliant and long handle formed of buffalo skin, dealt the flying enemy a blow on the head or back which caused him to sink dying on the grass A terrible fight, without quarter, it was, for the ghastly bodies of the dead soldiers, with the bleeding skulls where the scalps had been torn off, were alone left to tell what had occurred. It was greatly to the credit of the American people that when years afterwards we wished to get rid of Sitting Bull, who had taken refuge on Canadian soil, amnesty was granted to him and his people, and in reply to the query addressed by the Canadian Government as to his probable treatment should he surrender to the Americans. Mr. Evarts, United States Secretary, replied, "He will be treated as a great nation always treats its prisoners of war." We were anxious to be rid of his presence, for he and his 5,000 were eating up the scanty game of our own Indians, and he himself, from his well-known astute and warlike character, gave anxiety to us, in that we never knew whether he were not harbouring against our republican friends some evil design. He was often reported as about to embark in a raid or cattle-lifting expedition, an amusement for him which it would have been difficult for us, at that time, to prevent, and which might have yet led to a rupture of that friendship and excellent understanding which has most happily always prevailed along our north-western borders. The redoubtable Sitting Bull and his tribe are now safely placed upon an American reserve of land, where the old warrior will be allowed to end his days in peace, and in whatever comfort the industry of his people and the generosity of the United States Government may bring him. After the Sioux, the most interesting people now left, and still retaining much of their aboriginal traits and customs, are the Blackfeet. Their braves say that their first ancestor received from the morning star, their war god, a magic ointment, wherewith if he anointed his feet, he would be endowed with such swiftness that the antelopes would flee in vain before him. There are many stalwart men amongst these people, and it was most interesting to observe them in the great councils we held with them in 1881. They came to the appointed place of meeting mounted, and in full battle array, firing their Winchester repeating rifles in the air, and shouting and waving their weapons. Behind them tripped, in gay colours, the women, bringing their children, for the children could not be left in camp, and the women must see what their lords and masters were after in their conference with the white chief. Arrived close to the tent where I awaited them, they sprang from their horses, and advanced to shake hands, which ceremony was performed by the chiefs and the head men; these then sat down in front of me, the chiefs in the front row, the head men behind, and ranged around in a deep half circle was the rest of the tribe; on the right an allied set of cousins, with their aunts and sisters behind them; while on the left, in triple ranks, crouched on the ground, sat the warriors, round limbed and lithe young fellows, clad with little but paint on the body, and with long war locks, braided with brass, depending from their temples; the rest of their hair—after being gathered up upon the crown, so that if an enemy wanted to have a good tug at the scalp, he could do so without trouble—being allowed to fall in long dark masses over their shoulders.

From the flank of the line of braves, round in front to the right, stretched the ruck of the tribe and the women and children. A good deal of quiet sitting and smoking was indulged in before a word was spoken, and then it was always necessary to look on at a dance for some time longer, before business was opened up, for nothing could be done until the pipe had been smoked and a dance had been performed. Strange, and weird, and uncouth these dances are; the magicians sit on the ground beating a tom-tom, and in a circle, following each other in single file, strut, and bow, and jibber, and jig the braves detailed for the duty, making hideous noises, and pretending occasionally to be in pursuit or in flight, round and round they go until the music ceases, when all sit upon the ground. Sometimes the young men would insist on recounting their deeds in war, boasting of stealing cattle and of killing their foe. When by these processes the chiefs have sufficiently gathered together their thoughts to be able to detail their desires, each man rises in succession, and speaks, while the interpreter stands listening, and at intervals turns to the white chief, and tells him in substance the eloqnent and fervid harrangue to which all are listening. Usually, amid much flowery rhetoric, the speech resolves itself into a demand for more favours, and is, in short, nothing but an exclamatory beggar's oration. Often the interpreters will not take the trouble to render all the flowery language, although they themselves are half-breeds. On one occasion, after much eloquence had been exercised for an hour, and the interpreters had said nothing, it was asked, "Why do you not interpret—what does he say?" All the translation vouchsafed was,—"Oh! he say grub!" The pleading for this very necessary article was backed by the certainly very cogent argument that the coming of the white man had taken from them their land, or rather, what they valued upon their land, that is to say, their great game, the buffalo; each year the white man's presence had marked a decrease in the buffalo; and what was the Indian without the buffalo; how could he get skins for himself, for his house; how procure food or sinews to sew the clothing together; how live without his beloved buffalo. The argument would certainly hold good, for although it is the improvement in the weapons of the chase, and the introduction of fire-arms, which has mainly contributed to diminish the numbers of the buffalo, yet the very introduction of these fire-arms was due to the coming of the stranger. And what does the white man give in return for the evil thus inflicted? He gives 5 dols. for every man, woman, and child in the tribe, every year, to the chief to be apportioned for the good of his nation; he gives, also, when he is obliged to do so, a ration of flour; and he gives above all, and every year to an increasing degree, that knowledge of husbandry which can alone save the red race. Already, in 1881, although these Blackfeet, of whom I am speaking, had but lately been engaged in hunting parties, some effect could be produced upon them by speaking of the advantages of potato growing. After haranguing them upon the subject, the chief warrior rose when the council had finished, and grasping my hand, and putting round my arm the bridle-cord of his horse, he asked me to accept the animal as a present (which, of course, could not be accepted), and repeatedly assured me that, although he had hitherto been the first in fighting, he would now be the first in working. I am sorry to say, he did not seem very much pleased when he afterwards received a fowling piece instead of a rifle for a present, but the latter would have been of no use to him for duck shooting, and I hear that he has kept his promise, and got his own potato patch this year. There is another great and scattered people, the Crees, and yet another with a stranger name, dwellers in the rocky country on this side of Winnipeg, but calling themselves the Ojibbeways. Differing in origin and language, the red men fought constantly against each other, and these wars, and the epidemic diseases to which, as they averred, they had become subject after contact with the whites, made them less numerous than the enormous extent of country over which they hunted would lead us to suppose. It is, however, only when the savage cultivates in some measure the ground that he can greatly multiply. Champlain and Frontenac found the Indians of the St. Lawrence growing corn. There is no evidence that the wild horsemen of the plains ate of any plant sown by their hands. In warfare they employed some methods of defence and communication which show that recent European army regulations enjoin practices long known to Sioux and Blackfeet. Thus, pits, whence the archers could discharge their arrows, are seen within the lines of old entrenchments; and when the Canadian Mounted Constabulary regiment first entered the "Lone Land," they found that their movements were signalled to the tribes by a very good "heliograph" system of "flashes." No such signalling was at that time known in our armies, and the troopers, as they rode along over the vast grass-covered plains, could not at first understand the twinkling of the sun on the little mirrors of the "intelligence department" of the savages.

Amongst all these tribes the custom was formerly universal, and still obtains, to a great extent, to have a great annual feast called the Sun Dance, which is the occasion appointed when the young men may show of what mettle they are made by undergoing a voluntary torture. If I shock you with the details of these proceedings, pray stop me. The medicine man, the sage herbalist, doctor, and mystery man, stands in a great circular tent made of boughs, or skins, fantastically adorned with head-gear, and painted with streaks of orange, crimson, or blue; he has in his hand a gleaming knife, and when he is about to perform the final ceremony, the victims have already fasted for many hours. They come one after another and stand before him, and on the chest of each he makes four cuts, so as to divide the flesh into two bands; in the bleeding wounds he places two long spigots of wood, lifting the muscles so as to pass these through the incisions in the flesh. He then attaches to each end of each spigot of wood, cords, which are run up round a central pole. Then the drums and tom-toms beat, and while all stand admiring their courage, one youthful warrior after another tries to break away from the attached cords. The muscles start and strain, and the flesh is extended far from the chest; the wounds gape, and the sight becomes horrible, for the agony is dreadful. Still the wild dancing or hanging on the cords goes on, until the man falls exhausted, but free. It is almost inconceivable how much can be endured by these young men in their efforts to prove themselves worthy, in the eyes of the women and others of their tribe, of the manhood which gives important privileges that belong to him who has shown himself bravest in the camp of the savage. Buffalo heads, guns, and other heavy objects are dragged about attached in the same horrible manner, while it used to be considered a proof that the man would be the best at stealing horses who attached himself by the shoulder-blade to horses whose every motion as they stooped to feed brought a fresh pang of pain.

But enough of these terrible rites: they still continue, but the number who undergo the torture is diminishing year by year, and we may trust to missionary efforts to put an entire stop to it before long. Much is said of the knowledge possessed by the squaws of simples; it is certain that they are very clever in producing decoctions and in making poultices from various trees and shrubs whose healing properties are well known to science. Thus, from the bark of a certain species of willow, a preparation can be made which staunches hemorrhage, and quickly heals a wound. Strange tales were told us of the efficacy of some of their medicines. A gentleman employed in botanical research was puzzled by an application made to a slight wound he had sustained; he had, when shooting, hurt his thumb by the accidental discharge of his gun, and for some days, having nothing but water with which to bathe it, he was in considerable pain, and the thumb became much inflamed. Lighting, in the course of his march, one day on a camp of Sioux Indians, one of the women observed his hurt; she came to him, and gave him a milk-like liquid, and told him to apply this when he felt pain; he did so, and from the first application the pain ceased, and in a few days a very complete cure was effected. A sergeant in the Mounted Police was an eye-witness of the effects of an opiate given to a man for whom the ordinary remedies of opium, laudanum, and chlorodyne had proved useless. It was evident that the medicine man had some good stuff, although it was equally certain that he employed a great deal of what is known as *hocus pocus* in applying it. He asked for a vessel, and after a time poured into it a white liquid he had concocted. He then covered this vessel over with a skin, pierced holes in the covering, rolled up some pellets of buffalo hair in his hand, muttered some pretended incantations, and dropped these balls of hair through the skin into the liquid. After a while, the covering was removed, and it was seen that the vessel held no longer a white but a red liquor. This, with an amount of faith which one does not often find in a sick patient, was drained by the invalid, and a sound sleep, which was the beginning of a perfect recovery from the illness, appeared to be the result. There may be something worth discovering in the application made by the Indians of certain herbs, but it is to be noticed that the roots and plants hitherto found in the medicine-man's lodge have, as a rule, been plants whose properties are already well known to science. It is only as a matter of curiosity, and to vary the subject, that I have spoken at such length of the few savage tribes which yet remain in possession of their old customs and manners, for they do not form by any means a prominent feature of even the most unsettled portions of Canada. The talk is not of Indians but of engines, of the plough, of the self-binder, of the reaper, of the hay-cutter. It is of the price of timber for building, of the advantages of the long grass for thatching, of the utility of straw for burning, and of the great output of coal which is already assured from the newly-opened mines at Alberta. The expectations are not of a visit from the wild man, but whether the splendid crop in the ground shall be visited by any early frost, and of the facilities in the way of transport the railway already affords, or such and such a projected line may still further increase; or if a new steamer on some great river will be able to make her return trip in time to carry off some of the superabundant grain. And where you question the farmer, he will tell you that his roots were this year, and last year, and the year before, marvellous in size, and that, as a rule, his acre gives its thirty bushels of wheat.

As this is intended as a paper speaking only of the main features of the country which are of popular interest, and as drawing your attention only to the subject, which is treated in much fuller detail in the papers and pamphlets issued by railway companies and by local governments in connection with the country, I shall here say no more, but ask you to give your attention not only to the prospects of the recently opened land, but also to the very inviting districts which are to be found in many of the older provinces. Of course, the more complete a civilisation is, the more it invites those whose battle of life has been more than half fought; and in Ontario, Nova Scotia, and New Brunswick, excellent farms, complete in homestead, cowhouse, and orchard, can be had for prices which in England seem almost ridiculous. If a man prefers to become a tenant of a holding under new and more easy conditions than are attainable here, he can readily have such, for it is an entire mistake to suppose that every man possesses his own land in Canada; the vast majority do so, but some prefer to remain as tenants, at a light rent. Nothing can exceed the beauty and fertility of such valleys as those of Sussex and St. John, in New Brunswick, while in the same province, the regions about Miramichi and Bathurst, are excellent. No fairer land can be found than that which has been made so widely known by Longfellow, in his touching story of "Evangeline," where the old French dykes still show the acadian settlements of an earlier day. A more extended system of reclamation has won from the sea many tracts of rich red loam on the shores of the Bay of Fundy, and it is quite worth the while of anybody who wishes to change his abode, to recollect that it is not necessary to go as far as the north-west of Canada to find new land, and that within a ten days' journey by sea of where we are now assembled, farms can be secured, and all the comforts of civilisation enjoyed in the maritime provinces of the Dominion of Canada.

DISCUSSION.

Mr. Staveley Hill, Q.C., M.P., having been in Canada during the autumns of the last three years, said he was able to bear full testimony to the excellence of the work of the noble Marquis and of the illustrious Princess in that country. While they were sorry to lose him from Canada, they could not but realise that here in England he was doing as good work for Canada as he did out there. He could completely endorse all that had been said with regard to the intelligence and energy with which the Canadian Pacific line had been pressed forward. He first went out to Canada three years ago, during the bad times in the iron trade, to see for his constituents in West Staffordshire what sort a place it was as a field for colonisation. In 1881, he went up in the first train which took passengers to Brandon; and the following year drove along by the side of the line as far as Moose-Jaw Creek, and this year he went in the train up into the Rocky Mountains. To show the pace at which they went, he might say, that one day he was with them in the forenoon, and had left his buggy standing by the side of the rails, and at half-past 2 o'clock it was nearly a mile behind. Near the Rocky Mountains they had left the prairie country and got into the ranche land, where there was a belt of about 30 miles of the most wonderful grazing country. The hollows in the hills were so well sheltered, that even during the enormous cold of winter the cattle were able to stay out, and got quite fat and fit for the butcher, and were in excellent condition when the breeding season came round. This land was not very large, compared to other parts of the country, but it was a glorious country for cattle, whilst the other was more adapted to raising grain, so that both kinds of produce, requisite for a large population, could be obtained in the Dominion. The passes over the Rocky Mountains were the Crow's Nest, which he went through last year; the Kicking Horse, formerly called the Vermillion Pass, and close to that the Kananaskis Pass. Near the Crow's Nest there was another pass called the Kootenai; and as he stood at the door of a friend's ranche at the head of the Old Man River last year, and looked at the glorious line of snowy mountains, he thought it had no parallel in the world. The much-praised view of the Bernese Oberland, from the terrace at Berne, was certainly, by no means, equal to it. Having gone into the Crow's Nest Pass last year, he this year went up the valley between the rivers Belly and Kootenai, and hoped to get across into the Crow's Nest Pass, little thinking of the big hills between; he got, however, into the Boundary Pass, which took them about 160 miles through a most beautiful woodland track, with magnificent trees rising up 150 and 200 feet, until they come down on the Tobacco plains spreading out on the western side of the Selkirk range. This was a most easy pass; it was, perhaps, too close to the boundary line for the railway to take advantage of, but there was nothing to prevent the making of a wagon-road, and the construction of a railroad would be an easy task. You might really ride through it in two or three days. With regard to the Indians, there was a most marked difference between the Indians in Canada and those in the United States. In Canada he could sleep in the midst of eighty or ninety lodges and feel as safe as in that room; but as soon as you went across the frontier line, into Montana, Wyoming, or Washington, the whole state of things was different, and you could not trust the Indians to the same extent. The reason was told by the Americans themselves: good faith had ever been kept by Canada with the wild man, but in the States too often what the Government freely paid, the Indian agent pocketed; the whiskey trade was allowed to flourish in the States, whilst in Canada, following the example of the Hudson's Bay Company, it was rigidly prohibited, and thus the greatest curse in that part of the world was prevented. There was no necessity for any one to drink a drop of spirit there. Each time he had been in the north-west he had been eight or nine weeks in camp, and though he had his pocket pistol of whiskey in case of emergency, he had come home each year without unscrewing it. He had slept in camp with 61° of frost, 29 below zero, and never felt the need of a drop of alcohol. In that climate it was worse than unnecessary, for he believed that those who took it would be unable to stand the cold. In 1874, the mounted police came down, and the whiskey trade with the Indians was done away with, and instead of being swept away in a few years, they were now increasing in numbers. In return for their lands the Government undertook to give them so much beef and flour for each man, woman, and child, every two days, and a certain amount of money to buy blankets, and every single word of that promise had been kept. The Indians knew that justice was meted out equally to the white man and the red skin, and the one thing they loved was to be called King George men, or subjects of the Great White Mother, and looking with pleasure on Englishmen as their fellow subjects there was good feeling and friendship; at the same time they were an idle set of rascals, who would not do a stroke of work if they could help it. He had seen an Indian buck come up to his tent, with his unfortunate squaw following behind, bearing on her back his whole worldly goods, and perhaps one or two children besides. The Indians looked on hunting and fighting as the only proper thing for a man to do, and everything else, including the cultivation of the ground, was considered women's work. An Indian buck would be as much appalled at the idea of planting potatoes or wheat as an English agricultural labourer would at being asked to darn stockings. Until this nonsense was knocked out of their heads, the Indians would not be industrious. In conclusion, he would say that any person who had leisure, and wanted to spend a long vacation happily, he could not do better than go to Canada, and when he came home tell his friends what the country was like. He hoped the time would soon come when many of the idle people in England would be hard at work producing food in Canada.

The Hon. Donald A. Smith said the Canadians felt they were under a very deep obligation to the Marquis of Lorne for what he had done, and that the time during which he had administered the government would be marked in the history of Canada with a red letter, as being one of the most prosperous periods up to the present, and it was with the most sincere regret that they saw him and his illustrious consort leave their shores. The north-west had been indeed a great acquisition to Canada. Some fifteen or twenty years ago, there were some mutterings of annexation, or something of that kind, amongst a certain class, for you could never satisfy everybody, but the condition of things was very different then to what it was to-day. Then in the eastern provinces there was a long narrow line of country looking to the North Pole; but now in the north-west there was a magnificent country, equal to anything their friends in the South could show. True, the land was not all equally good, but there was abundance of land there to grow millions and millions of grains of wheat, and sufficient grazing land for millions of cattle. It was not all wheat-growing land, but that which was not, was excellent land for mixed farming, such as farmers generally delighted in, and this reached right up to the Rocky Mountains. In the neighbouring States of Dacota and Minnesota, only thirteen or fourteen years ago, when you got some sixty or eighty miles north of the present city of St. Paul, or within 400 miles of the international boundary, the country was an entire desert, not a single bushel of corn being grown there, but to-day a railway had been run through the district, and this last year that railway had carried upwards of 20,000,000 bushels of wheat. The climate there was certainly not better than it was in the north-west of Canada, because as you went northward the ground sloped downwards, and the altitude was less, and the country was not so exposed as the more exposed parts of the Northern States. He did not say a word against those States, which were now peopled with a thriving and industrious set of farmers; but he wished to show what might be expected in a country where, on the whole, the climate was better. The cold, as registered by the thermometer, was no criterion to go by, for he had suffered more from the cold, perhaps, in London — but certainly in Edinburgh in the spring—than he ever did in Canada, where the air was so dry nd bracing. He had been farther north than Winnipeg, and had known the thermometer to fall to 55° below zero; but even then you could walk out without discomfort, and ladies accustomed to the climate of England were not inconvenienced. He could also confirm what had been said about not requiring alcoholic drinks. They required no wine there, still less spirits, unless it might be on St. Andrew's Day, when, perhaps, a little might be excused. He did not say that spirits were not required anywhere; that was a question on which there were different opinions; but it was certainly required less in Canada than anywhere else he knew of. The atmosphere was so exhilarating, you did not want champagne to add to it. Apollinaris water was much drunk there, either "straight," which meant pure, or "with a stick in it." A good many persons near the sea coast might prefer it with a stick, but in the north-west they did not care for the addition, and preferred it "straight." With regard to the Indians, we were most fortunate in following the Hudson's Bay Company; they had no troops to support them, and did not want any, because they dealt kindly and honestly with the Indians, and the Indians returned their kindness. Mr. Staveley Hill said they were very lazy, but he had known them turn to work; and the Sioux did good service to some parts of their country. No doubt the women did the greatest part of the work, but that was the case in most semi-civilised countries. There was an old custom amongst them in some parts, though he was afraid it was fast dying out, that when a squaw lost her husband by death, she carried his bones on her back for a certain number of years. This probably pointed to an Eastern origin for those tribes which practised this custom. The railway was, he thought, doing a great work, not only for Canada, but for the whole Empire. He believed it would be completed by the spring of 1886, and, when finished, it would have the effect of shortening the distance from London or Liverpool to Japan by 1,000 miles, and it would also be the shortest route from the Atlantic to the Pacific by about 300 miles. The gradients in two or three places were, no doubt, rather heavy, but it was only for a short distance, and they were not so heavy as on other lines, and could easily be surmounted by the aid of an additional engine, while all the rest of the road was remarkably level.

Mr. Stephen Bourne said he had no personal knowledge of Canada, but he hoped to go there next year, on the occasion of the visit of the British Association; and he considered the colony of immense importance, having regard to the condition of affairs at home. Some years ago, in a paper read at the Colonial Institute, he pointed out the necessity for extended colonisation, a subject on which the Marquis had also spoken recently in the same place, saying the time might come when the mother country would cry out to her colonies for aid in defending our trade, and support in any contest with our enemies. It struck him that the time had already come when a loud and bitter cry had gone out from this country to those on the other side of the Atlantic to come over and help us. We had lately been horrified by disclosures of the poverty and misery which existed in our large cities; and people were beginning to realise how much many of the poor suffered from the taking of those intoxicating liquors which he was rejoiced to hear were not needed, and in some places could not be procured, in Canada. The great cry from our crowded cities was to furnish the means whereby those who were destitute and oppressed might find refuge on those fertile plains of which they had been hearing; so that they might settle there, and produce not only their own food, but food for those who were left behind. They wanted to transport the surplus labour of this country, where, in many cases, it was a drug in the market, to a place where it would be employed in feeding those who where now half-starved, and at the same time raise up a nation of consumers for our home manufactures. The effect of emigration would thus be twofold. He trusted the effect of this paper would be to stir up those who could not find means of support in this country, to seek for new homes, and so benefit not only themselves, but those who were left behind. Probably none knew better the benefits of this large railway than the constituents of Mr. Staveley Hill, who had experienced a reaction in the iron market by the demand from Canada for rails to be there laid down. The Canadian Government were bridging over the distance between one side of that vast continent and the other. If there were these vast fields only waiting to be tilled, surely it was a reproach to British statesmen, capitalists, and philanthropists, to allow those fields to remain uncultivated, whilst our own cities were so densely crowded. This was the great problem of the day, and though he did not underrate the difficulties in the way, he was convinced that the sooner statesmen endeavoured to solve it, the better. In conclusion, he desired to bear testimony to the endeavours of the Canadian Government to provide for the spiritual wants of the emigrants who went over.

Mr. Wm. Botly remarked that this paper afforded great encouragement to English farmers to emigrate to Canada. He would recommend all persons interested in agriculture to study the report which was now published of some gentlemen who went as a deputation from Scotland to inquire into the capabilities of Canada as a field for emigration.

The Chairman, having proposed a vote of thanks to the Marquis of Lorne for his paper, which was carried unanimously,

The Marquis of Lorne briefly acknowledged the compliment, and the meeting adjourned.

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION.

The following Sub-Committees, appointed by the Executive Council of the Exhibition, have met at the Society of Arts:—

Food.—Group I.

Monday, December 17th.—Present: Sir J. B. Lawes, Bart., LL.D., F.R.S., in the chair; Professor Church; Prof. George Fleming, LL.D.; Sir B. T. Brandreth Gibbs; Professor H. N. Moseley, F.R.S.; Dr. David S. Price; Mr. John M. Thomson; Dr. Voelcker, F.R.S.; Mr. H. Trueman Wood.

The Dwelling House.—Group III.

Friday, December 14th.—Present: Sir Robert Rawlinson, C.B., in the chair; Dr. Alfred Carpenter; Mr. H. H. Collins; Mr. C. N. Cresswell; Mr. T. W. Cutler; Mr. J. Bailey Denton; Mr. W. Eassie; Mr. R. E. Farrand; Mr. Rogers Field, M.Inst. C.E.; Captain Douglas Galton, C.B., F.R.S.; Mr. George Godwin, F.R.S.; Mr. E. Hoole; Mr. Baldwin Latham; Mr. Shirley F. Murphy; Dr. G. V. Poore; Mr. George Shaw; Dr. Thorne Thorne; Mr. E. Turner, F.R.I.B.A.; Mr. George Vigers; Mr. H. Trueman Wood.

Wednesday, December 19th.—Present: Captain Douglas Galton, C.B., F.R.S., in the chair; Mr. A. T. Atchison; Mr. W. R. E. Coles; Mr. H. H. Collins; Dr. Corfield; Mr. Thomas W. Cutler; Mr. Heisch; Mr. Baldwin Latham; Professor T. Hayter Lewis; Professor Chandler Roberts, F.R.S.; Mr. Frederic Scott; Mr. George Shaw; Mr. George Vigers; Mr. Greville Williams, F.R.S.; Mr. H. Trueman Wood.

The School (Group IV.), and Education (Group VI.)

Tuesday, December 18th.—Present: Mr. E. N. Buxton, in the chair; Mr. B. St. John Ackers; Dr. T. R. Armitage,; Mr. J. G. Fitch; Dr. J. H. Gladstone, F.R.S.; Major-General Hammersley; Mr. T. C. Horsfall; Mr. A. C. King; Colonel W. R. Lewis; Deputy Inspector-General F. J. Mouat; Mr. E. R. Robson, F.R.I.B.A., F.S.A.; Mr. H. Trueman Wood.

The Workshop.—Group V.

Saturday, December 8th.—Present: Dr. G. Buchanan, F.R.S., in the chair; Dr. A. Dupré, F.R.S.; Mr. Alexander Redgrave; Mr. Gilbert Redgrave; Mr. H. Trueman Wood.

Saturday, December 15th.—Present: Dr. George Buchanan, F.R.S., in the chair; Dr. Edward Ballard; Mr. J. H. Bridges; Mr. A. Redgrave; Mr. G. Redgrave; Mr. H. Trueman Wood; Mr. W. Woodall.

Sick and Ambulance.

Tuesday, December 18th.—Present: Director General Crawford, in the chair; Deputy Surgeon-General Bostock, C.B.; Brigade-Surgeon W. G. Don; Surgeon-Major G. J. H. Evatt; Mr. John Furley; Deputy Inspector-General F. J. Mouat; Director General John W. Reid; Dr. J. C. Steele; Mr. H. Trueman Wood.

NEW GUINEA AND ITS INHABITANTS.

New Guinea, or Papua, lies wholly in the south of the Equator, between 0° 22′ and 10° 42′ south latitude, and 130° 50′ and 150° 50′ east longitude. Its extreme length is 1,530 miles, and its breadth varies from 30 to 410 miles. Consul Griffin, of Auckland, says that the island appears to have been discovered by the Portuguese as far back as 1526, and it is known that the Spanish navigator Ynigo Ortez de Retes visited it in 1546, and first gave it the name of New Guinea, on account of the resemblance of the inhabitants to the negro race. In 1606, Torres took possession of it in the name of the king of Spain, and Tasman landed on the north coast in 1643. New Guinea was also visited by a number of Dutch navigators, who claimed to be entitled to the honour of conducting nearly every important discovery on the island for a period of two hundred years. Its best known bays and rivers still have Dutch names. The native inhabitants appear to present several distinct types of race, the colour of their complexions varying from a deep sooty brown, or black, to a shade not much darker than that of the Malay. The blood of the tribes dwelling along the coast has been intermixed with that of the inhabitants of other islands in the Pacific. The typical Papuan has a peculiar black, rough woolly hair, the word *papua* being derived from the Malay *puapua*, meaning woolly or curly. In stature he is a little taller than the Australian blacks, who are invariably below the medium height. His frame is stouter, and his limbs are more symmetrical. He has a long face, projecting eyebrows, and a large nose, and in this respect he differs from the native New Zealander, whose face is round, and nose not at all prominent. The New Zealander, moreover, has straight black hair, and possesses a quieter and more dignified demeanour than the Papuan. The six principal tribes inhabiting the island of New Guinea are the Ilema tribe, inhabiting the coast from Muro, a little north of Freshwater Bay, as far as Diabu, situated about ten miles above Yule Island; the Maiva, living on the coast from Oiabu to Kapatri; the Motu, whose territory extends along the coast from Kapatski to Kapakapa; the Kaitapa living on eminences overlooking the sea, and occupying the country of the Motu; the Kairapunu, extending along the sea-coast from Kapakapa to Mura; and the mountain tribe called Koiari by the Motu, and Kuni by the Kirapuno, occupying a large area in the interior. A different language or dialect is spoken by each o these tribes, but these dialects greatly resemble one another, and can be traced to the same common origin. The language may be described as a soft and musical one. It is composed principally of vowels and liquids, and has no harsh-sounding consonants The natives, who reside near the Maikasa, or Pearl River, are believed to be cannibals. Their country is thinly populated, and during the rainy seasons exceedingly unhealthy, on account of the prevalence of malaria. The Papuans pierce their ears and nostrils, and wear in them as ornaments bamboo sticks and bright coloured feathers. Some of them file their teeth to a sharp point. Their faces are disfigured with huge dark welts, burnt in with red-hot coals, and rubbed with various kinds of dyes. They pass their time principally in hunting and fishing, dancing and fighting. Their weapons consist of bows and arrows, clubs and spears. At Astrolabe Bay they have knives and axes of flint, and a weapon made of hard wood, exquisitely carved. The food of the various tribes consists principally of pigs, dogs, fowls, kangaroos, lizards, fish, insects, yams, cocoanuts, bananas, melons, mangoes, bread fruit, and sugar cane. They possess a rude knowledge of agriculture, and cultivate extensive plantations, the soil everywhere being fertile, and they plough or break the ground with pointed sticks. Their houses are built of bamboo, and raised on piles, and some of their dwellings have very low roofs, slanting almost to the ground. They possess a vague sort of belief in a Supreme Being, and erect temples for worship. They practice polygamy, and entertain the belief that man has a right to as many wives as he can support. The inhabitants of the village of Dorey, and along the shores of Geebrink Bay, possess a much better intellect than the other tribes, and often have European features. It is believed that they have Hindoo blood in their veins, and it is stated that their religion may be traced to Oriental origin. In the interior of the island the inhabitants display great skill in carving clubs out of a substance closely resembling the *pœnamu*, or greenstone of New Zealand. The Kirapuno tribe are described as being very handsome. The hair of their children is of a light golden colour, which becomes darker as they grow older, turning first to a rich amber, and then black with a reddish tinge. All the tribes delight in painting their faces and bodies, the favourite colours being black, yellow, and red. They are addicted to murder, and their highest chiefs do not hesitate to beg and steal. The tattoo marks on the breasts of the chiefs indicate the number of men they have slain. They wear for ornaments head dresses made of the feathers of the bird of paradise, necklaces or boar tusks, and bracelets cut from a species of clear white shell. The men are noted for their slender waists, which approach almost to a deformity, produced by drawing tightly round their bodies a girdle made of native cloth. The women, on the contrary,

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

FOREIGN AND COLONIAL SECTION COMMITTEE.

A meeting of this Committee was held on Thursday, 20th inst., to arrange for the proceedings of the Section during the coming Session. Present:—Sir Rutherford Alcock, K.C.B. (in the chair), Mr. Hyde Clarke, Mr. B. Francis Cobb, Mr. Trelawney Saunders, Mr. P. L. Simmonds, with Mr. H. Trueman Wood, Secretary, and Dr. R. J. Mann, Secretary of the Section.

JUVENILE LECTURES.

The first lecture will be delivered on Wednesday next, January 2, at 7 p.m.

All the tickets having been disposed of, the issue has ceased. As all the available accommodation will be required for those members who have received tickets, it will be understood that no member can be admitted without a ticket.

The Secretary will feel greatly obliged if any member who is unable to use his ticket will kindly send it back.

Proceedings of the Society

CANTOR LECTURES.

THE SCIENTIFIC BASIS OF COOKERY.

By W. Mattieu Williams, F.C.S.

Lecture I.—Delivered Monday, Dec. 3, 1882.

Although by no means disposed to quibble about words, and having but small respect for etymologies, I am constrained to commence these lectures with an etymological protest. I refer to the now popular use of the term "technical education," which, in my opinion, is misapplied. If this was merely a question of derivations, I should not notice it, but, as now used, it is very inconvenient, and provokes confusion of ideas. It has prevented me from giving the proper title to these lectures, which should have been "The Technology of Cookery;" but, in the prevailing confusion between "technical" and "technological," such a title would not have been understood.

There are two distinct branches of all industrial education. The first is that which is conducted in the workshop, or, as regards cookery, in the kitchen. This is technical, and should be so named in accordance with the signification of the Greek word τέχνη, *i.e.*, art, trade, or profession, and also in accordance with the established usage of the English words, technical, technicality, &c.

The other branch of industrial education is that which teaches the philosophy or *rationale* of the technical processes. Established usage, and unquestionable convenience, has assigned, in other cases, the appending of the Greek word λόγος in English form to the Anglicised Greek name of the general subject, to express such special philosophy. Thus we have geology, the science of the earth; biology, the science of life; anthropology, the science of man, &c. In strict accordance with this, the science of trade, art, or profession, should be named technology, and its corresponding adjective technological, corresponding to geological, biological, anthropological, &c.

The distinction between the technical and the technological is specially and personally demanded for my present subject. I venture to present myself as a technological teacher of cookery, while I should be guilty of impertinent charlatanism if I came forward as a technical teacher of this important art. I am repeatedly compelled to make strong protests against the prevailing absence of intelligence respecting the distinction between the technical and the technological, on finding myself consulted on the technicalities of cookery, or challenged to display my skill by the concoction of a banquet or some of the elements thereof.

The technology of cookery is but a subdivision of general domestic technology, a very broad subject, about the broadest of all the technologies. In the majority of trades, only a limited range of material is handled, but the housewife has to deal with a multitude;

the house itself, with its sanitary arrangements and furniture, its adaptations to comfort and elegance; food and its preparation; clothing; the rearing of infants, and the general preservation of health during health, and nursing during sickness; these demand for every woman a wider range of technological education than is necessary for men, who follow only one or two of the modern sub-divisions of labour. The technology demanded for the technical specialist is usually more exhaustive in detail, but is rarely, if ever, so wide in its grasp of many subjects. This should always be remembered in connection with the education of women. They certainly cannot afford to devote the larger half of their youthful working life to the study of dead languages, or any other demands of scholastic pedantry.

The operations of cookery are mainly chemical, and the chief agent in affecting these is heat. Thus the cook is a practical chemist, and the kitchen is a chemical laboratory, whose practice demands for its regulation no small amount of chemical knowledge. I do not refer to the sort of chemical knowledge most valued by the chemical specialist, who is working in the hazy region which forms the outer boundaries of science, and lies between the known and unknown, becoming, therefore, obscure and difficult; but to the solid foundations of chemical science, those great laws, or general facts that are now so well established as to be clearly understood, and therefore easily explained. Divested of shallow pedantries they are intelligible to everybody.

The laws of heat stand first, that is, the actual facts concerning heat. These should be well understood by every cook and every housewife. They are extremely simple, provided they are not obscured by any envelopment in the mathematical complications of thermostatic and thermodynamic theories, which merely record the hard struggles of bold intellects in grappling with the unknown. These belong to the science of the university, not the simple, clearly understood, and easily taught, technology of the kitchen.

In this short course I can only touch very briefly on this subject,* just referring to the the modes by which heat can be communicated, or the conditions on which this powerful agent will consent to become a servant to the cook. It must be either by means of *conduction*, *convection*, or *radiation*, either direct or reflected.

The two first demand contact with the heating agent, the third is the name for the manner in which heat is communicated to bodies at a distance from its source.

Conduction will be practically understood by simply holding a pin by one end, and placing the other end in the flame of a candle. The thumb and finger of the experimenter will presently communicate the fact that some of the heat of the candle flame has travelled from one end of the pin to the other. This unostentatious travelling of heat through the substance of body is called *conduction*.

By substituting for the pin a piece of charcoal or of wood of the same length (a match, for example), it will be found that one end of this may be made red hot without the other being sensibly warmed. A filament or stick of glass will display intermediate properties in this respect. We thus prove that bodies differ in their conducting power.

Metals generally are the best conductors, organic substances and carbon the worst among solids. The metals vary considerably among themselves. Silver and copper are the best of conductors; iron is inferior to these.

An important and less generally understood fact connected with this, is that bodies which thus take or conduct heat into themselves most readily are just those which give it out most readily, *by contact* with other bodies.

This is well illustrated by the boy's trick of placing a kettle of boiling water on the palm of the hand, and holding it there without inconvenience. The success of this depends upon the kettle being incrusted with a tolerably thick coating of carbon, in the form of soot deposit. The hand would be badly burned if the experiment were made with a new kettle, the heated metal of which would at once communicate its heat to the hand. In taking a Turkish bath, I frequently sit in a chamber the air of which is raised to the boiling point of water or thereabouts, and do this without inconvenience, provided the seat is covered with a bad conductor, and the floor also. If I attempted to wear my spectacles in that chamber the result would be very painful.

Convection is very different from this, although it demands contact. The laws of convection of heat were first clearly expounded by the man that I profoundly respect as my great teacher of the technology of cookery, Benjamin Thompson, Count of Rumford, Knight of the Orders of the White Eagle and St.

* I have treated it more fully, but without the theoretical complications, in "A Simple Treatise on Heat," published by Messrs. Chatto & Windus.

Stanislaus, Chamberlain, and Privy Counsellor of State of His Most Serene Highness the Elector Palatine, Reigning Duke of Bavaria, and Commander-in-Chief of the general staff of his army, F.R.S., &c.

This remarkable man, who began life as a poor village schoolmaster in America, and afterwards earned, by genuine honest work, the above titles, and many others that I have not time to specify, happened to scald his mouth when eating some rice porridge. The consequences were momentous, for it led him to investigate and discover the mode in which heat is communicated through liquids and gases, and to devise a multitude of important inventions based upon this. I quote his own account of the accident. He tells us that :—"Being engaged in an experiment that I could not leave, in a room heated by an iron stove, my dinner, which consisted of a bowl of thick rice soup,* was brought into the room, and as I happened to be too much engaged at the time to eat it, in order that it might not grow cold, I ordered it to be set down on the top of the stove. About an hour afterwards, as near as I can remember, beginning to grow hungry, and seeing my dinner standing on the stove, I went up to it, and took a spoonful of the soup, which I found almost cold, and quite thick. Going, by accident, deeper with the spoon the second time, the second spoonful burnt my mouth." This was followed up by reflecting on the fact that tea or coffee or thin soup is never thus cool on the surface and hot below. Why not ?

Up to this time, it was supposed that when we boil water in a kettle, saucepan, &c., the whole becomes heated by contact with the metal, and by conduction through the water, similar to the conduction of the heat through the bottom of the pot from the outside to its inside. Count Rumford ultimately proved that water and most other liquids, that air, and all gases are very bad conductors of heat, absolute non-conductors, he supposed; and that when we make water hot in saucepans, boilers, &c., the heating is effected by continual movements of the liquid, a film of which, touching the bottom of the heated vessel, is heated by direct contact, expands, and thus becoming lighter, ascends, and gives place to another cold film, which does the same, and so on until the whole is heated; or, otherwise expressed, the heat is conveyed throughout by such motion, and hence the term convection. A device of Count Rumford's illustrates this very prettily. He placed in tall cylindrical jars of water small fragments of amber, having the same specific gravity as the water, and, therefore, neither predisposed to sink nor float. These, by their movements, displayed the movement of the water itself. When such a jar was placed before the window of a room, heated above the temperature of the outer air, the amber moved downwards on the side of the jar facing the window, and ascended on the side presented to the interior of the room, and *vice versa*; if inner and outer temperature were equal, the amber remained stationary. He thus learned a domestic lesson, but little understood even now, viz., when to open and when to shut windows in the summer time. His convection glasses proved that a house is often kept cooler by shutting doors and windows than by opening them.

It will be seen at once how largely we avail ourselves of convection in the application of heat in cookery. Boiling, stewing, and frying, are examples of this, a bath of water or of fat being the convection medium by which the heat is communicated to the viands to be cooked.

All heated bodies radiate their heat to those around them, and all bodies are receiving radiant heat from their neighbours. If the temperature of a body is equal to that of its surroundings, it receives just as much heat as it gives out, and, therefore, is neither warmed nor cooled. If it is cooler than its surroundings, it receives more than it emits, and thus is warmed; if warmer, it radiates more than it absorbs, and thus is cooled proportionally. But the amount of heat thus radiated or absorbed by a body, in a given time, is not exactly proportionate to these differences. Some have greater radiating and absorbing powers than others. Thus, if we have two teapots of the same size and shape, and fill each with hot water from the same kettle, the water within them may or may not cool down at equal rates when similarly exposed. If one is of bright metal, especially burnished metal, and the other is of the same metal, but with a rough or porous surface, the rough will radiate more heat than the polished, and the water in it will cool more rapidly. In solid bodies the surface is the chief determinent of what I may term specific radiating energy. Radiation and absorption are, in this respect, exactly

* I commend this *menu* of the Lord High Chamberlain and Commander-in-Chief to the consideration of citizens and others who are not ashamed to sit down to a meal that costs two or three guineas per feeder.

co-equal; the conditions which favour one equally favour the other. One of the best radiators and absorbers is a surface of soot. Thus, a teapot should be bright in order to keep the water as hot as possible, but a tea-kettle that is heated by radiation from glowing coal, should be thinly coated with smoke deposit, in order that it may absorb freely. The advantage of fire-clay as the backing of a grate depends upon this. It is an excellent absorber and radiator, far better than iron or any other metal. Therefore, it is readily heated by the coal, it absorbs much of the heat that would otherwise pass by convection up the chimney, and, while doing this, is also actively radiating it into the room, or towards any object placed before it for the reception of such heat.

Bright surfaces are good reflectors of heat, though bad radiators. The difference of this should be clearly understood by the cook. Radiation is the giving off of the heat possessed by the radiant body as its own temperature. Reflection is the rejection of the heat radiated against the surface of the reflector, some of which it does not choose to accept, but scornfully throws back again to the giver if received perpendicularly, or casts aside at an angle equal and opposite to that of its reception if received obliquely.

A radiating body gives out its heat equally in all directions. A necessary consequence of this is that the intensity of the heat is diminished in proportion to the outspread, that outspreading being proportionate to the square of the distance. The *rationale* of this may be understood by supposing it to be received on the inside of a spherical shell surrounding the radiant body; as the area of that shell increases with the square of its radius, or the distance from its centre, the quantity of heat received on a given measure of the surface of the shell must be inversely as the distance from the centre, *i.e.*, at double the distance the surface of the sphere will be four times greater, and outspread heat four times, or diluted to $\frac{1}{4}$, at three times $\frac{1}{9}$, and so on.

In roasting a joint before the fire without any screen, the radiant heat from the coal is only used; the meat is heated only on one side, that next to the fire, and, as it turns round, is radiating its heat away from the other side to the wall, &c., of the kitchen. If a meat screen of polished metal is placed behind the meat, the rays of heat not intercepted by the meat itself are received upon the screen, and reflected back towards the meat, and thus both sides are heated.

The Dutch oven is a device for utilising the otherwise wasted radiant heat, by reflecting some of it to the part of the meat not opposite to the fire. Other devices for this purpose are familiar to all, and, if time permitted, I could show you how a reflector might be made to concentrate the heat in such wise that one part of the meat turned away from the fire should be more heated than that exposed directly to the fire. I merely give these examples to show that a study of the laws of heat have a direct bearing on practical cookery.

The oven is an apparatus for cooking by radiation. In this case the meat or other object of cookery receives radiant heat from the heated walls of the oven. If this chamber, with radiant walls, be so arranged that the heat shall be radiated equally on all sides, and is capable of regulation, it becomes a roaster, which theoretically does its work more perfectly than an open fire, even when aided by a screen.

Rumford proved this by constructing such a roaster. It was a cylindrical chamber, with a surrounding flue, which heated the chamber about equally all round, excepting at the bottom, which stood directly over the fire, and therefore was the hottest. Over this stood a dish containing water, and above the water a sort of gridiron, upon which stood the meat, over a dripping pan above this water pan. It was thus heated by nearly equal radiations from all sides up to the ordinary cooking point (of which I shall presently speak), and in the midst of *its own* vapours plus some steam from the water in the dish. When this heat had penetrated to the centre of the meat, so as to effect the chemical changes presently to be described, and which constitute ordinary cookery, the special peculiatity of roasting, that is, the browning of the surface, was effected by means of what he called "blowpipes," *i.e.*, metal tubes under the roaster, which were made red hot by direct exposure to the fire, and were so arranged that, by opening suitable plugs and valves, a blast or current of hot air was made to pass through the roaster, and thus the meat was browned on the outside, while it remained delicately tender inside, from having been previously cooked there in its own juice, and surrounded by its own steam.

To test its merits, practically, he took two legs of mutton of equal weight, and from the same carcase, had one of them roasted by an expert cook in the usual manner before the fire, and the other cooked in the roaster. When cooked, both were weighed. That cooked in the roaster was 6 per cent. heavier than the one cooked before the fire. They were both brought on table at the same time, "and a large and unprejudiced company was assembled to eat them," a poor and hungry company, if I understand rightly. Both were found good, but a decided preference was given to that cooked in the closed roaster, "It was more juicy, and was thought better tasted." Both were fairly eaten up, nothing remaining of either that was eatable, and the fragments collected. "Of the leg of mutton which had been roasted in the roaster, hardly anything visible remained, excepting the bare bone, while a considerable heap was found of the scraps not eatable which remained of that roasted on a spit." The silent eloquence of these scraps is to my mind irresistible.

But why has the Rumford roaster so completely disappeared that I am unable to obtain a specimen from the exhibition of cooking utensils that we have below?

There are two reasons. First, that one of the primary conditions of Rumford's experiment with the two legs of mutton are generally unobtainable in England, viz., the "perfectly unprejudiced company," to test its merits. A prejudice against baked meat, or meat roasted in an oven, is hereditary in Englishmen. Not one in a hundred who denounce it has ever consciously tried the experiment of comparing such meat with that roasted in an oven, although every one of the hundred has again and again eaten and enjoyed baked meat, believing it to be roasted. If he has not done so at home, he has at hotel dinners, and other costly banquets.

I have fairly compared both, and have not the slightest hesitation in affirming that moderate-sized joints, properly roasted in a closed chamber, are far better than similar joints cooked with the utmost skill in front of a fire. The smaller the joint, the greater the advantage of the closed chamber. A baron of beef or a whole ox may possibly be as well cooked on a spit before a large fire as in an oven. I have tasted such from the spit, but never from an oven, and therefore suspend judgment in this exceptional case.

All prejudices, all traditions, however unreasonable now, have had some reasonable or semi-reasonable origin. Whence came this one against baked meat? Though far from being an archæologist, I claim to have discovered the origin of this tradition, this domestic superstition. My theory is this. Once upon a time, and within the memory of living men, the great middle class of Englishmen, such as now reside in suburban villas, and scorn to associate with the local shopkeepers, lived in London; in the back parlour, behind their own shops, on week days, and in the first-floor drawing room over the shop on Sundays. These now aristocratic and fastidious people kept but one servant in those days, and she of the type of Dick Swiveller's beloved marchioness. At certain times, the mistress could not herself superintend the cooking of the dinner. The joint was then placed on a triangular support, in an earthenware dish, with potatoes below, and sent to the nearest baker, to be cooked in his oven, for a fee of one penny, or thereabouts. In this oven was closely packed a variety of viands sent there by a variety of people, pork, or goose, stuffed with sage and onions, side by side with beef and mutton; high and gamey hare next to delicate lamb or chicken. The whole of the hermetically sealed chamber was thus filled with heterogeneous vapours and flavours, with a fair probability of one or two joints being of objectionable quality. But this was not all. An ordinary baker's oven is constructed for baking bread. The walls are heated to a maximum temperature, the fuel then removed, and the bread placed in it to "soak," as it is termed. The oven gradually cools down, and its contents are cooked at a gradually diminishing temperature. This is just the opposite of the action of Rumford's roaster, and certainly adapted to produce very unsatisfactory results when meat takes the place of bread

The second cause of the disuse of Rumford's roaster is, that it is not adapted to our fireplaces. He fitted it over a specially constructed fireplace, which offered the cook no opportunity of indulging in her favourite pastime of wasting coal. With our ordinary fireplaces or kitchen furnaces, the blowpipes of the Rumford roaster would be oxidised and burnt through in a week or two.

Roasting-ovens, however, do exist, and are attached to all the best forms of kitcheners; and I find at home, and in other domestic kitchens that I have visited, the double water-pan, the dripping-pan, and meat-stand of precisely the same model as contrived and pictured by Rumford as essential to his roaster.

On one point, however, in the philosophy of roasting, I differ from my teacher. He begins at a low temperature, or the mean temperature. I think it desirable—and have tested this theory experimentally—to begin at a temperature above that which is to be maintained throughout the roasting. The object of this is to produce a crust on the surface of the meat that shall partially seal it, and keep in the juices as much as possible. Then the temperature may fall to the average, which should be well kept up, and rather raised towards the last. This comes about automatically in the ordinary course of cooking with a roasting-oven. When empty and closed, it is receiving heat, and only radiating to its own opposite sides, from which the same amount of heat is mutually received. When the cold joint goes in, these radiations are obstructed, and each side is giving to the joint far more than it receives from it; therefore, according to the simple law already stated, the sides must fall in temperature. As the meat becomes cooked, it takes less from the oven walls, and thus they become hotter.

I may add that the sealing is more demanded by a joint of beef than by one of mutton of given size, because in the beef there is more of cut surface, exposing the ends of the fibres of the meat. In a leg of mutton, for example, this exposure is only at one end, the rest is partially protected by the skin of the leg.

The *rationale* of basting appears to be that it assists in the sealing, and diminishes the evaporation of the juices of the meat, the chief difference between well roasted and ill-roasted meat depending upon this. I have defined the roasting and grilling of meat as processes of cookery by means of which the meat is stewed in its own juices. The flavour depends on this: no water being used, these juices are not diluted—they are, on the contrary, more or less concentrated by evaporation; but if this evaporation be carried too far, a drying-up occurs, and this desiccation, for reasons that will be explained presently, is accompanied with toughness and indigestibility, as well as sacrifice of flavour.

The smaller the joint, the greater the risk of such desiccation. This principle brings us at once to grilling, which is another kind of roasting, *i.e.*, of cooking by radiation. A beef steak or mutton chop is not roasted by turning it round and round in front of the fire, because so large a surface is exposed in proportion to the mass, and such treatment would evaporate from that large surface too much of the juices. Rapidity is the primary condition of success in grilling. When a large and specially-constructed grill, placed over a large coke or charcoal fire, is available, the heat radiated on the exposed surface of the meat rapidly browns or carbonises the exposed surface, and partially seals its pores.

If flesh were as good a conductor of heat as silver or copper, two or three minutes would be sufficient for a chop or steak, and ten or fifteen for a sirloin of beef; but as the heat has to pass through very slowly, the time is proportionately extended. If we attempted to grill a baron of beef or a whole ox, it would be actually burned to a cinder on the outside before the centre became warmed. Hence the necessity of the continuous basting of these great masses of meat.

Chops and steaks are commonly spoiled in domestic cookery from want of understanding these principles, and from mistaken notions concerning different kinds of flames. Every cook knows that if the flame of a coal fire comes in contact with a steak, a villainous flavour of tar is the result. This arises from an actual deposition of tarry soot on the meat. Hence she scrupulously avoids contact with any kind of flame. This is quite unnecessary; the flame caused by combustion of the fat of the meat itself makes no such tarry deposit, however much it may blacken the meat. I said that I am not a practical cook, but I make exception in the matter of grilling. When a bachelor, living in lodgings or an institute, I found such difficulty in obtaining a decently cooked steak or chop, that I frequently cooked my own, and my mode of proceeding may be described, as it illustrates these principles.

First I removed all the flaming coal, even though in so doing the fire was reduced to very poor dimensions. Then I cut off a piece of the fat, cast this in the middle of the fire, and as soon as it made a good flame recklessly plunged my dinner into the midst of it. It spluttered and frizzled, dropped more fat, made a bigger flame, but, still I refused to raise the gridiron, and thus cooked it throughout in its own flame. A few minutes sufficed. The outside edges were black, certainly, but the violent expansion of the juices within, when so suddenly heated, plumped up the lean almost to bursting; the inside was juicy red meat, fully cooked, though apparently raw, and the outside a crust that was by no means objectionable, though it might arouse the prejudice of the uninitiated. I do not recommend the exact following of this in detail where a good fire is available, but refer to it as illustrating the effect of rapid grilling.

Before going into the subject of boiling and stewing, I must say something about the boiling of water, as this is curiously misunderstood in most kitchens. When water is heated in a glass vessel over a flame where the action may be watched, bubbles are first seen growing on the sides of the glass, gradually detaching themselves, and rising to the surface. These are merely bubbles of air that was dissolved in the water. After this, other and larger bubbles form on the bottom just above the flame. At first they are flat, and continually collapsing. Presently they become hemispherical, but still they collapse; then they become more and more nearly spherical, and afterwards quite spherical; afterwards they detach themselves, and start upwards, but perish in the attempt, by collapsing somewhere on the way. At last they reach the surface, and break there, ejecting themselves as steam into the air. Now the water boils, and a thermometer dipped into it registers 212°. After this, it matters not whether the boiling is very violent or only the gentlest simmering, no further rise of the thermometer is perceptible, showing that the simmering temperature and the "galloping" temperature are the same.

It is most difficult to make a cook understand this. If something is to be kept below the boiling point, she puts the saucepan where the water will only simmer, firmly believing that thereby she is maintaining a temperature considerably below the boiling point, and, on the other hand, she believes that by making the water boil violently she is raising its temperature above the ordinary boiling point. This single, and almost universal, kitchen fallacy, prevailing as widely among the mistresses as the cooks, wastes a serious amount of fuel, and spoils tons and tons of good food every day, proving most strikingly the demand for a knowledge of the laws of heat by all concerned in cookery.

The temperature of water cannot be raised above a fixed boiling point, because every ounce of steam carries off nearly 1,000° of heat, *i.e.*, it requires so much to expand it as steam. Time will not permit me to go further into this subject of latent heat; all housewives and cooks should carefully study it.

The actual cooking temperature for animal food is considerably below the boiling point of water, and is regulated by the coagulation of albumen, which commences at rather below 160°, *i.e.*, more than 50° below the boiling point of water. The further elucidation of this belongs to the subject of my next lecture, but I may illustrate it in the meantime by what occurs in the cooking of the white of an egg, which is nearly pure albumen.

If this be gradually heated in a suitable glass vessel, with an immersed thermometer, the clear viscous liquid shows signs of change at about 134°, when white fibres commence forming within it. These go on increasing, until at about 160° the whole mass becomes gelid and semi-opaque. It is now delicately cooked, and best fitted for easy digestion without any of the disagreeable rawness of the uncooked slimy liquid. If the heat is continued up to 212°, the opacity and hardness increases; if this temperature is maintained, the albumen becomes of horny hardness; if exceeded, it becomes so tough that a powerful cement may be made, and is made by smearing the edges to be cemented with white of egg, and then heating them. Thus hardened it is unfit for food.

Now, apply this practically to the boiling of an egg for breakfast. By the ordinary method of the three minutes' immersion in continually boiling water, the white becomes hard and indigestible before the yolk is fairly warmed, and half-a-minute too much, or half a minute too little, will nearly ruin the operation. Cockney cooks know very little concerning new-laid eggs, but farmhouse cooks are well aware that a new-laid egg demands nearly a minute more of that sort of cookery than one of full London flavour.

The proper mode, as I pointed out years ago, in my first book on Norway, is to place the egg in boiling water, and then remove the saucepan from the fire altogether, and leave the egg in the water from ten minutes to a quarter of an hour. About half a pint for one egg, three-quarters of a pint for two eggs, or a pint for four eggs, is the quantity demanded if the saucepan is well covered.

The cold egg, or eggs, speedily reduce the temperature from 212°, to near the cooking temperature, and before the egg is warmed throughout, it is quite down to 160°, so that it matters little whether it now remains five or ten minutes longer in the water. In making experiments with eggs, I have discovered that the temperature of coagulation of the yolk is lower than that of the white, and thus, if the egg is kept in water at 160° for a long time, the yolk may become harder than the white, the centre having time to become nearly as warm as the outside. But for this, the egg might be kept in the water at about 160° for an hour or two.

I have here exhibited, by Mr. Burton, an apparatus specially constructed for the cooking of eggs. It is called an "egg coddler."

Being made of bright metal, and well covered, the heat of the water is retained, and a smaller quantity than I have named is sufficient. The eggs are supported in a moveable frame, which can be taken out, carrying the eggs with it; nothing more is necessary than to place these on the breakfast table duly charged with eggs, fill it with boiling water about ten minutes before the attack on the breakfast is anticipated, and if this should be delayed ten minutes later, no serious mischief is done; the eggs are not hard, and are still hot. Coddle your eggs, never boil them.

In my next I shall show the bearing of these principles of albumen coagulation upon the cooking of all kinds of animal food.

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION.

The following Sub-Committee, appointed by the Executive Council of the Exhibition, has met at the Society of Arts since the meetings of the other sub-committees recorded in the last number of the *Journal*:—

INDIA.

Thursday, December 20th.—Present: Sir Joseph Fayrer, M.D., LL.D., K.C.S.I., F.R.S., in the chair; Sir Rutherford Alcock, K.C.B.; Sir George Birdwood, C.S.I., M.D.; Col. Sir Owen Tudor Burne, K.C.S.I., C.I.E.; Mr. Andrew Cassels; Deputy Surgeon General N. Chevers, M.D., C.I.E.; Mr. Robert A. Dalzell; Surgeon-General Gordon; Col. J. Michael, C.S.I.; Mr. W. G. Pedder; Mr. Harold Arthur Perry; Mr. J. R. Royle; Dr. George Thin; Deputy Surgeon-General Townsend, C.B.; Mr. Frederick Young.

WINE-MAKING IN SICILY.

Consul Churchill, writing on the trade and commerce of Palermo and Sicily, says that the English were the first to establish factories in Sicily for the making of the wine known by the name of Marsala. This description of wine was previously made in the country, but it was not appreciated in foreign countries until it began to be prepared by the English, who chose the best grapes for the purpose, which are those known under the names of *cateratti* and *trebianno*, and which grow principally in the districts of Castelvetrano, Campobello, and Mazzara, situated in the south-western part of the island. These qualities of grapes, and more particularly the first, are rich in saccharine matter, tender skinned, and juicy. To secure the choicest fruit, the manufacturers make contracts with growers, and advance them money, to be returned in fruit or must of a superior quality. They reserve to themselves the right of inspecting th vines, and seeing that they are properly attended to, and they fix the date of the vintage, which usually takes place towards the end of September. If the crop is an abundant one, the manufacturers accept whatever may have been produced over and above the contracted quantity at the market price. If the crop is a poor one, they do not insist upon getting the full amount of fruit they ought to receive, which would force the growers to procure the deficit at ruinous prices from other sources, but they agree to receive their due the following year. As the quality of the crop cannot be ascertained in advance, the growers accept the rates fixed by the manufacturers, and it is in the interest of the latter to act loyally towards the growers. Under no circumstances is bad fruit allowed to be pressed, nor is must accepted that does not contain the required quantity of alcohol-producing matter. The labours of the vintage having been brought to a close, those of the factory begin—that is the choice and trial of the wine. When the new wine is brought in, it is placed in casks of about twelve hectolitres, or two hundred and sixty-two gallons. For the English market, Marsala wine requires to be highly alcoholised, in order to stand the voyage and to keep. This, however, is not necessary for the Italian market, hence the necessity of choosing the strong wines for the former. Alcohol is added to wine made for exportation, both after racking and at the time of exportation increasing its volume by seven per cent. The strength of the Italian wines is from 16° to 18°, while that for the English market comes to 20° and 22°. The alcohol is produced from the superior qualities of wine; but latterly, owing to the heavy taxes levied upon spirits manufactured in Italy, other means have been resorted to, to replace alcohol or to produce it naturally. With this object in view, the must is boiled until its volume is reduced by two-thirds, and it is then added to new wine in lieu of alcohol. At first, this cooked wine was added at the first racking, but it was found that the results were not good, so the practice was altered, and it is now added to the new wine as it is being casked, in the proportion of from five to ten per cent. The cooked wine is generally added before the must begins to ferment, as then the whole mixes up well and produces a stronger wine; after this it is allowed to clarify. Two months before casking a preliminary trial is made, which consists in examining each cask, to see if the wine has the required qualities of the well known Marsala; those that have not are marked, and put aside for distilling; those of doubtful quality are set apart for further trial. Great experience is required to appreciate the quality of the wine contained in each cask by sight, smell, and taste. Towards the end of March and the beginning of April, a further trial is made on the wines put aside as doubttul. Then the racking commences, the wine being put into casks containing about twelve hectolitres. If any wine is found in imperfect condition it is alcoholised, and is put by for the rest of the season. In the English manufactories, pumps and tubes are not used, as the wine is usually poured into cans, so that it may be seen when it begins to run thick. During the ensuing year, before the time of the vintage, a fresh trial is made, after which those wines that require it are cleared. This is done by dissolving a certain quantity of isinglass, so as to produce enough froth to cover the surface of the wine contained in the cask. This froth is poured in through the bung-holes, and with a short stick, flattened at the end, the surface of the wine is moved to and fro, so as to spread the froth over the entire surface. It is then left alone, and the isinglass gradually finds its way to the bottom, carrying with it every foreign substance, and leaving the wine clear. The English manufacturers used formerly white of egg and blood to clarify their wines, but it is now found more advantageous to employ isinglass. The wine once clarified is drawn and put into casks, care being taken to add alcohol to those that require it. Two months after this operation, the wine is subjected to a further trial, when all that is not condemned to be distilled is poured into large vats, containing as much as seventeen thousand six hundred gallons each. Smaller vats, from two thousand eight hundred to three thousand nine hundred gallons, are also used, and in order to obtain an unvarying type of wine, care is taken never to empty these vats except when absolutely necessary for repairs, but to add the new wine to the old. These vats are in the shape of two truncated cones set one against the other at the large ends. Those of average capacity are laid down on their sides, and by never emptying them, they get so impregnated with alcohol that for repairs it is not only necessary to empty them completely, but to leave them open for some time, in order to get rid of the alcoholic vapours, which would be sufficient to kill the coopers employed if sent in too soon. In these large vats the wine gets matured, and previous to exportation it is alcoholised according to its being for the English or the Italian market. Great care is exercised in making the casks for Marsala, and when made, they are filled with boiling water, in order to close up all pores of the wood, and after a month they are emptied and filled with a poor wine for two or three months, after which a better description of wine is poured into them for the same period. When required for exportation, they are emptied and cleaned by the use of chains. When filled, they are put into an outer cask for better protection.

FORESTS IN CEYLON.

A report upon the conservation and administration of the Crown forests in Ceylon has lately been published by Mr. F. D. A. Vincent, of the Madras Forest Service. The author notices the past history of the island, and arrives at the conclusion that a large proportion of the existing forests, usually spoken of as virgin or original, are but a secondary growth, which sprang up on the disappearance of a large population some time between the eighth and thirteenth centuries. On clearing the better timber out of this secondary forest, these species threaten to disappear, leaving a forest, entirely different in economic value. There is no material difference in the forest vegetation throughout Ceylon, for "where certain forests grow, we can ascertain from history and from the ancient remains that there were once cities and cultivated fields, but in other places without any remains there is precisely the same forest vegetation." Calculations are made with the object of deciding what area of forest there is in Ceylon. Roughly, speaking it appears that the area of private lands is $3\frac{3}{4}$ million acres, or about one-fourth of the island. Of the remaining three-fourths, the greater part belongs to the Crown. It is to be noted that, of the areas sold, 750,000 acres are estimated to belong to Europeans, 500,000 acres having been bought in the hill country for coffee, tea, cinchona &c., and 250,000 acres in the low-country for the cultivation of tea, Liberian coffee, cocoa, cocoanuts, and cinnamon. There are nearly sixteen million acres of land in the colony, of which only 2,500,000 are cultivated. Mr. Vincent allows four million acres for the large areas of natural scrub forest, for open bush country, for village tanks, roads, rivers, &c., and then half the total area is left on which the absence of forest is not explained by any natural causes; he believes that, with the exceptions mentioned, the whole of Ceylon was at one time covered with forest. He attributes this state of things to one cause—chena cultivation. This destructive form of cultivation has always enjoyed special advantages, as regards taxation over paddy, the permanent food grain cultivation. The range of rainfall is very varied in different parts of the island, as is seen from the fact that at Mannar, in the north, the amount is set down at 33 inches, while at Ratnapura, in the centre of the island, it is 149 inches.

There are many species of trees grown in Ceylon, but the species which are saleable at present are few. Mr. Vincent says that in the dry zone the small proportion of the valuable timber to the valueless is still more remarkable. "The general condition of the forests is that the trees of one or more of the saleable kinds are mixed with a very large variety of the valueless woods. The former never exists as a pure forest by themselves, and collectively, even in the most favourable situations, never form more than one-tenth of the whole. Looked at from a professional standpoint, the forests are most disappointing. They exhibit very poor growth, and the great mixture of species suggests at once great difficulties of management, and comparatively high working expenses. Throughout the same, great difficulty of treatment presents itself. The valuable trees are far apart, and are much in the minority." The reproduction of most of the best species has been very bad, the seedlings being, as a rule, overgrown by the valueless kinds before they can obtain a proper footing. Continual attention will, therefore, be required in the future to aid the natural reproduction. In the arid zone, including the Northern Province chiefly, there has for many years been a considerable trade in timber, and nearly all the mature ebony and satinwood has been cleared out; "pale and yavarani appear to be the only trees of which there should be any regular fellings for some time. But there is much hope that, at least from some parts of the Province, the commoner woods may in future be utilised, and that in connection with reproductive measures it may be possible to get firewood exported to India." In the moist zone the forests assume quite a different character to those in the dry and arid zones; there is to be found a luxurious tropical growth, the trees growing rapidly to a large size, with a dense undergrowth of shrubs, herbaceous species, rattans, &c.; but the wood is generally inferior to the slow-grown timbers in the dry zone. Here the area of the forests has been much reduced by chena cultivation and by land sales.

CULTIVATION OF THE ORANGE TREE IN SPAIN.

The United States Consular Agent, at Gras, writing on the propagation and cultivation of the orange tree in Spain, says that it does not thrive in the open air, except above 43° latitude, and then only in sheltered spots. When the average temperature reaches from 15° to 16° Réaumur, the apparent vegetation of the orange tree commences, which, as a rule, takes place in the month of March. The blossoming requires a mean temperature of 18°, the first flowers appearing in April, and frequently continuing throughout the whole of May. The blossoms are found on the secondary branches, but principally on the tertiary ones, or, in general, those formed during the previous year; but this is not an invariable rule. The soils in which the orange tree thrives well are of very distinct compositions, as there are as many orangeries in Spain on sandy as on clayey soils. Great attention is generally paid by the cultivators not only to the surface but also to the subsoil, as there are frequently parts where the soil is loose and of good quality on the surface, but very compact and bad beneath, or *vice versa*. Orange trees may be propagated either from seed or from cuttings; the former system perpetuates the species and creates new descriptions, afterwards improved by cultivation. The second method, either from shoots, cuttings, or grafting, continues the race, and, at the same time accelerates the fruitage, which is always later with the trees produced by the first-named system; but, in exchange, the trees raised from seed are more robust, and live to a much greater age. in cultivatin plants from the seed, attention must be paid to the soil, in order that it may be of good quality, and free from creeping herbs or seed, and it must be in a good situation so as to receive the sun in all parts, besides which it must have an abundance of water for irrigation. All seeds are sown in flat plots, and if delicate, the soil is lightly manured, and at the same time excavated and loosened, so as to give the plant greater freedom for growing. The plots, when prepared, are opened out in parallel rows of about four inches deep, and about one foot apart from each other. To obtain the quantity of seed required for sowing, when the proper times arrives, the general method is to divide the orange with a knife, taking care not to cut it so deeply as to touch the seeds, or to in any way injure them. These are then picked out, and placed in the shade to dry, after which they are preserved either in paper packets or earthenware pots in a dry place. When the seed is once obtained, and not required for use for a certain time, it is placed in layers of sand, to prevent it becoming too dry or opening. When the time has arrived for the seed to be sown, the soil is carefully prepared, being well watered and dug up. If the earth is compact and formed of hard lumps, these are broken up and smoked, and made up in *hormigueros*, which are heaps of dry vegetable refuse, covered over with earth, having a small opening near the ground, in which is introduced a wisp of straw. On setting fire to the straw, the whole mass gradually consumes itself, forming a small heap of vegetable ashes and earth. These ashes are equally distributed over the surface of the soil, and this is immediately afterwards manured. The ground has to be divided in long and narrow plots, having small irrigating canals between each, which must be sufficiently deep so as not to allow the water to reach the superficies of the rows. The seed is soaked in water for two days, and afterwards thickly sown. The young plants are from four to six weeks before appearing above the surface, and, as soon as they have acquired a certain development, which occurs at the end of a year, the plantation is commenced. This generally takes place from the middle of February to the beginning of March, according to the condition of the plants. The trees are planted in the plantation at a distance of from forty to fifty centimetres apart, and on transplanting the young trees a series of light beds are made. The trees are planted in regular files, but on the opposite side of the beds to that where they are irrigated, thus preventing the water from reaching the young shoots. The top soil is frequently loosened with a weeding hook, and thus the beds gradually get lower, until they become level with the surrounding earth, at the time when the plants have taken firm root, and are flourishing. The plantation is irrigated once in every three weeks in ordinary weather, but oftener when it is very dry. At the expiration of a year in the plantation, the young plants are sufficiently advanced for grafting, this being one of the most important means for the propagation of the orange tree. The system of grafting generally adopted is that of the grafting of a bud. These buds are selected from those of the previous year, and of the June shooting; and according to the size of the parent stem, one, two, or even four are placed, for should the parent stem be thick, and have only one bud grafted on it, the excess of sap would suffocate it. On placing the buds, the parent stem is probed, and they are applied to the most salient parts which the stems may present, as it is considered that it is here where the greatest quantity of sap is found, and it is done, when possible, in the part facing the north. The grafts are tied with esparto grass, and allowed to remain in this state for twenty-one days; if at the end of this time the bud continues green, the grafting is correct, in which case the shoot is cut off about four inches above, and it at once moves if it has dried. Sometimes it commences moving before the grafting has thoroughly taken place, in which case it is immediately cut. Great care is taken in transplanting the roots; they are dug out with a large spade, with a quantity of earth adhering to them, and this earth is surrounded with rotten or dried leaves, and tied round with cords. When the orange trees are taken to the spot for planting, the bottom of the holes is first lined with the earth which has adhered to the roots, until it is estimated that on planting the young tree it will be, after irrigating the soil, at about the same depth as when in the nursery, and as soon as the tree is placed in position, the virgin earth remaining round the sides of the hole is thrown in. Before closing up the hole, about twenty quarts of water is thrown in, if there is a probability of irrigating within a few days; if not, a small quantity of water is added. The orange may be submitted to two systems of cultivation, planting the trees at a considerable distance from each other, or planting them close to one another. The latter system is the most costly, but is productive of better results. In the first year of transplanting, ridges are formed at the sides of the rows of orange trees, at about the distance of about seventy centimetres from the trees, and in the month of April the trees are manured, at the distance of about fifty centimetres from the trunk, and a trench dug round it, in which the manure is placed and covered over. In February of the second year, about two or three pounds of manure are placed at the edge of the ridges, and manure is again deposited in April round each tree. In the third year the young roots have reached as far as the ridges, and the trees commence bearing fruit. The ridges are now broken down, the whole surface irrigated, and *hormigueros* are made. At the distance of about a yard from the trunk of each tree, small holes are dug, and two or three pounds of guano deposited in each, after which they are covered up. In the fourth year the fruit is plucked, and the pruning of the trees is commenced, this operation being generally effected between February and May, and repeated every year. All dry branches are cut off, as are also all ricketty shoots, and the crooked branches which cross one another, and as soon as the pruning is completed the working of the soil is commenced. Consular Agent Loewenstein says that the orange cultivator must be always on the watch, both as regards the weather and the condition of the soil, the utmost care and vigilance being required to ensure the successful cultivation of the tree, and the production of a good supply of fruit.

MINERAL WEALTH OF COLORADO.

An American author speaks of Colorado as a country lined with gold and silver, surrounded with iron, and scattered with lead. It contains the mining district of Leadville, 75 miles N.W. of Denver, the production of which has, in four years' time, attained a value of £10,000,000. This country has scarcely been worked six years, and yet it produces more gold, silver, lead. and iron than any other of the same size. A correspondent of the *Bulletin des Mines*, at the beginning of the present year, gives an account of the mineral production, from which the following particulars are taken:—

Mining industry is pursued with an activity not to be met with elsewhere; and the production of last year exceeded £3,400,000 in value, which is £300,000 more than that of 1881. Twenty mines give employment to from 75 to 400 hands each, the yearly wages amounting to £100,000. The ore extracted embraces silver, gold, lead, iron, and other substances which are utilised in the reduction of the metals, all the substances necessary for smelting and refining, except salt, being found on the spot.

Coke is indeed imported at present; but it can be made in the district in sufficient quantity, if a new method of treating the ores, invented by Professor Stamm, gives practically the results expected from it. Besides effecting a diminution of 75 per cent. in the expense of smelting, it will permit of the reduction of ores that are now considered too poor to pay for treatment. For reducing a ton of ore, the cost of fuel now amounts to nearly £1; but this will be reduced to 5s. 6d. by the new process. The economy consists in utilising the highly bituminous coal, which is converted into coke and gas in retorts. The coke is mixed with the ore; and the gas is injected into the middle of the incandescent mass, thus developing a higher degree of heat, and at lower cost than can be effected by any other means. Among the numerous mines worked to a profit in the district of Leadville, those of the La Plata Company, whose capital is £400,000, are among the richest. They are La Plata, Montgomery, and Gnesen, and employ 100 miners and 110 men in the smelting works. The wages amount to £30,000 yearly, and the monthly deliveries of metal reach 800 tons. The Leadville mines produced more during the last three months of 1882 than at any other similar period, and the works are encumbered with ore, notwithstanding the fact that many have been enlarged. The production of the different metals during the three months was as follows:—Copper, 9,734 tons; lead, 9,687 tons; silver, 50 tons; and gold 225 Troy lbs., amounting in value to £900,000.

Notes on Books.

Hand-books issued in connection with the Great International Fisheries Exhibition.

LITERATURE OF SEA AND RIVER FISHING. By J. J. Manley, M.A. London, 1883.

Mr. Manley deals with something more than the titles of the books he notices, and in this hand-book he has analysed the contents of the chief English books on fishing, from 1486, when the "Book of St. Alban's" was published, to the present time. He has divided his subject into eight chapters, the first of these treating of bibliographies and the last of periodical literature of sea and river fishing.

SEA FABLES EXPLAINED. By Henry Lee, F.R.S. London, 1883.

In this hand-book, Mr. Lee has followed up the subject treated by him in a previous volume, viz., "Sea Monsters Unmasked," and here he treats of the Mermaid, the Lernæan Hydra, Scylla and Charybdis, the "Spouting" of Whales, the "Sailing" of the Nautilus, and Barnacle Geese.

Papers of the Conferences held in connection with the Great International Fisheries Exhibition.

A SKETCH OF THE FISHERIES OF JAPAN. By Narinori Okoshi.

WEST AFRICAN FISHERIES, with particular reference to the Gold Coast Colony. By Captain C. A. Moloney.

THE FISHERIES OF SPAIN. By Lieut.-Col. Francisco Garcia Sola.

NOTES ON THE SUPPLY OF NORWAY. By Fredrik M. Wallem.

THE SWEDISH FISHERIES. By Prof. F. A. Smitt.

These five papers, read at the several Conferences, contain information respecting the fisheries of some of the countries represented at the Exhibition, and are fully supplied with the latest statistics from official sources.

ALL ABOUT PAINTING ON CHINA, with twelve descriptive lessons. By Mrs. Conyers Morrell. London: Kennedy and Brown. 1883.

In this little manual, the authoress has given a list of the materials required for painting in enamel colours, with a list of the colours themselves, some general directions, and a series of practical lessons, intended to teach amateurs who wish to paint upon china.

Correspondence.

WOODEN WATER PIPES.

At the present moment, not far from the Society of Arts' House, is a curious exemplification of the progress of our manufactures in our own time. On the embankment, next the City of London School, there are now some of the old wooden pipes of the New River Company, such as living members of the Society have seen laid; these are logs bored. They show the creation and expansion of branches of the iron trade in mains and pipes, which have superseded timber.

HYDE CLARKE.

General Notes

CANAL FROM ST. PETERSBURG TO CRONSTADT.—Communication between St. Petersburg and Cronstadt, says *Engineering*, is at present carried on by means of a narrow and sinuous canal, which crosses the vast delta of the Neva. Its depth is variable, the minimum being 6 feet 6 inches, and it is, of course, injuriously affected by the floods to which the basin of the Neva is so liable when the river is full, and a strong westerly or north-westerly wind blows back its waters. It was, therefore, decided to construct another and larger canal, in a new line, instead of attempting to enlarge the old one; and in the year 1876 the works were commenced, and are now about two-thirds complete. The canal starts from the mouth of the Neva, where it will open into a large basin, and proceeds southwards for nearly two miles. In this part of its course it will have a navigable width of 207 feet, and will be carefully embanked. Taking a wide curve, it will then join the canal which goes direct to Cronstadt; and from the same point a branch will proceed to meet the Neva above St. Petersburg. It will have a uniform depth of 22 feet. The soil is easy to work, consisting almost entirely of clay, sand, and gravel, and a total quantity of 47,737,000 cubic yards of ballast has been extracted, being about two-thirds of the whole. The remainder will be excavated by the end of next year. The dredgers employed were all English, except two small ones made at St. Petersburg, and one in Belgium; they number altogether ten, and are capable of excavating a total of 188,354 cubic yards in ten hours' work. Eighty-six barges and lighters are also in use, capable of transporting 153,038 cubic yards; twelve tugs, of a total force of 600 horse-power; one steamboat and two steam launches, for purposes of inspection; two floating dredgers, one Gabert excavator, and seven locomotives with a centrifugal Neut and Dumont exhausting pump. Any deficiencies in this plant are supplied by hiring.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

JUVENILE LECTURES.

The first of these lectures, on "Crystals and Crystallisation," was delivered by Mr. J. Millar Thomson, F.R.S.E., Sec. C.S., on Wednesday evening, the 2nd inst. The lecture was illustrated by a large number of specimens, and by a series of crystals thrown on the screen by means of the electric light, which were shown by Mr. Cottrell. The lecturer commenced with an explanation of crystalline structure, and pointed out that the difference between crystalline and amorphous bodies was well exemplified in sugar-candy and in fat. The same difference is seen in nature in the structure of rocks, where will be found a gradual passage from one state to the other, as in limestone, marble, feldspar, and fluor spar. A crystal was described as a solid body exhibiting an original and not artificial regular form. Of these original forms there are six large groups or systems, viz.:—1. Tesseral; 2. Tetragonal; 3. Hexagonal; 4. Rhombic; 5. Monoclinic; 6. Triclinic. In order to obtain bodies in a crystalline form, the particles must have freedom to move, and this is given them by solution, "volatilisation" and "melting," or "fusion." These processes were then practically shown in operation. The general characters of solution were explained, and the difference between solution and mixture was shown. The solution of a salt in water produced cold, and this fact was taken advantage of for the purpose of artificial cooling, but, on the other hand, a combination with water produced heat.

In conclusion, the phenomena of sympathetic inks were explained, and change of colour was obtained in several experiments on specially prepared drawings, by the application of heat.

The second lecture will be delivered Wednesday, January 9th, at seven p.m. As previously announced, all tickets are disposed of.

Proceedings of the Society.

CANTOR LECTURES.

THE SCIENTIFIC BASIS OF COOKERY

By W. Mattieu Williams, F.C S.

Lecture II.—Delivered December 10th, 1883.

In order to understand the changes which cookery effects upon food, it is, of course, necessary to know something of the chemical composition of the food, and, as we shall presently see, something also of its mechanical structure.

Reduced to its primary elements by what has been called "ultimate analysis," all our food is very similar in composition. Its bulk is made up of carbon, hydrogen, oxygen, and nitrogen, with very small additions of such elements as phosphorus, sulphur, chlorine, and minute quantities of certain metals. Such ultimate analysis is, however, but of little concern in the *rationale* of cookery, for when the materials of food are reduced to these, they are food no longer—they have returned to their original place in the mineral world, and may be food for plants, but not for animals.

The growing vegetable is a synthetic laboratory, wherein the mineral compounds of the soil and the atmosphere are wrought into new combinations, which have been named the "proximate elements" of organic matter, those of which the tissues of the plant are built up, and which also exist in a state of solution in some of its juices. Upon these the animal feeds, and they are found slightly modified as the material of which the animal organs are constructed.

One general distinctive characteristic of these proximate organic elements, is the looseness or the chemical bonds which unite their ultimate elements.

They are easily dissociated by heat, or decomposed by the agency of the rival affinities of other substances. As an example of such chemical rivalry, I place in this glass vessel some white sugar, composed of carbon and water, or of carbon and the elements of water. I now add to it some concentrated solution of sulphuric acid, which has a strong affinity for water. On stirring them together, the sugar blackens and forms a sort of pitch; the union of the water with the sulphuric acid is attended, as in all cases of chemical combination, with an evolution of heat which is now sufficient to boil the water separated from the carbon of the sugar, as you see by the outburst of steam, and the curious expansion of the piece of coke to which the sugar is reduced.

Another and familiar example of the looseness of the chemical bonds by which the elements of organic compounds are held together, is supplied by putrefactive decomposition, which, as we all know, occurs spontaneously when such substances are exposed to the air. This putrefaction is a more or less complete return of the elements to their original mineral and more stable combinations. This facility of decomposition, or re-arrangement of elements, is an indispensable condition of nutriment. Such loosely bound elements may be easily converted into the materials demanded for the building up of the structure of the animal that feeds upon them, by the action of the saliva, gastric juice, bile, &c. They are also easy of oxidation in the moist state, *i.e.*, of slow combustion, by means of which the animal heat is maintained.

Water, which is so large a constituent of the animal structure, is an exception to this. It is a mineral rather than an organic compound. It differs from the organic constituents of food in the fact that it enters the body as water, remains there as water, is water always, subject to no decomposition whatever. The same is the case with a few soluble salts, of which common table salt may be regarded as an example.

In the last lecture, I described albumen as typically represented by the white of egg, selecting this because the changes effected on it by cookery are the most decided and best understood, and are practically the most important that occur in the cookery of animal food. You will remember the action of different degrees of heat upon it, and the great change of properties which the heat effects. The position held by this albumen in the structure of meat demands further explanation. It is the universal lubricant of the animal machinery. It is, as shown by the peculiar slimy properties of raw white of egg, remarkably well adapted for this purpose. The so-called "joint oil," or *synovia*, is albumen secreted (*i.e.*, concocted from the blood) by a special membrane lining the joints—the synovial membrane.

The contractile fibres of the muscles are bathed in it, and thus it constitutes one of the juices of lean meat, the lean meat being the muscular substance. Time will not permit me to discuss the other physiological functions of this unctuous liquid, so universally diffused throughout the animal body. I may merely mention that it probably acts as a nutrient fluid, not only diminishing the mechanical wear and tear of the working tissues, but supplying them with building material, by means of which their inevitable wear and waste is compensated.

The nutritive value of albumen from our present point of view, *i.e.*, as cookable food, is unquestionable. It not only contains the materials demanded for nutrition, but holds them in a most easily digestible form, provided always the cook does not verify a certain irreverent adage, by converting it into the indigestible, shrunken, leathery substance already described as the result of overheating.

Gelatine is another and very important constituent of animal food. As far as regards quantity, it is more so than albumen, as it is the chief material of the animal tissues. Haller says that half of the animal body is gelatine. The walls of the cells of which the animal is built up are of gelatine; the membranes enveloping the fibres of the muscles, the same; the ligaments and tendons are fundamentally composed of it. It is the chief constituent of the skin. The bones are built by means of cells composed of gelatine, in which the hard mineral matter, the phosphate of lime, is deposited. These facts justify the labour of the Bone-soup Commission of the French Academy, already referred to.

Its familiar form is that of the prepared gelatine of the shops, the jelly of stock, calves'-foot jelly, &c. Carpenters' glue is the same, but dirty. These, however, are not exactly the same as the material of the membranes as they exist in the flesh. The membranes are raw gelatine, these preparations are cooked gelatine. The gelatine, as it exists in the tissues, is not readily soluble in water. This is easily shown by immersing in water a piece of any animal membrane, or of tendon, or, better still, that structure of exceptionally pure gelatine known as isinglass, which is the shredded swim-bladder of a fish—of the sturgeon, or of some substitute for the sturgeon. It resists cold water, but yields to the continued action of boiling water. After having been thus treated, it becomes readily soluble. In this primary cooking it combines with a certain quantity of water. I venture to call it hydrated gelatine.

Here, then, we have a curious contradiction in the cookery of animal food. The cooking of albumen is the conversion of a viscous liquid into a solid, that of the gelatine, the conversion of a solid to a viscous liquid. The proper cooking of albumen demands a temperature of about thirty degrees below the boiling point of water, that of gelatine may be conducted at the full boiling point, but, fortunately, this is not necessary. If time is allowed, the gelatine may be quite as well cooked at 180° as at 212°. Even gelatine is spoiled if kept at 212°, when not under water, as the carpenter knows full well, and, therefore, he uses for the solution of his gelatine a vessel immersed in water—a *bain-marie*, or water-bath, rendering it impossible for the glue itself to reach the boiling point.

There are varieties of gelatine, or the tissue that produces gelatine when cooked, which time will not permit me to describe. *Chondrin* is that obtained by digesting the cartilages of the ribs, the larynx, or of the joints, for eighteen or twenty hours in hot water. *Fibroin*, obtained by a similar cooking of spiders' web, or the silk of silkworms and other caterpillars. The material of these fibres originally existed in the animals as a liquid, which has solidified on exposure to the air. The fibres of sponge yield a kind of gelatine. Another kind constitutes the basis of the structure of insects, and has been named *chitin*. *Chitin* soup may be made by boiling down grasshoppers, locusts, or the shells of lobsters, crabs, shrimps, and other creeping things that I need not specify. Neither will I here discuss the merits of this crustacean soup, as compared with the more popular preparation obtained from the callipash and callipee of marine reptiles.

I have eaten fried shrimps at Naples, where they are cooked, as we cook whitebait, shells and all, without any previous boiling. They are excellent, and I understand that locusts similarly cooked are not distinguishable from them, but have not yet had an opportunity of practically testing this delicacy. That large tracts of country should be periodically desolated by locusts, is a striking proof of the neglected condition of the science of cookery. If the locusts devour the crops, why not cook, preserve, and eat the locusts? As regards any inherent repulsiveness in the idea of eating them, they are far less objectionable than pigs, and not worse than oysters and periwinkles.

I have already referred to the Bone-soup Commission of the French Academy. Its object was to determine whether or not the vast quantities of gelatine contained in bones, and which is commonly wasted, might be used in making soup in hospitals and other public institutions. The academicians arrived at a negative conclusion on the main question of the nutritive value of gelatine. They found that dogs, fed upon it exclusively, at first appeared satisfied with it, then ate it with difficulty, and finally rejected it, and died of starvation when supplied with no other food. Some of the academicians experimented on themselves, but did not carry their researches so far as with the dogs. They reached the loathing stage, and then retired from the investigation, and dined as usual.

A multitude of such experiments led to the conclusion that gelatine is not nutritious—a conclusion curiously at variance with ordinary experience. Liebig stated it very broadly and positively. Further investigation has, however, refuted this conclusion, and the experiments of the academicians are explained by understanding that gelatine alone does not contain certain materials that are absolutely necessary for building up the body, and that starvation may ensue from the want of these. It is worthy of note that this later conclusion of science is but a confirmation of the intuitions of our natural instinct—our sense of taste. The gelatine obtained from bones is nearly tasteless—pure gelatine quite so; the addition of a little table salt improves it, but not satisfactorily. If, however, we add to insipid gelatine the juices of fruit, as when jellies are made for evening parties, or to tasteless broth the saline juices of flesh—of which I shall speak presently—then we obtain a mixture that men, or dogs, or other animals, eat with satisfaction. It has also been found that the addition of a very small quantity of meat juices is all that is required to render gelatine nutritious.

What, then, are these juices of meat? As we have already seen, albumen exists in a liquid state between the fibres of lean meat, and, therefore, is one of them; but when the juices of meat are particularly specified, reference is usually made to the juices that are not coagulable—to juices that are saline, and which partake of the general properties of mineral salts rather than organic compounds. Some of them may be regarded as standing between the organic and inorganic.

This is especially the case with two of the most characteristic of these juices, kreatine and kreatinine, which have been described by some physiologists as products of the wear and tear of the used-up tissues that are about to be removed from the body. Besides these, we find in the meat lactic acid and certain salts of potash, such as the phosphate of potash and minute quantities of other salts.

Time will not permit me to enter upon the details of the composition of these. I must need lump them all together, as the saline and sapid juices of flesh. When tasted alone, in concentrated form, their flavouring energies are strikingly manifested; they are painfully acrid to the tongue and palate.

There is one characteristic of these that is very little understood, but is very important. Although they are constituents of food, *they are not digested.* They are not converted into chyme by the gastric and mucous secretions of the stomach, then further changed into chyle by the secretions of the liver and pancreas, and afterwards passed along the alimentary canal, gradually taken up by the lacteals, and further changed by the mesenteric glands, before reaching the blood. Instead of all this, they pass directly through the walls of the wondrously delicate miles and miles of blood vessels which form a velvet on the inner coat of the stomach. These juices thus enter the general current of the blood directly, as water does.

That any liquid should pass through a water-tight membrane seems impossible, but it is nevertheless a fact that it can and does. If a wide-mouthed bottle be filled with salt water, or with a solution of sugar, and a piece of air-tight and water-tight bladder be tied firmly over the neck, so that no mechanical leakage can take place, the solution of salt or sugar will pass out through the bladder, if the bottle thus filled be immersed in water deep enough to cover the bladder. Or if a bladder itself be filled with brine, tied firmly, and then immersed in distilled water, the same occurs, as may be shown by adding a few drops of a solution of nitrate of silver to the outside water, after the bladder has been immersed in it for a short time. A white precipitate will be thrown down, the same as would be seen if a little of the salt water had been poured out of the bladder into the distilled water.

This is called endosmosis, when the passage is from without to within a vessel, or exosmosis when from within to without. They usually occur simultaneously, though not in equal degrees.

As the saline juices of meat are contained, for the most part, within the cell walls of the muscular fibre, or the sheaths of the bundles of fibres, we may avail ourselves of this mysterious action, and extract these saline juices by exosmosis. In spite of its unfamiliar name, it is one of the most familiar of kitchen operations, both useful and mischievous. When meat is rendered tasteless in the course of boiling or steaming, it is due to the exosmosis of its juices. On the other hand, in making meat broth, or soup, or beef tea, exosmosis is usefully applied to produce an intended result.

The making of beef tea is a good example of this, especially when made by simple maceration, *i.e.*, by using cold water only. To work out the *rationale* of this, the distinction between colloids and crystalloids must be understood.

Certain solutions perform the endosmosis and exosmosis I have just described, while others do not. On comparing them, it has been found that those which do thus pass through animal membranes are solutions of crystallisable salts, while those which do not are solutions that, when evaporated down, form jellies, mucilage, or amorphous, formless masses; hence the terms colloid and crystalloid. This being the case, it is evident that if we immerse a piece of gravy beef in cold water, only one class of its juices will pass through the enveloping membranes; this class will include the saline juices of which I have spoken, and will not include the albumen, nor any gelatine that may be dissolved. If the beef is minced, as in ordinary practice, a little of the albumen will be washed off the surface exposed by the cutting, and a modicum of gelatine may be dissolved from these surfaces. If, on the other hand, we stew beef in water heated just below the temperature at which albumen coagulates, more of this albumen will be washed out, and much more gelatine will be dissolved.

Thus we shall obtain two kinds of beef tea, the first containing only those juices which are directly absorbed by the capillaries of the stomach, and thus pass directly into the blood; and the second containing these same, *plus* some gelatine which has to be digested after the manner of solid food. In both cases the albumen is separated from the liquid, by heating it to the boiling point of water. It then rises to the top as a "scum."

I have been asked which is the proper method of making beef tea, by cold maceration, by moderate stewing, by or boiling. The boiling may be at once dismissed, for reasons that will be understood by all who have listened to what I have said concerning the coagulation of albumen.

The relative merits of the other two processes demand further consideration. If the beef tea is required for a very delicate invalid the "cold drawn" may be the best, but this conclusion pre-supposes a condition of the body demanding a supply of these particular saline juices which perform certain parts of the work of nutrition, and appear to have a kind of stimulating influence. A skilful physician is required to decide whether this is or is not the case.

If the beef tea is made for a convalescent regaining digestive power, and demanding full nutrition, there can be little or no doubt that the liquid prepared by digesting minced beef in warm water (which I prefer to call beef broth, or beef soup, restricting the name of beef tea to the cold drawn) is the best. In this there is a little gelatine, together with abundance of the saline juices, which render the gelatine digestible and nutritious.

Liebig's extract of meat, when properly prepared, is what I have called beef tea proper, in a concentrated form. When it was first introduced, great expectations were formed, based on the theory that it is concentrated nutriment. Further investigation has proved that it has many great merits, but it is not a complete nutriment, and that, after being used for a while, it becomes nauseous. Hence the preparations that are offered to supersede it, meat essences, &c., which are merely equivalent to Liebig's extract *plus* gelatine, and may be made by stewing beef in warm water, or by adding Liebig's extract to calf's-foot jelly, or to its equivalent, the jelly made from isinglass, or the prepared gelatine sold by grocers. I am not aware whether jelly for invalids is ever prepared thus, by adding a little dissolved Liebig before consolidating; but I believe that it would form a very good and easily prepared form of delicate food, always remembering that it is still but a partial diet, as it lacks the carbon-food supplied by sugar, and the farinaceous compounds, of which I shall have to speak in the next lecture.

I have yet to describe another constituent of flesh, viz., the actual fibre of the muscle itself; that which in life possesses the wonderful property of contractility—of shortening itself when commanded to do so by the mysterious agency of the nerves.

This has been named *syntonin*, also *fibrin*, the first name being given to distinguish it from the fibrin of the blood, which it resembles, but with which it is not quite identical. I can only describe it in relation to cookery. In this aspect it stands between albumen and gelatine, rather nearer to albumen. It is coagulable, like albumen; and soluble, like gelatine, but in a less degree. Like gelatine, it is tasteless and non-nutritious alone. This has been proved by separating the albumen and juices, and giving it to dogs. The washed fibrin of the blood, which closely resembles the washed-out muscular fibres, is similarly worthless alone.

I now come to stewing, and venture to describe this, an almost unknown art in England so far as ordinary domestic cookery is concerned. This is curious, because among our neighbours across the Channel it is the primary process of ordinary domestic cookery, and is well understood by the wife of every peasant.

The prevailing idea in England is that stewed meat only differs from boiled meat by being kept in the water for a longer time—that stewing is simply protracted boiling. I venture, nevertheless, to declare the total fallacy of this, and to assert that, so far as flesh food is concerned, boiling and stewing are diametrically opposite, as regards the special objects to be attained. In boiling a joint—say, a leg of mutton—the best efforts of the cook should be directed to retaining the juices within the meat, and allowing the smallest possible quantity to come out into the water. In stewing, the business is to get as much as possible out of the meat, to separate the juices from the meat and convey them to the water. This is the case, whether the French practice of serving the liquid *potage*, or *bouillon* as a separate dish, and the stewed meat or *bouilli* as another, or the English and Irish fashion of serving the stewed meat in its own juices or gravy, as in the case of stewed steak, Irish stew, &c. The cruel murder that is commonly perpetrated upon good mutton chops, in preparing Irish stews, is very deplorable. The chops are put into a saucepan in water, and the water is *boiled* or "*simmered*," *i.e.*, kept at 212°. whereby the albumen is at once coagulated, thus hindering the ready exosmosis of the juices. This is continued until both albumen and fibrin are so much hardened that they contract (as the white of egg does when used as a cement). The meat curls up curiously in consequence of this contraction, the albumen is made to resemble gutta-percha, and the fibrin to resemble cotton wool, before the extraction of the juices is completed.

Not so with the frugal stew of the poor French peasant, who does more with one pound of meat, in the way of stewing, than the English cook with three or four. The little bit of meat, and the large supply of vegetables are placed in a pot, and this in another vessel containing water—the *bain marie*. This stands on the embers of a poor little wood fire, and is left there till dinner time, under conditions that render boiling impossible, and demand little or no further attention from the cook; consequently, the meat, when removed, has parted with its juices to the *potage*, but is not curled up by the contraction of the hardened albumen, nor reduced to stringy fibres. It is tender, eatable, and enjoyable, that is, when the proper supply of saline juices of the meat, *plus* the saline juices of the vegetables, have been taken into the system.

Eaten alone, like our roast beef, it would be like the bone soup offered to the dogs by the academicians; but eaten with these juices, it is wholesome, and sufficiently savoury. Whether the *potage* and the meat should thus be separated, or whether they should be stewed together, as in an Irish stew, &c., is merely a matter of taste and custom; but that a stew should never be boiled, nor placed in a position on the fire where boiling or "simmering" is possible, should be regarded as a primary axiom in cooking where stewing is concerned.

The subject of frying, properly belonging to the programme of this lecture, must be postponed to the next; and also that of casein, another very important constituent of animal food.

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION.

The following Sub-Committees have met at the Society of Arts since the two meetings recorded in the last numbers of the *Journal*:—

THE DWELLING HOUSE.—GROUP III.—SUB-COMMITTEE A.

Friday, December 28th.—Present: Capt. Douglas Galton, C.B., F.R.S., in the chair; Mr. H. H. Collins; Dr. W. H. Corfield; Mr. Rogers Field; Mr. Charles Heisch; Mr. Baldwin Latham; Mr. George Shaw; Mr. H. Trueman Wood.

THE DWELLING HOUSE.—SUB-COMMITTEE B.

Friday, December 28th.—Present: Mr. George Godwin, F.R.S., in the chair; Mr. C. N. Cresswell; Mr. T. W. Cutler; Mr. R. W. Edis; Mr. R. E. Farrant; Mr. E. Hoole; Mr. Malcolm Morris; Mr. George Shaw; Dr. R. Thorne Thorne; Mr. Ernest Turner; Mr. George Vigers; Mr. H. T. Wood.

THE WORKSHOP.—GROUP V.

Saturday, December 29th.—Mr. Gilbert R. Redgrave, in the chair; Mr. J. H. Bridges; Dr. A. Dupré, F.R.S.; Mr. Warington W. Smyth, F.R.S.; Mr. H. T. Wood.

DRESS.—GROUP II.

Monday, December 31st.—Present: Mr. Frederick Treves, F.R.C.S., in the chair; Mr. T. W. Cutler; Mr. J. D. Linton; Deputy Surgeon-General Jeffery Marston; Surgeon-General Townsend, C.B.; Hon. Lewis Wingfield; Mr. W. H. Weldon; Mr. H. T. Wood.

THE DWELLING HOUSE.—SUB-COMMITTEE C.

Tuesday, January 1st, 1884.—Present: Captain Douglas Galton, C.B., F.R.S., in the chair; Sir Frederick Abel, C.B., F.R.S.; Mr. A. T. Atchison; Mr. W. R. E. Coles; Prof. T. Hayter Lewis; Mr. W. H. Preece, F.R.S.; Professor W. Chandler Roberts; Mr. Greville Williams; Mr. H. T. Wood.

THE SCHOOL (GROUP IV.) AND EDUCATION (GROUP VI.)

Tuesday, January 1st.—Present: Lord Reay, in the chair; Mr. B. St. John Ackers; Dr. T. R. Armitage; Mr. E. N. Buxton; Mr. J. G. Fitch; Dr. J. H. Gladstone, F.R.S.; Major-General Hammersley; Colonel W. Nassau Lees; Mr. Philip Magnus; Deputy Inspector-General F. J. Monat; Mr. T. Nordenfelt; Sir Francis R. Sandford, K.C.B.; Mr. H. T. Wood.

FRUIT FARMING.

An article on this subject, the particulars of which were drawn from a paper by Mr. Charles Whitehead, of Maidstone, in the *Journal of the Royal Agricultural Society*, and from some books published in America, appeared lately in the *Times*. The following facts are selected from that article:—

It appears that in England, between the years 1872 and 1882, fruit-growing land increased no less than 26,696 acres, while an analysis shows that this increase is apparent in twenty-six counties, all the others showing a decrease. The most important increase is shown in the five fruit-growing counties of Hereford (with 5,944 acres), Kent (5,362 acres), Somerset (with 4,324 acres), Worcester (4,290 acres), and Gloucester (with 3,251 acres increase); while Devonshire—in which county apples were cultivated so long ago as 1520—shows only an increase of 358 acres.

An important proportion of the increased fruit consumption is due to the demand for jam for home and foreign consumption. Jam is becoming a common article of food throughout the country. It may seem strange that fruit should be so dear as it was in 1882, for example, when it is seen that the amount of raw fruit sent into this country during this year was 4,045,691 bushels, of the value of £1,718,909, independently of the large quantities of fruit in the form of pulp, or dried by the sun or artificial processes. The annexed return will show the amount of raw fruit sent into England in 1871 and 1882 respectively, and the various countries from which it was sent:—

Name of country.	1871.		1882.	
	No. of bushels.	Value.	No. of bushels.	Value.
		£		£
Germany	62,519	22,104	515,604	151,096
Holland	160,392	59,542	444,886	182,876
Belgium	276,286	95,822	593,158	669,164
France	354,606	214,542	524,683	335,543
Portugal, Azores, and Madeira	73,979	57,081	133,124	81,245
Spain and Canary Islands	59,712	48,795	462,082	277,757
United States	56,441	40,604	1,065,076	387,190
British North America	55,150	37,004	222,128	90,077
British West India Islands	10,063	10,750	20,168	15,810
Other countries	12,520	9,863	14,197	7,581
Channel Islands	...	...	50,584	20,574
Total	1,218,668	596,107	4,045,690	2,218,913

Not only are the French, the Belgians, and the Germans increasing their area of fruit land, and improving their methods of cultivation, but the Americans are also planting fruit, and are adopting, with characteristic zeal, new and improved systems of packing and preserving it. In the report of the American Commissioner of Agriculture for 1878, it is stated that there were more than two millions of acres under cultivation as apple orchards, and that in twenty years the value of the products had increased from £1,320,000 to over £10,000,000. Besides apples and many other small fruits, the peach crop of the United States is estimated at the annual value of £11,500,000; so that it is not surprising that there is occasionally a superabundance of fruit, especially of peaches and apples, upon which pigs are fed. This waste has been in a great degree obviated by the ingenuity of the Americans in preserving the fruits and drying them. At Baltimore particularly, as well as in other cities which are centres for the accumulation of fruit, large establishments have been built and furnished with the most improved machinery and appliances for the rapid drying and evaporation of the watery parts of fruits. By an ingenious process the water is slowly separated from the solid parts, which at the same time undergo a chemical change, the acid and the starch being converted into grape-sugar. The Commissioner of Agriculture, in the report alluded to, says of this:—"The proof of the pudding is in the eating, and it is said that an apple-pie made from fruit evaporated by these processes cannot be distinguished from one made of fresh fruit; and yet only one half of the quantity of sugar is required to sweeten it; and the same fact is true in regard to tomatoes, and all fruits and vegetables." Iron stoves, and machines constructed on the principles described above for drying fruit, but portable, and costing only about £15, are used in many districts in the country far from towns. These will, it is said, thoroughly and perfectly dry as much fruit as a family can peel and slice in a day. All kinds of salad and delicate vegetables—such as onions, peas, asparagus, celery, Lima beans—are preserved by these new processes, fresh and "dehydrated," like the fruits of all seasons of the year, for all the markets of the world, returning, placed in water, at any time when desired for use, to their original fulness, colour, flavour, and other properties.

Much fruit is produced in Canada. The acreage of fruit land has been extended largely in the last fifteen years, and the greatest interest is taken by the Government and by the farmers themselves, in the promotion of this industry. The main part of the fruit-land is in Ontario, or Western Canada, in which it is said that any fruits can be grown that are produced in the temperate zone. There is a large fruit-growers' association in Ontario, devoted to the improvement of the cultivation, packing, and preserving of fruits. In 1880, a Commission was appointed by the Lieutenant-Governor, to inquire into the progress of agriculture, and in the report of the Commissioners valuable information as to fruit is contained, which is not only most useful and interesting to Canadian cultivators, but also to all other fruit-producers. Very fine apples are grown in Ontario, better, it is alleged by the Canadians, than those that are grown in the United States. It is said that when Canadian apples are good the Americans buy them and brand them "Americans," and when they have indifferent samples of their own growth, they brand these "Canadians." Canadian apples have undoubtedly a great reputation in the English markets. A large fruit-grower in Ontario, in his evidence before the Commissioners, says:—"There is nothing to prevent our apples from competing successfully with the English apples in England, if they are properly sent. We have beaten them in their own market with the Ribston-pippin. It sells in England at £3 per barrel." Not only do the Canadians exercise the greatest skill in the cultivation of apples, but they understand the art of storing them.

In England, however, Lord Sudeley is the only landowner who has taken up the question in a thorough and businesslike manner. He has already planted 500 acres, and is intending to plant 200 acres more at once. The land is a fairly free working moderately good soil on the Lias formation. It was deeply steam-ploughed and well manured, and standard trees of apples, pears, cherries, plums, and damsons were put in 16 feet apart; 3,000 apple trees were planted of the best sorts, including Lord Suffield, Keswick, Codlin, Grenadier, Cox's Orange Pippin, Cellini, and Warner's King; 812 pear trees have already been put in—Beurré de Capiaumont, Easter Beurré, Louise Bonne, Jargonelle, Beurré d'Amanlis, Doyenné d'Ete, and other choice varieties. There are 32,000 plum trees of forty-four different kinds, such as Diamond, Pond's Sneedling, Early Orleans, greengage, Victoria, and Autumn Compote. Of damson trees there are 9,000, nearly half of which are known as Brittenden's, so largely grown in Kent, and the remainder are the Shropshire prune, Cheshire, common prune, and black.

Only 522 cherry trees have been hitherto put in, as Lord Sudeley is not quite certain as to whether they will flourish at Toddington. These are of the best kinds, such as the late and early Bigarreau, Black Heart, Kentish, and Flemish, and at present are looking very well. Gooseberry or currant bushes and strawberry plants are set between the standards, and in some cases raspberry canes are put between the gooseberry and currant bushes. There are over fifty acres of black currants, raspberries, and strawberries by themselves, without standards. There are 100 acres of strawberry plants in all, and sixty acres of raspberry canes. Some of the apple trees are pyramids, which do very well. Gooseberry bushes number 130,000, and consist of no less than forty-five varieties. No less than 228,000 black currant bushes have been put in of the leading kinds, such as Lee's Prolific, Baldwin's Black, Black Naples, and Prince of Wales. Belts of poplars, Scotch firs, and other quick-growing trees, have been placed round the plantation, to shelter it from the prevailing winds. Beds of osiers have been formed on the banks of the little stream Isbourne, which have taken so well that all the baskets required for the fruit are now made on the estate. Ten acres more are to be planted at once with osiers. A nursery for raising trees and bushes has been formed in a convenient and well-sheltered spot, where standards, pyramids, and bush-trees of all sorts and sizes are seen, well grown, well trained, and worked upon the most approved stocks, as well as all descriptions of fruit bushes. About 100 tons of fruit will be grown on the estate this year, which is a capital quantity, considering that no fruit trees were planted until the autumn of 1880.

The Orange Judd Company of New York (London: Trübner) have just issued a volume by Dr. Oemler, in which we have clear evidence of how far vegetable and fruit culture has taken root in that country. The tomato is grown very largely in New York State, one farmer growing no less than fifty acres annually. They sell at about three dollars (12s.) per bushel crate, and as the average yield is 150 of such crates to the acre—the return for several years has been 450 dollars, or £112 per acre. In Florida, 400 bushels per acre are easily obtained, but as the fruit does not get to New York in quite so fresh a condition, only about two dollars per crate can be obtained. This is just 800 dollars (or £200) per acre, out of which must be deducted, however, cost of transit and a middle profit, so that probably the grower gets no more than the grower in New York State with his smaller yield. The cost of cultivation is not large, the labour being the chief item. It is put down at 100 dollars (£25) per acre, and from this it will be seen that a good rent for the land and profit for the cultivator is made. In a catalogue of a Rochester (New York) firm of lithographers, who specially issued coloured plates for nurserymen's lists, there is a list of no less than 664 plates of different varieties of apples, 150 of pears, 203 of peaches, 84 of new plums, 12 of apricots, 111 of cherries, 124 of grapes, 20 of blackberries, 96 of strawberries, 62 of raspberries, 24 of gooseberries, and 36 of currants. When we come to mere ornament, we find but 400 plates of roses, flowers of all descriptions and evergreens—less than two-thirds of the plates of apples alone. This is but characteristic of American farming.

Mr. J. C. R. Okes wrote subsequently to *The Times*, to point out that Cambridgeshire was not mentioned in this article, among the fruit-growing counties of England, and added the following particulars:—

"It is, I believe, not generally known that very large quantities of gooseberries and other fruits are grown in the neighbourhood of Wisbeach, where the soil seems admirably adapted to the production of fruit and vegetables. The local papers state that large sums are obtained from the sale of this crop. If my memory is correct, the gooseberry crop last year (1882) sold for nearly £100 per acre, and this year (1883) for £75 per acre. The chief markets are Birmingham and Manchester, to which places there is good rail accommodation. Possibly this is the nearest approach as regards prices to those obtainable in Canada and America."

NEW PATENT ACT.

Unusual activity prevailed at the Patent-office, on the 1st inst., when the new Patent Act came into operation. One enthusiastic inventor, hailing from north of the Tweed, took up his station outside the door soon after midnight, and his patience was rewarded by the honour of appearing as "No. 1" under the new law. Towards 4 o'clock, he was joined by two others, and when the hour for opening had arrived, a small crowd of about fifty eager appli-

Journal of the Society of Arts.

No. 1,625. Vol. XXXII.

FRIDAY, JANUARY 11, 1884.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

SWINEY PRIZE.

The adjudicators under the will of the late Dr. Swiney are summoned to meet on Monday, the 21st January, 1884, at the Rooms of the Society, at 3.30 p.m., to make the award in conformity with the terms of the bequest contained in the will of the testator.

By order,
H. Trueman Wood, Secretary.

16th January, 1884.

MULREADY PRIZE COMPETITION.

The Council of the Society of Arts, acting on the report of the Judges appointed by them, have awarded the Society's Gold Medal to Charles J. Adams, of the School of Art, Leicester, for his drawing from the nude figure, submitted in competition for the prize offered by the Society "to that student in a School of Art in the United Kingdom who exhibits the best drawing from the nude figure, executed in black and red chalk, in the manner so successfully practised by Mulready."

PRIZES FOR ESSAYS.

The Council have to announce that they have accepted a very liberal offer made by Mr. William Westgarth, a member of the Society, to provide a sum of £1,200 for prizes for essays upon the construction of Dwellings for the Poor of the Metropolis, and on plans for reconstructing Central London. The prize for the former essay will amount to £250; for the latter there will be one prize of £500, and three prizes of £150 each. Full particulars of the conditions will be published immediately.

JUVENILE LECTURES.

The second of these lectures, on "Crystals and Crystallisation," was delivered by Mr. J. Millar Thomson, F.R.S.E., Sec. C.S., on Wednesday evening, the 9th inst. The lecturer first described the solution of substances in solvents other than water, such as alcohol, and pointed out that, in these cases, as in the case of solution in water, crystalline salts may be obtained termed alcoholates. He next dwelt upon the union of water with salts at low temperatures, and described the formation of those crystalline bodies which Dr. Guthrie terms cryohydrates. The next portion of the lecture dealt with the passage of light through certain crystals, as in the case of Iceland spar, where the pencil of light becomes divided, giving rise to the phenomenon of double refraction. After showing this phenomenon on the screen, Mr. Thomson drew attention to the action of polarised light when passing through films of crystals of different thickness, and exhibited in the beam of the lantern patterns made from different thicknesses of the crystals. He then passed to the consideration of abnormal cases of solution and crystallisation, alluding to the phenomena of supersaturation. He first showed that a flask containing such a supersaturated solution, when opened to the air of the room, suddenly became solid. Minute solid particles, derived from the air, appear to be instrumental in causing the crystallisation of such solutions, and Mr. Thomson showed that if such a solution be placed in a flask furnished with two tubes closed with plugs of cotton wool, it was found that on withdrawing the plugs, and blowing air through one of the tubes dipping into the solution, crystallisation does not take place, apparently from the air having been deprived of the particles causing it; for if the air be blown through the same solution with bellows, it solidifies almost instantaneously. After explaining the conditions of isomorphism between certain groups of crystals, Mr. Thomson pointed out that crystals of different bodies may be dropped through supersaturated solutions, provided such crystals were of a different form from that of the body in solution. He also showed that a solution may be stirred with a glass rod provided it be thoroughly clean, but the moment it is withdrawn and touches some other body, it takes up some nucleus which starts the crystallisation. After alluding to the separation of substances by this means, if they are of different forms, Mr. Thomson concluded his lecture by showing two supersaturated solutions in a tall cylinder, one above the other. A crystal of the body in the lower one was dropped in, when it passed through the upper solution, solidifying only the lower layer; on touching the upper layer, however, with a crystal of itself, the top layer then became solid.

CANTOR LECTURES.

THE SCIENTIFIC BASIS OF COOKERY.

By W. Mattieu Williams, F.C S.

Lecture III.—Delivered December 17, 1883.

According to the classification adopted in the first lecture, frying ranks with boiling and stewing, rather than with grilling. When properly conducted, it is one of the processes in which the heat is communicated by convection, the medium being hot fat instead of the hot water used in the so-called, and miscalled, "boiling" of meat.

I say "when properly conducted," because it is too often very improperly conducted in domestic kitchens. This is the case whenever fish, cutlets, &c., are fried on a merely greased plate of metal, such as a common frying-pan. Pancakes or omelettes may be thus fried, but no kind of fish or meat. These should be immersed in a bath of fat sufficiently deep to cover them completely. To those who have not reasoned out the subject, such complete immersion in so large a quantity of fat may appear likely to produce a very greasy result. The contrary is the case.

Let us take, as an example, the frying of a sole. On immersing this in a bath of fat raised to a temperature above that of boiling water, a violent hissing and crackling noise ("frizzling") is heard. This is caused by a series of small explosions due to the sudden conversion of water into steam. The water was originally on the surface and between and within the fibres of the flesh of the sole. The continual expansion of this water into vapour, and its outbursting, prevents the fat from penetrating the fish, so long as the temperature is maintained above 212°, and thus the substance of the sole is cooked by the steam of its own juices, and its outside browned by the superheated fat.

Now, let us suppose that a merely greased plate, like the bottom of a frying-pan, is used. Only one side of the sole is cooked at first—the side in contact with the pan—therefore it must be turned to cook the other side. When thus turned, the side first cooked with its adhering fat is cooling; its steam is condensing between its fibres, and the fat gradually entering to supply the place of steam, while the other side is cooking. Thus it is more greasy than if rapidly withdrawn from the bath of hot fat, and then allowed to drain before the steam commences to condense.

Here is a frying-kettle, exhibited by Mr. Burton, with a wire frame or grill, fitting the bottom. On this the fish is laid, and by this it is raised immediately it is cooked, and the fat drained away. A stew-pan, or any other suitable kind of kettle, may be used, if provided with the wire basket for lifting; or a frying-pan of the ordinary kind, if deep enough.

Although the quantity of fat required for starting this kind of frying is considerable, the consumption at each operation is less than when the greased plate is used; the material of the fat bath can be used again and again with occasional clarifying by methods well understood in the kitchen, but the fat used for smearing the frying-pan is nearly all wasted by the overheating and carbonizing of a portion of it. Of course, two or more supplies of fat are required, one for fish, another for cutlets, &c., and another for such delicacies as apple fritters, which especially require the fat bath.

There is yet to be described a constituent of animal food that is not contained in any kind of flesh, nor even in the blood, and yet is of the highest nutritive value, This is *casein*, the substantial basis of milk. It is separated as curd in the familiar operation of making curds and whey, and in the first stage of the manufacture of cheese. When thus separated from whole milk, it is by no means pure casein, as it carries with it nearly all the oil globules, *i.e.*, the cream contained in the milk.

Pure casein, as prepared in the laboratory for the study of its special properties, is obtained by first skimming the cream from the milk, then precipitating the curd from this, and washing it with ether, to remove the small quantity of cream still adhering to it.

Before describing its properties, I must say a few words concerning the precipitation of the curd. Rennet is commonly used. This is the inner or mucous membrane of the stomach of a calf, a little salted piece of which, or a solution from it in hot water, will precipitate all the casein from many thousand times its own weight of milk. The precipitation may also be effected by acids, and it is probable that the rennet sets up a sort of fermentation, or incipient putrefaction, which liberates lactic acid (the acid of sour milk), and that this souring of the milk goes on until all the curd is separated. What, then, is the nature of the change that induces this precipitation? It is a coagulation nearly resembling that of albumen, excepting that casein is not coagulable by simple heating.

There is one lesson here that I am particularly anxious to impress, viz., that casein may exist in two forms, the insoluble casein of the precipated curd, or of cheese, which is simply pressed curd more or less salted; and the soluble casein, which exists in milk. The practical application I make of this will be seen presently.

If skim milk from which all the fat has been removed be carefully boiled down, we may obtain soluble casein in a solid form and dry. It is an amber-coloured translucent substance, tasteless and inodorous, when pure. If added to a small quantity of water, a yellowish viscous liquid is obtained. Condensed milk is this, *plus* cream and sugar, and its solubility is familiar to all.

Casein that has been coagulated by rennet or acids is insoluble. This is the condition of the casein of cheese, and I think sufficiently explains the difference between the digestibility of cheese and that of milk. An infant that feeds on milk would be killed by a raw cheese diet.

This indigestibility of insoluble casein is very serious, as dry casein has about the same composition as dry albumen, fibrin, or gelatine, and, if as easily digested, would have equal nutritive value. But this is not all. We do not use either our albumen, fibrin, or gelatine, or casein, in the dry form as obtained in the laboratory, but the first three in the form of flesh meat, and the latter in that of cheese. In both cases we have an addition of fatty matter, either the fat of the animal tissue, or that of the cream. But in both the meat and the cheese there is another constituent, viz., water. In the best part of lean beef an average of 72½ per cent. of water is found; in mutton, 73½; in veal, 74½; in pork, 69½; in fowl, 73½; while in Cheshire cheese the average only amounts to 30½ per cent. Other cheeses about the same.

Taking the composition of a whole skinned and prepared sheep, or ox, as it hangs in a butcher's shop, the amount of nutriment it contains is about equal to one-third of its weight of cheese. The fat is about the same in both, but the difference is due to the bones and excess of water. Thus, 20 lbs. of cheese contains as much nutritious material as a sheep of 60 lbs. weight, and would have the same value as practical nutriment, if it could be as easily digested.

To us, in this densely populated country, so largely dependent on imported food, this is of vast importance, cheese being the most portable of all food—even more so than wheat—on account of the greater value in given bulk. We may obtain it from nearly all parts of the world, and it can be used as ballast, if obtainable where ballast is required.

I, therefore, claim to have done the State some service in having worked out the problem of restoring the casein of cheese to its original soluble form, as it existed in the milk, and thereby rendering it easy of digestion. My method is very simple, and, after what I have just explained, so obvious, that I am surprised at being unable to find any record of its having been done before.

As everybody now knows, acids are neutralised by alkalis. If then, the casein was rendered insoluble by acid—say lactic acid—it is probable that it may have its solubility restored by adding as much alkali as will neutralise that acid. I have tried this with complete success, have thus dissolved cheese both in milk and in water.

But you will say that this is bringing too much of the laboratory into the kitchen—this neutralisation by alkali, and will very properly ask, what alkali? and how this alkali will act in the body; whether as food, or as medicine, or as poison?

The alkali I use is potash, in the form of bicarbonate, which readily gives up its alkali to any fixed acid when hot; a little explanation will show that it not only renders the cheese digestible, but supplies just that which cheese requires in order to render it a complete food

Salts of potash exist in milk, but they are all so soluble that when the curd is precipitated in the cheese-making they are left behind in the whey, causing the cheese to be in a condition somewhat analogous to that of the gelatine of the academicians, or still more nearly to that of salt junk, from which the juices have passed by exosmosis into the brine.

In the course of my youthful wanderings, I had a very instructive experience of this. With a fellow tourist (the late C. M. Clayton, son of the diplomatist concerned in the "Clayton-Bulwer treaty"), I took passage in a small schooner from Malta to Athens. We were both pedestrians, had walked together, "roughing it," in Italy and Sicily, and proud of our powers of enduring hardships. Consequently, in providing our food for the voyage, we took nothing but a lump of cheese and some loaves of bread. A gale of wind blew us far out of our proper course, and made the journey a long one. We ate our cheese heartily enough for about three days, then it became hard work to go on with it. It grew worse and worse, until at last we gladly exchanged the remainder for some of the vile broth made by the dirty sailors, in the still dirtier forecastle, and composed of horse beans and stale cabbage leaves, boiled in water. On landing at the Pireaus, we devoured cucumbers, fruit, and lettuces with strange avidity. We were evidently on the road to scurvy, and should have reached some of its uglier symptoms had we continued the cheese diet much longer.

We were craving for the potash salts wanting in the cheese, and which the raw vegetables supplied, just as sailors crave for the like after a long course of salt junk and biscuits.

This is my recipe for restoring the casein of cheese to its original soluble condition. Grate the cheese, or cut it into shreds, then add bicarbonate of potash at the rate of a quarter of an ounce to one pound of cheese (this proportion I have calculated as about supplying the amount of potash which originally existed in the quantity of milk from which the cheese was made). Put these in three or four times their own bulk of water or milk, slowly raise o the boiling point, and keep hot, stirring until all the cheese is dissolved. The solution thus obtained, thickens into a custard-like mass on cooling. Any larger quantity of water or milk may be used if a more liquid result is required.

I use common English or American cheese, in spite of the cookery books, which prescribe Parmesan whenever grated cheese is demanded. Parmesan grates readily, because, as they say in the Midlands, "its butter has gone to market." It is similar to what is there called "skim Dick," the hard dry cheese given to farm labourers, or sold at about 4½d. per lb. It is made from skimmed milk. Parmesan is but glorified skim Dick, glorified by its peculiar and fine flavour. The solution of cheese may be used in many different ways. Stirred into oatmeal porridge, boiled rice, bread crumbs, mashed potatoes, hasty pudding, or other similar farinaceous preparations, it supplies a highly nutritious, economical, and digestible dish, a meal in itself equivalent in composition and nutritive value to beef and potatoes.

I have given these concoctions the general name of "cheese porridge." They are not likely to be acceptable to pampered epicures, to whose requirements I give no attention, but those who work hard with brain or muscle will, I think, appreciate them. Their preparation may be simplified, and, I think, rather improved, by adding the bicarbonate of potash to the water in which the meal, rice, &c., is boiled, and, throwing in the grated cheese, well mixing it, just before turning the porridge out of the pot.

The following is an excellent dish—cheese custard, or improved digestible *fondu*. Dissolve grated cheese in milk with bicarbonate of potash in the proportions already given, flavour with mustard and pepper, &c.; then beat up eggs, yolk and white together, at the rate of two or three to every ¼ lb. of cheese. Add these to the cheese solution. Now take a shallow dish that will bear heating, put a little butter on it, and heat the butter till it frizzles; then pour the mixture into this, and bake or fry until it is nearly solidified, and very lightly browned. This is a rich dish, requiring bread. It is best cooked in little dishes, one portion in each, and eaten from the same.

By using a larger quantity of milk to dilute this cheese custard, a very wholesome and delicious cheese pudding may be made. Bread cut in slices, with or without butter, is laid in a pie dish one slice above the other, and the diluted cheese custard poured upon it cold, and allowed to stand an hour or more until the bread is fully saturated. It is then baked until the surface is lightly browned.

The cooking of milk is very simple. The only notable change which occurs is the coagulation of the small quantity of albumen it contains. This is shown by the scum formed on the surface of boiled milk. There is, however, a special reason why the milk supplied to

London and other large towns, from sources unknown, should all be boiled before using it. There is now no further reason to doubt that certain disease germs, or species of microbia that disseminate disease, are nourished by milk, increase and multiply therein, and may thus be introduced into the blood, and produce very serious consequences. As these microbia are killed by subjecting them to a temperature of 212° (the boiling point of milk is a little above this), there is little, if any danger, in milk that has been boiled. The loss of albumen as scum is very trivial.

Butter may possibly convey these germs, and I think this subject worthy of further investigation than it has received.

A great revolution is in progress as regards butter. I greatly amused some of my friends, about twelve years ago, by predicting that such a revolution would occur—that dairy butter would, to a great extent, be superseded by butter manufactured from the waste fat of slaughtered animals. This is now the case. I have obtained samples of this product, technically named "bosch," at various times, and from various sources, since I wrote about it in 1871, and have observed a steady improvement from the early attempts, which resulted in a yellow, granular fat-like dripping, to a very recent sample, which neither myself nor the wholesale butter factor who showed it to me could distinguish from first-class fresh butter. It was offered, and largely sold, at 8½d. per lb., done up very neatly in rolls, wrapped in linen, and packed in boxes. I know one family, very particular in the matter of butter, who ate 24 lbs. of it, believing it to be superior cream butter. Many others do so, but pay more than double the price I have named, and are thereby assured that it must be real Devonshire.

Most of the other samples I have recently tried were slightly tainted with a resinous flavour, due, I suspect, to careless preparation with apparatus or utensils, made of resinous pine, or deal wood. More carefully prepared, and sold honestly for what it is, there is no good reason why it should not take the place of butter very largely. It does so now, by dishonest admixture, and by being sold under false pretences.

I must now pass to the cookery of vegetable food. Its ultimate elements are the same as those of animal food. This is at once obvious, seeing that beef and mutton are made from grass.

The proximate elements differ but slightly. The fat of the animal is represented by the starch, sugar, oils, and resins of vegetables. We do not eat the latter, and only a selected few of the oils, but starch and sugar, composed of carbon and the elements of water, constitute the greater part of the bulk of vegetable food generally.

Arrowroot is nearly pure starch, tapioca and sago are similar, rice and potatoes are chiefly composed of starch, and in a less degree it contributes to the bulk of wheat, barley, oats, and maize. In all these it exists as minute granules enveloped in a special membrane. Arrowroot, as sold in the shops, consists of granules that may be felt between the fingers, or seen distinctly by the aid of a microscope of very moderate power. Such raw starch does not dissolve in cold water. The granules merely fall to the bottom, and rest there as granules.

The cookery of starch resembles the cookery of gelatine; it is a conversion from an insoluble to a soluble or hydrated form, when heated in water. The change takes place very readily; at 140° the granules absorb water, swell and burst; the result being the formation of the well-known mucilaginous material used by laundresses for stiffening linen. Here we have a case of endosmosis through the envelope of the granule.

A dry heat of 320° converts the starch into *dextrin*, or "British gum," which has the same composition as starch, but is freely soluble in cold water. This conversion of starch into dextrin is also affected by a curious substance called *diastase*, or *mucin*, which is formed during the germination of grain and seeds generally. Like albumen, casein, gelatine, &c., this diastase is a nitrogenous substance, but is not very well understood. Very minute quantities act. It is estimated that one part of diastase will change above a thousand times its own weight of starch into dextrin.

The vegetable germ, lying dormant in the dry seed, is surrounded by the material of its food, the starch; but this insoluble uncooked starch is not food for the germ. When the conditions of germ growth are fulfilled, the germ mysteriously produces a modicum of diastase; this cooks or renders soluble the starch, which now becomes dextrin; and after this, by further change, is converted into sugar, upon which the germ feeds freely.

The malster uses this action by starting the germination, and carrying it forward until the sugar is formed; then, by heating the malt, he kills the germ, and appropriates its food.

The saliva of man and other animals converts starch into dextrin, and then into sugar, by a similar action, that has been ascribed to a rather hypothetical compound called animal diastase, or salivary diastase.

The chemist can easily imitate this in his laboratory, and convert any quantity of starch into sugar. I have not time to describe the process, but may add that he can do more than this, he can convert cellulose or woody fibre into sugar. Sugar may be made from linen and cotton rags, or from paper pulp, or even from sawdust, but, at present, it does not pay to carry this out commercially. Nature does it for us very cheaply.

The ripening of fruit is an example of this. The best pears are those which, when gathered in autumn, are woody, sour, and uneatable. By simply storing them for a month or two, they become deliciously soft and sweet. The woody fibre is converted into sugar, the process being probably aided by the acid, as the chemist uses an acid in effecting the metamorphosis I have just described.

This leads me to a subject on which I have been pondering lately, viz., the possibility of applying the principle of ensilage, which is a sort of slow cookery, in the preparation of human food. You have heard, of course, of the ensilage of cattle fodder, how by storing very coarse fibrous vegetable matter, such as pea-stalks, the stem and flags of maize, &c., and leaving it in a humid condition, but covered from the air and well pressed together, it becomes digestible and nutritious fodder, well appreciated by cattle.

If I mistake not, the change which takes place in the silo is similar to that which occurs in the ripening pear, a partial conversion of woody fibre or cellulose into sugar. Standing faithfully to my own subject, I may describe it as slow cookery, very gentle and deliberate stewing.

I must now briefly refer to the nitrogenous constituents of vegetable food, those which correspond to albumen, gelatine, fibrin and casein, and have been classed together as albuminoids. Gluten is one of these, and being the flesh-forming constituent of bread, claims first rank. If some wheat flour, moistened to form a dough, be wrapped in a piece of loosely woven linen, and held and kneaded in running water, the starch granules may be washed out, until there remains a tenacious gluey substance. This is the gluten, having a composition almost identical with albumen, casein, fibrin, and gelatine, and a corresponding value as food It is rendered less tenacious, and more soluble by cooking.

Peas, beans, lentils, and other seeds of leguminous plants yield a somewhat different albuminoid, legumin, so nearly resembling casein, that it has been named vegetable casein.

Like animal casein it is highly nutritious, and is difficult of digestion. Peas, beans, &c., contain far more nutriment than any kind of grain, and would be practically more nutritious, weight for weight, than either grain or flesh, if this casein could be rendered easy of digestion. I am experimenting upon it with growing prospects of success. These experiments have thrown a new light upon the old doggrel—

> "Peas pudding hot, peas pudding cold,
> Peas pudding in the pot, nine days old."

Why "nine days old?" In these words I see a deep prophetic meaning, the foreshadowing of a great vegetarian future, when by the ensilage or slow stewing of the cellulose, and similar treatment of the casein of some of the most abundant of vegetables, we shall obtain many new varieties of food that will supersede altogether our present barbaric dependence upon the digestive and assimilating organs of sheep, cows, pigs, &c., for the preparation of our food from its primary source, the vegetable world.

I find that oatmeal porridge "nine days old" is more digestible, and I believe more assimilable or nutritious, than freshly made porridge. My studies of peas-pudding are at present limited, but are sufficient to indicate that this and pease brose may be rendered easily digestible by means of a sort of ensilage, when duly mixed with farinaceous or even fibrous vegetables, and aided by a little bicarbonate of potash. My difficulty hitherto has been mouldiness, but this is merely incidental, and may be prevented by better arrangements for the exclusion of air, and a more capacious silo.

The advantages possessed by flesh food do not depend upon its composition, but upon its condition. This is shown by the following comparative statement of the chemical composition of the nitrogenous constituents of animal and vegetable food:—

	Animal Casein	Vegetable Casein.
Carbon	53·83	53·46
Hydrogen	7·15	7·13
Nitrogen	15·65	16·04
Oxygen, Sulphur, Phosphorus	23·37	23·37

	Albumen.	Gluten.
Carbon	53·5	53·27
Hydrogen	7·0	7·17
Nitrogen	15·5	15·94
Oxygen, Sulphur, Phosphorus	24·0	23·62

	Animal Fibrin.	Vegetable Fibrin.
Carbon	52·7	53·23
Hydrogen	6·9	7·01
Nitrogen	15·4	16·41
Oxygen, Sulphur, Phosphorus	25·0	23·35

Remembering that vegetable oils, and sugar, and starch, have a similar food value to fat, nothing is easier than to select a purely vegetable *menu* that shall contain, in the same weight and bulk, exactly the same constituents as any given *menu* including animal food; but at present we cannot supply it in a condition so easy of assimilation. There is more work to be done after swallowing the vegetable meal, in order to convert it into blood, than is demanded by the flesh food of corresponding composition, and consequently some of it escapes, or the demand on our vital energy made to assimilate the vegetable food takes too much away from our other working powers.

Nothing is wanted here but more science applied to cookery, the problem is clearly definable and defined, and is obviously less difficult than many others that science has already solved.

I must conclude by simply naming some of the other nutritive constituents of vegetables, such as *pecten*, the jelly of fruits; and the saline juices of vegetables that contain all that is contained in the saline juices of flesh, and are of similar value as completing the dietary. They are subject to little or no change in cookery, are quite as good when raw as after being cooked.

In connection with this, I must again be egotistical, by proclaiming another result of my own researches, viz., the determination of the difference between baked potatoes, and boiled or steamed potatoes, and between potatoes boiled in their jackets, and potatoes peeled before boiling. I find potash in the water in which potatoes have been boiled. It is evident that some of the soluble potash salts of the juice of the potato passes out by exosmosis into the water. By baking them, or frying them, this is entirely prevented. We all know that there is a difference between a baked and a boiled potato. I attribute it mainly to this.

As regards the great question of jackets or no jackets, I can only speak theoretically at present. I suppose that the natural envelope does resist the out-going of some of these saline juices, but have not yet proved it analytically. The highest of all practical authorities on this subject, the Irish peasant, has very firmly decided for himself. I have never seen raw potatoes in a state of nakedness in Ireland, and suspect that natural appetite has discovered that there is something in the full-dressed potato that is demanded in the system, just as it teaches the sailor to crave for potash food, as I and my fellow cheese eater did in in Greece.

For the same reason raw salads are better than boiled vegetables of similar composition, unless the water in which they are boiled is used as a *potage* or *soupe maigre*. The Irish demand for "a stone in the middle" of his potato may be due to the better retention of the potash by the under-cooked tuber.

I must now conclude with apology for the necessary imperfections of this very short sketch of a large subject, which can only be treated in barest outline in three lectures. But the time you have spent in listening to them will have been well spent, if they have only awakened an interest in the subject, and induced you to prosecute it further, by proving that there really is a "scientific basis of cookery."

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION.

The following Sub-Committees have met at the Society of Arts since the meetings recorded in last week's *Journal*:—

Sick and Ambulance.

Thursday, January 3rd.—Present: Director-General Crawford, A.M.D., in the chair; Deputy Surgeon-General Bostock, C.B.; Brigade-Surgeon W. G. Don, A.M.G.; Surgeon-Major G. J. H. Evatt, M.D., A.M.D.; Mr. John Furley; Deputy Inspector-General F. J. Mouat; Dr. J. C. Steele; Mr. H. T. Wood.

METEOROLOGICAL.

Friday, January 4th.—Present: Professor F. De Chaumont, M.D., F.R.S., in the chair; Mr. W. B. Bryan; Captain Douglas Galton, C.B., F.R.S.; Mr. T. Hawksley; Mr. Robert H. Scott; Mr. G. J. Symons; Dr. J. W. Tribe; Mr. H. T. Wood.

FOOD.

Friday, January 4th.—Present: Dr. J. H. Gilbert, F.R.S., in the chair; Mr. J. Bell; Dr. T. Lander Bruton, F.R.S.; Mr. C. A. Buckmaster, M.A.; Mr. W. Carruthers, F.R.S.; Professor F. De Chaumont, M.D., F.R.S.; Professor A. H. Church; Dr. Spencer Cobbold; Director-General Crawford, A.M.D.; Dr. A. Dupré, F.R.S.; Prof. Charles Graham, D.Sc.; Dr. Wilson Hake; Professor H. N. Moseley, F.R.S.; Dr. F. W. Pavy, F.R.S.; Sir Henry Thompson; Dr. C. M. Tidy; Mr. T. Twining; Mr. G. W. Wigner; Mr. H. T. Wood.

THE DWELLING HOUSE.—GROUP III.—SUB-COMMITTEE A.

Tuesday, January 8th.—Present: Dr. Frankland, F.R.S., in the chair; Mr. H. H. Collins; Mr. J. Bailey Denton, C.E.; Mr. Rogers Field, M.Inst.C.E.; Mr. Shirley F. Murphy; Mr. George Shaw; Mr. H. T. Wood.

The various Committees are preparing memoranda upon the classes which come under their direction. The following have been issued by the "Workshop" Committee, and by the Committee on Heating, &c.

"THE WORKSHOP."—GROUP V.

It is desired to illustrate, in as practical a manner as possible, the relation of Industrial Conditions and Processes to Health; and to the Sub-Committee charged with advising on this department of the Exhibition the name of "The Workshop Sub-Committee" has been given. The place of production of all articles used by man is for the present purpose spoken of as "The Workshop."

In this department the following classes of the Exhibition are comprised:—

Class 41.—Designs and models for improvements in the arrangements and construction of workshops, especially those in which dangerous or unwholesome processes are conducted.

Class 42.—Apparatus and fittings for preventing or minimising the danger to health or life from carrying on certain trades. Guards, screens, fans, air-jets, preservative solutions, washes, &c.

Class 43.—Objects for personal use. Mouth-pieces, spectacles, dresses, hoods, &c., for use in certain unhealthy and poisonous trades.

Class 44.—Illustrations of diseases and deformities caused by unwholesome trades and professions. Methods of combating these diseases. Preservative measures, &c.

Class 45.—Sanitary construction and inspection of workshops, factories, and mines. (*a*) New inventions or improvements for ameliorating the condition of life of those engaged in unhealthy occupations. (*b*) Means of economising human labour in various industrial operations.

Class 46.—Literature, statistics, diagrams, &c., relating to this Group.

The following heads show the principal subjects which the Sub-Committee are anxious should be illustrated in the several classes of this department, the illustrations being expected to include alike the conditions of injury to health and the means proposed for improvement.

Besides apparatus used, or proposed for use, with a view to minimise danger to life and health, the exhibits may comprise models, drawings, specimens, both of harmful products and improved products, &c., and the Committee will be specially glad to receive collections of specimens, models, diagrams, photographs, &c., showing existing evils or noxious conditions which have been modified by recent improvements.

(a.) Ventilation of the workshop—By simple discharge of internal air; by destroying offensive or injurious quality of discharged air.

(b.) Effluvium nuisances — By condensing and utilising vapours; by consuming vapours; by other means, as in gas works.

(c.) Dust nuisances, *e.g.*—In needle grinding, mother-o'-pearl working, in weaving sheds.

(d.) Danger from mineral poisons, *e.g.*—In arsenic works, white-lead works, playing-card making, card-bronzing; phosphorus and match manufacture.

(e.) Danger from animal poisons, *e.g.*—In wool-sorting, rag-picking.

(f.) Prevention of accidents in the workshop, *e.g.*—Protection against heat, injury to eyes; against explosions in the mine and elsewhere.

THE DWELLING HOUSE.—GROUP III.

Classes 24, 25, 26, *Heating, Lighting, Ventilating, and Smoke Abatement.*

The portion of Group 3, the Dwelling, with which this Committee proposes to deal, is that comprised within Classes 24, 25, and 26, the following being the official classification:—

Class 24. — Grates, stoves, kitcheners, ranges, boilers, &c., for domestic use. Apparatus for heating and warming, smoke abatement, &c.

Class 25.—Ventilators, air-inlets and outlets, cubic space of rooms, cowls, air straining and cleansing.

Class 26.—Lighting apparatus—(*a*) Electrical apparatus for illumination and domestic use, secondary batteries, electroliers, accumulators, &c.; (*b*) apparatus for lighting by gas, gas producers, gas meters, gas fittings, chandeliers, &c.; (*c*) oil and other lamps, and stoves; mineral oil, wax and other candles, vegetable and animal oils.

In Class 24, will be included methods of warming:—(1) by open and closed grates and stoves; (2) by water, air, steam, and gas apparatus, designed to heat only; (3) by similar appliances, but combining provision for ventilation and the heating of more than one apartment; (4) by similar appliances for domestic use, specially designed for the economical consumption of fuel, and intended to minimise the production of smoke or other noxious products of combustion.

Domestic kitcheners will be included in this class. but appliances for cookery on a large scale will more properly be arranged under Class 6 (Cookery, &c.)

Furnaces and steam boilers for manufacturing operations are not considered to be within the scope of the present Exhibition.

In Class 25 will be included special appliances for ventilation, other than those which may be considered more suitable for Class 24; these will include means for cooling air supplied to rooms, means for improving the condition of the air in rooms, methods for testing air, the results of experimental researches into the state of air vitiated by combustion or by respiration; results of experiments on ventilation, and any other means of effecting improvement in matters relating to this class, or of diffusing knowledge about them.

The official classification sufficiently indicates the class of exhibits which are desired for Class 26. It may be added that electric lighting is to be limited to illustrations of its application to domestic lighting. Its use on a large scale will be practically illustrated by the arrangements made for lighting the Exhibition itself. In the same way, the commercial manufacture of gas is not included, though its production on a small scale for private use is. Exhibits showing the progress of domestic lighting, and affording means of comparison between old and new systems are specially desired. Photometric and other tests for illuminating materials may be added to the list contained in the classification, and it is desirable that methods of gas-lighting should be shown, which either assist, or do not interfere with, the ventilation.

TIMBER TRADE OF CHILI.

Timber, according to the *North-Western Lumberman* (Chicago), is somewhat abundant in all the provinces south of Santiago. There are said to be over one hundred kinds of indigenous trees, of which not more than thirteen ever shed their leaves, and these are mainly utilised in shipbuilding and house carpentering. There are a few ornamental woods but such trees are scarce. The Araucanian pine grows on the mountains south from the Biobio, the trees looking from a distance like gigantic umbrellas The Chilian cedar is regarded as the most important tree. The most abundant timber is the Lombardy poplar, and silver-leaf poplar or aspen. The Jesuits began planting these trees two to three centuries ago for fencing purposes, and miles of poplars in line are found following the courses of ditches, or marking out areas. When sufficiently large, these great hedgerows are attacked with the axe, the trees being cut down so as to leave the stumps about 8 ft. high. The Lombardy variety is principally used for making brake-blocks, and the aspen makes good timber.

Facilities for receiving and getting out lumber have always been meagre and miserable. There is no harbour at Valparaiso, and the vessels arriving are obliged to lie at anchor within easy reach of the shore, while the cargo is unloaded by swarthy and muscular natives who station themselves at intervals of about two rods out in the surf, on a line reaching from boat to beach. They pass the lumber from one to another along the queer line of transportation. The natives go on a jog trot through the shallow surf, and often keep up the action all day with little cessation.

Up to a recent period there has been no means of manufacturing the domestic timber. It was simply formed by hand, and made up into boards of certain dimensions, which were regarded as standard, but never figured in feet, being sold by the piece. In some of the less progressive sections, boards have passed as a medium of exchange. To the lumber that is received into Chili from foreign ports, the Government applies the metric system of measurement, on which its duty collections are based. In addition to lumber, considerable wood is cut in the tan-bark business. Red-wood is being raised in the coast region 1,000 miles from Valparaiso. The timber country is generally mountainous, while the rivers abound with bars. In addition to the woods that have been mentioned, there is a fine variety which resembles beech, while another has a fine grain, and there is a third variety of a reddish colour which polishes nearly as finely as cedar.

Latterly, however, several portable saw-mills have been brought to Chili from the manufactories of the United States, and other improved means are being employed, while the imports of lumber are increasing. Very little manufacturing of goods from wood has been carried on, but enterprises in this direction are contemplated, and, in fact, in course of establishment. Furniture and similar articles have been imported somewhat extensively, but the duties have been made very heavy on such goods, and are reckoned by the weight instead of the exact value in each case. The inhabitants have found importing to be a very expensive business, and it is proposed to build factories for the manufacture of boxes, the importation of which has been heavy, sash, doors and blinds, furniture, &c. Men of capital are now engaged in investigating the details in connection with such enterprises.

From fifty to seventy-five vessels are engaged in trade between Valparaiso, which is the most important west shore port except San Francisco, and other points. Lumber and common freight are combined.

The wages of peons are from 40 to 50 cents. per day, two pieces of bread and one meal of beans being conceded in addition. General unskilled labour commands 1·25 dols. per day among the natives, and artisans obtain 2·50 dols. per day and find themselves. Intelligent foreigners can get from 3 to 6 dols. per day. In the case of the surf-packmen, they obtain large pay, sometimes making as high as 10 dols. per day.

PHYSICAL FEATURES OF COCHIN CHINA.

The following details are taken from a communication by M. Fuchs, engineer-in-chief of mines to the French Geographical Society, made last year with M. Saladin :—

The populations are concentrated in the three large valleys of the Yellow River, the Mekong, and the Meinam, the estuaries of which are rapidly increasing. Two principal races occupy the country, viz., the pro-Malays, including the Siamese, the Laotians, the Khmers, and the Cambogians, on the west; and the yellow race, chiefly represented by the Annamites, on the East. The former attained a high degree of civilisation towards the eighth or ninth century, while the latter are characterised by a predominance of the civil over the military element, and by the accessibility of all offices through public examination.

The vast chain, detached from the Mountains of Thibet, and running south, nearly touches the east coast of the great peninsula. It is composed of granitic rocks, which have, in places, upheaved and penetrated thick strata of ancient shales belonging to the Devonian period. At the bottom of the basins thus formed are large deposits of coal, which appear of slightly later date than those of Europe. Sometimes enormous masses of metamorphic limestone are met with; and above the coal measures are thick strata of sandstone, like that of the Vosges and Thuringia. But there is no trace of either secondary or tertiary formations, so that Cochin China must have emerged since the end of the carboniferous era, and has subsequently been invaded only by diluvial waters.

The coal deposits equal those of France in extent, one of them having been traced for a length of over 100 kilometres, or 62 miles. Three groups of seams have been proved, the actual thickness of coal exceeding 10 metres, or 33 feet. The most accessible deposit, near the Bay of Honggâa, might be connected with the coast by a series of small-guage tramways, and serve for coaling vessels, which are now dependent on Japan and Australia for their supply in the extreme East.

Analyses made at the Ecole des Mines show that the coals may be divided into two classes:—(1) Semi-bituminous (so-called) leaving after combustion a very pure ash; and (2) poor coals burning with a long flame, containing 38 per cent. of volatile matters, and kindling with great facilities.

There is a great abundance of iron ore, both present with the coal and underlying it, but at present worked only in the most primitive manner. There exist deposits of copper, lead, and tin, the extent of which could not, however, be ascertained. There is also an auriferous deposit in the delta of the Tonquin river, formed by the sand washed down by streams from quartzose veins, and containing 30 grammes, or 463 Troy grains, to the ton of sand; but difficulties were encountered from the Government in an attempt to obtain the right of working.

THE GEODETIC CONGRESS AT ROME.

At the Congress recently held at Rome, twenty-eight States were represented, and resolutions embodying the following principles were adopted by the delegates present :—

1. The unification of longitude and of time is recommended to all Governments, as forming a suitable basis for international treaties; the scientific and practical advantages resulting from such an arrangement more than compensating for any inconvenience attending its introduction. This arrangement would be carried out in all astronomical and nautical almanacks, except as regards any data in which a local meridian and local time are indispensable.

2. That information should be diffused as to the decimal subdivision of the quadrant, and that this system should be partially introduced as regards calculations, &c., although the present system can hardly be superseded with respect to navigation, &c.

3. The meridian of Greenwich being the most generally accepted, it is recommended for adoption in the proposed international arrangements.

4. It is suggested to reckon longitude only from west to east, starting from the meridian of Greenwich.

5. For purposes of railway, steamboat, post and telegraphic services, the adoption of a universal time is recommended; local time being still used for ordinary purposes.

6. The foundation of this international time would be noon according to Greenwich time; the hours being reckoned from 0 to 24.

7. States which accept the new system of unification should adopt measures for its introduction as soon as possible.

8. The adoption of the English meridian will, it is

hoped, urge England to take steps as to the question of uniformity of weights and measures.

9. The proposal of the United States Government for a special Conference is approved; and wishes for the holding of an international convention for the ratification of the proposed uniformity of longitude and time are also expressed. The only important case of absence from the voting was that of the representatives of Holland, the Government of that country preferring to await the result of the Congress to be held in 1884 at Washington.

General Notes.

Import of Jute into Germany.—According to the *Central-Blatt für Textil Industrie*, six full cargoes of jute were discharged at Bremen during the first nine months of 1883. Four of these were imported from Calcutta by one large German manufacturing establishment. The total quantity of jute thus received was about 60,000 bales, worth £175,000.

Artificial Mineral Waters.—Messrs. Struve and Co., the manufacturers of the "original Brighton Seltzer," write to contradict a statement in Mr. Bruce-Warren's paper on "Mineral Waters," to the effect that there are at present no scientific mineral-water manufacturers in the kingdom. Messrs. Struve refer to reports in the *British Medical Journal*, and in the *Lancet*, showing that their mineral waters strictly follow the composition of the natural waters they are intended to resemble; and refer also to several eminent physicians as being ready to testify that their manufactures are produced on scientific principles.

Silk Waste.—An article on this subject lately appeared in a German contemporary. From the facts which it contains, it would seem that the modern idea of the treatment of silk waste in this manner is, to a certain extent, the following out of the system of treatment applied to flax for centuries past. England and Switzerland, it is remarked, are entitled to recognition as having perfected, the processes of combing, &c., by means of which silk waste has been utilised. The employment of the waste in the velvet manufactures of the Rhenish districts, dates from the year 1861. For a time the English spinners of the article had the exclusive command of the trade, but in 1867 Switzerland arrived at the requisite degree of perfection to allow of successful rivalry, in the German market, with the products of English industry. Austria, Italy, and Alsace have since entered the field of competition. In 1870, a process was introduced in Crefeld, by means of which the yarn was gassed after being dyed, the result being that its brightness was increased. A progressive increase in the employment of silk waste has taken place in the Crefeld district, the quantity used in 1882 having been about 270 tons.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, eight o'clock:—

Dates Fixed.

January 16.—"Electric Launches." By A. Reckenzaun. W. H. Preece, F.R.S., Vice-President of the Society, will preside.

January 23.—"Science Teaching in Elementary Schools." By William Lant Carpenter, B.A., B.Sc. Sir John Lubbock, Bart., M.P., F.R.S., Vice-President of the Society, will preside.

January 30.—"Coal Gas as a Labour-saving Agent in Mechanical Trades." By Thomas Fletcher, F.C.S.

Dates to be Hereafter Announced.

"Sanitary Progress." By B. W. Richardson, M.D., F.R.S.

"The Progress of Electric Lighting." By W. H. Preece, F.R.S.

"Forest Administration in India." By Dr. Brandis, F.R.S.

"Reclamation of Land on the North-Western Coast of England." By Hyde Clarke.

"Water Regulation in England." By General Rundall.

"Telpherage." By Professor Fleeming Jenkin, F.R.S.

"New Process of Permanent Mural Painting," invented by Adolph Keim, of Munich. By Rev. J. A. Rivington.

"Slate Quarrying." By W. A. Darbishire.

Foreign and Colonial Section.

Tuesday evenings:—

January 29.—"Canada as it will appear to the British Association in 1884." By Joseph G. Colmer, Secretary to the High Commissioner for Canada. The Marquis of Lorne, K.T., will preside.

February 12.—"The Portuguese Colonies of West Africa." By H. H. Johnston.

February 26.—"Reflections on Chinese History, with reference to the present situation of affairs." By Demetrius G. Boulger.

March 18.—"Borneo and its Products." By B. Francis Cobb, Vice-President of the Society.

April 1.—"The Rivers Congo and Niger entrances to Mid-Africa." By Robert Capper.

APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings :—

JANUARY 24.—"Manufacture of Gas from Limed Coal." By Professor WANKLYN. DAVID HOWARD, F.C.S., will preside.

FEBRUARY 21.—"The Upper Thames as a Source of Water Supply." By Dr. PERCY F. FRANKLAND.

MARCH 27.—"Cupro-Ammonium Solution and its Use in Waterproofing Paper and Vegetable Tissues." By C. R. ALDER WRIGHT, F.R.S., D.Sc.

APRIL 24.—"Economic Applications of Seaweed." By EDWARD C. STANFORD, F.C.S.

MAY 8.—

MAY 29.—

INDIAN SECTION.

Friday evenings :—

FEBRUARY 15.—"State Monopoly of Railways in India." By J. M. MACLEAN.

MARCH 7.—"The New Bengal Rent Bill." By W. SETON-KARR.

MARCH 28.—"Trade Routes in Afghanistan." By GRIFFIN W. VYSE.

APRIL 25.—"The Existing Law of Landlord and Tenant in India." By W. G. PEDDER.

MAY 9.—

MAY 30.—

*** The dates given above are subject to alteration.

CANTOR LECTURES.

The Second Course will be on "Recent Improvements in Photo-Mechanical Printing Methods." By THOMAS BOLAS, F.C.S.

LECTURE I. Jan. 28.—New Developments of the Woodbury Type Process.

LECTURE II. Feb. 4.—Type Blocks from Line Drawings and Half Tone subjects.

LECTURE III. Feb. 11.—Intaglio Plates. Collotypes. Photo-Mechanical Methods, as applied to the Decoration of Pottery. Miscellaneous Processes.

The Third Course will be on "The Building of London Houses." By ROBERT W. EDIS, F.S.A. *Dates*—February 18, 25; March 3.

The Fourth Course will be on "The Alloys used for Coinage." By Prof. W. CHANDLER ROBERTS, F.R.S., Chemist of the Royal Mint. *Dates*—March 17, 24, 31; April 7.

The Fifth Course will be on "Some New Optical Instruments and Arrangements." By J. NORMAN LOCKYER, F.R.S., F.R.A.S. *Dates*—April 28; May 5.

The Sixth Course will be on "Fermentation and Distillation." By Professor W. NOEL HARTLEY, F.C.S. *Dates*—May 12, 19, 26.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 14...Surveyors, 12, Great George-street, S.W., 8 p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. Henry Blackburn, "The Art Season of 1883."

TUESDAY, JAN. 15...Royal Institution, Albemarle-street, W., 3 p.m. Mr. R. S. Poole, "The Interest and Usefulness of the Study of Coins and Medals." (Lecture I.)

Civil Engineers, 25, Great George-street, Westminster, S.W., 8 p.m.

Statistical, School of Mines, Jermyn-street, S.W., 7¾ p.m.

Pathological, 53, Berners-st., Oxford-st., W., 8½ p.m.

Zoological, 11, Hanover-square, W., 8½ p.m. 1. Mr. W. F. R. Weldon, "The Placenta of *Tetraceros quadricornis*." 2. Mr. E. J. Miles, "Some Crustaceans from the Mauritius." 3. "Varieties and Hybrids among the Salmonidæ."

WEDNESDAY, JAN. 16...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. A. Reckenzaun, "Electric Launches."

Meteorological, 25, Great George-street, S.W., 7 p.m. Annual Meeting and Presidential Address.

Entomological, 11, Chandos-street, W., 7 p.m.

Archæological Association, 32, Sackville-street, W., 8 p.m. Dr. Joseph Stevens, "The Remains found in the Anglo-Saxon Tumulus, at Taplow, Bucks."

Civil and Mechanical Engineers, 7, Westminster-chambers, S.W., 7 p.m. Mr. G. Simonds, "The Science of Mechanics as applied to the Fine Arts."

THURSDAY, JAN. 17...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. J. G. Baker, "Revision of the Tuber-bearing Species, *Solanum*." 2. Mr. A. D. Michael, "The Hypopus Question, or Life History of certain Acarina." 3. Mr. W. Joshua, "Burmese Desmidicæ."

Chemical, Burlington-house, W., 8 p.m. 1. Mr. C. T. Kingzett, "Camphoric Peroxide and Camphorate of Barium." 2. Dr. Edward Divers and Mr. Michisada Kawakita, "Decomposition of Silver Fulminate by Hydrochloric Acid;" "Supplementary Note on Liebig's Production of Fulminating Silver without the Use of Nitric Acid." 3. Dr. Edward Divers and Mr. Tamemasa Haga, "Hyponitrites."

London Institution, Finsbury-circus, E.C., 7 p.m. Mr. H. Dixon, "The Nature of Explosions."

Parkes Museum of Hygiene, 74A, Margaret-street, W., 8 p.m. Mr. T. Pridgin Teale, "Economy of Coal in Private Houses."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. E. Pauer, "The History and Development of the Music for the Pianoforte, &c." (Lecture I.)

Historical, 11, Chandos-street, W., 8 p.m.

Numismatic, 4, St. Martin's-place, W., 7 p.m.

FRIDAY, JAN. 18...Froebel Society (at the HOUSE OF THE SOCIETY OF ARTS), 8 p.m. Annual Meeting.

United Service Inst., Whitehall-yard, 3 p.m. Surgeon Major G. J. Evatt, "Army Medical Organisation in War, with suggestions as to Militia and Volunteer Aid."

Royal Institution, Abermarle-street, W., 8 p.m. Weekly meeting, 9 p.m. Prof. Tyndall, "Rainbows."

Philological, University College, W.C., 8 p.m. A Dictionary Evening, by Dr. J. A. H. Murray, President.

Medical Officers of Health, 1, Adam-street, Adelphi, W.C., 7½ p.m.

SATURDAY, JAN. 19...Royal Institution, Albemarle-street, W., 3 p.m. Prof. H. Morley, "Life and Literature under Charles I." (Lecture I.)

Journal of the Society of Arts.

No. 1,626. Vol. XXXII.

FRIDAY, JANUARY 18, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

SWINEY PRIZE.

The adjudicators under the will of the late Dr. Swiney are summoned to meet on Monday, the 21st January, 1884, at the Rooms of the Society, at 3.30 p.m., to make the award in conformity with the terms of the bequest contained in the will of the testator.

By order,
H. Trueman Wood, Secretary.
16th January, 1884.

Proceedings of the Society.

SIXTH ORDINARY MEETING.

Wednesday, January 16th, 1884: William Henry Preece, F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Bentley, Richard, Upton, Slough, Bucks.
Cameron, Lieut.-Colonel Donald Roderick, R.A., Sheerness.
Clapp, William John, Nantyglo, Monmouthshire.
Glover, James, B.A., 30, Crosby-road, Birkdale, Southport.
Godwin, John, 19, St. Mary Abbotts-terrace, Kensington, W.
Graham, Mrs., 40, Woodstock-road, Bedford-park, Chiswick.
Head, John Merrick, London-road, Reigate, Surrey.
Phelips, Richard Charles Hungerford, Cucklington, Somerset.
Huntington, Charles P., Astley Bank, Darwen, Lancashire.
Leeming, Thomas Henry, 2, Lee-terrace, Barking-road, Plaistow, E.
Mackenzie, Colin, Junior Athenæum Club, 116, Piccadilly, W.
Morris, Malcolm, 63, Montagu-square, W.
Newton, Henry Charles, Belsize-court, Hampstead, N.W.
Pike, Luke Owen, 201, Maida-vale, W.
Renouf, Philip Louis, Grove-lodge, Thistle-grove, S.W.
Shearer, John Ronald, 10, Basinghall-street, E.C.
Siemens, Lady, Sherwood, Tunbridge Wells.
Traill, William A., Giant's Causeway, Portrush and Bush Valley Railway, Portrush, Ireland.
Trenchard, Edward Penny, junior, 63, Granville-park, Blackheath, S.E.
Van Praagh, W., 17, Fitzroy-square, W.
Waymouth, George, Angleside, Crouch-hill, N., and 23, Moorgate-street, E.C.
Williams, Rowland, Birch Vale, Derbyshire.
Willink, Henry George, 29, Albion-street, Hyde-park, W.
Wilson, Albert Edward, Redbourn Hill Iron Company, Frodingham, Brigg, Lincolnshire, and Scunthorpe, Lincolnshire.

The following candidates were balloted for and duly elected members of the Society:—

Bennett, John Wheeler, Carisbrooke, Bromley-common, Kent.
Chaytor, Rev. Edward Clerevaux, Elstree School, Herts.
Coleman, Thomas Henry, Regent-street, Wrexham.
Ellis, George Henry, Knighton Hayes, Leicester.
Fielden, John Ashton, Centre-vale, Todmorden.
Lovelock, James Frederick, Rokeby-house, Bishop's-road, Highgate, N.
Smith, William, Sundon-house, Clifton-down, Bristol.
Willis, William H., Ockham-house, Culverden-road, Balham, S.W.

The paper read was—

ELECTRIC LAUNCHES.

By A. Reckenzaun.

It is not my intention to treat this subject from a shipwright's point of view. The title of this paper is supposed to indicate a mode of propelling boats by means of electrical energy, and it is to this motive power that I shall have the honour of drawing your attention.

The primary object of a launch, in the modern sense of the word, lies in the conveyance of passengers on rivers and lakes, less than for the transport of heavy goods; therefore it may not be out of place to consider the conveniences arising from the employment of a motive power which promises to become valuable as time and experience advance. In a recent paper before the British Association at Southport, I referred to numerous experiments made with electric launches; now it is proposed to treat the subject in a wider sense, touching upon the points of convenience in the first place; secondly, upon the cost and method of producing the current of electricity; and thirdly, upon the construction and efficiency of the propelling power and its accessories.

Whether it is for business, pleasure, or war purposes, a launch should be in readiness at all times, without requiring much preparation or attention. The distances to be traversed are seldom very great, fifty to sixty miles being the average.

Nearly the whole space of a launch should be available for the accommodation of passengers, and this is the case with an electrically-propelled launch. We have it on good authority, that an electric launch will accommodate nearly double the number of passengers that a steam launch of the same dimensions would; therefore, for any given accommodation we should require a much smaller vessel, demanding less power to propel it at a given rate of speed, costing less, and affording easier management.

A further convenience arising from electromotive power is the absence of combustibles, and the absence of the products of combustion—matters of great importance; and for the milder seasons, when inland navigation is principally enjoyed, the absence of heat, smell, and noise, and, finally, the dispensing with one attendant on board, whose wages, in most cases, amount to as much or more than the cost of fuel, besides the inconvenience of carrying an additional individual.

I do not know whether the cost of motive power is a serious consideration with proprietors of launches, but it is evident that if there be a choice between two methods of equal qualities, the most economical method will gain favour. The motive power on the electric launch is the electric current; we must decide upon the mode of procuring the current. The mode which first suggested itself to Professor Jacobi, in the year 1838, was the primary battery, or the purely chemical process of generating electricity.

Jacobi employed, in the first instance, a Daniell's battery, and in later experiments with his boat on the river Neva, a Grove's battery. The Daniell's battery consisted of 320 cells containing plates of copper and zinc; the speed attained by the boat with this battery did not reach one mile and a quarter per hour; when 64 Grove's cells were substituted, the speed came to two and a quarter miles per hour; the boat was 28 ft. long, 7½ beam, and 3 ft. deep. The electro-motor was invented by Professor Jacobi; it virtually consisted of two discs, one of which was stationary, and carried a number of electro-magnets, while the other disc was provided with pieces of iron serving as armatures to the pole pieces of the electro-magnets, which were attracted whilst the electric current was alternately conveyed through the bobbins by means of a commutator, producing continuous rotation.

We are not informed as to the length of time the batteries were enabled to supply the motor with sufficient current, but we may infer, from the surface of the acting materials in the battery, that the run was rather short; the power of the motor was evidently very small judging by the limited speed obtained, but the originality of Jacobi deserves comment, and for this, as well as for numerous other researches, his name will be remembered at all times.

It may not be generally known that an electric launch was tried for experimental purposes, on a lake at Penllegaer, near Swansea. Mr. Robert Hunt, in the discussion of his paper on electro-magnetism before the Institution of Civil Engineers in 1858, mentioned that he carried on an extended series of experiments at Falmouth, and at the instigation of Benkhausen, Russian Consul-General, he communicated with Jacobi upon the subject. In the year 1848, at a meeting of the British Association at Swansea, Mr. Hunt was applied to by some gentlemen connected with the copper trade of that part, to make some experiments on the electrical propulsion of vessels; they stated, that although electricity might cost thirty times as much as the power obtained from coal, it would, nevertheless, be sufficiently economical to induce its employment for the auxiliary screw ships employed in the copper trade with South America.

The boat at Swansea was partly made under Mr. (now Sir William) Grove's directions, and the engine was worked on the principle of the old toys of Ritchie, which consisted of six radiating poles projecting from a spindle, and rotating between a large electro-magnet. Three persons travelled in Hunt's boat, at the rate of three miles per hour. Eight large Grove's cells were employed, but the expense put it out of question as a practical application.

Had the Gramme or Siemens machine existed at that time, no doubt the subject would have been further advanced, for it was not merely the cost of the battery which stood in the way, but the inefficient motor, which returned only a small fraction of the power furnished by the zinc.

Professor Silvanus Thompson informs us, that an electric boat was constructed by Mr. G. E. Dering, in the year 1856, at Messrs. Searle's yard, on the River Thames; it was worked by a motor in which rotation was effected by magnets arranged within coils, like galvanometer needles, and acted on successively by currents from a battery.

From a recent number of the *Annales de L'Electricitè*, we learn that Count de Moulins experimented on the lake in the Bois de Boulogne, in the year 1866, with an iron flat-bottomed boat, carrying twelve persons. Twenty Bunsen cells furnished the current to a motor on Froment's principle turning a pair of paddle wheels.

In all these reports there is a lack of data. We are interested to know what power the motors developed, the time and speed, as well as dimensions and weights.

Until Trouvé's trip on the Seine, in 1881, and the launch of the *Electricity* on the Thames, in 1882, very little was known concerning the history of electric navigation.

M. Trouvé originally employed Planté's secondary battery, but afterwards reverted to a bichromate battery of his own invention. In all the primary batteries hitherto applied with advantage, zinc has been used as the acting material. Where much power is required, the consumption of zinc amounts to a formidable item; it costs, in quantity, about 3d. per pound, and in a well-arranged battery a definite quantity of zinc is transformed. The final effect of this transformation manifests itself in electrical energy, amounting to about 746 watts, or one electrical horse-power for every two pounds of this metal consumed per hour. The cost of the exciting fluid varies, however, considerably; it may be a solution of salts, or it may be dilute acid. Considering the zinc by itself, the expense for five electrical or four mechanical horse-power through an efficient motor, in a small launch, would be 2s. 6d. per hour. Many persons would willingly sacrifice 2s. 6d. per hour for the convenience, but a great item connected with the employment of zinc batteries is in the exciting fluid, and the trouble of preparing the zinc plates frequently. The process of cleaning, amalgamating and re-filling is so tedious, that the use of primary batteries for locomotive purposes is extremely limited. To re-charge a Bunsen, Grove, or bichromate battery, capable of giving six or seven hours' work at the rate of five electrical horse-power, would involve a good day's work for one man; no doubt he would consider himself entitled to a full day's wages, with the best appliances to assist him in the operation.

Several improved primary batteries have recently been brought out, which promise economical results. If the residual compound of zinc can be utilised, and sold at a good price, then the cost of such motive-power may be reduced in proportion to the value of those by-products.

For the purpose of comparison, let us now employ the man who would otherwise clean and prepare the primary cells, at engine-driving. We let him attend to a 6 horse-power steam-engine, boiler, and dynamo machine for charging 50 accumulators, each of a capacity of 370 ampère hours, or one horse-power hour. The consumption of fuel will probably amount to 40 lbs. per hour, which, at the rate of 18s. a ton, will give an expenditure of nearly 4d. per hour. The energy derived from coal in the accumulator costs, in the case of a supply of 5 electrical horse-power for 7 hours, 2s. 9d.; the energy derived from the zinc in a primary battery, supplying 5 electrical horse-power for 7 hours, would cost 17s. 3d.

It is hardly probable that anyone would lay down a complete plant, consisting of a steam or gas-engine and dynamo, for the sole purpose of charging the boat cells, unless such a boat were in almost daily use, or unless several boats were to be supplied with electrical power from one station. In order that electric launches may prove useful, it will be desirable that charging stations should be established, and on many of the British and Irish rivers and lakes there is abundance of motive power, in the shape of steam or gas-engines, or even waterwheels.

A system of hiring accumulators ready for use may, perhaps, best satisfy the conditions imposed in the case of pleasure launches.

It is difficult to compile comparative tables showing the relative expenses for running steam launches, electric launches with secondary batteries, and electric launches with primary zinc batteries; but I have roughly calculated that, for a launch having accommodation for a definite number of passengers, the total costs are as 1, 2·5, and 12 respectively, steam being lowest and zinc batteries highest.

The accumulators are, in this case, charged by a small high-pressure steam-engine, and a very large margin for depreciation and interest on plant is added. The launch taken for this comparison must run during 2,000 hours in the year, and be principally employed in a regular passenger service, police and harbour duties, postal service on the lakes and rivers of foreign countries, and the like.

The subject of secondary batteries has been so ably treated by Professor Silvanus Thompson and Dr. Oliver Lodge, in this room, that I should vainly attempt to give you a more complete idea of their nature. The improvements which are being made from time to time, mostly concern mechanical details, and, although important, a description will scarcely prove interesting.

A complete Faure-Sellon-Volckmar cell, such as is used in the existing electric launches, is here on the table; this box weighs, when ready for use, 56 lbs.; and it stores energy equal to 1 horse-power for 1 hour = 1,980,000 foot-pounds, or about 1 horse-power per minute for each pound weight of material. It is not advantageous to withdraw the whole amount of energy put in; although its charging capacity is as much as 370 ampère hours, we do not use more than 80 per cent., or 300 ampère hours; hence, if we discharge these accumulators at the rate of 40 ampères, we obtain an almost constant current for 7½ hours; one cell gives an E.M.F. of 2 volts. In order to have a constant power of 1 horse for 7½ hours, at the rate of 40 ampères discharge, we must have more than 9 cells per electrical horse-power; and 47 such cells will supply 5 electrical horse-power for the time stated, and these 47 cells will weigh 2,632 lbs.

We could employ half the number of cells by using them at the rate of 80 ampères, but then they will supply the power for less than half the time. The fact, however, that the cells will give so high a rate of discharge for a few hours, is, in itself, important, since we are enabled to apply great power if desirable; the 47 cells above referred to can be made to give 10 or 12 electrical horse-power for over two hours, and thus propel the boat at a very high speed, provided that the motor is adapted to utilise such powerful currents.

The above-mentioned weight of battery power—viz., 2,632 lbs., to which has to be added the weight of the motor and the various fittings—represents, in the case of a steam launch, the weight of coals, steam-boiler, engine, and fittings. The electro-motor capable of giving 4 horse-power on the screw shaft need not weigh 400 lbs. if economically designed; this, added to the weight of the accumulators, and allowing a margin for switches and leads, brings the whole apparatus up to about 28 cwt.

An equally powerful launch engine and boiler, together with a maximum stowage of fuel, will weigh about the same. There is, however, this disadvantage about the steam power, that it occupies the most valuable part of the vessel, taking away some eight or nine feet of the widest and most convenient part, and in a launch of twenty-four feet length, requiring such a power as we have been discussing, this is actually one-third of the total length of the vessel, and one-half of the passenger accommodation; therefore, I may safely assert that an electric launch will carry about twice as many people as a steam launch of similar dimensions.

The diagram on the wall represents sections of an electric launch built by Messrs. Yarrow and Company, and fitted up by the Electrical Power Storage Company, for the recent Electrical Exhibition in Vienna. She has made a great number of successful voyages on the River Danube during the autumn. Her hull is of steel, 40 ft. long and 6 ft. beam, and there are seats to accommodate forty adults comfortably. Her accumulators are stowed away under the floor, so is the motor, but owing to the lines of the boat, the floor just above the motor is raised a few inches. This motor is a Siemens D_2 machine, capable of working up to 7 horse-power with eighty accumulators.

In speaking of the horse-power of an electro-motor, I always mean the actual power developed on the shaft, and not the electrical horse-power; this, therefore, should not be compared to the indicated horse-power of a steam-engine.

I am indebted to Messrs. Yarrow for the principal dimensions and other particulars of a high-pressure launch engine and boiler, such as would be suitable for this boat. From these dimensions I prepared a second diagram representing the steam-power, and when placed in position it will show at a glance how much space this apparatus will occupy. The total length lost in this way amounts to 12 feet, leaving for seating capacity only 15 feet, while that of the electric launch is 27 feet on each side of the boat; thus the accommodation is as fifteen to twenty-seven, or as twenty-two passengers to forty, in favour of the electric launch.

Comparing the relative weights of the steam-power and the electric-power for this launch, we find that they are nearly equal, each approaches 50 cwt.; but in the case of the steam launch we include 10 cwt. of coals, which can be stowed into the bunkers, and which allow fifteen hours' continuous steaming, whereas the electric energy stored up will only give us seven and a-half hours with perfect safety.

I have here allowed 8 lbs. of coal per indicated horse-power per hour, and 10 horse-power giving off 7 mechanical horse-power on the screw shaft; this is an example of an average launch engine. There are launch engines in existence which do not consume one-half that amount of fuel, but these are so few, so rare, and so expensive, that I have neglected them in this account.

Not many years ago, a steam launch carrying a seven hours' supply of fuel was considered marvellous.

Our present accumulator supplies 33,000 foot-pounds of work per pound of lead, but theoretically one pound of lead manifests an energy equal to 360,000 foot-pounds in the separation from its oxide; and in the case of iron, Prof. Osborne Reynolds told us in this place, the energy evolved by its oxidation is equivalent to 1,900,000 foot-pounds per pound of metal. How nearly these limits may be approached will be the problem of the chemist; to prophesy is dangerous, whilst science and its applications are advancing at this rapid rate.

Theoretically then, with our weight of fully oxidised lead, we should be able to travel for 82 hours; with the same weight of iron for 430 hours, or 18 days and nights continually, at the rate of 8 miles per hour, with one charge. Of course, these feats are quite impossible. We might as well dream of getting 5 horse-power out of a steam-engine for one pound of coal per hour.

Whilst the chemist is busy with his researches for substances and combinations which will yield great power with small quantities of material, the engineer assiduously endeavours to reconvert the chemical or electrical energy into mechanical work suitable to the various needs.

To get the maximum amount of work with a minimum amount of weight, and least dimensions combined with the necessary strength, is the province of the mechanical engineer; it is a grand and interesting study; it involves many factors; it is not, as in the steam-engine and the hydraulic machine, a matter of pressures, tension and compression, centrifugal and static forces, but it comprises a still larger number of factors, all bearing a definite relation to each other.

With dynamo machines the aim has been to obtain as nearly as possible as much electrical energy out of the machine as has been put in by the prime mover, irrespective of the quantity of material employed in its construction. Dr. J. Hopkinson has not only improved upon the Edison dynamo, and obtained 94 per cent. of the powers applied in the form of electrical energy, but he got 50 horse-power out of the same quantity of iron and copper where Edison could only get 20 horse-power—and, though the efficiency of this generator is perfect, it could not be called an efficient motor, suitable for locomotion by land or water, because it is still too heavy. An efficient motor for locomotion purposes must not only give out in mechanical work as nearly as possible as much as the electrical energy put in, but it must be of small weight, because it has to propel itself along with the vehicle, and every pound weight of the motor represents so many foot-pounds of energy used in its own propulsion; thus, if a motor weighed 660 pounds, and were travelling at the rate of 50 feet per minute, against gravitation, it would expend 33,000 foot-pounds per minute in moving itself, and although this machine may give 2 horse-power, with an efficiency of 90 per cent., it would, in the case of a boat or a tram-car, be termed a wasteful machine. Here we have an all important factor which can be neglected, to a certain extent, in the dynamo as a generator, although from an economical point of view, excessive weight in the dynamo must also be carefully avoided.

The proper test for an electro-motor, therefore, is not merely its efficiency, or the quotient of the mechanical power given out, divided by the electrical energy put in, but also the number of feet it could raise its own weight in a given space of time, with a given current, or, in other words, the number of foot-pounds of work each pound weight of the motor would give out.

The Siemens' D_2 machine, as used in the launch shown in the diagram on the wall is one of the lightest and best motors, it gives 7 horse-power on the shaft, with an expenditure of 9 electrical horse-power, and it weighs 658 lbs.; its efficiency, therefore, is 7-9ths, or nearly 78 per cent.; but its "co-efficient" as an engine of locomotion is 351—that is to say, each pound weight of the motor will yield 351 foot-pounds on the shaft. We could get even more than 7 horse-power out of this machine, by either running it at an excessive speed, or by using excessive currents; in both cases, however, we should shorten the life of the apparatus.

An electro-motor consists, generally, of two or more electro-magnets so arranged that they continually attract each other, and thereby convey power. As already stated, there are numerous factors, all bearing a certain relationship to each other, and particular rules which hold good in one type of machine will not always answer in another, but the general laws of electricity and magnetism must be observed in all cases. With a given energy expressed in watts, we can arrange a quantity of wire and iron to produce a certain quantity of work; the smaller the quantity of material employed, and the larger the return for the energy put in, the greater is the total efficiency of the machine.

Powerful electro-magnets, judiciously arranged, must make powerful motors. The ease with which powerful electro-magnets can be constructed, has led many to believe that the power of an electro-motor can be increased almost infinitely, without a corresponding increase of energy spent. The strongest magnet can be produced with an exceedingly small current, if we only wind sufficient wire upon an iron core. An electro-magnet excited by a tiny battery of 10 volts, and, say, one ampere of current, may be able to hold a tremendous weight in suspension, although the energy consumed amounts to only 10 watts, or less than 1-75th of a horse-power; but the suspended weight produces no mechanical work. Mechanical work would only be done if we discontinued the flow of the current, in which case the said weight would drop; if the distance is sufficiently small, the magnet could, by the application of the current from the battery, raise the weight again, and if that operation is repeated many times in a minute, then we could determine the mechanical work performed. Assuming that the weight raised is 1,000 lbs., and that we could make and break the current two hundred times a-minute, then the work done by the falling mass could, under no circumstances, equal 1-75th of a horse-power, or 440 foot-pounds; that is, 1,000 lbs. lifted 2·27 feet high in a minute, or about one-eighth of an inch for each operation; hence the mere statical pull, or power of the magnet, does in no way tend to increase the energy furnished by the battery or generator, for the instant we wish to do work we must have motion—work being the product of mass and distance.

Large sums of money have virtually been thrown away in the endeavour to produce energy, and there are intelligent persons who to this day imagine that, by indefinitely increasing the strength of a magnet, more power may be got out of it than is put in.

Large field-magnets are advantageous, and the tendency in the manufacture of dynamo machines has been to increase the mass of iron, because with long and heavy cores and pole pieces there is a steady magnetism ensured, and therefore a steady current, since large masses of iron take a long time to magnetise and demagnetise; thus very slight irregularities in the speed of an armature are not so easily perceived. In the case of electro-motors these conditions are changed. In the first place, we assume that the current put through the coils of the magnets is continuous; and secondly, we can count upon the momentum of the armature, as well as the momentum of the driven object, to assist us over slight irregularities. With electric launches we are bound to employ a battery current, and battery currents are perfectly continuous—there are no sudden changes; it is consequently a question as to how small a mass of iron we may employ in our dynamo as a motor without sacrificing efficiency. The intensity of the magnetic field must be got by saturating the iron, and the energy being fixed, this saturation determines the limit of the weight of iron. Soft wrought iron, divided into the largest possible number of pieces, will serve our purpose best. The question of strength of materials plays also an important part. We cannot reduce the quantity and division to such a point that the rigidity and equilibrium of the whole structure is in any way endangered.

The armature, for instance, must not give way to the centrifugal forces imposed upon it, nor should the field magnets be so flexible as to yield to the statical pull of the magnetic poles. The compass of this paper does not permit of a detailed discussion of the essential points to be observed in the construction of electro-motors; a reference to the main points, may, however, be useful. The designer has, first of all, to determine the most effective positions of the purely electrical and magnetic parts; secondly, compactness and simplicity in details; thirdly, easy access to such parts as are subject to wear and adjustment; and, fourthly, the cost of materials and labour. The internal resistance of the motor should be proportioned to the resistances of the generator, and the conductors leading from the generator to the receiver.

The insulation resistances must be as high as possible; the insulation can never be too good. The motor should be made to run at that speed at which it gives the greatest power with a high efficiency, without heating to a degree which would damage the insulating material.

Before fixing a motor in its final position, it should also be tested for power with a dynamometer, and for this purpose a Prony brake answers very well.

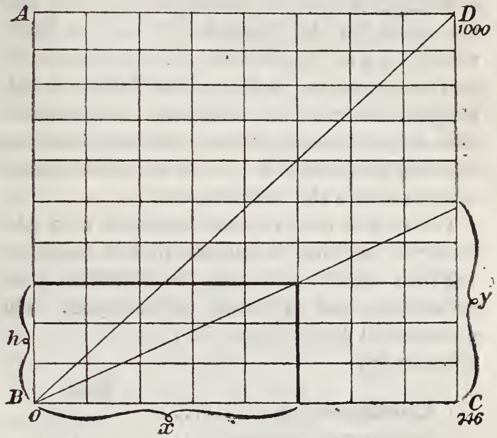
An ammeter inserted in the circuit will show at a glance what current is passing at any particular speed, and volt-meter readings are taken at the terminals of the machine, when the same is standing still as well as when the armature is running, because the E.M.F. indicated when the armature is at rest alone determines the commercial efficiency of the motor, whereas the E.M.F. developed during motion varies with the speed until it nearly reaches the E.M.F. in the leads; at that point the theoretical efficiency will be highest.

Calculations are greatly facilitated, and the value of tests can be ascertained quickly, if the constant of the brake is ascertained; then it will be simply necessary to multiply the number of revolutions and the weight at the end of the lever by such a constant, and the product gives the horse-power, because, with a given Prony brake, the only variable quantities are the weight and the speed. All the observations, electrical and mechanical, are made simultaneously. The electrical horse-power put into the motor is found by the well-known formulæ $C \times E \div 746$; this simple multiplication and division becomes very tedious and even laborious if many tests have to be made in quick succession, and to obviate this trouble, and prevent errors, I have constructed a horse-power diagram, the principle of which is shown in the diagram. (Fig. 1.)

Graphic representations are of the greatest value in all comparative tests. Mr. Gisbert Kapp has recently published a useful curve in the *Electrician*, by means of which one can easily compare the power and efficiency at a glance. (Fig. 2.)

The speeds are plotted as abscissæ, and the electrical work absorbed in watts divided by 746 as ordinates; then with a series-wound motor we obtain the curve E E. The shape of this curve depends on the type of the motor. Variation of speed is obtained by loading the brake with different weights. We begin with an excess of weight which holds the motor fast, and then a maximum current will flow through it without producing any external

Fig. 1.—Reckenzaun's Electrical Horse-power Diagram.

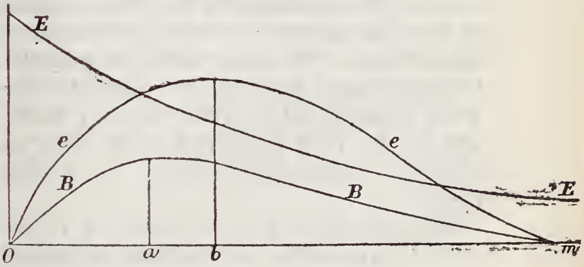


Draw a square A B C D—divide B C into 746 parts, and C D into 1,000 parts, or, generally, let a division on C D be ·746 of a division on B C, so that we can use the horizontal lines cutting A B as a horse-power scale. A B, in the above diagram, gives 1,000 horse-power, if the line B C represents 746 volts, and C D 1,000 ampères. Let $x =$ any number of volts, y the ampères, and h the horse-power, then

$$\frac{h}{x} = \frac{y}{746} \therefore h = \frac{xy}{746}.$$

A fine wire or thread stretched from o as a centre to the required division on C D, will facilitate references.

Fig. 2.—Kapp's Diagram.



work. When we remove the brake altogether, the motor will run with a maximum speed, and again produce no external work, but in this case very little current will pass; this maximum speed is $o\ m$ on the diagram. Between these two extremes external work will be done, and there is a speed at which this is a maximum. To find these speeds we load the brake to different weights, and plot the resulting speeds and horse-powers as abscissæ and ordinates producing the curve BB. Another curve $e = \frac{B}{E}$, made with an arbitrary scale, gives the commercial efficiency; the speed for a maximum external horse-power is *o a*, and the speed for the highest efficiency is represented by *o b*. In practice it is not necessary to test a motor to the whole limits of this diagram, it will be sufficient to commence with a speed at which the efficiency becomes appreciable, and to leave off with that speed which renders the desired power.

I have now to draw your attention to a new motor of my own invention, of the weight of 124 lbs., which, at 1,550 revolutions, gives 31 ampères and 61·5 volts at terminals. The mechanical horse-power is 1·37, and the coefficient 373.

	Ohms.
Armature resistance	·4*w*.
Field-magnet resistance......	·17*w*.
Insulation resistance	1,500,000*w*.

This motor was only completed on the morning before reading the paper; it could not, therefore, be tested as to its various capacities.

We have next to consider the principle of applying the motive power to the propulsion of a launch. The propellers hitherto practically applied in steam navigation are the paddle-wheel and the screw. The experience of modern steam navigation points to the exclusive use and advantage of the screw propeller where great speed of shaft is obtainable, and the electric engine is pre-eminently a high-speed engine, consequently the screw appears to be most suitable to the requirements of electric boats. By simply fixing the propeller to the prolonged motor shaft, we complete the whole system, which, when correctly made, will do its duty in perfect order, with an efficiency approaching theory to a high degree.

Whatever force may be imparted to the water by a propeller, such force can be resolved into two elements, one of which is parallel, and the other in a plane at right angles to the keel. The parallel force alone has the propelling effect; the screw, therefore, should always be so constructed that its surfaces shall be chiefly employed in driving the water in a direction parallel to the keel from stem to stern.

It is evident that a finely-pitched screw, running at a high velocity, will supply these conditions best. With that beautiful screw lying on this table, and made by Messrs. Yarrow, 95 per cent. of efficiency have been obtained when running at a speed of over 800 revolutions per minute, that is to say, only 5 per cent. was lost in slip.

Reviewing the various points of advantage, it appears that electricity will, in times to come, be largely used for propelling launches, and, perhaps, something more than launches.

In conclusion, quoting Dr. Lardner's remarks on the subject of steam navigation of nearly fifty years ago, he said:—

"Some, who, being conversant with the actual conditions of steam engineering as applied to navigation, and aware of various commercial conditions which must affect the problem, were enabled to estimate calmly and dispassionately the difficulties and drawbacks, as well as the disadvantages, of the undertaking, entertained doubts which clouded the brightness of their hopes, and warned the commercial world against the indulgence of too sanguine anticipations, of the immediate and unqualified realisation of the project. They counselled caution and reserve against an improvident investment of extensive capital, in schemes which still be only regarded as experimental, and which might prove its grave. But the voice of remonstrance was drowned amid the enthusiasm excited by the promise of an immediate practical realisation of a scheme so grand.

"It cannot," he continues, "be seriously imagined that anyone who had been conversant with the past history of steam navigation could entertain the least doubt of the abstract practicability of a steam vessel making the voyage between Bristol and New York. A steam vessel, having as cargo a couple of hundred tons of coals would, *cæteris paribus*, be as capable of crossing the Atlantic as a vessel transporting the same weight of any other cargo."

Dr. Lardner is generally credited with having asserted that a steam voyage across the Atlantic was "a physical impossibility," but in the work from which I took the liberty of copying his words he denies the charge, and says that what he did affirm was, that long sea voyages could not at that time be maintained with that regularity and certainty which are indispensable to commercial success, by any revenue which could be expected from traffic alone.

The practical results are well-known to us. History repeats itself, and the next generation may put on record our weak attempts, our doubts and fears of this day. Whether electricity will ever rival steam, remains yet to be proved; we may be on the threshold of great things. The premature enthusiasm has subsided, and we enter upon the road of steady progress.

DISCUSSION.

The CHAIRMAN, in inviting discussion, said that no doubt those present would like to know something about the cost of such a boat as Mr. Reckenzaun described, and he hoped that gentleman would give them some information on that point.

Admiral SELWYN suggested that electrical propulsion would be specially applicable to lifeboats. A lifeboat must be expected at times to capsize, and very often to be full of water, which rendered steam-boiler an impossibility, but perhaps something might be done with electricity. His attention was drawn to this matter by a coastguard officer in Ireland, who wrote to him asking a variety of questions about motive power, which he was obliged to tell him savoured too much of perpetual motion. He told him then that there was but one answer to the question, and that was an electrical answer, provided they could abandon the ideas now prevalent about particular metals. Chemists would agree with him that iron and several other metals could be used for this purpose, some of which combined lightness with the capacity for complete oxidation, and some of which would probably be used in future. But with all that possibility he thought Mr. Reckenzaun was a little below the mark when he talked about the dream of getting 5 horse-power for one pound, he would not say of coal, but of fuel. For some months he had seen 1-6th lb. of fuel produce 1 horse-power, and he knew it could be done. That fuel was condensed concentrated fuel in the shape of oil. When this could be done, electrical energy also could be obtained much cheaper, but if it were extended to yachts, he thought that would be as far as anyone now present could be expected to see it go. Still he thought there was a future for it, and that future would be best advanced by considering the question on which he had touched. Firstly, the mployment of a cheaper mode of getting the power n the steam-engine; and, secondly, a cheaper and ighter secondary battery. In a railway train weight was a formidable affair, but in a floating vessel it was still more important. He did not think, however, that a light secondary battery was by any means an impossibility. Mr. Loftus Perkins had actually produced by improvements in the boiler and steam-engine two great things; first, one indicated horse-power for a pound of fuel per hour, and next he had devised a steam-engine of 100 horse-power, of a weight of only 84 lbs. per horse-power, instead of 304 lbs., which was about the average. Those were two enormous steps in advance, and under a still more improved Patent-law he had no doubt things would be brought forward which would show a still greater progress. Within the last fifteen days, nearly 2,000 patents had been taken out, as against 5,000 in the whole of the previous year, which showed how operative a very small and illusory inducement had been to encourage invention. He had long been known as an advocate of Patent-law reform, and, therefore, felt bound to lose no opportunity of calling attention to its importance. Invention was in the hands of the inventor, the creator of trade. If, without robbing anybody one wished to produce property, it must be done by improving manufactures as a consequence of inventions. In one instance alone it had been proved that a single invention had been the means of introducing twenty millions annually, upon which income-tax was paid.

Lord SUDELEY thought they were much indebted to Mr. Reckenzaun for the very clear way in which he had explained the subject. There were considerable delays before this launch arrived at Vienna, and when at last the boat got there, some part of the machinery had been left behind at Antwerp, which caused additional delay, and, perhaps, added to the interest with which it was regarded. When at last it was all in order, and set to work on the Danube, it excited great admiration. It went along silently, without vibration, and was able to stem a rather swift current, and showed that England had made a very great step, at any rate, in one particular direction. On one occasion he had the honour of being on board with Sir William Thomson, Sir William Siemens, and Sir Frederick Abel, and one or two Austrian electricians, whose opinions were all highly favourable; for they one and all said it was a very great success, and did the designer and builders very great credit. There was no doubt that in the future there would be a very great opening for such boats, depending, no doubt, in great measure on what could be done with secondary batteries, in which there was, as yet, great room for improvement. Then, again, there was the question how far they could be used, unless there were conveniences at different places for charging, or re-charging them. Another important question was, how far these boats could be used in harbour defences, or in torpedo warfare, which would be a great boon, on account of the large amount of space at disposal. Whether it would be safe to take them in a rough or chopping sea, he was not prepared to say; but no doubt their adaptability to such uses was only a question of time.

Mr. CROHNE (Messrs. Yarrow) said he had the highest opinion of this launch, having carried through the experiments. It was very convenient and pleasant; there was no noise, dirt, or vibration, and in every respect he considered it with great respect.

One very important point in connection with this boat was that the weight was so low down as to ballast her in the most perfect manner, such as could not be attained in any steamer. He had had as many as fourteen men in the boat, sitting on the rail and gunwale, and she was so staunch that there was not the slightest danger; but in a similar boat propelled by steam, this would have entailed the greatest risk; in fact, he could not have got the same number of men into a steam launch at all. The accommodation was very great, and the stability enormous. In the case of a life-boat, the weight being so low down would be of the greatest service; in fact, it would be almost impossible to capsize the boat. He was afraid there was no chance of using such boats for torpedo warfare, torpedo boats being cram-full of steam power; one of that size, for instance, would be about 100 indicated horse-power; and he did not know how 70 actual horse-power was to be got from electricity in the weight such a boat would carry. He was not an electrician, but he had not heard of any means by which it could be done. For ordinary speeds, however, he considered such boats a great success.

Mr. LIGGINS said he had studied the subject of steam launches for a long time—in fact, since the first one was built at Cowes, about sixteen years ago, for the *Pantomime*, which was 24 ft. long. She turned out so satisfactory that it was thought at first that every yacht over 100 tons would have a steam launch, in order to tow her in calm weather. He was, at that time, cruising in Mr. Ashbury's yacht, the *Cambria*, and that gentleman at once gave an order for a steam launch, and he (Mr. Liggins) was so enthusiastic in its favour from the delight he took in cruising about the Isle of Wight in her, that he thought every yacht owner in England would have one. It was found, however, that, owing to the dirt and smoke, and the annoyance from the steam, &c., they did not meet with very much favour. But he suggested to Mr. Yarrow the desirability of fitting up such launches. He took the hint, and having the first boats built by Messrs. Forrest, they turned out a very great success, and were very popular; though, at that time, eight or nine miles an hour was thought a great speed, as showing the wonderful improvement that had been made in them, he had just read that one of their torpedo boats had shown a speed of twenty miles an hour. That led him to believe that the speed of these electric launches would, in like manner, be increased, and that they would become the pleasure boats of the future. Of course they could not be used generally, unless gentlemen had small steam-engines with which to charge the batteries. It was not so many years ago since Dr. Lardner was reported to have said that a steam vessel could never cross the Atlantic, though, in fact, at that very time the voyage had been made by the *Sirius*, a steamer built to ply between London and Dublin. They all knew the immense strides which had been made in steam navigation since then, a large vessel of 5,000 tons and 5,000 horse-power having just left the Clyde, which had a speed of nearly 20 miles an hour; and he had, no doubt, that similar advances would be made in electricity. He would ask if there was not a necessity to keep the accumulators constantly at work, because it had been stated that otherwise a film formed over the lead plates, which materially interfered with their efficiency. He did not think the question of cost was of very much importance, as it would, no doubt, be lessened as the demand increased.

Lieut-Colonel WEBBER thought the allusion made by Lord Sudeley to the use of this sort of launch for torpedo purposes was not intended to refer to the so-called torpedo boats mentioned by Mr. Crohne, having a very high speed, but rather to the advantage of having a boat with the large space, such as was here afforded, for the purpose of laying out torpedoes for the defence of harbours. Besides the advantage of a large space, it would allow of a smaller boat being used, which was of great importance, as all would recognise who had been engaged in this service. Again, when torpedoes had to be laid out at night in the neighbourhood of an enemy, the silence, and the absence of glare and reflection from the funnel, would be of the highest advantage.

Mr. CRAMPTON said he did not think steam could ever compete with electricity, under certain circumstances; but, at the same time, it would be a long time before it was superseded. He should like very much to see the compressed oil, one-sixth of a pound of which would give 1 horse-power per hour.

Admiral SELWYN said he had seen a common Cornish boiler doing it years ago.

Mr. CRAMPTON said it had never come under his notice, and he had no hesitation in saying that no such duty ever was performed by any oil, because he never heard of any oil which evaporated more than eighteen to twenty-two pounds of water per pound. However he was delighted to hear of such progress being made, and though he had been for so many years connected with steam, he never expected it would last for ever. He was now making experiments for some large shipowners, for the purpose of facilitating feeding and doing away with dust, but let him succeed to to what extent he might, steam would never compete with electricity for such small vessels as these launches.

The CHAIRMAN asked if he rightly understood Admiral Selwyn that he had recently seen an invention in which one-sixth of a pound of condensed fuel would give 1 horse-power per hour.

Admiral SELWYN said it was now some years ago since he saw this going on, but the persons who did it did not know how or why it was done. He had studied the question for the last ten years, and now knew the *rationale* of it, and would be prepared shortly to publish it. He knew that 22 was the theoretical calorific value of the pound of oil, and never supposed that oil alone would give 46 lbs., which he saw it doing. He had found out that by means of the oil forming carbon constantly in the furnace, the hydrogen of the steam was burned, and that it was a fallacy to suppose that an equal quantity of heat was used in raising steam, at a pressure of, say, 120 lbs. to the square inch, as the hydrogen was capable of developing when properly burned. There were, however, conditions under which alone that combustion could take place—one being that the heat of the chamber must be 3,700°, and that carbon must be constantly formed.

Mr. Gumpel said it was not so much the present position of the electric launch, as its promise for the future, which was of interest and importance, for as yet it might be looked upon almost in the light of a plaything; but, at a future time, the records of that meeting and the opinions now expressed would be referred to as they now looked back to the supposed utterances of Dr. Lardner with regard to steam. The whole weight in the vessel being placed so low, giving great stability, and the small space occupied, were both points of great importance; but one point to which he would call attention was the great speed of the propeller. It had about 9 inches pitch, and worked at 800 revolutions a minute. Now some experiments he made in 1859 and 1860, and the discussions on the subject, which had taken place in the Society of Naval Architects and elsewhere, had shown that there was a certain limit to the pitch of a screw, and that you might lose too much power by friction. He believed that if Mr. Reckenzaun could construct a motor which would give a less number of revolutions, but develop the same amount of propelling power, there would be greater efficiency. With regard to the use of electricity by means of the secondary battery, when the vessel had run seven and a-half hours, and the electricity had been discharged, the question arose as to recharging the cells, for which purpose the boat must be laid up somewhere where there was the means of charging the batteries, or they must be replaced. With regard to the general application of electricity to the propulsion of vessels as well as to railway trains, he believed that many of those present would live to see electricity applied to that purpose, because there were so many minds now applied to the problem, that before long he had no doubt we should see coal burned in batteries, as it was now burned in steam boilers. The utmost they could do, then, would be about 50 per cent. less than Admiral Selwyn said could be accomplished with condensed fuel. He could not but wonder where Admiral Selwyn obtained his information, knowing that a theoretically perfect heat-engine would only give 23 per cent. of the absolute heat used, and that a pound of the best coal would give but 8,000 and hydrocarbon 13,000 heat units, whilst hydrogen would give 34,000, and calculating it out, how was it possible to get out of one-sixth of a pound of carbon, or any hydrocarbon, the amount of power stated. No doubt, when Admiral Selwyn applied the knowledge which physicists would give him of the amount of power which could be got out of a certain amount of carbon and hydrogen, he would find that there was a mistake made somewhere. He greatly admired the manner in which Mr. Reckenzaun had brought forward the subject, which formed a pleasant contrast to some papers they had heard from inventors of particular motors; and he thought it would be very useful if he would prepare another paper on the different forms of motors, and the conditions necessary for their efficiency. It was a most important subject, which he hoped would be further discussed there, and in which much progress might be made.

Mr. Reckenzaun, in reply, said it would be very difficult to answer the question put by the Chairman, as to the cost of an electric launch—quite as difficult as to say what would be the cost of a steam launch. It depended on the fittings, the ornamental part, the power required, and the time it was required to run. If such a launch were to run constantly, two sets of accumulators would be required, one to replace the other when discharged. This could be easily done, the floor being made to take up, and the cells could be changed in a few minutes with proper appliances. As to Admiral Selwyn's remarks about one-sixth of a pound of fuel per horse-power, he had never heard of such a thing before, and should like to know more about it. Mr. Loftus Perkins's new steam-engine was a wonderful example of modern engineering. A comparatively small engine, occupying no more space than that of a steam launch of considerable dimensions, developed 800 horse-power indicated. From a mechanical point of view, this engine was extremely interesting; it had four cylinders, but only one crank and one connecting rod; and there were no dead centres. The mechanism was very beautiful, but would require elaborate diagrams to explain. Mr. Perkins deserved the greatest praise for it, for in it he had reduced both the weight of the engine and the consumption of fuel to a minimum. He believed he used coke, and took one pound per horse-power. He should not like to cross the Channel in the electric launch, if there was a heavy sea on, for shaking certainly did not increase the efficiency of the accumulators, but a fair amount of motion they could stand, and they had run on the Thames, by the side of heavy tug-boats causing a considerable amount of swell, without any mishap. Of course each box was provided with a lid, and the plates were so closely packed that a fair amount of shaking would not affect them; the only danger was the spilling of the acid. Mr. Crohne had remarked that a torpedo boat of that size would have 100 indicated horse-power, but then the whole boat would be filled with machinery. What might be done with electricity they had, as yet, no idea of. At present, they could only get 33,000 foot-pounds from 1 lb. of lead and acid, though, theoretically, they ought to get 360,000 foot-pounds. Iron, in its oxidation, would manifest theoretically 1,900,000 foot-pounds per lb. of material. As yet they had not succeeded in making an iron accumulator; if they could, they would get about six or seven times the energy for the same weight of material, or could reduce the weight proportionately for the same power, and in that way they might eventually get 70 horse-power in a boat of that size, because the weight of the motor was not great. With regard to the formation of a film on the surface, no doubt a film of sulphate of lead was formed if the battery stood idle, but it did not considerably reduce its efficiency; as soon as it was broken through by the energy being evolved from it, it would give off its maximum current. They knew by experience that, with properly constructed accumulators, 80 per cent. of the energy put into them was returned in work. It was quite certain, as Mr. Crampton said, that it would be a long time before steam was superseded; he did not prophecy at all; and he entitled his paper "Electric Launches," because it would be presumptuous to speak of anything more until larger vessels had been made and tried. With regard to Mr. Gumpel's remark on the friction of the propeller, he would say that it was constructed to run 900 revolutions; if it were driven by a steam-engine, and the speed reduced to 300, not only would the pitch have to be altered, but the surface would have to be larger, which would entail more friction. Mr. Crohne would bear him out that they lost only 5 per cent. by slip and friction combined, on an average of a great number of trials, both with and against the current.

Mr. GUMPEL remarked that Sir E. J. Reed had pointed out in that room that it was a fallacy to suppose that slip in itself was a loss. You must have slip for the purpose of propelling the vessel. The 5 per cent. loss would not give any idea of the efficiency of the propeller in itself.

Mr. CROHNE said he had always been of opinion that such a fine pitch would not do at all, and they had an electric launch made with gear to reduce the speed of the propeller; but, practically, he found he was mistaken. He had expected that negative slip and the friction of the propeller would be a serious impediment, but he found he was entirely mistaken. This wonderfully fine pitch of about 10 inches, and a diameter of 20 inches, was quite unknown before, as far as he was aware, but it gave very good results indeed.

The CHAIRMAN, in proposing a vote of thanks to Mr. Reckenzaun, said he rejoiced to find that that gentleman had proved, to one practical man at least, that his views had been mistaken. He found in these days of the practical applications of electricity, that the ideas of most practical men were gradually being proved to be mistaken, and every day new facts were being discovered, which led them to imagine that as yet they were only on the shore of an enormous ocean of knowledge. It was quite impossible to say what these electric launches would lead to. Certain points of great importance had been pointed out; they gave great room, and they were always ready. For lifeboat and fire-engine purposes, as Captain Shaw pointed out at Vienna, this was of great consequence. At first, they were led to believe that there was great stability, but that idea had been a little shaken, not as to the boat itself, but as to the influence of the motion of the water upon the constancy of the cells. But these boats were only intended for smooth water, and if they could not be adapted for rough water, he feared Admiral Selwyn's suggestion of the application of this principle to lifeboats would fall to the ground; but if secondary batteries were not calculated as yet to stand rough usage, it only required probably some thought on Mr. Reckenzaun's part to make them available even in a gale. Enormous strides were being made with regard to these batteries. No one present had been a greater sceptic with regard to them at first than he himself; but after constant experiments—employing them, as he had done for many months, for telegraphic purposes—he was gradually coming to view them with a much more favourable eye. The same steps which had rendered all scientific notions practicable, had gradually eliminated the faults which originally existed, and they were now becoming good, sound, available instruments. At present, he could only regard this electric launch as a luxury. He had hoped that Mr. Reckenzaun would have been able to say something which would have enabled poor men to look forward to the time when they might enjoy themselves in them on the river; but he was told at Vienna, when he enjoyed two or three trips in this boat on the Danube, that her cost would be about £800, which was a little too much for most people. They wanted something more within their reach, so that at various points on the river they might see small engines constantly at work supplying energy to secondary batteries, and so that they might start on a Friday evening, and go up as far as Oxford, or higher, and come down again on Monday morning. He must congratulate Mr. Reckenzaun on the excellent diagrams he had constructed. The trouble of calculating figures of this sort was very great when making experiments; and the use of diagrams and curves expedited the labour very much. At present they were passing through a stage of electrical depression; robbery had been committed on a large scale; the earnings of the poor had been filched out of their pockets by sanguine company promoters; an enormous amount of money had been lost, and the result had been that confidence was, to a great extent, destroyed. But those who had been wise enough to keep their money in their pockets, and to read the papers read in that room, must have seen that there was a constant steady advance in scientific knowledge of the laws of electricity and in their practical applications, and as soon as some of these rotten mushroom companies had been wiped out of existence, they might hope that real practical progress would be made, and that the day was not far distant when the public would again acquire confidence in electrical enterprise. They would then enable inventors and practical men to carry out their experiments, and to put electrical matters on a proper footing.

The vote of thanks having been carried unanimously, the meeting separated.

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION.

The following Sub-Committees have met at the Society of Arts since the meetings recorded in last week's *Journal*:—

INDIA.

Wednesday, January 9th.—Present: Sir Joseph Fayrer, M.D., F.R.S., in the chair; Sir George Birdwood, M.D., C.S.I.; Colonel Sir Owen Tudor Burne, K.C.S.I., C.I.E.; Deputy Surgeon-General N. Chevers, M.D., C.I.E.; Surgeon-General Gordon; Mr. P. Macfadyen; Colonel J. Michael, C.S.I.; Mr. Harold A. Perry; Surgeon-General Townsend, C.B.; Mr. Frederick Young; Mr. A. Stirling; Mr. H. Trueman Wood.

SCHOOL (GROUP IV.) AND EDUCATION (GROUP VI.)

Thursday, January 10th.—Present: Lord Reay, in the chair; Mr. B. St. John Ackers; the Venerable Archdeacon Emery; Mr. J. G. Fitch; Mr. Arnold Graves; Mr. T. C. Horsfall; Mr. T. E. Heller; Mr. A. C. King; Mr. Philip Magnus; Mr. T. Nordenfelt; Mr. H. T. Wood.

METEOROLOGICAL.

Friday, January 11th.—Present: Professor F. De Chaumont, M.D., F.R.S., in the chair; Mr. Robert H. Scott, F.R.S.; Mr. G. J. Symons, F.R.S.; Dr. J. W. Tripe; Mr. H. T. Wood.

THE DWELLING HOUSE.—GROUP III.—
SUB-COMMITTEE A.

Saturday, January 12th.—Present: Captain Douglas Galton, C.B., F.R.S., in the chair; Mr. H. H. Collins; Dr. W. H. Corfield; Mr. Rogers Field, C.E.; Mr. Shirley F. Murphy; Mr. George Shaw; Mr. H. T. Wood.

THE WORKSHOP.—GROUP V.

Saturday, January 12th.—Present: Dr. George Buchanan, in the chair; Mr. Joseph Dickinson; Mr. Alexander Redgrave; Mr. Gilbert R. Redgrave; Mr. Warington W. Smith, F.R.S.; Mr. H. T. Wood.

THE DWELLING HOUSE.—GROUP III.—SUB-COMMITTEE ON SANITARY AND UNSANITARY HOUSES.

Monday, January 14th.—Present: Captain Douglas Galton, C.B., F.R.S., in the chair; Mr. H. H. Collins; Dr. W. H. Corfield; Mr. Rogers Field; Mr. Ernest Turner; Mr. H. T. Wood.

DRESS.

Tuesday, January 15th.—Present: Mr. Frederick Treves, F.R.C.S., in the chair; Mr. George Erskine; Prof. W. H. Flower, LL.D., F.R.S.; Deputy Surgeon-General Jeffery Marston; Mr. George D. Ramsay, C.B.; Mr. George Scharf; Mr. Thorn; Surgeon-General Townsend, C.B.; Hon. Lewis Wingfield; Mr. H. T. Wood.

SCHOOL AND EDUCATION.—GROUPS IV & VI.

The following is the classification of these two Groups:—

GROUP 4.—THE SCHOOL.

Class 34.—Designs and models of improved buildings for elementary schools, infant schools and crèches.

Class 35.—Apparatus and fittings for warming, ventilating, and lighting schools; school latrines, closets, &c.

Class 36.—Special school fittings for storing and drying clothing.

Class 37.—School kitchens and arrangements for school canteens; methods of warming children's meals, &c.

Class 38.—Precaution in schools for preventing the spread of infectious diseases, school sanitaria, infirmaries, &c.

Class 39.—Special apparatus for physical training in schools, gymnasia, apparatus for exercise, drill, &c.

Class 40.—Literature, statistics, diagrams, &c., relating to Group 4.

GROUP 6.—EDUCATIONAL WORKS AND APPLIANCES.

Class 47.—Crèches and infant schools—(*a*) Apparatus and fittings for crèches and infant schools; (*b*) games, toys, and kindergarten amusements; (*c*) models and appliances for teaching; (*d*) examples of school work.

Class 48.—Primary schools—(*a*) Apparatus and fittings; (*b*) models and appliances for teaching; text-books, diagrams and examples; (*c*) specimens of work done in elementary schools.

Class 49.—Domestic economy in schools for girls—

(*a*) Models and apparatus for the teaching of cookery, housework, washing, and ironing, needlework, and embroidery, dressmaking, artificial flower-making, painting on silk, pottery, &c.; (*b*) specimens of school work.

Class 50.—Handicraft teaching in schools for boys—(*a*) Apparatus and fittings for elementary trade teaching in schools; (*b*) specimens of school work.

Class 51.—Science teaching—(*a*) Apparatus, and models for elementary science instruction in schools; apparatus for chemistry, physics, mechanics, &c.; (*b*) diagrams, copies, text-books, &c.; (*c*) specimens of the school work in these subjects.

Class 52.—Art teaching—(*a*) Apparatus, models, and fittings for elementary art instruction in schools; (*b*) diagrams, copies, text-books, &c.; (*c*) specimens of art work, modelling, &c., in schools.

Class 53.—Technical and apprenticeship schools—(*a*) Apparatus and examples used in primary and secondary schools for teaching handicrafts; (*b*) models, plans, and designs for the fitting up of workshop and industrial schools; (*c*) results of industrial work done in such schools.

Class 54.—Schools for the blind and for the deaf and dumb—(*a*) Apparatus and examples for teaching; (*b*) specimens of school work.

Class 55.—Literature, statistics, and diagrams relating to Group 6, and to the effects of "cramming" and overwork on the young, &c.

Class 56.—Collective displays of school work and appliances.

It will be seen that in Group 4 are comprised all the exhibits relating to school construction, to the improvement of the sanitary condition of school buildings, and to means for promoting the health of the scholars by physical exercises and otherwise.

The classification sufficiently shows the character of the exhibits the Committee would wish to see provided. They would, however, lay special stress on those included in Class 39, and relating to physical education. They would be glad to see included as many models as may be convenient of typical elementary schools, and they would appeal for this purpose to school authorities and managers in this and other countries, and to architects who have given special attention to school construction, for the loan of such models, as well as of plans and diagrams. The admission of the latter, however, must be to a certain extent limited by considerations of space.

As regards Class 40 of this Group—and the same remark will apply to Class 55 in Group 6—the Committee are anxious that this Class should be limited, with a view to preventing the Exhibition being overburdened with literature. Books stowed away in glazed cases, the backs only being visible, as is the usual custom in exhibitions, are of little practical value or interest; and if available for examination a constant watch is necessary.

Group 6, which forms the second division of the Exhibition within the province of this Committee, relates entirely to educational works and appliances, these being restricted to such in the first instance, as attach to primary schools, and secondly, to scientific, artistic, and technical education in secondary and higher grade schools, it being understood that Class 49 comprises what may be considered as technical education for women. Regarding this Group, it will be noted that in every Class where they can come in, examples or specimens of school work are included. In the case of primary and infant schools, the Committee would be glad to see this part of the Exhibition strictly limited to what is important or characteristic, and the same remark to a great extent applies to Class 49.

The Committee would wish to arrange for as large a display of maps and diagrams as the wall space available will permit.

Of the specimens of work of a handicraft or technical character, the Committee would be glad to see as full a collection as possible, especially of the higher class of work done in certain foreign schools.

The Committee do not consider it at all necessary that extensive collections of apparatus and fittings for infant and elementary schools in use in this country should be shown, especially when it is remembered that the educational collection of the South Kensington Museum is in the close neighbourhood of the Exhibition.

Among other points, on the importance of which the Committee would lay stress, may be mentioned the artistic decoration of school-rooms, the exhibition of works of art suitable for use in schools, and the exhibition of objects suitable for school museums, or possibly of a typical school museum.

As regards the instruction of the blind and of the deaf and dumb—as in all other departments—the Committee would like the various systems to be fully represented, and it should be understood that no preference would be given to one system above another on account of any individual views which members of the Committee might entertain.

It will be noticed that in Class 55 are included the effects of cramming and overwork on the young. The Committee understand that this subject is mentioned in the classification merely in order that it might be included amongst the subjects for conferences, and they do not understand that any exhibits intended to illustrate it will be sought for.

As regards collective displays (Class 56), the Committee will endeavour to organise displays of this character, which are likely to have a higher educational value than the exhibition of separate articles.

Memorandum from "The Indian" Sub-Committee.

The object which this Sub-Committee think should be kept in view in considering the arrangements for the Indian Section of the Exhibition, is the illustration, in as vivid a manner as possible, of the actual life of the masses of the people of India, as regards the three especial objects of the Exhibition, their

Food, their Dress, and their Dwellings, also, but to a less extent, their Education.

The Committee feel that they must not rely solely on contributions from India, but that they must also expect the aid both of traders and of private individuals in England in securing an effective Indian display. They are, therefore, anxious that it should be distinctly understood that applications for space from Indian traders in England will be readily considered, provided of course, that the proposed exhibits are of a character suitable for the Exhibition.

As regards Group 1, Food, it will be desirable that there should be complete collections of the ordinary food of the people in some selected districts of each principal province. Where possible, it would be desirable to have the prepared food itself; when this cannot be done, the raw materials and models might be shown. Thus, for a Deccan district, samples of Bajra and jowar, the chief grain foods, of wheat, dhal, and pulses, and of the flour as prepared by the natives for use; models of the chowpattis or loaves; then the condiments, salt, pepper, pickles, &c., as actually used; ghi, gur, and sweetmeats, with the grindstones; models of "chulas," or cooking stoves and the like; cooking pots, dishes, &c., as used. For a coast district, rice in its various preparations, salt and dried fish, &c.

Specimens also of Indian food-stuffs imported in this country are desired, as well as specimens of the various condiments, pickles, preserves, &c., manufactured either for European or local use. Models of edible fruits, especially those known in this country in a dried state, would be useful. Also representations or stuffed specimens of animals and fish used as food.

Any illustration of the processes of preparing rice, tea, coffee, &c., would be welcomed. It would certainly create great interest here if a few native cooks could be brought over, with plenty of materials, who would cook daily, for sale, say a good Mussulman dinner, and a good Hindu dinner, with accompaniments such as are used at caste feasts, weddings, &c.

As regards Group 2, Dress, the most important thing will be to show the clothing, &c., of representative classes in representative districts of each province; thus, from Bombay, there might be a Gujerat Patidar, a Deccan Banya, a Konkan fisherman, a Borah trader, a Parsee merchant—with their women; from Bengal and Madras similar typical examples. The dresses should be shown on lay figures, and should be the ordinary habiliments of the people with their ordinary ornaments, also with Charpais, Kamlis, rasais, &c.

Exhibits illustrating the construction of Indian fabrics, and specimens of any fabrics of special interest are desirable, also illustrations of silk culture (especially tussur).

In Group 3, the Dwelling, possibly there might be exact models of the better classes of houses in representative districts (say of a cultivator of the better class, a banker, a shop keeper), of the cottages of the lower class, the huts of weavers, fishermen, &c., of European up-country bungalows, and of a bit of a bazaar in an up-country town. With these models should be shown small figures, dressed to represent the people at their usual avocations; models of their furniture and of their domestic animals might be put into their houses.

Models of native schools, and any matters connected with the education of the people would be acceptable.

Punkas, Tattis and Thermantidotes should be admitted, and other means of cooling air, drinks, &c.; also means for carrying and preserving water.

If, besides the cooks above mentioned, other Indian workmen could be brought over, potters, blacksmiths, weavers, clothworkers, embroiderers, silversmiths, &c., it would form a most interesting feature in this Exhibition, and, as illustrating the life of the people of India, possibly not a unsuitable feature.

GUTTA-PERCHA.

By James Collins.

The earliest notice concerning gutta-percha I have come across, is contained in John Tradescant's catalogue of his "Rarities preserved at South Lambeth."* In this is mentioned "plyable mazer wood, being warmed in water, will work to any form." It is also by no means impossible that some of the historical "mazer cups" may have been made from this material,† the mottled appearance of gutta-percha answering to the descriptions given, and its lightness, strength, and non-liability to fracture, would render it a good substitute for the true maple. "Mazer-wood tree" is also one of the vernacular names of the gutta-percha tree.

To Dr. William Montgomerie, a surgeon in the East India Company's service, belongs the honour of first bringing this substance before the commercial world. He first noticed it in Singapore in 1822, and experimented on it; and in 1842, whilst again in Singapore, he recommended it to the Medical Board of Calcutta as a substance useful in the making of surgical splints. He also sent samples to London to the Society of Arts, who warmly took up the subject, and, in 1844, awarded Dr. Montgomerie their gold medal. In 1843, Dr. (afterwards Sir) José d'Almeida sent a sample to the Royal Asiatic Society, and some persons have confounded these two circumstances. Dr. d'Almeida, it should be remembered, sent gutta-percha as a curiosity, whilst Dr. Montgomerie, long before this date, experimented on the substance, and recommended it as likely to prove of great utility in the arts and manufactures.

In 1847, Sir W. J. Hooker‡ named the plant *Ison-*

* "Museum Tradescantium."—London, MDCLVI.

† *Vide* Spenser's "Shephearde's Calendar," and "Faerie Queene."

‡ "Lond. Jour. Botany," Sept. 1847, p. 404.

andra gutta, from specimens supplied by Mr. Lobb, who was at that time collecting plants for the Messrs. Veitch, the eminent nurserymen; and Mr. Motley, whilst in Borneo, added materially to our information. Dr. de Vriese, on the part of the Dutch Government, did good work in this direction, he giving descriptions of eighteen plants yielding this substance.*

Gutta-percha, as it appears in commerce, is of a reddish or yellowish hue, nearly as hard as wood, and of a porous structure. When cast or rolled, it assumes a fibrous structure, and acquires a tenacity in a determinate direction. At a temperature of 32° to 77° Fahr., it has as much tenacity as thick leather, but not at all elastic, and less flexible. In water, towards 120° Fahr., it softens and becomes doughy, although still tough; at 145° to 150° it becomes soft and pliant, assuming the elasticity of caoutchouc, becoming again hard and rigid on cooling. It is highly inflammable, burning with a bright flame, and its electrical properties are well known.

Gutta-percha, like many other milky juices, is found stored up in an irregular network of tubes (*Cinenchyma*, or lactiferous tissue), in the middle layer of the bark; the outer layer, largely developed in the cork oak, is known as the corky layer, or *epiphleum*, and the inner, largely developed in fibre-plants, is known as liber-layer, or *endophleum*. Thus the bark has to be cut into to free the milky juice.

Gutta-percha trees are confined to the natural order Sapotaceæ, an order yielding succulent fruits, such as the sapodilla plum (*Achras sapota*), vegetable butters as from the seeds of various species of *Bassia*, whilst from species of *Dichopsis* (*Isonandra*), and other genera, we have the peculiar gum-resin, or hydrocarbon, known as gutta-percha. A short description of the better known tree will be sufficient for the present purpose.

Dichopsis gutta (Isonandra gutta) is known uuder various names, such as gutta-percha, gutta tabán (the more correct), gutta durian, gutta niato, and many others. The word gutta, gutah, gatta, gittáh, as it is variously spelt, signifies in Malay, gum or juice. The second name is the name of the tree producing this gum, the same tree having a different name in different localities. The tree is found in the Malay Peninsula, Sumatra, Borneo, and throughout the Malayan Archipelago generally. It grows to a height of 60 to 80 feet, with a diameter of 2 to 5 feet. The leaves are inversely egg-shaped and entire, pale green on the upper side, and covered beneath with a reddish-brown shining down. The flowers are arranged in clusters of three or four in the axils of the leaves. The fruit is a small oval berry. The gutta, as it flows from the tree, is of a greyish colour, at times somewhat roseate in hue, possibly arising from the colour of the bark. There is also an oblong leaved variety of this species. Of other kinds mention may be made of the following:—

* De Vriese, Plantæ Batavæ Orientalis, Lug. Bat. 1856; De Handel in Getah-Pertja, 1856.

Dichopsis macrophylla, the Ngiato putih or white gutta-percha of Borneo, the gutta of which, according to Motley, is of a second-rate quality.

Dichopsis Motleyana, yielding a very low kind, known as gutta kotian (Motley).

Payena dasyphylla, yielding a second-rate quality, known as gutta benton, in Borneo (Motley).

Payena Leeri, yielding gutta balem-tandoek, &c., in Sumatra and Java.

Beside these there are species of *Chrysophyllum*, *Sideroxylon*, *Bassia*, *and Mimusops*, also said to yield gutta-percha.

The names of varieties of gutta-percha are exceedingly numerous, and many are no doubt synonymous, and a bare mention of a few of these will suffice. In all, the words gutta-percha may be used as a prefix to these names.

Waringen.—Borneo. Well spoken of.

Nettu.—Borneo. Said to be of a second quality.

Ploot.—Borneo. A third quality.

This is a Dyak term, and seems to be applied to varieties all alike.

Papua.—Borneo. Fourth class.

Rana.—Borneo. Very low quality.

Katella, Jankar and Kladi guttas are only used for adulterating better qualities.

Daging.—In the Malay Peninsula, gutta daging is well known, the term daging meaning "flesh," the gutta having a very gristly character. It is much like Balata, and is a capital gutta.

Muntah.—Under the name gutta muntah, or white Borneo, this kind made its appearance in the English market some years ago. Muntah means "raw," and is applied to all guttas which have not been cooked or prepared. Hence the term is applied to the lowest as well as the best varieties. If not speedily used up, it loses all its value by becoming resinified.

In the Brow and Boolongan districts, on the east coast of Borneo, Captain Lingard informed me that there are three kinds of gutta-percha recognised by the natives.

(1.) Kalapeieh, or Lota lanyut, or "tough gutta," is the first and best quality. It is known in the English market as Lingard's "Nina" brand.

(2.) Kalapeieh, or Lota mooka, or "spongy gutta" yields about 10 per cent. less gutta, and the tree is more difficult to cut down.

(3.) Kalapeieh, or Lota kapur, yields about 20 per cent. less than No. 1, and in the wet season even 30 per cent less.*

(*To be continued.*)

INDUSTRIAL PROGRESS IN RUSSIA.

Russia at present displays in the provinces of Livonia, Esthonia, and Kourland, as well as in Poland, great industrial activity. The *Central-Blatt*

Journal of the Society of Arts.

No. 1,627. Vol. XXXII.

FRIDAY, JANUARY 25, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

SWINEY PRIZE.

A meeting of the adjudicators of this prize, appointed by the will of the late Dr. Swiney, was held on January 21st, 1884, at the Rooms of the Society of Arts. R. E. Webster, Q.C., Member of Council, in the chair.

The Secretary read the advertisement convening the meeting.

The Secretary read a report from the joint Committee of the Society of Arts and the College of Physicians, recommending that the prize should be awarded to Professor Sheldon Amos, M.A., for his work entitled "A Systematic View of the Science of Jurisprudence."

It was thereupon moved by Mr. B. Francis Cobb, Vice-President of the Society of Arts, and seconded by Sir Henry Pitman, M.D., Registrar of the College of Physicians, and carried, "That the prize, a silver goblet value £100, containing gold coin to the same amount, be adjudged, and the same is hereby presented to Professor Sheldon Amos, M.A., the author of a published work on jurisprudence entitled 'A Systematic View of the Science of Jurisprudence.'"

The cup has been executed by Messrs. Garrard, from a design made expressly for the Society by the late Daniel Maclise, R.A.

PRIZES FOR ESSAYS ON DWELLINGS FOR THE POOR, AND ON THE RECONSTRUCTION OF CENTRAL LONDON.

The Council of the Society of Arts have had placed at their disposal by Mr. William Westgarth, a member of the Society, a sum of £1,200, to be awarded in prizes for essays on the above subjects.

The first prize will be a sum of £250, for the best practical essay upon the re-housing of the poorer classes, and especially of the very poorest classes, of the metropolis.

The second prize will be a sum of £500, for the best practical essay upon the whole subject of the sanitation, street re-alignment, and reconstruction of the central part of London.

The essays should include the following points:—

I. Reconstruction of the central part of London with regard to the plan of the streets.

II. Removal of the old and poisoned soil.

III. Re-arrangement of the levels, and provision of subterranean ways for the accommodation of electric wires, pipes for water supply, sewage, &c.; also provision for warehousing.

In addition to the above, there will be three further prizes of £150 each:—

1. For the best treatment of the engineering considerations.
2. For the best treatment of the architectural considerations.
3. For the best treatment of the sanitary considerations. Any or all of these

last-named prizes may be awarded to the same essay as that to which the £500 prize may be awarded, or they may be awarded separately.

The essays must be sent in to the Secretary of the Society of Arts, John-street, Adelphi, not later than December 31, 1884. No essays can be received in manuscript. Two printed copies of each essay must be submitted, and it will be convenient that they should be printed in pages, with wide margins. The essays should be accompanied with such maps, plans, drawings, &c., as may be necessary, and these need not be in duplicate.

The Council reserve the right of withholding any of the prizes, or of awarding the amounts, or parts of the amounts, in any manner which may seem to them desirable. They also reserve the right of publishing any essay to which a prize may be awarded.

The name of the writer must not appear on the essay, but each essay must have written or printed thereon a motto, and be accompanied by a sealed envelope containing on the outside the same motto, and within the name and address of the writer.

The awards will be made by the Council upon the recommendation of judges, to be appointed by them, and will be final.

H. TRUEMAN WOOD,
Secretary.

John-street, Adelphi.
January. 1884.

*** Mr. Westgarth's own views are embodied in a memorandum prepared by him, copies of which can be obtained on application at the Society's offices.

A paper entitled "Suggestions on the Rehousing of the Poor, and on the Reconstruction of Central London" will be read by Mr. Westgarth, before the Society of Arts, on Wednesday, February 6th.

Proceedings of the Society.

SEVENTH ORDINARY MEETING.

Wednesday, January 23rd, 1884: Sir JOHN LUBBOCK, Bart., M.P., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Blyth, Alexander Wynter, M.R.C.S., The Court House, Marylebone, W.
Bond, Henry Charles, Brasenose, Bromley, Kent.
Campbell, F. J., Royal Normal College and Academy of Music for the Blind, Westow-street, Upper Norwood, S.E.
Johnston, Archibald, 6, Paternoster-buildings, E.C.
Lascelles, Brian Piers, 9 Holywell-street, Oxford.
Palmer, Walter, B.Sc., F.C.S., Westfield, Reading.
Ruscoe, John, Albion Works, Hyde, Manchester, and Prospect-house, Hyde, Manchester.
Stopes, Henry, 24A, Southwark-street, S.E., and Kenwyn, Cintra-park, Upper Norwood, S.E.
Van Gelder, Pieter, Sowerby-bridge, Yorkshire.

The following candidates were balloted for and duly elected members of the Society:—

Appleton, R. H., Woodside-hall, Eaglescliff Junction, by Darlington.
Houston, Frederick H., Carlisle-terrace, Belfast.
Pott, Henry, 81, Cornwall-gardens, S.W.
Prosser, William Owen, 5, Trinity-place, Swansea.
Rea, Russell, 19, Primrose-hill-road, N.W.
Tomkins, Daniel, The College, Great Yarmouth.
Wildsmith, James H. S., 131, Upper Kennington-lane, S.E.

The CHAIRMAN said he was glad that the Society of Arts was about to take up the subject of science teaching, which was one of very great importance. The Duke of Devonshire's Commission had reported that the neglect of science—and, he might add, of modern languages—in our schools, was a national misfortune; and though, no doubt, there was some improvement since that time, almost the same might be said now. Considering how much science had done and was doing for us, the general, though happily not now universal, neglect of it in our schools was astonishing. If we did not avail ourselves to the utmost of the resources of nature, our great and growing population would become more and more miserable, and we should be distanced in the race of competition by foreign nations. He believed the public did not realise the present state of affairs. He had recently made some statements on the subject at Bristol, and was told that they were simply incredible, and that he was speaking of schools as they existed thirty or forty years ago. He adhered, however, to all he then said. Though almost incredible, it was quite true. Of course he did not say that there were not schools in which science and modern languages received due attention, no doubt there were some bright examples, but he was speaking of schools generally. A Parliamentary return, published in 1879, gave the number of hours devoted to different subjects in all schools with an endowment of more than £500 a year. Of course there would be some change since then, but probably not much. The return comprised 233 schools, but there were three or four in which the figures were unintelligible. As regards the other 230 schools, there were 30 in which neither science or modern languages were taught, 64 in which less than one hour a week was given to science, 33 in which an hour a week was devoted to science. The time occupied in "preparation" was not included in the return. Allowing an hour a week for this, he found that out of the whole 230 schools, 168 devoted less than three hours a week to science, 38 from three to four hours, and only 24 more than four hours. As regards modern languages, 87 schools devoted less than three hours, 44 from three to four hours, and 93 more than four hours. According to their last report, the Oxford and Cambridge School Examination Board examined 60 schools. Less than half of these schools presented any boys at all for examination in science, and out of the whole 60 schools only 200 boys altogether were presented for examination in science, and under 400 in modern languages. The loss inflicted on the nation by the present system was incalculable. No doubt the system pursued at the Universities of Oxford and Cambridge made it difficult for schools to alter their arrangements. He wished that all our universities, would insist on some science not on a smattering, but on a good groundwork being laid. Passing on to the elementary schools, we also found the same discouragement of science. There were four class subjects, as they were technically called, namely, history, geography, English, and elementary science. Schools were only allowed to present children in two of them, and one of the two must be English. History and geography were excluded. Of course, as often happened in England, our practice is better than our system. In spite of the Code, some of the stronger School Boards do teach science. In one part of Birmingham the science lesson was given on washing-day. As the science lesson was so popular, the mothers could not keep their girls at home, and they were obliged to change the washing-day. He thought the Code required alteration in this respect, on several grounds. Some schoolmasters could not teach grammar in an interesting manner. Secondly, it was a mistake to insist on the same system all over the country, without any reference to the condition or requirements of the district. Again, we ought not to dictate to School Boards on such a point; and lastly, he must protest against an arrangement which tended to exclude the book of Nature from our elementary schools.

The paper read was—

SCIENCE TEACHING IN ELEMENTARY SCHOOLS.

By William Lant Carpenter, B.A., B.Sc.

The object of the present paper is not merely to draw attention to the crying need for elementary scientific instruction in our primary schools, but also to point out how such instruction can best be given, and to show that this can be, and has been, done on a large scale with extraordinarily beneficial results to the children thus taught, without any more expenditure of time than at present. I shall, in fact, give reasons for believing that science, properly taught, may excite such an interest in children's minds as to prove actually a relief from that overstrain in education of which we have heard so much during the past few months, and I shall adduce many instances of a very large increase in the per-centage of passes in the three R's, in schools which have devoted an hour or two weekly to science demonstrations of the kind to be described, such time being taken from that previously devoted to the ordinary routine, and in too many cases mechanical, instruction which is so much in vogue.

It may perhaps be well to define at this point the sense in which the terms science, and scientific instruction, will be used in this paper. That orderly arrangement of facts to which, in a broad sense, we give the name of science, or the scientific method, may be, often is, and still more ought to be, applied to the treatment of all subjects of instruction; a lesson on an air-pump may be thoroughly unscientific, while a lesson on the infinitive mood may be scientific in a high degree. For my present purpose, however, I wish to be understood as meaning by science that knowledge of the facts and phenomena of that universe around us, with which every one of us is in daily relation (though we too seldom realise the fact), to which the phrase natural science is sometimes applied, including both physics and biology (using those terms in the widest sense), the sciences essentially of experiment and observation.

During the first year or two of the life of an ordinary child, the amount of positive information obtained by him regarding the external world is indeed remarkable. The late Dr. Whewell, in congratulating a friend, famous for his knowledge and ability, on the birth of a son, remarked, "Young as he is, he will learn more than you in the next twelve months." And, in the words of Professor Tyndall:—

"As the child grows he is still an experimenter; he grasps at the moon, and his failure teaches him to respect distance. At length his little fingers acquire sufficient mechanical tact to lay hold of a spoon; he thrusts the instrument into his mouth, hurts his gums, and thus learns the impenetrability of matter. He lets the spoon fall, and jumps with delight to hear it rattle against the table. The experiment made by accident is repeated with intention, and thus the young student receives his first lessons upon sound and gravitation. There are pains and penalties, however, in the path of the inquirer; he is sure to go wrong, and Nature is just as sure to inform him of the fact. He falls downstairs, burns his fingers, cuts his hand, scalds his tongue, and in this way learns the conditions of his physical well-being. This is Nature's way of proceeding, and it is wonderful what progress her pupil makes."

In October, 1869, the Pedagogical Society of Berlin issued a circular, requesting the managers of the eighty-four established schools of that city to put a series of questions to their pupils, the avowed object of which was "to determine the individuality of the children, so far as conditioned by the concepts arising from their immediate environment." More than 2,000 children were thus questioned, and an abstract of the results will be found in the Berlin *Statisches Jahrbuch*, Jahrgang 4, s 59. With the advantages of many suggestions, and not a few warnings, from this experiment, Mr. G. Stanley Hall, of Boston, U.S.A., made out a list of questions "suitable for obtaining an inventory of the contents of the minds of children of ordinary intelligence, on entering the primary schools of that city," which are attended, as I can testify from personal experience, by children of all social grades. In order that they might not suggest answers to each other, the children were questioned three at a time, in a small room, by four of the best trained and experienced Kindergarten teachers, and the results were tabulated. Many most amusing details are to be found in the article in the *Princeton Review*, where Mr. Hall gives an account of the work.

"Tables are given showing the per-centage of children of various kinds, and with different previous training, ignorant of several common objects or concepts. For example, 55 per cent. did not know that wooden things came from trees; 69 per cent. were ignorant of the origin of woollen things; 75·5 per cent. did not know what season it was; to 61 per cent. the words 'growing potatoes,' 'a snail,' or 'a spade' conveyed no idea. Of 48 children questioned, 20 believed sun, moon, or stars to live; 15 thought a doll, and 16 thought flowers, would suffer pain if burned. Of all the children questioned, 48 per cent. thought that at night the sun 'goes, or rolls, or flies, is blown, or walks, or God pulls it up higher out of sight. He takes it to heaven, and perhaps puts it to bed; or even takes off its clothes and puts them on in the morning; or, again, it lies under the trees, where the angels mind it. It may stay where it is, only we cannot see it, for it is dark, or the dark rains down so, and it comes out when it gets light so it can see.' So also the moon comes around when people forget to light lamps; sometimes a piece is cut off, and it is only half stuck or buttoned into the sky. 'God lights the stars with matches, and blows them out, and opens the door and calls them in, in the morning. Lightning is when God strikes many matches at once; He makes rain up in Heaven out of nothing, keeps it in a big tub, and lets it down with a water-hose through a sieve. Thunder was due to God rolling barrels about, or grinding snow, having coal run in, hitting the clouds, or, in some cases, merely to ice sliding off lots of houses, or to piles of boards falling down.'"

Most of us probably can, or could if we took the pains to ask such questions, give similar results from our own knowledge. The four-year old child of a friend of my own, having attentively watched an upholsterer nailing leather on bookshelves with brass-headed nails, pointed to the stars, on the evening of that day, with the question, "Mama, are those the nails that keep Heaven up?" A member of the Glasgow School Board, having listened to a lesson on a robin, given to nearly 120 children, asked "how many had seen a robin." Six or eight hands were held up, and selecting the brightest-looking owner, he said, "Well, my boy, as you have seen a robin, tell me anything whatever you like about it." "Please sir, it's a bird with a red spot on its tail!" was the result of a good deal of deliberation.

There is, I am told, good foundation for the remark that the best elementary schools of twenty years ago were nearly, if not quite, equal to those of to-day; and that the improvement in the intervening period, of which so much has been said, has been rather in the direction of the quantity of the work (by a multiplication of good schools of one pattern) than in its quality. It is to this latter that I am about to ask your attention.

It will, I think, be acknowledged by all those whose experience enables them to judge, that one of the great shortcomings of the present system is the mechanical nature of the work done, which reduces the children to the state of machines rather than of thinking individuals. The Government inspectors complain unceasingly of the monotony, want of ease and power, and lack of "general intelligence" exhibited by the children. They read correctly, but the words represent or convey no ideas to their minds. "They can" (to quote an official utterance) "usually work 'straightforward' sums with quickness and precision, but they rarely succeed in solving the easiest problem." I have read various statements by teachers of large experience as to the evil effects of the "payment by results," and of the individual examination system; I will only trouble you with two—"There is not time to train children to think," and "What will pass, not what will educate, is the incentive." In fact, of the two great mistakes which, according to some writers, vitiate the whole organisation of English education, from the elementary schools upwards, the one with which we are concerned now is, the conception of intellectual training as the acquisition of information, rather than as the development of faculty.

That this deficiency in the present system has been lately, to some extent, practically recognised by Mr. Mundella, all true friends of education—using this word in the etymological sense of "drawing out the faculties"—will greatly rejoice. Although the individual examination is to remain the same (not for many years longer, let us hope), an entirely new element is introduced in the shape of a "Merit Grant," and henceforward the instructions to inspectors are explicit, that they shall in future take due account of, and give full credit for, the general intelligence of the children, as indicative of the manner in which they have been taught.

I desire now to point out the enormous—I had almost said the superlative—value of science teaching in thus quickening this general intelligence, as well as the very great practical value of the knowledge imparted, provided that the teaching is conducted in a proper manner. For this it is absolutely essential that the children should be so taught as to attach definite ideas to the words used by their instructors and by themselves. That great danger exists of their not doing so in their ordinary reading lessons, I have already tried to show; and this to a great extent disposes of the argument used by many opponents of reform who nevertheless admit, to a certain degree, the utility of science teaching, but who assert that science can be properly taught, and reading improved at the same time, simply by reading short extracts upon scientific subjects in the ordinary school lesson books. To scientific men such a statemeut carries its own refutation on the face of it, but it is extremely difficult to convince many people of the fact; and it is hoped that the education of the public mind upon this point may be, to some extent, improved—to however small an extent—by these remarks, and more particularly by the expressions of opinion on the same subject, from men far more qualified to address you on the general question than I am, which I trust we may hear in the discussion that will follow this paper. In the most recently published "science readers" for elementary schools, viz., Messrs. Gill's excellent *Albany Series*, attention is drawn in the preface to the necessity for illustrating the reading lessons by experiments, specimens, &c.

It may, perhaps, not be undesirable to call attention here, very briefly, to the main features of an ordinary public elementary school. In towns, each school is ordinarily divided into three departments—(1) the infant school, with children of both sexes from four to seven years old; (2) a girls' school; (3) a boys' school; each of the two last containing children from seven to fourteen years of age, classified, according to the Government requirements, into seven standards. In addition to the three R's, any child above Standard I. may be taught any two of the so-called "class subjects," one of which must be English, the others being geography, elementary science, and history; and for evidence of successful teaching in these, an extra payment of from 1s. to 2s. is made. Lastly, and this is the special point with which we are now concerned, children in the 4th and higher standards may, in addition, take up any two of ten named "specific subjects of secular instruction"—viz., algebra, Euclid and mensuration, mechanics, chemistry, physics, animal physiology, botany, principles of agriculture, Latin, French, domestic economy. Any other subject may be taken under this head, subject to the approval of the inspector. For each individual pass in these, an additional grant of 4s. per head is made.

The origin of the system of scientific instruction to which I now invite your attention is thus described in a paper by Mr. E. M. Hance, clerk to the Liverpool School Board, published in the *School Board Chronicle* for November 1st, 1879:—

"However important, I might say essential, may have been the system of payment by results introduced by the Revised Code, I think that there can be little doubt that the effects of it as first applied—and, to a modified extent, the same still holds good—was to reduce education in, I might say, the majority of Government-aided schools to a monotonous 'grind' at reading, writing, and arithmetic, of which the ultimate aim appeared to be the attainment of mechanical accuracy. This not only did very little, if anything, to develop the intelligence of the children, but was directly calculated to defeat that object by generating in a large proportion of cases a positive distaste for intellectual attainments. The Liverpool School Board, as soon as they had any schools to manage, were, like most other School Boards, greatly impressed with the necessity of providing a somewhat more varied curriculum. They also felt strongly the importance of introducing some subject specially calculated to awaken and exercise the observing faculties of the children, and, by making this subject common to all their schools, to render it a distinctive feature in their educational system. With this object, they sought and obtained the valuable advice of Professor Huxley, Colonel Donnelly, and other gentlemen of eminence in the world of science. The result would, if they had felt themselves entirely free, have probably been the adoption of "elementary physics" for both boys and girls; but, in view of the provisions of the New Code as to Government grants, and of the importance of having the work tested by independent examination, it was decided not to go outside of the subjects provided for by the Code. Under these circumstances, the Board, at the suggestion of the gentlemen before mentioned, ultimately selected 'mechanics' for boys, and 'domestic economy' for girls, as the subjects most suitable for their purpose —the definition of these subjects given in the New Code being of such a nature as to allow of the instruction being considerably expanded in the one case in the direction of elementary physics, and in the other in that of elementary chemistry, physics, and physiology. In reference to the system of instruction, it was, by the same advice, decided to absolutely abandon the use of text-books by the scholars, and to rely upon oral instruction, accompanied by, or rather explaining, appropriate illustrations and experiments."

The general idea of the scheme thus suggested was first worked out in detail in Liverpool, but was speedily adopted by the Birmingham School Board, and by it still further developed. I have had considerable opportunities of studying its working in both towns, and consider the results obtained to be so extremely valuable, that I am devoting a good deal of time to making them known, and am now in correspondence with several School Boards on the subject. As recently as Friday last, January 18th, I addressed a large meeting of teachers in Bristol on this subject, and I have the permission of the chairman of the Glasgow Board to say that a meeting of that Board was specially summoned last month, to hear a statement from me upon the subject, at the close of which I was requested to come again, to confer not only with them but with some of their teachers.

The special feature of the scheme, and one which is rightly regarded as of the very highest importance in connection with it, is that these science demonstrations are given not by the ordinary staff of the school but by a specially appointed expert, whose sole duty it is to go round from school to school, giving practically the same lesson in each one, until all have been visited. The apparatus necessary is kept, and the experiments are prepared, at a central laboratory at one of the schools, and whatever is needed for a given lesson is carefully packed in neatly partitioned boxes, and is taken from school to school in a hand-cart, drawn by a boy employed for the purpose. In this way the Birmingham demonstrator, Mr. W. Jerome Harrison, F.G.S., is able to give four lessons per day, of about forty-five minutes each, in as many different schools; and at present all the thirty Board schools, or sixty departments, are thus receiving such instruction, which is given to about 2,800 boys and 1,600 girls, from among the 17,944 who were presented for examination in 1883. Mr. Harrison has two assistants in this teaching, and one laboratory assistant; and it occasionally happens, as was the case at the time of my "surprise" visit, that he may be teaching mechanics to boys, and one of his assistants expounding domestic economy to girls, in different rooms of the school at the same time. Carriage of apparatus is thus saved. In addition to these, 485 boys are being taught magnetism and electricity, and 95 boys and 90 girls are similarly learning animal physiology, the instruction being in every case given by one of the special demonstrators.

In the eighteen Board schools of Liverpool last year, 10,512 children were presented for examination, 7,203 of these were examined in some of the class subjects; moreover, every boy in Standards IV. to VI. was examined in "mechanics" and every girl in the same standards in "domestic economy," the numbers being 1,868 boys, and 1,334 girls. The previous years' returns of this board afforded very clear testimony to the fact that elementary instruction in science so quickens a child's mental life, as to render him more generally intelligent. The "passes," as compared with the numbers presented for examination in ordinary subjects, were:—

In 1873-4	74·4 per cent.	
" 1874-5	74·5 "	
" 1875-6	74·4 "	
" 1876-6	79·1 "	Year in which "class subjects" were first examined.
" 1877-8	85·6 "	Year in which the system of science demonstrations was introduced.
" 1878-9	87·1 "	
" 1879-80 ..	88·4 "	
" 1880-1	89·7 "	
" 1881-2	88·5 "	

From this it appears that, while the average per-centage of passes in ordinary subjects for the three years prior to the introduction of this particular form of science teaching was 74·4, the average per-centage in the same subjects in the five years succeeding its introduction was 87·8, an actual increase of $13\frac{1}{2}$ per cent., and an increase on the quantity under consideration of 18 per cent, or nearly one-fifth.

It is a somewhat remarkable point, and one that has only been recently noticed, that whereas the figure of merit in the Liverpool Board schools is only slightly above that of the whole country in reading and writing, these schools are very decidedly superior in arithmetic, their per-centage of passes being 87·13, as against 77·27 per cent. for the average of schools in the country. This result is considered by the Board as due in a great degree to their system of science teaching. The clerk to the Birmingham School Board writes as follows:—

"Our head teachers unite in saying that the science lessons do the children so much good, that although they have to afford time for them which used to be devoted to the ordinary work for the Government examinations, they, nevertheless, gain in results, and they would feel it to be a loss if they were to be deprived of such lessons. This is even the case in the girls' schools, where they were so heavily handicapped by the time that has to be devoted to needlework, that they can ill afford time for any extra lessons whatever."

In Birmingham, the lessons are given fortnightly. One of the regular staff of the school is always present, and it is his duty in the intervening week to go over the lesson again to the class, and drive it home. After this, each child writes out notes of the lesson, often in reply to questions set, and these notes are revised by the demonstrator himself, before he next visits the school. I looked over several of these notes, selected at hazard, and was much surprised at the ability displayed in some of the answers. I also conversed on the subject with my friend Dr. Poynting, Professor of Physics, &c., in the Mason College, Birmingham, who, at the request of the Board, had examined a number of boy candidates for a scholarship offered in connection with the system, and he spoke in very strong terms to me of the excellent results noticeable throughout the examination, as well as of the individual excellence of the successful candidates. The boys showed that they had seen and understood the experiments which they described—that they had been taught to reason for themselves upon them—and that they were not merely using forms of words which they had learnt without attaching physical ideas to them.

The practice of having one or more of the ordinary teachers present at the demonstration, is fraught with more important consequences than at first sight appears. Their attention is thus drawn to science, and to science well taught, as the following quotation from a teacher's letter to Mr. Harrison will show. The writer is one of the hardest-working assistant teachers in Birmingham, and his testimony was spontaneous:—

"I have attended eight or ten science classes, and gained several certificates, but from them all I have not gained so much knowledge as by listening to your lessons."

I venture to hope that this system of science teaching in elementary schools, by specially appointed demonstrators, will obtain authoritative endorsement as the the right one. Dr. Crosskey, the chairman of the School Management Committee in Birmingham, tells me that he has had to fight for it against objections of the following kind:—

I. "The regular teachers can do all the science which is needed." Those, however, who know how completely their time is occupied under the present system, can see at once that there is really no time available for the necessary experimental preparations.

II. "Only a few elementary principles can be taught, and this special supply of apparatus and demonstrators is beyond the mark." To this it is sufficient to reply, that the careful scientific demonstration of the simplest principles is a necessity for their apprehension. As my father, Dr. Carpenter, said to me once, "I hold that every child should have his hand on an air-pump receiver, while the air is exhausted from beneath it, and should see for himself the circulation of the blood in the frog's foot." As his son, I can testify to the vividness of the impression made upon my boyish mind at about eight years old, by these very things.

III. "It will interfere with the ordinary school work," was frequently urged. The best answer to this is the results, which show that the schools in which the Birmingham Board passes most in science, are also the best in the ordinary school work, since the general intelligence is so much quickened. Moreover, the past year has shown an "advance all along the line" in these schools, which never before contained so many children in the upper standards.

This special instruction is given to *every child* in the Liverpool and Birmingham Board schools who remains at the school after having passed the fourth standard. As this is usually done at eleven years of age, most of the children get from two to three years of this teaching.

The general scheme of instruction is as follows:—

Boys. 1st stage.—Matter in three states, solids, liquids, and gases. Mechanical properties peculiar to each state. Matter is porous, compressible, elastic. Measurement as practised by mechanics. Production of a plane surface. Measures of length, time, and velocity.

In Birmingham this is given in twenty-one lessons, in Liverpool in thirty-four. Both courses include such practical subjects as the spirit-level, air-pump, thermometer, clocks, hydrometers, filters, &c.

Boys. 2nd stage.—The meaning of force, and work done; gravitation and the three laws of motion; the idea of energy, both kinetic and potential, and of its conversation.

Boys. 3rd stage.—The principles of the six simple mechanical powers, the hydrostatic press, and the parallelograms of forces and of velocities.

As arranged for the girls, the instruction in the so-called "domestic economy" is as follows:—

Girls. 1st stage.—Functions of food, and its distribution by the blood; the chemistry of oxygen, hydrogen, carbon, and nitrogen; the proximate composition of various kinds of food; clothing and its uses, and the mechanics and chemistry of washing, both as regards the person and the clothes.

Girls. 2nd stage.—Food, its functions and composition, treated more in detail than in the first stage; and the physical and chemical principles involved in warming, cleaning, and ventilating a dwelling.

Girls. 3rd stage.—Rules for health; the management of a sick room; the preparation and culinary treatment of food; and lessons on expenditure and savings.

As regards the expense of the scheme, the cost to the Liverpool School Board was about £100 for the stock of apparatus, and £470 yearly for the instructor and his assistants. In Birmingham more than £200 has been spent upon apparatus, and the present annual expenditure is—chief demonstrator, £300; two assistants, £255; two juniors, 10s. and 12s. per week, say £55; or a total of £610, or about £10 per year, per school department. It is obvious that, under this plan, a maximum of highly efficient teaching is obtained at a minimum of cost; since the same demonstrators and the same apparatus are available for a large number of schools—in Birmingham, at present, for sixty school departments.

It may be objected that, although feasible in large towns, such a scheme is not practically useful in the number of smaller towns scattered over the country. I venture to think, however, that the objection is more apparent than real, and that a little concerted action on the part of neighbouring towns would soon remove the difficulty, in all but very outlying places in agricultural districts. In such thickly populated counties as Lancashire and Yorkshire, for example, four or five towns might unite in securing the services of one demonstrator. I know of several small towns where such joint action is ardently desired; and during a recent lecturing tour in the Border counties, in the course of which I advocated this scheme, the inhabitants of some of those Border burghs which are accustomed to such co-operation for political purposes, expressed a strong hope that some of their organising energy might be turned into some such educational channel as I have indicated. Moreover, the whole subject of this present paper was favourably discussed from various points of view, about three weeks ago, at the annual Congress of the Educational Institute of Scotland.

The duties of the Birmingham demonstrators, however, are by no means confined to the day-lessons, for ten evening science classes (under South Kensington) are conducted by them for teachers, and for children holding scholarships. The numbers under instruction at present are—physiography, 166; magnetism and electricity, 252; inorganic chemistry, 24; analytical chemistry, 24. The discovery of the manufactory of dynamite in Birmingham was due, in the first instance, to a youth who passed through these classes. He had, I believe, been taught the relation of glycerine to explosive compounds, and, living near Whitehead's premises, and seeing what he recognised as cans of glycerine and carboys and bottles of acid go in there, he communicated his suspicions to a friend who happened to be a detective policeman!

Further, Mr. Harrison, the chief demonstrator, devotes at least one evening per week in the winter months to giving elementary popular lectures at the various schools, illustrated with photographs and transparencies projected by a very good bi-unial lantern, presented to the Board for such purposes by Mr. Tangye, of Tangye Brothers, who also gave £250 to found scholarships. Of this work Mr. Harrison says, "The effect in improving the general intelligence of the children, in attracting them to school, and in improving the regularity of the attendance is, I believe, unquestioned." I may add that, for such purposes, the series of lantern photographs illustrating physics, already published by York and Son, and the series illustrating biology, at present in course of publication, are especially suited.

In this connection, also, I ought to mention that, acting upon a deficiency in their system pointed out by H.M. Inspector for the Birmingham district, the Board have just issued "Suggestions regarding the preparation of progressive schemes of object-lessons, in boys', girls', and infants' schools," in order to help the teachers to prepare the scholars of the first four standards systematically for the science courses which they enter upon when the 4th Standard is passed. The number of new lessons in any one year is fixed at thirty-six; and their aim is "to place the child in intelligent connection with the phenomena by which it is surrounded." The lessons, however, are confined to "objects," *i.e.*, matter; those which need reference to force being left until the 5th Standard is passed. It is true that in many of our schools, lessons, called by courtesy "object lessons," are already given; and the unsatisfactory results often attributed to them are due, chiefly, to the disconnected and "scrappy" choice of subjects, so that we find a lesson on flint succeeded by one on a pin, and this, again, by one on an oyster, and so on. Moreover, they are seldom prepared with sufficient care, and are often altogether deficient in the all-important point of illustration by tangible objects. One of H.M. Inspectors of London told me, for example, that he was present once at a lesson upon honey, the only illustration of which was a hermetically sealed specimen tube, containing a few grains of that substance!

A very important suggestion for the better illustration of object lessons, is at present under discussion in Liverpool, between the School Board and the museum authorities. It is due to the Rev. H. H. Higgins, the chairman of the museum sub-committee, and proposes the utilisation of duplicate specimens of the museum for the establishment of a circulating museum. The frequent failure hitherto of small school museums has arisen mainly from the insignificant individuality of the specimens, and the familiarity of the children with them. A specimen of considerable excellence, say a mineral, fossil, stuffed animal, or shell, will not only assist the teacher in more firmly imparting the knowledge he wishes to convey, but the beautiful and uncommon thing itself, if carefully handled, &c., by the children, will exercise a good moral and refining influence upon them, by calling out the faculties of observation and admiration.

The results of the system here advocated, which have been incidentally alluded to, are thus summed up by those who have watched it from the commencement:—

(1.) The general quickening of the intellectual life of the school.

(2.) The sending of a large number of lads to science classes after leaving school.

(3.) The finding out of lads of exceptional scientific ability, and setting them on their road.

(4.) The attracting the attention of the ordinary teachers to science, and to the results of teaching it.

Much might be said, did time permit, of the good effects of a variation in the monotonous routine of the school, afforded to the pupils by the science lesson; and, paradoxical as it at first appears, there is ample evidence to justify the conclusion that this mode of teaching really affords a relief from the overstrain in education, of which so much has lately been said and written. "The interest displayed by the children," writes one, "is in the highest degree pleasurable to witness. It is pleasant, too, sometimes to see a half-timer, who has stolen in from his work for this one lesson, standing by the side of the class, with grimy arms and rolled-up apron; or a little knot of girls released temporarily from 'minding the baby,' and waiting outside the locked door in order to obtain admission to the science lesson." Dr. Crosskey writes—"It is a wonderful thing to see the power of experimental science over the roughest lads. My own belief is that in our young blackguards we have a most amazing reserve power of scientific research; they are alive in every sense, and I have watched them at the science lessons as keenly interested as if they were up to mischief in the streets." Another man of very wide experience writes, "I have not the smallest doubt that there is a large class of minds whose activity is more easily promoted, and whose imagination is more readily fired, by physical science than by literature, especially of the class most met with in elementary schools."

It will have been observed that, in the system of instruction which has been described, there are two essential features which distinguish it from other systems of elementary science teaching. In the first place, the instruction is given orally, and with demonstrations, by a specially-appointed "expert." The next and more important point is that it forms an essential part of the teaching of every child who has passed the 4th Standard in every Board school in Liverpool and Birmingham. Let me now ask your attention very briefly to what is being done in the same general direction in the Board schools of some other provincial towns, and I may take this opportunity of thanking the clerks of the respective Boards, and other correspondents, for much information courteously furnished to me. I have purposely omitted London in my inquiries, since I hope we may hear during the discussion some account of what is actually done in London Board schools, and of what some members, at any rate, of the Board hope eventually to see accomplished.

In the Leeds Board schools, a somewhat similar scheme has been in operation since 1877, but the instruction is confined to elementary physiology and domestic economy, and is only given by an experienced and specially-trained female teacher, who, in the course of a fortnight, gives one lesson in each of thirty-five girls' and mixed schools. The class consists of the upper standards, but only scholars in the 5th and 6th Standards are required to answer the questions, which, as a rule, are written as a composition school lesson. These lessons are illustrated by models, diagrams, and simple experiments, the apparatus being carried round in a hand-cart. The course lasts for the school year, and the lessons are selected from Mrs. C. M. Buckton's excellent little work, "Health in the House." This lady not only gave the instruction herself in the first instance, but subsequently reduced it to a system, and personally superintended it for many years. It is much appreciated both by parents and scholars, and though it is a valuable aid in preparing girls for passing intelligently the Government examination in the two "specific subjects" of animal physiology and domestic economy, it is of the greatest value in thus early awakening an idea of paramount importance of the laws of health amongst those who are specially concerned in its maintenance. Five hundred and thirty-nine children passed in domestic economy, and 547 in physiology, in 1883, the total passes in 71 schools being 19,182.

It should also be mentioned, in connection with the work of the Leeds School Board, that a very excellent scheme of practical instruction in cookery is now carried out in twenty girls' schools, in both day and evening classes, under specially qualified instructors. This also was worked out by Mrs. C. M. Buckton, and I need scarcely say that it is founded on the same principles as that "Scientific Basis of Cookery" which was so well brought before this Society by Mr. W. Mattieu Williams, in his recent course of Cantor lectures; the particulars of it are to be found in a little volume, "Food and Home Cookery," written by Mrs. Buckton, and published by Messrs. Longmans and Co. The arrangements of the Glasgow School Board are such that every girl in Standard IV., or upwards, receives instruction in cookery during one or two courses. Over 1,500 girls attended these classes last year.

In the forty-seven schools of the Glasgow School Board, the average attendance is 30,600 children. Of these, 7,381 are studying two of the specific subjects, something less than half taking the scientific ones; physical geography and domestic economy, however, absorb more than 75 per cent. of these pupils. Only three out of the forty-seven schools teach any physics at all, and these are devoted to light and heat, and to magnetism and electricity. Mechanics, in the sense understood in Liverpool and Birmingham, appear to find no place in the Glasgow scheme. It will be noticed that here, as elsewhere, elementary science is taught in a few upper grade schools, the subjects selected being very much according to the idiosyncrasies of the masters thereof; but that science teaching, *per se*, does not form a part of the mental training of every child above Standard IV., which is the particular point I am now urging, as well as that it should be given by a specially appointed expert, and be of a particular character. I may say that this distinction is clearly apprehended by the Glasgow Board, who, as I have before hinted, are disposed to value very highly, for its own sake, the practical value of the information thus given.

This brings me to another point, viz., the great value to boys of such elementary training in the principles of mechanics as is given in Liverpool and Birmingham, as a preparation for the technical training which is now so strongly desired, and for which such ample provision is at last being made. There is a scheme at present under discussion in Birmingham for making another link in this chain, by providing workshops and a young skilled mechanic, where, Mr. Harrison thinks, probably one-third of his class in each school having learnt the principles by day, would carry them out practically in evening classes. At present, however, the best development of this idea is to be found at Sheffield, where a class in the Central Higher Board School "aims to give a systematic course of practical instruction in the science of mechanics." The majority of the scholars there are drafted into it from the public elementary schools of the town, and the majority leave it between fourteen and fifteen years of age. The class in mechanics has about two hours' workshop practice per day, in which considerable manipulative skill is acquired, as well as correctness in applying geometrical principles. The results of this school have been tested in machine construction and drawing, in mathematics, and in chemistry, by the examinations of the Science and Art Department, with remarkably good results. Here again, however, I would remark that in Sheffield the teaching is given to a selected few, and not to every child.

In Manchester, science is taught in only four Board schools by day, 650 children being under instruction, which is given in mathematics, chemistry, physics, physiology, and hygiene. These classes, however, are organised with a view to the May examinations of the Science and Art Department, and they are largely supplemented by the science and art classes, held in the Board schools in the evenings, when 2,500 pupils are at present in attendance. In Manchester, the nearest approach to the Liverpool and Birmingham system, is in the employment of a peripatetic teacher, who gives instruction in the elements of botany, and in the "class subject" known as elementary science. In this city, the School Board awards annually fifty elementary school scholarships of the value of £10 each, and "science and art" scholarships of £15 each, open to both sexes, and tenable at the Central Board school, where special attention is given to the scholars. This system, therefore, much resembles that in Sheffield, and is open to the same objection, viz., that it is the selected few to whom science is taught, and that it is not made a part of the mental training of every child who remains in Board schools over eleven years of age.

In drawing this paper to a conclusion, I desire briefly to ask your attention to the way in which the teaching of science in elementary schools is handicapped under the present regulations of the Revised Code, including the system of "payments by results."

Under Art. 16, of the New Code, the subjects of instruction for which grants may be made are the following:—

(*a*) Obligatory subjects—Reading, writing, arithmetic; and needlework for girls in day-schools.

(*b*) Optional subjects (i.) taken by classes throughout the school:—Singing, English, geography, elementary science, history, called "class subjects"; (ii.) taken by individual children in the upper classes of the school, the ten "specific subjects" before detailed.

Under Art. 109, a grant of 1s. or 2s. on examination in class subjects is made, and no more than two class subjects may be taken, one of which must always be English. Hence, of the remaining subjects, elementary science has only one chance in three, Moreover, it does not earn a higher grant than geography or history, either of which can be much more readily taught, both as regards the usual acquirements of the average teacher, and the absence of any further provision for teaching than books and maps. Elementary science, as defined in Schedule II. of the New Code for the first three standards, comprises "a progressive course of simple lessons on some of the following topics, adapted to cultivate habits of exact observation, statement, and reasoning—common objects, such as familiar animals, plants, and substances employed in ordinary life;" and for Standard IV., "a more advanced knowledge of special groups of common objects, such as (*a*) animals or plants, with particular reference to agriculture; (*b*) substances employed in arts and manufactures; (*c*) the simpler kinds of physical and mechanical appliances, *e.g.*, the thermometer, barometer, lever, pulley, wheel and axle, spirit level." It is obvious that, to give a series of lessons to children in the first four standards on these lines, special collections of objects and of apparatus are necessary, as well as an amount of knowledge not usual on the part of the schoolmaster. It is evident therefore, since the grant is the same for all class subjects, that not only is there no inducement to the ordinary teacher to teach elementary science as one of them, but that a premium is actually put upon instruction in one of the other optional class subjects by the facility with which they can be taught. Hence, as long as human nature remains what it is, and as long as the regulations of the Code are unaltered, we must expect to see that elementary science is but little taught as a class subject. The case of the Glasgow schools may be cited as an example:—The geography and history grant in the year ended June 30, 1883, was paid for 27,498 children, or 89·8 per cent. of the number in average attendances; the grammar and intelligence grant for the same period was paid for 27,634, or 90·3 per cent. of the average attendance. The elementary science grant was paid for—not a single child! In giving these figures, however, on the hard and fast definitions and classifications of the New Code, I ought to point out that geography for the first four standards, as defined in Schedule II., includes the physical and political geography of the British Isles, British North America, and Australia, with knowledge of their productions, and to refer to what I said in an earlier part of the paper, as to the scientific method of teaching any subject.

What I have said about the "class subjects" applies with even greater force to the "specific subjects," since the instruction in science is more specialised, and requires more perfect illustration. To quote again from the returns of the Glasgow School Board for the year ending June 30th, 1883 (the permission of the Inspector had been given for the introduction of subjects other than the ten named in the Code), the numbers studying were:—

English Literature	5,176	in	45	schools.
Latin....................	687	,,	18	,,
Greek	27	,,	3	,,
French	884	,,	21	,,
German	39	,,	2	,,
Domestic Economy	3,194	,,	46	,,
Physical Geography	1,803	,,	28	,,
Mathematics	323	,,	19	,,
Chemistry.............	104	,,	2	,,
Physiology	872	,,	14	,,
Light and Heat	59	,,	1	,,
Magnetism and Electricity	239	,,	2	,,

It thus appears that the number studying English literature was thrice the total number of those studying physiology, chemistry, physics, and mathematics—and that mechanics was not taught to any one of these 30,000 children. Moreover, if physical geography be omitted from both sides of the calculation, the number studying English literature alone, considerably exceeded the total numbers of those studying science, including in that term domestic economy as taught in Glasgow, not as taught in Birmingham or Liverpool.

The following are the numbers presented for examination in the ten named specific subjects in the year 1881-82, over the whole country.

			Per cent. of the whole.
English Literature	127,313	....	49·25
Latin................	1,006	....	0·40
French	3,360	....	1·30
German..............	34	....	—
Physical Geography ..	34,382	....	13·30
Mathematics..........	6,174	....	2·39
Mechanics............	2,458	....	0·96
Animal Physiology....	25,886	....	10·00
Botany	1,903	....	0·74
Domestic Economy....	55,993	....	21·66
	258,509		100·00

Here we see that the study of English literature alone absorbs as many children in the upper standards as all the other nine "specific subjects" together—a subject taught by the reading of books alone, and which, however excellent and refining in itself, gives a child little or no knowledge of its relations to the outside world, and of the facts and phenomena by which it is surrounded, and upon which its very life depends.

The points, then, which I would most strongly urge are—

(1.) That instruction in some branch of elementary science, preferably mechanics or physics for boys, and domestic economy for girls, should form a necessary part of the education of every child who remains in a public elementary school above Standard IV.

(2.) That such instruction should be oral, accompanied by demonstrations and experiments, and given by an "expert" in such teaching, whose services may be best utilised by his being employed at many schools in succession.

(3.) That such teaching can be given during the ordinary school hours, not only without detriment to the instruction of the three R's, but with an actual increase of efficiency, as judged by that standard as well as by the general intelligence of the scholars.

(4.) That such alterations should be made in the scale of grants under the New Code as should encourage the teaching of elementary science, and especially the employment of specially appointed teachers, as at Liverpool, Birmingham, and Leeds.

In this age, most educated persons are keenly—in some cases perhaps too keenly—alive to solecisms and other errors of grammar, considered from the literary point of view. Let us hope that the day is not far distant when ignorance of the grammar of Nature will be held in equal aversion. In that good time to come, such a picture as one in the last Royal Academy Exhibition in which a rainbow was represented with the violet streak in the centre of the spectrum, will be as sternly rejected for contravening the laws of physical science as other pictures now are for disregard of the canons of art; such answers, too, as that of the Eton boy, who assigned as a reason for the greater length of the day in summer, the expansion of all bodies by heat, will be considered as disgraceful as a false quantity in a Latin quotation, or a slight error in syntax is now. The attainment of such a result is a noble object to strive for, and I trust that the reading of this paper, and the discussion thereon, may have some influence in drawing attention to this essentially practical scheme for science demonstrations in Board schools—a scheme suggested by the matured experience of most eminent men of science, worked out in practical detail by Boards controlling two of our largest centres of population (would that it were adopted in London also!), and proved to have given, under their management, such admirable results. I will conclude by simply recording my very firm conviction that, if this work can be set moving, it will end in a moral and intellectual revolution for the mass of our people, and that the national results of it will be great.

DISCUSSION.

Dr. GLADSTONE, F.R.S., said he agreed with nearly all the views expressed by Mr. Carpenter, and did not think he had gone at all beyond the truth in his description of the results of the experiments carried on in Birmingham and Liverpool. He had not had the pleasure of visiting the schools at Liverpool, but he spent a very pleasant morning in Birmingham a short time ago, and saw the work Mr. Harrison was doing there. He heard him give a lesson on the different states of matter in a superior class; and afterwards, in another school in one of the lowest parts of the town, he saw his two assistants giving lessons, one to the boys on the inclined plane, and the other to the girls on domestic economy, coal being the special subject of the day. It was very pleasing to see the delight with which the girls listened to the explanation given them, and examined through a hand microscope the structure of the coal, and to hear the inquiries they made. He He was sorry that he could not give quite so good an account of the teaching of science in the London Board Schools, but still it was advancing, he hoped surely, although slowly. In the infant schools, object lessons had been given from the commencement, perhaps not very systematically, but it was made a condition that they should be given on the objects themselves, and, as a rule, the teachers had fair specimens from which to teach. The formation of museums was also encouraged, in which the children themselves assisted by bringing specimens which interested them. Of course all kinds of rubbish was brought, but this soon got eliminated, and what was of any value remained. A cabinet was furnished in which the specimens might be kept, and in many cases more than one was asked for. In the boys' and girls' department, it was laid down from the commencement that object lessons should be given systematically. This, he feared, to some extent, had been rather a rule on paper than in practice, but since the New Code had been in force, it had been more rigidly insisted on. In order that experiments might be made, a little box of apparatus had been got up, and he frequently saw it in use when visiting the schools. In October, 1882, a circular was issued, saying "The School Management Committee have decided that elementary science shall be taught throughout the boys' and girls' departments, in place of the present object lessons, and the instructions to teachers on object lessons have been modified according." This meant that elementary science was to be taught more or less in all the boys' and girls' schools, and it was finding its way into them all, but they could not always ensure its being well taught. They did not insist upon its being taken up as a second-class subject, and many teachers preferred geography, or history, or needlework; but they did require that some elementary science should be taught, either as a class subject or not; and in some schools it was being very well taught. The favourite specific subject was animal physiology. He was not altogether prepared to defend this choice, as it was mainly taught by text-books and diagrams, and did not give the same amount of mental training as some other subjects. From a return he had lately procured of what was being done in the schools which had been first examined under the Mundella Code, he found there were 61 schools, with about 2,000 boys and 310 girls, in which animal physiology was being taken. The next favourite subject was magnetism and electricity, which was being taught in 8 schools, with 400 scholars. Botany, chemistry, mechanics, and even agriculture, were also being taught. The position of pupil-teachers was a very important question; they had several centres where pupil-teachers were taught, and care was taken that these had instruction in science. It was laid down in the Code that pupil-teachers, before entering the training school, should be examined in certain things, but natural science was not amongst them, and yet these pupil-teachers were expected to teach object lessons, and in future years they would, no doubt, be expected to teach science. They were able, certainly, to gain marks by presenting a South Kensington certificate, and they went in for those examinations to a great extent; but these examinations were very special, and the pupil generally crammed up for them, instead of really studying the subject. They were now endeavouring to introduce into pupil-teachers' centres such a syllabus of education in natural science as would give them primary notions of nature, which they might afterwards develop into chemistry, mechanics, physiology, or any other science. If they went through this course, they would have studied all which South Kensington understood by physiography, and would also be able to acquire chemical or biological certificates, with a little more study. The important point was to insist on training for the mind, not merely the acquisition of information, and nothing so tended to develop the powers of perception and comparison as natural science subjects studied experimentally, and this would also lead on to technical education, which was absolutely essential. Our artisans and domestic servants were being trained in the elementary schools—the men and women who had to do the hard work of the world—and the educational appliances must be adapted to their needs. It seemed to him that there was great danger in thinking that, in order to educate the lower classes, they had only to adopt the methods which were considered to be the best for educating the middle and upper classes in the Middle Ages. The lower classes did not want a scholastic education. Let them have a knowledge of poetry, and everything else which would cultivate the mind; but what they specially wanted was a knowledge of the natural forces and materials with which they would have constantly to deal and contend, and which would become their masters if they did not learn how to make them their slaves.

Dr. W. B. Carpenter, F.R.S., said the facts and conclusions stated in the paper entirely accorded with his own experience; and he also agreed with what Dr. Gladstone had said on the importance of what might be called living knowledge of these subjects, in opposition to dead knowledge. For instance, the use of an air-pump had been referred to; nobody could teach a child the action of a pump or the use of a barometer without explaining the pressure of the air, but that was merely a form of words unless the child had the air exhausted from under his hand, and felt that a considerable force was required to withdraw it. From a long experience of examinations, he could entirely endorse what had been said of the cramming system of getting up subjects from books. He had examined in science for the Indian Civil Service, and had often found candidates giving the most excellent descriptions, entirely from memory, out of books of objects which they did not even know by sight when put before them. That was not scientific knowledge at all, it was merely something committed to memory; the only use of which was that it exercised the memory, but it did not exercise the capacity for observation and reasoning upon observation, which was the special value of scientific teaching. The results shown in the general improvement of the pupils entirely corresponded with what he had heard from various experienced teachers in higher class schools. Many years ago, Dr. Greenwood, principal of Owen's College, now Vice-Chancellor of Victoria University, told him that when he found a lad stupid and taking no interest in his language lessons, he recommended him to attend a course of chemistry, and he generally found that he would come back with a much quickened intelligence, and disposed to take more interest in his classical work. Mr. Percival also, formerly Principal of Clifton College, and now President of Trinity College, Oxford, told him exactly the same thing. It was his wish that every boy in the school should go through a course of elementary chemistry, and also have laboratory instruction. All who had attended to the subject came to the same conclusion, but of course it required attention, because the obvious objections were just what Dr. Crosskey has pointed out, and which he had met with over and over again. The first was that it was occupying time which might be more usefully spent. But when the large amount of time spent in giving instruction of a very vague kind, which excited little definite apprehension in the mind of the pupil, was considered, it would be seen that lopping off some of that, and substituting for it science teaching, would have a most beneficial effect. A daughter of the late Robert Chambers, some years ago, took much interest in introducing the teaching of animal physiology in primary schools, and she used to go into one of the schools in the Cowgate, Edinburgh, twice a week, and give lessons in it, and no doubt her teaching was of the most attractive kind; at any rate, the children were so much interested in it, that some of the clerical managers of the school were annoyed that the children cared so much more for this subject than for their ordinary lessons. No doubt there was a great deal of teaching about the dimensions of the Tabernacle, and the number of fringes on the high priest's garments, and so on, which the children did not appreciate so much as the animal physiology, and the result was that Miss Chambers was asked to discontinue; but the children held a meeting, and passed resolutions that they would not come to school at all if she were not allowed to go on, and as she described, the clergy came and requested her to continue her teaching. This was a good illustration of the fact, which all who attended to the subject knew, that science well taught was apprehended by children in a remarkable degree. A very young child apprehended what was put before it intelligently; and, in an older child, reasoning went on concurrently with observation.

Miss DAVENPORT HILL said the London School Board was by no means behind hand with regard to the teaching of cooking; though it was not carried on quite in the same way as at Leeds. Small kitchens were built in certain schools, where an instructor was appointed, who taught the girls from the schools all round. Roughly speaking, about one-fifth of the girls at school were taught, and as they hoped that all the girls would remain five years at school, there was an opportunity for all to learn in their turn. The instruction given was thoroughly practical. The instructor having given the pupils the ingredients and method, which the children wrote down, cooked the dish before them, and then, having well washed their hands, the children did it themselves under her supervision, and succeeded very well. There were twenty-eight cooking centres, and having visited many of them she could speak with much satisfaction of the results. Of course, at all these centres, a good deal of food was cooked, which had to be sold, or else a great expense would be incurred, and she was happy to say that in November last, when the accounts were made up, there was only a difference of 6s. between what they had bought and sold in that month. It was not very expensive, therefore, so far as materials went; of course there were the salaries and other expenses, but she was quite satisfied that whatever was spent in teaching cookery was well spent, and did not think there was much chance of the ratepayers grumbling about it. They were always adding to these centres, and in the case of isolated schools, too far from any centre to take advantage of it, they adopted the same plan as Mrs. Buckton did at Leeds.

Mr. E. C. ROBINS said when he last read a paper in that room on the subject of technical education, he made some remarks which he thought were novel, but he began to find they were not, and that the importance of science teaching, even to the lowest stratum of society, was beginning to be widely acknowledged. He was delighted to find this system growing so extensively in Birmingham, Manchester, and Liverpool, and that the representatives of the London School Board were also able to say that they had overcome former prejudices, so much as to be able to introduce some kind of science teaching. From his connection with the City Guilds Technical Institute he had learned some facts which were of great importance; for instance, it was found that some of the scholars who presented themselves had not received sufficient preliminary education to enable them to commence at once with the technical curriculum, and, therefore, special provision had to be made for them. He hoped before long this subject would take such a hold of the public mind that, both from primary and secondary schools, they would have scholars coming forward able to take advantage of the facilities offered by the City Guilds, for until this was done, technical education itself could never be put on a satisfactory basis, such as would enable England to compete on fair terms with other countries.

Mr. T. E. HELLER (Secretary of the Teachers' Association) said this subject was one which commanded the sympathy of every educationist, but yet, as the representative of a large body of teachers, he found himself in some difficulty with regard to it. He believed the diagrams were somewhat fallacious, but, at the same time, the paper would do much good in drawing attention to a most important subject. Twenty years ago he had charge of an elementary school, in which he ventured to say that the intellectual scientific teaching, properly so-called, was infinitely better done —and the same might be said of a large nnmber of elementary schools in the country—than was possible at the present day. Mr. Carpenter had hinted at some of the chief causes which led to that result. The Revised Code had been, in some respects, advantageous, but it had practically killed intellectual education; not only by making it worse than it was, but by retarding the natural progress which might have been fairly expected had an intelligent system of inspection and of grants been then established. With regard to the tables, Mr. Carpenter seemed to assume that the improvement in per-centages in elementary subjects was due to one specific cause only; but he thought he could show another School Board of equal importance with Liverpool, where no definite attempt had been made to introduce general scientific teaching over the whole school, in which a corresponding improvement had taken place in the same period. There were several circumstances which might produce that result. He believed that about 1876 or 1877, there was an important change in the inspector of the district, and it might be that a different standard was adopted, or it might be that the arrangements of the staff had been changed. But with all this, he did not mean in any way to disagree with the proposition, that if you could introduce intelligent teaching of a scientific character, based on actual observation, it must re-act on the general intelligence of the scholars. He gave up school-keeping about the time the New Code came in, but during the previous ten years, he never gave up systematic object lessons, or the addition of some scientific subject, such as mechanics, for the higher boys, and he was not prepared to say that the results in reading, writing, and arithmetic in any way suffered; on the contrary, he believed there was an improvement. But at the present time, they were met with the fact that the system of examination and inspection was dead against the adoption of anything like an intelligent system of scientific teaching; and until that could be altered, teachers would be afraid to crowd in any fresh subject. Those interested in this question, therefore, should look to a change of the system, at any rate simultaneously with the introduction of any new subjects; the time-table did not suffer from want of variety; there was plenty of that, but there was a dull mechanical striving after accuracy without knowledge. He did not in the least oppose science teaching, but you could not force more subjects into the curriculum, if they were to be examined in the same mechanical way as most subjects now were by the representatives of the Education Department. With regard to the teaching of cooking by the London School Board, they were not at all behind any provincial work in the solid work which was done, and he might add to what had already been said, that it was laid down as part of the scheme that the practical lessons should be preceded in the school by theoretical teaching on the nature and chemical properties of food.

Dr. ARMSTRONG, F.R.S., said the paper was not only very important in itself, but it raised several important points for discussion. Mr. Carpenter not only told them what had been done, but recommended a particular system, that adopted at Birmingham, for general use. It appeared to him, however, as a teacher of science, that that was not the best system. He did not see why science should be treated as a peripatetic subject, and wheeled about in a cart. No doubt everything which was done for the teaching of science was of value, but it was another question whether they were to accept this system as final. There were also certain recommendations as to the subjects which should be taught, viz., mechanics or physics for boys, and domestic economy for girls. He could not help thinking that they did not want any specific subject chosen, but a new subject got up specifically for the purpose; what was wanted was to teach boys and girls to go about with their eyes and minds open; to understand what was going on about them; to have a fair knowledge of natural materials, forces, and laws; and so to teach these things in the schools as not to kill the spirit of inquiry which was so pregnant in children. At present, they were not in a position to do anything of the kind. The Chairman had alluded to the difficulty which masters of higher schools were under with regard to the Universities; but beyond that, schoolmasters might say to men of science—"You are no doubt right in the main in urging us to teach science, but you have not yet put before us a proper method of teaching science; it is not yet sufficiently developed; there are too few teachers." And when a schoolmaster asked what book you would recommend him for teaching any particular science, they were obliged to confess that they could not honestly recommend any, for most text-books were tainted, more or less, with the vice which had been alluded to, that they tended rather to teach bare facts, than to develop the intellectual faculties. What was wanted, was more co-operation on the part of those who understood the subject, not a few people here and there introducing systems of their own. They also wanted instruction as to the meaning of science; the public generally did not know what science meant; and had no idea that the intention was to teach boys and girls to use their eyes and their minds.

Mr. LIGGINS objected to science being universally taught, though he was delighted to hear that the London School Board was teaching girls cookery. The first diagram he thought most unfair, because it compared the whole of England, including the agricultural districts, with one of the most civilised towns in the country. They were about on a par in reading, but in writing Liverpool was far ahead, and naturally so; they saw much more of it, while country children scarcely ever saw pen and ink except at school. And the same with regard to arithmetic; country children scarcely ever saw anything to make them acquainted with figures. Again, one of the most useful sciences or arts, drawing, was left out altogether. All children should be taught to draw, because all would find it useful, but what was the use of physical geography to a man who was to be a carpenter or bricklayer all his life? Chemistry again, or mathematics, would be no advantage to a navvy. To attempt to teach all these sciences universally would be a great waste of strength; because each child would only have the aptitude for studying one out of the number, and trying to make him learn the others would be only a waste of time. Science was all very well for employers, but it would be of no use to those who had to get their bread by the sweat of their brow.

NOTICES.

CANTOR LECTURES.

The first of the Second Course of Cantor Lectures on "Recent Improvements in Photo-Mechanical Printing Methods," was delivered by Mr. Thomas Bolas, F.C.S., on Monday, the 28th inst. The special subject of the lecture was new developments of the Woodbury-Type process.

The lectures will be printed in the *Journal* during the summer recess.

Proceedings of the Society.

APPLIED CHEMISTRY & PHYSICS SECTION.

Thursday, January 24th, 1884; David Howard, F.C.S., in the chair.

The paper read was—

THE MANUFACTURE OF GAS FROM LIMED COAL.

By J. Alfred Wanklyn.

Although the distillation of coal in the process of gas-making forms the chief source of the ammonia of commerce, it is a well ascertained fact that only a small fraction of the total nitrogen of coal is made to assume the form of ammonia in the process of gas-making, as commonly carried out. From the great importance of an abundant supply of ammoniacal salts in agriculture, the economising of a larger proportion of the nitrgoen of coal becomes a matter of national concern; and the introduction into the gas industry of a process which renders useful a larger fraction of the nitrogen in coal, ought to meet with a hearty welcome at the hands of all who are interested in the prosperity of agriculture.

Such a process is Cooper's plan of liming coal, as a preliminary to distillation in the gas retorts. The following quotation from the specification, which is dated June 2nd, 1882, will serve to indicate the nature of the process:—

"To the coal, either in a lumpy condition (such as that in which coal is used in gas-making), or, by preference, in a state of fine division, I add lime in the condition of hydrate of lime, or slaked lime, and I cause the mixture to be well incorporated. When I employ the mixture in gas retorts in gas works, I find it convenient to employ about half a hundredweight of quicklime to every ton of coal, and I slake the lime with about its own weight of water (*i.e.*, five gallons of water), whereby it is brought into such condition as to be readily mixed with the coal."

From this quotation it will be seen that Cooper proposes to make gas from a new gas-generating material, which may be appropriately designated "limed coal."

The products which arise in the distillation of "limed coal" differ materially from those given in the ordinary course of gas manufacture by distilling coal pure and simple.

Limed coal yields a larger fraction of its nitrogen in the form of ammonia; a slightly larger fraction of its carbon in the form of volatile compounds (*i.e.*, there is an increase in the tar and gas taken conjointly); a smaller fraction of its sulphur in volatile forms; and it yields limed coke instead of common coke.

Here is a specimen of limed coke from the Tunbridge Wells Gas Works, where the new process has been in operation for the last three months. As you will perceive, there are hardly any physical differences between limed coke and common gas-coke; an occasional white speck, where the lime has failed to mix perfectly with the coal, being the only apparent distinguishing feature. The differences show themselves when the coke is burnt.

Common coke, as most persons know by experience, gives off very abundantly the pungent fumes of sulphurous acid when it is burnt. Limed coke, on the other hand, evolves very little sulphurous acid on combustion, and, granting that the original admixture of lime and coal were absolutely perfect, would evolve absolutely no sulphurous acid.

The limed coke has another advantage, and that advantage was quite unexpected, when the investigation of Cooper's process was begun in the laboratory before the filing of the specification. Inasmuch as lime, and calcium compounds generally, are pre-eminently non-volatile, the addition of lime to the coal before distillation must be equivalent to the addition of so much mineral matters to the ash of the coke given by the coal. Limed coke, manufactured from a given quality of coal, must necessarily contain more fixed matter or ash than common coke from the same quality of coal. We dislike fuel which leaves much ash; and, indeed, ash in fuel is recognised as not only unprofitable but "profligate"—to borrow a term from agricultural chemistry. It was anticipated, therefore, that limed coke would not burn so well as common coke. This anticipation has been negatived. A very large quantity of limed coke has been produced and burned under a great variety of circumstances, and it has been observed that the limed coke burns brighter, and quicker, and readier than common coke. And when we seek for an explanation, we are led to see a potent oxygen-carrier in the thin film of calcium compound, which coats the coke as it is gradually burnt away in the fire. Especially is limed coke adapted for domestic consumption in dwelling-houses.

Limed coal yields a larger fraction of its nitrogen in the form of ammonia. In order to gain a proper idea of the actual production of ammonia in the gas industry, the records of the London gas works may be consulted with advantage. In the aggregate, the London gas works carbonise upwards of two million tons of coal annually, and obtain from 5 to 6 lbs. of ammonia from each ton of coal.

If all the nitrogen in the coal were got into the form of ammonia, the yield of ammonia would be from 25 to 50 lbs. of ammonia per ton of coal carbonised. The production of coke appears to be incompatible with the complete transformation of the nitrogen into ammonia, for coke contains a solid carburet of nitrogen, endowed with great stability, and resolvable into ammonia only when the coke is made to assume the gaseous form, by combination with oxygen and hydrogen.

Cooper's process increases the yield of ammonia very considerably, without making a sacrifice of the coke. Experiments made in my laboratory on the yield of ammonia by Cooper's process, shows that the ton of coal may be made to give from 12 to 15 lbs. of ammonia, when it is limed, upon being distilled. And I look for a similar result in practice on the large scale, not immediately, but in course of time.

A substantial gain in ammonia, due to the liming process, has been shown by the following engineers:—Mr. Trewby, at Beckton; Mr. Jones, at the Commercial Gas Works; Mr. Paterson, at Cheltenham,; Mr. Wilton, at Silvertown; Mr. Eastwood, at Batley; Mr. Botley, at Wormwood Scrubbs; and Mr. Dougall, at Tunbridge Wells. The highest comparative yield, *i.e.*, the greatest difference between the same sample of coal in its limed and its unlimed condition, has been shown by Mr. Botley, at Wormwood Scrubbs. Mr. Botley showed that, in his experiment, the yield of ammonia was doubled when the coal was limed. The highest absolute yield of ammonia has been shown by Mr. Dougall, at Tunbridge Wells.

In the course of these trials, which have been going on during the last eighteen months, I have been strongly impressed with the inadequacy of the arrangements for the collection and storage of the gas liquor in most gas works, and especially in old gas works. At the old Bankside Works, belonging to the South Metropolitan Gas Company, no gain of ammonia was registered. At the Vauxhall Works, another branch of the South Metropolitan Gas Company, there was no gain of ammonia, and yet some 30,000 tons of coal had been limed. I entertain no doubt whatsoever that the failure to get the gain of ammonia depended on the bad arrangements which prevail at those works.

(2.) The slight increase in the fraction of the carbon which assumes the volatile condition when limed coal is distilled has been dealt with on a recent occasion, and I will pass it over without further mention.

(3.) The great diminution of the fraction of the sulphur which assumes the volatile condition when "limed coal" is distilled will now engage our attention.

Chemists are quite familiar with the fact that sulphur present in organic compounds can be caused to attach itself firmly to calcium, by simply heating the organic compound in contact with lime; and, in accordance with general chemical principles, a perfect mixture of coal with excess of lime cannot possibly evolve sulphur compounds when it is heated strongly. It will, therefore, be intelligible that limed coal should yield little or no volatile sulphur compounds when it is employed in gas-making.

In a preliminary experiment, in which gas was made from limed coal in the laboratory, so striking was the absence of sulphur compounds from the gas, that the patentee recognised the gas as being fragrant rather than fœtid, as is the case with common crude gas. Sulphur, as is well known, occurs in crude-coal gas partly and mainly in the form of sulphuretted hydrogen, and partly in the form of what is by gas managers termed "sulphur," or "sulphur compounds other than sulphuretted hydrogen." These sulphur compounds consist of bisulphuret of carbon and a variety of other volatile sulphur compounds which are little understood.

As has been said, the main portion of the sulphur exists as sulphuretted hydrogen. I have found from 0·8 to 1·5 vols. of sulphuretted hydrogen in different samples of common crude-coal gas. The "sulphur other than sulphuretted hydrogen" in common crude-coal gas, as far as I have been able to ascertain, is less than 0·3 vols. per 100 vols. of gas.

Both the sulphuretted hydrogen and the "sulphur compounds other than sulphuretted hydrogen" are diminished by the application of Cooper's process. Even when Cooper's process is very imperfectly carried out, that is to say, when the mixing of the lime with the coal is very imperfect, the diminution of the sulphur in the crude gas has been observed. Thus, for instance, at the Vauxhall Gas Works, where the coal has been very imperfectly limed, the following observations were recorded in January, 1883:—Vols. of sulphuretted hydrogen in 100 vols. of crude-gas from

		Limed coal.	Unlimed coal.
Experiment	I.	0·42	0·61
,,	II.	0·45	0·61
,,	III.	0·42	0·58
	Mean	0·43	0·60

In addition to the evidence of the diminution of H_2S afforded by examination of the gas itself, there is other and equally conclusive evidence afforded by the prolongation of the time during which purifiers retain their activity. Thus, at Tunbridge Wells, the duration of the active life of an oxide of iron purifier has extended so that a life of ten days has been prolonged to much more than fifty days. In fine, this diminution of the sulphuretted hydrogen by Cooper's process is so palpable that it cannot be overlooked. Equally certain is the diminution of the "sulphur compounds other than sulphuretted hydrogen," and the diminution is palpable, even in cases when the mixing of lime and coal has been very imperfect.

At the Vauxhall Gas Works there were, in the early part of last year, supplies of crude gas from limed coal in one retort house, and of crude gas from unlimed coal in another retort house. Comparative testings of the gas were made with the following results:—

1883.		Limed.	Unlimed.

,,	V.	10·6	—

On the 14th February, 1883, all three retort houses at Vauxhall were placed under Cooper's system, and there was no gas from unlimed coal at the Vauxhall Works, and the comparative testing came naturally to an end. In the above investigation the circumstances of the case precluded the employment of the Referee's method, and Harcourt's method had to be resorted to. Each figure in the above statement is the mean of some four or five readings.

After 15th February, when all the gas at the works was made from Cooper's limed coal, a pipe from the main in one of the retort houses was caused to convey a portion of the crude gas to a small condenser, and then the gas went through a scrubber, and then through three boxes charged only with oxide of iron, and then it was collected in a small holder which was filled every day. The gas was tested by the Referee's method, and gave the following results:—

1883.	Grains of S. per 100 cubic feet of gas.
20th February	11·8
21st "	13·5
22nd "	12·2
23rd "	13·2
24th "	13·6

On 26th February very little lime was added to the coal, next day no lime was mixed with the coal, and Cooper's process was stopped till 5th March, when it was recommenced, and continued for many weeks.

Continuing the tabular statement, the figures were as follows:—

28th February	24·5
1st March	31·0
3rd "	18·2
6th "	24·4
7th "	12·4
8th "	8·0
10th "	3·3

The amount of coal carbonised at that time at Vauxhall amounted to about 3,000 tons a week; and the success of the process was so manifest, that even the officials of the South Metropolitan Gas Company were moved; and on March 9th, on the occasion of the emptying of one of the large lime purifiers at the Vauxhall Works, the opportunity was seized to substitute oxide of iron for the lime. About a week later, a second lime purifier was refilled with oxide of iron, and on March 24th, a third lime purifier was charged with oxide of iron; and from that time forward, for a considerable period, no lime other than that employed in the Cooper process was used at Vauxhall.

As I have already mentioned, the liming of coal, as carried out at Vauxhall, was very irregular and imperfect. Since that time, Cooper's process has been put in operation under less unfavourable conditions. By the aid of the admirable machine which the gas industry owes to Mr. West, a good and regular admixture of the lime with the coal has become practicable; and at the Tunbridge Wells Gas Works—notwithstanding that the coal is rather highly sulphurous, containing 1·7 per cent. of sulphur—an average of 3·0 grains of sulphur per 100 cubic feet of gas has been maintained for three weeks. Not only has the lime purifier been abolished at Tunbridge Wells, but so altered is the function of the oxide of iron, that the manufacture of gas in Tunbridge Wells has been correctly designated by Mr. Spice as an operation in closed vessels.

With the sulphur reduced to 3 grains per 100 cubic feet of coal gas, and with purifiers which require changing only once or twice a year, the gas industry enters upon a new era.

In dealing with the financial side of the liming process, I have first to direct attention to an almost unique feature which distinguishes this process from what is usually brought before the gas industry. No new plant is required, but on the contrary, plant is diminished. Neither is any new material brought into the gas works, for lime has been there ever since the gas manufacture began. Computing on the one ton of coal carbonised, as is customary among gas-makers, the cost of the lime itself, and the slaking of it, and its application to the coal, is about 6d. per ton of coal carbonised. A small allowance for extra retort room has to be made, for a ton of coal without lime gives practically, about the same quantity of gas as a ton of coal with lime. This allowance is 2d. The debit side of the account is therefore 8d.

On the credit side there are a variety of items. First of all, the cost of the lime is, to a great extent, recovered when the coke is sold. The presence of the lime in the coke, as has been explained, is useful. And buyers of coke have already acknowledged the utility of the lime in the coke by paying for it. The saving in the cost of gas purification is a most important item. There is a saving of 90 per cent. in labour, and almost an entire saving of the purifying material. The saving in purification may be set down at 7d. Then there is the gain in ammonia, 9d., and the gain in tar 2d. On these items alone, there is a balance of one shilling per ton of coal carbonised. This is a very moderate estimate, and at Tunbridge Wells Gas Works has been greatly exceeded.

Besides the above advantages, which are immediate, and on the surface, there are other advantages. The saving in purifying plant is a very great advantage. Many gas works are in great straits, by reason of the inadequacy of the purifying plant to meet the requirements of the winter make of gas. In these instances, the adoption of the liming process is a vital matter. The question of the abatement of nuisance has a financial aspect, and the possibility of doing away with the lime-purifier will enable many a gas works to continue in existence in the midst of a dense population.

I have, at the Southport meeting of the British Association, called attention to the sanitary aspect of this subject. To stop the pollution of the general atmosphere with sulphurous acid is, briefly, that which the adoption of the liming process will achieve. To accomplish that, is to bring back vegetation into our towns, and to remove one of those general agencies which tend to depress the vital energy of the population.

By the production of an illuminating gas of unprecedented freedom from sulphur, the liming process will greatly benefit the gas consumer in his home. Gas, as hitherto known, has been one of the most destructive agents which has ever entered our houses. Gas practically free from sulphur, that is to say, gas such as the liming process furnishes, will cease to be destructive, and will become as harmless as the electric light itself.

DISCUSSION.

Mr. KING (Liverpool) said this subject first came under his attention nine or ten months ago, when Mr. Cooper called on him and explained the process. Finding that there was a probability that this would meet what the gas-makers felt was a matter of difficulty and expense, viz., the removal of the sulphur compounds, he was glad to have the opportunity of at once putting it into practice; and he must say, at the outset, that the matter appeared so simple, and, as he was led to believe, that there was every prospect of accomplishing the special object they had in view, he was throughout the whole process strongly prejudiced in favour of the patent. Therefore, if in any respect the results obtained did not come up to his expectations, it certainly did not proceed from any unfavourable bias. The process was at once adopted at two of the Liverpool gas works, 6,300 tons of coal being limed at one works, and 5,700 tons at the other, making a total of 12,000 tons. The recommended quantity of 2½ per cent. of lime was used, the slaked lime being mixed with the coal and cannel as efficiently as possible by hand labour. The object had been simply to carry out the patentee's views as thoroughly as possible, without having regard to how the mixture might be most economically conducted. The results might be summarised thus:—In the first instance, there was no increase of gas obtained per ton of coal; the mixture gave practically the same quantity of gas as the unlimed coal did. The illuminating power also remained the same; there was no difference beyond the merest fraction of a candle. Then, coming to what was the object mainly in view, the removal of the sulphur compounds, in that respect also they failed to obtain the fulfilment of their hopes. Had they been under the Referee's clauses, which were in force in London, with regard to the quantity of sulphur, other than sulphuretted hydrogen, allowed, which he believed was 22 grains in winter and 17 in summer, with the exception of one day, he believed the quantity would have been exceeded. Certainly some of the sulphur was removed; but using the oxide of iron purifier simply, and carrying on the process in the ordinary way in that respect, the mixture of lime and coal would not have enabled them to comply with the requirements of the London Gas Referees. He had been very much disappointed in this, as it was the point of all others to which he had specially looked forward. There was certainly an increase in the quantity of ammonia, but he could not give the exact figures, as their arrangements hardly admitted of exact measurement. They had had no difficulty in selling the thousands of tons of coke produced, except in a few instances, where the parties said it did not suit their purposes. They had no difficulty, generally speaking, in selling it for domestic purposes, such as to workhouses and prisons, where the coke was required for heating purposes, but in their own works they experienced great difficulty from this limed coke, from the very rapid destruction or deterioration of the furnaces, and the choking of the flues of the retort settings. This appeared to him to be a great difficulty in carrying out the process. It was somewhat extraordinary to see the different results obtained from this process in different places. Mr. Eastwood, of Batley, had published results which certainly, to a large extent, seemed to confirm his own experience; he spoke not of the gain in money, but taking the debit and credit side of the account, the words he used were that the process would not pay. Such discussions as that in which he took part were very valuable, for it was only by comparing different results that the truth could be arrived at. They did not meet either to depreciate or laud any particular process, but to get, if possible, at the truth of the matter. He thought generally speaking, gas engineers would be only too glad to accept a process so simple, if the results hoped for really could be obtained. Possibly one difference in the results obtained in the north and in the south might arise from the very different nature of the material used. The softer coal used in the south might permit of a more intimate mixture with the lime; whereas in the north of England, particularly in Liverpool, where a large proportion of cannel was used, the gas being 21½ candles, the lime might be differently affected.

Mr. HARRIS said he should propose to give a short statement of the experience he had with regard to the process, though it was a very remote one, and consequently he was perhaps not in so fair a position to judge of the merits of the case as those who had tried it more recently. Professor Wanklyn drew his attention to the matter some eighteen months ago; he had then no opportunity of trying the process on a large scale, but he had the opportunity of mixing some lime with the coal, and did so under his directions to the extent of 3 per cent. His principal object was to see what effect the lime would have upon the coke, and he must say that, from what he saw, he came to the conclusion that it would have a very deteriorating effect, because the particles of lime were apparent in the coke, and he came to the conclusion that it would be prejudicial. In the first place he presumed the effect would be produced which Mr. King had explained was produced on their furnaces, and as for domestic use, he thought the white appearance would be considered detrimental. He did not make sufficient coke to try it practically, and it was not so serious a defect as to utterly deter him from using it, and therefore he introduced it at the works at Silvertown, where it was tried for some time. He had not statistics with him of the result, but the general effect was that there was no great advantage derived from the use of this lime process on the coke. Undoubtedly there was an increase in ammonia, but at that time the question had not arisen as to the effect on the sulphur compounds, which appeared to have arisen from subsequent experiments, and, therefore, his attention was not directed to it. One thing occurred to him with regard to the commercial value of the process, supposing it were a commercial success, from the statistics given him at the time, it appeared that the expense would be 6d. per ton for the lime added to the coal, and then came the question how that 6d. was to be paid for. He could not see that it would be paid for by any subsequent purification, because he did not consider the use of lime in the retorts would obviate the necessity of using lime in the subsequent process of purification. The great bulk of lime used at the present time was neutralised by the carbonic acid in the gas, and he could not see that the addition of lime to the coal would prevent that production of carbonic acid, though possibly it might be so. He, therefore, considered that the subsequent process would be partially the same as at present. Then came the question whether the extra ammonia produced would be of more value than the lime added to the coal, and, at the then price of ammonia, the conclusion he came to was that it would be about equal. If the ammonia ordinarily produced was worth 2s. per ton, a 30 per cent. increase would be about 8d., which would have to be placed against the 6d., and the extra labour required. Since then, however, as he had said, the question of the sulphur compounds had cropped up, which might put a different complexion on the subject.

Mr. BROADBERRY said, something like fifteen or sixteen years ago, the idea of using limed coal occurred to him, and he tried some experiments with it, using about two bushels of lime to the ton, and mixing it as had been described. He did not carry the experiment out to the end, for the simple reason that he found the coke fluxed the furnaces so much that he abandoned it before coming to any definite conclusion on the question of sulphur. At the time they did not think anything about ammonia, the only trouble being how to get rid of it. He should certainly be very careful how he introduced limed coal into his furnaces, or how he used the resulting coke, for he found in three days it thoroughly destroyed the furnace, and he could easily run out two sets of furnace bars every day. He should like to ask Professor Wanklyn what apparatus was used for testing for ammonia, the ordinary method, or Mr. Harcourt's. It was stated that you might get an increase of 30 to 40 lbs. of ammonia per ton, but was it to be understood that there was that quantity of ammonia in the coal which, in this way, could be got from it. Again, 2d. extra was put down for one ton, and he did not understand how that was arrived at.

Mr. WILLIAM FOX remarked that this question was not entirely one of monetary gain, but, if the purification could be carried on in closed vessels, it was of immense importance as a matter affecting public health and vegetation. It had been stated to him by workmen that they had no trouble whatever in ascension pipes, which was a matter of great importance, and that the coke certainly gave out more heat than ordinary coke, which could be well understood if the lime could be used as a carrier of oxygen. This would account for the damage done to the furnace bars. It was not simply a question of the gain per ton in tar or ammonia, but rather of the advantage which it would be to the public health, which was of importance. It was a pity that they had not more information as to the quality of the tar produced.

Prof. REDWOOD said this question was one of considerable interest to him, as having had some experience in connection with gas manufacture, and certainly one great difficulty, which had presented itself more than any other when he had been called in to advise, was that occasioned by the offensive smell arising from the charging of the lime purifiers. If this process enabled the use of lime purifiers to be dispensed with, it would be an immense advantage. He had heard with considerable interest the remarks of Mr. Harris, with whom he had been engaged in gas experiments in former years, and knew that full reliance could be placed upon whatever he said. It did not appear, however, that he was able to offer a very definite opinion with regard to the effect of the process upon the sulphur compounds. There appeared to be strong evidence to indicate that an increase of ammonia took place, and, theoretically, such a result might be expected, and that was so far satisfactory as regarded the economy of the process. Still, he looked to the improvement in the quality of the gas by the reduction of the sulphur—not only that which first came over in the crude gas, but that which would ultimately remain in the purified state—

as the most important object in many respects—both in a sanitary sense and in an economic sense, as related to the consumers—because, undoubtedly, the sulphur in gas was the cause of great destruction to furniture and apparatus. He knew of some towns—Exeter, for instance—where, for a long series of years, great difficulties had been experienced on account of the offensive odour constantly emitted from the process of gas-making, much of which would, no doubt, be done away with if the sulphur could be fixed in the gas retort, instead of having to be taken out in a volatile condition subsequently. One point that occurred to many was, why was not this done before? because it appeared so very natural that gas manufacturers who, from the first, had been using lime for purifying the product of distillation, should have thought of putting lime in with the coal itself. He might recall Mr. Harris's recollection to an experiment which he saw him make a great many years ago upon a small scale, of a similar description—mixing the lime with the coal before carbonising—and if he recollected rightly, the conclusion then arrived at was, that it diminished the sulphur, but at the same time diminished the illuminating power.

Dr. SAUNDERS thought the author of the paper had not taken sufficient credit to himself for this process, because, when they came to think that gas giving off sulphurous acid caused headaches, and injured furniture and works of art, it would be seen that if they could do away with the sulphurous acid in gas an immense service would be done; even if there were no increase in the ammonia, if they could do away with the lime purifiers, it would be a great thing. He had unusual opportunities of seeing and smelling a large number of provincial gas works, being a medical officer of health for a large combined district, and he found one of the principal sources of nuisance was the lime purifiers, not only when they were emptied, but when they were redisturbed by the farmers to carry away the stuff. This was a continual nuisance to those who lived near the works.

Mr. MACKINNON said he understood Professor Wanklyn to say that heat would not drive away the sulphur from the sulphur compounds, but that did not quite agree with the process now carried on at the South Metropolitan Gas Works. There they took the lime from the purifiers and submitted it to a process in an oven specially constructed for driving off and burning away those sulphur compounds. He could not see why the same result would not follow the burning of coke in houses, because he thought the heat would be quite sufficient, and he presumed the sulphur was in the form of sulphide of calcium, the decomposition of which would drive off the sulphur. He should imagine that a great portion of the sulphur would form a sulphide, and would therefore spoil the lime for building purposes.

Mr. COOPER desired to say a word or two on the statements made by Mr. King, of Liverpool. That gentlemen had not told them the cost of the damage to his furnace per ton of coal, which he complained of, but when he was at Liverpool, he informed him that it amounted to a fraction of a penny per ton. If that were so, he thought he had made rather more of it than the matter deserved, especially as the profit which was evident from the process in other ways, namely, the gain in ammonia and in tar, might come up to 2s. or 3s. per ton. Mr. Harris had referred to the question of sulphur compounds as if it were an afterthought, and had only been found out since the process was used on a large scale, but he might say that within a few days of the filing of the provisional specification, he issued a circular in which he put forward the fact that the sulphur compounds would be reduced without the use of lime purifiers, and with a reduction in the quantity of oxide employed.

The CHAIRMAN said the discussion had shown, even more clearly than the paper itself, the importance of this process being thoroughly worked out, and the advantages and disadvantages—and every new process had to be fairly and carefully weighed, before any decision was come to. The advantages promised were by no means trifling. The increased yield of ammonia was in itself no light matter to a chemist, or to an agriculturist either. No doubt the recent drop in price might have discouraged some people from saving ammonia, but from what he had seen himself of the effect on increased consumption from drops in price, he thought there was no fear of the extinction of the manufacture of the sulphate of ammonia from the present small reduction in price. An increased yield of ammonia, even to the extent of 30 per cent., especially considering the much larger per-centage of the ammonia in the coal which was now lost, was a step in the right direction. No doubt the object in making gas had hitherto been to make pure gas of high illuminating power, and it was only recently that the bye-products had been considered of importance. He could remember when ammonia liquor was thrown away; in the country it was to be had by simply sending a tank barge for it; and when the dead oils could be had for the fetching, large quantities being what was politely called burned—run into gravel pits—until everybody who had the misfortune to live on the same gravel bed, within a considerable distance, found it out; when, in fact, everything except gas and coke was considered worthless. They were only on the threshold of the possibilities of the distillation of coal viewed from the side of the bye-products, vast as were the steps which had already been made. If, therefore, this process fulfilled its promise, as shown in more than one experiment, of increasing the quantity of ammonia, and also of tar, and especially of light naphthas, it would be very valuable. He had had some experience of burning coke both in large and small furnaces, and it appeared to him that the difficulty experienced in furnaces was no proof that it was unfit for domestic use. In small fires, even under boilers, the evil of coke was undoubtedly the dust which it made, there not being lime enough in it to make it into a clinker; and the very fact of the coherence of the dust which would be produced by a certain quantity of lime in a moderate heat, would make it a potent flux if put into a strong furnace; and in such circumstances he could well understand that the limed coke would be exceedingly injurious to the furnace bars. But that did not prove that in small furnaces, and especially in domestic fireplaces, the presence of lime would be injurious. He thought a case had been made out for saying that, in the presence of an excess of lime and oxygen, sulphurous acid was not given off in the process of burning, which, from a sanitary point of view, was most important of all. Great complaints were made of fogs, and very unpleasant they were, but the worst part of them was not the carbon which, though it was nasty, did no particular harm, but the presence of sulphurous acid and sulphuretted hydrogen. The use of gas fires, coke, and improved fire-places might do something to reduce the amount of smoke; but so long as the sulphurous acid was sent up into the air, they would never have a pure atmosphere. If any one wanted to see the effect of burning coke, let them go into a freshly plastered room, where coke was being burned in an open fire-place. It seemed to be established that the addition of lime to coke prevented it giving off sulphurous acid in burning, and there would be an immense improvement in sanitation. Another point to be remembered was that one great evil of smoke was that it acted as a nucleus for fog; therefore, if coke were more largely used, it would diminish the vesicular state of the atmosphere, which caused fog. Undoubtedly the question of £ s. d. was a most important one, and if the process did not pay, he feared they would go on poisoning one another, sending sulphurous acid into the air by thousands of tons, and grumbling at the result. The figures wanted careful looking into, and the process should be tried on a large scale, and under favourable circumstances, before any conclusion could be arrived at. It might possibly be that, in Liverpool, special difficulties had occurred from the character of the coal, and a process offering so many advantages was not to be dismissed lightly. He could not look upon it as the final possibility in coal distillation, but it was certainly a step in the right direction—a step which he could thoroughly appreciate, living, as he did, in a district where the impurities in the gas seemed to be what was charged for. Those who enjoyed the benefit of the high degree of purification attained by the great London gas companies, did not know so well as those who lived in the outskirts, or in the country, what impure gas was. There was one advantage, that it never leaked without your knowing it. He could speak from experience of the terrible nuisance which gasworks sometimes were to those who lived near them, or who burned the gas. There was always a difficulty in carrying out a new process, and one of the greatest misfortunes of manufacturing chemists, amongst whom gas managers must be included, was that they never had any rest. As soon as they thought they had made things all right, something new turned up; but there were very few new processes which entailed less trouble in the shape of new apparatus than this one.

Prof. WANKLYN, in reply, said it was a marvel to him, from what he saw of the liming which took place at Liverpool, how any result whatever could be obtained. The coal, instead of being the usual mixture of lumpy and small coal, was in large blocks, 40 per cent. to 60 per cent. being cannel. The mixing performed was of the most rudimentary kind, and it spoke very highly for the process that, under those conditions, the gain in ammonia was so marked that Mr. King could not fail to recognise it. The lowering of the sulphur compounds was also very marked, and, as he had been informed, Mr. King wrote to Mr. Livesey, saying that they had solved the sulphur problem. That occurred soon after the introduction of the process. With regard to the destruction of the furnace bars when the process first came out, no one could possibly have felt more keenly than he did that they would have to contend with almost insuperable prejudices, that it would be said that the coke was spoilt and everything destroyed. Now, at Vauxhall, the process was put on to one of the retort houses in January, and continued up to June, about 1,000 tons of coal being carbonised weekly, and no damage had occurred to the furnaces that he had heard of. If it damaged the furnaces in one place it should in another. No damage either was done at Tunbridge Wells; but this immense damage was done in Liverpool. No doubt this depended upon the peculiarities in the way the work was carried on. Mr. Harris had asked what they did with the carbonic acid? Now, the use of lime in the retort did not diminish the proportion of carbonic acid which came out with the gas, but the extra ammonia which was formed absorbed some of it, and practically, in the gas as it left the purifiers, there was a smaller amount of carbonic acid. In the ordinary process, as conducted in London, the carbonic acid was taken out, not because it did no direct harm, but because it must be removed before you could use lime so as to lower the sulphur compounds. When carbonic acid occurred in considerable quantity, it was worth taking out, but traces of it were not, as there was no process by which you could take them out which would not itself lower the illuminating power of the gas to as great an extent as the carbonic acid itself. He was afraid he had not made himself quite clear with regard to the improvements claimed for this process. It was claimed that they, in one sense, abolished all purifiers whatever; that only the oxide of iron required to be used, and that the purifier need only be opened once or twice a year, just as a scrubber had to be opened occasionally; the lime purifiers disappeared altogether, and the oxide of iron lasted so long, that the process became one of work in closed vessels. There was a very beautiful theoretical explanation of the fact. The gas, as it left the retort, contained ·4 of sulphuretted hydrogen, and one per cent. of air entering the gas would give sufficient oxygen to consume that sulphuretted hydrogen. What was really done in this process, when properly carried out, was to make use of the traces of air which entered, and practically, to do all the purification by means of that trace of air. The oxide of iron purifier became a sulphuret of iron sponge, the function of which was to transfer oxygen from the traces of air to the sulphuretted hydrogen. That was why the process was one of operating in closed vessels. A question had been asked about the adhesion of sulphur to calcium. One of the prejudices he knew they would have to deal with arose from the well-known fact that the contents of the lime purifiers, when taken out and exposed to the air, evolved sulphuretted hydrogen. That sulphuretted hydrogen did not come from sulphate of calcium, but from a compound of sulphuret of calcium with sulphuretted hydrogen. That sulphuret of calcium adhered to the sulphuretted hydrogen, but when the compound became heated by oxidation the sulphuretted hydrogen parted company with the sulphuret of calcium; but really sulphuret of calcium in the presence of an excess of lime did not part with its sulphur. So certain was this adhesion of sulphur to calcium, that you might actually measure the amount of sulphur in coal by taking powdered coal, weighing it, mixing it with about half its weight of slaked lime, and then igniting in a platinum crucible. In that way you got sulphate of lime, which you could wash off and convert into sulphate of baryta. He had determined the amount of sulphur in coal in that way, which seemed to him an absolute proof of the perfect manner in which sulphur and calcium held together.

Mr. KING asked permission to say a word in explanation. As he before remarked, he had been from the first strongly prejudiced in favour of the process, so much so that, when an opportunity again occurred next spring or summer, he intended to make further experiments. The gas works at Liverpool he had thrown open to these two gentlemen, whom he had the pleasure of showing over them, and requested the benefit of their advice, and he should have been only too glad if they could have spent a week or more at the works. The whole process of mixing was shown them, and they had not a single suggestion to make, except, that large quantities of Cannel being used, possibly the lime might slide off a smoother surface. Having investigated the matter day by day himself, and having gentlemen under him at the works who had every desire to make the process a success, he did not believe that any deterioration of the furnace was due to want of care on the part of the workmen. They had had to give it up in the autumn, on account of the destruction to the bars and the furnaces, and the stoppage of the flues, but they intended repeating the experiment in the spring.

The CHAIRMAN, in proposing a vote of thanks to Professor Wanklyn, said he was sure that gentleman did not mean to imply that there was any wilful inability on Mr. King's part to make the process work. He had no doubt there would be difficulties to be got over, especially when dealing with very different qualities of coal.

The vote of thanks having been carried unanimously, the proceedings terminated.

Mr. R. R. SPICE writes as follows:—"As the advantages of the process appeared to me to be considerable, I resolved to make an effort to secure such a critical examination of the method as would enable me to determine, for myself, whether the drawbacks which were said to hinder its use were such as really to counterbalance the benefits, admitted to be desirable; and having brought the question under the notice of the Tunbridge Wells Gas Company, I obtained the consent of the directors for such an experiment to be made at their works. Operations were accordingly commenced at the end of October last, and are still being continued—two months' working up to the end of December. The effects derivable from the use of the process are, an increase in the quantity of ammonia, the average value of which, from carbonising 10,000 tons of coals, may fairly be put at

fairly be put at	£450
The saving in cost of labour in purifying	80
And in cost of purifying materials	480
Value of advantages..........	£1,010
Less by additional cost of wear and tear, and the lime mixed with the coal	240
	£770

There is thus a difference between my first estimate, printed in the *Journal of Lighting, Water Supply, and Sanitary Improvement*, owing to my misconceiving Mr. Dougall's meaning, of £18, which may be regarded as important; and I am of opinion that a fair year's working with sulphate of ammonia, at an average price in the market, may result in my original estimate being fully realised. I have heard something about the destructive action of the limed coal in the retort furnaces at one of the Liverpool works; but as nothing of the kind has been felt at Tunbridge Wells, I am not prepared to admit that the injurious effects spoken of as having been experienced at Liverpool is rightly attributable to the cause which my friend Mr. King assigns it to. After three months' work at Tunbridge Wells, the only complaint reported to me concerning the objection felt at Liverpool, is that the furnace bars are quickly destroyed, which is easily understood; and this I have considered in making the allowance of 10 per cent. on the previous cost of wear and tear. That having been £1,400, I have added £140 to it. But above all questions of mere convenience or cost, I say, let the economy of the process be more or less than I have stated, the value of it will be found, in very many instances, to be beyond all such considerations; and I shall be greatly surprised if the invention be not generally appreciated by the gas manufacturers as a body, on account of the positive blessing it confers on all, in offering an opportunity of abolishing a cause of grievance and expense—which has led, in past years, to a vast amount of bitter controversy, and extensive and costly litigation —concerning the difficulty of dealing with impurities called sulphur compounds."

FOREIGN AND COLONIAL SECTION.

Tuesday, January 29th, 1884; The MARQUIS OF LORNE, K.T., in the chair.

The CHAIRMAN, in introducing Mr. Colmer, said that amongst his other duties, one was to watch and, if necessary, to contradict, the rumours sent from the other side of the Atlantic to this country, with regard to Canadian affairs. He (the Chairman) had been surprised to see a most extraordinary telegram, which emanated from New York, making out that the finances of the Dominion were generally bad, and that there was no hope for the country at all. He had, however, been relieved next day by receiving a letter from Mr. Colmer, pointing out that every single set of figures in that telegram was wholly and entirely erroneous, being, in many cases, wrong by several hundreds of thousands of dollars. This remarkable circumstance led him to the conclusion that, although there were many persons in America who were kindly affected towards things British, there were certain other persons who were by no means in the same state. For his own part, he could only speak most lovingly of the American people; but, at the same time, we must not let our love for our kinsmen across the Atlantic make us forget that we owe our first duty towards our flock on that continent. The reply to such rumours was in the almost unanimous experiences of the settlers in the North-West, who had succeeded on the farms in which they had been placed. On the subject of emigration, the Chairman read extracts from a pamphlet by Lady Hobart, the honorary secretary of the East London Family Emigration Fund, to show how successful those who had left this country for Canada had been in bettering their fortunes. He also mentioned that the Princess Louise had been working with the Ladies' Emigration Society, whose principle was that inquiry should be made in England as to persons to be sent out, intimation given to the Canadian Government of the result of this inquiry, and the sanction of the latter for their transmittal. He thought the action of the private individuals forming these societies might be seconded by the Government. He doubted whether lump sums should be devoted by Parliament to such objects, but it might be made a matter for Government consideration, on the recommendation of the local authority in congested districts like the East of London or the West of Ireland, whether they should not put down something like a pound a head for persons sent out to Canada, who were approved for emigration both on this and the other side. In conclusion, he said he believed Canada to be a country to which men might be sent, both for its own benefit and for that of England.

The paper read was—

CANADA AS IT WILL APPEAR TO THE BRITISH ASSOCIATION IN 1884.

By JOSEPH G. COLMER,
Secretary to the High Commissioner for Canada.

It is gratifying to see indications, on every side, that the development of the Colonies is attracting much greater attention now than was formerly the case. They are proud to be recognised as important sections of the British Empire, and to know that there is a strong feeling in this country in favour of drawing the bonds of union still more closely together. Much of the indifference shown, not so many years ago, arose, undoubtedly, from the want of knowledge that prevailed, and this is not difficult to explain. Communication was not easy, and correspondence not very frequent. In the schools, the rising generation were told that the sun never sets upon the Empire; but they were taught little or nothing respecting the importance and resources of the Colonies, and the position they were destined to occupy in the world in the near future. I am prepared to admit, as my opening sentences indicate, that this lack of interest does not exist at the present time to the same extent as previously; but a great deal still remains to be done. The Colonies of course owe their origin to the mother-country, but to many minds they occupy somewhat the same position as the little girl in the story, who insisted that she had "growed the rest herself." Lines of steamers now leave for Canada, Australasia, the Cape, and other British possessions at regular and frequent intervals; and it is becoming more and more the fashion—and a good one it is—to visit the Colonies. It is also significant that the emigration to their shores grows larger every year. I have spoken so far generally of the Colonies, but all that I have said applies with particular force to Canada. It can therefore be imagined with what pleasure the Canadians learned that the British Association for the Advancement of Science had departed from its usual custom, and had decided to hold its meeting in 1884 in the City of Montreal. I may add that the Marquis of Lorne (the late Governor-General) has from the first given the matter most hearty support.

I do not propose in this paper to say very much respecting the early history of Canada, or its progress in the first century after it was ceded to Great Britain. I shall take it for granted that an audience meeting in the rooms of the Society of Arts will be acquainted with these things, and rather treat of its development since the Confederation of the various provinces, which, as you will be aware, was inaugurated under the British North America Act of 1867. Neither do I intend to explain the detailed arrangements that have been made by the Montreal Committee for the conveyance of members of the British Association to the place of meeting, and for their comfort during their stay in that country. These particulars will be supplied in the circular about to be issued. My intention is to place before you some information respecting the social, commercial, and political aspects of the Dominion. Later on, I propose to say something of Montreal, and of the principal excursions to be undertaken; and in the meantime must ask you to consider yourselves for a short time in the Economic Section of one of the annual gatherings of the Association.

The rapidity with which Canada has progressed during the last four or five years has been remarkable, and has attracted much attention in Great Britain. The revenue has expanded, the trade has increased, immigration has been growing larger annually, and the rapid construction of the Canadian Pacific Railway has been watched with wonder and surprise in every part of the world.

Before entering upon these points in a somewhat more detailed manner, I must say just a few words as to the extent of Canada, for no paper on the subject would be complete in the absence of that information.

The Dominion, as at present constituted, is estimated to contain 3,470,392 square miles. It occupies about one-half of North America—in the opinion of Canadians not the least important half—and is as large as the United States, exclusive of Alaska. You will be able, perhaps, to form a better idea of its extent when I say that its area is nearly as great as that of Europe. The country is divided into eight provinces — Ontario, Quebec, Nova Scotia, New Brunswick, Prince Edward Island, British Columbia, Manitoba, and the North-West Territories. This latter district, about which I shall have something more to say presently, has recently been divided into four smaller territories, called Assiniboia, Saskatchewan, Alberta (after her Royal Highness the Princess Louise), and Athabaska. They each have an area of about 100,000 square miles, so that the word smaller can only properly be used in a relative sense. The older provinces, including Manitoba, but excluding the more recently formed territories, have local Legislatures, which have authority in matters affecting civil rights and property, the administration of justice, education, control of municipal institututions, and other local questions; while the Dominion or Federal Parliament controls public debt and property, trade and commerce, postal service, census statistics, militia and defence, navigation and shipping, quarantine, currency and coinage, banking, weights and measures, bankruptcy, patents, copyrights, naturalisation, marriage and divorce, &c. At the head of the Government, and representing her Most Gracious Majesty, is the Governor-General, holding the position which was recently occupied with so much distinction by our noble Chairman. It is hardly necessary for me to say that under this system of government the country has greatly prospered. I think I may safely add that the members of the Society of Arts, and of that most valuable association, the Royal Colonial Institute, are not without hope that the principles of its confederation may in the near future be extended—not only to Australasia and the Cape, but that they may have a still wider application.

At the last Dominion census, in 1881, the population numbered 4,324,810, the larger proportion being of English, Irish, and Scotch origin. The French Canadians number, however, more than a million, and there are also to be found natives of most of the other countries of Europe. But few, if any, national prejudices are at work. Settlers soon become thoroughly Canadian, and call themselves so; and, should they come from the United Kingdom, do not forfeit the right of being also Englishmen and Englishwomen. In fact, the population of the Dominion—heterogeneous though its origin may be—is thoroughly loyal to the Queen, and to the Empire. Visitors are generally surprised to find that there is no poor-law system in Canada. There are no general poor rates, and none of the workhouses so common in this country; consequently there is but little vagrancy or beggary. In most of the large cities and towns there are benevolent societies (named after the patron saints of England, Ireland, and Scotland—St. George, St. Patrick, and St. Andrew) which deal with any cases of real distress that may arise, according to nationality. The Germans and French have similar institutions. The question of the population leads me to state a fact which I do not believe is as well known as it ought to be, that, compared with the United States, the growth of Canada has been more rapid than is supposed. In 1776, the former contained about 3,900,000 inhabitants, and in 1881 about 50,000,000, an increase of about 1,250 per cent.; Canada, on the other hand, at the census in 1784, numbered less than 150,000, while in 1881 it had advanced to 4,324,810, an addition of 3,000 per cent. In other respects, the progress of the country has been equally satisfactory, and in no way justifies the stigma that, until a few years ago, it was the custom to cast upon the energy, intelligence, and enterprise of the Canadians. Considering the disadvantages under which they have laboured; that their growth has been accomplished without much direct assistance from the mother country, and in competition with the great nation, their neighbour; that the western prairies of the United States have been accessible since 1840, while those of Canada have only had railway communication for about five years, I think it must be admitted, apart from possible national prejudices, that the progress of Canada has been very creditable to its people; and that they have endeavoured, in the words of Sir Alexander Galt, spoken at the Colonial Institute, in 1881, to prove worthy of the great race from which they have sprung.

The revenue, which in 1869 was about fourteen millions of dollars, had increased in 1872 to twenty-three millions, and in 1883 to to nearly thirty-six millions. The expenditure, according to the custom of most civilised countries, advanced also, but not for the whole of the time in an equal ratio. During the last three years, the surplus has amounted in the aggregate to about seventeen millions of dollars, which, as a general rule, has been applied to the reduction of the taxation of the country, and to the cost of the great public works that are now in progress. This will be understood by a reference to the public debt of Canada. In 1880, this amounted to 152,451,588 dols., and in 1882 had advanced to 153,661,650 dols., an increase of 1,000,000 dols. only, although in the same period 24,000,000 dols. had been expended on capital account. The customs duties form the foundation of the revenues of the Dominion, out of which grants are made to the provinces, according to population, towards the expenses of the local governments. Taxes are also imposed by the provinces for educational and other purposes, and by the municipal authorities. These, however, will compare favourably with those levied in other countries. With the increase in the revenue, the prosperity of the people has also been advancing. In the chartered banks the deposits have been growing rapidly, and this is still more apparent in the Dominion and Post-office Savings Banks. The amount standing to the credit of depositors in the latter institutions, in 1879, was 9,207,683 dols., and in 1882, 21,768,661 dols. A still further increase is apparent in 1883, but I am not in possession of the actual figures.

Trade and commerce have advanced by leaps and bounds since the confederation, and I trust you will excuse me if I trouble you with a few more figures. In 1868, the total exports and imports were valued at 130,000,000 dols., while in 1882 the figures were 221,556,000 dols. —an increase of 70 per cent. for fourteen years. The exports are divided into seven heads—the mine, the forest, fisheries, animals and their produce, farm and agricultural produce, manufactures, and miscellaneous. Timber, agricultural produce, and animals are among the most valuable of the exports, but the manufacturing industry is yearly becoming more important. It will have been seen by those who visited the late International Fisheries Exhibition, that Canada has immense wealth along her coasts, and in her rivers aud lakes. The produce of the fisheries in 1882 was valued at 16,800,000 dols.; about one-half was exported to different parts of the world. The important maritime position of Canada is well known. The total number of vessels on the register books on the 31st December, 1882, was 7,312, measuring 1,260,777 tons. Assuming the average value to be 30 dols. per ton, the value of this shipping would be about £7,500,000 sterling. The imports include raw material and manufactured goods. The proportion of the aggregate trade with Great Britain is very nearly fifty per cent., the balance being divided between the United States and other countries. There seems to be no reason why the development to which I have referred should not be as great in the years to come as it has been in the past. I do not mean to say that periods of depression may not be experienced; they occur in every country and under every condition of things, no matter what the fiscal policy has been, and may be described as "national medicine." They are not pleasant experiences, but are not without good results. Still, I must say that in Canada, and in the other Colonies, there should, in my opinion, be less chance of any serious difficulties of this kind than in some of the European countries. In the older provinces of Canada the population is growing rapidly; the area of land under cultivation is annually becoming larger (although there is still an immense extent of territory unoccupied), and the investment of capital in manufactures is increasing. I notice in the census of 1871, that there were in that year only twenty-two cities and towns with populations of 5,000 and upwards, aggregating 494,699. In 1881, the number had increased to thirty-seven, with 641,703 inhabitants. Manitoba and the North-West Territories (which did not appear to advantage in the last census, having at that time only had railway communication for three years) must not be left out of any calculations of the kind. Villages and towns are springing into existence within their boundaries, particularly along the route of the Canadian Pacific Railway, as the British Association will be able to judge this summer. These districts are progressing at a wonderful rate, and there can be no doubt that the future of Canada is largely connected with their development, and that of the Pacific Province of British Columbia.

I regret that the time at my disposal will not permit me to make some extended remarks respecting the public debt of Canada. I may say, generally, however, that it has been applied to the useful work of developing the country; in subsidising railways; in constructing the system of canals connecting the St. Lawrence with the Great Lakes; for lighthouses; the improvement of navigation; and other public works. It is not a record of war and bloodshed, but of peaceful and rapid progress. Many particulars of an interesting nature could also be given respecting the postal and telegraphic system, the various useful purposes for which electricity is utilised, the patent laws for the encouragement of inventions, copyright regulations, the franchise, and many other matters. Anyone, however, who reads a paper on a subject so vast as Canada, and who is limited to one hour, is obliged to omit much that might with advantage be said. I desire, however, to say a few words respecting the educational system; the laws in operation for the regulation of the liquor traffic; the railway and canal systems of the country; and the question of the climate which the Marquis of Lorne has properly described as the bugbear of the Dominion.

Long before School Boards were established in England, Canada was in the enjoyment of a well organised educational system. Every township is divided into sections sufficiently large for one school, and trustees are elected to undertake the management of the affairs. This is also the case in the cities and towns. In districts where the inhabitants are divided in their religious opinions, and mixed schools are not possible, the law enables separate schools to be provided. The necessary funds are raised partly by tax upon the ratepayers, and partly by grants from the provincial treasuries. Teachers are prepared and trained at normal schools, supported and maintained at the public expense. As a rule, no fees are charged. Education, however, does not rest at this point; for those who can afford it—and the cost is comparatively small — there are schools of a higher grade. In all parts of the country grammar schools are to be found, managed, like the common schools, by trustees. At these, as well as many excellent private schools, the pupils receive a classical education, and are trained and prepared for the legal and other professions. There are also colleges, possessing university powers, endowed with scholarships of considerable value, open to youths prepared in the lower schools. Toronto, Montreal, and other places have schools of medicine; while the various leading religious denominations have institutions at which young men are prepared for the ministry. For the higher education of girls there are excellent schools, many of which are denominational in character. Some of the schools have libraries of judiciously chosen collections of books for the use of the pupils. In fact, means of education, both for the rich and the poor, abound in the Dominion. In very many cases the children of immigrants who have arrived in Canada in a state of poverty, very little removed from absolute pauperism, have received a thorough education, and have secured the highest prizes the country offers.

In all the universities scientific education forms a part of the course in arts, and in most of them there are honour courses in natural and physical science. McGill College, Montreal, has a faculty of applied science, including the subjects of civil, mechanical, and mining engineering, and practical chemistry; and in its honour course prepares for field work in geology. The University of Toronto has similar courses. These institutions, as well as some others, have good chemical laboratories. Elementary science, more especially chemistry, botany, and physiology, is taught in most of the higher, and, more or less, in the lower schools. The teachers are prepared for work of the kind in the provincial normal schools, in which, among other things, agricultural chemistry is taught. There are also several well appointed agricultural colleges in the provinces of Ontario and Quebec.

The following are the principal scientific societies in Canada, and they all publish their transactions :—The Royal Society of Canada; The Natural History Society of Montreal; The Canadian Institute of Toronto; The Nova Scotia Institute of Science; The Natural History Society of St. John, New Brunswick; and the Scientific and Historical Society of Winnipeg. Such, in a few words, is the educational system of the country. I trust that one of the many results sure to follow the visit of the British Association will be the formation of a similar institution in the Dominion, and that it will do as valuable work in Canada as the old Association has accomplished in the United Kingdom.

The Dominion occupies a prominent position in connection with the promotion of temperance. In the great North-West, that we hear so much of, spirituous liquors are not allowed to be sold under any circumstances, in consequence of which the Indians in that territory occupy the satisfactory position they do today. At first sight this prohibition might be considered as not likely to be favourably regarded by the European, Canadian, or American settler. But the principle has been so far accepted, and its benefits recognised, that on the recent extension of the western boundary of Manitoba, the population in that portion of the North-West Territories which it was desired to include, petitioned that the prohibition should be continued. I hope the existence of regulations of this kind will not deter members of the British Association from taking the excursion through the country to the Rocky Mountains. The Lieut.-Governor of the province has power to give a "permit," that is, to allow a small quantity of alcoholic liquor to be conveyed by travellers, but it is exercised only in cases of illness, as a medical necessity. I state this as a matter of fact, and disclaim any intention of another nature, to which unkind persons might perhaps attribute it.

A new Act was passed during the last Dominion Parliament (it came into operation on the 1st of January), which, I think, will be very interesting, as showing the rapid progress that is being made in social reforms in Canada. The measure provides that the country shall be divided into license districts, identical, so far as possible and convenient, with existing counties, electoral districts, or cities. A Board of Licensing Commissioners, consisting of three persons, will be appointed in each district. One member of the Board must be a county-court judge, or other judicial officer; another the mayor of a city, or warden of a county, as the case may be; and one is to be appointed by the Government for one year. I mention this to show that every care is taken to ensure the important work being in good hands. A Chief License Inspector, and one or more inspectors, will be nominated by the Board in each district. The feature of the Act is that it determines the number of hotel and saloon licenses to be granted. In cities, towns, and incorporated villages, one license may be issued for every 250 of the first 1,000 of the population, and one for each full 500 in excess of that figure, but there may be two hotels in any town or incorporated village where the inhabitants number less than 500. In county towns five licenses may be granted. Two hotels beyond the number the population may warrant may be licensed for a period of six months, commencing on May 1 in each year, in any locality largely resorted to in the summer by visitors. In incorporated villages, townships, or parishes, no saloon licenses will be granted. Shop licenses, which authorise the holders to sell and dispose of any liquors—not less than one pint in quantity—not to be drunk in and upon the premises, may be granted, one for each 400 up to 1,200 of the population, and one for each 1,000 beyond. Any person applying for a license who is not already a licensee under the Act, or under any previous Act, must be supported by a certificate signed by one-third of the electors of the district. Ten or more electors, and in an unorganised division five or more, out of twenty householders, may object to any application, and can be heard by the Board, and it will be refused if two-thirds of the electors petition against it. Before any license is granted, the applicant must enter into a bond in the sum of

500 dols., with two sureties for 150 dols. each, for the payment of all fines and penalties which they may, for infractions of the law, be condemned to pay. No license will be granted by the Board within the limits of any town, incorporated village, township, or other municipality, excepting counties and cities, if three-fifths of the qualified electors have declared themselves in favour of a prohibition. Hotels and saloons and shops are prohibited to sell liquors from seven on Saturday night, till six on Monday morning, and from eleven at night till six in the morning on other days, except for medical purposes, under proper restraint. Lodgers in hotels may, however, be provided on Sundays, during meals, between the hours of one and three, and five and seven in the afternoon. The hotels and public houses are closed on the polling days for Dominion, provincial, or municipal elections. A very important provision enables two Justices to forbid any licensees to sell drink to any person who "by excessive drinking mis-spends, wastes, or lessens his or her estate, or greatly injures his or her health, &c.," in any city, town, or district in which the drunkard may be likely to resort. Another clause provides that any husband or wife, whose wife or husband may have contracted the habit of drinking intoxicating liquor to excess; the father, mother, curator, tutor, or employer of any person under the age of twenty-one afflicted with the same weakness; and the manager or person in charge of an asylum in which any person resides or is kept, may require the chief inspector of the district to give notice in writing to any person licensed to sell liquors that he is not to supply them to such interdicted person. If I have dwelt at some length on this subject, I hope you will forgive me; but knowing the importance with which the question—particularly with reference to local option—is regarded in this country, I ventured to believe that the experience of Canada might be interesting to you. The measure, as you will observe, is a very drastic one, but its principle has been well received, and it is the natural consequence of previous legislation.

The construction of railways in the Dominion of Canada has been very rapid since the confederation; and efforts are being made at the present moment to extend and complete the system. In 1870, there were only 2,497 miles open for traffic; in June, 1882, this had increased to 8,069 miles, and in the last eighteen months another 1,000 miles, at least, have been added. There are now, therefore, over 9,000 miles in operation, affording means of communication from the province of Nova Scotia to Ontario, and again from the western shores of Lake Superior to Winnipeg, and through the North-West Territories to the Rocky Mountains. The total amount of capital invested in the construction and equipment of railways in Canada, to the end of the fiscal year, 1882, was 389,285,700 dols. The Canadian Pacific Railway—one of the greatest national undertakings of the age—is being rapidly constructed. It is nearly ready for operation from Montreal to Algoma Mills, on Georgian Bay, and is now being worked from Port Arthur, on Lake Superior, to the Rocky Mountains, a distance of nearly 1,400 miles; and from Winnipeg south to the international boundary, where it connects with the United States railway system. Large numbers of men are being employed on the other sections of the line, and it is confidently expected that in 1886 there will be direct communication from the Maritime Provinces to the Pacific coast entirely through Canadian territory, the importance of which, to Canada and to the British Empire, it is impossible to exaggerate. Many persons may remember that at the last meeting of the Association at Southport, Sir Charles Tupper, the High Commissioner for Canada, also Minister of Railways and Canals, gave a most interesting and graphic description of the railway; and there is no one better qualified to speak respecting it. Prior to 1881, the work was being carried out by the Government; but in that year it was transferred by Act of Parliament to the Canadian Pacific Railway Company. There are about 2,000 miles constructed at the present time, and the track has been laid during the past season at the rate of between three and four miles per day. The difficult work in British Columbia, and on the northern shore of Lake Superior, is being accelerated as much as possible. The line, when complete, will, including branches, be about 3,300 miles long. It has been largely subsidised by the Government, and the work would have been an onerous one for a country with a much larger population than that of Canada. The completion of the line must have a great effect upon British Columbia. That province has not yet been in the enjoyment of railway communication with the other parts of the Dominion, but as soon as this is accomplished, its natural resources and favourable climate will ensure its taking an important position, as it is the only British possession on the Pacific coast of the American continent.

The inland navigation of the Dominion has cost a large sum of money, but is a work of which the country may well be proud. The canals were constructed to overcome the obstructions of river and lake navigation. What is the result? Vessels of 600 tons can now proceed from the western end of Lake Superior, and from the United States ports of that vast inland sea, to Montreal, by way of Lakes Huron, Erie, and Ontario, and the River St. Lawrence—a distance of nearly 1,300 miles. The locks on the Welland Canal, connecting Lakes Erie and Ontario—rendered necessary by the Niagara Falls—have recently been enlarged, and are now 270 feet long, 45 feet wide, and 14 feet deep. The Canadian route, from the lakes to the ports of transhipment, compared with that to New York and other American ports, possesses some advantages. In the year 1882, abont 3,000,000 bushels of grain from the United States were, in consequence, shipped to Europe from Montreal. Take, for instance, the distance from Chicago, on Lake Michigan. It is nearer by some 150 miles to Montreal than it is to New York, *viâ* Buffalo and Erie Canal; and there are 16 more locks and 89½ feet more lockage by the American than by the Canadian route. In addition, Montreal is 300 miles nearer to England than New York. Atlantic steamers of 5,000 tons can now be moored alongside the wharves at Quebec and Montreal.

The question of the condition and progress of the Indians in the different parts of Canada is always an interesting one. They number about 100,000, and are, probably, in a more satisfactory position than the aboriginal inhabitants of many other portions of the empire. There is a special department of State, under the able administration of Sir John Macdonald, entrusted with Indian affairs. Efforts are being made for the elementary education of the children, and, according to the latest information, there is a regular attendance in such schools of about 4,000. In addition, there are farms and industrial schools for their tuition in agriculture and in industrial pursuits. The following is an extract from the Report of the Superintendent-General of Indian affairs, presented to the Canadian Parliament during its last session:—

"The increased desire among Indians of the older provinces for additional schools, on reserves on which none have as yet been established, or where those already in operation are deemed insufficient, may be regarded as an indication that the much to be desired demand for enfranchisement on the part of some, not of many, of the bands, may follow as the result of this inclination for further enlightenment, and every facility, compatible with reason, to enable them to become enfranchised, should be offered those anxious for the step. The law might possibly be, with advantage, amended in this respect, so as to give those desirous of enfranchisement increased facilities for accomplishing their object."

This must be regarded as a very satisfactory statement.

The condition of the Indians in the North-West Territory, considering that they have only been under the direct control of the Government for a few years, is also encouraging. Sir John Macdonald says:—

"I am glad to be able to report that the advanced condition of the Indians settled upon reserves in several localities in the territories admitted of the closing, during the past season, of the instructor's farms in those localities. The object for which they were established, namely, the practical exemplification to the Indians of the manner in which farms should be managed, has been attained. It is hoped that next autumn the Indians in several other localities will be sufficiently advanced to admit of a similar change being effected."

It is not to be supposed, however, that, although these farms have been closed, the Indians will be left without oversight in their agricultural operations, as they might, in such circumstances, rapidly relapse into their old habits. Competent and reliable men will be placed on each reserve to encourage and direct their efforts.

The judicious treatment of the Indians by the Government in all their dealings with them is sure to have its effect in the future. The Bishop of Saskatchewan, in a very interesting address delivered last year, said:—

"By-and-bye I have no doubt that we shall see a very grand result in the Dominion of Canada in reference to these Indians. I am one of those hopeful individuals who look forward to the day when we shall see the Indian population making their bread honestly side by side with the white men, who have come into the country as immigrants; and all this will be the direct result of that eminently wise and farseeing and thoroughly English policy which has been so consistently pursued by those who conduct the destinies of the Government of Canada."

It has often struck me as a significant fact that the complaints against the climate are made to refer, at the present time particularly, to Manitoba and the North-West Territories. It will be remembered, however, that the statements now being made respecting

Manitoba were formerly applied to Ontario, Quebec, Nova Scotia, and New Brunswick. These provinces, it is said, never grow fruit to any extent; it would be impossible that they should ever become famous for raising cattle; and the season is manifestly too short to permit of agricultural operations being carried on successfully and profitably. It is hardly necessary to state how completely these prophecies have been falsified. Canada has a reputation for fruit far beyond its boundaries. Canadian apples probably bring the highest price of any that are imported into the English markets. Those who have visited the country will know that it is famous for many other fruits besides apples, and that many species grown in England under glass, flourish there in the open air. An important portion of a recent article in the *Times* on "Fruit Culture" was devoted to Canada. As a cattle country it is taking an important position. Not only are there sufficient cattle and sheep and other animals to supply the demands of its own population, but on an average about 60,000 to 70,000 head of cattle, and 300,000 sheep are exported annually. The larger proportion of the cattle are sent to Great Britain, while the sheep principally go to the United States. There are many articles of Canadian farm produce which have attracted considerable notice in this country. The total value of the exports under the heading of "Animals and their Produce," in 1882, was 20,500,000 dols.; of this, the United States took about 6,500,000 dols., representing, chiefly, horses, horned cattle, sheep, butter, and eggs.

With regard to agriculture, a good deal of misapprehension seems to prevail; but that the climate is not in any way unsuited to that important pursuit, is proved by the increase of the population, the largely extending area of land brought under cultivation, and the rapidly increasing quantity of the produce that is grown and exported. In 1882, the value of the agricultural exports was 31,000,000 dols.; of this, 18,000,000 dols. represents barley, oats, rye, wheat, hay, potatoes, &c., sent to the United States. It is not generally understood that the farmer in Canada has to perform in the winter very much the same sort of work as the farmer in this country; after the harvest is over, he does as much ploughing as possible, and this is the case in England. Very little actual work is done on the land in either country during mid-winter, for equally obvious though different reasons. But cattle have to be fed, cereals threshed, machinery put in order, buildings repaired, and carting done, which latter, by the way, the Canadian farmer owing to the snow, is able to do very cheaply. Then again, snow in Canada is not considered a disadvantage; it destroys insects and pulverises the soil. It may be that the spring commences two or three weeks later than in England; yet the conditions for the rapid growth of all produce are so favourable that the crops of the two countries are about equally advanced by the middle of July. It is commonly stated, even now, that Canada has an eight-months winter. I feel that it is hardly complimentary to the intelligence of this audience to notice such a remark seriously, but I came across some very interesting statistics the other day which seem to me to refute, very clearly and forcibly, statements of this kind, I refer to the dates of the opening and closing of the navigation of the St. Lawrence during the last twenty years, and of the canals connecting the river with the great lakes. I find that, at Montreal, the river on an average, for the last ten years, was closed for navigation 141 days annually; at Toronto, 123 days; and on the Welland Canal about the same period. In considering these figures it must be remembered that, although navigation is reported as closing or opening on a particular day, the river or canals are properly navigable for several days in addition, as the steamers and other vessels have to leave before the frost commences, and they do not enter the river for some days after there is open water. The average winter may, therefore, be taken at about four and a-half months—sometimes it is longer or shorter by a few days. Between Manitoba and the North-West and Ontario, there are a few days' difference in favour of the latter. British Columbia probably posseses the finest climate in North America; it has all the advantages of that of England, without its disadvantages. Ask a Canadian, or an Englishman who has spent a winter in the Dominion, which he prefers, the climate of Canada or that of this country, and you will find that he will not hesitate in his answer.

The cold is not always to be estimated by the thermometer. The humidity of the atmosphere is the real criterion by which the effects of the temperature must be judged. I have worn in England clothing as warm as I have found necessary in Canada. If the climate were as humid as that of Great Britain, the low temperatures that prevail might be detrimental; but the dryness of the air prevents any such consequences, and the country is a very healthy one. Another thing, in Canada one is always prepared for the cold. Here it is not so. It is not usual there for ladies to put on shawls when passing from one room to another. In winter the houses are far warmer than in this country.

In the spring you will find wild flowers as prevalent as in England; and in August, wild fruits and delicate ferns abound. Besides, if the climate were the wretched one that has been described by persons who have but little knowledge of it, and so detrimental to the prosperity and progress of the country, so many people would not have gone there, and the population and the agricultural industry would not have increased with the rapidity that is now apparent.

Having endeavoured briefly to give an idea of Canada, as it will appear in several aspects to the members of the British Association, I will now make a few remarks respecting Montreal, and some of the excursions to be undertaken after the meetings are over.

The first thing that strikes the visitor to Montreal is the grandeur of the River St. Lawrence, and the splendid position the city occupies. It is situated on the left bank of the river, at the south-east corner of a triangular island formed by the mouths of the River Ottawa, where, after a course of 600 miles, it enters the St. Lawrence. The waters of the two rivers do not at once mingle; the line of junction is apparent for many miles—the clear blue water of the St. Lawrence washing the right hand, and the turbid stream of the Ottawa the left hand, bank. The city is built on a series of terraces rising towards Mount Royal, from which it takes its name. The summit of the mountain—as it is there called—is about 700 feet above the level of the river. I have seen no place of its size (its population numbers about 190,000) which contains so many fine buildings, both for business and residential purposes.

A whole paper could very easily be written about Montreal, and a very interesting one it would be. In the business portion one cannot but be impressed with the splendid piles of warehouses and premises, giving it an appearance of solidity not very common in colonial cities, while up towards the base of the mountain will be found street after street of handsome residences, hardly to be surpassed even in England. Then to climb up to the mountain and see the city stretching beneath you, with the river in the distance spanned by the Victoria-bridge, is a sight that once seen will not soon be forgotten. Montreal is known in America as the city of churches, and some of them are very fine specimens of architecture. Mark Twain, in a speech at the Windsor Hotel, not very long ago, said that "he never was in a city before where one could not throw a brick-bat without breaking a church window." I will not say that the churches are quite so numerous as the remark would imply. Whether the people are, however, better than their neighbours for their religious surroundings, I shall leave their visitors to judge.

Montreal is the chief commercial city of Canada, and although it is 900 miles from the ocean, the largest steamers crossing the Atlantic will be found moored along the wharves. Between Quebec and Montreal there is always a depth of 30 feet of water, excepting for a distance of thirty miles, chiefly in the lake St. Peter. In 1851, when the work of deepening the channel at this part of the river was commenced by the Harbour Commissioners of Montreal, there was not more that 11 feet of water on the flats of the lake. This, however, has now been increased to 26 feet, and the artificial channel is 300 feet wide at its narrowest part. This great engineering work has made Montreal. Had it not been accomplished it could not have occupied the position it does to-day. The total length of the wharf accommodation is $4\frac{3}{4}$ miles, of which two-thirds is available for vessels drawing 25 feet. It has every convenience for loading and dispatching ships, and I remember myself that on one occasion a large ocean-going vessel arrived one day and was unloaded, re-loaded, and despatched the next day. A walk along the river street will give an idea of the bustle and activity of the place. The wharves at which the ships discharge are several feet below the level of the road, so that the whole proceedings can be surveyed at a glance. Not only is Montreal the Liverpool of Canada, but it is a large and growing manufacturing centre. A fitting companion to the splendid wharves and shipping accommodation is the Victoria-bridge, designed by Robert Stephenson, which must be considered one of the finest structures of the kind in the world. It is 9,184 feet long—in fact, nearly 2 miles—and carries the Grand Trunk Railway over the St. Lawrence. The first stone was laid in July, 1854, and the first passenger train passed over it on the 19th December, 1859. The total cost amounted to £1,200,000.

The appearance of the city from the river is very attractive. Mr. W. D. Howells, the American writer, says of it:—

"For miles the water front of Montreal is superbly faced with quays and locks of solid stone masonry, and thus she is clean and beautiful to the very feet. Stately piles of architecture, instead of old tumble-down warehouses that dishonour the waterside in most cities, rise from the broad wharves, behind these spring the twin towers of Notre Dame, and the steeples of the other churches above the roofs."

Of the view from the tower of the Parish Church of Notre Dame, which is 220 feet high, he says in one of his works:—

"So far as the eye reaches it dwells upon what is magnificent. All the features of that landscape are grand. Below you spreads the city, which has less that is really mean in it than any other city of our continent, and which is everywhere ennobled by stately civic edifices, adorned by stately churches, and skirted by full-foliaged avenues of mansions and villas. Behind it rises the beautiful mountain, green with woods and gardens to its crest, and flanked on the east by an endless fertile plain, and on the west by another expanse, through which the Ottawa rushes, turbid and dark, to its confluence with the St. Lawrence. Then those two mighty streams commingled, flow past the city, lighting up the vast country to the south, while upon the utmost southern verge, as on the northern, rise the cloudy summits of far-off mountains."

The British Association will probably hold its sectional meetings in the buildings of the McGill University. This institution owes its origin to a Montreal citizen, James McGill, who died in 1813, leaving a fortune valued at that time at £30,000, for the purpose. The property of the college is now estimated at more than half a million dollars. The latest large benefaction which it has received is the Peter Redpath Museum, valued at more than 100,000 dols. This was opened in 1882, and was the gift of a gentleman of that name. Its forty professors and lecturers include some of the most eminent men in their department in the Dominion, and its students may be stated in round numbers at about 500. It has four faculties—arts, applied science, medicine, and law. Being non-denominational, it has no theological faculty, but it offers advantageous terms of affiliation to colleges where such degrees may be obtained. There are other excellent educational institutions in the city.

There are many objects of interest in and around Montreal well worth seeing, for which facilities will be provided. Means of conveyance are abundant, excellent, and moderate in cost. I would specially mention the Lachine Rapids; but there are others too numerous for me to mention. Further afield are Quebec, Ottawa, the capital of the Dominion (the residence of the Governor-General), with its splendid Parliament buildings, and its miniature Niagara; the eastern townships of Quebec, with their romantic lake and landscape scenery; and there are also excursions through the famous Thousand Islands of the St. Lawrence. Niagara Falls will certainly not be omitted. I have said a good deal of Montreal in this paper, but it is not the only city worth visiting by any means. In addition to Quebec and Ottawa, there are Toronto (known as the "Queen City of the West"), Hamilton, London, and many others; while the maritime provinces of Nova Scotia and New Brunswick will be very interesting to those who are able to visit them on the journey home, embarking at Halifax for England.

The principal excursion will be to Winnipeg and the Rocky Mountains. The present arrangement is for a special train to start from Montreal over the Canadian Pacific Railway to Algoma Mills on Georgian Bay. At this point passengers will embark on board the new large steel steamships of the Company, and proceed to Port Arthur, at the western end of Lake Superior, the voyage occupying about twenty-four hours. The scenery through the lake is grand and picturesque. From Port Arthur the party will be conveyed by rail to Winnipeg, where, I imagine, a short stay will be made. This city was formerly known as Fort Garry, one of the posts of the Hudson's Bay Company. In 1870, when the Territories were taken over by the Government, the population numbered a few hundreds. Now it is estimated to contain 30,000 people. The journey from Winnipeg to the Rocky Mountains will probably take about two or three days, according to the stoppages that are made on the way. The North-West Territories, *i.e.*, that portion of the country between the boundary of the Province of Manitoba and the Rocky Mountains, are estimated to contain about 250,000 people, while a few years ago the only inhabitants were the Indians. I must not, however, omit to mention the officers of the Hudson's Bay Company, and those devoted servants of the Church to whose fair treatment, careful management, and civilising influences, the satisfactory position which the Indians occupy to day is greatly due. The country is dotted with settlements here and there, formed by men from England, Ireland, Scotland, and different parts of Europe, besides Canadians and Americans, who have removed their homes to this region. The "illimitable wilderness" as the late Lord Beaconsfield described it, is gradually being cultivated; and golden fields of wheat, and other cereals, are taking the place of those vast seas of grass which formerly covered the prairies. It is truly said that he is a public benefactor who causes two blades of grass to grow where but one grew before, and in my opinion the same remark will apply to those who, in Manitoba and the great North-West, have made fields of wheat to grow where but wild grasses flourished before.

The visit will also be most important from ethnical and anthropological views, from the investigation by our scientific men of the vast extent of treeless prairie they will pass over, and in connection with the geological features of the country. For a time it was said that its settlement would never be possible owing to the absence of timber, both for building and fuel. Both these difficulties have been removed by the discovery that immense forests exist, and that beds of coal and lignite underlie the whole of the western portions of the territory. Those who were present when the Marquis of Lorne read his recent interesting paper at Exeter-hall, will remember having seen a specimen of the coal in the room. It has since been subjected to analysis, at the Royal School of Mines, with most satisfactory results, and it is stated to be suitable for both domestic and mechanical purposes. In this connection I call to mind a remark made by the Bishop of Saskatchewan on the occasion to which I have previously referred, to the effect that if the country had not been intended to provide homes for millions of our fellow men, Providence would never have placed the hidden treasure of an inexhaustible coal supply there for the use of man.

Emigration may not be a matter connected with abstract science, but I do not think my paper would be complete without some reference to it. It is an economical problem of immense importance both to Great Britain and to Canada. Here there are thousands upon thousands who are unable to procure a living, and the wonder is that they manage to exist at all. In Canada there are millions of acres of land practically unoccupied, capable of affording food and employment for any number of people. It is an admitted fact that some outlet must be found for the surplus population of this country, and it is equally necessary for Canada to add to its population. The annual increase in the number of its inhabitants is small compared with the extent of the land waiting to be occupied, and the rapid development of the country is therefore very much connected with the question of emigration.

Five millions of people have left Great Britain during the last thirty years, of whom 1,400,000 have gone to the Colonies, and 3,300,000 to the United States. If means could have been found, years ago, to direct this stream of wealth to our own possessions, they would have occupied a much greater position than they do to-day. The Empire would have been much stronger, and the stream would have continued to flow in that direction to the advantage of our trade and commerce. It would for ever have settled the question of the food supply of the country, besides many other subjects that are now troubling economists.

The Canadian Government has been endeavouring, and, considering all the circumstances, with some success, to encourage settlement in the Dominion. Not only are "assisted passages" offered to the different kinds of labour—particularly farm and general labourers, certain classes of mechanics, and domestic servants—which have been in great demand during the last few years, but free grants of land may be obtained by those who are able to command a small capital. In the older provinces, these are covered with bush, and are not, therefore, altogether suitable for European settlers; but in Manitoba and the North-West Territories there are millions of acres of fertile land available, ready for the plough, and any *boná-fide* settler may obtain 160 acres on payment of £2, to cover the cost of the survey and the preparation of the necessary documents; he has also the right to pre-empt a similar quantity at from 8s. to 10s. per acre. Before obtaining a title to the land, the settler is obliged to reside on the homestead at least six months, annually, for three years, and to perform certain minor conditions of a not very onerous nature, viz., to put a reasonable but undefined portion of the ground under cultivation, and to erect a house.

For those who are possessed of capital, and do not desire to brave the exigencies of pioneer life, improved farms—farms under partial cultivation, with the necessary buildings erected, &c.—can be purchased in every province at from £2 to £20 per acre, according to position, and the conveniences that are offered.

As a general rule, the emigration to Canada, during the last few years, of which I have personal knowledge, has been both satisfactory to the Dominion and to the people who have settled there. Thousands of persons have proceeded to the country during that period, through the offices of the Canadian Government, and I am able to say that hardly a complaint has been received from any such persons, that they were not satisfied with their reception, or with their prospects. This is a particularly gratifying fact. The conditions of successful settlement are very similar to those which will command success anywhere. If a man is prepared to work and adapt himself to circumstances, there is no reason whatever why he should not, with ordinary good fortune, do well in Canada. The Colonies are certainly not the places for what are known as "soft things," and I have no doubt that some of the failures of which we hear arise from unrealised expectations of the kind, or from the persons having proceeded without obtaining proper advice as to whether they are suitable, and as to what they should do on their arrival. There are agents of the Government in every important place, to whom new setlers of every class are directed to proceed, with the certainty of receiving proper advice and, almost invariably, where it is necessary, assistance in obtaining employment.

I have no doubt that when the members of the British Association see the enormous resources and capabilities of Canada, and its suitability for the absorption of an immense population, their thoughts will revert to the condition of things as they are now to be found, not only in this country but in other parts of Europe, and one good object will have been served if the visit should result in some well organised and systematic proposal for a remedy of the evils, resulting from the rapid increase of the population, and the competition in the labour market, which have recently been attracting so much attention.

In a few days a circular will be issued by the British Association, explaining in detail the arrangements that have been made in connection with the meeting in Montreal; but I have, in advance, endeavoured to place before you, briefly, some of the more prominent of the social, political, and commercial aspects of the country at the present time. If I have not succeeded as well as I should have liked, I have the satisfaction of knowing that among those present, there are many eminently qualified to supply any deficiencies of which I may have been guilty. There is every reason to believe that the gathering will be a success in every way, and I trust the Association will bring back with them very pleasant reminiscenses of the occasion — as warm and as cordial as the feelings of satisfaction and pleasure with which they will be received, not only in Montreal, but throughout the Dominion.

DISCUSSION.

The CHAIRMAN, in inviting remarks on the paper, said he believed there were many members of the British Association present, who would be glad to hear a few remarks from Sir Alexander Galt, who besides his many other claims to their attention, had long been a resident in Montreal.

Sir ALEXANDER GALT shared in the gratification they must all have felt at hearing the very excellent paper of Mr. Colmer. The Canadian Government were fortunate in being represented by that gentlemen on this occasion, and the members of the British Association were no doubt well aware that he had been one of the most active in bringing about the visit to which they all looked forward with so much pleasure this summer. Mr. Colmer, in his lucid statement, had touched upon many of the points which would certainly attract the attention of the members of the British Association, or indeed of any stranger who might visit the country. In Canada they looked forward to receiving the greatest advantage from that visit, when they would have in their midst gentlemen of the highest scientific ability, bringing with them the knowledge they had gained in Europe, and he ventured to think that the benefit would be reciprocal. Up to this time, the British Association had confined their meetings entirely to this country, and they had not "in the midst of our old civilisation" had placed before them, as they would have in Canada, the conditions under which the bonds of society were created. Many of the problems which had been of late receiving the attention of intelligent men here would be seen to have found a partial, if not a complete, solution in Canada. Mr. Colmer had referred to the educational and municipal systems there, and to the regulations to which the trade in intoxicating liquors was now subjected. Those were all questions which had been dealt with by a people who were freer, in the sense of having more votes, than the people of England. Those measures were the results of a very popular system indeed, and great advantage would be found in studying the application of such principles to this country. Canada certainly possessed a better municipal system than we have here, and by studying it they would be able to avoid many obstacles, and to take advantage of a system which was sound in principle. In fact, the visit of the British Association would be useful not only to the Colony, but to the whole empire. At the present time they had Mr. George among them here, giving them lessons on the nationalisation of the land; but it was strange that it had not occurred to that gentleman, an American himself, that within the last ten years there had been in Canada enormous tracts of land which had been absolutely in possession of the people, and without an owner, and what had they done with it? They had found that land without inhabitants was good for nothing, and that security of possession was what gave value to the land, as it gave value to everything else. Take away the security of possession, all the value was destroyed. They had not made their 200,000,000 acres of land in the North-West one great farm which anyone might go upon and cultivate, and which the stronger man might elbow his neighbour out of, but it was ready now to be taken up on payment of a small sum per acre. It was, in one sense, God's gift to man, and he was happy to say that man in Canada was not withholding it from his fellow creatures.

Mr. STAVELEY HILL, Q.C., M.P., in reference to Mr. Colmer's remarks upon Canada in the future, said it was often remarked that no man should prophesy unless he knows, but that qualification belonged pre-eminently to Mr. Colmer, because nobody knew better than he what were the existing conditions there. He envied the British Association their first view of Canada, and then, following the line suggested by Mr. Colmer up the St. Lawrence past Montreal, across the lakes to Winnipeg, and from Winnipeg over the boundless prairie up to the Rocky Mountains, they would have something to see the like of which they had never seen before, and much also to learn. But really from England to the Rocky Mountains was not now so far as people had been accustomed to consider it. It was often said what a pity it was that people should go so far from home, but after they had been five or six times across the Atlantic they would think no more of it than of crossing the Channel, and it was certainly far preferable to do so, on the score of comfort. They would have great pleasure not only in the scenery but in studying the Indians, the old inhabitants of the country, and they would find them, savages it might be, yet still rendered a happy people by the kind and just treatment they had ever received from the Government of Canada. They would come back impressed with the aspect of a country which had a great future before it, and in which poor people leaving England would find happy homes and plenty to give them enjoyment in life. Going there emigrants would none the less look upon England as their home because they were settled in Canada. It should be impressed upon all how necessary it was that Canada should be still more closely connected with this country, and that the time might come when our Parliament should be not the Parliament of the British Isles alone, but the Parliament of our federated Empire throughout the world.

The BISHOP OF SASKATCHEWAN said that for twenty-five years he had lived in Canada; for the first five in Ontario, and for the last seventeen in Manitoba and the North-West Territory. For ten years past he had been Bishop of Saskatchewan, and had travelled over the whole of that vast country. He could endorse every word Mr. Colmer had said. That gentleman had told them that of the 5,000,000 people who had left the shores of Great Britain within the last thirty years, some 3,400,000 had gone to the United States, and it was a grave question to ask what that meant commercially to England? How many of those emigrants were trained artisans? The exact money value of a trained mechanic to a country could be calculated, and it would easily be seen what the United States had gained, and what England had lost, by that one fact. And he would ask the same question politically—What did that fact mean? In the early days of Canada, emigrants wended their way to the plains of the Far West of the United States; but that was now changed, for it was found that Canada too had plains of her own inferior to none. How many of those 3,400,000 emigrants had taken the oath of allegiance as citizens of the United States? No emigrant could obtain the privileges of an American citizen without doing so; and that fact should come home to Englishmen, for by that oath they swore to discard all fealty to Queen Victoria and their native land. That was something terrible to contemplate in the event of a war between England and the United States Professionally, he was a man of peace, but he preferred peace with honour to peace at any price. The Canadian fisheries were mentioned also in the paper, and it should be known how important they were, and what an enormous stretch of coast Canada afforded for the promotion of that industry. But there was a great political question connected with that, too. It was of the highest importance to England that she should retain the coast which formed a nursery for hardy seamen, for the day had not yet gone by when the fleet must be considered the great safeguard of the liberties of England. It was necessary that England should have in the future a still larger naval reserve than she had in the past, and where, outside England, would she be able so well to obtain it as on that magnificent line of seaboard round the great Canadian Dominion. With reference to the climate of the great North-West, Manitoba was, no doubt, cold, but it was a healthy cold. He had been seventeen years in that territory, and had never suffered from it, though he had traversed the great snowfields for hundreds of miles north of the point where there were likely to be any settlements for the next fifty years, camping out, in the months of January and February, in the open with no covering but the sky. Mr. Colmer had mentioned, too, the way in which the Indians had been dealt with, both by the Hudson's Bay Company and the Government. In that respect the action of the Hudson's Bay Company had been beyond all praise, and their officers, who had had the management of the Indians during bygone years, had paved the way for the peaceable position of the Government in the magnificent North-West. Then Mr. Colmer had spoken of the educational interests of the country. The Chairman would remember that while he was Governor-General, the Dominion Parliament had passed a Bill for instituting a university in the Saskatchewan district, and the reason why he (the Bishop) was in England to-day, instead of in his diocese, was that he was trying to meet the requirements of the Bill for establishing that university on the banks of the Saskatchewan, where, a few years ago, there were no inhabitants but wild Indians and the buffaloes. That fact showed how well the Canadian Legislature were caring for the education of every man who came into the country.

Capt. J. C. R. Colomb wished to avoid taking a merely abstract view of the subject, while losing sight of the particular identity of the country under view. Remembering that the exports and imports of Canada were now in excess of the total exports and imports of France at the time the British Association was founded, they would obtain some idea of the progress of the country; and the tonnage entered and cleared last year from Canadian ports was double the aggregate tonnage entered and cleared in the ports of the United Kingdom, when the British Association held its first meeting at York. The completion of the Canadian Pacific Railway was but the carrying out of the policy which dated back to the days of Queen Elizabeth, to make for England a highway across the world. From the days of Drake down to the time of Franklin, efforts had been directed to the discovery of a short cut to the Pacific. He believed in the ability of the British Empire to stand firm and secure when the hour of danger came, but the real danger was not of invasion, it was the possible failure of the food supply. With the sea threatened, one-half of the population of England would find their food supply cut off; but that great railway would open up a country to them where they could grow their food on their own flank, and no longer be dependent on their present eighteen different sources of supply. Their command of the sea in the Pacific largely depended upon their ability to hold that valuable portion of the territory, British Columbia. From that point down to Cape Horn, there was no coal, and there alone could they obtain the coal necessary to enable the English fleet to keep the sea. Isolated, it could not be utilised, but now the whole of our naval force could be fed by that railway. It would also give greater facilities for populating and developing the territory. England last year voted £100,000 for a State-aided emigration scheme, and 16,000 people had been sent away from Ireland; but for one man who had been sent to Canada, ten had been sent to foreign countries. He did not think Englishmen realised what Parliament was doing in that respect. They were facilitating the transfer at the public expense of men who would be valuable producers under our own flag, to territory under a foreign flag. From the few families who had emigrated to Canada, he had not seen one single bad account, while he had heard very bad accounts from families who had gone to the States.

Captain Bedford Pim, R.N., said it was one of the happiest days in his life when he found the British Association intended to go over to Canada, and he was heartily glad to say he was himself partly responsible for it. He quite believed in temperance, and that temperance had made the Canadians what they were; but he hoped the British Association would not suffer any inconvenience from the strict carrying out of those principles. As to the great value of the Canada Pacific Railway, Captain Maury had told him, that when it was made, it would be the return route for the whole of the commerce from China and Japan, though outwardly this might go by San Francisco. That was an idea which was worth noting, and which, perhaps, had not yet presented itself to the statesmen of the Dominion. The Marquis of Lorne had alluded to the creation of an association there for the advancement of science, and he hoped that would be one of the results of the visit of the British Association, to whom he wished every possible enjoyment.

Mr. Cornelius Walford referred to the great advance made by Canada since 1851. For a long time the Dominion had stood still, and the States appeared to have made a very rapid march ahead of her; but at that time they had not the facilities which they now possessed since railway enterprise had set in. Toronto alone had fourteen lines of railway radiating away from it, and would become one of the great centres of Canadian commerce. It must be felt that the present policy of the Canadian Government, in opening railways, was the right policy, and the visitors would see that there was really room for everybody who wanted to go to the country. Doubtless, some of the emigrants who had started for Canada were not adapted for the life there, and people who went to Canada should be capable of earning their living out in the country. Even if there had been people to cultivate it before, it would have been of no use to the population of this country, because there were no facilities for bringing the produce down; but now that that they had them, the progress of Canada would be equal to that of the States. Canada was now in every way a flourishing country, and he hoped to live to see the day when the Dominion and all the Colonial possessions of Great Britain would form one United Empire.

The Chairman said they were all very much indebted to Mr. Colmer for his excellent paper. He could not express how glad he was that the British Association had decided to make the voyage to Canada. He did not think they would find it a very formidable one. It was but a short one after all—six days at sea was not a very great matter, and it must be remembered that they would have two days in the St. Lawrence before they reached Quebec. He would advise them not to land there, but to go straight on to Montreal. Quebec was well worth seeing, but it could be easily visited afterwards. The members of the Association would find awaiting them an organised society ready to provide them with every facility they could require. A Royal Society had been founded in Canada, and some of the most distinguished men had given their names as members of it. One other point he would refer to was the geology of Canada. As they were aware, Nova Scotia presented specimens of almost every measure, from the oldest to the newest. It was in the cretaceous measures that the excellent coal was found which was now being got by Sir Alexander Galt. It was similar to that which was found in Vancouver's Island, and no better coal existed. He asked the meeting to join in a cordial vote of thanks to Mr. Colmer for his very interesting paper.

Mr. COLMER briefly thanked the gentlemen who had taken part in the discussion for their assistance in elucidating the subject, and the meeting generally for the kind attention they had accorded to him.

EIGHTH ORDINARY MEETING.

Wednesday, January 30th, 1884: Prof. W. CHANDLER ROBERTS, F.R.S., F.C.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Chaimsonovitz, Elieson Prosper, 7, Drayton-terrace, Drayton-road, Leytonstone, E.
Colthurst, Sir George St. John, Bart., Blarney Castle, Co. Cork.
Dalton, William Henry, 118, Gower-street, W.C., and Melbourne, Australia.
Knowles, Thomas, Fir Tree-cottage, Turton, near Bolton.
Miller, John Ezra, 1, Tunstall-road, Sunderland.
Nicholson, Robert, J.P., Loanend-house, Norham, near Berwick-on-Tweed.
Pengelly, Thomas, Bodriggy-villas, Hayle, Cornwall.
Richardson, H. Cameron, 2, Carlton-villas, Elm-park-road, Finchley, N.
Sadler, Lieut.-Colonel, The Southlands, Preston-on-Tees, *viâ* Darlington.
Scott, Major-General Alexander de Courcy, Woodfield, Lytton-grove, Putney-hill, S.W.
Staples, Henry John, 87, Avenue-road, Regent's-park, N.W.
Thornton, Thomas Henry, C.S.I., D.C.L., Leigham Holme, Streatham, S.W.

The following candidates were balloted for and duly elected members of the Society:—

Bentley, Richard, Upton, Slough, Bucks.
Cameron, Lieut.-Colonel Donald Roderick, R.A., 10, Hornton-street, Kensington, W.
Clapp, William John, Nantyglo, Monmouthshire.
Glover, James, B.A., 30, Crosby-road, Birkdale, Southport.
Godwin, John, 19, St. Mary Abbotts-terrace, Kensington, W.
Graham, Mrs., 40, Woodstock-road, Bedford-park, Chiswick.
Head, John Merrick, London-road, Reigate, Surrey.
Huntington, Charles P., Astley Bank, Darwen, Lancashire.
Leeming, Thomas Henry, 2, Lee-terrace, Barking-road, Plaistow, E.
Mackenzie, Colin, Junior Athenæum Club, 116, Piccadilly, W.
Morris, Malcolm, 63, Montagu-square, W.
Newton, Henry Charles, Belsize-court, Hampstead, N.W.
Phelips, Richard Charles Hungerford, Cucklington Somerset.
Pike, Luke Owen, 201, Maida-vale, W.
Renouf, Philip Louis, Grove-lodge, Thistle-grove, S.W.
Shearer, John Ronald, 10, Basinghall-street, E.C.
Siemens, Lady, Sherwood, Tunbridge Wells.
Traill, William A., Giant's Causeway, Portrush and Bush Valley Railway, Portrush, Ireland.
Trenchard, Edward Penny, junior, 63, Granville-park, Blackheath, S.E.
Van Praagh, W., 17, Fitzroy-square, W.
Waymouth, George, Angleside, Crouch-hill, N., and 23, Moorgate-street, E.C.
Williams, Rowland, Birch Vale, Derbyshire.
Willink, Henry George, 29, Albion-street, Hyde-park, W.
Wilson, Albert Edward, Redbourn Hill Iron Company, Frodingham, Brigg, Lincolnshire, and Scunthorpe, Lincolnshire.

The CHAIRMAN, in introducing Mr. Fletcher, said he had to express his regret that an accident which he had met with in the performance of his public duties, prevented the Chairman of the Council, Sir Frederick Abel, from being present. He was, however, glad to hear that he was progressing favourably, and would soon be again amongst them.

The paper read was—

COAL GAS AS A LABOUR-SAVING AGENT IN MECHANICAL TRADES.

By THOMAS FLETCHER, F.C.S.

Gas, as a fuel, is an absolute necessity to the economical carrying out of many commercial processes. It is often used in the crudest and most costly way; a burner may be perfect for one purpose, yet exceedingly wasteful for another, and however good it may be, an error of judgment in its application may lead to its total condemnation. An excess of chimney draught, in cases where a flue is necessary, may pull in sufficient excess of cold air to almost neutralise the whole power of the burner, unless a damper is used with judgment. With solid fuel, an excess of draught causes more fuel to be burnt, but with gas, the fuel is adjusted and limited; there is no margin or store of fuel ready to combine with the excess of air, which, therefore, lowers the amount of work done by its cooling power. The power of any burner, for any specified purpose, depends not only on its perfection, but to a far greater extent on the difference in the temperature of the flame, and of the object to be heated. For instance, if a bright red heat is required, it is not possible to obtain this temperature economically with any burner working without an artificial blast of air, the difference between the temperature of the flame, and that of the object heated, is too little to enable the heat to be taken up freely or quickly, and the result is a large loss of costly fuel. If we want to obtain high temperatures economically, an artificial blast of air is necessary, and the heavier the pressure of air, the greater the economy. On the contrary, low temperatures and diffused heat are obtained best by flames without any artificial air supply.

For such purposes as ovens, disinfecting chambers, japanners' stoves, founders' core drying, and similar requirements, the best results are obtained by a number of separate jets of flame at the lowest part of the enclosed space, and the use of either illuminating or blue flames is a matter of no importance, as the total amount of heated air from either character of flame is the same. If there is any preference, it may be given to illuminating flames, as the proportion of radiant heat is greater, and this makes the average temperature of the enclosed space more equal; but, on the other hand, may be considered the greater liability of the very fine holes, necessary for illuminating flames, to be choked with dust and dirt. This may, to a great extent, be obviated by using very small union jets, and setting them horizontally, so as to make a flat horizontal sheet of flame. Burners placed this way are practically safe from the interference of falling dust or dirt, but not from splashes. Falling dirt or splashes must always be considered in the arrangement of any burners, and the ventilation must be no greater than is absolutely necessary for the required work. In cooking, this limit of ventilation may be exceeded, as most things are better cooked with a free ventilation, the extra cost of fuel being well compensated for by the better quality of the result.

The air in an oven or enclosed space heated by flames inside is similar in character to highly superheated steam. It contains a large proportion of moisture, and yet has the power of drying any substance which is heated to near its own temperature. A mass of cold metal placed in the oven is instantly bedewed with moisture, which dries up as the temperature of the metal rises. This is, for many purposes, an objection, and the remedy is to close the bottom of the oven and place burners underneath. If for drying purposes, and a current of air is necessary, the simplest way is to place in the bottom of the oven a number of tubes hanging downwards in such a position that the heat of the flame acts both on the bottom of the oven and the sides of the tubes which, of course, must be long enough for the lower opening to be well below the level of the flame. The exit may be at any level, but for drying purposes it is better at the top, and it should be controlled by a damper to prevent cooling by excessive currents of air. If not otherwise objectionable, the arrangement of flames inside the oven is far the most economical in use.

Where an oven or drying chamber is used continuously, it should be jacketted with slag wool or boiler composition, but for many purposes this is no advantage. As an example both ways, I will instance the drying of founders' cores where there is only one blow per day. The cores of an ordinary foundry can be dried by gas in a common sheet-iron oven in about half-an-hour; any accumulation of heat after that time would be useless, and a jacketted oven would be of no advantage.

For the disinfection of clothes in vagrant wards and hospitals for infectious diseases, on the contrary, a continued heat is necessary, and in this case the accumulation of reserve heat, which takes place slowly in a jacketted oven, becomes of value, as the gas can be turned low or out, and the ventilators closed, ensuring a more complete disinfection with a much smaller gas consumption. Where an oven or heated chamber is much used for periods of over half-an-hour at once, a non-conducting casing pays well by reduced gas consumption.

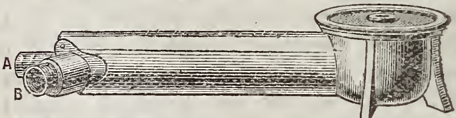
For albumen and glue drying, leather enamelling, tobacco drying, and purposes where a large space has to be very slightly and equally warmed when the weather is unfavourable, steam-pipes are generally used, but, not being always available, an exceedingly good arrangement may be made by placing at intervals in the room gas burners, of any construction, close to the floor, and surrounded with a sheet-iron cylinder, say, 2 ft. or 3 ft. high. The top of these cylinders must be connected throughout with a fairly large flue, which will take the products of combustion from the whole, and this flue must be carried either horizontally, or with a slight rise, so as to utilise all the waste heat. The reason for having a number of stoves at intervals is that the heat in a flue will not carry, for any useful purpose, more than about 8 ft. or 10 ft., and a single stove would give an irregular temperature in any except a very small room. If all are not used at once, the flues of those not in use may be closed by a damper to prevent down draught. The use of hot-water pipes heated by gas may also be occasionally advisable, but, unless for some special reason, it is much more economical to use coal or coke, as the bulk of water makes an exceedingly good regulator, and makes a fire practically as steady and reliable as gas, thus superseding the more costly fuel.

For one of my own purposes I need hot-water pipes, having very little variation in temperature night and day, and using coke for economy's sake, I get a regular temperature by heating a large quantity of water, about 200 gallons, with the fire, and enclosing this in a tank jacketted with slag wool. My circulating pipes run from this tank, and a practically steady temperature, night and day, can be obtained with the most irregular firing, and occasional extinction of the fire for several hours at once.

For the heating of liquids, the greatest economy is to be obtained from one single flame, of as high a temperature as can conveniently be obtained, and the flame must be in actual contact with the vessel to be heated. In jacketting vessels, to prevent draughts, care must be taken that the jackets do not cause currents of cold air to rise rapidly up the sides of the vessel, and so cool it. If this is the case, the use of a jacket, instead of being an economy, is a positive expense, and waste of heat. Many processes, such as making oil and turpentine varnishes, require a heat under instant control, and in these, the use of gas is an important matter, as the loss and risk of fire are very serious elements of expense, more especially in small works where special and costly preparations for contingencies cannot be afforded. I have here a burner which, for its power, is, perhaps, the most compact, and gives the highest temperature of any burner yet known, and it is easily made in almost any size; it has, I think, many special advantages.

FIG. 1.

SPECIAL HIGH POWER BURNER



SHEWING ATTACHMENT B WHEN USED WITH A BLAST OF AIR

The use of gauze, which is its only weak point, is more than compensated for by the very high duties obtained in practice with it, owing to the compactness and concentration of the heat obtained. The following extract from my communication to the Gas Institute will give all particulars as to the constructive detail of this burner. Those who wish to go further into the matter, will find the paper referred to in the publication of the Gas Institute for the current year, and also in the *Journal of Gas Lighting*, June 26th, 1883, and the *Review of Gas and Water Engineering*, June 16th, 1883.

"The first and most important part is the mixing chamber or tube, one end of which is supplied separately with gas and air, which at the other end are, or should be, delivered as a perfect mixture. It may be taken as a rule that this tube, if horizontal, should not be less in length than four and a-half times, or more than six times its diameter. It is a common practice to diminish or make conical-shaped tubes. All my experience goes to prove that, excepting a very trifling allowance for friction, the area of the smallest part of the tube rules the power, the value of the mixing-tube being no more than that of the smallest part. If the mixing-tube is upright, new sources of interference comes in; notably the varying specific gravity of the mixture. Except with one definite gas supply, the result is always more or less imperfect, and regular proportions cannot be obtained. This is now so well known that the upright form has been practically discarded for many years, and is now only used where the peculiar necessities of the case give some special advantage.

"The diameter of the mixing-tube is a matter of importance, as it rules the quantity of gas which can be satisfactorily burnt in any arrangement. With large flames, given a certain size of gas-jet, the diameter of the mixing-tube should be not less than ten times as great. For instance, at 1 inch pressure, a jet having a bore of 1-8th inch will pass about 20 cubic feet of gas per hour. To burn this quantity of gas, a mixing-tube is necessary 10-8ths or $1\frac{1}{4}$-inch in diameter. By the first rule this tube must be in length equal to four and a-half times its diameter, or $5\frac{5}{8}$ inches. It would appear that the mixing-tube, having 100 times the area of the gas-jet, is out of all proportion to the size necessary for obtaining a mixture of one of gas to nine or ten of air; but it must be remembered that the gas is supplied under pressure. It is therefore evident that no mere calculation of areas can be taken into account, unless the difference in pressure of the supply is also considered. A complete reversal of this law is shown in that ruling the construction of blowpipes, which I have already given in a previous paper on 'The Use and Construction of the Blowpipe.' In these, the air supply, being under a heavier pressure, is much smaller in area than the gas inlet; and, to obtain maximum power, the air-jet requires to be enlarged in proportion to the gas pressure.

"Given a certain area of tube delivering a combustible mixture, the outlet for this mixture must be neither more nor less than the size of the tube. Taking an ordinary drilled tube, such as is commonly made, and of the dimensions before given—*i.e.*, $1\frac{1}{4}$ inch bore—if the holes are drilled $\frac{1}{8}$ inch in diameter the tube will supply $10 + 10 = 100$ of these holes. In practice this rule may be modified.

"The variations from the rule, however, must be a matter of experience with each form of burner. There is also the fact that with small divided flames it is not necessary to mix so large a proportion of air, as each flame will take up air, on its external surface; but in this case the flames are longer, hollow, and of lower temperature. As a matter of actual practice, where a burner is used which gives a number of flames or jets, the diameter of the mixing-tube does not need to exceed eight times the diameter of the gas jet; the remainder of the air required being taken up by the surfaces of the flames.

"Wire gauze, made of wire the thickness of 22 iron wire gauge, 20 wires to the linear inch, and tinned after weaving, has an area in the holes of 1-4th its surface. By calculation, the area of a gauze surface in a burner should, therefore, be taken at four times that of the tube, and our standard of $1\frac{1}{4}$ inch tube requires a gauze surface of $2\frac{1}{2}$ inches in diameter. This rule is subject to variation in burners of a small size, owing to the air that can, if required, be taken up by the external surface of the flame, which, of course, is much greater in proportion in a small flame than in a large one. Where the diameter of the gauze is, say, not over one or two inches, the theoretical maximum gas supply may be exceeded, and a varying compensation is necessary with each size. My rule is intended to apply to burners of larger diameters, where the external air supply plays a comparatively unimportant part.

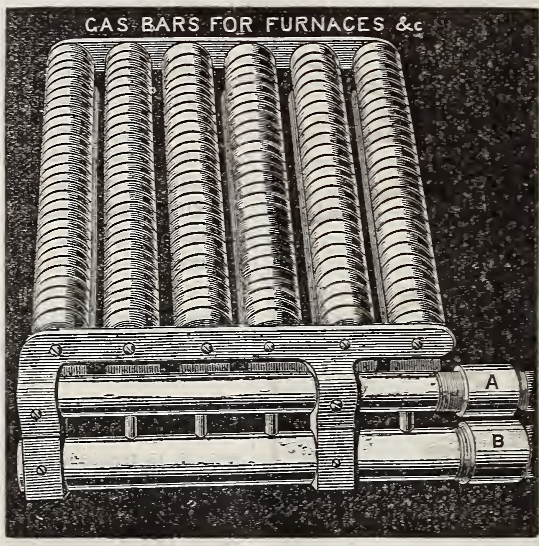
"It must be remembered that burners of this class, which burn without the necessity of an external air supply in a flame which is solid, require the mixture to be correct in proportions. A very slight variation makes an imperfect flame. Not only does the gas-jet require to be adjusted with great precision, but it also needs more or less adjustment for different qualities of gas. An ordinary hollow or divided flame is able to take up on its surface any deficiency of air supply; but with the high-power solid flames the outside surface is small, and the consequence is that one of these burners, adjusted for gas of poor quality, may, when used with rich gas, give a long hollow or smoky flame, unless the gas-jet be reduced in size. When perfect, the flame shows a film of green on the surface of the gauze; and if a richer gas is used, the green film lifts away. To cause this to fall again, and to produce a solid flame, it is necessary to take out the gas-jet, and tap the end with a hammer until, on trial, it is found correct. If too small, the green film lies so closely as to make the gauze red hot. Where the 'tailing up' of the carbonic oxide flame is objectionable, there is no practical difficulty whatever in constructing these burners as a ring, with an air supply in the centre, which greatly reduces the length of the 'tail.' In practice it is a decided advantage to have a centre air-way in all burners of more than about 2-in. diameter, as it enables the injecting tube to be slightly shortened, and lessens the liability of the green film to lift with varying qualities of gas. In this class of burner I have adopted the small central air-way as a decided improvement in the burners."

In such processes as the roasting of coffee, chicory, grain, &c., a diffused heat is necessary, but of much greater intensity than can be obtained with economy from heated air. In these cases the application of a direct flame is necessary, and it may be in actual contact with the substances to be heated, provided these are kept in constant and rapid motion.

The use of a revolving cylinder brings in complications with any burner which is supplied with gas at ordinary pressures without any artificial air supply, as the currents of air caused by the motion of the cylinder interfere with the satisfactory working of any burner, and the air supply must be either protected from draughts and irregular air currents, or the air must be applied artificially from some independent source. One exceedingly good way of making any burner work, independently of the currents caused by a revolving cylinder, is to apply the flame inside the cylinder at the centre, making the substances to be heated to fall in a continuous stream through the flame. This system is not applicable to fine powders, or sticky substances, as it necessitates the perforation of the cylinder, to allow of the escape of products of combustion.

For this class of work, a very concentrated heat is not desirable, as a rule, and a slit, or perforated burner is preferable. Of this class of burner I have here a sample, which is not only new in its constructive details, but has great and special advantages for many purposes. As you see, it resembles a number of ordinary furnace bars, with this difference, that each bar is a burner; in fact, it is an ordinary furnace grate, which supplies its own fuel. With the usual day pressure of gas, = 1 inch of water, this burner will, at its maximum power, consume about 100 cubic feet of gas per hour, per square foot of burner surface, and as it can readily be made almost any form or size, its adaptability for a great number of uses is evident. I have made it in many sizes and shapes, to give flames from ½ inch wide by 5 feet long, to large square or oblong blocks. By applying a blast of air at the ordinary gas jets, and supplying the gas by a separate pipe, or series of pipes, below the open end of the burner, this can be converted into a furnace of extraordinary power. It is quite possible to burn as much as 2,000 cubic feet of gas per hour, per square foot of burner surface, producing a heat sufficient to fuse any ordinary crucible. You see its power when I place a bundle of iron wire in the flame; it is, in fact, a concentration of hundreds or thousands of powerful blowpipe flames in one mass. It has also this advantage, that with a blast of air it will burn and work equally well any side up, and the flames can therefore be directed straight on their work without loss. It is, in one form or another, almost a universal burner, as it can be readily adapted to almost any purpose, from tempering a row of needles to making steam for a 200 horse-power steam-engine. It is easy to make, easy to manage, practically indestructible, and for commercial purposes has, I think, a general adaptability which will bring it, in one form or another, into almost universal use. I may say that when we are in a special fix, this has in every case landed us out of the difficulty.

Fig. 2.



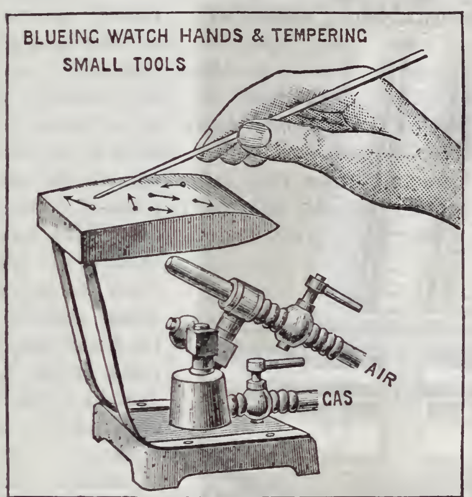
For heating large plates of metal equally, for drying paper impressions for stereotypers, hot-pressing hosiery, crumpet baking, working up plastic masses which can only be worked hot, and work of this class, a number of separate flames equally diffused under the whole surface of the plate are necessary to equalise the heat, unless the plate is very thick, and these are better if produced by a mixture of gas and air, but in heating wide plates one difficulty must always be remembered, the burnt gases from the centre flames can only escape by passing over the outer flames, and therefore a space must be left between the top of the flame and the plate, or the outer flames will be smothered and make a most offensive smell.

In hosiery presses, printers' arming presses, and many others, the top plate also requires to be heated. The best way to do this is to use a number of blowpipe flames directed downwards. In many cases the supply of air under pressure is a practical difficulty and objection. This is overcome, to a certain extent, by the use of a thick upper plate with a number of horizontal holes, into which a Bunsen flame is directed. In every case I have seen, without one single exception, the holes are either too small, or the burner is placed too close, and the consequence is that the gas, instead of burning inside the holes, as it should, passes through partially unburnt, and is consumed at the opposite end, where it is absolutely useless, the flame not being in contact with or under the surface to be heated, and therefore doing no work. In hosiery presses this is a great objection, as the holes are so long that an equal heat is simply impossible, and the only remedy is to use a blowpipe flame, which forces sufficient air in with the gas to ensure combustion where the heat is necessary. The same remark applies to crape and embossing rollers.

For the production of heat in confined spaces and difficult position, the use of an artificial blast of air is becoming an acknowledged necessity, and the small Roots blowers now made for such purposes, and driven by power, are coming rapidly into use.

Sometimes a plate is required to be heated to a high temperature in one confined spot,

FIG. 3.



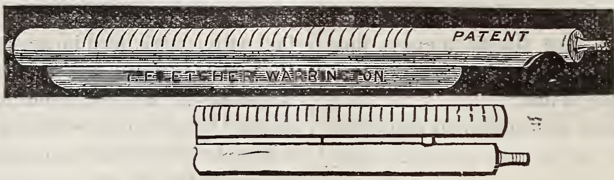
and, as a example of this, I may take the blueing of the hands of watches. For this purpose I have made several arrangements, and perhaps the best is a thin copper plate, bent down at one side to a right angle. In this angle, underneath is directed a very fine blowpipe flame on one spot, and the hands are passed singly over this spot until the colour comes, when they are instantly pushed over the edge. I have here the arrangement which is generally used for this purpose. For the blueing of clock hands, a larger and more equally heated surface is required, and this can be obtained by a small powerful burner without a blast of air, using a rather thicker plate to equalise the heat. The same arrangement may be used with advantage for tempering small cutters for ornamental turning, penknife-blades, &c., and in these cases the cooler part of the plate is of great value, as it enables the thicker parts to be slowly and equally heated up; the application of a mechanical arrangement to pass the articles to be heated in a regular succession is a matter easily managed.

Among other things which have several times come under my notice, may be mentioned cremation furnaces, but I have not yet met with, or been able to devise, any burner for ordinary coal gas which has worked satisfactorily. This fuel is apparently unfitted for the work, and the best arrangement I know is a number of pipes delivering ordinary "producer" gas from the Wilson or Dowson generators, in exactly the same way as is at present used for firing horizontal steam boilers. For heating book-finishers' tools, a ring-flame is the simplest, the tools being supported a little distance above the flame; the usual plan of heating a plate, and placing the ends of the tools on this, necessitates at least double the gas consumption as compared with an open flame. For type-founding machines, bullet moulding, stereotype metal melting, solder making, lead melting, &c., one burner, or rather one flame, should be used of a suitable power for the work, and this should be as perfect and of as high a temperature as possible to ensure economy. It is now a simple matter, owing to recent researches in the theory of heating burners, to obtain flames of any power without practical limit, which, without any artificial air supply, will do all which is necessary in this class of work, and the required arrangements are exceedingly simple. With these trades may be classed, also, the concentration and distillation of acids and liquids boiling at a high temperature, and we may also include baths for tinning small articles, and the tinning by fusion of sheet copper, the same burners being applicable, and perfectly suited to all these requirements, unless the tinning baths are long and narrow, in which case the furnace-bar burners again come to the front as the best; as, if we are to use gas economically, the flame must be the same shape as the vessel to be treated.

We may now consider the heating of blanks for stamping, hardening the points of spindles, finishing the ends of umbrella tips, and work where a small article, or a small part of any article, has to be heated to a high temperature with speed and certainty. For these a long and narrow flame is necessary, and I may mention that in cases where a high speed of delivery is required, and a small part only has to be heated, such as, for instance, in the hardening of the points of spindles for cotton machinery, I have made burners giving a flame of exceedingly high temperature only ¼-inch wide and 5 ft. long. This flame is produced by the assistance of a blast of air, and is of sufficiently high temperature to fuse the spindle in a few minutes.

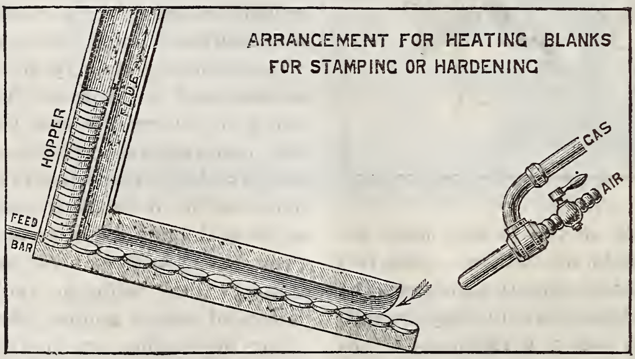
The points only project over the flame, and the spindles are carried mechanically at such a speed that at the end of the 5 ft. traverse they are red-hot, and drop into water. More than one hundred are in the flame at once, lying side by side.

Fig. 4.



For heating blanks for stamping, the furnace bar-burner is perfectly suited, and in this work the shoot supplying the blanks to the machine should be made of two fireclay sides, with an opening for the flame between the shoot and flame being placed at a sharp angle, to prevent risk of the blanks sticking or over-riding each other. A blowpipe may also be used with good effect, as shown in the above engraving, and in many cases it is preferable and much easier to manage.

Fig. 5.



In some cases, the direct contact of the flame would spoil the articles to be heated, and instead of the arrangement mentioned, a tube of iron, fire-clay, or other suitable material is heated, and the articles are passed through it. This system of continuous feed, through a tube, has been applied to the firing of small articles of pottery, and might possibly be well adapted, amongst other things, to the production of gas-burners.

Where the contact of air with the heated articles is injurious, many plans have been tried to keep the ends closed as much as possible, but I believe no more perfect and simple seal against the admission of air can be devised than to turn a jet of pure gas, unmixed with air, into each end of the tube. This is an absolute seal against the entry of oxygen in an uncombined state; free oxygen cannot exist at a very high temperature in the presence of coal gas.

For many trades there is a demand for hardened and tempered steel wire, either round or flattened, and the production of this has led to many attempts to obtain a satisfactory continuous process. The common method now, which is worked as a "secret" process by most firms, is to pass the wire through a tube to heat it, as already described, and to run it direct from the tube through a hole in the side of a box filled with oil, the hole being packed with asbestos, to prevent leakage; from this it is passed through another similar hole on the opposite side, either over a plate heated to the right temperature, or over a narrow open flame of sufficient length and power to give the correct heat for tempering.

Where absolute precision is necessary, the gas supply must be adapted by an automatic regulator on the main, to prevent the slightest variation of heat. Once adjusted, the production of flat and round spring wire by the mile is an exceedingly simple matter. It is quite possible to obtain absolute precision in temperature by a proper adjustment of the gas pressure, and as this is, for tempering steel articles and some other purposes, a matter of great importance, it is worth some consideration. No pressure regulator alone will give an absolutely steady supply; but if we put on first a regulator, adjusted to the minimum pressure of supply, say 1 inch of water; and then fix another on the same pipe, adjusted to a slightly lower pressure, say 9-10ths of an inch, the first regulator does the rough adjustment, and the second one will then give an absolutely steady supply, providing always that the regulators are both capable of passing more gas than is likely to be ever required. No regulator can be relied on for absolute precision, if worked up to its maximum possible capacity.

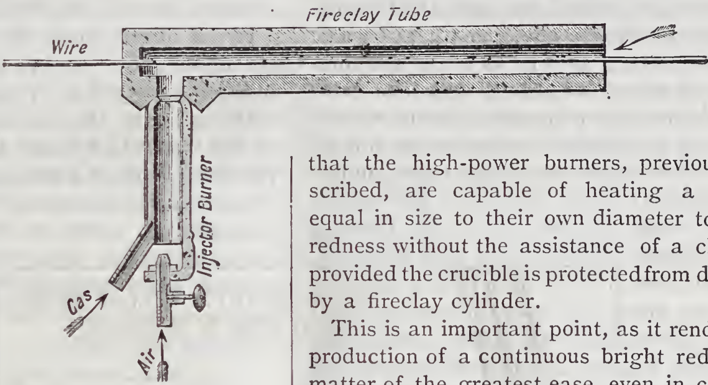
Amongst other applications of a long narrow flame of high power, may be mentioned the brazing of long lengths of tube, in fact the application of flames of this form, with and without a blast of air, for different temperatures, are almost endless.

The thousands of uses to which blowpipes are adapted are so well known, that they need no mention, except the curiously ignored fact that the power of any blowpipe depends on the air pressure. A compact flame of high temperature cannot be obtained except with a heavy air pressure, and the ignorance of this fact has caused an immense number of unexplained failures. Many people think that one blower is as good as another, and expect that a fan giving a pressure equal to, say, the height of a 2 inch column of water, should do the same work as a blower giving a pressure ten to twenty times as great. The construction and power of blowpipes, with the laws ruling the proportions and power, will be found in an article on "Blowpipe Construction," published in *Design and Work*, March, 1881, and as the matter is there fully treated, no further reference to the subject is necessary.

In the more recent forms of gas-engine, the charge is exploded by a wrought iron tube, heated to redness by the external application of a gas flame. This, although considered satisfactory by the makers, appears to me to be an exceedingly crude way of getting over the difficulty; and I offer it as a suggestion, that a very small platinum tube shall be used instead of iron. This, if made with a porous or spongy internal coating, would fire the charge with certainty, at a lower temperature than iron, and it could be made so thin and small in diameter, without risk of deterioration or loss of strength, that an exceedingly small flame could be used to heat it up. As it would be fully heated in a very few seconds, the delay in starting would be obviated.

There are many purposes for which a red heat is needed for slow continuous processes on a small scale, such as case-hardening small steel goods, annealing, heating light steel articles for hardening, and a great variety of other similar processes. This, until recently, has required the use either of a rather complicated furnace, or a blast of air under pressure, to increase the rapidity of combustion. Since the conclusion of my experiments on the theoretical construction of burners, I have found that the high-power burners, previously described, are capable of heating a crucible equal in size to their own diameter to bright redness without the assistance of a chimney, provided the crucible is protected from draughts by a fireclay cylinder.

Fig. 6.



This is an important point, as it renders the production of a continuous bright red heat a matter of the greatest ease, even in crucibles of a comparatively large size. Where the heat is steady, and certain not to rise above a definite point, it can safely be used for such purposes as hardening penknife blades, and other articles which are very irregular in thickness, the thin edges not being liable to be burnt or damaged by over-heating.

For the highest temperatures air under pressure is a necessity, as we require a large quantity of gas burnt in as small a space as possible with the maximum speed, and, given this air supply, we are very little hampered by conditions, as an explosive mixture may be blown through a gauze into a fireclay chamber, closed, except so far as is necessary to allow the escape of burnt gases. The speed of combustion is limited only by the speed of supply of air and gas, and by increasing these there is no practical limit to the heat which can be obtained. When we have to do with the reduction of samples of refractory ores, testing the comparative fusibility of different samples of firebricks, or alloys, &c., the use of an explosive mixture blown into and burning in a close chamber is invaluable, and the ease and certainty with which any temperature may be obtained has led to great discoveries, and the revolutionising of many commercial processes. Recent experiments have proved that, by a modification in the form of the well-known injector furnace, an enormous increase of temperature may be obtained. I have, in actual work, obtained the fusing point of cast-iron in two minutes, starting all cold, and have fused every furnace casing I have yet been able to produce. If infusible casings can be made, I think I am not overstating facts in saying that any temperature required can and will eventually be obtained with the greatest ease. What the limit is I have as yet not been able to discover.

There is one more application of gas, as a fuel, which, discovered and published by myself some two years ago, has yet to become generally known, and in some special processes may prove exceedingly valuable. This is the addition of a very small quantity of coal gas, or light petroleum vapours, to the air supplied by a blower or chimney pull, to furnaces burning coke or charcoal. The instant and great rise in temperature of the furnace, and the greater stability of the solid fuel used, are extraordinary. This is, in fact, a practical application of the well-known "flameless combustion," the only signs that the gas is being burnt being a great rise in temperature and a decreased consumption of the solid fuel; in fact, if the gas is in correct proportion, the solid fuel remains unburnt, or nearly so, in spite of the high temperature. In cases where a sudden rise in temperature is required in a furnace, or where the power is deficient, this method of supplementing and increasing the heat will be found of very great service, and processes liable to be checked by making up a fire with fresh fuel can be carried on without check, even after the solid fuel has almost entirely disappeared.

That a solid fuel is quite unnecessary, I will prove in a very simple manner, by burning a mixture of coal gas and air without a flame, in a bundle of iron wire. The heat is sufficient to fuse the wrought iron with ease, and the glare inside the bundle of wire is painful to the eyes. The same result could be obtained by a pile of red-hot lumps of firebrick, and the same heat obtained also without a trace of flame.

It is not possible to enter fully into such a wide and important subject in a single lecture, and the suggestions now given are simply hints for the guidance of those who need or desire to experiment. No doubt we shall have, after a time, some text-books and other literature on this subject, which is one of great importance to many industries; and it is necessary for experimental work and applications to new industries, that the experimenter shall not only be able to purchase special burners, but that he shall have fundamental laws laid down which will enable him to construct them for himself, so as to have his experiments under his own control. The difficulty in the way of literature on the subject is that those few who have worked in the matter are busy men, with little time which is not already fully employed.

Pioneers on new ground have a great liability to generalise and jump at conclusions, and the necessary exact work and detail must, to a great extent, be left to those who follow on tracks already roughly marked out.

Of the special trades which have come under my observation, I have only had time to mention a very few. It appears to me that there are very few manufacturing processes of any kind which could not be simplified by the use of gas as a fuel, from the production of electric light apparatus to the manufacture of explosives, cotton stockings, beer, catgut, glue, umbrellas, ink, fish-hooks, medals, stained glass windows, brushes, and other trades equally various, which come daily under my own notice.

DISCUSSION.

The CHAIRMAN, in inviting discussion on the paper, said it was well known that the general laws guiding the combustion of gaseous fuel had been laid down by Scheurer-Kestner, St. Claire Deville, and Frankland, and they all knew that the late Sir William Siemens had obtained splendid results by the use of gaseous fuel. Quite apart from the industrial application of gas, its use was of great importance, especially at a time when so many efforts were being made to get rid of the nuisance arising from smoke. Perhaps the most interesting point developed in the paper was the fact that explosive mixtures of gas and air could safely be introduced into a chamber, provided it was previously heated. In many of the appliances, ordinary illuminating gas was employed, and that, of course, was not the most economical method; but these were put forward rather as labour-saving appliances than as being economical in every respect. He could speak with real gratitude of Mr. Fletcher's labours, for he was constantly using several of his furnaces in the Mint, for ordinary assaying purposes. With regard to the difficulty he had found in getting a material sufficiently fire-resisting to stand very high temperatures, he would ask him if he had tried lime, and particularly the very refractory kind resulting from the ignition of dolomite. That was a material which withstood the melting of platinum, even with a whole battery of oxyhydrogen blowpipes. He must say that Mr. Fletcher's fertility of resource was sometimes almost a cause of embarrassment to chemists and metallurgists, for he (the Chairman) was frequently asked by students whether they should procure a particular form of burner, or wait a few days for the improvement Mr. Fletcher would be sure to make; but still that in no way diminished the gratitude they must all feel towards him.

Mr. W. R. E. Coles said he could endorse from his own experience what the Chairman had said of the value of Mr. Fletcher's apparatus for laboratory purposes; and he also knew that some of his cooking stoves were very effective. He was able to state that gas was coming very considerably into use for heating purposes, and it was not at all unreasonable to look for its introduction in towns for many purposes for which coal was now used, producing a great deal of smoke, and being objectionable in many respects. One recent introduction of gas, since the Smoke Abatement Exhibition at South Kensington, was for bakers' ovens, which had not only the advantage of preventing smoke, but it made the preparation of the bread more cleanly, and improved the hygienic condition of the bakehouse. He looked forward to the time when there would be very considerable improvements in the heating of towns.

Mr. Bower remarked, that he had used Mr. Fletcher's furnaces for a long time in his laboratory as an amateur; and so far from finding fault with the improvements which he made from time to time, he was quite sure that each new one gave him greater power than he had before. However they might dislike to have an old friend turned out and replaced by a new one, yet if the new one was better, they should certainly have it. But they would never get the full benefit of these improved burners and furnaces until they had a higher and more constant pressure of gas. He only spoke as an amateur, but manufacturers must feel the difficulty still more; they did not want to be plagued by having at one time a pressure of 1 inch, and at another of more than 3 inches, thereby continually altering the temperature of the furnace they were using. Again, he did not think the full benefit of gas would ever be obtained until there were two kinds supplied, the higher quality for illumination, and the second, which though inferior for lighting purposes, was equally efficient for heating, being supplied from a separate meter, and at a cost which would bring gas fuel into general use.

Col. Meakins, M.P, said it would be impossible for a gas company to maintain the same pressure constantly in the mains without increasing leakage, and the amount of gas unaccounted for, thereby decreasing its profits, and thus preventing the supply becoming cheaper. Perhaps Mr. Fletcher could devise a pressure-giving governor which could be applied by each individual for his own purposes, taking the gas at the normal pressure, and adding to it such pressure as he might wish by his own governor. He did not know if this was a practical suggestion, but if it were, no doubt Mr. Fletcher would be able to put it into shape.

Mr. Haughton protested against the idea that gas companies could never be expected to make their pipes tight. Much had already been done in the way of preventing leakage, which gas companies used to say was unavoidable; and where they had gone to the necessary expense, they had stopped it entirely. Those who used gas in the arts, and in chemical laboratories, were specially indebted to Mr. Fletcher for his many improvements, and he had also conferred many benefits on those who used it in their kitchens; he would be adding still further to the obligations under which they were already, if he could devise an apparatus for grilling over the flame; for none of the gas cookers he had yet seen would grill properly either a steak or a chop. You could cook meat under the flame, but you could not grill it, the radiated heat not being sufficient for the purpose.

Mr. Johnson said he had a little apparatus, 16 in. square and 20 in. high, in which he could grill a chop or steak in the most satisfactory way, as was testified by all those who had tried the results.

Mr. Coles added that he had just been informed by Mr. Kinnear Clark that there were several very efficient grillers, in some of which the meat was placed over the flame, and in some under.

Colonel Campbell asked Mr. Fletcher whether he thought there was a possibility of using the gas from peat as a source of motive power. He had lived a long time in the west of Ireland, where the manufactures which had once existed had been destroyed, and he would not say anything about the possibility of their being revived; but there was no part of the world where traction, either by land or water, was not required, and in the district he referred to, if peat gas could be used for gas-engines, it could be had in any quantity. He knew the calorific power was small, but he believed it was as nearly as rich in hydrogen as coal gas, and if it could be made to serve as a motive power, there would be a large future for it.

Mr. Gumpel said there were many places in the country where coal gas was not available, and he should like to know if the gas produced by the "Alpha" or the "Sunlight" machine could be used with Mr. Fletcher's apparatus.

Mr. FLETCHER, in reply, said he understood the Chairman wished to know whether his assistants should buy a burner now or wait a couple of days for the next improvement. He could only say that if they wanted the burner, they had better procure the best they could; but if they did not want it, they had better wait. If this were meant as a hint to him to discontinue his experiments, he could only say it would have no effect. He had tried lime casings, and found that he required a new case every time. If such casings were used in Professor Roberts's laboratory, his assistants would not have to wait two days, for they would be sure to constantly have the latest improvement. As to the pressure of gas, that was out of his department. A pressure-giving governor was equivalent to what was known as a power-meter; a meter driven by a weight which would give pressures considerably above what were now obtained. This apparatus could be obtained from several makers. The grilling of meat over a flame was already done successfully, and the appliances were to be had. He had had no experience in the use of peat gas, and could not, therefore, say anything about it, as he confined himself entirely to that which he had actual knowledge of. There was a pretty extensive peat-bog near to where he lived, and if ever it were utilised, and peat gas made he might be able to say something about it.

The CHAIRMAN then proposed a vote of thanks to Mr. Fletcher, which was carried unanimously, and the proceedings terminated.

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION.

The following Sub-Committees have met at the Society of Arts since the meetings recorded in last week's *Journal*:—

FOOD.—SUB-COMMITTEE C.

Wednesday, January 23rd.—Present: Sir Henry Thompson, in the chair; Professor A. H. Church; Mr. H. Trueman Wood.

SICK AND AMBULANCE.

Wednesday, January 23rd.—Present: Director-General Crawford, A.M.D., in the chair; Deputy Surgeon-General Bostock, C.B.; Brigade-Surgeon W. G. Don, A.M.G.; Surgeon-Major G. J. H. Evatt, M.D., A.M.D.; Mr. John Furley; Mr. V. B. Barrington-Kennett; Surgeon-General W. A. Mackinnon, C.B., A.M.D.; Director-General Reid; Dr. J. C. Steele; Mr. H. T. Wood.

DRESS.

Thursday, January 24th. — Present: Mr. F. Treves, in the chair; General Erskine; Mr. C. M. McHardy; Deputy Surgeon-General Jeffrey Marston, A.M.D.; Mr. O. H. Morshead (for Mr. G. D. Ramsay, C.B.); Mr. Samuel Osborn; Mr. T. Thorn; Surgeon-General Townsend, C.B.; Mr. H. T. Wood.

THE DWELLING HOUSE.—GROUP III. SUB-COMMITTEE A.

Thursday, January 24th.—Present: Captain Douglas Galton, C.B., F.R.S., in the chair; Mr. H. H. Collins; Dr. W. H. Corfield; Mr. J. Bailey Denton; Mr. Rogers Field; Dr. E. Frankland, F.R.S.; Mr. Charles Heisch; Mr. Baldwin Latham; Mr. Shirley F. Murphy; Mr. George Shaw; Mr. H. T. Wood.

THE DWELLING HOUSE.—GROUP III. SUB-COMMITTEE C.

Friday, January 25th.—Present: Prof. T. Hayter Lewis, in the chair; Mr. A. T. Atchison; Mr. W. R. E. Coles; Mr. Charles Heisch; Prof. W. Chandler Roberts, F.R.S.; Mr. E. C. Spagnoletti; Sir Harry Verney, Bart., M.P.; M. C. Greville Williams, F.R.S.; Mr. H. T. Wood.

WORKSHOPS.

Saturday, January 26th.—Present: Dr. George Buchanan, in the chair; Dr. J. H. Bridges; Mr. Alexander Redgrave, C.B.; Mr. Warington Smyth, F.R.S.

LABORATORY.

Monday, January 28th.—Present: Sir Joseph Lister, Bart., F.R.S., in the chair; Dr. George Buchanan, F.R.S.; Mr. Watson Cheyne; Mr. H. T. Wood.

SCHOOL AND EDUCATION.

Monday, January 28th.—Present: Lord Reay, in the chair; Mr. B. St. John Ackers; Mr. Alfred Bourne; Mr. E. N. Buxton; Rev. Canon Cromwell, M.A.; Sir Philip Cunliffe-Owen, K.C.M.G.; Dr. J. H. Gladstone, F.R.S.; Rev. Thomas Graham, D.D.; Mr. T. E. Heller; Mr. A. C. King; Colonel W. Nassau Lees; Lieut.-Col. W. R. Lewis, R.A.; Inspector-General F. G. Mouat, M.D.; Mr. T. Nordenfelt; Mr. Owen Roberts, M.A.; Rev. T. W. Sharpe; Mr. H. T. Wood.

MEMORANDUM FROM THE SUB-COMMITTEE ON "FOOD."

The following is the official classification of Group 1 of the Exhibition, in which are comprised Classes 1 to 12:—

Class 1.—Selected displays of unprepared animal and vegetable substances used as food in various countries. Stuffed specimens of animals, birds, &c. Models, drawings, and illustrations of the same.

Class 2.—Prepared vegetable substances used as food, including tin, compressed, and preserved fruits and vegetables. Bread, cakes and biscuits of all kinds.

Class 3.—Prepared animal substances used as food in a preserved form—tinned, smoked, salted, compressed and prepared animal foods of all kinds. Food produced by insects, such as honey, &c.

Class 4.—Beverages of all kinds—*(a)* Alcoholic; *(b)* non-alcoholic; *(c)* infusions (tea, coffee, cocoa, chocolate, &c.).

Class 5.—New varieties of food, food for infants, food for invalids, new concentrated foods of all kinds.

Class 6.—Cookery practically demonstrated—Economical cooking, workmen's and other kitchens, cheap restaurants, bakeries, cafés, foreign cookery, &c.

Class 7.—The chemistry and physiology of food and drink. The detection of adulteration, materials used as adulterants, analyses, food constituents and equivalents, tables, diagrams, &c.

Class 8.—Diseases due to unwholesome and improper food. Drawings and models of animal and vegetable parasites, &c.

Class 9.—Practical dietetics. Army and Navy rations, prison and workhouse diet, foreign dietaries, &c.

Class 10.—Publications and literature, models and diagrams relating to Group 1.

Class 11.—Apparatus and processes for conserving, storing, conveying, and distributing fresh foods of all kinds.

Class 12.—Machinery and appliances for the preparation of articles under Group 1.

In the first three classes are included what may be termed the raw materials of food. In Class 1, specimens of the actual foods themselves may, when possible, be exhibited, and when this cannot be done, they should be represented by models. The exhibition, for instance, of uncooked meat would be neither desirable nor practicable, but any exhibits tending to give information as to the various animals used for the food of man, their nature, habits, characteristics, &c., will be welcomed. In the case of cereals and other food-stuffs, the raw grain and the products may be exhibited. Fruits and vegetables will for the most part be represented by models, but the Executive are also considering the establishment of periodical shows, at which the articles themselves can be exhibited (and sold). Specimens of foreign fruits, &c., will be gladly received for this purpose. Models of the different fruits imported in a dried or preserved state into this country are specially desirable, in order to illustrate their natural forms.

The classification sufficiently indicates the class of exhibits desired for Classes 2 and 3. It may be added that, where possible, preserved provisions should be put up in bottles, so that they may be visible, not in tins. Not more than three specimens of each kind should be sent in.

In Class 4 are to be included every sort of drink, including milk, as well as those enumerated in the classification. It will take in all exhibits connected with the production of tea, coffee, and other beverages (except those relegated to Class 12), and all illustrating new or little-known beverages, such as Maté or Paraguay tea, Coca, Koumiss, &c.

The exhibition, in Class 5, will naturally also be capable of being placed in one or other of the previous classes, but this arrangement has been adopted with the view of giving prominence to any novelties. Food for children and invalids will form a special feature in this class.

As regards Class 6, the Committee think it well to draw attention to the announcement already made by the Executive, that, as refreshments come within the scope of the Exhibition, all methods of preparing the same, whether by cookery or otherwise, and the display and sale thereof, will be matters of separate arrangement with those wishing to be represented in this section.

One principal object to be kept in view in this department of the Exhibition will be the diffusion of information as to the economical cooking of food, and the best way of utilising the various kinds of food available to the people of this country. Cheap cooking, both at home and by means of public kitchens, should be amply illustrated. For the purposes of comparison there should be illustrations of every class of foreign cookery, not only of the luxurious sort, but of that practised in the homes of the well-to-do, of the middle class, and of the poorer classes, in foreign countries. As a matter of interest, and with the object of diffusing information on the manner of life of nations differing yet further from ourselves, the Committee hope that means may be found for exhibiting the practice of Eastern cooks, Chinese, Japanese, Indian (Mohammedan and Hindoo), &c.

Bakeries will be included in this class, and the Committee hope that the fittings and appliances of the most modern establishments (both English and foreign) may be fully shown.

The object of Classes 7 and 8 is to diffuse popular information as to the nature, constituents, uses, and adulterations of food. Exhibits illustrating these and similar points will be welcome. The Committee trust that the Science and Art Department will assist this portion of the Exhibition by lending (and supplementing) one of the collections formed by Professor Church.

As regards the last item in Class 8, it should be noted that parasites or other organisms injurious in any way to food or its sources are included.

As regards foreign dietaries in Class 9, the Committee consider that this expression must be taken in its widest sense, and as including the food of savage races all over the world. It would therefore comprise specimens of the animal and vegetable substances used as food, beverages, stimulants, &c., by savages or native races of low civilisation, both in the raw and prepared condition, together with appliances and utensils of all kinds used in their manufacture or consumption. Models and drawings illustrative of the subject would also be desirable. As examples may be mentioned, sago, and its native manufacture by Malays, natives of New Guineas, &c.; cassava, and its manufacture, in British Guiana; taro, the Polynesian food, and the manfacture of roi from it; kaava and kaava bowls of Fiji and elsewhere. The Committee hope that the materials for a valuable ethnological collection of this sort would be forthcoming from private owners in England.

The exhibits admissible to Class 10 are clearly indicated in the classification.

Classes 11 and 12 are added as separate classes, because it is necessary that all machinery should be placed together in one gallery where the motive power is provided. Among the processes which the Committee hope to see illustrated, may be mentioned methods of cold storage and transport of fresh meat, ice making, dairy operations, the preservation of food, making bread, biscuits, &c., the manufacture of confectionery, of condiments, of coca and chocolate, the production and bottling of aërated waters.

GUTTA-PERCHA.

By James Collins.

(Continued from p. 150.)

The trees yielding gutta-percha are very restricted in their geographical distribution. Gutzlaff defines the limits as 6° N. and S.L., and 100° to 120° E.L., but I am inclined to think this area much too wide. In this I am supported by Captain Lingard, who has traded largely in gutta-percha, and collected it on the spot. He gives the limits 4° N. and 3° S., still further restricting the finer varieties to 4° 50′ N. and 1° S., with a temperature whose outside limits is 66° to 90° Fahr., and a very moist atmosphere. The lower kinds, of course, grow outside of these circumscribed limits, and are found near the sea coast on low but not swampy ground, whilst the best varieties grow inland on hill slopes and in groves, surrounded by other forest trees, at an elevation said to be from 100 to 600 feet above the sea. Gutta-percha trees are indigenous to Singapore, although only two or three are now to be seen as curiosities. In that island the mean total rainfall for five years ending 1873 was:—1869, 90·63 in.; 1870, 123·24; 1871, 109·45; 1872, 75·30; and in 1873, 85·60 inches. This rainfall is variable at different periods, and the year may be divided into three periods of four months each:—

1st. From January to April, during which the rainfall is very variable and uncertain.

2nd. From May to August, which may be termed the dry season, and is the period, as a rule, in which the rainfall is least.

3rd. From September to December, which may be called the wet season, and during which, as a rule, the rainfall is greatest.

As to temperature for the same period:—The highest was in 1869, 92°; 1870, 93°; 1871, 91°5′; 1872, 92°; 1873, 92°5′. The lowest was in 1869, 69°; 1870, 69°; 1871, 69°; 1872, 67°; 1873 68°5′.

It appears, therefore, that gutta-percha trees thrive best where they have a light loamy soil, at the foot or slopes of hills, surrounded by primitive jungle, and with a moist temperature not rising above 95° or sinking below 66° Fahr.

The collection of gutta-percha generally takes place directly after the rainy season is over, as in the dry season the gutta does not flow so readily; during the rainy season much gutta is washed away as it flows out, and the collectors are more liable to ague and jungle fever. Often the natives go in companies, receiving advances in money, clothes, food, and tools to be afterwards deducted, although it is not uncommon that through the non-success, death, or knavery of the collectors, the trader loses both principal and interest. Natives, too, collect gutta in their own vicinities, and barter it at trading stations.

The yield of a well-grown tree of the first or best variety is from 2 to 3-lbs. of gutta-percha, whilst full-grown trees of from 100 to 140 feet high have been known to yield as much as 50 to 60-lbs. of gutta. The average yield of different varieties, differs materially, sometimes as much as 30 per per cent. Gutta-percha, too, often loses 35 per cent. of its weight in drying during the first six months after collection.

The method of extracting gutta-percha is much the same among the Malays, Chinese, and Dyaks. The trees are cut down just above the buttresses by means of "billiongs," a chisel-like axe, a "parang," or long knife with a sword-blade, 12 to 14 inches long, or an axe perfectly wedge-shaped. The last is used by Chinese, the two former by Malays; they are all of native manufacture. As soon as the tree is felled, the greatest haste is made to lop off all the branches, otherwise the gutta-percha ascends to the leaves and is thus lost. Narrow strips of bark, 1 inch broad, and six inches apart, are next cut out around the tree, except the part of the trunk buried in the ground, the contained gutta of which, about 25 per cent., is lost. The bark is then beaten with mallets, and the gutta flows slowly, changing from a yellowish white to a reddish tinge, and rapidly concreting. Bamboos, pieces of bark, &c., receive the juice as it flows. This "raw" or gutta-muntah, is collected together and pressed into a ball or slab, a hole being made in it for facility of carriage. It often reaches our market in this raw state. For the preparation of good gutta, these balls are boiled in a shallow iron pan, called a "quali," kneaded into balls or fanciful shapes, and then the result is ready for exportation. This boiling is most important if the good qualities of the gutta are to be preserved.

There is a further process which the gutta-percha has often to undergo at the port of shipment, that of "reboiling." This consists of classifying and assorting the numerous parcels, of all sizes, shapes, colours, and qualities, into certain classes. These parcels are often adulterated to an alarming extent. The Chinese are great adepts at this classification, and the custom is to mix together small parcels of different varieties, so as to produce a "standard sample." This is done by slicing the gutta, boiling in large shallow iron pans, and constantly stirring. Sometimes the juice of the lime fruit or cocoa-nut oil is added during the boiling, the former to hasten coalescence, and the latter to give a better appearance to the product. When sufficiently boiled, the gutta is taken out of the pans, pressed into large moulds, and packed for shipment.

At various periods during the last 15 years, the subject of gutta-percha and its supply for commercial purposes has engaged my attention, and a brief *résumé* of the results of these inquiries may not prove out of place. In these remarks I may have to repeat a little of what I have stated with regard to pseudo-guttas, but this I do for sake of completeness.

As will be seen, there are numerous varieties of gutta-percha, and these differ most materially in character and value. These varieties are often mixed by natives, and great harm is done thereby to a good gutta. But the greatest harm in this direction is done by the Chinese and others, at the port of shipment, by the process of "reboiling." Parcels of different varieties, particularly if of low or inferior quality, are mixed together, and a certain quantity of best gutta added to give "tone" to the parcel, and allow of its passing muster. Sometimes this "tone" only consists of a skin of good gutta over a core of bad. Now, some of these "low varieties" have no right to be classed as "gutta-percha," unless, indeed, we extend or "expand" the significance of the term so as to include such substances as kowrie gum, gambier, and cutch. This indiscriminate mixing, to a manufacturer, is a serious matter, and I believe that, in some cases, where a "fault" occurs in a cable, it arises from the fraudulent admixture in the gutta of some such resinous substance and its subsequent crystallising out. It must be borne in mind that a small per-centage of such an admixture may render a cable utterly useless at a most critical moment. That such a reprehensible practice of admixture does take place, I have had personal opportunities of observing. There are many varieties of gutta-percha which are valuable, but the mixing of these different varieties should be left to the manufacturer at home, as he alone can best judge of the mixture or blending most adapted for the purpose he has in contemplation.

That there is a necessity for boiling gutta-percha before sending it home seems to me conclusive, and if not properly performed by the natives it should be done by the merchants before shipment, and for the following reasons:—

Pure gutta-percha, as it flows from the tree, is a viscid fluid, acquiring milkiness and concreteness on exposure to the atmosphere. By the absorption of oxygen it splits up in time into two resins, known as *albine* and *fluavile*. This proneness to resinification in gutta-percha I have often noticed and experimented upon, and that by boiling the gutta-percha as soon as possible after collection this is arrested, I have proved both at home and abroad. Thus if a piece of "raw," or gutta-muntah, be taken, and the half be well boiled and pressed, it will retain its good qualities, whereas the other will become a resinous mass. Thus, through the gutta not being thoroughly well boiled at first, what would otherwise be of good quality becomes deteriorated in quality, or absolutely useless.*

In preparing gutta, therefore, for market, all large blocks should be cut open, well boiled, and pressed in the form of small thin slabs. This should also be done with gutta-muntah, and thus not only will freight be saved, but gross adulteration and depreciation of value by chemical changes will be reduced to a minimum.

In my paper at the Society of Arts, on "India-rubber," and my report on the same subject to the Secretary of State for India, I gave the opinion that it was not necessary to cut trees down to obtain the India-rubber, and that trees, after allowing a certain period of rest, could again be "tapped." This, where carried out as I indicated, has not only proved practicable, but also a great saving, and a much more economical method of working a forest.

The native evidence against "tapping" gutta-percha trees is nearly overwhelming. They insist on the necessity of cutting down the trees. This may arise from indolence, a wish at one operation to obtain the greatest possible quantity without a thought to future supply, or from the want of sufficient aggregation of the trees within a reasonable distance, to obtain a sufficient quantity of gutta to repay collection. Gutta-percha does not flow so readily as Caoutchouc does, and also more rapidly concretes. The yield in the rainy season is nearly double that of the dry season, due possibly to two reasons, first, that nature has not yet been called upon to use up the gutta-percha for the elaboration of new tissues, or, second, the greater amount of moisture causing greater fluidity in the gutta-percha milk. The Dutch Government tried to induce the natives to practice "tapping," but without success, and "boring," as is practised with the sugar maple, met with a like result. The question can only be set at rest in a well regulated plantation.

The many and various purposes to which gutta-percha is now applied are legion, rendering an enormous and regular supply absolutely necessary. For our commercial supplies of any staple article, we cannot long depend on the spontaneous products of the forest; a statement that, to an economic botanist, has the full force of an axiom. These products are collected in a most reckless and destructive manner, and then only when other and better, or, at least, easier means of livelihood fail. The requirements of civilisation and space for agricultural pursuits, jungle fires, &c., are great destructive agents to the existence of forests. Often have I seen a spot which had cost nature centuries to fill with her wondrous handi-

* *Vide* "Remarks on Balata and other Pseudo-Guttas," Jour. Soc. Arts, Nov. 23, 1883, pages 15 and 16.

work, turned by recklessness into a veritable charnel house.

As to the number of gutta-percha trees which have been destroyed, Dr. Oxley calculated that to supply the 6,918 piculs (1 picul equal $133\frac{1}{3}$ lbs.) exported from Singapore, from the first of January, 1845 to 1847, 69,180 trees were sacrificed; and, according to the *Sarawak Gazette*, 3,000,000 trees were required to supply the 90,000 piculs exported from this district during 1854 to 1874. These are only two instances, the first, showing the trade in its infancy; and the second, that of a limited and comparatively small producing locality. In fact, the gutta-percha tree has only been saved from utter annihilation because trees under the age of 12 years do not repay the trouble of cutting down. Still, it is clear that the growth of young trees of the best varieties has not kept pace with the destruction, but are becoming much scarcer, so that recourse now, more than ever, has to be had to the products of very inferior varieties.

At the present time there is a great difficulty in obtaining sufficient supplies of the best varieties, especially for telegraphic purposes.

Cultivation and acclimatisation is our only resource, and the Government of the Straits Settlements have a splendid opportunity for carrying this matter out. We have now a great amount of power and influence in the Malayan Peninsula, and could easily introduce a form of Forest Conservancy. By letting or "farming" out these forests for collecting gutta and other forest products, the working expenses of conservancy would be secured, the native rajahs paid a small royalty, and possibly an addition made to the colonial revenue. A clause to be stringently enforced should be inserted in all such contracts, namely, that for every tree cut down, two or three should be planted in the place thereof.

The Indian Government, acting on the advice of the late Mr. Howard, F.R.S., Mr. Markham, Dr. Spruce, and others, did, with rare forethought, undertake the initiative in introducing the cultivation and acclimatisation of the cinchonas, and private planters, seeing the success achieved, have also taken up the matter. They have also taken up the India-rubber question. The Colonial Government should now take up the question of gutta-percha. Borneo, Labuan, the southern portions of the Malayan Peninsula, are the natural homes of these trees; possibly the Nicobars, Ceylon, and some parts of Assam, would prove equally congenial, and Singapore could be used as a nursery for the young plants.

Correspondence.

ELECTRIC LAUNCHES.

The discussion following Mr. Reckenzaun's paper on Wednesday, January 16th, as also the many erroneous statements made in the daily and weekly papers with regard to the efficiency of primary batteries, induces me to send the following figures, relating to the quantity of fuel required to produce 1 horse-power per hour by means of steam, and by electricity. Perhaps these figures may be thought of sufficient interest for insertion in your next issue.

		Foot-pounds.
1 Heat-unit (Fahrenheit)	=	772
Ditto (Centigrade)	=	1,390
1 Horse-power per minute	=	33,000
Ditto per hour	=	1,980,000

Ditto ditto in heat-units—

$$\frac{1,980,000}{1,390} = 1,425$$

Heat-units (Centigrade) contained in—

1 lb. of coal..............	=	8,000
1 lb. of hydrocarbon (liquid)	=	11,000 (about)
1 lb. of hydrogen	=	34,000

Assuming with Professor Adams (see opening address at the Society of Electricians), the greatest efficiency of a theoretically perfect heat-engine to be = 23 per cent. We have—

for coal	23 per cent. of 8,000	= 1,840
for hydrocarbon	,, ,, 11,000	= 2,530
for hydrogen ..	,, ,, 34,000	= 7,820

Hence, 1 horse-power requires for its development in such a theoretically perfect engine at least—

$$\frac{1,425}{1,840} = 0{\cdot}774 \text{ lb. of carbon,}$$

$$\text{or } \frac{1,425}{2,530} = 0{\cdot}563 \text{ lb. of hydrocarbon,}$$

$$\text{or } \frac{1,425}{7,820} = 0{\cdot}182 \text{ lb. of hydrogen.}$$

The effieiency of a perfect voltaic battery and electric motor may, at the lowest estimate, be assumed as 90 per cent.

1 lb. of zinc = 1,300 J; 90 per cent. = 1,170. One horse-power developed in an electric motor by a current from a voltaic battery requires hence at least—

$$\frac{1,425}{1,170} = 1{\cdot}133 \text{ lbs. of zinc.}$$

The above will elucidate the assertion about 1 horse-power being produced by 0·166 lbs. of hydrocarbon, against the lowest possible 0·563 lbs.; but it also shows Mr. Reckenzaun's modest estimate of 2 lbs. of zinc per horse-power per hour in its proper light.

I may here add, that D'Arsonval (see *La Lumière Electrique*, vol. v., p. 90) has obtained 368 kilogramme metres with 1 gramme of zinc; this corresponds to a consumption of 1·42 lbs. of zinc per horse-power per hour.

C. GODFREY GUMPEL.

VISIT OF THE BRITISH ASSOCIATION TO CANADA.

It gave me much pleasure to attend last night at the meeting of the Society of Arts, and to listen to Mr. Colmer's paper, and the discussion that followed it. Had time not been fully taken up by speakers who had better claims on the audience, I should have been glad of the opportunity of saying that it was strongly felt by the Committee of Section F (the Statistical and Economic Section) at Southport, that their work at Montreal should be the collection of materials for a complete and authoritative survey of the economic condition of the Colony. The following subjects were specially chosen as the most suitable for discussion :—Agriculture; education—(1) primary, (2) scientific, (3) technical; fiscal policy and foreign trade; fisheries; population and immigration; pauperism; shipping; tariff.

It is probable that your *Journal* containing Mr. Colmer's paper will be extensively read, not only by members of your Society, but also by many persons connected with or resident in Canada, and that you may be able, through its means, to promote the success of the Economic Section of the British Association at Montreal, by giving publicity to its object.

It may be well to state that it is the practice to devote each day to the consideration of one or more special topics, according to the number of papers prepared on each subject. The papers should not take more than twenty-five or thirty minutes at most in the reading; and it was thought desirable, in view of the length of time inevitably taken up in communicating by post, that all papers from Canada should be sent in to the Secretary of the British Association, 22, Albemarle-street, not later than the beginning of June.

I hope that you will accept as my excuse for troubling you, that I am pledged to do my best to promote the success of the Economic Section at the Montreal meeting.

JOHN B. MARTIN.

68, Lombard-street, London,
Jan. 30, 1880.

General Notes.

TYPOGRAPHIC ETCHING ON GLASS.—The new Sydney paper, *The Australian Graphic*, is illustrated by typographic etchings on glass plates, made by the process of Mr. H. S. Crocker. The writing or drawing is executed with a resist crayon made of a waxy material, and it need scarcely be said that hydrofluoric acid is used as the etching fluid. It has been noticed that the tendency to undercutting is remarkably small, so that no precautions are required but an occasional stopping out of the finer parts. The glass plates are cemented down on metal blocks for use in the printing machine, but it is not stated how the clearing out of large whites and the turning of the blocks is effected. It is said that the inventor originally intended to print from electrotypes taken off the glass, but this was found unnecessary in practice, as no inconvenience is caused by the use of the glass itself in the printing press.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, eight o'clock :—

FEBRUARY 6.—"The Sanitation and Reconstruction of Central London." By WILLIAM WESTGARTH. Sir FREDERICK ABEL, C.B., F.R.S., Chairman of Council, will preside.

FEBRUARY 13.—"New Process of Permanent Mural Painting, invented by Adolph Keim, of Munich. By Rev. J. A. RIVINGTON. HUBERT HERKOMER, A.R.A., will preside.

FEBRUARY 20.—"Reclamation of Land on the North-Western Coast of England." By HYDE CLARKE.

FEBRUARY 27.—"Vital Steps in Sanitary Progress." By B. W. RICHARDSON, M.D., F.R.S.

MARCH 5.—"The Progress of Electric Lighting." By W. H. PREECE, F.R.S.

MARCH 12.—"Water Regulation, in regard to Supply, Floods, Drainage, and Transit." By General RUNDALL.

FOREIGN AND COLONIAL SECTION.

Tuesday evenings :—

FEBRUARY 12.—"The Portuguese Colonies of West Africa." By H. H. JOHNSTON. Sir FREDERICK JOHN GOLDSMID, K.C.S.I., C.B., will preside.

APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings :—

FEBRUARY 28.—"Recent Progress in Dynamo-electric Machinery." By Professor SILVANUS P. THOMPSON.

MARCH 13.—"The Upper Thames as a Source of Water Supply." By Dr. PERCY T. FRANKLAND.

INDIAN SECTION.

Friday evenings :—

FEBRUARY 15.—"State Monopoly of Railways in India." By J. M. MACLEAN. SIR JAMES CAIRD, K.C.B., will preside.

CANTOR LECTURES.

The Second Course will be on "Recent Improvements in Photo-Mechanical Printing Methods." By THOMAS BOLAS, F.C.S.

LECTURE II. Feb. 4.—Type Blocks from Line Drawings and Half Tone subjects.

LECTURE III. Feb. 11.—Intaglio Plates. Collotypes. Photo-Mechanical Methods, as applied to the Decoration of Pottery. Miscellaneous Processes.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 4...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. Thomas Bolas, "Recent Improvements in Photo-Mechanical Printing Methods." (Lecture II.)

Farmers' Club, Inns of Court Hotel, Holborn, W.C., 4 p.m. Mr. S. B. L. Druce, "The Agricultural Holdings (England) Act, 1883."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, Westminster Town-hall, S.W., 7½ p.m. 1. Presentation of Prizes by Mr. Jabez Church. 2. Inaugural Address by the President, Mr. Arthur Rigg.

Chemical Industry (London Section), Burlington-house, W. 8 p.m. 1. Mr. C. C. Hutchinson, "The Disposal of Sewage Sludge." 2. Mr. J. H. Porter, "The Porter-Clark Process for the Purification of Water." 3. Paper on "Some Technical Applications of Keiselguhr."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. W. H. White, "Review of the Education and Position of Architects in France, since the year 1671."

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 7, Adelphi-terrace, W.C., 8 p.m. Mr. Ernest A. Budge, "Nebuchadnezzar, King of Babylon—On Recently Discovered Inscriptions of this King."

London Institution, Finsbury-circus, E.C., 5 p.m. Prof. Ruskin, "The Storm Cloud of the Nineteenth Century."

TUESDAY, FEB. 5...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Geikie, "The Origin of the Scenery of the British Isles." (Lecture II.)

Central Chamber of Agriculture (at the HOUSE OF THE SOCIETY OF ARTS), 11 a.m.

Civil Engineers, 25, Great George-street, Westminster, S.W., 8 p.m. Mr. F. R. Conder, "Speed on Canals."

Pathological, 53, Berners-st., Oxford-st., W., 8½ p.m.

Biblical Archæology, 9, Conduit-street, W., 8 p.m. 1. Mr. J. Peters, "The Babylonian Origin of the Phœnician Alphabet." 2. Mr. George Bertin, "Notes on Babylonian Contract Tablets."

Zoological, 11, Hanover-square, W., 8½ p.m. 1. Dr. W. Leche, "Notes on some Species of Chiroptera from Australia." 2. Mr. P. L. Sclater, "The Lesser Koodoo, *Strepsiceros imberbis* of Blyth." 3. Prof. F. Jeffrey Bell, "Contributions to the Systematic Arrangement of the Asteroidea. —Part II. The Species of *Oreaster*." Mr. R. Bowdler Sharpe, "Description of a new Species of *Laniarius* from Ashantee."

WEDNESDAY, FEB. 6...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. William Westgarth, "The Sanitation and Reconstruction of Central London."

Geological, Burlington-house, W., 8 p.m. 1. Mr. T. Mellard Reade, "A Delta in Miniature—Twenty-seven years' work." 2. Professor John W. Judd, "The Nature and Relations of the Jurassic Deposits which underlie London." With an Introductory Note on a Deep Boring at Richmond, Surrey, by Mr. Collett Homersham. 3. Mr. G. W. Lamplugh, "A Recent Exposure of the Shelly Patches in the Boulder-clay at Bridlington."

Shorthand, 55 Chancery-lane, W.C., 8 p.m.

United Service Institution, Whitehall-yard, S.W., 3 p.m. Captain R. F. Johnson, "Night Attacks." (Part II.)

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m. 1. Messrs. Wyndham R. Dunstan and F. W. Short, "Report upon the Pharmaceutical Preparation of Nux Vomica" (continued). 2. Messrs. Wyndham R. Dunstan and Francis Ransom, "The Assay of Atropa Belladonna." (Part I.) 3. Mr. Boverton Redwood, "A Sample of Sophisticated Oil of Turpentine."

Entomological, 11, Chandos-street, W., 7 p.m.

Archæological Association, 32, Sackville-street, W., 8 p.m. Mr. Alfred B. Wyon, "The Seals of Henry VI. as King of France."

Obstetrical, 53, Berners-street, Oxford-street, W., 8 p.m. Annual Meeting.

THURSDAY, FEB. 7...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. F. O. Bower, "The Gemmæ of *Aulacomnion palustre*." 2. Rev. A. E. Eaton, "Monograph of Recent Ephemeridæ" (Part II.). 3. Mr. B. T. Lowne, "Compound Vision of Insects." 4. Mr. H. N. Ridley, "Cyperaceæ of West Africa." 5. Rev. A. M. Norman, "European and North Atlantic Crustacea."

Chemical, Burlington-house, W., 8 p.m. 1. Mr. L. T. Wright, "The Influence of the Temperature of Distillation on the Composition of Coal Gas." 2. Mr. R. Meldola, "Researches on Secondary and Tertiary Azo-Compounds." (No. II.)

London Institution, Finsbury-circus, E.C., 7 p.m. Prof. Norman Lockyer, "The Last Two Eclipses of the Sun."

South London Photographic (at the HOUSE OF THE SOCIETY OF ARTS), 8 p.m. Paper on "Willesden Paper and Canvas, and Some of their Uses in connection with Photography."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. E. Pauer, "The History and Development of the Music for the Pianoforte, &c." (Lecture IV.)

Archæological Institution, 16, New Burlington-street, W., 4 p.m.

FRIDAY, FEB. 8...United Service Inst., Whitehall-yard, 3 p.m. Captain C. O. Brown, "The Present Position of the Armour Question, with a Summary of the Recent Plate Experiments."

Royal Institution, Abermarle-street, W., 8 p.m. Weekly meeting, 9 p.m. Professor G. J. Romanes, "The Darwinian Theory of Instinct."

Astronomical, Burlington-house, W., 8 p.m.

Quekett Microscopical Club, University College, W.C., 8 p.m.

Clinical, 53, Berners-street, W., 8½ p.m.

New Shakspere, University College, W.C., 8 p.m. 1. Miss Grace Latham, "Ophelia." 2. Mr. G. B. Shaw, "Troilus and Cressida."

SATURDAY, FEB. 9...Royal Institution, Albemarle-street, W., 3 p.m. Prof. H. Morley, "Life and Literature under Charles I." (Lecture IV.)

Physical, Science Schools, South Kensington, S.W., 3 p.m. Annual General Meeting.

Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.

Journal of the Society of Arts.

No. 1,629. Vol. XXXII.

FRIDAY, FEBRUARY 8, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CANTOR LECTURES.

Mr. Thomas Bolas, F.C.S., delivered the Second Lecture of his Course of Cantor Lectures on "Recent Improvements in Photo-Mechanical Printing Methods," on Monday, the 4th inst., in which he dealt with various processes of making type blocks from line drawings and half-tone subjects.

The lectures will be printed in the *Journal* during the summer recess.

FOTHERGILL PRIZE.

The Council of the Society of Arts, having carefully considered the models, plans, drawings, &c., submitted in competition for the prize of a Gold Medal, or £20, offered for the best invention having for its object the Prevention or Extinction of Fires in Theatres, have determined that the papers by Captain Shean and Mr. Ernest A. E. Woodrow, on arrangements for the prevention and extinction of fires in theatres, are the best of all the contributions sent in; but they are of opinion that neither of these papers come within the terms of the offer of the prize. They have, therefore, decided not to award the prize.

Proceedings of the Society.

NINTH ORDINARY MEETING.

Wednesday, February 6th, 1884: Sir Frederick Abel, C.B., D.C.L., F.R.S., Chairman of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Baillie, Major-General John, 4, Queensborough-terrace, W.
Bostock, John Yates, M.R.C.S., M.B., 73, Onslow-gardens, S.W.
Evans, Edward Probert, Ross-house, London-road, Worcester, and Royal Porcelain Works, Worcester.
Lewin, Miss Constance, 25, Wimpole-street, Cavendish-square, W., and The Bourne, Widford, Hertfordshire.
Macdonald, Thomas, 5, Essex-court, Temple, E.C.
Mackinnon, W., Balinakill, Clachan, Argyleshire.
Scudder, Frank, 22, Devonshire-street, All Saints, Manchester.
Wilkinson, Captain Edward, R.N., Army and Navy Club, S.W.

The following candidates were balloted for and duly elected members of the Society:—

Blyth, Alexander Wynter, M.R.C.S., The Court House, Marylebone, W.
Bond, Henry Chas., B.A., Brasenose, Bromley, Kent.
Campbell, F. J., Royal Normal College and Academy of Music for the Blind, Westow-street, Upper Norwood, S.E.
Johnston, Archibald, 6, Paternoster-buildings, E.C.
Lascelles, Brian Piers, 9 Holywell-street, Oxford.
Palmer, Walter, B.Sc., F.C.S., Westfield, Reading.
Ruscoe, John, Albion Works, Hyde, Manchester and Prospect-house, Hyde, Manchester.
Stopes, Henry, 24A, Southwark-street, S.E., and Kenwyn, Cintra-park, Upper Norwood, S.E.
Van Gelder, Pieter, Sowerby-bridge, Yorkshire.

The Chairman said it was a source of great pleasure and thankfulness to him that he was able to take the chair at this meeting, and introduce Mr. Westgarth, who had given an immense amount of study to this important subject. He had gone so zealously and patriotically into it, that he had offered prizes amounting in the aggregate to £1,200, for essays on the reconstruction of Central London.

The paper read was—

THE SANITATION AND RECONSTRUCTION OF CENTRAL LONDON.

By William Westgarth.

Introductory Remarks.

Owing to the attention which has of late been so strongly aroused to the insanitary condition—and, as it has been emphatically and most deservedly called, the horrible condition—of the dwellings of the poorer classes of London, there seems to me a favourable opportunity for arousing a like attention the still larger and not less pressing question which I propose to discuss with you this evening—namely, the sanitation and reconstruction of our Central London. The suitable rehousing of the poorer classes of the metropolis, which is now such an absorbing public topic, is also a part of my present question, although not the largest or most important part; and I shall have occasion further on to allude to the experience already acquired towards enabling us to deal successfully, and in a purely business way, with that difficult problem. The name of Miss Octavia Hill comes before us as associated with much of the most practical and useful of that experience. But my principal subject is, as I said, the larger, and, as I may add, the not less pressing question of the sanitation, the street re-alignment, and the reconstruction of our Central London. Much the larger interests, very much more of human life, and in every rank and class of it, are at stake in this larger question. I may add that, in this larger question also, I bring before you a self-supporting business project, and no mere scheme of philanthropy.

The Increasing Greatness of London.

Those of my audience who may have read the late admirable address of Sir J. W. Bazalgette, delivered, as President of the Institution of Civil Engineers, on the 8th ultimo, and reported in the papers of the following day, will have already a good idea of that great London which I am now to discourse upon, and whose traffic-blocked and insanitary central areas call so urgently to-day for relief. The remarkable growth of the Institution itself, of which he is the distinguished head, is strikingly illustrative of that of his subject, London; for whereas the membership of all grades numbered only 351 when he joined it in 1838, there is now a total of no less than 4,443. Our great metropolis, as defined by the Act of 1855, stands upon an area of 117 square miles, and that area is now covered with half-a-million of houses, and very nearly four millions of people. The growth which now characterises the metropolis has been, in regard at least to its present rapidity of pace, a feature limited to this century, and especially to its later half. In this respect, indeed, London, it may be said, only follows with other cities and countries in the wake of that striking progress everywhere which is the conspicuous feature of our modern civilised life. That is, happily, the common case; but London, as we may claim, is already specially conspicuous in the common rule, and we must hope that a resanitated and reconstructed London will still be much more so.

But the rapid growth of London, which I have alluded to as the feature of this century, is, as I have said, much more in the century's later than its earlier section. Indeed, the law of modern progress, as exemplified by London at least, appears, if I may so distinguish it, to be geometrical, and not merely arithmetical. The advance of the last ten or twenty years seems to be always greater, actually and relatively, than that of any previous like interval. This is shown in the population returns, but is still more striking in those of the City valuations. In 1841, the rateable yearly value of the city amounted to six million pounds. In 1855 it was ten and a half millions. But to-day the advance is to no less than twenty-eight millions. I call your special attention to this very remarkable advance of value, because we are to be much concerned with this feature of value increment in our projected sanitation reconstruction project. Some part of this striking increase is attributable—as Mr. St. Quintin, with his large experience of City valuations past and present, informs me—to a stricter system, of late years, in assessing value, and it must be largely due, of course, to extension of the City. But the increase in question is not due wholly, or perhaps even chiefly, to either of these causes, but arises also from what economists have, rather invidiously, called the "unearned" increment; as an increment of value due not to capital expended in improvement, but to increase of commerce, wealth, and population upon a limited and inextensible site area.

Its Overcrowded and Insanitary Condition.

Such, then, is the great London which I bring before you. Its central parts have become congested by the vast increase of traffic that daily struggles through the narrow and tortuous streets and lanes of an earlier and much smaller London; while the highly insanitary conditions are proportionately injurious and distressing to the crowded human life which is daily and nightly packed in these unsuitable quarters. The science or art of sanitation has now happily advanced sufficiently to give us some due appreciation of these evils, as well as the desire to remedy them. The difficulty has lain in the question of the best kind of agency for grappling with the evil, and even more in that of meeting the enormous cost of the work. In the following remarks I propose to deal with both of these most important questions, and to offer a solution which will, as I hope, admit of the great work being carried out. I wish to show that this great work may be done by private enterprise, in reliance upon an ultimate recoupment of cost from that natural increment of site value which, as I have shown, has been, and inferentially still is, the sure result of our modern progress. Let me add, that we are all concerned not only to have this work done, but to have it done promptly. Every year's delay continues, of course, a comparatively high death-rate; and this means not only premature death to many thousands of citizens, but, what is even still worse, constant deterioration of health, vigour, and vital enjoyment during the abbreviated life. But further, every year's delay also increases the cost and difficulty of the work, because the business to be disturbed is greater, and the necessary expropriations more expensive, while the current desultory efforts at improvement and reconstruction have mostly, I fear, to be undone, or to be done over again, in the grand street re-alignment which seems to me indispensable to the new city.

The Scope and Method of my Subject.

With these introductory remarks, I now proceed to explain how this great and beneficial work may be undertaken in an ordinary business way; how it may be done so as to prove self-remunerative, and how we may best minimise the expropriations and other social or business disturbance of such a vast undertaking. I shall first describe Central London as it is, in its irregular, narrow, and tortuous streets and lanes, with their most insanitary condition. I shall then sketch out, in some prominent features, what I think London ought to be—what also it may be, if its people have the courage to face the work. Lastly, I shall take up the business part of the question, explaining the ground of reliance for balancing the vast way-bill of costs, and the fitting special constitution of the company or trust which is to accomplish the undertaking.

Central London as it is.

We are all familiar with the map of our Central London, meeting our eyes as it does in the shops of every street, and at every Metropolitan Railway Station. Consider the chance-medley of even its main streets, as they pervade the map in utterly planless directions. They seem to run all about to nowhere in particular, and to reach that abstract destination in lines most oddly devious and independent. The feature of a straight street, such, for instance, as the old "High" street of Cheapside and the Poultry, does here and there occur, and ought of undesigned and mathematical right to occur in the ordinary doctrine of probabilities; but it is the very rare exception of the case. The newer streets, such, for instance, as King William-street and Queen Victoria-street, introduce principle and design into all this bundle of accidents. They give us broad, straight, uniform ways to definite objects, whether river bridges, railway stations, or other chief destinations. But these benefits have come only latterly out of the costly process of destruction of this planless past, and re-alignment and reconstruction.

Origin of its Irregularity of Plan.

There is no difficulty in guessing how our old London has come down to us so oddly parcelled out. The chance-medley process goes on even to-day, and so near us as the London suburbs. There is first a devious pathway through the fields. This broadens into a road, with dwellings and gardens on either side. Then, as population streams out, it is a thoroughfare, or main street, and eventually it is surrounded by modern streets and squares, which adapt themselves as they best can to the hap-hazard lines of the original free field path. I am an old enough resident of Western London to have witnessed all this process, in the case, for instance, of the old Portobello-road, running between Notting-hill and Kensal-green. I have often sauntered through the pleasant original field pathway, have seen it graduate into the thronged thoroughfare, then into the compact and crowded street, until now it forms the oddly independent diagonal amongst the regular streets and squares of a principal outer section of the great metropolis. In the marvels of London's progress, too, all this has happened within the brief space of the last twenty-five years. If you could transport yourselves back nearly as many centuries, you also might traverse field pathways that have since become the oddly twisting Lombard and Fenchurch-street, Cornhill and Leadenhall-street, the Old Broad-street, Threadneedle, Gracechurch and Bishopsgate streets of our old central city.

But, unfortunately, our central city is not, like modern Notting-hill, with its Portobello-road, one irregular which is all surrounded by the regular. Its case is an exact reversal, for it consists nearly all, so to say, of Portobello-roads, and its regularities have yet to come by force of almost entire stieet realigment and reconstruction. London has been expanding all over its circumference much in the wondrous way which we have seen as to Notting-hill, and now there is hopeless congestion in those narrow and devious tracks of the original city.

Its Insanitary Condition.

Let me turn now to the sanitation question. Although possibly less objective, this is of far more serious import than questions of the traffic block, or of any other merely material or business inconvenience. But only those comparative few who have given intelligent attention to the subject can fully realise the terrible condition. To all others it is, more or less, an unknown and incredible quantity. The latter may, however, realise something of the case, if they will glance into the many small courts and narrow passages on either side of such a principal city thoroughfare, and of such fair external pretensions as, for instance, Fleet-street. Indeed, in this matter of externals, our most central parts are getting to be, comparatively speaking, perfect, for the cleanness and neat finish of the asphalte paving, throughout even our very narrowest lanes, seems to leave nothing to be desired. But, alas! it leaves everything untouched within the buildings themselves on either side, packed as they usually are, from underground basement to attic, with teeming and toiling human life.

We may, perhaps, best form a correct idea of the insanitary conditions of this crowded central scene, by looking at those of other metropolitan quarters much less crowded, and, as we might suppose, much more cared for by comparatively wealthy occcupants. "In the older streets of the West-end," says the *Medical Times*, "it is probable that a perfectly sanitary dwelling could only be obtained by rebuilding from the basement. The old brick drains have, in many cases, been leaking for years; and even where they have been replaced by earthenware, the whole subsoil still remains permeated with the filth of generations." The poisoned subsoil, as I shall presently have occasion to say, is one of the chief evils of which, as I feel assured, we must thoroughly purge our central city. The journal I quote goes on to allude to the sanitary ignorance and incompetency in the building art of the past. Indeed, it is only within the last very few years that proper sanitary principles have been so fully and generally known as to ensure their practical application. The whole metropolis is now hopefully alive—to a degree never before attained—to sanitary defects and dangers; and efforts, at a vast collective cost, are now being made everywhere to remedy them.

The London Death-rate.

Sir Joseph Bazalgette has given us a comparison between London and some other great city death-rates. When London, which has now, in its sanitary march, such excellent sewerage, is compared with great cities without sewerage, such as St. Petersburg; or with those of still more crowded housing, and still worse sanitation generally than itself, such as Vienna, our capital appears to no small advantage. Its death-rate is now down to 21·4 yearly per 1,000 of population, after having been about 24 for twenty years prior to 1870, and 22·5 for ten years thereafter. The St. Petersburg rate is 35·2, and that of Vienna 29·2, while that of Cairo is 37, and of Pekin 50.

But the improvement hitherto in the reduction of the London death-rate—where so very much still obviously remains to be done in improving the sanitation—shows us what better things may still be hoped for. After the notable instance of Salisbury, as well as of other re-sanitated towns, it seems not impossible still to reduce our London mortality rate almost by one-half. It is not unlikely that, by due attention to sanitary rules, the centre of London may enjoy a less—even much less—mortality than the healthiest country districts hundreds of miles away, where sanitary ignorance and negligence still prevail. In our Scotch Highlands, for instance, to which so many of us Londoners annually flee for change and health, the careless country people too often vitiate their pure outside atmosphere surroundings by pestiferous "middens," while, in most cases, within doors, the fresh air, as the common enemy, is studiously excluded. We thus explain much sickness, physical suffering, and early death, in those otherwise healthful regions.

Now what, let me ask, is the full meaning of such a reduced mortality? It means, of course, a much longer average duration of life. But it means also something besides, whose social and moral importance far exceeds that of more prolonged existence. It means all the joy and all the vigour of healthful life. We are too much in the habit of thinking that if the stomach of the toiling millions is filled with good and sufficient food, there is nothing else to think about in that particular direction. But we have, all of us, yet another stomach in our system, which must also be filled with its own proper food, and that is the lungs, with pure air; otherwise even the best of food may, in its comparatively imperfect digestion, give weakness and pain instead of strength and enjoyment. Let us hope that such attainments are not to continue to pertain only to mere dreamland, but that we may some day, and that, perhaps, a day not very far a-head, realise the vigorous and joyous life of a resanitated London, and all the benefit, economic and social, which is to come of it.

Central London as it Ought to be.

I must content myself with very general remarks on this part of my subject; for although it may be called the most important of all, as embodying the final outcome of result, it is much too technical in character for any closer treatment at my hands. I speak, however, as a London citizen of long standing, who aims to rise to an adequate idea of all the greatness of his adopted City, and who has been long impressed, and each succeeding year more and more strongly, that its accommodations and its general aspect fall utterly short of the needs of its millions of people, and of its surpassing position in the wealth and commerce of the world.

Two Chief Central Sites.

I have spoken of the hap-hazard direction of our original City thoroughfares. In this comparatively limited area with which our project has more especially to do, two chief centres stand out before us. The lesser of the two, comprising the site of St. Paul's, I would distinguish as the art centre; the greater being, of course, that great centre of the world's commerce and finance, which is now indicated as the fertile site of our Royal Exchange and Stock Exchange, of Lloyd's, of the Bank of England, other chief banks, Lombard-street, and of the Mansion-house. Is it too much for London to claim that these two chief centres should be connected by the grandest of streets, not merely of London but of the world? From these centres, but especially from this latter business centre, should radiate all the chief thoroughfares of great London. Sir Christopher Wren, and others after him, have in vain draughted plans for a reconstructed London. The great fire of two centuries ago might have given a fitting opportunity, but it was not availed of. To-day, in attempting the work, we would not have quite the same freedom of the ideal, for there are not only the many river bridges to be considered, but well nigh a host of great railway stations penetrating and permeating London. The plan of a reconstituted London of to-day must be, therefore, an artisto-economic contest mainly with reference to those bridges and stations.

The Great Business Centre.

But let me return for a moment to the great business centre. When our noble St. Paul's has been "unstifled," by concession of some little more of surrounding breathing room, when we have the finest of streets running from the noble cathedral to that other centre, what ought we to aspire to as worthy of the latter? Our climate is suggestive of the comfort and convenience, to say nothing of modern possibilities of elegance, of the arcade form of edifice. Repeatedly, as I stood under the beautiful new structure of this kind in Central Milan, constructed, too, as I was told, by English enterprise and capital, I have asked why London should be so contemptibly inferior in that way. If we, then, are also to have a central arcade, let us hope that it is to excel in magnificence even that of Milan by as much as London excels, in population, wealth, and commerce, her fair rival of Northern Italy.

But I have yet another idea with regard to London's grand business centre. It is already, as we have seen, the common meeting-gronnd of many of our leading city interests. I would complete, as far as might be, this central representative character, by providing accommodation for every kind of institution with which the public were largely or frequently concerned. There would not, of course, be full accommodation for all, but all might "enter an appearance," and the modern facilities of telegraph, telephone, &c., would do the rest. I do not limit this idea to public institutions, such as Parliament, the various Government offices, the legal and judicial, the postal, the customs and excise, and so on. The chief trading interests might be there also, including even hotels, theatres, &c. The railways also, of course, must enter their appearance here, and perhaps adequate subterranean accommodation might permit of a convergence of all the lines to this great centre.

Centralising of the Public Offices.

When we have once experienced the incredible business facilities of this centralising official system, we shall look back with amazement upon our present utterly unsystematic site scattering of all these public and business interests, and the time and trouble which are thus involved to everybody. Indeed I have long entertained the still larger idea, in the interests of economies and conveniences of every kind, of bringing together all the chief public offices into one great commodious common edifice. No central site is now possible for so comprehensive a structure, but a near suburban site might still be found, and a special railway service at nominal charges might bring these collective offices, as a whole, much nearer to every citizen than at present. Of course any hope for this very disturbing idea arises out of a reconstructing of London.

Other Chief Considerations in the Sanitation and Reconstruction.

I must now hasten through some other chief considerations of a reconstructed Central London. As we are to indulge in unprecedented width of our chief streets, we may recompense the sacrifice of accomodations in one direction by seizing upon more of them in another; that is to say, by giving a greater height to our new buildings. We have plenty of room both towards heaven above, and in the earth beneath, and the modern facility of perpetually-going lifts will almost abolish wearisome staircases. Let us begin with our subterranean. We must eject all the old poisoned soil, and, in so doing, institute a new level of construction. An ample subterranean will give us at once business storage, and the due facility for availing of all the progress of art and science in the future, in our lighting, watering, sewerage, and the application of energy or power in all ways, without the heretofore incessant breaking up, over and over again, of our streets.

Next, we have a lofty ground floor—so lofty as to allow, without serious reduction of light to that floor, a terrace or upper promenade, with bridged connections, for foot passengers, so as to put an end to those countless street dangers and accidents which already cost London and its suburbs the yearly sacrifice of 270 lives. This level, as well as that of the ground, will have its shops and traffic, to swell out a remunerative rent roll.

We continue our ascent through successive floors of offices or dwellings, until the public lift lands us, without fatigue, upon the roof. Here is something entirely new to London experience, and possibly to any other as yet, but entirely attainable under a systematic reconstruction. In short, the roofage of our chief streets is a public promenade, a continuous park or garden. The original idea in this grateful direction is due, I believe, to Dr. Richardson, who, in removing the too savoury kitchen from the very bottom of the house to the very top, would have the house surmounted by a garden. The chief or only obstacle in the way of such enjoyments is the difficulty of dislodging the ordinary Englishman from his accustomed groove of comparative discomfort. In this time of scientific promise and attainment, we may venture to prohibit smoke entirely to the new city. The sanitary conditions will thus combine with the scenic to give us, with these "hanging gardens" of the modern Babylon, a new era of health and enjoyment for its crowd of citizens.

The Business Part of the Project.

The project we are now discussing involves the turn over of probably not less than one hundred millions of money. How is all that money to be duly found, and how is the great work, with all this great cost, to be remuneratively executed? This may seem, at first thought, the most difficult section of the whole project. But after much consideration of the subject, based on large business experience, I feel myself on surer ground and more at home in this section of my project, than in the somewhat technical bearings of the other sections, to which I have already alluded.

The great difficulty hitherto in the way of the much needed clearing and improving of the congested centres of our larger towns has been the terrible amount of the unrecouped balance of the cost. The famous Paris reconstruction has certainly given a most enviable result, so far as regards improvement, but it has been at the cost of a very onerous heritage of City debt. In proposing, as I now do, to execute all the reconstruction of Central London without any such undesirable heritage, and even without appeal to the State for any pecuniary help whatever, I must explain how very differently we are to conduct the proposed work from the methods adopted in Paris and elsewhere, and even in London itself, so far as reconstruction has yet proceeded.

The spirit of improvement and reconstruction is indeed already manifest all over our crowded metropolis. But if we except the occasional larger aims of the Board of Works, this enterprise has mostly been mere individual effort, with the result of a grotesque effect within the narrow tortuous lines of our old streets and lanes. Let us mark, however, that although these many isolated and individual efforts must be made at great disadvantage amongst unimproved surroundings, yet, from their great collective total, we may infer not only the pressing urgency of the general case, but also that such work does, in a business sense, prove ultimately remunerative, or it would not otherwise be so largely undertaken. This is a very important encouragement to our project, and we are further furnished with guidance from these operations as to the method we should adopt in that project. The difference of method and of result between a private interest and a public body in effecting such improvement works is usually very apparent, especially as affecting the profit and loss account. In the Paris case, for instance, a great area would be completely and simultaneously expropriated and cleared out, and be shortly afterwards resold in a market which, with the large supply of the article offered, and the necessarily suspended or diverted traffic of the locality, was more or less of a forced character. No wonder, therefore, that the result has been that, on the one hand, of a great debt bequeathed to Paris, and on the other, of a great reward eventually to the new proprietary, inheriting as they did the increase of value due to time and to the improved city. Thus we are instructed to adopt methods which shall minimise business disturbance, and not too readily part with the unavoidable expropriations. So far as I can learn, the Paris reconstruction cost eighty millions sterling, and the recoupment did not exceed twenty millions, thus leaving sixty millions of city debt.

The Natural, or So-called "Unearned" Increment of Site Value.

Let me now briefly allude to a chief factor in the great recoupment question. This is what economists have termed the "unearned" increment of site value—of the value generally of our real estate—due to the simple effluxion of time in any progressive society occupying a limited site area. The theory which underlies this increment is neither uncertain nor unintelligible, but until quite recently it was left all but entirely to the theories of economists, and anything approaching a practical application of its principle was hardly dreamt of. The past experience of the advance of London site values and rentals, and more especially of those of the central areas of the City, indicates clearly to us now that the cost of a great reconstruction scheme, such as that here proposed, would have been entirely recouped within any thirty years of the past of this century. I mean that if, for instance, in the year 1854, such a great project of reconstruction as I now suggest had been actually undertaken, the present enhanced values of the expropriations, had these been held over until now, would have recouped the whole cost, after the fullest compensation at the time to all the expropriated parties. The practical question for us is as to this "unearned" increment of value, or as I would less invidiously call it, this natural increment, continuing to be a feature of the future as of the past. We can hardly doubt that this will be the case, seeing that the causes to which it is assignable are still in as full force as ever; namely, the increase of commerce, wealth, and population, upon a site area which is itself inextensible.

We must not overlook a subwave feature of this increment. Over long intervals its course is steadily upwards, but intermediately there are reactions of depression and elevation. We had the elevation for some years succeeding the great Franco-German war, and the depression has succeeded and still continues. This temporary condition, however, is peculiarly favourable for inaugurating our project. Had it been begun ten years ago, the excited real estate market would have placed our project at serious disadvantage as compared with our present prospect.

We are to bear in mind, however, with regard to this said future increment, that the more it is explained and generally understood, the more will the effect be to convert future value, by intelligent speculative anticipation, into present value. But, on the other hand, there will always still remain a substantial future increment, both because the calculation must ever be wanting in elements of precision, at least, as regards any particular cases of site investment, and because present values and rentals will always depend more upon the present scale and returns of business than upon any speculative estimate as to what these may possibly attain in the next generation. And, again, behind this prospect of recouping increment, we have in store all the additional value of a resanitated London, a value which, in its heretofore unknown quantity and power, may possibly prove the most secure and effective factor of all.

Method of Procedure so as to Reduce Cost and Minimise Disturbance.

Presuming that my proposition is to carry out this project in an ordinary business way, by means of a company or joint-stock trust, I shall offer a few practical remarks upon the method of procedure, before dealing with the proposed trust, and certain specialities of constitution and management to be given to it.

There construction of Central London, in all that thoroughness of resanitation which I would advocate, in the interests of the daily life and health of perhaps above a million of human beings, would probably involve still larger monetary figures than even that of Paris. The total turn-over of money might not be short of £100,000,000. How is the trust to find so large a sum, and how is the recoupment and the final wind-up of the trust to be arranged? The great object of the trust, in this direction, should be to minimise disturbance of every kind. This policy should be enjoined on the trust; but, happily, it is also for the trust's own interests. Let us look then at some chief points of this ameliorating procedure.

1. The expropriations, instead of being complete, as in the Paris case, will, as far as possible, be optional to the proprietary or lessees, who may retain their sites, subject to co-operation in the proposed improvements. Some must needs be expropriated, partially or wholly, were it only in giving greater width to the streets; but it may suit some also to prefer to accept the full compensation to be offered, relatively in the cases (probably many) where street re-alignments have cut up old sites, or practically displaced them from old positions. On this latter account, indeed, there must be much and varied special arrangement. On the whole, it is not unlikely that the trust may be able to meet satisfactorily every case, and entirely to avoid coercive expropriation. Looking at the vigour with which individual reconstruction now goes on, in its patching way, along the old lines, and under the disadvantages of unimproved surroundings, as already alluded to, we may safely infer that very many would prefer to co-operate rather than surrender their interests. By this means, therefore, the dimensions of the reconstruction account will probably be reduced—so far as the trust is concerned—to a mere fraction of the great estimated total.

2. Reconstruction must be gradual, in the sense of minimising interruption to business. But this does not necessarily mean slowness of work, as work may so go on simultaneously in many places. On the contrary, it is to the interest of all concerned to effect the reconstruction quickly, and perhaps the modern modes and resources will prove unprecedentedly marvellous in this respect. An entirely new street realignment seems, at first, a far more disturbing course than merely to widen the devious old ways; but alike in the interests of sanitation and non-disturbance it is really the least so. We are thus enabled to effect a thorough reconstruction, and also to minimise business disturbance by having the new lines progressively ready ere the old lines, marching more or less alongside, are invaded.

3. Business disturbance may prove a serious item of cost to the trust, if treated in the offhand mode of the Paris reconstruction. Public bodies are less adaptable in such cases than may be expected of our proposed trust. In taking all possible care to avoid the interruption or divergence of the current tide of business in each locality dealt with, the trust should replace the evicted trader, with as little delay, and as nearly as may be relatively in his old position. The occupant in a superseded old main street should have the refusal of the relatively same position in the new thoroughfare. We thus minimise that serious item of all reconstruction schemes, business disturbance; and even disturbance in general ought always to be part of a fair and full compensation. I quite approve of Mr. Cohen's proposed Act for giving the poorer classes, even when without leases, compensation for disturbance. To evict a large number of such at one time, who, in perhaps a comparatively limited market, are to compete with each other for their rehousing, may cause not only great inconvenience, but also what is to them serious pecuniary loss. Our proposed trust may lean even to the generous side of fairness, seeing that it has, as I feel assured, ample prospective guarantees of ultimate success to enable it to do so.

The Agency to be a Joint-stock Company or Trust.

Certainly it has been the rare exception to carry out any great urban reconstruction as a matter of ordinary independent enterprise. We have the exceptional case of Newcastle-on-Tyne, about half-a-century ago, which has proved a success eventually, although, at the time, upon a rather ambitious scale for the attainments and wants of the place. But, in general, this kind of work, when not to be longer delayed, has been at the hands of the Government or the municipality, or, as in the case of London latterly, those of a *pro re nata* Board of Works. The usual result has been, as is conspicuously illustrated in the Paris case, a heritage of more or less inconvenient debt. Occasionally, in some partial field, there may have been a full recouping result, as with that great improvement of our West London, the new Northumberland-avenue. But the rule in such cases has been loss, and relatively no small loss too; while, as to our great London, all efforts, whether of public bodies or of private interests, have been as yet of a totally inadequate character. One chief defect in all these attempts has been their comparatively limited range, as the improved sections have thus been left bedded, so to say, in all the disadvantages of unimproved and insanitary surroundings.

Constitution of the Trust: its Special Character.

The proposed Central London Reconstruction Trust should have an adequate, but not a too exacting, guarantee of capital. Accordingly I would have a capital, nominally, of £10,000,000, with £1,000,000 to be paid up, and £9,000,000 to remain as liability. In view of raising the enterprise above the shiftings of the Stock Exchange, I would have the shares to be of £10,000 each, and would hope for a comparatively permanent proprietary of one thousand persons with one share each, and the trust receiving throughout interested and intelligent co-operation from all of them.

The board of management of the trust should include a representation of the Government and the corporation, so as to place all its procedure under control of these authorities. There may also, with advantage, be a representation of the Board of Works. There should be the best representation of the science or art of the engineering, architecture, and sanitation of urban improvement and reconstruction.

The trust, in a loyal spirit of confidence in the mutuality of aim, will submit to the condition that no step is to be taken without consent of the Government and corporation, represented, as I have said, upon its Board. Indeed the Government should have absolute intervention power at all times, and be the final arbiter in all possible differences. Under these safeguards to the public, the trust may apply for the fullest and most free powers of action. The powers may extend to the entire metropolis, as the trust need not limit its beneficial action to the central section, if it can also find any useful remunerative field outside.

The trust, in addition to its capital, will find money for its purposes by the issue of stock, whose security will be based, first, on the capital and effects of the trust, and ultimately, if need be, on the rating of the improved City.

The remuneration of the trust I would propose thus:—On the paid-up amount a dividend annually of 6 per cent.; on the liability amount 1 per cent. Although there is thus the apparently high dividend of 15 per cent., if we regard only the actual money advance, yet, viewing the whole ten millions as available guarantee, the reconstruction scheme is weighted to the extent of a dividend of only 1½ per cent. upon that quasi-capital account.

But this dividend may be reasonably increased, should the prospect so warrant, as the undertaking proceeds. Any such increase, however, should release the City from rating liability, and in that case all preceding stock issues secured by that liability should, in the interests of the City, become a first charge on all the trust assets. The trust thereafter must raise its money supplies by issues of stock secured solely upon its own means and credit. Thus the trust will not depend upon, nor will it seek financial aid from, the Government.

In a work which in itself is so noble and interesting, there need be no necessity for shareholding, at least as regards the representative element invited from outside.

Termination of the Trust.

I have suggested some considerations from which it might be hoped that the enterprise in question would prove remunerative, under the adaptive methods I have proposed, even without reference to the recouping guarantee of "the natural increment of value." But as we must rise to our grand prospect, and not "scamp" the future city, either in its street-widths or its other sanitations, conveniences, and adornments, we are wise to secure all the guarantees we can get. The trust will, therefore, demand thirty years of value-recouping time. This does not necessarily protract the reconstruction to a like term. On the contrary, I fully expect that modern modes and modern resource may finish the work within half that time. I shall not raise questions of detail or deal with specialities. The best arrangement, as the general rule, would probably be to grant thirty years' leases, terminable at any time by optional purchase, at a price that clears all cost to the trust. This price to each plot should not be merely one that exactly clears its share of the account. The price should, in each case, be something substantially more, so as to provide a fund in the nature of a guarantee for particular localities which might possibly fall short in the estimated value-increment. There might thus arise a considerable surplus fund for eventual distribution. This would belong to the trust; but not entirely, as some consideration would be due to the City for the benefit the trust may have derived from the rating liability.

Concluding Reflections.

Allow me a few concluding thoughts on a thoroughly reconstructed and resanitated London. What is its full meaning? Taking, naturally enough, only a business view of the question, we think of unimpeded traffic and all other business convenience and accommodation, and in the same direction we may think also of the increased wealth-producing power of the population from their greatly improved health and vigour. But all this business part of the case is, comparatively speaking, of a very secondary importance. Social and moral interests, although possibly the last to be thought about in such a business concentration, must stand even there pre-eminently first. Conceive our great city clean swept, not only of its fever dens and all other unsanitariness, but of all those dark recesses which are the favouring haunts, the shelter, the breeding grounds of vice and crime. The night owls of evil are thus unhoused, and thrust naked and defenceless into the clear light of day.

The whole field is thus improved, thus rendered more fitting and less inaccessible to every good end and purpose. My project is directly and strictly one of business, but much else may follow in its wake. I have alluded repeatedly to the improved health of city life, and all that hangs upon this result in the chequered lot of the people. The law will have increased facilities for the detection, or far better the prevention, of crime; and organised charity may permeate its great field with more system, and with less danger and less shock, especially to its many missionaries of the other sex. The pariahs of society, in the sense of its sanitary and cleanly aspects, will have a new leaf turned over for them, and we may hope that it is not to be all blotted and blurred over again like the preceding pages.

I promised, at the beginning of my paper, to recur to the great rehousing question, as regarded the masses of the poorer classes. But the great length of the paper leaves space for only the very briefest further notice. This subject, although not, as I have remarked, the chief section of my great scheme, is yet of vast importance, seeing that a great mass of the working and poorer class both work and live within the bounds of that crowded centre with which I propose to deal. Nor need we be limited to this central area as regards any useful improvement in this or in any other direction, which is suitable or remunerative to the trust. As very much experience has of late been brought to bear upon this question, all tending more or less to smooth the way towards a purely business or self-supporting result, I look for large possibilities and much social amelioration in this particular direction. Miss Hill's experience, alike as to management and remuneration, is highly promising. I have not time here for details, but will briefly allude to one plan of minimising difficulties which I should like to see tried and superadded to others, namely, that of giving to tenants a proprietary interest in their respective rooms or homes. A redemption fund spread over a term, say of thirty years, would add but 4d. to 6d. per week to rent, and this, in the economies of the great scale of the trust's business, would scarcely be felt. Another plan, found successful in rudimentary forms in present cheap common lodging houses, gives a great common hall or sitting-room to all the tenants, which may have great social and recreational as well as economic benefits. The active public discussion now going on in all branches of this question, is daily supplying an invaluable guidance of practical suggestion. I should be glad to see the same public attention, and the same useful guidance from actual results, bestowed also upon my larger question of the sanitation and reconstruction project. It was, indeed, partly in view of arousing such attention, that I lately offered, through this Society, a series of prizes for essays connected with this larger question, as well as with the other. If my project is successful, the information to be derived from these expected essays will find its use.

Miss Octavia Hill, whose name is so closely associated with this great housing and rehousing question of our poorer classes, has lately organised a courageous band of her own sex to take in hand, for purposes of improvement, but in a business and remunerative way to proprietors, some of the existing ill-favoured but improvable quarters of crowded London. There are some, even of the weaker sex, whose moral courage is equal to anything, as Miss Hill in one direction, and Miss Isabella Bird (now Mrs. Bishop) in another, may aptly illustrate. But these are the rare exceptions. Female delicacy shrinks from the revolting and even dangerous conditions of unsanitary and unimproved London. The success of our project, as not the least valuable of its results, will expand in every way the sympathising action of society in response to the wants and needs of its many suffering sections.

APPENDIX.

The two following appendixes deal more at large with parts of our subject which are of great general interest, but which have, of necessity, been very cursorily alluded to in the foregoing paper. They concern, first, some particulars, specially obtained, of the great Paris reconstruction; and, second, the experiences now available in dealing, in a purely business way, with the improved rehousing of the poor and the poorest classes:—

A.—The Reconstruction of the City of Paris.

In reply to my inquiries on this subject, I have been favoured with the following very interesting letter from the Secretary to the British Chamber of Commerce at Paris, kindly procured for me by Mr. Murray, the Secretary of the London Chamber:—

"The system adopted by Baron Haussman for the reconstruction of Paris was this:—

"The expropriations were complete. The city bought out the tenants of houses, compensating them for their compulsory removal according to the nature of their business, and especially the length of the leases unexpired. Persons in business were very liberally paid, the landlords also. If the offer was not accepted, the parties went before a jury, and the award was generally about midway between the sum offered by the city and that demanded by the landlords or tenants. Persons without leases received no compensation beyond one quarter's rent. The property being bought by means of a loan raised for he purpose, the city pulled down the houses, laid out the new thoroughfares, making the roads, &c., and then sold the ground for building by tender. Purchasers were bound by certain rules relative to the height of the houses, façades, thickness of walls, and in some measure as to the architecture. The ground was sold freehold and absolutely, and the city retained no interest in the future improved value of the property. The debt of the city is much greater than mentioned by Mr. Westgarth. The total loans raised during the last thirty years amount to nearly £80 millions, and possibly about £60 millions is still due. The present annual charge, interest and redemption, is nearly £4 millions, which, at 6 per cent. for interest and redemption, would represent £64 millions. The reconstruction was not carried out by the city, and the debt represents principally the difference between the price at which the ground was sold and the sum paid for purchase, compensation, levelling, and road-making, excepting of course the portions of the loans expended in municipal buildings, which was considerable, for the city has built or rebuilt mairies or town-halls in most of the twenty arrondissements of Paris, theatres, hospitals, churches, &c., besides the new Hotel de Ville. Some of the buildings, the theatres for example, produce a revenue, but they were built with borrowed capital.

"Builders also worked with borrowed money, obtained from the Credit Fonciers, and generally sold the houses when finished; many were rented or bought by insurance companies as a permanent investment. In most cases the builders, and particularly the purchasers of houses, have done well, as the improvements were carried out in central parts of Paris. The population has increased very rapidly during the last thirty years, and as the number of houses built was much less than those pulled down—more space being occupied by the thoroughfares—rents have risen enormously in the neighbourhoods in which the improvements were carried out. As an inducement to builders to purchase the ground and build on it, the new houses were freed from all municipal taxes for a certain period, thirty years I believe, but I am not sure that the practice is continued.

"In fine, the unearned increment has benefited the landlords alone, and the city derives no direct benefit from the increase in the value of house property."

B.—The Experience now Available in Dealing, in a Purely Business Way, with the Improved Rehousing of the Poorer and the Poorest Classes.

I do not doubt that the proposed trust, if successfully established, would early turn its attention to this question, looking to its extreme interest even as an economic problem, and apart from its social importance. In comparing notes with Miss Hill and others, as well as drawing upon twenty years' thought of the subject on my own part, I have arrived at the following conclusions upon the leading points:—

1. The poorer classes will now readily accommodate themselves to living in great edifices of many homes, and hence economies of the most important kind in their housing.

2. But they will not co-operate; they must be individually free.

3. Hence, these buildings must be under a proprietor or manager, with whom the tenants or occupants freely deal.

4. The modern great lodging-houses for the very poor supply our typical building, and we must improve upon its lines; that is to say, our building should have many separate homes, of one or more rooms, grouped around a commodious hall or common sitting and recreation room, which comprises common kitchen, manager's shop or store, &c. The manager may supply things cooked as well as raw. On a great scale of operation, he might have a very first-class cook.

5. When this common hall is well lighted and warmed, could not fires, kitchens, and even lighting apparatus in the various homes be all dispensed with, to the incredihle economising alike of the time and money of the occupants?

6. Partial furnishing, by the way of fixtures, of an ndestructible and incombustible kind, would, at a very small addition to rent, greatly help poor tenants, and exclude much cause of dirt and vermin, and risk of fire.

7. The danger of fire is thus minimised in this direction, and further by dispensing with firing and lighting in the rooms. The warm air of the hall fills the rooms, and plentiful use of glass allows light also to pass into them.

8. Rent should include a redemption fund, to make the tenant eventual proprietor, and possess him, meanwhile, of a fund of savings to fall back upon. This may be so protracted as to make it unfelt in the economies of the system. It will ensure more care of the property, and it may save to the management all trouble and loss from unlet rooms or homes. But, on the other hand, a new occupant, selected by the vacating tenant as offering the highest price for the title deed, may be an objectionable person. Miss Hill, although alive to the advantages, fears that control may be less effective over such prospective proprietors. But, altogether, the balance of advantage for this plan seems to me undoubted.

9. Lastly, comes the profit and loss account, the business part of the question. Two shillings a week seems as yet the lowest price of a room in and about London, and 6d. must be added for a thirty years, redemption. Elsewhere than London, the houses come cheaper, and Mr. Forwood mentions the low price of 2s. 6d. to 3s. as the rent of three rooms in Liverpool. Doubtless there are "rooms and rooms," and we must aim at a good room. The scale of our proposed operations, as well as all previous experience, will help the economy, so that even Sir R. Cross's 1s. 3d. a room may be approached. A little more is due for redemption, and still a little more for the use of the hall, which is practically a sitting-room added to each bed-room. Miss Hill seems sure that 5 per cent. may be cleared out of well-managed buildings, and this has been already done lately at Glasgow, even under municipal management, as Mr. Chamberlain mentions in his article in the December (1883) issue of the *Nineteenth Century*. Nor does this redemption plan quite deprive us of all the "natural increment" resource, because the ground floor, and even ground and first floors, may be made shops or warehouses, and separately dealt with. The comparatively cheap financing of the company would be a further resource, as the 5 per cent. of expected profit stands against only $3\frac{1}{2}$ per cent. or so of the probable cost to the trust of raising money. There seems thus the promise of even more than enough proportion from this particular source towards the proposed company's dividend. An interesting experiment would be some very large building of this kind, so as to test to the full all its possible economies. It might comprise an agency for mutual lending and borrowing, upon the security of the titles to each room or home. Punctuality of rent payment must be strictly enforced, but all facilities may be given to meet emergencies by temporary loans on the title deeds.

DISCUSSION.

The CHAIRMAN said he felt sure that many present could bear testimony to the truthfulness of the picture which had been drawn of Central London, but Mr. Westgarth had gone on to draw a most attractive picture of what Central London might be, and had also pointed out how that picture might be realised.

Mr. CATES said he had anticipated hearing this subject dealt with in a more practical manner than it was in the paper, for he thought the scheme suggested was somewhat Utopian. The picture the author had drawn of the London of the future was very beautiful, and made everyone regret that they did not inhabit such a healthy and charming city; but he feared the period of thirty years would be long gone by before any such dream were realised. It would be impossible to enter into the financial details without a careful study of the paper, but they could only judge by the experience of the past how impossible it was to carry out such a scheme. He had himself had some experience in metropolitan improvements, and in every instance they had resulted in very heavy loss. The special case of Northumberland-avenue was very exceptional, the expropriation being almost confined to one house and garden, whilst the new thoroughfare formed a grand avenue leading to the Embankment. Mr. Westgarth had spoken of the congeries of alleys, and tortuous and devious ways and streets which constituted the centre of London, but, notwithstanding their narrowness, in them the whole of our commerce was concentrated. It might be unfortunate that nearly all our literature should originate in Paternoster-row, and that Wood-street and other great seats of commerce should be so narrow, but he must say he contemplated with something like horror the idea of driving a new street through the centre of those crowded localities. If a plan on a larger scale had been exhibited, with all the small freeholds and separate properties marked upon it which would be interfered with, many of which would entirely vanish under the arrangements for Mr. Westgarth's broad thoroughfares, and the owners of which could not at any reasonable cost be provided with fresh accommodation, every one would be appalled at the character of the scheme. He hoped that, from all the study and attention the author had given to the subject, some more feasible plan would be evolved; but whilst thinking of Central London, it would be as well if he also paid some attention to what had been going on in the outskirts during the last twenty-five years. There was hardly any city which possessed more spacious thoroughfares or better roads of approach than London, but what had become of them? They were now mere crowded streets, with shops up to the pavement, where some few years ago there were pleasant gardens and tree-planted margins to the roads. The grasping devices of the landlords, the so-called energy of the shopkeepers, and the absence of all proper control by the authorities, had been the cause of this change; in place of the gardens, shops were built out on the forecourts, no provision being made for the increased traffic, except in a few instances. The most remarkable fact was that the great thoroughfare—the New-road—which might have been equivalent to the Boulevard des Italiens, but which was now become quite a term of reproach, was actually protected by the Act under which it was formed from any such encroachment, for there was an express provision that no building should be erected within fifty feet of the margin of the road, under penalty of being destroyed as a common nuisance. The execution of the Act, however, seemed to have been left in the hands of the Vestries, and the result might be seen by any one who would walk from the Portland-road Station to Islington. It was only by good fortune that the portion of the road in the parish of Marylebone, which was mostly in the hands of one large landowner, had escaped the same fate.

Mr. MARTIN WOOD said it was very usual to speak of the French economists as possessing superior ability in their science, at any rate in its exposition; but, to night, they had an instance in which a Scotch economist showed a practical application of one of the central truths of political economy, which was to his mind very gratifying. He referred to the way in which Mr. Westgarth had treated the doctrine of unearned increment. He spoke of this phrase as being rather an invidious one, for what reason he did not quite understand; but, at any rate, the term he used was a strictly scientific one, and nothing could be more admirable than the practical way in which he applied the principle as the keystone to the financial portion of his scheme. With regard to the other aspect of the matter, the constitution of a trust, he did not see why such an enterprise should not be undertaken by a proper civic authority, not such as now existed, and had sacrificed the public interest in the way described by the last speaker, but such an authority as might be easily supposed to exist. Mr. Westgarth proposed that the Board of Works and the Corporation of London should be represented on the trust, and he could not see why a truly imperial municipality should not manage the whole thing in the public interest.

Mr. KLENCK had been somewhat disappointed with the paper, and did not think there was the least chance of success for a scheme which contemplated an expenditure of a hundred millions, and yet only proposed that one million of capital should be called up in cash. A trust of ten millions, with one tenth called up, would never execute such a work as was proposed. It would soon be found that the whole ten millions would have to be called up, and 6 per cent. would have to be paid on the whole; and thirty years was certainly not long enough to realise the property, and recoup the outlay. If Mr. Westgarth went carefully into the subject, he would find that it would take considerably more than one hundred millions to remodel London.

Mr. C. F. HAYWARD desired to thank Mr. Westgarth for his paper, and thought they ought to welcome the scheme rather than attempt to throw cold water on it. The map exhibited only showed a very small portion of the centre of London, in which it might be very difficult to carry out the desired improvements; but London was not one square mile, but 117, and he believed that only that small portion had been shown because it would have been impossible to represent the whole area on a sufficiently large scale. The West Central district was as important as the City proper. He recollected in 1869, a Committee of the Society of Arts holding many sittings to consider the subject of the Thames Embankment. If such a comprehensive scheme as that now brought forward had been carried out then, and the frontages towards the river had been properly utilised, it would long since have repaid the outlay The same thing might have been done with the space surrounding the new Law Courts, including Clare-market and the district immediately adjoining and reaching from the Strand to Holborn. He had studied that neighbourhood with a view to seeing if some large building scheme could be carried out there, and he was satisfied that if a good scheme had been launched at the time the foundation of the new Law Courts were being laid, not only might good approaches to that building have been provided, but sufficient room might have been found for artisans' dwellings. Ample accommodation for offices, &c., might also have been provided, and the whole expense could have been recouped. He was not in favour of a grand street from St. Paul's to the Mansion-house in a straight line, which they were so anxious for in Paris, and which to his mind, gave a very monotonous appearance to that city. He did not think such an improvement necessary, or that it would pay; but in other directions, improvements might be made on the same lines, and in any such scheme the accommodation of the poorer classes must not be forgotten. It must also be remembered that, as was found in the case of railways, unless the scheme were large enough, it would entail a great loss. Those who had to do with railway undertakings knew that, unless sufficient property were taken, they simply improved the adjoining property, and had themselves to bear all the expense, but if they took enough they shared in the improvement, and got their outlay recouped.

Mr. LIGGINS said that London was not to be improved in the way described by the reader of the paper in thirty years, nor yet in 300. He was disappointed not to hear something said about the accommodation of the working classes, who certainly would never live in the magnificent buildings which had been described. Some fifty years ago, he visited, in company with his friend Mr. Forrester, better known as Alfred Crowquill, many of the worst slums of the metropolis. He was soon after followed by Charles Dickens; but from that day to this very little had been done to remedy the evils which were then depicted by those writers. But this was the fault not of the citizens, not of the vestries, but of the law makers. As a vestryman of Kensington, he was often grieved that he could not do his duty to his poorer brethren, because the law was defective. But it was a fact that proper buildings could be erected for the working classes, which would pay a profit of 4 per cent., as he had been informed by a trustee of the Peabody Fund; and it was also a fact, which some might not be aware of, that the rents paid by the tenants of that Trust were over a thousand pounds a week. Mr. Westgarth seemed to forget that most of the London thoroughfares had been very much widened; Portobello-road had been more than doubled, and though the shops were not equal to those in Bond-street, they were suited to the wants of the neighbourhood, and the sanitary arrangements were not unsatisfactory. Many of the streets from Kensington to Hyde-park-corner had been widened considerably within the last few years; the high brick wall which formerly bounded the Green-park in Piccadilly was removed by Sir Robert Peel, and the road was widened by at least one-third, and the streets all over London had been treated in the same way. He remembered when parts of the Strand were not half the present width, and when Trafalgar-square was a ploughed field. It was the Board of Works which had made most of these improvements, and the ratepayers found the money. The same thing had taken place in the City—in the Poultry, in Eastcheap, and Queen Victoria-street. But at what cost was it done? Many persons were ruined by being turned out of their premises. It was no use to tell them they should have the first choice in the new street; they found plate-glass and polished granite fronts, and had to pay three times their former rent, which left them no chance of making a living. Again, with regard to covered ways and arcades, he did not consider they were suitable for London; the cost would be immense, and until smoke was abolished, which it was far from being yet, the glass would get so covered with blacks as to prevent sufficient light coming through for purposes of business. This scheme was very grand, but at the same time it was very limited, and would, practically, do nothing to remedy the evils they had to encounter.

Colonel CAMPBELL said that poor men wanted good dwellings, but they wanted also food, and to enable them to get food they wanted work. One of the reasons why they congregated in places like London and Glasgow was because the food coming from abroad was brought in ships to these large seaports, and thus a state of congestion was established. After the Haussmannising period in Paris, the working classes were in a very miserable condition, and this was caused not only by the turning out of the poor, but because so many new houses had been built, that hardly any repairs were needed, and there was a great scarcity of work. If any large reconstruction scheme were carried out, that must be the result. Paris had been improved, and now they were beginning to cheapen the means of transport, spending £40,000,000 in improving the water ways, so that coal and building materials might be brought there more cheaply. In the case of a large city, the question of cheap transport ought to precede that of reconstruction. A great deal had been said lately on the question of improved dwellings, but how could you have cheap dwellings while the carriage of building materials remained at present rates. London, big as it was, was but an incident in the valley of the Thames, and improved transport by means of the Thames was certainly worth consideration before the question of reconstruction was gone into.

Mr. DIPNALL said he had resided in London for the last 30 years, and could speak not only of the rise in value, but also of the great improvements in health and in the buildings generally, which had taken place. In former days, however, the windows of the houses were all lighted up after dark, and had the comfortable look of residences, but now the City of an evening looked like an uninhabited place. It was crowded by day, but it was the dullest of all dull places at night and on Sundays. He had recently observed the splendid buildings erected by the Peabody Fund in Bunhill-row, and also in Bethnal-green and elsewhere, and there was no doubt that great efforts had been made to improve the dwellings of the poor, but still there were many defects. Where in the Peabody-buildings was there any accommodation for the storage of the merchandise which the people dealt in, or for the donkeys which many of them kept to aid them in their trade? If the city of London were to be rebuilt in thirty years, what would be its condition in the meanwhile? It would be like a city in a state of siege, with earthworks thrown up everywhere, and no possibility of carrying on either business or the traffic of the streets. Paris had been referred to, and he considered that it had lost much of its charm by the construction of so many broad and straight thoroughfares. He thought that both this generation and the next would die out before the fringe of this subject had been touched. He did not doubt the good intentions of Mr. Westgarth, but he feared that, both in his facts and figures, he was considerably astray.

Mr. WESTGARTH, in reply, said it was, of course, rather formidable to look forward to so great a work, but if the task were to be done thoroughly, there was no other course. Business people were very apt to look with terror at such an upturning as he had described, but there was the sanitary aspect of the question to be considered, and, bearing that in mind, he did not see how it was to be avoided. Mr. Liggins said it would be an impossibility to rebuild the whole of London in thirty years, but that was no plan of his; he proposed not to rebuild the whole 117 square miles, but probably less than one, for he referred only to Central London. No doubt something beyond that might be done also, and if the trust came into existence, the desirability of grand streets going north, south, east, and west, would no doubt be considered; but his own idea was to limit this great reconstruction to the crowded central part only. Mr. Klenck said it would be impossible to carry out so great a work with so small a capital. That was a business question on which he thought he could speak with some authority. It was not a very small capital, for though he only proposed that one million should be paid up, the remaining nine would be guaranteed, and the greater part of the money would no doubt be raised by the issue of 3½ per cent. stock, secured on the rates of the improved city. Besides, he reckoned that the larger portion of the proprietary would prefer not to be expropriated, but to join the undertaking, so that the £100,000,000 might very likely be considerably reduced.

The CHAIRMAN remarked that Mr. Westgarth had only touched very briefly on the points which had been mentioned in the discussion, and his modesty had prevented him from referring to one subject on which complaint had been made without, as he thought, sufficient justification. He alluded to the question of dwellings for the poor, which had certainly occupied a very prominent place in his mind when considering this subject, as was shown by the fact that the foremost rank amongst the subjects for which he had offered prizes was the best means of constructing dwellings for the poor in great cities. Many of the ideas he had thrown out would no doubt set them thinking, even if they were not at once accepted, and when they fructified in that way, by leading those who were technically qualified to deal with the various branches of the subject, might lead to very great improvements, which all would agree were needed, not only in Central but in London generally. He would conclude by proposing a vote of thanks to Mr. Westgarth for his able paper.

The vote of thanks was carried unanimously, and the meeting separated.

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION.

MEMORANDUM FROM THE SUB-COMMITTEE ON "AMBULANCE."

The following heads indicate the articles and appliances which the Committee are anxious may be shown by the Army Medical Departments of various countries, the societies established to render aid to the sick and wounded in war, and other organisations which may be able and willing to contribute.

1. Personal surgical equipment as carried by the medical officers of the army in question.

2. Appliances for treatment of wounds, carried by the soldier himself in the field.

3. Personal surgical equipment carried by ambulance attendants in the field, consisting of surgical haversacks (*havresacs sanitaires*), medical panniers (*caisses sanitaires*), surgical knapsacks, field companions.

4. Ambulance appliances carried by men, such as stretchers (*brancards*), hammocks, dhoolies, and palanquins.

5. Wheeled conveyances wheeled by men—wheeled stretchers.

6. Ambulance equipment carried by mules, horses, &c. Cacolets, litières, mountain ambulance equipment (*ambulance de montagne*), cooking equipment for mountain campaigns—portable medicine chests, compressed drugs, &c.

7. Wheeled vehicles used for the conveyance of sick, fourgons containing the equipment of hospital corps, surgery waggons, equipment waggons, field cooking waggons, pharmacy waggons, nursing utensils carried in waggons of field hospital. Books of instruction for use, diagrams.

8. Railway ambulances, consisting of carriages for wounded, with fittings, cooking carriages, and all the equipment of ambulance trains. Materials for converting ordinary carriages into ambulance carriages.

9. It would be useful if some attendants accustomed to the use of the *materiel* accompanied the articles.

The articles will be arranged in accordance with the following classification :—

Group IIIa.—Ambulance.

Class 31a.—Aid to sick and wounded in war. Transport—(*a*) By human agency ; stretchers, litters, dhoolies, palanquins, handcarts, stretchers on wheels. (*b*) By animal traction ; mule litters and chairs, camel and elephant litters, wheel carriages. (*c*) By mechanical means ; railway ambulances, ship or water carriage. Treatment (with portable appliances and portable drugs). (*a*) On the field. (*b*) In hut hospitals. (*c*) In tent hospitals.

Class 31b.—Aid to sick and injured in peace. Transport—(*a*) By human agency; stretchers, litters, dhoolies, palanquins, hand-carts. (*b*) By animal traction ; for accidents and injuries, for infectious diseases, for ordinary sickness. (*c*) By mechanical means ; railway carriages for sick and invalids, water carriage. Treatment (with appliances). (*a*) Hut hospitals for infectious fevers and for epidemic diseases. (*b*) In tent hospitals. (*c*) In hospital ships. (*d*) In sick rooms.

Memorandum from the Sub-Committee on "Dress."

The following is the classification of the Group :—

Class 13.—Collections illustrative of the history of dress, national costume, &c.

Class 14.—Waterproof clothing, india-rubber, gutta-percha, &c.

Class 15.—Furs, skins, and feathers, dresses for extreme climates, &c.

Class 16.—Dress for sport, hunting suits, &c.

Class 17.—Life-saving dress, divers' dress, fire-proof dress, &c.

Class 17a.—The comparative value of different dress materials for articles of clothing.

Class 18.—Publications and literature relating to Group II, patterns, statistics, diagrams, models.

Class 19.—Machinery and appliances for the preparation of articles under Group II.

Class 17a, has been added at the suggestion of the Sub-Committee. Under it should be displayed a number of illustrative specimens to show the comparative value or different dress fabrics with reference to their "warmth," their hygroscopic properties, the influence of the colour of materials in modifying the effects of sun-heat, and the like.

It would be well to show under this class models and drawings illustrative of the effects of poisonous dyes (in clothing) upon the skin. Materials dyed with poisonous and non-poisonous dyes could be placed together for purposes of comparison.

The scope of this class may be considerably extended, and the section be made to demonstrate the scientific bases of healthy clothing.

The subject of underclothing is of such great importance that the Sub-Committee are prepared to arrange for a special display of materials and garments, &c., worn next to the skin. Some of these will be shown in a special annexe, to which females alone will have access, or which will, at least, not be open to both sexes at one time. As one special feature in such an exhibition, the Sub-Committee would suggest a series of models displaying the first clothing of infants as adopted in the various countries of the world—so far as such examples could be obtained.

Class 13.—It is suggested that, as far as possible, dresses and costumes shown should be displayed upon lay figures, and that the exhibition of ancient costumes should be encouraged in preference to modern reproductions of the same.

Class 15.—It is suggested that the subject of suitable dresses for extreme climates should be demonstrated with as much detail as possible.

Class 16.—Under this class it is suggested that especial attention should be given to dresses suitable for women engaging in exercise, such as dresses for mountaineering, for the moors, for swimming, for horse exercise, for gymnastics and the like.

Class 17.—Under this class should be actually demonstrated the value of certain substances used for making muslin and like fabrics non-inflammable. The various artificial starches made for this purpose should be displayed, and their use and effect demonstrated.

The dress of female operatives engaged among machinery may be dealt with in this class, also special dresses recommended, or in use in factories and occupations of special character, *e.g.*—dresses for lead and other factories; dresses of nurses and sick attendants; of soldiers and sailors; life-saving dresses; firemen's dresses.

Class 18.—Under this class will be exhibited dress injurious to health, casts of feet deformed by boots, &c., spinal and thoracic deformities ascribed to tight-lacing, models to show the position of the viscera displaced by such practices and the like.

Class 19.—The Sub-Committee would suggest the following under this heading :—Machine *versus* hand-weaving, glove-making by machinery, lace-making illustrated by operatives from Honiton, Nottingham, Brussels, &c., the making of hats, the making of boots and shoes, and of lasts for the same, the dressing of furs and certain skins, sewing and knitting machines, &c. (in limited number), the manufacture of waterproof fabrics, the making of crape and some special fabrics, the application of jute to the manufacture of dress fabrics, imitation fabrics.

THE ORANGE TRADE.

Few importations have increased so rapidly as that of oranges during the last ten years. It is within the memory of many that they were really a scarce fruit, and comparatively dear, and when none could be got at all for many months of the year. But now we have oranges all the year round, and they can often be bought at the rate of three or four a penny in almost every street. The recognised season for importation covers, generally speaking, about nine months of the year, beginning in November and ending in July, but consignments continue to come in after that, though not large ones, and so the market is never without oranges. The revolution in, and development of, the trade has been brought about mainly by the employment in it of large steamers, the first of which exclusively engaged in the trade arrived in London, in November, 1867. In the recent Christmas week there were nine ships of various kinds laden with oranges in the port of London. The first mention of oranges being brought to this country is in the reign of Edward I., when it is recorded that in 1290 that the Queen bought various fruits from the cargo of a Spanish ship which came to Portsmouth, and that among them were seven oranges *(Poma de Orenge)*. But no mention of this fruit is found in the "Libell of English Policy" or the "Liber Albus of London," in which most articles of fruit and grocery find a record. We read, however, of oranges in the reign of Henry VI. (1432); and they are mentioned in the "Paston Letters" in 1470. They are entered in the "household expenses" both of Henry VIII. (1530), and in that of his daughter the Princess Mary (1539); and by the end of the 16th century they were recognised as a notable article of commerce, and, according to Stow (1598), Billingsgate was the principal quay at which they were landed. Sir Walter Raleigh, "the father of tobacco," is credited with having brought oranges to England, and it is said that Sir Francis Carew, who married his niece, planted their seeds and produced orange trees at Beddington, in Surrey; of which Bishop Gibson, in his additions to Camden's "Britannia," speaks as having been there for a hundred years previous to 1695. These trees perished in the "great frost" in 1739. At Hampton Court there are still several orange trees, believed to be 300 years old. The most interesting feature in the growth of the orange tree is that it bears at one time what may be called three different stages—the blossom, the immature fruit, and the ripe oranges. We read of oranges in Shakespeare; and the famous Mistress Nell Gwynne carried her orange basket in Drury-lane, and probably from an earlier period "bills of the play" were associated with oranges. When Pepys went to the "King's Playhouse" with an "order," the successors of "pretty, witty Nelly" with these orange baskets were a recognised institution; and to the present day the odour of orange peel has a peculiar affinity to the flare of the footlights, at least among the "gods of the gallery."

Our chief orange supply comes from Valencia and other Spanish seaports; but Lisbon, Villa Real, Ariero, and Oporto also contribute their quota. Other consignments hail from the Azores, Brazil, Palermo, and Malta, and other Mediterranean port. The St. Michael's oranges are held in high esteem by connoisseurs, and they are pre-eminently the Christmas fruit, as they do not begin to arrive in this country till the end of November. The St. Michael's crop was, in 1882, almost a total failure, in consequence of a disease among the trees, caused, it is supposed, by some insect; and fears were entertained that eventually the supply from the island would almost cease, as it has from others of the Azores group, such as Terceira, Fayal, and St. George's, which once produced a large quantity of fruit. St. Michael oranges, as are most Brazilian, are separately wrapped, in the packages, in the leaves of Indian corn, while oranges from all other parts are wrapped in thin paper. The "blood" oranges, as they are called, come mostly from Valencia, but a few from Malta. The aromatic and delicious Tangierenes hail from St. Michael's, and also from Lisbon, and vary considerably in price, according to the supply. Seville oranges (specially alluded to in Shakespeare's "Much Ado about Nothing") come from the place of that name, and, as most people know, are now almost exclusively used for making marmalade and orange wine. For both these purposes, however, the Palermo "bitters" are really better adapted; and it may not be generally known that the best marmalade of all is produced from the shaddock, a sort of cross between the orange and the lemon, and named after a Captain Shaddock, who first brought it from China, or, as some say, from Guinea, and planted it in the West Indies, whence we derive our limited supply. It is the bitter element in the Seville and Palermo oranges which fits them for marmalade, as it preserves their skins while they are drying. We need not be much alarmed at the stories we hear of orange peel being collected at places of entertainment and in the streets for marmalade making, as the skins of ordinary oranges, instead of drying, simply become rotten.

The head-quarters of the orange trade is Pudding-lane, Lower Thames-street, where, during the height of the season, the chief brokers hold sales three or four times a week. Pudding-lane, where the Great Fire of London is said to have begun, is not exactly an orange grove, but the fruit trade makes it about as busy a spot as any in the City; and if an unwary passenger happens to get in the way of the "fellowship" porters carrying along it, without intermission, the wooden packages of oranges, he is not unlikely to become the object of some Billingsgate vernacular. The trade in oranges and other fruits has now become so enormous, that Lower Thames-street and its vicinity is all too small to accommodate it, even if the fish trade were removed. There are many things more unlikely than that this may be eventually the case, and that the more sweetly-smelling fruit trade may one day occupy the historical market of Billingsgate itself. A large quantity of the oranges sold in Pudding-lane afterwards finds its way to Duke's-place, a quarter of the Hebrew region on the west of Houndsditch, where it is re-sold to shopkeepers and costermongers. This locality is redolent of oranges, and it is no exaggeration to say that, in wet weather, you may walk literally ankle-deep in orange pulp and peel, mixed with cocoa-nut fibre. The appetite for oranges among the masses in London seems almost insatiable, and it is said that nearly half the retail trade in them is done by the itinerant street vendors. A package of oranges contains, on an average, 400; and in the season of 1881-2, nearly a million packages were landed in London; and not far short of that number were landed in Liverpool. Glasgow receives a large, and each year an increasing supply; while Bristol and Hull account for many thousands. Altogether, it was computed that in the season of 1881-82, two and a-half million packages were imported into this country, which would represent something like 1,000,000,000 of oranges for home consumption. This season will show a still greater advance, as in most orange-growing districts the supply is plentiful; and the market value of the total importation, including lemons, will represent something not far short of two millions sterling, first hand. The increase in the trade is due not only to increased facilities of transport, but to the abolition of the duty on the fruit. Formerly, 2s. 6d. per package was the impost; in 1853 it was reduced to 8d; and was altogether abolished in 1861. Happily, the orange is a very harmless, if not a decidedly wholesome, fruit.

Correspondence.

CHINESE COOKERY.

In the Cantor Lecture (II.) delivered December 10th, 1883, Mr. Mattieu Williams observes, at page 115:—"That large tracts of country should be periodically desolated by locusts, is a striking proof of the neglected condition of the science of cookery. If the locusts devour the crops, why not cook, preserve, and eat the locusts?"

It may be of interest to note, in connection with this suggestion, that the Chinese, who have anticipated western nations in so many things, have shown the way in this matter also.

Chancing to be at Teintsin in the early part of the summer of 1877, when the country was being devastated by dense flights of locusts, I observed the natives to be busily employed in catching them; and writing in connection with this circumstance, remarked as follows:—"The insects are much used as food, and the people thus compensate themselves, to some degree, for the loss of crops. The insects are fried in fat, wings and all, just like a fish. They are caught mostly by dragging the fields with nets, but when quite young and unable to fly, they are trapped as follows:—A triangular enclosure of matting is built, open at the base, and a hole dug in the ground, containing a large jar at the apex. The fields are then beaten, and the locusts driven into the enclosure, and then at last in the jar."*

There are many points in connection with the science of cookery in regard to which we might, with profit, take some hints from our "Celestial" friends, especially with reference to the utilisation of waste, and the methods of turning to account, in a savoury way, the good things of nature. The poorest family in China rarely sits down to a meal of less than three varieties of hot cooked food, and there are a few more interesting sights than watching the preparation of the family meal.

The boilers in which the staff of life in Southern China—rice—is prepared, is made of the thinnest cast iron, so thin that a very slight tap is enough to fracture it, heated over an earthenware vessel, containing a few pieces of charcoal; and, directly the cooking is completed, each piece of charcoal is carefully lifted out, extinguished, and put away for future use. An enterprising European firm once thought to supersede the "jimcrack" native pot by a good substantial article of Birmingham make, but the natives soon found that, with the "improved" article, three times as much fuel was required to heat the metal through as would cook their meal in the old one, and so the superior Birmingham boiler was discarded.

HENRY N. SHORE,
Lieut. R.N.

Coastguard, Greenock.
February 2nd, 1884.

ECONOMY OF FUEL.

In the year 1867, I had the pleasure of showing the late Professor Macquorn Rankine, at Messrs. Field's Paraffin Works, Lambeth, a boiler burning mineral oil, which he told me was the first time he had ever seen chemical combustion perfectly attained on the large scale. This was under the Wise, Field, and Aydon patent. Afterwards, at my special request, he read at the United Service Institution, on the 1st of April, 1867, a most valuable paper on the "Economy of Fuel." This will be found in the journal of the institution of that date, and will serve to correct some of Mr. Gümpel's impressions as to the efficiency of heat-engines; as also the idea that I, personally, am ignorant of the chemical theory involved. I much prefer the "British" unit of evaporation, used in the paper referred to, to the centigrade unit, because the "British unit" shows the theoretic evaporation value of each substance used as fuel, in terms of pounds of water evaporated from, and at 212° Fahr.; but the centigrade unit involves further calculation, thereby rendering the theory more obscure. Later on, I

* "Jottings in China, &c."

shall be prepared to show how, under what conditions, and to what extent, the burning of the hydrogen of the steam used to blow in the oil, can add to the total calorific power of liquid or condensed fuel, so as to bring it up to the 46 lbs. of water per pound of oil, which I announced as having been obtained under a common Cornish boiler, in my paper on "Liquid Fuel," read before the Institution of Naval Architects, April 2nd, 1868. I could not then account for the fact which I recorded, but by continued study of the subject, I believe I have now established the conditions under which that result can be constantly and readily obtained. This, as in that paper I showed, was not the case with those who were then, by a fortunate but accidental combination, obtaining, at intervals, that extremely satisfactory result of replacing 3 tons per diem of Butterley coal by 109 gals. (1,090 lbs.) of oil, *i.e.*, six times the duty of coal, nearly.

When this is done, and Mr. Perkins's engines and boilers are used, which now give one indicated horsepower per hour, according to Sir Frederick Bramwell's observations on the *Anthracite* (a comparatively small steamer), for 1·2 lbs. of coal per hour, I think it will be evident that an indicated horse-power will be obtained for considerably less than one-sixth of a pound of fuel, and corresponding facilities will be available for those who wish to develop the question of electric launches, or electric lights, or the conversion of heat into electricity for whatever purpose. Among such purposes, not the least important, in my opinion, is the deposition of metals from the solutions of their ores in a perfectly pure state, after the applications of the humid processes of metallurgy.

J. H. Selwyn.

16, Gloucester-crescent, Hyde-park,
February 5th, 1884.

General Notes.

Grocers' Company.—Three Scholarships, each of the value of £250 per annum, tenable for one year, with eligibility for re-appointment, for the encouragement of original research in sanitary science, are offered for competition by the Grocers' Company. Two of these scholarships will be filled up in May next, and candidates (British subjects only) must not apply later than the last day of April. In addition to these scholarships, a Discovery Prize of £1,000 will be offered for universal competition once in every four years. The subject for the first award relates to a method for the cultivation of the vaccine contagium apart from the animal body, in some medium not otherwise zymotic. Essays must be sent in before December 31st, 1886. Particulars can be obtained on written application to the Clerk of the Grocers' Company, Grocers'-hall, London, E.C.

New Paper Material.—Consul Gade, of Christiania, has submitted to the United States Government a report relative to a new industry, or, rather, the use of a raw material for the manufacture of paper, which will soon be in use in Norway and Sweden. Among the raw materials already employed in the manufacture of paper are rags, esparto, straw, and wool, but all these are expensive, and this new and cheaper one, which consists of white moss, will now be added to the list. The moss is found in immense quantities in Norway and Sweden, but it is not the living plant as it grows in the fields which is used for making paper, but the remains of this kind of moss which have gradually accumulated in the woods. The mouldering which the moss has gradually undergone constitutes a preparation for the paper manufacture made by nature herself. A factory is now building for the manufacture in Sweden, and examination has shown that near this place many millions of pounds of the raw material are to be found; in fact, a quantity sufficient to support a large manufactory for many years. Paper of different thicknesses, and pasteboard made of the white moss, have already been shown, the latter even in sheets three-quarters of an inch thick. It is as hard as wood, and can easily be painted and polished. This manufacture is said to be very well suited for taking the place of wood for many purposes. It has all the good qualities but none of the defects of wood, as it neither cracks nor warps. The pasteboard can consequently be used for door and window frames, and for architectural ornaments of all kinds of furniture. —*The Times*.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, eight o'clock:—

February 13.—"New Process of Permanent Mural Painting, invented by Adolph Keim, of Munich. By Rev. J. A. Rivington. Hubert Herkomer, A.R.A., will preside.

February 20.—"Reclamation of Land on the North-Western Coast of England." By Hyde Clarke.

February 27.—"Vital Steps in Sanitary Progress." By B. W. Richardson, M.D., F.R.S.

March 5.—"The Progress of Electric Lighting." By W. H. Preece, F.R.S.

March 12.—"Water Regulation, in regard to Supply, Floods, Drainage, and Transit." By General Rundall.

Foreign and Colonial Section.

Tuesday evenings:—

February 12.—"The Portuguese Colonies of

West Africa." By H. H. Johnston. Sir Frederick John Goldsmid, K.C.S.I., C.B., will preside.

Applied Chemistry and Physics Section.

Thursday evenings:—

February 28.—"Recent Progress in Dynamo-electric Machinery." By Professor Silvanus P. Thompson.

Indian Section.

Friday evenings:—

February 15.—"State Monopoly of Railways in India." By J. M. Maclean. Sir James Caird, K.C.B., will preside.

Cantor Lectures.

The Second Course will be on "Recent Improvements in Photo-Mechanical Printing Methods." By Thomas Bolas, F.C.S.

Lecture III. Feb. 11.—Intaglio Plates. Collotypes. Photo-Mechanical Methods, as applied to the Decoration of Pottery. Miscellaneous Processes.

The Third Course will be on "Building of London Houses." By Robert W. Edis, F.S.A.

Lecture 1. Feb. 18.—Their Arrangements, Aspect, Design, and General Planning.

Lecture 2. Feb. 25.—Sanitation, Lighting, Heating, and Ventilation.

Lecture 3. Mar. 3.—Fittings, Planned Furniture, Constructive Decoration.

MEETINGS FOR THE ENSUING WEEK.

Monday, Feb. 11...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. Thomas Bolas, "Recent Improvements in Photo-Mechanical Printing Methods." (Lecture III.)

Surveyors, 12, Great George-street, S.W., 8 p.m. Discussion on Mr. T. M. Rickman's paper, "Building Risks and their Incidence."

Geographical, University of London, Burlington-gardens, W., 8½ p.m. 1. General Sir Frederic J. Goldsmid, "My Recent Visit to the Congo." 2. Mr. E. Delmar Morgan, "Notes on the Lower Congo."

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Professor Ruskin, "The Storm-cloud of the Nineteenth Century."

Tuesday, Feb. 12 ... SOCIETY OF ARTS, John-street, Adelphi, W.C. (Foreign and Colonial Section.) Mr. H. H. Johnston, "The Portuguese Colonies of West Africa."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. Geikie, "The Origin of the Scenery of the British Isles." (Lecture III.)

Medical and Chirurgical, 53, Berners-street, Oxford-street, W., 8½ p.m.

Civil Engineers, 25, Great George-street, Westminster, S.W., 8 p.m. Adjourned discussion on Mr. F. R. Conder's paper, "Speed on Canals."

Photographic, 5A, Pall-mall East, S.W., 8 p.m. Annual Meeting.

Anthropological Inst., 4, St. Martin's-place, W.C., 8 p.m. 1. Mr. J. Park Harrison, "Exhibition of Skulls and other Remains from a Cemetery at Wheatley." 2. Dr. G. B. Barron, "A Humna Skull found near Southport." 3. Miss A. W. Buckland, "Traces of Commerce in Prehistoric Times." 4. Mr. John T. Young, "Some Palæolithic Fishing Implements from the Stoke Newington and Clapton Gravels."

Colonial Inst., St. James's Banqueting-hall, W., 8 p.m. Mr. Murray Smith, "The Australasian Dominion."

Parkes Museum of Hygiene, 74A, Margaret-street, Regent-street, W., 5 p.m. Mr. J. P. Seddon, "The Ventilation of Theatres."

Wednesday, Feb. 13...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Rev. J. A. Rivington, "New Process of Permanent Mural Painting, Invented by Adolph Keim, of Munich."

Graphic, University College, W.C., 8 p.m.

NOTICES.

CANTOR LECTURES.

The third and last lecture of the course of Cantor Lectures on "Recent Improvements in Photo-Mechanical Printing Methods," was delivered by Mr. Thomas Bolas, F.C.S., on Monday, 11th instant, in which he dealt with the subject of intaglio-plates, collotype, and photo-mechanical methods, as applied to the decoration of pottery. The lecturer concluded with a description of some miscellaneous processes.

The Chairman (Mr. B. Francis Cobb, Vice-President of the Society) moved a vote of thanks to Mr. Bolas for his interesting course of lectures, which was carried unanimously.

The lectures were illustrated by a large number of specimens kindly lent by various gentlemen and firms, and the following may be especially mentioned:—Mr. Geo. Smith, of Colebrooke-row, Islington; Messrs. Woodbury Treadaway and Co., of South Norwood; Dr. Pick (the representative of the Meisenbach Photo-Block Company), Mr. Dallas, Mr. E. de Zuccato, the Autotype Company, and Mr. Frewing, of Clapham.

Proceedings of the Society

FOREIGN AND COLONIAL SECTION.

Tuesday, February 12, 1884; Sir Frederick John Goldsmid, K.C.S.I., C.B., in the chair.

The paper read was—

THE PORTUGUESE COLONIES OF WEST AFRICA.

By H. H. Johnston.

Few Englishmen—and for the matter of that few Portuguese—often realsie or take into account that Portugal possesses more territory in Africa than any other European power. Without counting the lands over which she has merely a nominal right unenforced by occupation, there still remain over a million square miles of the African Continent, and its small adjacent islands, which belong to, and are administered by, the Crown of Portugal, and of these large colonies about one-half lies on the West Coast of Africa.

It is my intention to-night, with your kind permission, to give a brief account of my recent visit to these West African colonies of Portugal, and endeavour to lay before you, as succintly as possible, their present condition, and their future prospects.

Of course the first Portuguese possession off the Western Coast of Africa is Madeira, but this is too well-known for me to touch on, so I will pass on to the Cape Verde Islands, an archipelago lying about 300 miles out at sea opposite Senegal, between the parallels of 14° and 17° N. These islands are ten in number, not counting many smaller barren rocks, and their entire population is about 100,000, or 30 to the square mile. In spite of their apparently barren and sterile look from the sea, they are productive, and in the interior of most of the islands there are springs of water which, with careful manipulation, irrigate large quantities of fertile soil, and compensate for the almost entire absence of rain. The productions of the Cape Verde archipelago consist of superior coffee, cacao, orchilla-weed, castor-oil, rum, maize, salt, cotton, indigo, oranges of fine quality, limes, lemons, pine-apples, cocoa-nuts, bananas, and most tropical fruits, sugar-cane, tobacco, coral, and much cattle and other live stock, including a hardy and veiy serviceable breed of horses, which are constantly exported to the neighbouring continent.

The largest island of the group is Santiago, whereon is the seat of government for the whole archipelago. Its superficies is a little under 500 square miles. The interior is fertile and well cultivated, and traversed by excellent roads, with strongly made bridges across the many ravines. The mountains rise to over 4,000 feet, and from their sides gush springs of delicious water which is carefully husbanded, and used to irrigate vast plantations of Indian corn, castor-oil plant, sugar-cane, pine-apples, and tobacco. Water is also conveyed in leaden pipes from a considerable distance into the town of Praia, the capital of the island, where it is stored in an immense reservoir.

Though Santiago is the largest island of the Cape Verdes, it is but little known to English people, for only Portuguese steamers call at its port, which is not a remarkably safe one; on the other hand, the miserable little desert islet of Sao Vicente, owing to its splendid harbour, is become a place of cosmopolitan resort, where the Anglo-Brazilian Telegraph Company has a station, and where many great lines of steamers have their place of call. The jagged coast of Sao Vicente is grandly awful in its sublimity of desolation. Sharply peaked and precipitous mountains descend to the water's edge; and in between their masses are little inlets of blue foam-streaked sea. The mountains are variegated with the long sloping lines of their different strata; they are scarped, and worn, and twisted into fantastic shapes, and they look like the earth's throes of agony hardened into stone. There is not a sign of life, not a bird or a plant visible about them. As they stand out in their dead neutral tints against a glaring blue sky, they might represent a landscape in a lifeless planet. In the interior of Sao Vicente there is one spring of water where a little vegetation grows, and a few people live and try to raise fruit and vegetables for the town, but, as a rule, Sao Vicente is entirely nourished by the great island of Sant Antao opposite, from which it receives not only food and water, but even the very soil necessary to grow the few plants and trees which decorate its sandy streets.

The town itself is tidy, clean, and prosperous, with a fluctuating population of about 5,000, very mixed in nationality. There are English, French, Italian, Spanish, Portuguese, German, and Dutch hotels and restaurants. Steamers and warships of all nations come here to coal and telegraph, and the shops and stores are excellent and well provided with all necessary articles.

When we leave the prosperous and civilised Cape Verde Islands and arrive at the Portuguese possessions in Senegambia, which lie some 500 miles to the south-east, the contrast is very great in every way. We find ourselves in a most typically African part of Africa. The high and arid mountains of the Cape Verde archipelago are exchanged for a flat, marshy country, covered with the densest forest, and civilisation yields to utter savagery. Portuguese Guinea, which extends from about the 13th parallel to the 10th, just comes in between our colonies of the Gambia and Sierra Leone. This territory has about 200 miles of coast line, and offers many ways into the rich interior, by means of the great and navigable rivers, Casamança, Geba, and Cochen. Portuguese Guinea is, in fact, little more than the vast delta of these three great rivers, which communicate with each other by many natural canals. There is also the large archipelago of the Bissagos Islands, lying close to the mainland, and on one of these is placed the capital of the province, Bolama, where the Government and principal merchants reside. This town has a very pretty and inviting appearance from the river, its houses being mostly white with red roofs, or entirely built of red bricks, and surrounded by the brightest green vegetation. Fine lofty trees are dotted here and there, and the general aspect of colour is very pleasing and gay. The town is large, and the streets are broad, clean, and lighted throughout with lamps. Several well-built houses are to be seen, especially that of the Visconde d'Almeida, a Portuguese merchant, and about most of the buildings is a Moorish look, suggested by the Portuguese style of architecture which prevails, and which has inherited its long arcades and hollow squares, or *patios*, from its Arab parentage. This is a mode of building far better suited to the climate of Africa than many of the absurdly incongruous houses of Sierra Leone. Bolama possesses handsome and extensive barracks, and a fine church, all built of red brick and iron, very pleasing in appearance, but, I am told, rather hot. The most prevalent type of native house is one of rectangular shape, with an immense thatched roof stretching right out at an angle of 45° towards the ground, and forming a sort of sheltered court all round the house, wherein the inhabitants sleep in the daytime.

Bolama can exhibit a great concourse and diversity of African races. These are the indigenes of the island and neighbouring mainland, the Papeiis, a race whose skins are literally black as soot, and whose faces offer a singularly low and degraded type, with prognathous jaws and retreating forehead. Their figures are tall and well built, and they generally go about stark naked, the Portuguese not being so squeamish on this point as the English, and leaving the natives full liberty in their sumptuary laws. Then there are Mussulman people who come to Bolama to trade, Fulahs, Mandingoes, and others, always noticeable by their finer features and Moorish clothing. Besides these may be noticed many different tribes of negroes, each distinct from the other, and each speaking a widely different language; and further, the Krumen of the south, the hybrids between all these races; and lastly, the intermixture of Potuguese mulattoes add to the diversity of types and the Babel of tongues.

Amongst the white inhabitants, those of Portuguese nationality naturally prevail, owing to the soldiers and officers of the garrison, but all the principal merchants are French, and the commerce of Portuguese Senegambia is almost within their hands. They have many commercial houses, not only in Bolama, but in most of the neighbouring islands, and the greatest trade is done in the export of ground-nuts, of which shipful after shipful is sent to Marseilles, there to be turned into spurious olive oil. Besides this, wax, coffee, cacao, india-rubber, sugar, ivory, and wild beasts' skins are also exported. Gold is found in the interior.

The principal centres of Portuguese rule and trade in Senegambia are Bolama, the capital; Bissan and Cachen, fortified places; the rich island of Gallinhas; Colonia, at the mouth of the Rio Grande; Géba, a hundred miles inland on the river of that name; Ganjarra and Fâ, on the same river; Farim, on the Cachen; Bolor, on the Casamança; and Jafunca, and Zeginchor.

The temperature of this part of Africa is very high, and the heat is more oppressive than in most parts of the continent; nevertheless, Portuguese Guinea is not very unhealthy. Yellow fever is quite unknown, and marsh fevers with rheumatism and ague are the most prevalent forms of disease. Everywhere the most perfect drinking water, cold and sparkling, is to be procured, not on the surface, but from wells of about 20 ft. in depth. Time forbids me to descant on the extreme richness of this possession, or, more strictly, on the latent richness of its soil and productions. Vegetation here reaches a development almost unparalleled; and I might state that Portuguese Guinea for the naturalist and anthropologist is one of the least known and most promising fields of study.

Though many traces of ancient Portuguese occupation may be found on the Gold Coast and the Niger Delta, the only remaining relic of their former possessions in this part of Africa is the solitary fortress of Sao Joao d'Ajudà, in the kingdom of Dahomé. "Whydah" it is called by the English, and it is the principal or the only seaport of that still independent kingdom. Sao Joao d'Ajudà is a useless possession to the Portuguese. They have had it ever since 1680, but to this day have made no attempts to increase their hold in the country. They retain this solitary fortress solely at the good pleasure of the King of Dahomé, who wishes the Portuguese to remain, so that no more powerful or energetic nation may step into their place. Last summer a rumour floated about the coast that England was going to take over Whydah from the Portuguese. Thereupon the French, who are jealous of us in this quarter, went and told the King of Dahomé, and this irascible monarch threatened to cut off the heads of the Portuguese garrison if they dreamt of yielding their fortress to the dreaded English. The King of Dahomé knows that if we possessed Whydah, we should irresistibly interfere in the horrible and foul customs of his wicked rule. Whydah is almost the only place of importance that separates our colonies of Lagos and the Gold Coast from one another. It is almost inaccessible from the sea, owing to the furious surf that rages along the coast. Ships of any size cannot approach nearer than seven miles, and the safest mode of reaching Whydah is to land at Lagos, and journey along the shore, crossing Lake Avon on the way.

At the present time, Whydah, or, as the Portuguese call it, Sao Joao d'Ajudà, is under the administrative government of the colonial district of Sao Thomé and Principé. These latter are two islands of singular natural wealth and incomparable natural beauty, lying from one to two hundred miles from the African coast, about the region of the equator.

Principé, which is distant from its sister island about a hundred miles, offers to the delighted gaze of a Nature worshipper one of the most beautiful spectacles in the world. As you enter the fine lake-like harbour of its only town, a wealth of vegetation is spread before you. On the spits of projecting rock and sand, coco palms grow in sturdy groups, while the rapidly rising land is one dense mass of dark green forest. Immediately behind the town, a great sugar-loaf peak rises nearly 3,000 feet into the sky, clothed up to the very top, save for one small streak of grey rock, with velvety forest which, from its proximity to the shore, presents a most imposing spectacle.

In the town, there is a general appearance of desolation and decay. Soon after landing on a stone quay projecting into the water, and evidently a fortunate relic of the magnificence of former days, you pass through some ramshackle streets, and cross a stone bridge over the little river. Here, there is a charming view of the distant peak reflected in its still waters. Many coco palms droop over the stream. Women come here to wash clothes, and their little naked children chase the mud fish and land crabs through the ooze. There are, in this town, no less than five ruined churches, their roofless interiors choked with ferns. But whichever way you turn, nothing but ruin, abandonment, decay, meets the saddened eye. It is like a dead town surprised by some calamity, and offering its ruined houses—many of them of magnificent proportions—and its deserted public buildings as a mute record of the disaster. The river, in its different branches, was once spanned by fine stone bridges, whose massive foundations attest their former stability; now, shaky and miserable structures of planks and ropes offer a hazardous method of crossing the stream dry shod. A little way in the interior, immense cacao plantations begin where the undergrowth is a thick brake of pine-apples, loaded with deep red fruit. Very little of the land in Principé is under cultivation; the principal estate belongs to a merchant in Sao Thomé. Cacao is the chief product of the island. Coffee hardly exists, although to encourage its cultivation the Government has made its exportation free of duty, whereas in Sao Thomé, coffee exported pays 5 per cent. The interior is very mountainous, and covered everywhere with unbroken forest. The uplands enjoy a fairly healthy climate, although occasionally the whole island is subjected to attacks of marsh fever, caused by the emanations from the dreadful Niger delta, which the north wind blows over to Principé.

The island possesses at the present day some 3,000 inhabitants, of whom not more than 100 are white. The black population is descended from old slaves, most of them Guinea negroes. There are two white padres for the church, a Government doctor, a military commander of the one fort—a building which I took at first sight for a summer-house on the cliff—finally, the Governor, who receives £300 a-year, and is a poor incapable old man in his dotage.

The prosperity of Principé fell, because the sugar-cane plantations which caused its wealth were forbidden by the Portuguese Government, some two centuries ago, in case they should interfere with the rising sugar trade of Brazil. The island, however, still continued wealthy until the middle of the present century, when the abolition of slavery gave the finishing touch to its ruin.

The population of Principé was once 30,000; it is less than 3,000 at the present day. Its palaces and churches of former days have become magnificent ferneries, and if it were possible to forgive this retrogression of civilisation, it would be so from the beautiful mask of vegetation that everywhere conceals the ruin and decay.

Sao Thomé presents a much more cheering prospect. While in its natural beauties and its great fertility it rivals Principé, it far exceeds that island in population, cultivation, and development. The superficies of Sao Thomé is about 700 square miles. It is traversed by the equator. The character of the island is extremely mountainous, some of the peaks reaching 6,000 feet in height, and many of them assuming the most fantastic forms. The climate varies greatly. In the lowlands it is hot and unhealthy, on the upper plateaux it is salubrious and warm, and high up on the mountains, it is mild and sometimes even chilly. Europeans can live in perfect health and comfort in the uplands, and, indeed, the Portuguese that reside there are most favourable specimens of colonists, with their pretty wives and their large families of fresh-coloured children.

The capital of the island and town of Sao Thomé extends along a shallow bay, which is one of the few harbours of the island. It contains several fine buildings in good repair, and its streets are clean and well kept, patrolled by a police force, and are planted with shady trees. There are public gardens and fountains, plenty of churches and good schools, shops, cafés and clubs, and a large hospital.

Shortly after my arrival at the island, I made an excursion into the interior to visit some of the "roças," or country houses situated between two and three thousand feet above the sea, on the thickly wooded mountain sides. My guide and companion was a kind and erudite Portuguese, who was a Government doctor and medical officer to many of the great coffee and quina plantations in the interior.

In the cool of the afternoon we left the city of Sao Thomé, and journeyed along an excellent road, bordered with the most splendid vegetation, amidst which nestled the little wooden houses of the coloured inhabitants. Sao Thomé must be the ideal of a black man's paradise, and the negroes of Sao Thomé the happiest in the world. These little homesteads are surrounded by innumerable bananas, with plantations of manioc and sweet potatoes. Pine-apples form the rank undergrowth of their gardens, and the ground nut is a weed. Here and there is an old chapel with lichen-stained belfry and silent bells. A civilised feature amid these little hamlets is the general shop, where a quaint assortment of things is sold, and where it is curious to see advertisements of English sewing-machines hung up to decorate the walls. By the side of the road are magnificent trees from most parts of the tropics, but principally from Brazil. Africa is represented by the baobabs, mimosas, fig trees, dracænas, and the bombax, or cotton wood. There are also guavas, oranges, limes, and papaws, and both the coffee and cacao are beginning, as the distance from the town increases, to take a prominent place. We crossed many brawling streams, and soon—were it not for the civilised-looking road—we might have believed ourselves in virgin Africa, for signs of cultivation began to disappear, and we wound higher and higher up the hills, through the most magnificent forest. The air was musical with the continued sound of falling water; but, except now and then a glint of spray amid the foliage, the tumbling brooks were invisible. The soil was a rich red colour, and when, as we ascended to some height, the bracken fern began to show itself, and to cover with its dewy fronds the steep banks that bordered the road, the scenery, with its red soil and intense greenery, recalled very forcibly the Monmouthshire lanes which border the River Wye in England.

The roças, or country houses, that now began to crown the heights, were very Swiss-like in appearance, generally several storeys high, and with many little outside ladders going from storey to storey. Sometimes the houses are dazzlingly white, and remind one of the charming little quintas of Madeira, like which they are pleasantly embosomed in bright flowers and vegetation of dark velvet green.

We passed the night in one of these little chalets, meeting with a most hospitable reception from its occupants. It surprised me to encounter, amid these wilds of tropical nature, little circles of civilisation like these Portuguese country houses, where there were white ladies of education and refinement, and where the male inmates were capable of discussing political and scientific topics with intelligence and discernment. Pianos stood in the prettily furnished salons, scientific periodicals and journals in different European languages were strewn on the tables, and the furniture and appointments of these houses would not have been out of place in any gentleman's house.

Early the next morning we started to visit the quina plantations, high up the hills, ascending to about 3,500 feet. The quinine plant, or quina, exhibits several varieties, all of which are cultivated in Sao Thomé. The propagation of this precious tree is fortunately easy. Besides growing it from the tiny and abundant seed, the new leaf-buds or "rebutes," as the Portuguese call them, are turned down by their long stalks, and fastened into little boxes of earth, raised from the ground to the proper height, and in these boxes the buds throw out roots and become new plants.

The price of quinine bark brings in, on an average, £4 per tree, when the tree has attained the age of six years. So that a man who plants 100,000 quina plants, at a preliminary cost of £100, stands to gain in six years' time £400,000. Nor does his fortune end there, for after stripping the tree of its bark, it is cut down, and in some five years more has sprung up again from the roots, and gives an even greater yield. Land is sold for a mere nothing in Sao Thomé, for only about one-third of the island is under cultivation; labour, thanks to the excellent system of Government apprenticeship, is cheap and plentiful; the climate on the uplands is perfectly salubrious; there are pleasant society, glorious scenery, and good horses are to be had. Why do not some of our younger sons try quinine growing in Sao Thomé?

I left this beautiful island with regret; but just as I was compelled then to continue my journeyings, so now, in my description of the subject in hand, though I would prefer to dilate on the lovely scenery and many charms of Sao Thomé, I am obliged to curtail my notice of the island, and pass on to other scenes.

Since I left West Africa, the Portuguese have formally taken possession of a point on the South-West Coast, a little to the north of the Congo. This is generally called Landana, and is situated close to the *embouchure* of the River Chiloango, an important highway into the interior. Landana is nearly a hundred miles from the mouth of the Congo, but receives a great deal of the Congo trade, which follows the course of the Upper Chiloango. It is a prosperous place, with four or five large trading establishments, a flourishing Catholic mission, a church, and a doctor. It is, in fact, a ready-made colony, into the possession of which the Portuguese have entered for no particular reason except that they were preferable to the French in the eyes of our Government. English Ministers seem to have the vaguest notions of geography; and when Portugal asked their permission to occupy Landana, they assented willingly, because they had no knowledge where Landana was. South of the Congo the Portuguese have, at present, no recognised possession before we arrive at Ambriz; unless, indeed, there be any fresh arrangement with the British Government empowering them to occupy territory north of the River Loge, in 7° 40′, S., their present limit. Ambriz has been a Portuguese possession ever since 1855, when they annexed it to Angola for the purpose of more effectually suppressing the slave trade which, to do them justice, they have really done.

The habitable town of Ambriz rises to the top of a bold red cliff, at the base of which great rollers dash themselves into foam. Ambriz is sandy, and infested with the horrible "jigger," or burrowing flea, originally introduced here from America, and now fast spreading over West Africa.

The local commerce of this district is in coffee, which grows wild on the neighbouring hills, and is also cultivated by the natives. Ambriz is the natural outlet for the trade of all the interior lying about the 7th and 8th degrees of S. latitude, and stretching inland to the River Luango; but it does not seem to prosper somehow, in spite of being the only kind of port between Loanda and the Congo. Many of its merchants have migrated across the Portuguese boundary to Kinsambo, where, perhaps, the landing is the most dangerous on all the South-West Coast, in order to escape the duties imposed by the Portuguese custom-house. Though these duties are much fairer and lighter than at Loanda or other Angolan ports, they are much complained of by traders; still in Ambriz, at least, there is some excuse for them, as the Portuguese have spent considerable sums in order to construct a pier, and render the landing of goods both safe and easy. Going south from Ambriz, we must travel by sea for a distance of thirty miles to reach the settlements on the River Dande. The intervening district between the Dande and Ambriz has never been conquered by the Portuguese, and still remains impassible to Europeans. A force of twenty armed policemen would suffice to clear the road, but although Portugal can dream of military expeditions to the Congo, she cannot afford a few soldiers to connect Loanda and Ambriz by land.

The estates in the fertile valley of the Dande are magnificent properties, growing immense quantities of sugar-cane, bananas, pine-apples, and oranges. The climate is good, and the scenery beautiful. Horses are successfully bred here, and supplied to the colony of Angola.

Continuing southwards from the Dande, we pass the great River Bengo, and soon afterwards, if the journey is by sea, arrive at the fine bay of Loanda. Sao Paulo de Loanda, the capital of Angola, the largest European city in all Western Africa, dates its existence from the 15th century. The early Portuguese discoverers had the wish to choose its fine harbour as the rendezvous of their ships, and the starting point of their African Empire.

Loando presents a decidedly picturesque and imposing appearance from the sea, placed in the centre of a nearly land-locked bay, faced by low islands, fringed with cocoa-nut palms, and with a sunset-blue sky above, and a violent sea at its feet, it has an imperial look as its white or orange-tinted houses climb the steep slopes, and crown the distant height with their not inelegant architecture. It comes to the African traveller, moreover, somewhat as a surprise. Yesterday, perhaps, or for many preceding days, he coasted along a savage shore, and whenever he landed it was to view the virgin wilderness, or, perchance, to frighten from the foaming beach a few miserable native fishermen. To-day he rounds the headlands of the Bengo, and now a fair and populated city rises before him, and seems by force of contrast civilisation itself. Loanda, to use a common English qualification, is not half a bad place, but it has some marked disadvantages. Its streets are ankle-deep in sand, and it has no drinking water of its own. Every drop of water that is drunk at Loanda, and all that is used for irrigation, must be brought in casks from the rivers to the north and south of the town, from either the Bengo or the Quanza.

The population of Loanda and its suburbs exceeds 14,000, of whom 1,500 are white. There are at present 800 degredados, or convicts, in the town, most of them at liberty, and even serving in the police force or the army. A man that may have committed a brutal murder in Portugal suffers no greater punishment than deportation to Angola, where he probably becomes a wealthy proprietor, and dies twice as rich and respected as he would have done had he vegetated in uprightness in his native country. The Portuguese sometimes say playfully that murder is the best passport to Africa. "Dar um passeio na Angola," "To make a trip to Angola," is a slang euphemism to express the punishment awarded to evil doers in Portugal.

The entire garrison of Loanda is 600 men. It is defended by Fort Sao Miguel. The Governor-General of Angola resides here in a vast but somewhat tawdry palace. His salary is £2,000. Loanda has a fine hospital, a theatre, several good markets well organised by the municipality, an observatory, and several churches and convents. There are fine promenades planted with trees, and many pleasant rides in the neighbourhood. A British consul and vice-consul reside here, and there are representatives of most European nations. There is pleasant and refined society; and regattas, picnics, dances, musical and theatrical performances are much in vogue. The trade of Loanda is greatly in the hands of a well-known English firm, who also manage the navigation of the Quanza.

The Quanza has been termed by many writers "the gem of Angola," and with reason, for this navigable river offers a great highway to the rich regions of the interior. The Quanza rises not far from the source of the Ku-néné, that other great river of the Portuguese Lower Guinea, in Lat. 14° S., and flows south and then westward to the sea, which it enters a little to the south of the Loanda.

It is navigable by river steamers of some burthen for over 200 miles from its mouth, and at this extremest point, just below the last falls, Dondo, an important commercial town, is placed. The old capital of the Quanza was Cambambe, founded by the Portuguese in the 16th century, Its ruins are still remaining, and lie about ten miles distant from the present site of Dondo. This latter place is extremely hot, and certainly unhealthy; whereas Cambambe was placed on the breezy heights, and was infinitely more salubrious. However, Cambambe was abandoned for the present capital on account of the difficulties of navigation that prejudiced the older city. Dondo can with ease be reached by steamers, but to ascend the river higher, to Cambambe, is difficult, and full of risk. As the point at which the commerce of the interior is focussed and concentrated in its relations with the coast, Dondo is a great emporium of Central African trade, and attracts to its markets the products of the far interior, of the Rivers Quango and Kassaï, both of them huge affluents of the Congo (the Kassaï being Stanley's Mobindu or Ikelemba), and all the outward trade of the Muata Yanvo's Empire. In fact, one may say, without exaggeration, that the trade of the Upper Quanza has relations with Nyangwé and the East Coast.

The inhabitants of Dondo, demoralised by the heat, no doubt, are inhospitable, fearful gamblers, and terribly immoral. They all look listless, miserable, and careworn. The town is of considerable extent, and is divided into several large and not ill-built squares. There is a Government doctor, a hospital, a powder magazine without a roof, and a church in the same condition; also a club, where the Dondoese play "batote" until six in the morning. The place is apparently very populous, and there is always a large assemblage of natives from the far interior, who come down to Dondo to exchange their ground-nuts, and other country products. There are people from Cassange, the turbulent Bangalas, who wear strange monkey caps, made from the skin of a *colobus* monkey, with long black and white hair. It is a curious coincidence that the same monkey-skin caps are worn by natives on the Upper Congo, and that there is a well-known race on that river also called Bangala. Dondo is a splendid place to study types of Bantu people. You have here, besides the Bangala, occasional specimens of Balunda, of the natives of Muata Yanvo's kingdom, and of races more remotely placed in the interior of Africa. There are Quissamas and Libellos from the south and south-east, Congo people from the north, and representatives of all the important tribes, Ambaquistas, and others. What Dondo might be made in the hands of a richer and more vigorous power than Portugal it is difficult to say; but, even as it is, we must not forget to give the Portuguese their due. Of all the European Powers that rule in Tropical Africa, none have pushed their influence so far into the interior as Portugal. And the Portuguese rule more by influence over the natives than by actual force. The garrisons at Dondo, Malange, and other places in the interior, range, perhaps, from 50 to 200 men, and these are almost entirely native soldiers. The country is so thickly populated, that the inhabitants could in a moment sweep away the Portuguese if they disliked their rule.

Although, during the Portuguese decadence of the last century, the establishments and commerce of the Quanza fell into complete decay; still, during the last half century great efforts have been made to resuscitate them. Silva Americano, a Brazilian, Oliveira Massango, and other Brazilo-Portuguese merchants, got up a service of excellent river steamboats to navigate the Quanza and develop its trade. These boats are now being worked on behalf of the company by an enterprising English firm, Messrs. Newton and Carnegie, of Loanda, and it was at their courteous invitation that I visited this river in detail by means of the comfortable steamers of the Quanza Navigation Company. Travelling here is quite as comfortable as, and slightly more interesting than, a journey up the Rhine. Not only is the scenery very pretty and thoroughly African, but the river contains more history than, perhaps, any other part of Tropical Africa; for, as I have before remarked, the Quanza has been continuously occupied by Portugal since the 15th century, and can show on its banks many signs of the former puissance and religious fervour of that interesting country.

South of the Quanza river, as far as the 12th degree of latitude, the Portuguese rule is confined to the strip of coast. The interior, where the powerful tribes of Kissamas, Libollos, and Ba-ilundo have their territories, is quite independent of Portugal, although on all but the careful German maps it is coloured Portuguese. Between the Quanza and Benguella, there are, however, several important places on the coast, such as Novo Redondo, and Catumbéla. This is the most wonderful country for wild animals. Benguella itself is quite an *entrepôt* for the supply of wild birds and beasts to divers Zoological-gardens and to dealers. Every homeward-bound steamer is laden with monkeys, parrots, cage birds of all descriptions, and occasionally even a lion or leopard may be seen.

Benguella is an important place, especially as regards trade. I have spoken of Dondo, on the Quanza, having relations with the far interior. How much more Benguella, whose merchants range all over Central Africa, encounter their countrymen from the East Coast on the Upper Zambezi, and even penetrate to the copper country of Katanga and Lake Bangwéolo, whence rises the Congo. The rule of the Portuguese extends nearly 500 miles inland from Benguella, and their political influence even further. From Benguella, now, there is a road to the mountain ranges of the interior, where a healthful and bracing climate is to be found, and where the scenery is of great beauty.

Benguella itself is said to be unhealthy. It has, at any rate, a bad reputation, although its sanitary condition has certainly improved since the surrounding marshes were drained. I always found it a very pleasant resort. Its inhabitants are pre-eminently hospitable, and in their comfortable, well-appointed houses, you may meet with unexpected luxuries. The town is unlike any other Portuguese settlement on the coast, and more resembles the outskirts of Algiers or some Mediterranean city. Its houses are somewhat Moorish in style, and each villa stands apart embosomed in vegetation. There is a beautiful public garden, full of flowers and shady trees, where a military band discourses music in the cool of the afternoon.

Benguella, like Ambriz, Loanda, and Mossâmedes, is the capital of a separate district, and has a governor and administration of its own. Between Benguella and Mossâmedes there is scarcely any place of importance. The coast becomes increasingly barren, and assumes an absolutely desert character.

Mossâmedes is the most flourishing town, perhaps, in all Portuguese Africa. It is situated in a tract of absolute desert, with a fine deep bay in front of the town. The houses have rather a formal look, as seen from the rocky eminence on which the fort is placed. The town, in fact, looked somewhat as if it had been "plumped" down into the desert already made, and had as little to do with the local soil as possible. The atmosphere is, of course, splendidly clear and dry. It does not rain here sometimes for seven years at a stretch, and the immense amount of fish refuse thrown up on the shore, from the great amount of fishing that goes on in the bay, is quickly withered up by the desert wind, and breeds no disagreeable smells. The houses at Mossâmedes are mostly whitewashed cubes, the streets are ankle-deep in shifting sand, and the only oasis of verdure is the well-kept public Botanical Garden. Above and beyond this all is blue sky, yellow desert, and ultramarine sea. But the inhabitants of Mossâmedes are mostly refined, well-educated, hospitable people. There is a surprising amount of civilisation here. Many retired officers of the Portuguese Army and Navy have settled here with their wives and families, finding it cheaper to live, and easier to keep up some appearance of state than in Portugal, so that there is quite a pleasant nucleus of society in the place. Afternoon receptions, musical evenings, tea and whist, and even periodical evening parties, give quite an air of gaiety to the ugly little place.

On the map, this part of Africa seems anything but devoid of water, and it appears incredible that the district of Mossâmedes should be what it really is, a great offshoot of the Kalahari desert; but the fact is, that the three principal rivers of this province, the Giraül, the Béro, and the Croque, are but occasional torrents, flowing for about two months in the year, when the heavy rains of January and February drain off the distant Serra de Chella. During the other months, the body of the river dries up, the water sinks some feet below the sandy bed, and only occasional great lagoons retain a portion of the flood which at one time covered acres of level plain. It is in these great river beds that lies the richness of the country. Their splendid soil can be made to grow cotton of superior quality, sugar-cane, maize, castor oil, oranges, limes, and vegetables of every description. But in most places, especially in the valley of the Croene, cotton is lord of all, and fetches such high prices, on account of its quality, that scarcely an inch of ground is spared to anything else. Forty miles south of Mossâmedes there are several rich plantations on the River Croque, which are at present the farthest extension of Portuguese colonisation to the southward, except the fort and settlement at Humbi, on the Cunéné. As this latter place was one of the furthest limits of Portuguese possession, I was anxious to visit it, and accordingly joined Lord Mayo's hunting party which was journeying in that direction. We travelled at first due west from Mossâmedes, crossed a desert tract of 40 miles in width, and then arrived at the first spurs of the Chella mountains. This range, which lies at a varying distance of 70 to 100 miles from the coast, is part of the mountain barrier or girdle which encircles the interior plateau of Tropical Africa. Some of the Chella peaks rise to 8,000 or 9,000 feet in height, while the forest scenery on their slopes is of unparalleled beauty. When the mountain chain is crossed, you arrive on the other side at an elevated plateau, some three thousand feet above the sea, eminently healthy, and possessing a delightful climate. Here there are several important picturesque settlements and garrison towns, such as Huilla and Quillengues, and here, too, are settled a colony of Transvaal Boers. This new and important element has lately been introduced into the somewhat sluggish province of Mossâmedes. The Boers that "trekked" away north from the Transvaal, as far back as 1874, after undergoing, thanks to their own obstinacy and ignorance, trials far more terrible and incredible than those of the boasted pilgrimages of antiquity, began gradually to approach the banks of the Cunéné in the year 1880. Here they halted for some time, and had many squabbles with the natives, from their overbearing behaviour and unscrupulous dishonesty, and on one or two occasions their enraged opponents nearly cut them to pieces. In the meantime, some of the less ignorant among them were negotiating with the Portuguese Government for permission to cross the Cunéné, and settle in the fertile lands beyond. An answer was some time in arriving. It needed a little consideration before the Angolan authorities could agree to the entry into their sleepy peaceful lands of these quarrelsome, turbulent, though energetic people. The Boers grew impatient, and sent word to say that if the local authorities could not arive at a speedy decision, they (the Boers) would "trek" farther north, and interview the King of Portugal himself. However, consent was at length given, and the Boers were assigned territories at Humpata, a district in the vicinity of the Chella mountains. Thither they proceeded, and have since settled down, and find little to grumble at in the indulgent rule of Portugal. Their lands form one of the finest corn-growing districts in all Africa. There is abundance of running limpid water, a rich soil, and a perfect climate. The great elevation of the Humpata plateau above the sea produces a European temperature, and the thermometer is frequently at freezing point before dawn. Here some sixty families of Boers have settled down to corn-growing and cattle-rearing, hoping to dispose of their agricultural produce in the markets of Angola. From Humpata to the Cunéné is a distance of about 200 miles, traversed by a waggon-road, and dotted at rare intervals with Portuguese forts and garrisons. There is a Government postal service along this route once a month, and it is everywhere safe travelling, except, perhaps, for the abundance of lions that at certain times infest it. The game is wonderfully abundant and varied in character. Great herds of giraffes, elands, zebras, and antelopes may be encountered, together with occasional elephants, rhinoceroses, and buffaloes. In fact it is one of the finest sporting countries in the world.

I found the only possession of the Portuguese, on the River Cunéné, was the fort of Humbi, which boasts of a commandant and a garrison of ten soldiers. The Portuguese, however, have great influence here, and rule the natives more by commerce than by any display of armed strength, which, indeed, would be quite ineffectual in coercing the 80,000 inhabitants of Humbi. As the Portuguese are extending their power and influence, little by little, in this direction, there is small doubt that in the course of time the whole course of the Cunéné will come under their sway.

And now, having rapidly sketched out the principal centres of Portuguese dominion in West Africa, from the Cape Verde Islands and the Casamança to the Cunéné, from 17° North of the Equator to 17° South of the line, I will, in conclusion, draw your attention to certain inferences and reflections that a careful consideration of the present state of Portuguese colonies suggests.

In the first place, although the Portuguese cannot offer the same imposing spectacle of colonising force as England, nor the organising genius of the French and Dutch, still, I am greatly of opinion that Portuguese colonisation is to be preferred to the pristine condition of a savage country governed by itself. Wherever the Portuguese go, they at least make roads, drain swamps, construct rivers, and build towns. In their colonies a traveller may travel in reasonable security, sure, moreover, of an unbounded hospitality from the kindly Lusitanians. I even go so far as to fancy sometimes that the Portuguese are wiser in their relations with the native races than either the French or English. The French are disposed to be cruel, and the English sentimental; the one brutalises the native, the other renders him insufferable with conceit. On the other hand, in any modern Portuguese colony, the natives regard the white man with respect, and, at the same time, with cheerful friendliness. One of the silliest mistakes in England is to accuse the Portuguese of cruelty towards the natives; they are, on the contrary, disposed to be almost too gentle in demeanour towards the black races, that require for their proper development and governance a firm and vigorous rule. The Portuguese, in contrast with the Boers, are "angels of light," and are as much liked by the natives of South-Western Africa as the domineering Dutchmen are hated. People at home do not do the Portuguese justice as regards their relations with African races. They sneer at the excellent and wise system of Government apprenticeship as slavery.

Wherever the Portuguese really rule, actual slavery is not practised, but a regularised system of apprenticeship is in vogue, which some have assumed to be the same thing. Somebody must till the soil, and if left to himself, the negro will prefer not to be the "somebody." He will never work unless he is obliged. Among the independent tribes, domestic slavery is universally practised, and when the country comes to be ruled by a civilising power, although slavery might be rightly, from principle, abolished, some system of enforced labour must be invented to take its place. And the Portuguese idea of apprenticing under Government supervision all minors whose parents or relations agree to it, and all indigent persons who apply for relief, for the present, at any rate, fills up the terrible want of manual labour.

Again, many people in England accuse the Portuguese of keeping their black subjects in utter ignorance. These unjust and hasty critics would be surprised to find, 500 miles from the coast, natives who have been taught in Portuguese schools, and who can read and write Portuguese with accuracy. It is astonishing to see how many full-blooded negroes there are in the Portuguese African administration. Moreover, under Portuguese rule all men are equal. Grades of colour are not developed into social castes, and negro blood is never sneered at. If I were a negro I would infinitely prefer to be a subject of Portugal than of any of the greater powers. That the Portuguese rule must be acceptable to the African, is shown by the almost nominal garrisons with which the vast possessions are retained, by the absence of outbreaks and disturbances, and by the fact that the army which defends these countries from disorder is autochthonous, is composed of natives of the soil. If, however, I have endeavoured to put Portuguese colonisation in a fairer light, and to show up its good points, I have not intended to do this as a plea for extension of Portuguese power over fresh parts of Africa.

Portugal, at present, resembles a greedy child, whose eyes are bigger than its stomach. Its political platter is covered with all sorts of good things, which it has neither consumed nor even nibbled at, and yet it hungers for other dainties beyond its reach. Portugal has sufficient colonies at the present day to last her all her national lifetime; and yet, while she pleads poverty as an excuse for not developing what she has already got, she can afford to equip costly expeditions in view of further and fantastic conquests. The idea of Portugal on the Congo is simply preposterous. She has no interests and no commerce to defend there, like the English or the Dutch, and while her ancient and legitimate colonies are crying out for railways and public works, and are being repulsed with the answer that there is no money in the national coffers, expensive and Quixotic expeditions are, at the present time, being fitted out to explore—I might say to re-explore—the Congo territories, with a view to political occupation. Even supposing Portugal was allowed by the English, French, and International African Association to occupy the Lower Congo, what would she do with it? Stick on differential duties, and try to divert the trade from Liverpool to Lisbon? Never! Manchester would intervene, and few of our Governments can withstand her terribly powerful Chamber of Commerce. Then, would Portugal really, as she pretends, care to act, in the interests of everyone but herself, as the platonic policeman of the Lower Congo, and exert a beneficent rule over this great river at her own expense, and from pure love of humanity? I think not; we live in a too material age, when there is always a *quid pro quo* expected.

If Portugal is wise, she will abandon any such idea, and seek to develop the admirable colonies she already possesses. Her colonists cry out for free trade, and complain that the differential duties not only hamper, as they are intended to do, the commerce of foreign countries, but also stifle the trade of the colonies themselves. Let every inducement be held out to the cultivation of virgin land; let the mountains of Sao Thomé grow forests of quinine, and the swampy lowlands of Senegambia be covered with the sugar-cane; let railways be built, canals dug, telegraph wires suspended. "Alas!" reply the Portuguese to all these suggestions, "we have no money and we have no men." Portugal is too poor and too thinly populated to be able to supply these essentials herself, and she is too much afraid of foreign aggression to invite them from other nations. There is, for example, such a great and important enterprise as the Ambaca Railway. This line, from Sao Paulo de Loanda to the heart of Angola, would bring all the trade of South-Central Africa into Portuguese hands, especially if it were extended to the River Quango, where it would somewhat tap the Congo trade. Yet, although the Portuguese know better than any one else its importance and feasibility, and have already made capital Government surveys to ascertain the difficulties and expense that would stand in the way, they are unable of themselves to find the money necessary to the making of this line, and at the same time refuse to grant the concession to either an English or American company.

Then there is the question of the Loanda water supply. Sao Paulo de Loanda is the only place fitted to be a great African capital between Senegal and Cape Town. It has a magnificent land-locked bay, which, with a little dredging, would simply be one of the finest harbours in the world. Loanda alone has an imperial look as it rises on its red hills above the glassy-blue bay. But it has no local water supply. The wells only give a brackish, unwholesome fluid, and every drop of water you drink, and every drop that you water your gardens with, must be brought in casks from the River Bengo, fourteen miles away. Now it would be neither difficult nor very expensive to make an aqueduct, either from the Quanza, sixteen miles distant, or from the nearer river Bengo. (The Quanza should be made the water supply of Loanda, as its water is much wholesomer than that of the Bengo.) Only, of course, it would cost some thousand pounds, which the Portuguese are not prepared to spend. So Loanda, the greatest European city of Tropical Africa, remains to this day dependent for its drinking water on the arrival of a fleet of little sailing boats. The more one travels in Africa, the more one arrives at the conclusion that the Portuguese have got the pick of the coastlands; but, unfortunately, another conviction forces itself upon the mind, that they have far more than they can be reasonably expected to develop with their individual resources. There is no reason why they should sell, cede, or exchange them, but let them be thrown open unreservedly to all comers and all capitalists, and Portugal will soon, as their suzerain, become a wealthy power.

DISCUSSION.

Dr. MANN remarked that the Society was greatly indebted to Mr. Johnston for the time he had given to preparing this paper; just when he was about to embark on a work of very great importance, and when every minute must be most valuable to him. For some little time he had been preparing to go to the eastern side of Africa, for a very definite and important purpose. All along the eastern side of that great continent was a great range of mountains, stretching from Cape Colony at a distance of some 200 miles, more or less, from the coast, right up into the highlands of Abyssinia, with only a few gaps through which the great rivers found their way to the coast. The dominant point of this whole range was the magnificent mountain Kilimanjaro, and it had been for a long time felt desirable that the natural and physical history of this almost unknown part of Africa should be well understood. The only way, however, in which it appeared possible to get exact information about it was for some enterprising traveller to stay for some time on the spot, and investigate the fauna and flora of the district. This Mr. Johnston was about to do under the auspices of the Royal Geographical Society and the British Association. He was to find his way as best he could to this mountain, whose summit rose about 12,000 feet above the sea, and was covered with perpetual snow; and to reside on the lower slopes for some six months, during which time he would scientifically investigate the plants and animals to be found there, in order that some light might be thrown on the question whether this mountain was really allied with the true mountain range of Africa, or whether it did not belong to the Asiatic system, the only break with which was formed by the basin of the Red Sea. It was quite possible that, at some earlier period of the world's history, the two might have been connected. If this were the case, evidence would undoubtedly be found in the forms of organisation now present on the spot. This was the problem which Mr. Johnston was going to attack. He would certainly perform this task in a very efficient way. He was quite sure that he would set out with the best wishes of all present, and he hoped that at some future time when he returned, he would be able to give them an opportunity to congratulate him on what he had accomplished.

The Rev. HORACE WALLER said he had listened with very great pleasure to the paper, which contained one of the most interesting chapters of geography it had ever been his lot to hear. If up to the present time Mr. Johnston had been able to make such good use of his eyes, ears, and artistic skill, he was sure that every one would look forward with great interest to his future travels in Eastern Africa. He had had the pleasure of seeing some of Mr. Johnston's sketch-books, and though he remembered those of Mr. Davis, who accompanied Dr. Livingstone, he must say that these were superior to them; in fact there were few, if any, in public exhibitions which would equal them, though the sketches were taken in many cases under most difficult circumstances. They included not only sketches of the country and beautiful landscapes, but the most exquisite delineations of animal and plant life. In fact, in these early years of his life he had already furnished the scientific world with an amount of treasure which might be considered full work from one of three times his age. Having listened to this interesting account of the Portuguese settlements, on the East Coast of Africa, his first idea was to contrast it with what he knew of the West Coast. It was not fair to taunt Portugal with her poverty, nor even with her ambition, considering her past glories, but she certainly was unreasonable. Take, for instance, the question of Whydah; she had clung to it more out of pride than anything else, and there had been a whisper that England was about to acquire it. If she did, there would probably soon be another little war, because it was on the borders of Dahomey, the king of which would probably much prefer the Portuguese, whom he could bully, to the English. With regard to the Congo, he was glad that one so well acquainted with the country had sounded the right keynote. It had been shown that Portugal had a great number of possessions there, and that in ancient times her explorers had pitched on the most desirable quarters, and the most valuable rivers, and she might well be contented without interfering with the mouth of the Congo. This was an enormous river, stretching half across Africa, and was about to bring the European nations into contact with millions of people who had never heard anything better than the tramp of the slave trader. Mr. Stanley had opened the country, Captain Cameron had been across it, and Dr. Livingstone had got as far as Nyangwè. If Mr. Stanley's accounts could be relied upon, there was water communication down to the edge of the plateau which, unfortunately, was found throughout Africa. All African rivers and lakes were on the first floor, as it were, and you had to come down a staircase before you got into the street. You might go some miles up these African rivers, and then you came to a series of cataracts, where you had to get out and walk overland until you got to the higher waters, upon which you could launch steamers in sections, and proceed into the interior. This was proposed to be done on the Congo, as it was done on the Zambesi and other rivers. The important question was, what was to become of the mouth of this river? At present it was no man's land, and such it ought to continue. It would be a great pity if Portugal were allowed to have control of the north and south bank. Large vessels could not ascend higher than Bomah, about eighty miles up the river, and there the goods would have to be transhipped into small steamers, or else carried on men's heads to the higher reaches of the river. It was most essential to the carrying out of the great scheme supported by the King of the Belgians that there should be no obstacle of any description; there should be no establishments of Portuguese at the mouth of the river; no fluttering of Portuguese flags; and, above all, no duties levied on overland transit. A year ago, all this was laid before the House of Commons, and it naturally attracted the attention of men of all shades of politics, more particularly in Glasgow, Manchester, Liverpool, and so on, and they all agreed that England must consent to no treaty granting to the Portuguese the north and south bank of the Congo. The consequence was that Mr. Gladstone said that if he found it necessary during the recess to sign a treaty with Portugal concerning the mouth of the Congo, at any rate, before it was ratified, full opportunity should be given for discussion and objection. He did not know whether things remained still in the same state; some persons said the treaty had been signed, but they might be mistaken; but, at any rate, he mentioned it in order that the public might be on the *qui vive*, because, if such a treaty were ratified, England would lose the most important chance connected with that part of West Africa. He knew what all this meant; it meant the future welfare of the tribes in the interior; it meant either more slavery or less; facilities for mission work or obstructions of all kinds. With regard to the Portuguese rule, he was delighted to find that a different state of things existed here to that which prevailed in other parts; but they must not forget the important fact that this was a penal settlement. At Loanda, for instance, as they had heard, there were 800 convicts, many of whom were murderers of the worst kind. The same state presented itself on the East Coast, and the people there had caused Livingstone an immense deal of trouble. Anything more atrocious than the cruelties practised by these men it was impossible to conceive. These degradados practised every villany on the natives, and when they were told of the influence which the Portuguese had over the natives, it was only right to say how that influence was acquired. It was simply a system of terrorism. A Portuguese came there with barrels of gunpowder and muskets, and had so many strong slaves whom he petted, and who became as great tyrants as he was himself, and if any unfortunate slave misbehaved he was put to death with horrible tortures. That was how their influence spread, the natives being cowed with horror at what they did. He defied any place to have 800 convicts in it without their leaving their black mark on everything around them. With regard to the Island of Saint Thomas, Captain Cameron reported that there was a covert slave trade carried on there.

Mr. JOHNSTON said he did not detect anything of the kind.

The Rev. H. WALLER said he knew an English officer who had a very queer story to tell about the apprenticeship system, as it was called. Five hundred or a thousand natives were brought down from the interior, they were asked by a man, who professed to know their language, if they would consent to go and work on one of these islands at so much a month for so many years; the interpreter said they were desirous of going, and immediately a piece of paper was handed to these poor wretches, who knew nothing of what it meant, and from that time they were in the hands of the master, and it very often happened that they did not live out the time of their apprenticeship. In East Africa about three years was the average period of life after the contract was made. Everyone who knew what the slave trade was, shuddered when they heard of this apprenticeship system.

Mr. LIGGINS said he knew nothing of Africa, but he knew something of the Portuguese, and had had them in his service as apprentices, on his West Indian estates, though they were not called by that name. They came from the island of Madeira, and willingly made contract of service to work on his estates in Antigua, and he denied that there was the slightest coercion or cruelty, either on the part of himself or of the authorities of the island. He quite agreed with Mr. Johnston that a certain amount of coercion or compulsory labour was necessary if work was to be done. He remembered the abolition of slavery in the West India Islands, and had received part of the compensation. Under the former law, every planter was compelled to have so many slaves for every acre of land, and for some of them he might have given £200 a-piece, for which he was paid compensation, perhaps, £17 a head. He denied that, because they were called apprentices, they were necessarily subjected to harsh treatment. Compulsory labour was necessary, and it was one of the most human and excellent things that civilised man could accomplish, to take a lazy indolent savage, and make him do honest work. He received wages which he could accumulate, and become wealthy, as some of them did, and in all cases they became better citizens, and more obedient to the laws of God and man. He hoped no cold water would be thrown on the attempt to reach the interior of Africa through the Congo; it would be well if the mouth could be kept open for all nations, but he questioned whether it would be to the benefit of the world at large for England to take possession of it. The obstruction and difficulties raised in England by such societies as the Anti-slavery Society, were enough to damp the ardour and ruin the pockets of all who engaged in any enterprise of this sort.

Mr. H. G. FORBES said he had travelled in the Island of Timor, in the lesser Sunda group, which was possessed partly by the Portuguese, and partly by the Dutch, and had found an immense difference between the two, greatly to the advantage of the Portuguese. The Dutch had supremacy on the western half of the island, and there it was almost impossible for a traveller to penetrate; but on the eastern side, he not only met with a most hospitable reception, but was able to travel right across the island accompanied only by an escort of one officer and one soldier. He was very much surprised to find the high esteem in which the Portuguese were held; many of the native rajahs spoke Portuguese, and though they had to pay a considerable tribute, they all said they would not be without the Portuguese Government on any account. There was neither apprenticeship nor slavery there of any kind. He had been exceedingly pleased with the paper, and especially to hear a good word said for the Portuguese, who were very generally caluminated.

Admiral Sir ERASMUS OMMANNEY, C.B., F.R.S., said Dr. Mann had referred to the scientific work which Mr. Johnston was about to undertake. But to his mind there was another piece of work of the same kind equally important, and that was a scientific exploration of the River Congo. Hitherto, even the main points of it were merely laid down by what sailors called "dead reckoning," and as to the means of navigation, their information was very hazy. From an able paper he heard on the previous evening, he found there were more cataracts than he was prepared for; but every one must agree that it was most important for this great artery to be opened to European commerce. He hoped the Society would take means to press this matter on the attention of the Government. This was the first time he had heard so full an account of the Portuguese colonies on the West Coast, but he could confirm a great deal of what had been said by his own experience.

The Rev. H. WALLER wished to add, in explanation, that in what he had said of the Portuguese character, he was referring to the convict settlements in Africa; of course, in either Madeira or Timor, the conditions were totally different, and such conduct as he had referred to would be wholly impossible. Mr. Liggins had spoken of slaves costing £200; the ones he had been speaking of cost three or four yards of calico, and he had known one of the officers he had referred to go up country and purchase 200 or 300 at such a price. If people found a costermonger driving a donkey which had cost him 30s., they would not expect that animal to have as good treatment as a thorough-bred colt which might have cost 3,000 guineas, and the same rule held good with human chattels. There might, in some countries, be slaves who were very valuable; but to learn what slavery was in its essence, they must go to the fountain head. He had seen the poor wretches in strings of several hundreds, and if they could not keep up with the march they were knocked on the head with an axe, and the children taken by the feet and their brains dashed out against the nearest tree.

Admiral Sir ERASMUS OMMANNEY said he must say, in justice to Mr. Waller, that for fifty years he had been in contact with brother officers who had served on the East Coast, and had heard but one opinion as to those parts of the country which were under Portuguese rule.

Mr. FORBES remarked that in Timor the Portuguese were quite uninfluenced by European public opinion.

The CHAIRMAN said the paper might convey the impression to some minds that the Portuguese rule in Africa was very admirable. They had heard both sides of the question stated, and he did not know that he was called upon to give his own opinion, but if he did, he thought he should prefer not to have the Portuguese as his masters, and he had seen something of them, both in the East and in Africa. He had been to those islands which had been described, and he was sorry to say that when coming from Loanda, on a Portuguese steamer, an officer, whom he knew, having asked him if he should like to see something, which, as he had not seen much, he was quite willing to do, took him to the forepart of the ship, where he saw some sixty or seventy natives of some part of the coast, each with a ticket round the neck, and not looking like ordinary servants, or ordinary human beings at all; they were all huddled together, and the women certainly looked very unhappy. He saw no cruelty, but the impression on his mind was that they were like so many sheep or cattle being exported to Saint Thomas. He said to his companion, "Surely these people are not slaves?" The answer was that they were under contract for five years, but they never came back again. That gave him a sort of idea of what this contract service was, very different to anything which would be tolerated in this country. It was no use to re-argue the question of slavery, which had been settled once for all by the English public. In other respects he did not think there was much difference of opinion, for although Mr. Johnston spoke in favour of the Portuguese, he did not advocate their having possession of the Congo, or, in fact, extending their territory in Africa at all. There was no doubt that their rule was very lenient in some respects, but it was a question whether that leniency was not carried too far, when the result was that you could not travel from one place to another on account of the unruly character of the inhabitants. You could not go from Ambriz to Loanda without a very considerable escort. He was not an Anti-Portuguese, but there was a philanthropy of expediency as well as a natural philanthropy, and he was afraid that a good deal of it was of the former on the part of the Portuguese. Every one would agree on the very great merits of the paper, and he had much pleasure in proposing a cordial vote of thanks to Mr. Johnston.

The resolution having been carried unanimously,

Mr. JOHNSTON said he might perhaps be a little prejudiced in favour of the Portuguese, but it was natural to every one to be susceptible to kindness, besides which, most Englishmen liked to stand up for those whom they thought were unfairly run down.

The Rev. H. WALLER desired to add, that he did not for a moment wish to imply that there were not many Portuguese gentlemen of the highest character; he had referred only to the inevitable consequences of the system pursued of placing convicts of the worst character in official positions.

TENTH ORDINARY MEETING.

Wednesday, February 13th, 1884; Lieut.-Col. C. E. WEBBER, C.B., R.E., Member of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Barker, Richard, Morialta, Forest-hill, S.E.
Binns, Edmund Knowles, The Rosary, 3, Montgomery-road, Sharrow, Sheffield.
Chester, Henry, 2, The Elms, Clapham-common, S.W.
Crossman, Colonel William, R.E., C.M.G., United Service Club, S.W.
Duncan, David John Russell, 32, Queen Victoria-street, E.C.
Habgood, William, 20, Farringdon-street, E.C.
Howard, Frank Geere, Oaklands, Cricklewood, N.W.
Humber, Thomas, Beeston, Notts.
Immisch, Moritz, 119, Torriano-avenue, Camden-town, N.W.
Jármay, Gustav, Winnington-park, Northwich.
Jones, Edward, 145, Strand, W.C., and Holmdale, Wimbledon.
Mills, Percy Batt, Belmont, Chigwell, Essex.
Parkes, Dr. Louis C., 51, Cadogan-square, S.W.
Sharp, Sidney, Millmead, Guildford, Surrey.
Wilson, Miss Lillian, Boston-house, Chiswick.

The following candidates were balloted for and duly elected members of the Society:—

Colthurst, Sir George St. John, Bart., Blarney Castle, Co. Cork.
Dalton, William Henry, 118, Gower-street, W.C., and Melbourne, Australia.
Elieson, Chaimsonovitz Prosper, 7, Drayton-terrace, Drayton-road, Leytonstone, E.
Knowles, Thomas, Fir Tree-cottage, Turton, near Bolton.
Miller, John Ezra, 1, Tunstall-road, Sunderland.
Nicholson, Robert, J.P., Loanend-house, Norham, near Berwick-on-Tweed.
Pengelly, Thomas, Bodriggy-villas, Hayle, Cornwall.
Richardson, H. Cameron, 2, Carlton-villas, Elm-park-road, Finchley, N.
Sadler, Lieut.-Colonel, The Southlands, Preston-on-Tees, *via* Darlington.
Scott, Major-General Alexander de Courcy, Woodfield, Lytton-grove, Putney-hill, S.W.
Staples, Henry John, 87, Avenue-road, Regent's-park, N.W.
Thornton, Thomas Henry, C.S.I., D.C.L., Leigham Holme, Streatham, S.W.

The SECRETARY announced that, owing to indisposition, Mr. Hubert Herkomer was unable to take the chair, but that Colonel Webber had kindly undertaken to preside. He drew attention to a head painted by Mr. Herkomer, which that gentleman had kindly sent as a specimen of the work done by the Keim process.

The paper read was—

A NEW PROCESS FOR PRODUCING PERMANENT MURAL PAINTINGS, INVENTED BY ADOLF KEIM, OF MUNICH.

By REV. J. A. RIVINGTON, M.A.

It is now rather more than forty years since the decision of Parliament to decorate the new Palace of Westminster with frescoes was welcomed as the beginning of a new epoch in English Art. The most sanguine hopes were entertained, and even confidently expressed, that this step would result in the formation of a great school of painting adapted to the new requirements of art in this country, and would, moreover, lead to the improvement of the sister arts of sculpture and architecture.

"The young artist may be assured," says a well-known writer on art at that time, "that fresco-painting will succeed, and be extensively practised in this country. The commencement has been most auspicious. The patronage of Government has been offered. The assistance of Parliament has been obtained; and with such encouragement and patronage, ability and genius will not be wanting. No opposition can now prevent its success. The die is cast, the path will be trodden."

Alas for these glowing anticipations, these flattering prophecies; not even the original project was carried to completion. One factor in the calculation, an all-important one, had not been taken into account. Not the patronage of Government, not the assistance of Parliament, not the genius or ability of the artist could avail anything against the power of an existing influence, fatally opposed to all such art works—the influence of the English climate.

A comparatively short time sufficed to prove that no dependence whatever could be placed on the permanence of works executed in fresco, and from that time to the present, it has been taken as an accepted fact that English art must develop itself in other directions than in that of fresco-painting, the field where it could find room for the highest and grandest expression of its powers. It is not, perhaps, too much to say that such a limitation to the development of art has something in it of the nature of a national misfortune, and that it would be hardly possible to over-estimate the value of any discovery which would make us independent, for art purposes in this direction, of all influence of weather or climate, under any conditions of exposure.

It is the confident assurance that I am able to bring under your notice an invention capable of securing to us this absolute immunity from climatic influence, in the highest and most perfect degree, that gives me courage to appear before you to-night.

And, first, I must claim your attention a few minutes for some brief remarks on other existing processes for mural paintings, which will help you to appreciate better the superiority of Mr. Keim's system.

Fresco-painting, properly so-called, is the process of painting in water-colours upon wet mortar containing lime. In this process, the action of the carbonic acid in the atmosphere converts the lime of the mortar into carbonate of lime, and this latter it is which forms the preservative or fixing medium for the colours. The carbonic acid is driven out of the limestone or chalk originally by the process of burning, and the lime remains. When slaked, the lime is converted into a pulp of hydrate of lime. In this form it exists in the mortar, and greedily absorbs the water with which the colours are applied. This water, together with that already in the mortar, dissolves a portion of the hydrate of lime, and after a time this solution finds its way, through the supervening layer of colour, to the surface, where it absorbs carbonic acid gas from the atmosphere. By this means it becomes converted into carbonate of lime, and lies upon the surface of the painting in the form of a thin crystallic film, protecting and securing it to such a degree that it will admit of being washed, provided no great amount of friction be employed.

Experiment has shown that in fresco-painting the colour does not sink further into the ground than in the case of any water-colour laid on a dry ground. On the contrary, the pigment becomes saturated with the solution of hydrate of lime which exudes from the mortar, and which can only become converted into a film of carbonate of lime on the surface; beneath this, the adherence of the pigment to the mortar is very slight, as may be easily proved when the crystallic film has been scraped off, or dissolved away by the application of an acid, or even removed, as is sometimes possible, by merely rubbing the surface with the moistened finger. After the removal of the protecting film of carbonate of lime by some such means, the pigment gives way readily when rubbed with the finger, and with even still greater readiness if moisture be also applied. A very striking illustration of this is afforded by the fate of the frescoes executed about eighteen or twenty years ago on the exterior of the new Pinakothek in Munich. On the northern and eastern sides, the hail and rain have destroyed and washed away not only the protecting film of carbonate of lime, but also almost every vestige of colour.

The tendency to peel off in flakes, which paintings executed in fresco have often shown, admits likewise of a very simple explanation.

As a consequence of the greedy absorption by the mortar of the water contained in the pigments, the particles of the latter adhere mechanically to the surface of the mortar by capillary attraction, and that so closely as to permit of a second layer being very shortly after laid upon the first, without mixing with it in any way. Similarly, the second layer will admit of a third being superimposed. All three layers now become saturated with the solution of hydrate of lime, and are united by a real process of cohesion. This process is, however, only in the highest degree perfect where the superimposed layers have been applied before the hydrate of lime has completely penetrated the pigments. In those cases where it has so penetrated, and the crystallic film has already partly formed, the saturation cannot be so perfect; and where colours have been laid on after the film is fully developed, these can only adhere to the surface in a very imperfect degree. It follows that damp, or other causes, are sufficient to induce them to peel off very readily from the more firmly attached layers beneath.

It has been thought by some that the paintings discovered in the excavations at Pompeii, and elsewhere, are evidence that the ancients were in possession of a process that would ensure the permanence of paintings for some two thousand years at least, and doubt was thrown, therefore, for a time, on the possibility of their being fresco work. But recent examination, while it has proved their claims to be classed among genuine fresco-paintings, has also explained the seeming mystery of their permanent qualities. In the first place, it must be borne in mind that they have been preserved from the action of air and light, and, in some degree at least, of damp also, for almost the whole of their existence, and in the next place, their apparently indestructible character has vanished before those simple tests to which fresco-painting has invariably succumbed.

All such paintings as have been, since their excavation, exposed to the action of the weather, have undergone rapid decay, so much so, indeed, that within the short space of nine years some of them have almost entirely disappeared.

I have felt it necessary to speak of fresco-painting at some length, and indeed it is due to a process which, for so many centuries, was the acknowledged system for all great works of art of this class, to discuss the causes of its failure with full consideration. It is a dead system now, or soon will be; but it has played a great part in the past, and art owes it a debt of gratitude. I feel that it deserves a worthier funeral oration than the amateur *post-mortem* examination to which I have just treated it.

With regard to the more or less inefficient modern substitutes for fresco, I shall not need to tax your patience so greatly, as they are infinitely less deserving of respect. Most of them, if not all, such as wax colour, casein, as employed abroad, do not profess to be capable of resisting the influence of weather, when exposed to the open air. They are, therefore, only comparatively permanent, even when used for interior decoration, and may be dismissed without further mention.

Mr. Gambier Parry's process of "spirit fresco" appears to possess merits beyond such methods as are employed abroad, but, like them, it is not intended for exposure to the open air, and cannot enter into competition with the process which is the subject of this paper. It is, perhaps, unnecessary to remind you that the only sure guarantee for the permanence of any painting must rest its claims on a thoroughly scientific observance of, and adherence to, the laws of chemistry. Unless the painting is executed under conditions which can be proved to comply with the demands of chemical laws, its permanence is a mere matter of hap-hazard experiment, and a perfectly open question, which even the test of time itself can hardly settle conclusively, since, without a thoroughly scientific basis, there is no real guarantee that the conditions will not vary.*

The process which it is my privilege to introduce to your notice this evening, claims our attention as being the result of nearly twelve years thoroughly scientific labour and research on the part of the inventor, and is based on the stereo-chrome process of Schlotthauer and Fuchs, differing however from that in such important particulars as to constitute, practically, an entirely new process of itself.

In the year 1848, Professor Schlotthauer, of the Munich Academy, who had for some time been engaged in experiments with a view to discovering some permanent process for mural paintings, turned his attention to the substance known as water-glass (silicate of sodium), the invention of the chemist Fuchs. The result was the adoption of the stereo-chrome process.

In this process the surface to be painted on consisted of an ordinary mortar of lime and sand, impregnated with water-glass. Upon this surface the painting was executed in water-colour, and was then fixed by water glass thrown against the surface in the form of a fine spray, the water-glass in this case forming the fixative for the painting.

In practice, it soon became evident that a simple spraying of water-glass, applied to heterogeneous pigments, without reference to their peculiar properties as regards chemical composition, cohesive capability, &c., was not sufficient to ensure their permanence. Certain colours in particular, as ultramarine, umber, and black, were observed to be always the first to detach themselves in the form of powder, or by scaling off from the painting; thus pointing to the fact that their destruction was not owing to any accidental defect in the manner of their application, but to some radical unsuitability arising from the chemical conditions of the process.

In Mr. Keim's process great regard is paid in the first instance to the ground upon which the painting is to be executed. A careful

* A substitute for fresco-painting has been adopted of late years in this country, for paintings on a small scale, by the employment of oil colours, with a matt medium to destroy the gloss peculiar to oil pigments, and to impart the dead surface so necessary to mural decorative paintings. Very little consideration is required to show that this method presents, perhaps, the least guarantee of any process, for the permanence of the painting. In oil colours, it is the oil which, by filling the pores of the pigments, serves at once as a preservative and binding medium, while the varnish forms an additional protection against atmospheric influence. The various mediums used to destroy the characteristic effect of oil, effect this by expelling or neutralising it. The volatile elements of the mediums then evaporate, leaving the pores open for the chemical action of carbonic acid gas, sulphuretted hydrogen, or any other deleterious agent in the atmosphere, to destroy the colour, while little or nothing remains to bind the substance of the pigments together. The comparatively rapid ruin of such paintings is the only possible result.

study of the best examples of the fresco paintings of former times, convinced him that the painting ground was a feature of supreme importance. I have here some fragments of Pompeian wall-paintings, which will illustrate the extreme care which was bestowed at that time upon the preparation of the wall surface. An examination of them shows that two different qualities of mortar, in distinct layers, were employed in their construction. That which lay underneath is coarser in texture, but very firm, and evenly mixed. Upon this is laid a very thin coating of a much finer composition, spread over the surface with the greatest care and accuracy. Here is a fragment of a Roman fresco, from Bavaria, of a much later date. The different character of the mortar can be seen at a glance. There is only one coating, and that one not only far coarser than even the first coating of the Pompeiian fresco grounds, but very roughly and carelessly mixed. No trouble appears to have been taken to sift the sand so as to produce evenness of texture, as is evident by the presence of small stones and lumps occurring throughout. The deterioration of character in the later specimen is very marked.

The preparation of the wall, then, in Mr. Keim's process, receives the most elaborate and careful attention. Great care is taken, in the first place, that the wall to be treated contains no damp or decaying stones or bricks, and the latter must have been sufficiently baked, otherwise they will develop an efflorescence most injurious to the process.

If the wall be already covered with stucco or mortar, this will serve as the first ground, provided it be in a thoroughly sound and dry condition, and it will then be sufficient to clean and level it before applying the second, or painting ground. If not, the stucco must be cleared off, the bricks laid bare, and the mortar between the bricks picked out to a depth of about three-quarters of an inch.

This more thorough preparation is always preferable in a work of greater importance, or where special pains are advisable to secure durability, as, for instance, when undertaking the exterior decoration of a building.

Upon this surface a thin squirting is cast, composed of the following mortar—coarse quartz sand, infusorial earth, and powdered marble, mixed in certain proportions. Of this mixture four parts are taken to one part of quick-lime, slaked with distilled water. Upon this squirting-cast, the object of which is to secure adhesion to the surface of the wall, follows mortar of ordinary consistency, composed of the same ingredients, to fill up all inequalities and produce a smooth surface, and upon this, again, the second or painting ground is applied.

The painting ground is composed of the finest white quartz sand, marble sand, artificially prepared, and free from dust, marble meal, and calcined fossil meal (infusorial earth). The sand composed of these materials, carefully mixed in the proper proportions, is mixed with quicklime slaked with parts of distilled water, in the proportion of eight parts sand to one part slaked lime. This mortar is applied to the wall as thin as possible, not exceeding one-eighth to one-quarter inch in depth.

For work executed on the exterior of buildings, Mr. Keim recommends the employment of pumice sand, in addition to the other ingredients of the mortar. When coated with a stucco of this composition, the wall presents so hard a surface as to admit of sparks being struck from it with a steel.

It is absolutely essential that throughout the work, only distilled, or filtered rain water be employed. The reason for this is to obviate any possibility of the water containing lime, as that would affect the solution employed for fixing so as to impair the effect of the painting.

It will be observed that in this process Mr. Keim not only is careful to follow the best examples of antiquity in the manner in which the stucco is laid on the wall, but that he has adopted the use of a mortar composed of carefully selected materials, in preference to that of an ordinary kind, such as was employed in the stereo-chrome process. The object of this is to attain a far higher degree of durability. The nature of the sand selected for this purpose is eminently calculated to ensure this. Marble sand, such as he employs (carbonate of calcium in crystalline form), has been proved by experience to add very greatly to the firmness of the mortar, containing many advantages above quartz sand, such as greater porosity for the absorption of the colours and fixing liquid, &c.

Again, the infusorial earth mixed with it (a form of silica), has a double effect in consolidating the mass. First, it acts mechanically, cementing and binding together, with the lime, the coarser particles. Secondly, it forms, to some extent, with the lime, a silicate of calcium, such as afterwards results from the addition of the water-glass. The presence of this silicate within the mortar adds, in a very high degree, to its hardness and power of resistance to chemical and mechanical influences.

The intense power of increased durability which Mr. Keim obtains by these improvements, can be best estimated by a regard to the fact that paintings executed by the stereochrome process, while they have for the most part lost the coating of paint or their colour, have, save in such cases where the preparation has been carelessly carried out, retained the painting ground up to the present day, after exposure to weather for nearly forty years, in perfect and sound preservation.

When the mortar is perfectly dry, down to the stone or brick of the wall, it is treated to a solution of hydro-fluo-silicic acid, to remove the thin crust of crystallic carbonate of lime which has formed on the surface, and thus to open the pores. It is then soaked with two applications of potash water-glass (silicate of potassium) diluted with distilled water, and when dry, the ground will be found hard, but perfectly absorbent, and ready for painting.

The surface layer of mortar, or painting ground, can be prepared in various degrees of coarseness of grain to suit the artist's requirements. The more smooth and polished however the surface is made, the greater are the difficulties in the subsequent process of fixing, owing to the absorbent qualities of such a ground being necessarily less perfect. The ground can also be prepared in any tint or colour that may be desired, and can be applied to any suitable substance, if needed for a removable decoration. Stone, tile, slate, wire-gauze, glass, and canvas form an efficient substitute for the wall in such cases. If applied to canvas, it can in this form be fixed to wood-panels, mill-board, ceilings, &c., and admits of being rolled with perfect safety. The advantage of this to the artist is sufficiently obvious. If a ceiling, for instance, has to be decorated by this process, it can be painted with the same convenience as an ordinary picture in the studio. After it is fixed, it can be rolled up, taken to its destination and fastened on to the ceiling, either temporarily or permanently, at the cost of very little expenditure of time or labour. Similarly (unless it were permanently fastened up), the ceiling would admit of being removed for the purpose of being cleaned.

I come now to speak of the colours used in this process. Certain pigments only are admissible, in order to ensure permanence, and regard must be had to the purity of these, and to their absolute freedom from adulteration. All the colours found available for the stereochrome process can be employed; these are, for the most part, composed of natural earths or metallic oxides, since experience has proved that the most permanent colours are those derived from such sources. In their preparation, due account has been taken of the well-known law in optics, which teaches that colour does not lie in the substances themselves, but in the rays of light, which are divided, reflected, or absorbed by the substances in such a manner as to produce the effect of colour upon the eye. Substances, therefore, which readily undergo change, whether by reason of their affinity to other substances with which they are brought into contact, or by the action of the light itself, which often causes molecular change, must, whenever such change takes place, lose, or modify their original colour, since, under their altered conditions they absorb or reflect the rays of light in a different manner.

It is clearly then of the greatest importance that each pigment should remain chemically unaffected by the substance of the painting ground on which it is laid, and by the substance of any other pigment employed, as well as by that of the material used for fixing them. To meet this end, the colours in this process are treated beforehand with alkaline solutions (of potash or ammonia), to anticipate any change of hue which might result from the use of the alkaline liquids which form the fixative. In addition to this, they are further prepared with certain other substances, such as oxide of zinc, carbonate of baryta, felspar, powdered glass, &c., as required by the peculiar properties of each, in order to obviate any other danger of chemical change taking place.

The colours found available present a very full scale. They are thirty-eight in number, and there are several other colours which could be added if required. They consist, speaking in general terms, of four varieties of white, six of ochre, two of sienna, ten of red, two of brown umber, two of Naples yellow, two of ultramarine, five of green, three of black, and cobalt blue. Cadmium will shortly be added to them. The whites are, perhaps, in unnecessary profusion. Zinc white, for its opaque qualities, and baryta white for purposes where great opacity is not desirable, would be probably found quite enough in practice.

Zinc white is oxide of zinc. It is especially valuable in this process, forming a silicate in combination with the fixing solution, and thus adding greatly to the hardness and durability of any colours with which it is mixed.

Baryta white is artificial sulphate of barium. It is useful for giving a lighter tone to colours without greatly detracting from their transparent qualities, and is on this account useful in glazing, where zinc white would be too opaque.

Of the ochres and siennas I need not speak in detail. They consist of various combinations of oxy-hydrates of iron, calcium, alumina, magnesia, and silica. The violet oxides of iron belong to this class. The colour is due to their being subjected to the action of heat for a longer period of time.

The reds are chiefly oxides. The chrome is a sub-chromate of lead. This colour, you will observe in the specimens before you, is prepared in dry powder instead of in a moist paste, as in the case of the others. The reason for this lies in the fact that the colour depends on the size of the crystals, which would be destroyed by further grinding, with the result of the pigments assuming an orange hue. It will, therefore, only admit of being mixed with water by the means of the brush. I need hardly observe that I am using a relative term in speaking of the size of the crystals. The pigment is in the form of an almost impalpable powder, but the exceptional degree of fineness which is attained in the other colours, forces me to speak of this in terms which might be misleading.

The lake is only suitable for interior decoration, and has been prepared by Mr. Keim, under protest, for artists who found themselves unable to forego its use. He does not guarantee its permanence if exposed to weather in the open air. He has proposed an ultramarine red as an efficient substitute.

The colour named mennig is an oxide of lead.

The umber is an oxide of iron and of manganese, combined with silica.

The Naples yellow is a compound of oxide of lead and antimony, or antimoniate of lead.

The ultramarine is artificial, and consists of silica, alumina, and sulphate of sodium.

The cobalt blue is protoxide of cobalt, compounded with alumina.

The cobalt green is protoxide of cobalt, in combination with oxide of zinc.

The green earth consists chiefly of silicic protoxide of iron. It also contains magnesia, alumina, and potash.

The chrome oxide green is oxy-hydrate of chromium.

Over no part of his process has Mr. Keim expended more labour and thought than in the preparation of the colours. From the various nature of the properties possessed by some of the pigments, it was found that their capacity for absorbing the alkaline silicate with which they were fixed varied very greatly. There was also a marked difference in the degree of mechanical cohesive capacity which they respectively possessed. To equalise them in these respects, without which the fixing would have been a work of great difficulty and uncertainty, alumina, magnesia, and hydrate of silica were added as required. The result is, that all the colours are equally acted upon by the fixing solution, and all attain an equal degree of durability after fixing, both as regards the mechanical and chemical action of this process upon them.

It is significant of the success which has attended Mr. Keim's thorough appreciation of the requirements of the pigments, that his labours in this direction have so perfectly adapted them to the chemical condition of the ground, as to show that, to a very appreciable extent, fixation will be found to have already taken place before even the application of the solution employed for that purpose.

In the year 1878, a large mural painting was executed by this process on the exterior of the parish church at Eichelberg, near Regensburg. Before its completion, and therefore before any of the fixing solution had been applied to it, it was drenched by a heavy storm of rain. Contrary to anticipation, it was found that the painting, so far from being in any degree washed away, had held perfectly firm, and even in some places seemed to be as hard as if already fixed. Mr. Keim's explanation of this unexpected result, which he subsequently confirmed by experiments, was, that a chemical cohesion had already taken place by the action of the alkali set free in the mortar upon the silicates in the pigments.

Again, when it was determined to execute the mural paintings in the Franciscan Monastery, at Lechfeld, in 1879, it was desired to wash off a painting executed in this process a year previously, which had never been fixed. Neither water, nor even a tolerably strong solution of acetic acid, had the slightest effect upon it.

If the process, so far as I have described it, appear to you, from the thoughtful and laborious pains bestowed upon it by the inventor, to be somewhat of a complicated character, involving considerable study to understand the nature of its claims to durability, as well as scrupulous care in the preparation of the materials, it will be at least a comfort and a relief to you to learn that exactly the reverse is the case, as regards the use of this process from the artist's point of view. For him are no complications or difficulties whatever. So far from approaching in any degree the difficulties or inconveniences possessed to a greater or smaller extent by fresco-painting, or any of its more modern substitutes, this process is even far pleasanter and easier to work in than oils or water-colours. Every variety of treatment is possible, and it adapts itself to any individual style of painting. It presents perfect facility for transparent glazing as a water-colour, and for painting in body colour it even surpasses the capabilities of oil colours in its power of opaque treatment.

The examples before you will be a sufficient illustration to anyone practically acquainted with oil or water-colours.

Moreover, the most delicate tints, when laid over darker tones, do not in the slightest degree darken over them, as they are apt to do in oils, but keep their full value perfectly. Retouching and correction can be effected with the greatest ease, and to an almost unlimited extent. The system admits also of great economy. To begin with, the pigments are by no means expensive, in spite of the labour expended on their preparation, and a very sparing use of them is sufficient to meet all possible requirements in painting, a far less amount requiring to be expended than in other processes. This is due mainly to their being ground so exceedingly fine, so that they need only be very thinly laid on; in fact, this consideration has always to be borne in mind, that the thinner the coat of painting is, the greater the degree of security that can be attained by the fixing. Moreover, there need be no waste of pigment at the end of the day's work, as in oils. The palettes employed for the process, as you see by the one before you, are constructed with small pans to hold the pigments. If any paint remains after the work is finished, it can either be replaced in the bottle, or it can be kept moist in the pan with distilled water for the next day's work. Even if a considerable amount of the pigment should by inadvertence have been allowed to become dry, all that need be done is to grind it up again with a little distilled water, a task involving no labour.

The process has the further recommendation of great cleanliness, distilled water being the only medium used in painting. The porous nature of the ground, and its peculiar texture, have had great fascination for those who have made practical acquaintance with the working of it.

The last stage in the process is the work of fixing. In the stereo-chrome process the fixing medium employed was silicate of potash, thoroughly saturated with silica, in combination with sufficient sodic silicate to prevent it from opalescing. The chief defect of this lay in the fact that it was often apt to produce spots upon the painting. Mr. Keim, after much careful study, has substituted silicate of potash treated with caustic ammonia and caustic potash. The action of the carbonic acid in the atmosphere and in the water during the process, leads to the formation of carbonated alkali, which makes its way to the surface, and would form, when dry, a whitish film over the painting. To obviate this danger, as well as to expedite the process of converting the silicate of potash with the basic oxides existing in the substance of the painting into silicate, the fixing solution is treated further with carbonate of ammonia. The effect of this upon silicate of potash is that silica is precipitated in a fine gelatinous form, and ammonia set free. This latter volatilises, and carbonate of potash is formed, which is easily removed by washing after the completion of the fixing.

Having regard to the value of heat in accelerating the action of chemical processes, the fixing solution is employed hot, with the advantage of obtaining a quicker and more perfect formation of silicate than was possible in the stereo-chrome process, where the solution was applied cold.

The effect of the fixing is not very difficult to understand. I have already pointed out, in speaking of the pigments, that the result of their being treated with certain substances is to effect the formation of silicate, both in the constituent parts of the pigments themselves, as well as of those in combination with the painting-ground. The additional presence of the fixing solution intensifies this process to the greatest extent. The free alkali of the solution acts upon certain of the substances which have been added to the pigments—such as oxide of zinc, hydrate of alumina, and hydrate of silica—at first by dissolving them. By the action of the carbonic acid in the atmosphere, these solutions are again decomposed by parting with the hydrates, which, through this process, are converted into silicates. The pure colours are enclosed in these silicates; whenever that is, the pigments themselves do not take part in the formation of silicate.

The hardening process of mortar I have

described—in speaking of fresco-painting—to be due to the formation of a crust of carbonate of lime upon the surface. The action of the fixing solution in Mr. Keim's process, when applied before and after the painting, is to form, in addition, a silicate of calcium with the particles of lime, the presence of which within the mortar increases beyond comparison the hardness and durability of the whole; silicate of calcium, no less than carbonate of lime being, as is well known, constituent parts of some of the hardest marbles.

Briefly described, then, the effect of the fixative as it sinks into the ground, which has already absorbed the pigments, is to convert the painting into a veritable casting, uniting with colours and ground in one hard homogeneous mass of artificial stone, partaking of the nature of marble in its power of resistance to mechanical disturbance, partaking of the nature of glass in the impervious front it presents to the chemical action of the atmosphere.

The finished painting has proved itself absolutely impervious to all tests. It will admit of any acid, even in a concentrated form, being poured over it (save, of course, hydrofluoric acid). Caustic potash, also, has no effect upon it, indeed nothing can be employed with greater advantage than this for cleansing the painting when its condition requires that process. I will give you a practical illustration of this, as well as of the perfect safety with which soap and water may be applied with a hard brush, as vigorously as may be desired. The surface is so hard as to present a perfect resistance if scratched with the finger nail. If anyone likes to convince himself of this, by making the experiment for himself at the close of the lecture, he is perfectly welcome to do so. I will only advise him, if he has any regard for his finger ends, to approach the experiment with caution. The hardness and durability of the finished painting has been subjected to very severe trials abroad. It has defied the elements in very bad climates, having been exposed to the weather on the exterior of buildings for some years.

In Munich a specimen of the process was subjected to incessant tests, and put to every form of torture without intermission, for two years, and I may say, in language which, if not classical, is at least familiar to English ears, it "came up smiling" after each attack, and, at the end, was as fresh and uninjured as at the beginning.

On the 25th of last month, I delivered over to Professor Barff four small specimens, to test their claims to resisting atmospheric influence. He is unfortunately prevented by ill-health from attending this evening, but he has supplied me with the following statement to read to you:—

"100, Abbey-road, Feb. 11th, 1884.

"The Rev. J. A. Rivington gave me four specimens of his painting to submit to any tests I pleased. Three of these were half protected and half exposed. No. I. was treated by me in the exposed part, first with a solution of oil of vitriol, one part oil of vitriol to four parts water, for some minutes, after that I washed it in cold water. It was then treated with bromine water for some minutes; after that, to destroy the yellow tint given by the bromine water, and to further test it, it was washed with a solution of strong caustic soda. A few days after, it was treated with saturated chlorine water. These tests proved that the protecting influence of the silicates is very great. Chlorine and bromine do not occur in the air, but they are most powerful bleaching agents, and, therefore, rapidly destroy unprotected colours.

"No. II was kept moist for nearly a week under a bell glass full of carbonic acid gas; I then placed it in water through which carbonic acid was passed continuously for twenty-four hours. This proves that the lime ground can resist the most powerful disintegrating agent which exists in the air.

"No. III. was placed for a week in a bell glass of sulphurous acid gas, and kept moist. The result is, that it resisted this most powerful disintegrating gas; it also resisted its bleaching powers. Sulphurous acid destroys substances by its becoming oxidised in the presence of moisture into sulphuric acid, which, continually applied, has a most destructive effect.

"My opinion, therefore, is that paintings properly executed with these materials will resist the destructive influences in the air. The fourth specimen proves that however dirty a painting in these materials may become, it can be made as fresh as when new by simple washing.

"I have studied silicious painting for thirty years, and have therefore had some experience.

"FRED. S. BARFF, M.A., Cantab."

Mr. Barff has left me to tell you the test he applied to the specimen No. IV. It was wetted, and then held over a gas-flame till thoroughly blackened. Scrubbing it with water completely removed the smoke stains, and when he showed it me it was as fresh and uninjured as when I gave it into his hands. He repeated the process of blackening it in my presence, in order that you might have a practical illustration of how little London smoke is likely to injure such paintings.

Now, these specimens, which have so successfully resisted such extreme tests, were not fixed with the utmost degree of care. I did not apply the solution hot, nor did I, as Mr. Keim recommends for the more practical formation of the silicates, allow from twelve to twenty-four hours to elapse between each application of the fixing solution. They received each four or five coatings, but were dried rapidly, and received a fresh coating as soon as they were dry. They were painted and fixed in the course of one day. I had, however, previously to giving them to Professor Barff, treated No. II. to a bath of undiluted sulphuric acid, scrubbed well in with a hard brush, and afterwards had treated it in the same way with undiluted caustic potash, so that I had tolerable confidence that they were fixed sufficiently to resist any legitimate test that might be applied.

We have now abundant testimony to the invulnerability of the painting to any chemical action of weather or climate, as well as to its power of resistance to injury from mechanical causes, such as friction. If it should be damaged by a violent blow from a hard instrument, it can be repaired and re-touched with the greatest ease. The carbonic acid of the atmosphere is distinctly beneficial to it, imparting to it by degrees the consistency and hardness of actual marble, when absorbed by the lime in its composition. The moisture of the atmosphere, even in the form of heavy rain, is also an advantage, in dissolving away the free carbonate of potash to which I have before alluded.

It is worth while pointing out that, although this process has been designed to meet the requirements of mural painting, it is capable of application to other purposes with great advantage. For instance, it would have great merit in its durable qualities, and in the readiness with which it can be cleaned, for scene painting, in addition to which it possesses the important advantage of being uninflammable, owing to the presence of the silicate.

For ordinary house-painting, it would last as long as the building itself, only needing to be scrubbed down from time to time. I need scarcely point out that it would, when used for this purpose, be an effectual protection against damp.

It can also be employed for tapestry painting. I am indebted to the kindness of the authorities of the Science and Art Department of the South Kensington Museum for the loan of the specimens before you. You will see that in this case no special ground is required. Canvas of proper texture, prepared by soaking it in a special solution, forms a suitable ground for the colours, which are laid on and fixed as in the case of the prepared mortar. The work is equally permanent in character, and entirely unaffected by light. It is uninflammable, and can be cleaned without the least injury to the most delicate colours.

It might, perhaps, be feared that such exceptional qualities could only be taken advantage of at a prohibitive cost, but this is not the case. The expense will bear favourable comparison with that of other systems, without taking into full account the lasting nature of the work executed.

It only remains for me to add the testimony of a Commission appointed in the spring of 1882, by the Royal Bavarian Academy, at Munich, to examine into and report on this process. The members of the Commission consisted of Professors Lindenschmit, Müller, and Max, artists; Albert Schmidt and Fritz Hasselmann, architects; and Dr. Lietzenmayer, chemist. The report was published on the 18th of May of the same year, and deals most exhaustively with the subject from three points of view—(1) the chemist's, (2) the builder's, (3) the artist's. The following is the summing up under each of these three heads.

1. The chemical report says:—

"Mineral painting guarantees with certainty that, by means of this process, mural paintings can be executed, which—presupposing a correct and conscientious treatment—are capable of the greatest and most enduring resistance to climate."

2. The architects conclude as follows:—

"The evident hardness and capability of resistance presented by the specimens laid before us, as well as the fact that, amongst others, Professor Lindenschmit has buried one such painting a whole winter under a roof gutter in the snow without its having received the slightest damage, leave no doubt that Mr. Keim has, through his very able method, succeeded in perfectly solving the problem of producing mural paintings indestructible by weather."

3. The artists on the Commission sum up their report with these remarks:—

"According to the foregoing opinions, Mr. Keim has undoubtedly succeeded in providing a method of monumental painting, carefully thought out, even to the smallest detail, grounded on scientific principles, and practically verified by visible facts, which is by far to be preferred to all methods of painting hitherto existent, and which, once recognised for its high value, would bring about a complete revolution in all our monumental and decorative art, and which deserves the widest publication and practical employment."

I have trespassed too long already upon your attention, but before I take leave of the subject of what I fear may seem to many of you to be somewhat hard and dry facts, I may perhaps be pardoned if I allow myself a little flight of fancy. I have confident hopes that the great merit and intrinsic value of this process will meet with that recognition in this country which it is already rapidly winning for itself abroad; nay, I will even venture to revive those dazzling but short-lived prophecies to which I referred at the beginning of this paper. I see, in the solid guarantees which this system affords us, the art of mural painting no longer a dream of Utopia, waiting for the labours of smoke abatement exhibitions to make room for its development, but an actual reality in English art. I see Westminster Palace glowing with the productions of the best masters of our day, productions which we should be proud to think of as carrying down to future generations the evidence of the genius of our times. I see London, and all our great centres of life, blossoming like a garden with artistic creations that serve to break the hideous monotony of nineteenth century streets. I see interiors decorated with scrupulous and cultivated taste, under a sense of having to select a style that will last as long as the walls themselves. I see Art, under these influences, taking its place as a mighty teacher, with a voice more potent and far-reaching than it ever could possess before, a voice that cries from the walls, the streets, the public buildings of our cities, that "those who run may read." I see Art opening in this way the door of history, of poetry, of nature, to those who else would lack instruction. I see the heroism of the past, the nobility of duty, the recognition of virtue, handed down to all ages to tell their living truths in language ineffaceable. I see these enduring appeals to the higher instincts of our being, lifting a nation above the grovelling cares of wealth, above the narrowing claims of selfish interests, above the petty jealousies of party strife. I see Art, by this means, developing patriotism, generosity, honour, and noble sacrifice of self. Above all, I see Art taking once more a place worthy of her powers as the handmaid of Religion, when our churches shall be no longer delivered over to the stunted mannerisms of mere decorative style, but when our greatest artists, encouraged by the thought that their work will prove enduring, will give their highest talents to teach the most sublime of lessons, seeing no worthier field than this, of usefulness and honour.

DISCUSSION.

The following letter from Mr. G. F. Watts, R.A., was received by Mr. Rivington:—

I am sorry that an engagement will prevent me from being present at your lecture. A method at once easy and durable might bring about the practice and re-create the habit of mural decoration, now fallen almost completely out of use, on account of the difficulty and uncertainty of known methods. The highest expression of painting, as an intellectual effort, belongs to designs composed with reference to architectural combinations, and I cannot but feel that when the habit of requiring and producing such works falls into absolute disuse, art must take the lower place of only a luxury.

G. F. WATTS.

Little Holland-house,
Feb. 11, 1884.

Professor CHURCH said there was so much in the paper that he could only touch upon the various subjects mentioned in a very rapid and possibly somewhat disconnected manner. Mr. Rivington seemed to have grasped the chemistry of a somewhat difficult process very accurately, and with considerable fulness of detail. With regard to his introductory remarks on frescoes, he would say that the climate of this country was not the only hostile agency against their preservation. The deterioration was in great measure caused by the sulphurous acid air produced by the combustion of gas which existed, not only inside buildings, but, unfortunately to a large extent, in the external air also, and which arose from the use of coal containing sulphur. It produced sulphate of lime and sulphate of magnesia, and caused not only the disintegration of the surface, but destruction of the stone itself, and the disappearance of the colour. With reference to the wax process, wax had long ago proved its feeble character as a binding material. Paraffin, however, which was positively unalterable by all influences, was an admirable substitute, and he felt sure painting with solid paraffin as a vehicle would, in some measure, take its place for internal, and, to some extent for external purposes. In calling this a new process, he thought an injustice was done to the memory of three men to whom the use of silicate of potash, silicate of soda, and alkaline silicate of soda, was really due. In the *Journal of the Society of Arts*, some quarter of a century ago, was published a process, with which they were all familiar, under the name of stereochromy, and nearly every feature claimed as a novelty in this process of Keim's, had been published and worked upon by numerous persons interested in the fine arts, for a great number of years.

Carbonate of ammonia, carbonate of potash, caustic potash, dolomite, or magnesian limestone, powdered marble, sifted marble, pumice and baryta water, but not infusorial earth, as far as he remembered, had all been employed, although not in the same systematic and perfect manner in which they were suggested in the process of Keim. It was, therefore, hardly right to call it a new process; it was the development, the perfectionment of a former process, and one which made a great step in advance, but not an original process. Having seen all the original papers, and having tried a few experiments himself, he thought the materials of the colours, although in some measure new, had been to some extent anticipated, not by Fuchs, but by Kuhlmann, who mixed water-glass with his colours, so that the action of this material in fixing might be anticipated, and so that you might not get so great a change in the fixing as occurred with some of the less suitable materials. He would not dwell on the use of hydro-fluo-silicic acid, but that the use of that material produced a certain degree of porosity had been long known, and had been actually patented here, in conjunction with another substance, for the preservation of stone; in this particular process it was no doubt a very desirable addition. With reference to the asbestos millboard, it was curious that his predecessor in the chair of Chemistry at the Royal Academy should have mentioned it to Mr. Rivington, for about sixteen months ago, he got a number of specimens of this material for stereochromy, and showed some at his last course of lectures at the Academy, in November and December last, with a few streaks of colour painted upon them. At present they had not got a millboard which was actually perfect in surface; the silky fibres were very useful to give a tooth for the ground, but they often lay in parallel masses, and interfered with the working of the colour. When they got a better millboard, he thought that it would, from its uninflammability and many other important properties, afford a splendid material, not only for this particular process but for oil painting. In this latter case, however, it was necessary to saturate it with a mixture of copal varnish and turpentine. The only other point he need mention was that he thought a little to much stress had been laid, not only by Mr. Rivington, but by the improver of the original stereochromic process, on the formation of silicate of lime. Countless experiments had been made on soluble silicates and carbonates of lime, and oxide of zinc even, and a large number of other substances which entered into composition when ground with the pigments, and the general result had been that you did not get silicate of lime, and silicate of magnesia, and silicate of baryta; but a double silicate of potash and lime, of potash and magnesia, or of potash and barium. It was not one silicate uniting with the carbonate to form carbonate of potash and silicate of lime, but the formation of an entirely new substance, consisting of two bases and one acid, the acid being silicic acid, and the bases lime and potash, or whatever other substance was employed. In conclusion, he must add that none of these remarks must be taken as in any way invalidating his opening words of commendation for the very clear exposition of the improvement of the imperfect, but still developable and useful, process originally called stereochromy, which depended on the use of soluble silicate of potash, without which neither process could exist. In both it was the essential element of fixation.

Mr. ARMSTRONG said that when, two years ago, he was at Nuremberg on the public service, he saw in the principal room of the Fine Art Exhibition a frieze of decoration and ornament which had so many charming artistic qualities, that he thought it would serve as a very useful encouragement to the students at South Kensington, and when he returned home he obtained leave to purchase a portion of it. He was sorry that a piece of it was not there that evening, but there were two pieces in the Architectural Court at South Kensington, one on the ground, and the other high up on the wall, in about the same position as the original occupied. He knew nothing at first of the process by which it was produced, but finding it was very interesting, he got permission to invite Herr Schraudolph, the artist, to come to England and illustrate his method before the students. He came over in May or June last, but, unfortunately, owing to various circumstances, the results of his visit were not so great as he had expected. Mr. Rivington had rendered great service by acting as an interpreter. The students saw the process at work, and did little bits of painting here and there, but there was no proper supervision. Herr Schraudolph also executed another piece of work somewhat similar to the one he had mentioned. Last autumn, being anxious to do something in the way of decorative painting—not on account of this particular method, but for other reasons—he selected two of the best students in the ordinary school competition, and set them to carry out a portion of his design on a large scale, one of which was now exhibited being in Keim's process, the other being in distemper. It was the first attempt of the student at this kind of thing, and was, he thought, a very creditable performance. He hoped they would have further opportunities of testing the process, and if there were any artists present who wished to practice a little in it, he should be very glad to afford them facilities for doing so. They had all the materials at South Kensington, and the pump for applying the fixing solution. He could not say much as to the process itself, or as to its permanence, until they had tried it longer. They had all heard of the person who being told that the raven lived a hundred years bought one to try, and they were somewhat in the same position as yet.

Mr. POWELL thought some mention ought to have been made of Professor Barff's process, described in that room in 1872, which consisted in the use of aluminate and silicate of potassium. Mr. Rivington had spoken of the necessity in preparing the ground for this process, to see that there was no damp; but in the majority of churches the walls were very damp, and this had been the cause of a great deal of trouble with regard to mural decoration. He should like to ask what would be the result if this process were applied to a damp wall, as it most likely would be very frequently, if it were adopted to any extent. They heard about silicate of lime and various other silicates, but it seemed to him very doubtful if these were really formed during the process. His own experience of silicates was that the majority of them required very great heat for their formation, and that those which did not were not generally very stable. Another question was whether there would be any danger of efflorescence after a series of years.

The Chairman said everyone who was engaged in building operations must have felt very strongly the want of some means of laying flat colours on wall surfaces in a permanent and durable manner. Great stress had been laid on the importance of properly preparing the ground before the colour was applied, and one of the greatest difficulties which builders had to encounter, was that the groundwork which existed in most London houses was of a remarkably defective character. In some neighbourhoods, built at a time when the so-called stucco was really of a most scandalous character in its formation and manner of application, it would be found that on scraping off the surface, a very rotten sub-structure was revealed; and it was obvious that if the larger proportion of London houses were covered in this way, this process could only be applicable after the complete removal of an enormous surface of bad work. Of late, however, builders who had been called upon by house-owners to replace this rotten surface had done so with a material which was, to a certain extent, hydraulic, and a chemical change had resulted which had perhaps rendered the groundwork suitable for the application of this method. If such were the case, it was quite within the range of hope that an owner might look forward to covering his house with a permanent surface of colour, either in one or several shades, the features of the architecture being tinted various shades according to fancy. In this way our gloomy and dreary streets might be enlivened to an extent and with a success far beyond anything at present achieved by the present method of applying oil colours. When ordinary colouring was applied to stuccoed walls, the result was often very disheartening. The colour was laid on with a mineral or vegetable vehicle, which for a short time resisted the influence of the weather; but in a little while, when you came to rub it, you found a velvety surface, and a large part of the colour came off. Take, for instance, the Wellington-barracks in Birdcage-walk: that building was coloured every seven years, at a cost of £400, but within the second or third year all the bright appearance disappeared, and for the remaining four it reverted to its original gloomy aspect. That was not a very satisfactory way of spending either private or public money, and if any process could be found which, once for all, would produce a colour which would be cheerful to the eyes of passers by, and which could be renovated simply by periodical washing, it would be an immense boon to our street architecture. Not being a chemist, he could not very well follow the reasons given for the indestructibility of the pigments, but there was one practical point apart from the artistic side of the question which all could appreciate, viz., what would be the probable cost, per yard super, of laying a flat colour by this process. Further than that, they would all be be glad to know that there was a plain, simple, specification ready for publication in trade journals, so that an ordinary painter and decorator would be able to apply the process to any building upon which he was engaged.

The Rev. J. Rivington, in reply, said he was very glad to find Professor Church present, as he had been trying for some time in vain to meet him, in order to obtain his services in testing the process. He regretted if he had, consciously or unconsciously, failed to do full justice to the former inventors of the stereochrome process; but he certainly had no wish, nor had Mr. Keim, to claim for the inventor any merit which was due to others; and he had certainly endeavoured to explain the former process and to show wherein it failed. His reason for calling this process new was, because it practically remodelled the system by improving upon every single detail. With regard to damp in walls making its appearance after a few years, when he was in Munich last year, a portion of the king's palace was being done, and some of the walls were being recoated with this process; Mr. Keim then showed him certain places where damp spots in the wall showed themselves. Even if it did not show itself when the wall was laid bare, the dampness would soon discolour the ground before the painting could be commenced, and the proper thing to do was to cut it out and replace the faulty stone. But Mr. Keim had means by which he could apply the process to an incurably damp wall, on which no one in his senses would think of putting a fresco; he did this by a system of glazed tiles. He had not gone into that himself, because it occurred to him that few persons would think of decorating an incurably damp wall. Mr. Keim also told him that he thought he saw his way soon to being able to modify the process, so that it would be entirely unaffected by dampness in the wall itself. What the Chairman had spoken of as so desirable, was exactly what could be done by this process. With regard to the cost of simple house-painting, it was reckoned at about 5s. per square metre; for decorative work, where a greater variety and perhaps more expensive colours were used, from 10s. to 20s., but that included the whole preparation from the bare bricks; everything in fact but the artist's work. With regard to a complete specification and price list, he should be very glad if one could be published, but at present it would be premature. He hoped someone would take the matter up commercially, and prepare the materials in England; at present they all had to be imported, which, of course, added considerably to the expense. If some commercial man could be found who had sufficient faith in the process to take it up, that difficulty would be got over.

The CHAIRMAN then moved a vote of thanks to Mr. Rivington, which was carried unanimously.

Mr. W. G. TREWBY writes:—"Respecting the paper on 'Mural Decoration,' I have always understood that the reason for the decay of the frescoes in the Houses of Parliament was not only the dampness of the surface, but also that the stone was constantly saturated by moisture from the River Thames." He adds that, "by the use of glazed tiles, arranged in the hexagonal form of the bee's cell, a perfectly waterproof back was obtained."

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION.

The following Sub-Committees have met at the Society of Arts since the meetings last recorded:—

TECHNICAL EDUCATION.

Wednesday, February 6th.—Present: Lord Reay, in the chair; Prof. W. Garnett; Mr. J. F. Moss; Mr. Gilbert Redgrave; Mr. H. Trueman Wood.

THE DWELLING HOUSE.—GROUP III.—SUB-COMMITTEE A.

Monday, February 11th.—Present: Capt. Douglas Galton, C.B., F.R.S., in the chair; Sir Frederick Abel, C.B., F.R.S.; Mr. H. H. Collins; Dr. W. H. Corfield; Mr. Baldwin Latham; Mr. Shirley F. Murphy; Mr. E. C. Robins; Mr. H. Saxon Snell; Mr. H. T. Wood.

THE LIBRARY.

Monday, February 11th.—Present: Mr. Ernest Clarke; Dr. W. Ogle; Mr. J. L. Clifford-Smith; Mr. D. Williams; Mr. H. T. Wood.

THE DWELLING HOUSE.—GROUP III. SUB-COMMITTEE C.

Tuesday, February 12th.—Present: Prof. W. G. Adams, F.R.S.; Mr. Arthur T. Atchison; Mr. W. R. E. Coles; Capt. Douglas Galton, C.B., F.R.S.; Prof. T. Hayter Lewis; Mr. W. H. Preece, F.R.S.; Prof. Chandler Roberts, F.R.S.; Mr. C. E. Spagnoletti; Mr. Greville Williams, F.R.S.; Mr. H. T. Wood.

SCHOOL AND EDUCATION.

Tuesday, February 12th.—Present: Lord Reay; B. St. John Ackers; Alfred Bourne, B.A.; J. G. Fitch; J. H. Gladstone, Ph.D., F.R.S.; Rev. T. Graham; Arnold F. Graves; Major-General F. Hammersley; T. E. Heller; T. C. Horsfall; A. C. King, F.S.A.; Lieut.-Col. W. R. Lewis, R.A.; Phllip Magnus; R. J. Mann, M.D.; Inspector-General F. J. Mouat, M.D.; C. R. Robson, F.R.I.B.A., F.S.A.; Rev. T. W. Sharpe, W. H. Stone; W. Woodall, M.P.

Other meetings of the several Committees have been held at the Exhibition Buildings, South Kensington, for the purpose of considering the applications for space.

WATER SUPPLY AND SANITATION OF THE DWELLING HOUSE.—GROUP III. A.

This Committee deal with the following Classes of Group 3—21, 22, 23, and 27, the following being the official classifications:—

Class 21.—Water supply and purification—Meters, filters, water-fittings, cisterns.

Class 22.—House drains, their construction and ventilation — Sewer disconnection; sinks, traps, gullies; the disposal and utilisation of house refuse.

Class 23.—Water and earth closets, ash closets, commodes, urinals, disinfecting powders and fluids, insect destroyers.

Class 27.—Fire prevention apparatus—Extincteurs, portable engines, domestic fire escapes, &c.

With a view of bringing before the public examples not only of thoroughly good sanitary arrangements, but also of the defects existing in ordinary houses, the Committee have, with the sanction of the Executive Council, undertaken to supervise the erection of two model dwellings in the grounds of the Exhibition, one of which will show, as far as can be done on the limited scale, a house with good sanitary arrangements, while the other will show the usual defects. In the latter case, no attempt will be made to exaggrate the ordinary conditions; but the object will be to reproduce accurately a state of things unfortunately but too common.

In erecting and fitting these typical houses, the Committee will have to rely on the assistance of manufacturers; but they wish it most distinctly to be understood that while they must of necessity adopt, for purposes of illustration, fittings made by particular manufacturers, they do not in any case recommend these special fittings for adoption, or wish to give the idea that the special fittings adopted are superior to those produced by other makers. In many cases it is quite certain that there are several appliances, all equally good; but the space at the disposal of the Committee will not permit examples of all these appliances to be shown.

Besides these typical illustrations, the Committee will be glad to receive from manufacturers whatever examples they may think proper to submit for exhibition of the articles indicated by the classification. It is to be borne in mind that in all cases the exhibits must have a distinct bearing on health, and that architecture or building construction generally is outside the scope of the Exhibition.

The exigencies of space will not permit the Executive of the Exhibition to invite contributions illustrative of schemes for drainage, water supply, &c., applicable to towns or large districts, and it is therefore to be understood that the exhibits must be confined to domestic sanitation alone.

The classification sufficiently indicates the class of objects desired for exhibition. The Committee would impress upon exhibitors the desirability of, as far as possible, exhibiting their own manufactures only, not those of other makers; and also of restricting their exhibits to typical examples of their appliances, and of not sending more than a single example of each article. Indeed, the Committee cannot undertake to find space for things which are substantially duplicates of one another.

As the Exhibition will be a place of popular resort, and is intended for the instruction of the general public rather than specialists, it will be desirable that exhibitors of sanitary wares should assist the Committee in making such arrangements as will bring the articles which it is necessary to show before the notice of the public in a manner as agreeable as possible. It will of course be necessary to show examples of closets, urinals, &c., but these should be so arranged that while it may be possible for anybody desiring to inspect their action to have full opportunity of doing so, they yet will not attract general attention in an undesirable manner.

Construction and Fittings of the Dwelling House.—Group III. B.

The portion of Group 3, the Dwelling, with which this Committee deal, is that comprised within Classes 20, 28, 29, 30, and 31. The following are the official classifications:—

Class 20.—Dwellings, models, and designs for the same, and specimens of buildings erected in the grounds. Fittings and accessories for dwelling-houses. Completely fitted apartments.

Class 28.—Materials for sanitary house construction—Roofs, walls, damp courses, solid floors, damp proof wall coverings, cements, &c.

Class 29.—Materials for sanitary house decoration, non-poisonous paints and papers, floor coverings, washable decoration, &c.

Class 30.—Objects for international decoration and use in the dwelling. Fittings and furniture.

Class 31.—Baths, bathing requisites, public and private wash-houses, washing apparatus, detergents, appliances for personal cleanliness, &c.

It should be distinctly understood, with regard to all the above classes, that only such exhibits as have a distinct bearing on health can be admitted. Specimens, therefore, illustrating building construction generally, the decoration of houses, or their furniture, cannot be admitted unless they are shown to have actual reference to the health of the inmates of the houses.

This Committee is co-operating with the Committee on Water Supply and Sanitation, in superintending the erection of two model dwellings in the Exhibition grounds, the one showing good, and the other showing defective sanitary arrangements. Further particulars about these model dwellings will be found in the Memorandum issued by the Sub-Committee above referred to.

It is desired that exhibitors should show, as far as possible, their own manufactures only, and not those of other makers, and they should restrict their exhibits to typical examples of their appliances, not sending more than a single example of each article.

In Class 20, it is desired to show not only models and designs for sanitary houses, but also, as far as possible, specimens showing their construction. It is desirable that those exhibitors who are prepared to erect specimens of actual buildings should, as far as possible, co-operate with other exhibitors who may be desirous of showing fittings or furniture for such buildings. The Executive Council will endeavour to facilitate such arrangements, but it will be desirable that the exhibitors should agree between themselves as to the manner in which such collective exhibits may be arranged.

The classification in Class 28 sufficiently indicates the objects it is desirable to show.

Under Class 29 may be included, in order to draw attention to existing defects, specimens of insanitary decoration, such as arsenical wall papers, hangings, &c., so that the public may be taught what to avoid. Special interest would attach to any evidence of equally good effects being obtained by the use of harmless materials, and in many cases it may be desirable to show, side by side for purposes of comparison, papers, fabrics, &c., treated with poisonous colouring matters, and also with colouring matters of a harmless character.

With regard to Class 30, it may be noted that specimens of furniture would be readily received which can be shown to have any connection with health.

The original arrangement of Class 31 has been somewhat altered. Matters relating to the care of the sick and wounded in war, or of those injured by accident at any time, have been taken out of this class, and a special group has been formed to which they have been referred, namely, Group IIIa. Ambulance. The Class has also been somewhat enlarged in another direction, so that it includes all appliances for personal cleanliness, public and private baths, &c. It is hoped that a full display of these may be forthcoming. The Executive Council have had under consideration the question of fitting up baths for actual use in the Exhibition, as was done in the Berlin Exhibition, but it has been decided that it would be sufficient to show baths completely fitted, without putting them into action.

NOTICES.

CANTOR LECTURES.

The first lecture of the third course of Cantor Lectures was delivered by Mr. Robert W. Edis, F.S.A., on Monday the 18th inst., the subject being the "Building of London Houses." The lecturer dealt with the arrangements, the aspect, design, and general planning of the houses. The lectures will be printed in the *Journal* during the summer recess.

Proceedings of the Society

INDIAN SECTION.

Friday, February 15, 1884; Sir James Caird, K.C.B., in the chair.

The paper read was—

THE STATE MONOPOLY OF RAILWAYS IN INDIA.

By J. M. Maclean.

I propose in this paper to examine the results of the policy pursued by the Government of India, in reserving to itself a right of property, in Indian railways, and the lion's share of authority in their management. Such an inquiry, if impartially conducted, ought to be of general interest at the present moment, when we seem to have gone back to the discussion of first principles, as regards the limits that should be assigned to the respective fields of action of private enterprise and State interference. Owing, no doubt, to the reduction which has taken place of late years in the profits of trade, producers and merchants are now obliged to scrutinise very closely indeed the cost of carriage of their goods to market, and both in England and in India the trading community has come to the conclusion that the railway rates for goods traffic are in many instances excessive, and not to be endured. But by a strange, and yet perhaps natural, contrast, while the cause of complaint is the same in the two countries, the remedies suggested are quite different. In England, on the one hand, where the doctrine of *laissez faire* has hitherto been applied with unbounded faith, and, as it seemed, with conspicuous success in the construction and administration of railways, a strong demand has now sprung up, at all events in some quarters, for the intervention of the State, to compel boards of directors to give to the public those benefits which had been vainly expected from the free competition of rival lines. From India, on the other hand, every mail brings vehement denunciations of the evils that have arisen out of the absence of competition, and urgent appeals that private capitalists may be allowed to step in, and take the place of the Government in supplying such an extension of the railway system as will provide adequate and cheap facilities of communication between the agricultural districts and the seaports. Parliament will probably be asked, in the present Session, to sanction, at one and the same time, an extension of the powers of Railway Commissioners in England, and a relaxation of the restrictions by means of which the Government of India has, till now, kept so tight a hand on the Indian railways. In these circumstances, a political philosopher might console himself with the reflection that there must be a good deal to be said on both sides of the controversy between *laissez faire* and State control. Still, it is well to look into the merits of the case on either side; and I trust that I may do useful service by trying to show both the advantages and the defects of the Indian railway policy. I should warn you beforehand, however, that I cannot pretend to speak with any technical knowledge of the working of railways, although for many years, while resident in Bombay, I took an active part in advocating the construction of new lines, and the modification of the railway tariff to suit the requirements of Indian commerce.

Monopolies have always struck root and flourished in the soil of India. Under the rule of its native princes, the crushing pressure of arbitrary power, exercised either in the form of the creation of distinct imperial monopolies, or in that of vexatious tolls and transit duties collected on all the roads and navigable rivers, was felt in every branch of industry and commerce. The East India Company inherited this fiscal system from the native governments, and did nothing to amend it. Indeed, a fellow feeling must have made the Company, itself the greatest of trading monopolies, be very kindly disposed towards financial advisers who recommended it to raise revenue after the manner of its native predecessors. We are apt to forget that it is only fifty years since the Company was forced to open the trade of the East to private adventurers, and to permit Europeans to hold land in India. Up to the year 1833, the commercial resources of both India and China had been strictly preserved for the exclusive profit of the proprietors of East India stock. A great change has occurred since those days. India is now emphatically a free trade country, free not only through the almost complete removal of duties on its international commerce, but through the abolition of that inland customs line described by Sir John Strachey, who had the honour of destroying it, as "a monstrous system to which it would be almost impossible to find a parallel in any civilised country." This line extended, even after some reduction had been made in it, a distance of more than 1,500 miles, and was guarded by some 8,000 men. If put down in Europe, it would have stretched from London to Constantinople. Along the greater part of its extent it consisted of a huge material barrier, which Mr. Grant Duff, speaking from personal observation, said "could be compared to nothing else in the world except the great wall of China; it consisted principally of an immense impenetrable hedge of thorny trees and bushes, supplemented by stone walls and ditches, across which no human being, or beast of burden, or vehicle could pass without being subjected to detention and search." But, although this abominable obstruction to inland trade has, to the credit of the Government of India, been done away with, the revenue of the State still depends chiefly on three great monopolies, those of the land, of salt, and of opium. I must not be misunderstood as wishing to find fault with these modes of raising money for the service of the State. The incidence of the land-tax is in some districts and seasons oppressive, but still the monopolies in question are equitable in character, and less unpopular than other forms of taxation would be with the natives of India. I only refer to them as illustrations of the much wider scope given to the functions of Government in India than in the countries of the West. Englishmen have not yet discarded their old conviction that the State should not attempt anything which can be equally well done by private individuals; while the Government of India, not content with looking after such matters of business as the working of the Post-office and the Telegraphs, is at once the greatest landlord, and the sole manufacturer of salt and producer of opium, in its wide dominions.

It is not surprising, then, that railways also should, from their first introduction into India, have been included in the list of Government monopolies. No doubt it will be said that this is an inaccurate description of the true state of the case, since most of the railways in India have been constructed by joint-stock companies. Thus, out of the total length of 12,655 miles open on March 31, 1883, the Government had built only 5,037 miles, including 597 miles in native States; and for the balance of 7,618 miles, India was indebted to guaranteed and assisted companies. But the very epithets, "guaranteed" and "assisted," imply the subjection of the private enterprise engaged in these undertakings to the supreme control of the State which gives the guarantee, or lends the assistance. Lord Dalhousie—who in framing, thirty-one years ago, a comprehensive plan of arterial railways for India, displayed a far-reaching grasp of mind worthy of the Governor-General whom Anglo-Indians love to speak of as the "Great Proconsul"—held that it was no part of the business of the Government "to conduct an enterprise which is undertaken mainly for commercial purposes, and which private parties are willing to engage for." In his famous railway minute of 1853 he deplored the lack of private enterprise in India. "One of the greatest drawbacks," he said, "to the advance of this country in material prosperity, has been the total dependence upon the Government in which the community has placed itself, and its apparent utter helplessness to do anything for itself." Hence, he maintained that it was the duty and the interest of the State to encourage the investment of "English capital and English energy" in India, by entrusting the work of supplying her with railways to the associations formed for that purpose. But, at the same time, he considered that the best system for the country would be "a union of private enterprise with State control." Lord Dalhousie had, as Vice-President of the Board of Trade in Sir Robert Peel's administration, been at the head of the Railway Department in England during the railway mania of

1845-46, and, while holding that office, he strenuously endeavoured, until overruled by the House of Commons, to preserve to the State a regulating power over the host of competing schemes that then sprang into existence. Fortified by the experience gained, in the interval between that time and the year 1853, of the evils of unlimited competition in this country, he determined to avoid a repetition of them in India, where at least he could have his own way. To quote his own words:—"The enlistment of private enterprise for the formation of these great works, directly, but not vexatiously, controlled by the Government of the country, acting for the interests of the public, was a principle for which I contended several years ago, when closely connected with that branch of public works. I may venture without arrogance to say that, if that principle had been then more fully recognised, the proprietors of railway property in England, and the suffering public, would have been in a better condition now than they appear to be."

State control, then, vigilant but not vexatious, was the essence of the system to which Lord Dalhousie gave the sanction of his name. The success of the system has been, in many respects, remarkable. It is a great thing, in the first place, to be able to say that the railway capital raised for investment in India has been spent honestly. The check applied by the Government has made jobbery and corruption all but impossible, and India has happily escaped the fate, reserved for so many other eastern countries, of becoming the prey of all the greedy speculators of Europe, eager to develop her resources at a profit to themselves of 50 to 100 per cent. on the nominal capital of their philanthropic projects. No doubt the cost of the guaranteed lines has been heavy, amounting on the average to £16,000 a-mile; but it must be remembered that the English engineers who built these railways had to buy their experience in a land where they were complete strangers, and where the physical obstacles they had to contend against were quite unfamiliar. They had to carry the iron road up lofty ranges of mountains, through pathless jungles, and across water-courses which, almost dry for the greater portion of the year, are swollen into rivers of mighty volume and force during the rainy season. The organisation of native labour, too, on which they had mainly to depend, was necessarily a tedious and expensive process. Then India could produce neither rails, machinery, nor carriages, and every single article of railway material had to be conveyed from England to Bombay or Calcutta, at a time when ocean freights were five or six times as heavy as they now are. When we think of the difficulties they had to overcome, we must acknowledge that the pioneers of railway enterprise in India, many of whom fell victims to their own zeal in labouring steadily on through the unhealthiest seasons, did their work economically as well as efficiently, and some portion of this credit may fairly be assigned to the strict supervision exercised by the Government. The expense of constructing the subsidised lines was increased in another way, by the adoption of a special railway gauge for India, that which is now known as the standard, or 5 feet 6 inches gauge. Lord Dalhousie was determined that India should not be annoyed with that battle of the gauges which had caused so many heartburnings, and wasted so much money in England; and, as all his resolutions were framed in an imperial mould—it might be said of him that "he nothing common did or mean, upon that memorable scene"—he would not take as the uniform gauge for India the narrow 4 feet 8½ inch gauge, which has now been found good enough for all the railways in this country. It was his ambition to build these new roads on a grand scale, and as solidly as the Romans built theirs; and travellers in India must always feel grateful to him for the comfort which this decision has secured to them. There is no better railway travelling to be had anywhere in the world, as I am sure our chairman (Sir James Caird) will admit, than that which is afforded by the guaranteed lines in India. The rolling stock is excellent in quality, although, as is said of the British infantry, there is sometimes not enough of it. The track is thoroughly well laid, and the width of the gauge allows a high rate of speed to be maintained without inconvenience to the passengers. But it must be confessed that a great saving of expenditure might have been effected if the gauge and the patterns of rolling stock had been the same as used in England.

The feeling that slighter and less costly works might have sufficed for a poor country like India was one of the motives that induced Lord Lawrence's Government,* in 1870, to

* Lord Mayo had succeeded Lord Lawrence as Viceroy when the first practical step was taken to give effect to this change of policy; but for the decision to make the change Lord Lawrence's Government must be held responsible. The minute recording this fatal decision was, says Sir John Strachey, "drafted by General Strachey, and accepted by Lord Lawrence without reservation."

resolve upon taking the extension of the Indian railway system into its own hands. The guaranteed lines, at that time, were far from paying their way; and the Government, alarmed at having to make good the yearly deficits, yielded to the plausible suggestion that cheap railways might be constructed, which would serve all the purposes of goods and passenger traffic, and be worked from the outset at a profit to the State. The decision was a most unfortunate one. The weakness of the Government of India is that it consists merely of able officials who have no practical knowledge of mercantile business. Had there been in Lord Lawrence's Council but one representative of the trading class, to support the protests of the military authorities against the introduction of break of gauge on Indian railways, the monstrous error could never have been committed of destroying one of the best features of Lord Dalhousie's scheme. It may safely be stated, as an axiom of railway construction, that the difference in cost of a narrow as compared with a broad guage is as nothing in comparison with the waste of time and money caused by break of gauge on a main line. Yet several Viceroys of India in succession, Lord Lawrence, Lord Mayo, Lord Northbrook, and Lord Lytton, have concurred in permitting General Strachey and his brother, Sir John, to spoil the usefulness of the railway from Bombay to Delhi and Agra, by insisting that this line, which has a 5 ft. 6 in. gauge as far as Ahmedabad, shall only have a 3 ft. 3·3 in. gauge for the rest of the distance. It is difficult to understand why this latter gauge was selected, unless its ingenious patrons conceived the brilliant idea that they would go as far below the ordinary English gauge as Lord Dalhousie had gone above it, and thus, between the two, make a fair average. Now that the mischief is done, there is one universal outcry in India against the metre gauge. No one has a good word to say for it, and the latest joke against it is that in Rajputana, lately, three different trains were required, on three successive days, to move a squadron of cavalry a distance of 240 miles. It would be true economy for the Government of India, even now, to take up the rails from Ahmedabad to Delhi and Agra, and reconstruct the line on the standard gauge. There has been some talk of repeating the blunder of break of gauge on the line from Nagpore to Calcutta, which will shorten by more than 123 miles the distance between the latter city and Bombay; but, as Sir John Strachey, since his retirement from the Indian Civil Service, has come forward as chairman of a company formed to lay down broad gauge lines in the poor native State of Hyderabad, where there is no through traffic, and where cheap railways would have sufficed for the local traffic, it may perhaps be assumed that General Strachey also will no longer raise his voice in the Council of India in defence of the metre gauge.

So much with regard to the construction of Indian railways under the supervision of the State. With the best of motives grave faults have been committed, faults which are absolutely inexcusable, for at a very early period in the history of English railways, Parliament, at the instance of Mr. Cobden, asserted the supreme importance of uniformity of gauge; and, had the autocratic Government of India deigned to take warning by the experience of the greatest of commercial nations, it might now have been in possession of a system of railways of unequalled excellence. But now let us consider what has been done with the railways since they were built. Has the management of this monopoly been of such a kind as to encourage a belief in the gain to be derived from the collective action of the State?

Colonel Stanton, the Director-General of Indian Railways, in his report for the year 1882-83, complacently remarks that "the net receipts for the year were sufficient to yield a dividend of 5·37 on the capital expended on the lines open for traffic." This is a very plausible way of stating the case; and the few members of the House of Commons who dutifully remain to listen to the annual discourse on Indian finance, at the end of the Parliamentary Session, feel quite re-assured as to the results of railway enterprise in India, when they are told on official authority that the net yield exceeds the guaranteed dividend, and is nearly one per cent. larger than the average return on the capital invested in the railways of the United Kingdom. But, when we come to look into this matter more closely, how do we find that the average is made up? Colonel Stanton gives figures to show that, in the year 1882, the East Indian Railway, originally a guaranteed line, but taken over in 1879 by the State, paid 8·56 per cent., and the guaranteed lines 4·94 per cent., while the State lines only earned a revenue of 3·03 per cent. But these figures include the share of the surplus profits on several of the guaranteed lines which was distributed among the shareholders, in addition to the regular interest of 5 per cent. By an arrangement which does not work very fairly for the State, the Government of India is bound by its contracts with the guaranteed companies to secure to the shareholders a payment of 2½ per cent. in each half year. If the net earnings of any line fall below this rate in a particular half year, the Government has to make good the deficit; if, on the other hand, the net earnings exceed the guaranteed rate of interest, the excess is equally divided between the Government and the shareholders. Now, in Western India, the traffic is not spread equally over the whole year. The first six months form the busy season, in which the bulk of the agricultural produce is moved down to the seaport of Bombay. The Bombay railways, therefore, earn in the first six months of the year surplus profits amounting to hundreds of thousands of pounds, of which the Government gets one-half, while in the second six months the net earnings may not suffice to pay the guaranteed dividend, and then the Government bears the whole burden of the loss. Thus, for example, in the year 1882, the Great Indian Peninsula Railway earned £7 11s. 10d. on the share capital; and yet, in the second half of that year, the earnings were only at the rate of £4 5s. 1d. per cent. per annum; so that the Government lost in one half-year a considerable proportion of what it had gained in the other. Thus we have the anomaly that the State may be a loser, even when a guaranteed line yields to the shareholders a return exceeding the stipulated 5 per cent. interest. In fact, during the financial year 1882-83, the net traffic receipts of the guaranteed lines, after deducting the moieties of surplus profits paid to the companies, only amounted to £3,054,500, while the guaranteed interest came to £3,301,180, so that the net loss on these lines to the State for the year was £231,380. In the same year the loss on the State lines was £176,186; and it was only the large gain of £891,150 on the working of the East Indian Railway which compensated for these deficiencies, and left the State a gainer on the whole of £483,584.

But the custom, which Indian financiers find so convenient when they are preparing their annual budgets, of regarding the Indian railways as one great property, and thinking all is well provided they can show a net surplus, leads to results which are by no means advantageous or just to the trade of the country. The inherent weakness of the State monopoly becomes apparent when we find that this system tempts the Government to cover deficits on unprofitable lines by making illegitimate gains out of excessive rates charged on the traffic of productive lines. To illustrate my meaning, let me point out that there are only four of the broad gauge railways, the East Indian, the Eastern Bengal, the Great Indian Peninsula, and the Bombay and Baroda, which have earned surplus profits. None of the others have yet come even within a measurable distance of paying their way, and those of them which have been built of late years by the State, viz., the Punjab Northern and the Indus Valley and Kandahar, are unlikely for many a year to come to yield a fair return on capital. The metre gauge lines, having been constructed much more cheaply, ought to show more uniformly good results; but here, again, the profitable working of the Rajputana, the Northern Bengal, and the Rangoon lines compensates for the shortcomings of the rest. (See Table, p. 266.)

These inequalities naturally suggest a suspicion that what may be called the commercial lines are forced to bear not only their own expenses, but also a large proportion of the cost of working the lines constructed mainly for political and military purposes. This mode of converting the Indian railways into a directly profitable pecuniary speculation for the State cannot but be unfair and injurious to the commerce and industry of India. Each railway ought to be treated as a separate undertaking. The East Indian and the Great Indian Peninsula should no more be required to yield a constantly increasing revenue, in order to make good the losses on the Punjab Northern and the Indus Valley lines, than the North-Western in this country should be expected to supply any deficiency in the returns of railways in Sutherlandshire or Galway. India is, first of all, a military empire, and a number of railways, which commercial men would have fought shy of, have necessarily been laid down to facilitate the transport of troops and warlike material within the country, and the strategical operations required for the defence of the inland frontier. Lord Dalhousie had the courage to foresee that perhaps none of the railways, the construction of which he recommended, might prove clearly remunerative; but for all that, he urged, the Government ought not to shrink from making them. Even, he said, "if the Honourable East India Company should be called upon to make good yearly a considerable portion of the interest it has guaranteed, the direct advantage it will derive from railways, in the reduction of military force which they will render

practicable, and the many other direct and indirect benefits which will accrue to it politically, commercially, and socially, from their existence, will render the payment of guaranteed interest a burden which the Honourable Company may cheerfully and contentedly bear; more especially when it calls to mind the peculiar relation "—that is to say, no doubt, the relation of a landlord to his tenants—"in which it stands to the people over whom it has been set to rule." It is unnecessary to remark that the indirect advantages the Indian Government has derived from railways have more than borne out these sanguine anticipations. This is now confessed on all hands. It is, then, a matter for profound regret that that Government has, nevertheless, taken a purely mercenary view of its connection with the railway system, and chosen to make the passengers and carriers of goods on the East Indian, the Great Indian Peninsula, and the Bombay and Baroda lines, pay for the unremunerative character of the traffic on military and administrative lines, the loss on which ought to fall upon the general taxpayer, in whose interest they were undertaken. With regard to the East India Railway, which has, for a good many years now, paid from 8 to 10 per cent., Sir John Strachey estimates that its purchase by the Government will, at the end of seventy years, bring in to the State a clear income of £2,500,000 sterling, and probably much more. This, of course, is on the supposition that its sole command of the Ganges Valley traffic will never be interfered with, and that its present tariff can be maintained. Nor, perhaps, is there wanting a special reason why the Government should consider itself entitled to make money out of this line, which runs through the districts where the State has deprived itself, by the permanent settlement, of its share in that increase of agricultural wealth which springs from improved communications. But this excuse does not apply in the case of the railways running from Bombay into the interior, which help to bring waste lands into cultivation, and to raise the rent of land already cultivated, throughout vast tracts of country where the State has not parted with the ownership of the soil.

Yet the rates for the carriage of merchandise on these lines are so high, that the Bombay Chamber of Commerce is engaged for the greater part of every year in a constant warfare with the Government and the Railway Companies, to secure a reduction in them. The Rajputana line, which is an extension under State management of the Bombay and Baroda, brought in a revenue of 5·87, in 1882, on capital borrowed by the Government at 4 per cent. In the same year the Bombay and Baroda itself paid the Government 5·91, or an excess of nearly 1 per cent. above the guaranteed interest. The Great Indian Peninsula yielded 7·29, or the full amount of the guaranteed interest, with a bonus of 2·29 per cent. These figures, too, as I have shown, do not represent the whole income of the guaranteed lines, as the shareholders in the Companies make a considerably larger per-centage of profit. Thus, in the first half of 1883, the Great Indian Peninsula paid to its proprietors £3 17s. 4d. per cent., and to the State £1 7s. 4d., the total net earnings thus amounting to £5 4s. 8d., or at the rate of very nearly 11 per cent. per annum. What great English railway is there whose shareholders would not rub their hands with joy at the prospect of receiving such a dividend?

But what makes the position of the Indian shareholders so much the more enviable is, that they are absolutely guaranteed against any risk of loss on their investments. A high rate of dividend one year is not counterbalanced by a low rate in the next. Whatever happens, the investor in Indian railways can never get less than 5 per cent. for his money, this being the rate secured to him by a Government whose credit stands as high as that of any of the Continental Powers of Europe. Now where, except in India, is it possible for a capitalist in these days to get an absolutely certain 5 per cent. for his money, with a fair chance of receiving, in addition, a bonus that doubles the interest?

Is it right that the Government of India should help its fellow-shareholders in the guaranteed lines to make these extravagant profits? Ought it to enable them to combine two things so rarely found in union with one another as excellent security and a very high rate of interest? It is idle to say that the charges on these lines are already very low. Even if that were the case, we all know that India is an exceedingly poor country, and that rates which, judged by our English standard, might seem reasonable enough, may be oppressive where the labourer's wages are only sixpence a day, and where the native merchandise carried by the railways consists almost entirely of bulky and cheap agricultural produce. Experience has recently shown, on the East Indian Railway, that a reduction in the fare for third-class passengers from 3 to $2\frac{1}{2}$ pies (*i.e.*, from $\frac{3}{8}$d. to $\frac{5}{16}$d.) a mile has caused an increase in one year of a million third-class passengers. Similarly, on the Bombay and Baroda Railway, a slight reduction in the rate for wheat had the remarkable effect last year of quadrupling the quantity carried on that line. We may reasonably, then, accept it as a maxim that low rates in India are invariably followed by increase of traffic.

But really low rates for goods traffic in India are out of the question, so long as the Government counts upon the large profits derived from this source to maintain the equilibrium of its finances. The Bombay Chamber of Commerce, in a letter commenting upon a most valuable pamphlet, "Indian Wheat *versus* American Protection," published at Calcutta last year, concurs with the writer of that pamphlet in the opinion that "Government should consistently reserve to itself the right of fixing absolutely the rates on all lines for the carriage of staple goods." But the Government practically possesses this power already; what is required, is the willingness to exercise it. In the contracts with the guaranteed companies, the right is reserved to the State of fixing the maxima of all rates and fares. Yet, after formally and ostentatiously declaring that its policy was to keep railway rates at a minimum, in order to encourage the development of the export trade in wheat, the Government "fixed as the maximum rate for food grain 12 pies (1½d.) per ton per mile, which," the Bombay Chamber of Commerce, in its letter of July 9, 1883, says, "is nearly double the general rates charged by the Great Indian Peninsula Railway, high as those rates are in comparison with those adopted on other routes. The Chamber, in September, 1881, protested against this maximum rate as being unnecessarily and excessively high, and represented that it should be reduced; but the Government of Bombay declined to interfere with the discretionary power vested in the Board of Directors, with the approval of the Government of India and the Secretary of State." This is an admirable example of the illusory nature of the check supposed to be applied by the action of the State to the money-making instincts of the ordinary shareholders in the railway companies. Whenever the commercial community has any complaints to make regarding the management of the railways, the companies' agents in India, the local Governments, the Government of India, the Boards of Directors in London, and the Secretary of State, straightway begin to play an elaborate and interminable game of battledore and shuttlecock with the public interests. Any suggestion that is offered is minuted upon, referred, transferred, and generally knocked about, till the authors of it are ready to abandon it in despair. The truth is, the State, which ought to be an independent judge in disputes between the railway companies and the public, is itself an interested party in such cases. When called upon to interfere, it is always, perhaps unconsciously, influenced by the thought that, if it sanctions increase of expenditure or reduction of rates, it may diminish its share of surplus profits.

Hence the unwise parsimony which leaves main lines insufficiently supplied with rolling stock to meet any sudden expansion of traffic. The American Civil War began, lasted over four years, and was brought to a close, long before the Great Indian Peninsula Railway had obtained an adequate number of engines and waggons to carry down to Bombay the cotton which choked all its stations. In like manner, since the export trade in Indian wheat began to assume large dimensions, merchants have been crying out in vain to the directors of the same railway to put more engines on the line, so that it might not remain blocked with bags of wheat. The directors gravely reply that they have been trying since 1881 to induce the Government to let them have more engines made; and at the half-yearly meeting in December, 1883, the chairman said, with a simplicity which is really laughable, that he was "happy to be able to state that the Government of India has, during the present year, sanctioned an addition of 100 engines to the stock of the company." These engines may be placed on the line in India perhaps by the end of 1885, so that it will have taken the most important commercial railway in India five years to procure the additional rolling stock declared by the directors to be absolutely necessary for the proper working of the line. The reluctance of the Government to sanction the application for more engines may easily be understood, when the chairman of the company tells us that "their cost, and that of shedding, workshops, and so forth, will require fully half a million of capital." It is this expenditure of fresh capital, which means a reduction of profits, that the Government grudges. Take, as another instance of this miserliness, the delay in making new sidings, or doubling the line, in the grain-producing districts. When the charge is urged that the railway is checking the development of the trade by its high rates, the ready answer is offered that this cannot be the case, as more grain is brought to the stations than can be conveyed to the coast. Of course, the true explanation of this state of things is that the single line is no longer equal to the increasing strain of the traffic, and that the Government and the railway company, secure in their monopoly, refuse to lay out any more capital.

Now there has been a good deal of discussion lately as to whether the rates of freight for grain and seeds in India can be reduced with advantage. The author of the Calcutta pamphlet estimates that, "taking the average distance from the seaboard of the principal centres of the wheat trade in India, Indian wheat is, through the indifference shown to the whole subject, unnecessarily weighted in the competition with America to the extent of more than 3s. a quarter." He also fixes upon the Government the direct responsibility for this unfair handicapping of the Indian wheat trade, by showing that the State is bound down in its recent contract with the Southern Mahratta Railway "to sanction a rate of 1·05 shillings per quarter each 100 miles, or double the American rate; and in the contract with the Eastern Bengal Railway a rate of 1·47, or actually more than three times the present American rates." The directors of the Great Indian Peninsula

Railway have made a desperate but vain attempt to prove that their rates are reasonable enough, as they allow wheat from Jubbulpore (616 miles from Bombay) to be laid down in London at 38s. 9d. a quarter. But the Bombay Chamber of Commerce has exposed the inaccuracy of this estimate, by pointing out that it does not include a number of mercantile charges which swell the total cost to 44s. 10·61d. in London.* The market price for Indian wheat in the London market has recently fallen as low as 32s. 6d.; but we may assume that this is an exceptional rate, and that an average rate of 44s. to 45s. may be counted upon. But Mr. Finlay Dun, in his book on "American Farming and Food," calculates than American wheat can be sold in Great Britain, with profit to growers, railway carriers, shippers, aud all concerned, at the moderate cost of 42s. per quarter, or 3s. a quarter below the present minimum cost of Indian wheat. India cannot, therefore, compete profitably with America till the cost price in London of Indian wheat is considerably reduced. How can this reduction be effected? The grower of Indian wheat does not make a very large margin of profit. The Chief Commissioner of the Central Provinces says that the cost of growing a quarter of wheat comes to 11s. 8d. The cost of cartage to the nearest railway station is about 3s.; so that, as the average price per quarter in the Jubbulpore railway market is 20s., the margin of profit left to the farmer is only 5s. 4d. a quarter, which, as the Chief Commissioner remarks, "does not seem very extravagant, especially when, as is often the case, it is divided between two traders." Indeed, the narrowness of the margin of profit is clearly proved by the fact that "wheat is at present only grown on the most productive soils." It is possible that a number of the petty charges for packing, cleaning, weighing, and so forth, might be done away with, if the Railway Company had the enterprise to introduce the labour-saving appliances employed in the United States; but everyone engaged in the Indian trade knows that the merchant now works at a very small per-centage of profit, and that no saving in this direction can be looked for. Ocean freights, again, which are taken in the Bombay Chamber's estimate at 35s. a ton, or 9s. 9d. a quarter, have now been driven down to so low a level as to be actually unprofitable. The distance between London and Bombay is twice that from New York to Liverpool, yet the ocean freight for American wheat is from 5s. to 6s. a quarter, as against 9s. 9d, from India, and there are no Suez Canal dues to be paid out of this amount. No further saving, therefore, can be made on the sea voyage. There remains only the supposition that the railway charges must be excessively heavy, and the fairness of this conclusion is borne out by the large profits earned by the Great Indian Penin-

sula Railway, mainly out of the transport of grain.* When a railway company, which has a dividend of 5 per cent. guaranteed, actually earns from 10 to 11 per cent., we may be sure that it does not act equitably towards its customers. The Government of India must be considered as part of the railway company, since it participates in the surplus profits; and I charge the Government, therefore, with deliberately hampering the Indian wheat trade in order to produce the impression that its railway system, as a whole, is remunerative. Whatever is charged on the carriage of wheat in excess of a fair profit is virtually a toll or transit duty levied by the Government on the export trade; so that, as a partner in the railway companies, the Government is now raising up again an inland barrier to the development of the commerce of India, as objectionable as that which it prides itself on having abolished when it cleared away the old inland customs line.

I cannot agree with the Bombay Chamber of Commerce, and the Calcutta pamphleteer, in thinking that the remedy for this state of thing is to be found in the reservation by the Government of the right of fixing absolutely the rates for the carriage of agricultural produce. I have given you sufficient reasons for believing that the Government cannot be trusted in the matter. An outside check must be applied, and it can only be applied by the English Parliament, which has no other interest than to remove obstacles to the free importation of Indian wheat into this country. What that check should be seems to me plain enough. The limits of the dividends to be paid by the guaranteed companies ought to be absolutely fixed. As the dividends cannot fall below the minimum of 5 per cent., so they ought not to be allowed to rise above the maximum of, say, 7 per cent. When larger profits are earned than would suffice to pay this maximum rate, the principle should be acted upon which has been successfully asserted in the negotiations between the English shipping interest and the Suez Canal Company, that the customers of a monopoly have a right to share in the gains earned at their expense; and the surplus profits, instead of being distributed between the Government and the shareholders, should be employed in reducing rates and effecting such an enlargement of carrying capacity as will, at all events, remove the scandal that, in districts served by railways earning 10 per cent., "existing means of communication" are declared on high authority to be "insufficient to carry away the annual surplus" of grain available for exportation.

* The Railway Company has reduced its rates from Nagpore and Jubbulpore to Bombay, from Nov. 1, 1883, by about 1s. a quarter, but this is a tardy and insufficient concession.

This paper would be incomplete if I failed to refer to the mischievous effect of the State monopoly in preventing the extension of Indian railways. For many years past no room has been left for doubt as to the immense advantages which India derives from the existing railway system; and everyone interested in the country has earnestly advocated the immediate construction of new lines. Sir James Caird, in his new book, "India, the Land and the People," expresses the general opinion of thoughtful men who have studied the problem of increasing the production of food in India, so as to cope with the steady growth of population, when he says:—"The greatest help that can be given towards this object is, the early construction of railways in all the richer and more populous parts of the country which are still without them. In the next ten years the present mileage of railways in India should be at least doubled, and even then India would not have 1-40th of the mileage, compared with the population and area under crop, which is at present possessed by the United States." Yet, while America goes on building new lines at the rate of 5,000 or 6,000 miles a year, the Indian Government contentedly crawls along with its miserable increase of 300 or 400 miles in the same period. It is not the want of money that makes the rate of progress in India so slow. The sum of £2,500,000 is available out of the annual revenue for the construction of new railways; but the Indian Government, instead of setting this amount aside for the payment of interest at 4 per cent. on a capital of £60,000,000—which it might borrow at once, and which would suffice for the construction of 8,000 to 10,000 miles of railway within the next five years—has the economical pedantry to insist on spending its 2½ millions year by year as principal, and thus renders itself incapable of making progress, except by driblets. The English people ought not to be misled by accounts which appear in the newspapers from time to time of fresh surveys for thousands of miles of railway, which have been completed by the officers of the Government of India. Enough money has been spent in Indian surveys to pay for constructing a line all the way from Constantinople to Calcutta. It is work done, not work promised to be done, which alone can be taken into account.

What, then, are you to think of a Government which sanctioned, eleven years ago, the extension of the Bombay-Nagpore line as far as Calcutta, but is still discussing what the gauge for this line should be, although in the districts through which it would pass the crops rot on the ground for want of carriage when there is a good harvest, and the unhappy peasant proprietor actually dreads having a bumper crop, because there is no market in which he can sell his grain? Do I misjudge the Government in suggesting that it really dislikes the idea of any railway extension which may lessen the profits of the East Indian and Great Indian Peninsula Railways, with which the Nagpore-Calcutta line would come into competition? If you look at the map of India, you will see that the Great Indian Peninsula Railway is at present the most prodigious monopoly in existence. From Delhi and Agra on the north, far away to the southern limit of the Hyderabad State, over an expanse of country as large as Germany and France put together, the Great Indian Peninsula Railway, with its subsidiary groups of lines in Central India and the Deccan, affords the only outlet for all the agricultural produce seeking exportation; and every bag of grain or seeds must be brought down by it to the only shipping port on the western coast of India—Bombay. So jealously has the Government guarded the interests of this monopoly, that the Bombay and Baroda Railway Company has been strictly forbidden to penetrate the interior of India with a competing line up the Nerbudda Valley to Indore, or from beyond Baroda to Rutlam and Gwalior, and has been forced to creep away round the western face of the Aravalli range of hills to the far north-west. Even this opening into the grain-producing provinces of Upper India has been barred by break of gauge, and by the high rates imposed upon the Rajputana State Railway, in order to bring in profits in excess of a fair interest on capital. It must be remembered, too, that the public is absolutely powerless to break down a railway monopoly. The sea is always open to competition, and a subsidised line of packets cannot make unfair profits. But a railway protected by the State crushes every form of competition. It is, therefore, essential that the Government of India should be coerced into sanctioning the construction of new lines, which will afford the producer a choice of means of sending his crops down to the seaboard, either on the east or west coast of India. I rejoice at the prospect of a decision being come to on this subject during the present session by a Committee of the House of Commons.

The question of railway extension is an urgent one, not for India only, but for England. Sir Evelyn Baring, the late Financial Minister of India, said, a year ago:—"It is to be observed that during the last two years the railway policy of the Government of India has been unsettled. I do not think that is a matter for surprise or regret." He then went on to explain that the Government had been accumulating experience as to the expediency of constructing railways through the agency of unaided private enterprise, and he added that he and his colleagues were prepared to "lay down a definite policy for the immediate future, say for five years." Nothing more has yet been heard of that policy; nothing will be heard of it, unless Parliament interferes, and takes the matter into its own hands. I cannot share the complacency with which Sir E. Baring regards the waste of a few years. There never was a time when railways could be constructed more cheaply than now, or when English capitalists were more favourably disposed towards investments in Indian lines. If some projects of working through the agency of private enterprise have miscarried, the explanation must be sought in the mystery that enfolds the dealings of the Government of of India. The public naturally looks askance on concessions granted secretly to financiers, however influential, or to retired Government officials, however distinguished. Private enterprise can only thrive on publicity and fair play. Let all the railway projects contemplated by the Government of India be frankly made known far and wide, and the terms on which capital may be invested in them, and there will be plenty of money forthcoming. The Government may very well raise the capital and do the work itself, if only Parliament once lay down certain principles for the protection of trade against the caprice or greed of officialism. But, above all, there should be no delay. The Government must abandon its dog-in-the-manger policy, and either do what is wanted itself, or let it be done by others. It would be superfluous for me to dwell on the supreme importance to English industries of a cheap supply of wheat from a country which is the best customer England has for her own manufactures, and which can make her quite independent of America. But the necessity for relying almost entirely on the Indian wheat supply may arise at any moment, as suddenly as the necessity arose in 1861 for looking to India alone for the cotton required to keep the mills going in Lancashire. The capacity of India to export grain is now recognised as practically unlimited. Her total production is estimated at 40,000,000 quarters, three-fourths of which is, except in years of famine, available for export, as not much wheat is eaten in India; and the United Kingdom only imports 11,000,000 quarters a year. All the conditions of an abundant and cheap supply—a most fertile soil, a most docile, industrious, and frugal population, a swarm of steamers at the seaports eagerly competing for cargoes of grain—are present in the Indian trade, with the exception of proper facilities of railway communication and low rates of land carriage. Nothing is wanted, therefore, on our part to emancipate ourselves from dependence on the United States for the bread we eat, but to infuse into the administration of Indian railways more courage and energy than the Government of India has hitherto shown itself possessed of, and a feeling of keener sympathy with that spirit of free enterprise which has raised Great Britain to such a height of material prosperity.

DISCUSSION.

Mr. J. T. Wood had listened with great attention to the very able paper which had been read, but he thought it hardly dealt sufficiently with the extent to which railways might be made, or would be made by private enterprise if that enterprise were unfettered, except as regards general regulations, such as were laid down in the Companies Clauses Act, from State interference. The question of exercising State control by general regulations was, about fifteen years ago, considered by different companies, and a draft was prepared, but, somehow or other, the matter was shelved, and nothing more was heard about it until a few months ago, when a paper upon the subject was read at the East India Association. In February, 1877, he made some remarks in that room, which would be found in the Society's *Journal*, which were not quite in accordance with what had fallen from the reader of the paper that evening. What Mr. Maclean had called the "money making instincts," had prompted him (Mr. Wood) to make some further remarks. He hoped the Parliamentary Committee would inquire if the guaranteed companies had met with any unfair or "vexatious" treatment—if he might use such words without disrespect—or whether their legitimate interests had been prejudicially affected by the State control. He thought the reader of the paper was somewhat inaccurate in describing the exact state of the railway contracts, for it must be borne in mind that the guaranteed companies had certain rights secured to them by contracts which, at the time the contracts were made, were considered fair and equitable by the contracting parties and by the community in India. The maximum fares, with some tentative exceptions, were fixed in India (pretty much the same as fares were fixed in England) before the lines were opened; and the interpretation put upon the contract was this, that those maximum fares could not be altered by the Government without the consent of the companies, until such time as the shareholders were receiving 10 per cent. But it was by no means clear that, if in any half-year the working expenses on a railway exceeded the earnings, the shareholders would get the whole of the 5 per cent. guaranteed. On several occasions, owing to accidental floods and the like, it had happened that the legitimate working expenses had exceeded the earnings, but it had always been so arranged as to spread that expenditure over several years. He recollected a despatch from the Secretary of State to the effect that it was the wish and intention of the Government that railway companies should earn a full dividend of 10 per cent., but there was hardly a single case in which that dividend had been earned by the shareholders. Mr. Maclean did not tell them what rate of interest on their own business capital would satisfy the people in Bombay. Mos people would agree that 10 per cent. was not an exorbitant rate. To go a step farther, the question was whether the profit made on the carriage of wheat was or was not excessive. Was the rate received for wheat sufficient to pay the proper proportion of the working expenses, and the proper proportion of the 5 per cent. dividend. In the case of the Great Indian Peninsula Railway, which was an exceptional railway, inasmuch as it had very steep gradients, and consequently the working expenses were very heavy, it would be found that where the ordinary net profits amounted to 50 per cent. of the gross receipts, in the case of wheat it would barely exceed 15 or 20 per per cent. Then they came to a very important question, namely, whether the good railways should be made to pay for the bad, and whether any payment in excess of the ordinary mercantile profit was, or was not, attached to the trade of the country. As far as the guaranteed companies went, the good railways could hardly be said to pay for the bad, but as regards the State railways, they might be looked upon as all belonging to the same great proprietor, and therefore, might be amalgamated as far as regards carrying his produce to market. The most lucrative of Indian railways was the East Indian, and the profit made by that railway last year was 16½ per cent. on the nominal share capital; of that sum £6 10s. went to the shareholders, and £10 to the Government. It was a matter well worthy of consideration whether the allegation that the £10 was a repayment to the Government of a loan made in respect of the deficits of the guaranteed interest, or whether the Government advances represented taxation on the fathers of the present generation. He thought the advances were paid by taxation of the country, and, therefore, he agreed with Mr. Maclean that the 10 per cent. was simply, under the guise of a tax upon the trade of the country, taxing the children for the special reason that you had taxed their fathers, and that both were able to pay it. It could never have been contemplated by Lord Dalhousie that the profits should exceed 10 per cent., and it would be unfair to reduce the profit of £6 10s. payable to the shareholders of the East Indian upon the nominal capital, which, to say the least, was more than 8 per cent. upon the original capital; but at the same time it would be desirable to reduce this tax on trade, and the only thing that could be done would be by reducing the already low rates which existed in the company by re-adjusting the proportion of the net earnings payable to the Government. The East Indian Railway was exceptionally favoured by easy gradients and facilities for traffic, and was able consequently to carry goods at a very low rate, but the rates were still fnrther capable of being reduced. India, as regards the import of wheat into England, was a favoured country, but it must be borne in mind that the Australian colonies and the Dominion of Canada, and also the interests of British agriculturists, had to be considered.

Mr. E. Kimber said he should fancy, from the way in which the remarks of the last speaker had been received, that there were many present in favour of the sumptuary law which, at some time or other, prevented ladies from wearing jewellery. What was the proposal which had been placed before them that evening by Mr. Maclean? He boldly proposed that the interest should be cut down to 7 per cent., that Parliament should enact that no profits should be made beyond a certain sum, and that the persons who had invested money in different undertakings should be cut short of all which the original contract provided. He would ask, in the first instance, was that fair, and in the second place, could it be done? The contract originally made was for the very purpose of inviting capital for the construction of railways, that the persons providing the capital should be guaranteed by the State 5 per cent., and that they should have half of the profits made by the concern after 5 per cent. was earned, and that if there was a deficit, the Government should find the difference. That was the original contract; could they upon any principle of justice or fair play depart from such a contract? If they could, then some fine new principles were coming in; and he did not hesitate to say that if those principles were received, the time would come when they would have a sumptuary law in this country. His second point was, could it be done? The persons who had invested their money had done so upon certain conditions, but it was now proposed absolutely and violently to abrogate those principles. That could not be done without returning the money which had been subscribed. Upon the commercial part of the question as to whether 10 or 11 per cent. was an extraordinary profit, it must not be forgotten that persons invested their money upon the construction of railways in India at a time when, according to Mr. Maclean, India was one mass of jungle, impenetrable morass, mountains and rivers, and, therefore, the undertakings required a little patting on the back by the Government. Was that principle of legislation to be cast to the wind? In his opinion, it was just legislation. It was the same principle upon which they proceeded now with regard to the encouragement of public works by local authorities. The important question which had been raised by Mr. Maclean was as to what Parliament should do, and no doubt the discussion that evening would have some influence on the House of Commons. Under no conditions whatever could Parliament be recommended to abrogate the obligations and provisions which they laid down when the present shareholders invested their money. The only true remedy for the evils complained of were those indicated by Mr. Maclean at the outset of the paper, though apparently ignored by him before he reached the end, and that was the encouragement of private enterprise by the means of competition. He hoped some conditions would be laid down by the Committee of the House, whereby private enterprise would be encouraged, and competition encouraged, so that the rates might be brought down.

Mr. Matthew said he most fully concurred in the concluding observations of the last speaker, but regretted that he could not agree with all his observations. What India wanted was a large extension of railways. The shareholders in the old guaranteed companies had benefited very largely by the control of the State in their operations. No doubt the important question was the minimum rate to be charged, for it was plain that they had not yet arrived at that low charge which was the profitable charge. The ships now running between Chicago and London had a greater carrying capacity than formerly, and consequently were enabled to carry at a lower rate, and it was well known that it paid better to run a train heavily loaded at a low price, than a half-empty one at a high price. In India, the passenger rates had been considerably reduced, with considerable profit to the company; and a further reduction would, in his opinion, be very beneficial to all concerned. The extension of railways would be a great benefit to the Empire, and profit to the State.

Mr. Martin Wood agreed that there never was a time when railways could be constructed more cheaply than the present, and that there should be no delay in making railways in India; also that in all matters connected with public works one of the great conditions required was early and prompt publicity, in order that the proposals might be examined by all parties concerned. With regard to what Mr. Maclean had stated as an axiom, that nothing could compensate for a break of gauge on a main line, he would ask them to take that as mere assertion. It was a question of comparative cost and relative distance, one which assumed entirely different proportions in a vast country like India, as compared with this small island. Break of gauge was a mere incident in the movement for reform in railways, which was instituted by Lord Lawrence, and had been followed by four successive Viceroys. Surely it might be supposed that these eminent men, and especially Lord Mayo, had very substantial grounds for promoting the more economical railway system, which had been disparaged in the paper before them. The cheaper method of railway construction had been supported by each Secretary of State for India, and by their responsible and experienced advisers. As to the abuses under the lavish system of the 5 per cent. guarantees, of which Mr. Maclean had spoken, these were all recognised in Lord Lawrence's minutes of 1868-9, and there could be no thought of returning to that plan; but without some definite though moderate guarantee English investors would not supply capital for Indian railways. There were two points arising out of the subject of the paper, but not mentioned in it, to which he wished briefly to refer. First, while it is good for England to draw large supplies of wheat from India, it might be more to the advantage of India itself to grow less bulky and more valuable products. Then, as this is a question of inland communications, it must be remembered that railways would not suffice to carry the bulky produce of India cheaply enough; but water would both increase the growth of produce and could convey that produce at low rates to the coast.

Mr. SETON KARR said, he might, perhaps, be permitted to correct one error which he noticed in the paper. Mr. Maclean had stated, "the feeling that slighter and less costly works might have sufficed for a poor country like India was one of the motives that induced Lord Lawrence's Government, in 1870, to resolve upon taking the extension of the Indian railway system into its own hands." Lord Lawrence was not in India in 1870. He left in 1869, and was succeeded by Lord Mayo. He entirely concurred in what had been said upon the subject of the break of gauge. Having been for many years a shareholder in the Great Indian Peninsula, he could contradict the statement that that company had paid dividends of 10 and 11 per cent.; it had never been his good fortune to have a share of more than 7 per cent. He concurred with what had been said as to the propriety of opening up railways to public competition, though he knew there would be great difficulties in finding persons, either English or native, to construct a railway without some guarantee from the State, because estimates for the construction of railways in India generally proved rather fallacious. When Lord Hardinge wrote his first minute very many years ago, about the construction of railways, he calculated that railways could be made for £5,000 a mile, but, as everyone knew, they had cost £10,000, and in some cases as much as £16,000.

Mr. MATTHEW remarked that he had built some hundreds of miles of railway in India, and in no single instance had he ever exceeded the estimate.

Mr. ANDREW CASSELS entirely agreed with Mr. Maclean as to the desirability of constructing more railways in India, and that there should be one uniform gauge. He had heard many hard words uttered about the stinginess of the Government in India in not spending money on railways, but he thought a good deal of that blame should be transferred to the shoulders of Parliament, because when the limit of 2½ millions was fixed for public works, that was done upon the recommendation of a committee of the House of Commons. Now that the question was once more to be considered by a committee, he hoped that they would see fit to relax that arrangement in some degree. He had heard of the most magnificent projects for spending £10,000,000 a year upon railways in India, and comparisons made between what was done in America; but it must not be forgotten that in India the lines were constructed by the Government, and that in America they were constructed by private enterprise. If the Indian Government was to be called upon to construct these railways at the rate so glibly proposed, he must ask seriously where was the money required to come from?

Mr. PEDDER said Mr. Maclean had spoken of the Government monopoly in India being opposed to the extension of railways, and that it was time for Government to construct railways themselves, or to permit private persons to do so; but he might say with some confidence, though he was not in the secrets of the Public Works Department, that if any company or individual would come forward and offer to make railways in India without State aid, the Secretary of State would hail the proposal with the greatest delight, and perhaps go so far as to give them the land for the purpose. But the fact was that no company would come forward and propose to make a railway without first asking for a guarantee, and of course if a guarantee were asked for, it was not unreasonable that the Government should retain in its hands some check upon the action of the company, and the way in which it dealt with public money. The real difficulty of constructing railways in India arose from the fact that the British public would not subscribe money for the purpose without having a guarantee.

Sir GEORGE CAMPBELL, M.P., said that Mr. Maclean had been somewhat hard upon the Government of India in his criticisms, but had not suggested a remedy for the evil. If there was one thing worse than a public monopoly, it was a private monopoly; and in England where they had private monopolies, they were beginning to rebel against them, and to think that they should be brought under the control of the State. In the case of private companies constructing works in India, they proceeded upon the principle of "Heads I win, tails you lose;" if they found the enterprise was profitable, they wished to stretch to the utmost their profits; but, on the other hand, if they found they had made a bad bargain, they immediately turned round to the Government, and cried for recompense. He was afraid that they had not yet arrived at a solution of the difficulty which presented itself. With regard to the observation about the miserliness of the Committee of the House of Commons in not providing more than two and a-half millions for public works in India, he might say that that sum was practically decided upon in the India-office rather than in Committee.

Mr. ANDREW CASSELS pointed out, he believed, that the proposal to spend two and a-half millions a-year originated with Lord Northbrook, who said that India could not raise more than two and a-half millions a-year, but the Committee in Parliament had sanctioned it.

Mr. CONNELL wished to point out the great difference which existed between railways in India and America. When capital was raised in India for railways it could not be got rid of, but in America a great deal of the capital was dropped, and rates were fixed upon without any reference to the capital so dropped. In the next place American railways recouped themselves, to a great extent, by the sale of land plots upon the side of the railway, which in India could not be done. Mr. Maclean had compared India with America in the production of wheat, but he might point out that India, with its teeming population, required the greater part of the produce of the country, whereas America did not. Having lately worked out the figures on this question, he found that, on many points, Mr. Maclean was not quite accurate, and that there was not the surplus of wheat in India which Mr. Maclean supposed. If more railways were constructed and did not pay, the Government would have to bear the burden, or rather the taxpayers would, and these people were not able to afford it. Comparing India with America was like drawing an analogy between the moon and the earth.

Captain MOLESWORTH thought the object of the reader of the paper was to make India the market of this country for corn, and that railways might be constructed so that wheat might be brought down to the coast at a price which would enable it to be sold in this country at a profit. One reason why the railways should be constructed was, because money could be obtained now at a cheap rate; and in the next place, because materials were now cheap. It had been asked, where was the money to come from for the construction of these railways, but there ought to be no difficulty upon that point, because, at the present moment, there was over £7,000,000 in the Bank of England lying idle, which could be utilised for the purpose, if the Government would only guarantee interest at the rate of 4 per cent. upon it.

The CHAIRMAN, in proposing a cordial vote of thanks to Mr. Maclean for his interesting and well-timed paper, said, no doubt it had lost some of its importance from the fact that the Government had moved for and obtained a Committee of Inquiry in the House of Commons, very much upon the question which had been discussed that evening. Mr. Maclean had established two points:—First, the evil of double control, which he feared was indispensable, as the Government could hardly give a guarantee without also having some control; and secondly, the great importance of having the interest of trade duly represented in the Viceroy's Council. Next to the preservation of peace in India, there was probably no interest to be represented in the Viceroy's Council so important as that of the prosperity of agriculture. With regard to the cost of production of wheat, he thought Mr. Maclean must have obtained his figures when the cost was exceptionally high, because the inquiries which had been made by the Board of Trade on Agriculture in India, did not support the figures mentioned. In a paper which had been presented to Parliament a year ago, by Mr. Buckland, it was shown that wheat could be produced under 2s. 6d. a bushel, that being about £1 a quarter, therefore making any argument on such a price as 8s. or 10s. a quarter was fallacious. Mr. Maclean had also understated the quantity of wheat imported by about one-half. India, during the last three years, had supplied from 10 to 14 per cent. of the whole quantity consumed in this country, and that would not have been produced were it not from the fact that agriculture had been encouraged. The rapid development of railways in America, from 1866 to 1880, had produced a remarkable result. It had enriched the country and the citizens, and at the same time had enabled those who had carried out the enterprise with great skill and economy, to lower the cost of transportation by one cent per ton per mile. That seemed a very small sum, but it was stated upon authority that that deduction on the quantity of goods carried on the railways of America, during the year, amounted to no less a saving to the consumer and producer than £64,000,000 sterling. What would be the amount of such a saving upon even the present traffic of India. Supposing the different descriptions of goods which passed over the railways amounted to over 500 millions, upon an average, the gain on 5,000,000 tons would be equal to £8,000,000 sterling. He hoped before long to see the mileage doubled, when the saving of one cent per ton per mile would effect a clear saving of £16,000,000 sterling to India. It was only by competition that this great result could be obtained. The extent to which this was applicable in India at present was shown by the proportion in which this country derived a supply of main articles from India, in comparison with that from other sources. The total value imported last year of wheat, seeds, hides, linseed, tea, and other articles was £170,000,000 sterling, of which India gave one-fifth, but that amount could be largely increased if the railway systems were considerably extended, so as to enable it to compete upon favourable terms with America. America produced most of the articles, excepting tea, which India did, and, therefore, it was only by lowering the rates of land carriage that India could hope to favourably compete with America. It had been said that the sea journey from India was longer than from America, but it must not be forgotten that that difference was compensated for by the extra number of miles that the goods had to be carried overland in America. As to the shipment of Indian wheat to Europe, he might perhaps be permitted to say one word. In the last three productive seasons it had grown up to 14 per cent. of the whole foreign supply, and as the foreign supply was about £43,000,000, India was a large and important market, to which the East and West might safely look in the future. The wheat grown in India had been found, after careful experiments, to be of a very valuable description, so that the demand for it might be expected to increase.

Mr. Maclean, in reply, repudiated the charge made by Mr. Kimber that he advocated a policy of confiscation. That was very far indeed from his desire. It was perfectly legitimate for Parliament to fix a maximum beyond which the dividends of guaranteed companies should not go. One gentleman said that 10 per cent. was very little for people to make in trade, but if people were guaranteed that they should not make less than 5 per cent., 10 per cent. was a great amount to make. Mr. Seton Karr had stated that he had never received more than 7 per cent., but he forgot to say that the Government had had the moiety of the balance of 11 per cent. He had suggested a way in which Parliament could interfere to check a railway company from earning large rates. The contract was only granted with certain restrictions; those restrictions had not been put in force, because the Government were interested in the company earning large profits. Lord Dalhousie, in his minute upon Indian railways, stated that a railway capital might be raised at 3½ to 4 per cent., and he (Mr. Maclean) was perfectly certain that Lord Dalhousie never contemplated that the railways should make the large dividends which they were now earning. The remarks which he had made in his paper not only applied to companies now in existence, but to companies which might hereafter be sanctioned by Parliament.

ELEVENTH ORDINARY MEETING.

Wednesday, February 20th, 1884; James Heywood, F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Brown, Henry, B.A., 10, Phillimore-gardens, Kensington, W.
Dewar, Prof. James, M.A., F.R.S., 19, Brookside, Cambridge.
Hogg, Stapleton Cotton, 68, Warwick-square, S.W.
Mitting, Ebenezer Kennard, Rye, Sussex.
Preston, Edward, 35, Cornwall-gardens, South Kensington, S.W.
Rivington, Rev. John Alfred, M.A., 32, Eardley-crescent, West Brompton, S.W.
Smith, Harry Fryer, 64, Leinster-square, W.
Venner-Morris, A. A., Ivernolen, Ammanford, R.S.O., Carmarthenshire.

The following candidates were balloted for and duly elected members of the Society:—

Baillie, Major-General John, 4, Queensborough-terrace, W.
Bostock, John Yates, M.R.C.S., M.B., 73, Onslow-gardens, S.W.
Evans, Edward Probert, Rose-house, London-road, Worcester, and Royal Porcelain Works, Worcester.
Lewin, Miss Constance, 25, Wimpole-street, Cavendish-square, W., and The Bourne, Widford, Hertfordshire.
Macdonald, Thomas, 5, Essex-court, Temple, E.C.
Mackinnon, W., Balinakill, Clachan, Argyleshire.
Scudder, Frank, 22, Devonshire-street, All Saints, Manchester.
Wilkinson, Capt. Edward, R.N., Army and Navy Club, S.W.

The Chairman, in introducing Mr. Hyde Clarke, referred to the possibility of hematite iron ore being found under the sands of Morecambe Bay, which would render their reclamation even more profitable than at first sight appeared.

The paper read was—

RECLAMATION OF LAND ON THE NORTH-WESTERN COAST OF ENGLAND.

By Hyde Clarke.

In a society like the Society of Arts, dating beyond a century, the same subject becomes over and over again the purpose of exertion, and from time to time comes under notice. The great end and aim of this Society, like its prototype in Holland, was to increase the national wealth and resources. It was intended practically to put into application those economical ideas which had been under discussion since the time of Elizabeth, and which, in the middle of the last century, became prominent. This period is popularly and familiarly known by the work of Adam Smith, commonly called the "Wealth of Nations," which dealt with the labours of his predecessors, and, in many cases, threw new light on the subjects by his own researches.

By the founders of the Society of Arts it was considered that the desired results would be promoted by the co-operation of the public and learned men, by serious discussion, and by giving honorary and pecuniary rewards as a stimulant to exertion.

The soil of these islands was regarded as the basis of our national wealth, and at a time when the agricultural societies did not exist, the energies of our founders and predecessors were greatly bestowed on plans and projects for reclaiming and planting land, or stimulating production. Although other institutions have taken up part of the work, it is greatly to be regretted that the purposes for which the Society was founded have never been adequately attended to in this country. It was not supposed that the Society was of itself sufficient; and though it greatly influenced the Board of Trade and the Colonial Department in the last century, it never succeeded in obtaining from the Government a proper provision for the administration of what concerns the national wealth. To this day, even with a favourable vote in the Legislature, there is no Ministry of Agriculture or of Commerce. A fitful effort was made when the Liberals came into power after the Reform Bill, to effect improvement, and to appoint commissions of inquiry into the means of increasing our commercial relations abroad, but there is no continuous exertion of policy.

Thus many matters which most affect the community as a whole, and cannot be dealt with except by the community, are left to casual action; and in defiance of the doctrines of political economy and the teachings of free trade, a kind of superstition has sprung up, that the State and the community are to do nothing, and that the citizen, as an isolated individual, is to compass all. We have come to an epoch when, by the growth of population, our water supply has become a matter of general concern, without having provided for it adequate legislation.

The improvement of waste soil can only, to a very limited extent, be accomplished by individual enterprise, and the same is to be said of the reclamation of soil from the water. In these matters even joint-stock enterprise is not always available, because the processes of recovery demand the application of much time as well as money. In Holland, and in England, large tracts have, from time to time, been saved from the sea, or taken absolutely from it. The great works in the Bedford Level, and in the Wash, in extending the productive surface of our eastern counties have added much to our national wealth, and in Holland the draining of the Haarlem Meer, in our days, is fully looked upon as a great conquest of engineering skill and perseverance. Our task on this occasion is less to refer to what has been done than to what remains to be done, and what is practicable of accomplishment in our north-western counties.

My connection with the subject, directly and indirectly, took place as far back as 1836. My own immediate call to action was in that year, in reference to the projected extension of what is now the London and North-Western system from Lancaster to Carlisle. That contemplated what was then, and justly deemed so, the great effort of passing the high mountain of Shap Fell in Westmoreland. Then, as always, the question of gradients attracted attention among engineers and the public, and considerable disfavour was expressed, perhaps without sufficient justification, towards the contemplated line over a mountain so well known at that time in the travelling world.

Into this controversy I, as a young man, was first privately, and then publicly drawn. The engineers of the Shap Fell plan maintained their project, because geographically it appeared impossible to obtain another route than through the natural pass. My chance and my advantage lay in this way, that part of my studies had been devoted to the engineering works of Holland, as some may still remember, from my treatise on that subject in "Weale's Quarterly Papers on Engineering." * Thus, to me, it may be said naturally to have occurred that the great Bay of Morecambe, so far from offering an obstacle, presented the very opportunity of obtaining a level junction between good gradients in North Lancashire and West Cumberland, and that like expedients would carry the line across the Solway, and into Scotland so as to reach Glasgow.

The idea was, in this case, absolutely my own; yet, as it is said there is nothing new under the sun, so it happened here. Half a

* "Weale's Quarterly Papers on Engineering." "Engineering of Holland Dykes." By Hyde Clarke. (London, 1849).

century before me, and nearly a hundred years before this day, in 1790, Mr. John Houseman is related* to have proposed to enclose the Bay, and he then valued the land at £40 per acre. It is also said that Mr. Wilkinson was so satisfied of the undertaking that he was willing to advance £50,000 towards it. This is all the history of the plan which has come n my way, and it seems to have slumbered in ocal tradition until my proposal revived it, and it was brought as evidence in favour of the scheme in 1838 and 1839.†

To some it will appear extraordinary that such a vast plan of embankment, justly regarded as a great undertaking, should date from a century back. There can, however, be little doubt that at that epoch the efforts of the Society of Arts had given a new impulse to such projects, and of this we shall find a direct proof. The Society of Arts was founded at a time when this as well as other European countries in the last century had favourable harvests, and when there was great activity among men of thought. The Society actually gave a prize for embankment in Morecambe Bay. As will be seen further on, one of my supporters, Mr. Edward Dawson, of Aldcliffe-hall, who reclaimed largely from the bay, received the medal of the Society for the skill and judgment with which the work had been effected.

It is not, indeed, at all remarkable that such a plan should be then brought forward as the Bedford Level reclamation had been accomplished a hundred years before. This, however, is worthy of note, that what is practicable should in this and other cases be delayed and neglected to the great prejudice of the national wealth. One great cause of the retardation of Mr. Houseman's efforts was our involvement in the wars of the French Revolution.

My originality as an engineer, as compared with Mr. Houseman's prior idea, consisted not in the proposal to embank Morecambe Bay, but in that of employing the embankment of the reclamation as a means of obtaining arterial communication. This railway, too, I proposed to construct to effect the embankment, and also thereby to obtain funds in the land reclaimed to replace the capital employed. There were also other practical portions, which belonged exclusively to myself. The fact is, that there is seldom anything that is ultimately accomplished, but what it has been obvious to some one, and this concurrence of thought becomes one means by which new inventions are carried out, for when they do appear, some minds are prepared for their reception and advocacy.

It is strange that in a country so well travelled as England, Morecambe Bay may be regarded as having been unknown, and at this day, many cannot tell where it is, though of course it figures clearly on every school and library map. It is a very remarkable indentation of our coasts among the mountains of the Lake District. It was not on the direct road to the lakes, and did not figure as one of the attractive features. Although it takes so large a space on the map, it attracted formerly no attention under the aspect of commerce and navigation. As the chief part of its large surface is bare at low water, navigation then ceases; and when the tide is up, the sandbanks and narrow channels of the rivers are impediments to shipping. In 1836, as for ages, the traveller had to creep by a circuitous route, less direct even than the present railway round the shores of the Bay, or to run the hazard of crossing the sands at certaln times, and in this venture many lives were lost, as the rising tide sweeps swiftly up, and forms quicksands.* Its dangers were too well known to all who travelled over its sands, on account of the constant shifting of the fresh water channels, and the treacherous nature of the sands, more especially during freshets in the rivers. This route has happily long since been superseded by the railway.

Morecambe Bay, it may be stated, is an arm, or bay, of the Irish Sea, situated to the west of Lancaster. Its average width is about twelve miles, and it extends about seventeen miles inland from the mouth, forming a deep gulf of picturesque character, and surrounded by beautiful scenery. A great portion of the bay is left high and dry at low water.

The best description of Morecambe Bay, and of the rivers Kent and Leven, is to be found in the paper read before the Archæological Association of the district, by Mr. John Fell, J.P., of Dane Ghyll, Furness Abbey, late Mayor of Barrow, and one of the trustees for the office of carters over the two fords. Mr. Fell, besides great local advantages, has made an extensive search of the records. These

* Report of Sir H. Le Fleming Senhouse, on West Cumberland and Furness Railway in *Whitehaven Herald*, &c., 1838; also MS. report of Hyde Clarke to Local Committee, 1836.

† It is stated in my MS. report that Mr. Houseman published a work on the topography of this region, p. 93.

* See on this subject the valuable paper of Mr. John Fell, on the "Carters of the Sands."

show the constant danger of the passage of the sands for many centuries, and Mr. Fell is, no doubt, right in supposing that the office of Le Carter had reference to the conveyance of passengers over the fords in a cart. The paper is of great interest.

I proposed to cross the estuaries of Morecombe Bay by embankments or dykes. By this means the land, dry at low water, was to be reclaimed, and this was provided as the resource to furnish part of the heavy capital for making a trunk line from Lancaster to Glasgow, through districts then sparse of population, and with feeble local traffic, and dependent for obtaining an adequate return on securing possession of the through traffic.

The practicability of the plan, bold as it was, was not much questioned among those who were brought into practical contact with it. The reason may have been this, that in those days the great hydraulic works of the east of England, and of Holland, had a stronger hold on the memories and thoughts of men, and their influence had not been weakened or effaced by the successes and remarkable achievements of the railway system. Hydraulic engineering then constituted a great school, in which James Walker and the Rennies, leading men of the day, had earned their distinction. Railway men were only slowly coming to the front, and had not achieved the supremacy and almost monopoly of the profession. During the transition, some who were unfavourable to the Institution of Civil Engineers, taunted it as the institution of railway engineers, in the same spirit as the Royal Academy has been termed the Academy of Portrait Painters.

It was calculated by me that in Morecambe Bay and the Duddon, one twenty-fourth part could be added to the surface of Lancashire. My estimate for the land in Morecambe Bay was 39,210 acres (40,000 acres) and in the Duddon, 4,000 acres. The passage of the Solway was contemplated to be by embankment, which would have provided another 20,000 acres, or more, according to the place of crossing; but this was put forward rather as an alternative.

In a project of mine I was not able to pursue, it was proposed to deal with the Ribble and the Dee. It is much to be regretted that these localities have not been systematically taken in hand, as national projects, instead of piecemeal treatment. Into this matter of the reclamation of the Dee I cannot now enter at length, but that I was right in proposing it has been sufficiently proved by subsequent experience. Although the works are not altogether satisfactory, some 3,000 acres were embanked there, but litigation is going on between the landholders and the River Dee Commissioners.

The opinion of Mr. Allen Wilson, M.Inst.C.E., who has great experience, concurs with mine, that by systematic action the Dee may be made an important harbour for the trade of the district, and that at the same time a large tract of land may be utilised. He agrees with me in preferring the experience of the engineers of Holland for the course of treatment.

In the case of Morecambe Bay, to produce so much surface from the sea, like Dartmoor or Woking Common, would not have been worth the labour. At the best, 40,000 acres of Salisbury Plain would only have grazed some sheep. In my own mind, there was little room for such doubt, as practical expedients for meeting such a case, and providing suitable soil, were suggested by experience. Still, experiment would have been necessary to convince the outside world. It proved, however, from the local tests, that good surface soil could be obtained. This confirmed me, too, as to the course to be adopted.

The local knowledge gradually obtained supplied practical confirmation. Thus it came out that on the Ulverston side small patches of sand had from time to time been reclaimed, and some before the beginning of this century. These had stood well, the land was good and rich, and worth £60 an acre.

In Morecambe Bay the case was very different from the embankment of the Haarlem Meer, the details of which were familiar to me, and also from conference with the engineers concerned. The Haarlem Meer was old inundated land, and during its whole time of being submerged it had been fed with good soil. Polders partially had shown the agricultural quality of the remainder, as the neighbouring enclosures had tested Morecambe Bay.

My provision included that of warping the sands in Morecambe Bay, leaving them to receive for the necessary time the land deposit from the rivers, and which is one of the most effective processes for such reclamation. The object was to produce good land, and although in the prospectus of the Grand Caledonian Junction Railway the value of the land to be reclaimed was taken at £15 to £20 per acre, no doubt was entertained by those who investigated the subject that, under proper treatment, the price realised would not be less than

£40 per acre, and possibly £50 or £60 per acre for much of it.

There was soon sufficient knowledge as to the difficulties to be encountered with existing riparian interests, or no interests, even to those who claimed a valueless foreshore of land to be created, and to which value was to be given by others.

Upon my entering into negotiations with the authorities of the Duchy of Lancaster, or the Crown, the usual contest ensued. In this case there were not only local but national interests concerned, but the Duchy would give no assistance. It set up a broad title to all lands to be reclaimed, would afford no contribution towards the work, and indeed would enter into no equitable compact. Recent experience has been in the same direction as to Preston, Southport, and Morecambe Bay. The large landowners were willing to come to terms, and their influences and those of the local communities were brought to bear in our aid. Crown and Duchy, for we had claimants in both departments, however, concurred in this determination, that they would come to no arrangement until the works were completed, when each assumed to be full proprietor of what might be recovered, and we were to depend on their mercy.

My undertaking received the aid of many influential supporters, Mr. John Rooke, of Akehead; Sir Humphrey Le Fleming Senhouse; Joseph Jopling, the mathematician; Colonel Landmann; William Blamire, M.P.; H. A. Aglionby, M.P.; Sir Hesketh Fleetwood, M.P.; Colonel Braddyll; Mr. Curwen, of Maryport; Sir Wilfred Lawson; Mr. Edward Dawson, of Aldcliffe-hall; Colonel Moody; Captain Beasley; Mr. Stockdale, of Cark; and many others, some of whom were well-known members of that Society.

A committee was formed in West Cumberland and Furness for its promotion, in which Sir H. Le Fleming Senhouse took a leading part. He collected much evidence, which is valuable to this day.

The following is an extract from a letter from Captain Beazley to Sir Humphrey:—

"My opinion certainly was, when I looked at Morecambe Bay, that it would be very possible to carry a bank across for the proposed railroad on the principle which I am adopting, so far successfully, on the Welland, but cannot at present say more, from present ignorance of the bay, having only had a casual view of it."*

* "Caledonian, West Cumberland, and Furness Railway." *Whitehaven Herald*, 12th April, 1838.

Mr. Edward Dawson was also a practical authority of great local influence. Of him Sir H. Senhouse said:—

"Before going further he felt it his duty to state that he had been greatly assisted in his inquiries on the subject of the embankment of Morecambe Bay by Mr. Edward Dawson, of Aldcliffe-hall, near Lancaster, a gentleman of much zeal and perseverance, who had himself embanked a great deal from the sea, and had received the medal of the Society of Arts for the skill and judgment with which the work had been effected. Mr. Dawson was of opinion that the only way of embanking across Morecambe Bay was after the manner in which a portion of the great Wash in Lincolnshire had been recovered; that was by turning the rivers, and quietly allowing the sea to deposit the silt thrown up upon it, so that in time it would enclose itself."*

Although local interests at Lancaster were formerly chiefly in favour of the Shap Fell undertaking, now a main line of the London and North Western Railway, there were yet wanting supporters like Mr. Dawson. At the present time Lancaster men are taking a leading part not only in the embankment, but in advocating the direct line to Barrow.†

I was succeeded as engineer for the embankment and the railway, as far as Whitehaven, by the late George Stephenson and the late John Hague. The railways formed in West Cumberland effected a connection with Carlisle, but that part of my undertaking which was in Scotland, not meeting with sufficient local support, ultimately fell into other hands, and was completed on the line of my original survey at the Glasgow South Western Railway. In the plan for the embankment George Stephenson had great confidence, and it was a favourite subject with him, as mentioned in his life.

Of Mr. Hague, Colonel Movely wrote to Sir H. Senhouse:—

"I sent the heads also of your inquiries to Mr. Hague, a civil engineer in London, who had been employed on the dykes against the sea in Holland under General Blonker, then chief engineer of the Water Staat Department, which I personally know to be scientifically and well conducted. I am sorry I cannot answer your enquiries as to Lincolnshire, but Mr. Hague, who executed extensive works in reclaiming 36,000 acres of land between Lynn and Ely, and embankments against the sea with only peat earth and puddling with clay, as is done in Holland, has promised me to call on you when he goes to Manchester; and as he also executed works in Holland, he

* "Caledonian, West Cumberland, and Furness Railway," *Whitehaven Herald*, 12th April, 1838.

† See the *Lancaster Observer*.

will be able to satisfy you on many points. He perfectly agrees with me as to the practicability of making embankments and a railway on the inner berme on your line." *

Mr. Hague proceeded to bestow his attention more particularly on the plans for Morecambe Bay and the Duddon. In this he was assisted by men who have since become distinguished in engineering circles, and among them his pupils, Sir Frederick Bramwell and Mr. T. R. Crampton.†

While Mr. Hague was employed on the Bay survey, Mr. J. M. Bastrick was engaged on railway survey‡ and both reported strongly in favour. The Government, however, held back against affording any support or co-operation, and the committee was dissolved. Thus the undertaking in this second stage of the West Cumberland and Morecambe Bay Railway once more collapsed.

The attention of the inhabitants of these districts had, however, been aroused by me, and a more decided spirit of energy manifested itself. Furness attracted the attention of many men of enterprise, and the local landowners co-operated.

In 1844, the leading men in Furness, in conjunction with the Duke of Devonshire, formed a committee to promote a mineral line from the iron mines to what had become the port of Barrow. This local line, ultimately carried out as the Furness Railway, became the means of connecting the main southern lines of the kingdom with those of West Cumberland, and thereby forming another but circuitous line of railway communication, reaching to the whole west of Scotland.

In 1851, a local company was formed in Furness, with Mr. Brogden as chairman, an Act of Parliament was obtained, and the line was laid out by Messrs. Maclean and Stileman. This prepared the way for the railway round the Bay, and the important works constructed by Mr. Brunlees, late President of the Institution of Civil Engineers. This may be looked upon as a tentative undertaking, which, by

* "Caledonian, West Cumberland, and Furness Railway." *Whitehaven Herald*, 12th April, 1838.

† When I read this paper last year before the Mechanical Section of the British Association at Southport, Sir Frederick came forward to state this fact, and to give some particulars of Mr. Hague's plans here described. I also read another paper on other features of Morecambe Bay, before the Section of Economic Science and Statistics. These papers were afterwards printed and published at Barrow.

‡ On this survey, Mr. John Fowler, late President of the Institution of Civil Engineers, was engaged, being one of the many men of eminence who have been connected with this undertaking.

carrying a railway and embankment across the estuaries, has prepared the way for the resumption of my original plan, and has afforded a demonstration of its practicability.

The embankment works in Morecambe Bay were described by Mr. Brunlees in a paper sent by him to the Institution of Civil Engineers, and to be found in the proceedings for the session 1854-5. This gives all the necessary details, and to it may be referred those desirous of further information. As much, however, relates to the viaducts, and not to the embankments, only partial extracts are here made.*

In Holland, most of the dykes are formed of sand faced with reeds or wicker-work. In the embankment in the Wash, in Lincolnshire, which is similar to Morecambe Bay, the works are formed of clay and sand, and in many parts of the British Channel wooden jetties are formed in the sea. With such examples, no doubt can be entertained of the practicability of the measure, and the question resolves itself into one of expense.†

On the existing line of railway over Morecambe Bay the sea-works, as carried out by Mr. Brunlees, are rather different from those originally proposed by myself, and afterwards by George Stephenson, Mr. Hague, and Mr. Walduck, in consequence of the present line being carried more inland than that proposed by me, so that the structures across the estuaries of the Kent and Leven are the principal works exposed to the sea. Although the reclamation of land was a secondary object with Mr. Brunlees in laying out this line, the railway embankments and weirs serve so far to fix the fresh water channels as to facilitate the reclamation of a considerable portion of the Bay, as well as to provide for future development.

The sands are to a great extent composed of calcareous matter washed from the limestone of the district, and of this the interior hearting of the banks is almost entirely composed. On the sea-slopes so formed there was placed a layer 12 in. thick of well prepared clay puddle. In the works in Holland this is the chief dependence. In Morecambe Bay, this clay puddle serves the twofold purpose of temporarily protecting the material during the formation of the embankment, and of permanently preventing the sand from being washed out from

* Long extracts were given by me in my paper before the British Association, and in the reprint at Barrow.

† "Caledonian, West Cumberland, and Furness Railway." *Whitehaven Herald*, 12th April, 1838.

between the joints of the pitching by the action of the sea. On the top of the puddle was laid a thickness of 18 in. of small rubble stones, technically termed "quarry rid;" this prevents the action of the sea upon the puddle. The pitching stones, varying from 8 in. to 16 in. in thickness, and of an average depth of 15 in., were compactly set together on this bed of "rid." The limestone from the excavations and the quarries in the immediate vicinity of the works yielded a very excellent stone for this purpose.

The embankment across the Kent Estuary differs from the others in the mode of execution. It is found that the sands stand well in still water, at a slope of 1½ to 1; such a quantity of "rid" was therefore used under the pitching as to prevent any abrading action of the water, and avert any action upon the sand. When it was consolidated by the passage of the horses and carts in the process of formation, and was set by the rains and spring tides, it was found to resist the passage of water through the embankment during the flood of the tides.

The railway over Morecambe Bay was opened in August, 1857, and it was soon demonstrated, by the passage of the ordinary passenger trains and heavy trains laden with minerals and goods, that not the slightest depression in the piles was produced, and but little vibration.*

Of the justice of these first and early plans and estimates, sufficient confirmation has since been obtained. Besides what—as a pioneer, though on a small scale—Mr. Brunlees has done, the Warton Land Company is engaged in reclaiming 7,000 acres of land on the Lancaster side of the Bay, and arrangements have been made with the Crown authorities for a further reclamation in the middle of the Bay of 11,000 acres.

The Warton Land Company, like the other undertaking, is due to the enterprise of Mr. H. J. Walduck, of Silverdale, Carnforth. It provides a sea wall which, by a sweep, is to enclose the east side of Morecambe Bay, in the estuary of the Kent, and in the neighbourhood of the town of Lancaster. This concession is held under a grant from the Duchy of Lancaster, and by arrangements made under the Act of Incorporation.

The engineers of the Warton Land Company are Messrs. Brunlees and McKerrow, and considerable sums have been spent on the works, and sufficient has been done to show that the works and undertaking are thoroughly practicable. Although the works have not been conducted with energy, from restricted means, they have been attended with this curious feature, that although stopped at the end of 1879, when the land was left at a certain level, it has still further silted up, showing a large accretion of soil without further expenditure of labour. An area of some 3,000 acres has thus been raised, as I saw last year.

The Cartmel Wharf reclamation of Mr. Walduck, which the Duchy of Lancaster authorities are prepared to approve, proposes, as stated, to deal with the main body of the sands in the centre of Morecambe Bay.

This plan, however, is connected with a design of Mr. Walduck for the Hest Bank and Barrow District Railway (Morecambe Bay Railway). He proposes to start from the same spot on the Lancaster or east side, at Hest Bank, that I did, and he follows much the same line to the west side of the Bay. For purposes of the through traffic I bore more upon Dalton, but Mr. Walduck wishes to strike the shore a little more south, so as to be nearer to Barrow-in-Furness, and to give it a direct railway communication.

At the mouths of the Leven and the Kent he provides wide viaducts, but the ultimate fate of these estuaries must be to be warped or silted, leaving only the river channels. By this route Mr. Walduck calculates that the distance to Barrow from Hest Bank to Barrow will be shortened from thirty-four miles to seventeen, a most material saving for passengers to that town, and ultimately to Cumberland, and the West of Scotland. The whole line will naturally be on a level.

Mr. Walduck has kindly favoured me with some results of his own experience.

"As to the history of the matter generally," he says, "the earliest reference I find is in Stoat's of Lancaster autobiography. He speaks of the marsh which extended from Arnside Well to Bare, near Morecambe, being washed away by the confluence of the rivers Kent and Kier, in 1677, and to its having been 'gathered in' about 100 years previously, which takes us back to the reign of Elizabeth. However, nothing was done to repair the embankments, or to recover the lands, until 1811, when under the Warton-with-Lindeth Enclosure Act, power was taken to appoint commissioners, to set out 'a large tract of land daily overflowed by the sea, but which is

* Brunlees on "The Iron Viaducts for the Ulverstone and Lancaster Railway," p. 7.

supposed to be capable of being recovered, embanked, and converted into arable land.' Power is also given to sell the land so to be set out to the highest bidder, and the fullest powers are given to the contemplated reclaimers to carry out the work.

"Nothing was done under this Act beyond the award which was duly made, and the tract set out, having for one of its boundaries the mid-stream of the River Kent; its acreage was of course continually varying.

"Then came the railway era and your great project of 1836, with a railway crossing the Bay, very much on the line I have recently advocated.

"Then followed Mr. Hague's plan, which was considered by Parliament, and his railway rejected, and that over Shap Fell (the Lancaster and Carlisle) adopted. Mr. Hague proposed to reclaim the whole Bay, and to put in gates for the Leven, the Kent, and the Kier, which he reduced to canals.

"In 1851, Mr. Brunlees carried the Ulverston and Lancaster Railway successfully across the sands, bringing together the ore of Furness and the coke of Durham, to the immense advantage of both districts.

"In 1864, I went to Carnforth to establish ironworks, which would not have been possible in that position but for this railway, and it was then I became acquainted with the Bay of Morecambe, and the possibility of a large work of reclamation being successfully and profitably carried out. The sands, no doubt, had been gradually rising on the western side, because the River Kent (through, it is said, the effect of its railway works, and training walls necessary to protect them) had shifted but little from the shore line from Grange to Humphrey Head. The time, therefore, was favourable, and I gave a good deal of attention to the subject, and also had reports and plans prepared by the late Mr. Scamp, C.E., who was very enthusiastic in the matter, and made some admirable suggestions.

"Negotiations were at length entered into with the parish of Warton, and in the result they agreed to put up their tract, about 10,000 acres, under the award of the Act of 1811, for sale by auction, and I became the purchaser for the sum of £6,300, in 1871. The land so purchased, however, was of an unsuitable shape for reclamation, it being rectangular, and necessitating a larger length of embankment than would be necessary if the corner pieces at Hest Bank and Arnside Point were secured.

"Then followed negotiations for the land on the south side of the Keir with the Duchy of Lancaster, and for the northerly corner, comprising the Silverdale Sands, between Lindeth and Arnside Point, with the lord of the manor of Silverdale. In the end, both purchases were concluded, but at a further expenditure of several thousand pounds. Here another difficulty presented itself. The Act of 1811 sufficed for the reclamation of the Warton tract, but there were rights of the inhabitants at both ends which I was advised could only be settled by Act of Parliament. It was about this time that Mr. Scamp's health having failed, Mr. Brunlees was called in, and by his recommendation I purchased from the Duchy an additional strip of sands covering the frontage of the London and North-Western Railway at Hest Bank. All was now ready for the application to Parliament, and to Parliament I went in 1874. I will not weary with an account of the Parliamentary struggle. The Bill had been so drafted that in the first instance it was thrown out on a technical objection. The address of our Parliamentary agents, however, got us on our legs again, and, after a debate in the House, we were referred back to the Committee. In the result, the Commons gave me all I asked; the Lords passed the Bill, but struck out that portion which applied to the Silverdale Sands. This was a misfortune: it destroyed the completeness of the work, occasioned delay, and some extra expense.

"In the meantime the Warton Land Company, Limited, had been formed, with a capital nominally of £150,000. The costs of the Parliamentary proceedings had been very great, about £7,000, so that my outlay was a very considerable one.

"The company took over all my purchases of land, and the Act of Parliament. They were to have paid for them half in cash and half in shares; but capital coming in slowly, it was arranged that they should only pay £15,000 in cash, so that I was, and am still, heavily out of pocket. No work was commenced for long. In 1876, it was determined again to apply to Parliament for the Silverdale tract, or, rather, to extinguish the rights of the inhabitants over it, but an offer of a limestone quarry being made at Jenny's Brown Point, it was purchased for about £2,000, and work commenced there.

"The work was continued for two years, and was very successful.

"The quarry, from the dip and nature of the stone, was very easily worked; some old buildings were on the ground, which were converted into barracks for workmen; and, so far as the money went, it was well laid out. Still the public would not subscribe, and then, in a fatal moment, we borrowed £10,000.

"This loan was guaranteed by the chairman, who made it a condition that he should have the office in Lancaster, and appoint the secretary, and, in addition, that the remaining uncalled capital of the company should be mortgaged to him, together with all its effects.

"The work still proceeded well, but no new money came in—times were bad—and the public had lost confidence in limited companies. Ultimately, the chairman agreed that one-half the uncalled capital should be applied to the continuance of the work; when that was expended he, with a certain number of directors, recommended liquidation and reconstruction. As this really meant confiscation of the existing interests, it was strongly opposed by myself, and as I have been supported by the majority of the shareholders, the evil day has been staved off, though, as I have told you, the last call has been made, and an action of foreclosure commenced by the chairman and mortgagee.

"I turn now from these weary details to a more interesting subject. Mr. Brunlees had already, from the Furness Railway, designed a form of embankment which had answered well, and a similar section he adopted in our case.

"The method of construction is first to tip a rubble stone foundation, which ensures the perfect security of the work. We found in practice that this is best carried out at a 14 ft. tide level, and the silt very rapidly accumulates behind it.

"The effect of running out the cross wall from Brown's Point has been to raise some 3,000 acres, at least 6 ft. in level, and the process is still going on, although of course more gradually each year, as a fewer number of tides flow over it, and leave their deposit. Some three square miles are now covered by a short, nutritious herbage, which makes an excellent sheep pasture. The area to be enclosed being surrounded with this foundation, and the 'silting up' being carried out to a minimum of 14 ft., the 'closure' of the top bank can be effected at neap tides in summer, without the slightest risk.

"The perfect confidence that I felt, from watching the work, in the method of construction, induced me to design the larger project for enclosing Cartmel Wharf and Sands, and carrying the railway direct from the Hest Bank to Barrow. After lengthy negotiations, terms were settled with the Duchy of Lancaster which, in my opinion, were favourable, and which I have reason to believe may still be obtained.

"The objects I had in view were:—(*a*) to give direct access to Barrow; (*b*) to reclaim 11,000 acres of land; and to do this in such a way as to interfere as little as possible with existing amenities.

"Cockling is a very important and lucrative trade in the Bay; a large number of men, women, and young persons are engaged in it. It is a healthy, hardy occupation, and the people are devoted to it.

"It is not without danger it is carried on in all weathers; the traffic amounts to some thousands of tons in a year; the bags of cockles go direct from the Bay to the manufacturing towns, and carry with them an unmistakable flavour of the ocean to many a cottage. The cockling trade, therefore, must not be interfered with. The cockles live and flourish in the sand, newly turned up by the action of the tide on the river channels; the cockles, in fact, follow the rivers—to live, they must be covered with sea water twice a day. The estuaries are, therefore, in my designs, left sufficiently wide to admit of the full area of the existing cockling grounds. Then property owners had to be considered.

"The line opposite Grange is fixed by the Warton Land Company's Acts of 1811 and 1874, and the line from Humphrey Head, in a south-easterly direction, can hardly be seen from either Grange or Kent's Bank. In the Leven there is no residential property of much importance.

"The outer embankment of the larger reclamation is attacked by the south western winds in a much more favourable position than would be the outer embankment of the Warton Land Company, which it shelters.

"Mr. Brunlees, who is the highest authority on the subject, has certified that there is no physical difficulty in carrying out the work, and the Duchy of Lancaster had a special report from the late Mr. James Edmund Smith, who was entirely favourable to it. Will it pay?

"From carefully prepared estimates, based on responsible tenders for similar work, I make—

The total cost	£750,000
To this I add for compensation, cost of land, and sundries	100,000
	850,000

The land should realise £50 per acre, giving for 11,000 acres	£550,000
Leaving as the cost of the 17 miles of railway	300,000

or less than £18,000 per mile.

"At the outset, assuming the above figures to stand, the cost is low as compared with existing lines.

"The Furness Railway Company's 108¼ miles of railway, had cost them, in 1879, £2,470,000, or about £23,000 per mile, but this was exclusive of the Barrow Docks, which have cost them £1,700,000, and on which dividend has to be paid. It cannot, however, be assumed that the whole of the dock work is productive, so that the cost of the railway per mile is practically increased; still large dividends are paid, and the shares command a premium.

"The 1,100 miles of the London and North-Western Railway had cost them, in 1879, £55,000,000, or, say, £50,000 per mile; but the public, at the present price of the shares, could not invest under £87,000 per mile. The directness of the route would, however, do much to create a passenger traffic. Mr. Smith, the eminent surveyor, was strongly of this opinion, and told me to rely upon it rather than on the mineral traffic, but the mineral traffic would be immense. The Lancashire coal field would be especially benefited, as would all inland business of hematite ore or Bessemer pig and steel.

"Prior to the opening of the Lancaster and Ulcester Railway, the trade in hematite pig-iron consisted of the produce of five small furnaces, producing about 20,000 tons per annum. At the present time, about ¾ million tons are produced, requiring, in round numbers, 2¼ million tons of minerals.

"In these remarks I have looked at the probabilities of traffic and dividend, but there could be no doubt, from a national point of view, the creation of some 18,000 acres of food-producing land is in itself a great and positive gain. Also, it is a positive loss to the nation that passengers, minerals, and goods, should be carried double the necessary distance, aggravated by the fact that they are taken over unnecessary inclines.

"If a dividend of 3 per cent. only could be shown, it might be supposed that it would attract the attention of capitalists, but a dividend of double that amount can be easily shown as likely to accrue.

"It has been said that no income would accrue until the work was finished, which is no doubt true in the main, but the same may be said of almost all works of magnitude.

"With the necessary capital, the whole of the works could be finished in four years. In this country we have not now to look so much at the gain or loss of particular districts, but to work so as to bring our minerals and products together at the lowest possible price, if we are successfully to continue to compete in the markets of the world.

"I have not touched upon the value of the through level route to Scotland by the West Coast, nor the probability of the existence of minerals under Cartmel Wharf."

The Warton Land and Cartmel Wharf undertakings, severally of 7,000 acres and of 11,000, constitute a total reclamation of 18,000 acres, a most important work in reference to the extension of the material resources of the country.

Among the successful reclamations of late years should be reckoned that effected by Mr. Brogden, M.P., at Meathrop, which has been valued at £60 to £70 per acre. The land reclaimed by the Railway Company at Winster Bay and at Holker is reckoned to be of the same value. Here, perhaps, may be noted the experiment of an early friend of the undertaking, Mr. Stockdale, of Cork, as related by Sir Frederick Bramwell. Mr. Stockdale, during the survey, to show what the soil was, sank a cart in the sands, planted potatoes, and in time sent the crop to be shown in London.

With regard to the Southport foreshore, which has afforded a recent and striking case of the difficulties in dealing with the Crown authorities in these cases, particulars will be found in the appendix.

It has been mentioned by me that one main feature of my plan was the development of the natural harbours of the district and the utilisation of their capabilities, more particularly of the Pile of Fouldry. To me this harbour seemed an endowment of nature given to England, which was lost and unknown. The whole coast from Liverpool to the Solway was unfavourable. Liverpool itself carries on an enormous commerce under the greatest difficulties. Perhaps it may be mentioned that I laboured several times to bring into execution a plan which, at that time, would have greatly assisted Liverpool. There was then a straight channel, probably the remains of a through channel, with good water to Formby Point. A harbour near the Ince Blundell Estate, with a short railway branch, and a short cut to the canal, would have given an outer port where the tide was an hour earlier and an hour later than at Liverpool Docks. At the Ribble I had also proposed an improvement.

Nothing in a region reaching to the Scotch coast could compare with the neglected harbour which could float a navy, and from which only some few cargoes of iron ore were casually shipped. The Pile of Fouldry, or Foudry, was better known from the line relating to it by the Elizabethian poet, Drayton, and from its obscure place in the mediæval history.*

Thus, by the geographical impediments of Morecambe Bay, a large north-western district of England was formerly isolated, including the Peninsula of Furness and Southern Cumberland, until the railway just described, and which is also circuitous, was constructed. So far as these regions were concerned, facilities of communication ceased at Lancaster. One chief means of access to Furness was by the small port of Ulverston. On the southern shore of the Bay was another unfrequented district of Lancashire, the Fylde, with a fine harbour, now known as the harbour of Fleetwood. The Fylde has now been brought within the range of active industry, and has become a practical addition to the resources of the country; for this we are indebted chiefly to three men, Sir Hesketh Fleetwood, Mr. George Walter, also projector of the Greenwich Railway, and Col. Landmann, R.E., the engineer of the Preston and Wyre Railway and Harbour undertaking, now absorbed by the Lancashire and Yorkshire Railway.

Proceeding in detail with the subject, the town of Barrow constitutes one prominent feature. The site of Barrow, as seen by me in 1836, had on it an insignificant hamlet. In ten years, in 1847, it had become a village of about 300. This, in another ten years, in 1857, had grown to a small town of 2,000.

The following return by Mr. Thomas A. Mercer, Borough Treasurer, in the volume—"Abridgement of Accounts of the Corporation of Barrow-in-Furness, 1882," p. 189, shows the successive increase:—

	1867	1872	1877	1882
Population	12,000 ...	18,000 ...	38,000 ...	50,000
Rateable Value ..	£43,534 ...	£76,182 ...	£163,800 ...	£215,000
Mortality per 1,000	...	...	18·84	18·50

The inventory of this town or city of 50,000 people, in the borough accounts, contains some interesting entries. There are enumerated portraits, a statue of Sir James Ramsden, Ramsden Baths, presented by Sir James, and numerous town buildings. The amount of the rateable value is, however, one of the best testimonies to the solid character of the progress of Barrow.

In my original report much future importance was attached to Foudrey (Barrow), and its availability for the Isle of Man and Irish Channel trade pointed out. This has been realised, but of late it has shown its capabilities as an ocean steam port. At the earlier time Fleetwood-on-Wyre, at first called New Liverpool, was but newly founded. It presented itself to me as one great advantage of Morecambe Bay in having these two ports of Barrow and Fleetwood as harbours of refuge and alternate ports to each other. Fleetwood was, however, then capable of much improvement, and I proposed to Colonel Landmann to get a scour by cutting through the neck of the western headland, which would have given greater advantages, but other counsels prevailed, and Fleetwood is relatively dwarfed.

At first I had contemplated dealing with the small estuary of the Wampool and the Waver, on the south shore of the Solway, so as to get across the great frith to the west, and obtain a shorter line into Scotland with a larger extent of reclamations. The examination of the channels of the Wampool and Waver was, however, very unfavourable, and I was induced to propose a crossing of the Solway higher up. It is by no means certain that my determination, although then expedient, was without objections. At some after time, under more favourable auspices, the Solway may be advantageously crossed. At that period no one dared to contemplate such works as those over the Forth and the Tay.

With regard to the Solway, I should certainly have preferred an embankment, with provision for navigation to Carlisle—in fact, the same kind of work as Mr. Brunlees afterwards executed in Morecambe Bay. The ultimate extent of land to be reclaimed was at least 8,000 acres.

Although the practical examples are here taken from one district, and although that is an important one, sites suitable for the reclamation of land from the sea, the estuaries, and the rivers, are to be found in many parts of our islands. Our eastern coasts and our southern coasts have localities suitable for enterprise. The success which has attended some reclamation undertakings in Ireland should be an encouragement to further efforts in that direction.

* "Barrow-in-Furness; its Rise and Progress," by Francis Leach, B.A., editor of the *Barrow Times*, Barrow, 1872.

Such undertakings are, however, treated as matters for individual enterprise, or by joint-stock companies, and in all cases, private and foreshore claims are so dealt with as to embarrass the execution of every plan. If a landowner reclaims a tract, he should be in every way encouraged; but where the owner of land, or of manorial or of paramount rights, has not profited by his opportunities for centuries, then, suitable compensation being provided, his claims should not be allowed to stand in the way of those of the nation.

To increase the soil of the country, and thereby to provide employment and food for a larger number of the population, is truly a matter of national concern, and should be so regarded. In Morecambe Bay alone, food for 100,000 people might be grown. A Minister having charge of the national wealth—as a Minister of Agriculture in truth should be—would be able to confer permanent benefits on the country without throwing burthens on the treasury.

What is any one's business becomes no one's business, and this is fully illustrated by the history of a hundred years of Morecambe Bay, where a feasible work left to this day unaccomplished, is only one instance of the neglect of opportunities; and this paper has been brought forward to make the facts better known by an example so striking, and to stimulate public attention to the necessity for action.

APPENDIX.

Statement of Facts Relating to the Southport Foreshore.

1. The Southport Corporation have, for a long time, felt the desirability of acquiring both in the interests of the town and in that of the public who resort thither, the foreshore in front of the borough, and in the year 1880, approached the Duchy of Lancaster with that end in view.

2. In the month of September, 1881, an agreement was come to between the representatives of the Southport Corporation and the surveyor of the Duchy of Lancaster for the purchase of the foreshore by the former on certain terms and conditions, on the necessary Act enabling the purchase to be carried out being obtained. The corporation were given until August, 1884, to apply for the Act.

3. A draft embodying the terms so agreed upon was, at the request of the Duchy solicitor, drawn up and submitted to him for approval.

4. This draft agreement (which is still with the solicitor to the Duchy) has never been either formally approved of or rejected by him, although in the course of a tentative discussion of its provisions with him (when he intimated that the Duchy would prefer to deal with a public body, and would do so on easy terms), he suggested other terms than those embodied in it.

5. The riparian owners, when they became aware of the intention of the corporation to purchase the foreshore, through their solicitors and agents, endeavoured to prevent the negotiations proceeding. They threatened both the Duchy and the corporation with litigation, with a view of proving that the foreshore in question belonged to them, but instead of commencing such litigation, after a delay of nearly a year, they delivered an abstract of title which showed that their claims were groundless.

6. On Friday, the 6th of April, 1883, while both the corporation and the riparian owners were engaged before a Committee of the House of Commons in opposing a private bill, negotiations were opened by the said riparian owners with the Duchy authorities for the purchase of the foreshore.

7. The negotiations were on the point of being concluded when on the 9th of April, the representatives of the corporation, then in London, accidentally heard of them. They immediately sought an interview with the Chancellor of the Duchy of Lancaster, for the purpose of laying before him the facts relating to the arrangement come to between them and the Surveyor-General, and urging that it was one morally binding upon the Duchy. The Chancellor of the Duchy declined to grant them an audience, or even twenty-four hours' time for communication with their colleagues in Southport.

8. Thereupon some of their number, under protest, and in consequence of an absolute refusal both by the Chancellor and officers of the Duchy to grant time for deliberation or consultation with the town council of Southport, made on that day an enhanced offer, which the Duchy officials gave them reason to believe, would be accepted, and personally undertook a heavy pecuniary responsibility in order to avert if possible the disaster to the town of Southport, which would result from the foreshore passing into the hands of private individuals. A copy of this offer is sent herewith.

9. The offer of the representatives of the town council was refused and one made by the riparian owners considerably lower in amount accepted.

10. The arrangement entered into by the Duchy with the riparian owners is not, the corporation of Southport are adviced by counsel of eminence, legally binding upon or enforceable against the Duchy.

11. Since the arrangement come to with the riparian owners, the Chancellor of the Duchy has received a deputation from the corporation of Southport, which was introduced by Sir R. A. Cross, and accompanied by several members of Parliament. After hearing the statements of the deputation, the Chancellor tendered his good offices for the purpose of obtaining an equitable settlement, whereupon the corporation made a further offer, the most liberal

they felt justified in doing in the interests of the borough.

12. The Chancellor has not informed the corporation whether this offer will be accepted or not, but has suggested that the matter should be submitted to arbitration. The terms of the reference which the Chancellor has suggested are, in the opinion of the corporation, however, so onerous and inappropriate that they cannot, having due regard to the interests of their constituents, accept them, and they have caused an intimation to that effect to be forwarded to the Chancellor of the Duchy.

NOTE.—The corporation of Southport has been compelled to come to an arrangement which it feels to be very inadequate to the just claims of the public.

DISCUSSION.

The SECRETARY (Mr. H. Trueman Wood) said Mr. Clarke had alluded to a medal given by the Society for the reclamation of land, and at his suggestion he had referred to the past records of the Society to see what had been done in that way. He found that in the last fifteen years of the last century, viz., from 1785 to 1801, no less than eight gold and two silver medals were given for reclaimed various portions of land, mostly in Essex, though one plot was in Cornwall. The total acreage amounted to nearly 4,000, but it was mostly in small plots, and he found that one of the recipients was the Rev. Bate Dudley, whose portrait, by Gainsborough, was now to be seen in the Royal Academy Exhibition. Mr. Clarke had referred to the case of a man who had planted a crop of potatoes in a waggon which he sunk in the sands, with the view of testing the soil, but he had omitted to give the sequel, which was that when the potatoes came up, he dug up the waggon and drove it to London, as a valuable piece of evidence for a Parliamentary Committee. Such, at least, was the story as he had heard it.

Mr. WILLIAM BOTLY, having observed on the interesting character of the paper, said he was fortunate enough to hear a similar one at the recent meeting of the British Association, at Southport, where it excited a good deal of interest. It was very much to be regretted that the Duchy of Lancaster, the Crown, or any one else, should have the power to prevent or obstruct such great improvements which were national in every sense of the word; since they would increase the area of land, the supply of food, and the opportunity for useful labour. He had seen land in Norfolk, 50 years ago, which had been reclaimed from the sea, growing excellent crops of roots, and he saw no reason why the same thing should not be done elsewhere. He hoped that one result of this paper would be to awaken public interest and discussion, so that eventually some substantial progress might be made in the direction which had been described.

The CHAIRMAN said one of the greatest difficulties in the way came from the Duchy of Lancaster, but he thought the difficulty might be got over. He happened to be one of the trustees of Dr. Williams' Library, in Grafton-street, and he remembered that when they wished to purchase some land there they were told they could not do so; they must rent it on lease; but by giving some £300 above the value of the land, they got over the difficulty, and purchased the freehold. Possibly, the Duchy might be willing to treat in the same way.

Mr. H. J. WALDUCK said he must take a slight exception to what had fallen from Mr. Clarke as to the action of the Duchy of Lancaster, as he had found them willing to offer every facility for the reclamation of the land in Morecambe Bay. He had bought from them two tracts of land, one of 2,000 acres, and the other of 1,700, at a price of £2 per acre, and both parties were satisfied with the bargain. In the same way, when the Warton Land Company had partially accomplished its work, and the larger idea occurred to him of enclosing Cartmel Wharf, he again went to the Duchy and showed them what he proposed; their reply was that they would consult their own engineer, and if his report were favourable, they would be willing to treat with him, and the result was that another contract was entered into for 11,000 acres of land for £10,000, or less than £1 per acre for the freehold. In a work of that magnitude, the payment of £10,000 to the Duchy was not a matter which seriously affected the ultimate issue; the Duchy reserved certain important interests, and were bound to get the full value for what they had to sell. The Duchy, in that contract, however, made certain reservations; they sold the rights of the Crown subject to the authority of Parliament, because there were certain other rights which could only be dealt with by Parliament. One great difficulty was that you had to deal with the two rivers, the Kent and the Leven, on which there were navigable and fishing rights. He found that from two stations on the railway there 160 tons of cockles were sent in the month of January, representing a commerce of about £7,000 per annum, and those fishing rights were reserved. The cockles required to be covered twice a day with salt water, and therefore the estuaries had to be kept of sufficient width, in order to preserve the rights of the cocklers. Again, there were residential rights to be considered, and the works had to be so designed as not to interfere too much with the natural scenery. Apart from these matters, there were very great difficulties in reclaiming the land in Morecambe Bay. When he went to Parliament in 1874, everybody who had any conceivable right presented a petition against the Bill—the railway companies, lords of the manor, fishermen, and lodging-house keepers — thirteen petitions in all. In the result, they were all arranged with but one, but since then times had not been propitious for raising money, and active operations had been suspended for three years. Nature, however, had not suspended her operations, but, as narrated in the paper, had gone on silting up behind the embankment, and there were now three square miles covered with herbage. With regard to the larger question of the railway, other opposing interests came in. It was natural to suppose that the town of Barrow would be benefited by better railway accommodation, and he, therefore, laid the scheme before the principal landowner, the Duke of Devonshire, but after consideration he had declined to support it. The Midland Railway Company was next applied to, with the same result, and with the London and North-Western he had had no better success. When you had to deal with powerful Companies, who were interested in carrying coke and ironstone double the distance it need be carried, you required a good strong backbone to be able to combat them. That was the great advantage of bringing the subject before the Society of Arts, as it enabled public opinion to be brought to bear upon, and he had no doubt, in due time, the facts put forward would bring forth fruit.

Mr. Martin Wood thought it was by no means flattering to our national pride to think that such an important work had been allowed to languish so long. He could not help thinking that if such a piece of land belonged to the Dutch, they would not have taken so long before reclaiming it. There was a popular opinion that the Duchy of Lancaster was something like a dog in the manger, and this idea seemed to be countenanced by Mr. Clarke, though the last speaker did not quite agree with it. The engineering aspect of the matter was very interesting, especially considering the way in which natural forces were relied upon to assist in the work; but he rather doubted whether the straight line he saw on the map was the most likely to be successful as an embankment with which nature was to co-operate. Those works which were most successful generally adapted themselves more to the original formation of the coast line, the channels, and the currents.

Mr. Liggins said he had often been in sight of these sands when yachting, and it had occurred to him what a dangerous place it would be to be driven on by a westerly gale. If it had not belonged to the Duchy, he believed an embankment would have been run across years ago, and it would have been converted into fertile sheep pasturage. No doubt there were local difficulties, though he was not aquainted with them. A few years ago it was proposed to reclaim the Maplin Sands, just below Southend, which were now only used as an artillery range for Shoeburyness, and fertilise them with the London sewage, which would have had the double advantage of affording a valuable adjunct to the food supply of London, and preventing the filling up of the river with the sewage which was now poured into it, but so many difficulties cropped up, that the proposed company did not succeed. Barrow was a mushroom city, only equalled by Chicago in rapidity of its growth, owing to the development of the iron and steel trade; he knew one gentlemen who received as much as £70,000 in one year from royalties from the Barrow Steel Company; and there was a very fine harbour there, but he feared there was little hope of getting assistance from the Duchy or any Government department for improving it. He saw that only last night the President of the Board of Trade rejected a suggestion for doing something to a port in the vicinity, Port Patrick. In former times, this was used for mail communication to Ireland, and was now largely used by fishermen, but it was now falling into utter decay for want of a little timely repair.

Mr. Dipnall remarked that the reclamation of land was not necessarily confined to that now covered by the sea, and there were large tracts of moorland in Yorkshire and elsewhere, to which capital could be more readily applied than to Morecambe Bay. He thought, perhaps, Mr. Clarke had valued the land at £40 an acre at a time when wheat was 100s. a quarter, and that the same estimate might not be correct at the present day. In past years a great deal of land had been enclosed and planted with larch and Scotch fir, and afterwards brought under cultivation; but with very poor results. It cost from £12 to £15 an acre to bring it into cereal cultivation, besides a considerable period of time. The Chairman had alluded to the possibility of iron ore being found under these sands, but no definite data had been given on which such an opinion could be founded. At the same time, seeing that land was constantly being lost on Essex and Sussex coasts, it was important that wherever possible the balance should be made good by reclamation.

Mr. Walduck explained, in reference to a remark of Mr. Martin Wood, that the plan he proposed was exactly such as that gentleman suggested, following the lines of the river channels, but the indications were too faint to be seen on the map. With regard to the question raised by the last speaker, as to the probability of the land coming into cultivation, he had with him a report from a gentleman who had been cultivating some of the land taken in by the Furness Railway, near Grange, in which he says:—"When this marsh is enclosed, cultivation can be proceeded with at once, and the produce will be much greater than on the sandy marshes alluded to. Clover seeds can at once be sown, and will produce large crops. What this description of land will do is best proved by my own experience on the Grange marsh, which I rented from Mr. Maude, when reclaimed by the Furness Railway Embankment. I took 180 acres at the annual rent of 45s. per acre, and the following statement of the stock I put upon it and fed off, during the first year of my occupation, will no doubt be interesting, as showing the early return this description of marsh land will make, before draining or other permanent outlay had been made. I find from my books that I fed off for market during the first year 811 sheep and lambs, and 110 beasts. Land capable of carrying this weight of stock per acre should be worth to rent from 45s. to 50s. per acre. This result, I should also state, was obtained without a plough entering the land, it was merely scarified and harrowed, and sown down with clover seeds." With regard to minerals, hematite ore was found both east and west of Cartmel Wharf, and the finest quality of ore was found at Morton Crag, nearly pure peroxide of iron.

Mr. HYDE CLARKE, in reply, said Mr. Dipnall's remarks had been in part met by Mr. Walduck, but he might add that his estimates of the value were not based on an excessive price of wheat, but on actual experience. He was much indebted to Mr. Walduck for the practical contribution he had made to the discussion, but he must still beg leave to differ from him as to the action of the Duchy, and he thought what Mr. Walduck had advanced had rather tended to strengthen the view which he (himself) had put forward in the paper. The Duchy had certainly shown to Mr. Walduck a larger amount of favour than to anyone else, but with all that, it seemed to him that the great obstacle was the Duchy of Lancaster. He thought it monstrous to require £10,000 for the Cartmel Embankment, on the ground that the Duchy was bound to get full value for what they had to sell. His position was that the Duchy had no right to such a payment, because they had nothing to sell, and the main question was whether the Duchy and those who took advantage of its obstructive position, should stand against the national interests. Mr. Walduck had certainly narrowed the case against the Duchy, but he (himself) had said nothing about the other causes of obstruction, except in general terms. His contention, however, was that it was this attitude of the Duchy which enabled the landowners and others to interpose these obstacles at every point. There could hardly be a stronger instance of this than what were called the fishing rights. They came simply to the right of cockling, the gross amount involved being £7,000 a year. Surely it was possible to give compensation for those rights, on a moderate scale; the idea that this small amount of shell fish was to stand in the way of the wholesale growth of food for the population, was a thing which he was quite certain neither the Society nor the public would countenance. The great obstacle had always been the residential rights. One large landowner wanted to see the water in the Bay when the tide was out, and obstructed the scheme on that ground. Again, the railway companies, which had carried a line in a circuitous way all round the Bay, were now trying to prevent direct communication with Barrow, and thus to impede the access of all the people of England to that town, and to Scotland. But after all, the Duchy of Lancaster was a public department, and he was not without hope that, when the matter had been carried a stage farther, it would be discussed in the Press, and in Parliament, and that, having got rid of the Duchy, they would be able to deal with the other enemies of the community. The whole point was the necessity of national action in matters of national interest, such as this. He agreed that it was very desirable to reclaim waste land wherever possible, and to attend to harbours. There should be a Minister to attend to such matters, which should be constantly and consistently carried out. This question would gain wide publicity through the columns of the *Journal*, and he had no doubt it would be taken up. He had no professional or pecuniary interest in the matter; but looked upon it as one with which that Society had been connected for more than a century, and he had great hopes that before long Mr. Walduck would be able to carry out his plans to complete success, with the greatest possible advantage to the community, as well as to those who were associated with him.

The CHAIRMAN then proposed a vote of thanks to Mr. Hyde Clarke, which was carried unanimously.

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION.

The following Sub-Committees have met at the Society of Arts since the meetings recorded in last week's *Journal*:—

THE DWELLING HOUSE.—GROUP III.—
SUB-COMMITTEE B.

Wednesday, February 13th.—Present: Mr. George Godwin, F.R.S., in the chair; Mr. E. Hoole; Prof. T. Hayter Lewis; Dr. Thorne Thorne; Mr. Ernest Turner; Mr. K. D. Young; Mr. H. Trueman Wood.

SICK AND AMBULANCE.

Wednesday, February 13th.—Present: Inspector-General F. J. Mouat, M.D., in the chair; Deputy Surgeon-General Bostock, C.B.; Brigade-Surgeon W. G. Don, A.M.D.; Mr. V. B. Barrington-Kennett; Surgeon-General W. A. Mackinnon, C.B., A.M.D.; Dr. J. C. Steele; Sir Harry Verney, Bart., M.P.; Mr. H. T. Wood.

THE WORKSHOP.

Saturday, February 16th.—Present: Dr. George Buchanan, in the chair; Mr. W. Warington Smyth, F.R.S.; Mr. H. T. Wood.

THE DWELLING HOUSE.—GROUP III.—
SUB-COMMITTEE A.

Monday, February 18th.—Present: Captain Douglas Galton, C.B., F.R.S., in the chair; Sir F. Abel, C.B., F.R.S.; Mr. H. H. Collins; Mr. Rogers Field; Mr. Baldwin Latham; Mr. Shirley F. Murphy; Mr. Samuel Osborn; Mr. E. C. Robins; Mr. H. Saxon Snell; Mr. H. T. Wood.

CREFELD TECHNICAL SCHOOL.

Technical schools have usually been arranged with the idea of affording instruction in the theory of the various mechanical industries comprised within their scope, the practical illustration of these fundamental ideas being, for the most part, reserved for the period during which the students actually entered the various branches of industry, with a view to which their theoretical studies had been carried on. Thus at Crefeld such means as existed of illustrating the actual practice of weaving were upon a scale calculated to represent the domestic industry, rather than the working of the modern system of factory production. The more extensive adoption of the latter principle in France necessitated similar measures in Germany, and the progress made in this direction has already been referred to in these columns.* With this modification of the general plan of working, a revision of the existing system of instruction became necessary, in order that students might acquire their technical knowledge under circumstances more closely resembling those of their future business career. The manifest need of the facility of illustrating on the spot the theories propounded by the various instructors led to the adoption of a scheme which necessarily comprised the principal features of a large manufacturing business.

Although the school has been established in its present shape mainly through the instrumentality of leading members of the Crefeld silk trade, its objects are by no means restricted to that branch of manufacturing industry. As the director (Herr Lembcke) remarked at the opening ceremony, the institution will, in all its various branches, pay attention to all kinds of weaving, dyeing, and finishing; keeping in view the idea of so bringing together the most varied results of the art of weaving, that manufacturers may acquire the facility of rapidly and with certainty utilising the effects of one material in connection with others, while refraining from being copyists in the ordinary acceptation of the term. The situation of Crefeld makes this programme quite appropriate, for the woollen manufacturing districts of Aix-la-Chapelle, Eupen, &c., are within a reasonable distance, while the important cotton industry of Gladbach is almost at its doors. There are in the immediate neighbourhood many factories engaged in various branches of the linen trade (which was at one time the staple employment of that part of Germany), and the Westphalian linen manufacturing district is not far off, so that the founders of the school have every reason to expect that the various centres of textile industry will be adequately represented amongst the students, the carrying out of their intentions on the subject as referred to being thus rendered possible.

The history of the foundation of the institution (lately opened by Herr Von Gossler, the Prussian Minister of Education), evinces the hearty co-operation of all concerned. The Crefeld Chamber of Commerce had, in the year 1878, given much attention to the question of remodelling the existing weaving school, and on the matter being submitted to the Minister of Commerce then in office (Dr. Achenbach), arrangements were made for sending an organised deputation to France, with a view of studying the operation of the technical educational institutions already existing in that country. This travelling commission included Herr Emil de Greiff, leading manufacturer, and Herr Heimendahl, President of the Chamber of Commerce. The invaluable and constant services of these two gentlemen, since that time, met with appropriate recognition at the inaugural festivities, and the success of the work now completed is attributed, in a great measure, to the practical knowledge of the requirements of the institution which are thus at the disposal of its founders.

The municipality of Crefeld gave the site (over an acre in extent), and contributed £7,500 to the work. According to a recent statement of the *Cologne Gazette*, the Prussian Landtag voted the amount of the cost of the building, which was upwards of £25,000. In addition to the necessary offices, class-rooms, lecture-rooms, &c., there is a shed building with an iron roof, containing eighty hand-looms and a number of power-looms. Electric light is used for illuminating purposes. Two large boilers supply the steam used as motive force. It is in contemplation to extend the present scope of instruction by fitting up a special department with the necessary machinery for testing the application of motive power to hand-looms, and thus allowing the domestic industry to share in the general manufacturing progress of the district. Amongst the incidents connected with the foundation of the school, is the action of the inhabitants of Crefeld, in establishing scholarships for young men wanting the pecuniary resources necessary for prosecuting their studies; this having been the form in which the golden wedding of the Emperor of Germany was commemorated at Crefeld. The maintenance of the school is provided for in the following manner:—One-half by the State, one-quarter by the municipality of Crefeld, and one-quarter by the Local Chamber of Commerce. The latter body has engaged to contribute a yearly amount of £750 from the proceeds of the silk condition house.

A notable addition to the educational resources of the school is afforded by the Krauth collection of tissues, embroidery, needlework, laces, trimming, wall-paper, &c., which was acquired by the State and presented to the school. The original school only had 21 students, while the new establishment has 140 in the weaving branch, and 30 in that devoted to dyeing and finishing.

The following summary indicates the principal features of the course of study at the new school:—
1. The instruction of foremen, designers and manufacturers for all branches of the weaving industry, and for mechanical engineering in connection with it.
2. The instruction of students who wish to learn

* Nov. 9th, 1883.

chemistry, by as thorough a training as possible in all branches of this science, and in its practical application. 3. The instruction of those students who wish to follow the dyeing, bleaching, printing, and finishing trades, in the manufacture of dyes and mordants, and in the methods of testing and valuing natural and artificial dyestuffs and chemicals. 4. The carrying out of practical operations in dyeing, bleaching, printing, and finishing in such a manner as to facilitate students carrying into practical effect the theoretical instruction they have received.

Herr Lembcke, the director of the school, had previously occupied an important position of a similar nature, at Chemnitz. The head of the finishing and dyeing branch is Dr. Lange, from Stuttgart.

THE SILKWORM DISEASE IN CHINA.

The gradual diminution of the exports of silk from Shanghai during the last few years is a subject which has been attracting interest, but of which a definite and consistent explanation has been wanting. From 1875 to 1880, the export of silk from the port in question varied between 65,000 and 85,000 bales a year. During 1881 and 1882, the annual quantity was only 50,000 to 55,000 bales; while the shipments for the season of 1883 will fall short of 35,000 bales; this limit (which was at one moment regarded as an exceptional one) not being even reached, on account of the complete failure of the second crop. The loss to the country is about £4,000,000 sterling, in addition to the diminution of customs receipts, valued at about £340,000.

These circumstances, and the facts which have brought them about, were detailed in a comprehensive manner by M. Paul Brunat, of Shanghai, in a letter addressed by him, on July 12, 1883, to his Excellency Li-Hung-Chang, Viceroy of Tientsin, and Minister of Commerce for the North of China. The district which is referred to is specially that which exports its products from Shanghai, and which (notwithstanding its important yield of silk) is of relatively small extent. M. Brunat has communicated to a Lyons journal a copy of his interesting statement, and explains the ignorance which has hitherto been general, as to the silkworm disease in China, by the fact that the foreigner is kept in the dark, as far as possible, by the natives of that country. The partial reduction alluded to in 1881-82 naturally pointed to the existence of disease, but it was not until the impending results of the present campaign became known, that microscopic research proved the existence of the malady known as *pebrine*, in a form resembling in gravity that which devastated at one time the silk-producing districts of France and Italy. That the disease existed in China in a latent form was well known to all concerned, but it was an equally recognised fact that the hardiness of the Chinese worm, and the favourable climate in which it was developed, kept in check any such grave consequences as would now seem to have resulted.

Attention is called to the fact that the diminution in shipments arises from no falling off in the foreign demand, as all the silk which arrives upon the Shanghai market is, as a rule, disposed of for export. The cultivation of mulberry trees has been on the increase, and the preliminary steps taken each season have been with a view to an augmented production. The reduced yield is attributed to the fact that a great proportion of the worms die before having made their cocoons, or make weak cocoons, poor in their quantity of silk. This season it would seem that, in certain localities, the production has only been 25 per cent. of the normal crop. Bad weather would, of course, exercise a certain influence, but the remark is pertinently made that bad weather is an accidental circumstance, the influence of which is proved to be unlikely by the regularity with which the diminution of yield has progressed of late years.

The facts quoted by M. Brunat, as to the silkworm disease in Europe, are of value in appreciating the situation of matters in China, as depicted by his further explanations. In 1853, the annual yield of silk in France was 40,000 bales, but the effects of a malady similar to that now existing in China gradually reduced the production, until a minimum annual quantity of 3,000 bales was arrived at. At first, it was thought that the disease was in the mulberry leaf, but subsequent investigations established the fact that the malady was hereditary in the silkworms themselves. It was attempted to import seed from lands where the disease had not yet appeared, but all the producing countries were gradually attacked, and although in China the disease only existed in a latent form, it manifested itself clearly in such Chinese seed as was imported into Europe.

During the period from 1865 to 1870, M. Pasteur was engaged (at the instance of the French Government) in carefully studying the causes of the disease, and in devising means of curing, or at least preventing it. His investigations allowed him to report to the following effect:—1. That the most destructive malady was *pebrine*, or disease of the corpuscles, which had caused the ravages of previous years. 2. That this disease is hereditary and contagious, and that it is developed by want of care in the rearing of the silkworms, &c. 3. That the distinctive character of this disease is the presence in the body of the diseased subject of small corpuscles, which can be seen with a microscope, and which increase in number as the malady develops itself. Further, that microscopic observation should be made use of in the selection of seeds or eggs for preservation.

This malady is compared with consumption in the human subject.

It is remarked that M. Pasteur's theories were at first met at times by disbelief, but it is upon the principles thus laid down that the measures were subsequently taken, which have resulted in the French and Italian yield of silk having recovered a good deal

Journal of the Society of Arts.

No. 1,632. Vol. XXXII.

FRIDAY, FEBRUARY 29, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CANTOR LECTURES.

Mr. Robert W. Edis, F.S.A., delivered the second lecture of his course on the "Building of London Houses," on Monday, the 26th inst., in which he dealt more particularly with sanitation, lighting, heating, and ventilation.

The lectures will be printed in the *Journal* during the summer recess.

PRIZES FOR ESSAYS.

The Council of the Society of Arts have had placed at their disposal by Mr. William Westgarth, a member of the Society, a sum of £1,200, to be awarded in prizes for essays on "Dwellings for the Poor," and on the "Reconstruction of Central London."

The first prize will be a sum of £250 for the best practical essay upon the re-housing of the poorer classes, and especially of the very poorest classes, of the metropolis.

The second prize will be a sum of £500, for the best practical essay upon the whole subject of the sanitation, street re-alignment, and reconstruction of the central part of London.

In addition to the above, there will be three further prizes of £150 each:—1. For the best treatment of the engineering considerations. 2. For the best treatment of the architectural considerations 3. For the best treatment of the sanitary considerations. Any or all of these last-named prizes may be awarded to the same essay as that to which the £500 prize may be awarded, or they may be awarded separately.

The essays must be sent in to the Secretary of the Society of Arts, not later than December 31, 1884. No essays can be received in manuscript.

The Council reserve the right of withholding any of the prizes, or of awarding the amounts, or parts of the amounts, in any manner which may seem to them desirable. They also reserve the right of publishing any essay to which a prize may be awarded.

Further particulars can be obtained on application to the Secretary, John-street, Adelphi.

Proceedings of the Society.

FOREIGN AND COLONIAL SECTION.

Tuesday, February 26, 1884; B. Francis Cobb, Vice-President of the Society, in the chair.

The paper read was—

REFLECTIONS ON CHINESE HISTORY, WITH REFERENCE TO THE PRESENT SITUATION OF AFFAIRS.

By Demetrius C. Boulger.

The complication in Tonquin has not developed in the rapid manner that would have been in accordance with the habits of this continent. The crisis between France and China continues, but, to all appearance, it is less acute at this moment than it has been for some months past, although the imminent attack on Hunghoa and Bacninh may have decisive results one way or the other. France remains in actual possession of much of the northern province of Annam. Her arms have been victorious on every occasion. The enemies she has encountered have experienced the gallantry and discipline of her armies. Even the obstacles of the climate have been vanquished by science. On the other hand, China has done nothing to secure respect for her pretensions, to retain the sympathy of those who believed that she had the moral right on her side, and to convince her opponent, and the world at large, that she has the power and the disposition to enforce respect for those rights which both Prince Kung and the Marquis Tseng have defined with much force and clearness, as will be found on reference to the pages of the Yellow Book. Yet, slow and disappointing as, in a certain sense, China's diplomacy has been to those who thought that she had acquired the decision in council and the celerity in action of a European power, I shall be bold enough to say that those who were convinced that the Chinese would act in their own way, and not in servile imitation of the practice of this continent, never believed in the Chinese Government taking some open step of hostility against the French in the prompt and gallant manner that would have received the transitory admiration of this and some other countries, and that would have entailed defeat and disaster. The Pekin Government has placed on record, in the clearest possible characters, the rights it possesses in Tonquin. Those rights have been infringed, and some may consider that they have been surrendered. But a brief study of Chinese history would suffice to convince the most sceptical that the Chinese have acted on the present occasion exactly in accordance with their own fashion, and as they might have been expected to do, as well as to prove that dilatoriness in enforcing rights must not, in the case of China, be held to indicate the determination to abandon them.

The fact above all others which the study of Chinese history impresses upon the mind, is the extraordinary and undeviating persistency of the people, and the resolution with which the Government ever recurs to the pretension of paramount authority throughout a vast surface of the Asiatic continent. It is true that that claim has frequently been reduced to an empty pretence, that there have been long periods of the cessation not merely of all authority but of all intercourse between the central authority and its tributaries, and that the task of conquest has had to be resumed, on many occasions at great sacrifice and under extreme difficulties. It is mainly because it has been so, that the fact is of more than historical importance, that it illustrates the pertinacity of the Chinese, and that it serves as a key-note to their character. In dealing with other peoples and empires, the historian finds the progress of national character and dominion marked by regular and duly ordered stages, until the apogee of power is reached, and the decline, rapidly accelerating in its descent, follows as inevitably as the night does the day, until the people are extinct or enslaved, and their greatness has become a tradition. It has been the same in Asia as in Europe. The famous dynasties of India, Persia, and Central Asia, have passed away as completely as the empires of Greece and Rome. But China has been the exception, since the beginning of tangible as opposed to traditional history. With her, the necessary penalty of decay has not followed. She has sounded the lowest depths of misfortune; she has reached the last stage of decrepitude; and then, by some marvellous essence in her composition, exhaustion, instead of entailing destruction, has facilitated the recovery of vigour. The historian could point to more than twenty occasions, within the last 2,500 years of China's existence, when it would, to all seeming, have been justifiable to exclaim over the dismembered fragments of the Middle Kingdom, *Fuit*. Yet it has emerged from all these calamities with undiminished power and reputation, and seems to have acquired renewed strength from the closer knowledge of misfortune. Sometimes the re-invigorating influence has come from a foreign conqueror, such as the Mongol, and the Manchu; but more frequently the restorer has emerged from the ranks of the people themselves, in the garb of a religious devotee, or of a social reformer. But whether it was Taitsong or Hongwou, Kanghi or Kublai, the result has been the same for the Chinese people. They have been rescued from the evils of civil war, or relieved from the oppression of effete despotisms; and in return, they have, by their diligence and assiduity in peaceful pursuits, restored the prosperity of the State, and sustained an administration capable of asserting the dignity and privileges of the Dragon Throne. The history of China is composed of successive periods of greatness, decay, and revival, which would be wearisome to the student were it not so peculiarly distinctive of this one State and people, and so opposed to the power, decline, and fall of less stable countries and less favoured nations. The Chinese have a traditional saying, that "after long abiding union dis-union must come, when again union will revive," and, while it accurately illustrates the course of Chinese history, it appropriately expresses the self-confidence of a great people, whose first article of faith is that their kingdom has been established by Heaven.

These periods of dissension and deliverance have been followed not merely by the restoration of domestic peace, but also by the vigorous reassertion of all claims to exercise paramount authority over the minor states adjoining the immediate territory of China proper. The same idea which urged Tsin Chi Hwangti—in the 3rd century before our era—to send his generals into Central Asia, Tonquin, Burmah, and, perhaps, even India, actuated Wang Kue, a famous Chinese general, a century later, when he collected a vast host for the express purpose of destroying the Tartars of the desert. Wang Kue failed, and committed suicide; but his successors, Wei Tsing and Hokiuping, waged a successful war against the barbarian enemy. During fifty years, the struggle continued, and although the Emperor Vouti had frequently to complain of the inconstancy of fortune, he extended the influence of China far beyond the desert of Gobi. Another century passed before the supremacy of the Chinese was fully recognised, but at last it was stated, in B.C. 50, that all the peoples from Shensi to the Caspian acknowledged it, and the "troops of justice," as the Chinese were called, returned. After the lapse of yet another century, the greatest of all the Han generals, Panchow, led his army through Eastern Turkestan to Bokhara, planted his standards on the Oxus and Jaxartes, and for a moment contemplated the possibility of crossing the Caspian, and carrying the terror of Chinese prowess into this continent, then subject to the sway of Imperial Rome. Fifteen kingdoms were stated to have been subjected by Panchow, and to have accepted the authority of his Emperor. I am obliged to direct your attention to this remote period, for the reason that it was then that most of the claims of Chinese suzerainty originated, not only in the Turanian regions, but also in Cochin China, Corea, Burmah, and Tibet. Moreover, these campaigns had the most important influence on European history; for before the legions of Panchow fled those Hiongnou, or Huns, whose descendants, four centuries later, lowered the pride of the Cæsars, and debased the majesty of Rome.

It is not my wish to obscure the practical point by detaining you over the events of that remote period. We have only to recollect the antiquity of China's pretensions in the first place, and in the second to consider how vigorously they have been repeatedly asserted, in the face of dangers that would deter the timid, who dread the responsibility of their own acts. When the present reigning dynasty conquered China, and assumed the personal direction of affairs, the Empire had been long exposed, under the degenerate Mings, to the attacks of foreign enemies, and to the insults of its vassals. But it had redeemed some of its diminished character, and had at least demonstrated its consistency, by successfully defending Corea against the invasion of the great Japanese ruler, Fashiba. The Manchu conquest, followed by the formidable revolt of Wou Sankwei, covered a period of more than half-a-century. When peace had been restored within the eighteen provinces of China, it left the young Emperor Kanghi in face of those obstacles and difficulties with which a Chinese ruler will always have to cope. Neither the pacific inclination of the Chinese people, nor the pre-occupation arising from the formation of a new administration, could avail to avert the complications continually arising with turbulent neighbours and refractory dependents. The latter part of the 17th century found China engaged in dealing with the same problem which had forced itself upon her two thousand years earlier. It was not without reluctance that Kanghi felt himself compelled to establish the claims attached to his high office by recourse to the sword, both in Tibet and in Mongolia. Even he, great ruler as he was, and assisted by the talent of Feyanku and other able generals, failed to secure a durable peace. He overthrew his adversary Galdan, one of the most remarkable men the deserts of Asia have produced, but he did not obtain the enduring peace which was desirable, and even necessary, in the interest of China, and which could only be obtained on the basis of her supremacy. The full accomplishment of his designs was reserved for his grandson, Keen Lung, who extended the dominion of China to the Pamir, garrisoned Tibet, and defeated the mountaineers of Nepaul, and enforced her suzerain rights among all the neighbours, who had been accustomed, in times past, to ask investiture for their rulers, and to implore aid in adversity as suppliants to the Dragon Throne. For the practical meaning of claims which some would have us disregard or treat as illusions, the Chinese, therefore, have only to go back for a period of less than one hundred years. In 1792, Keen Lung sent an army of 70,000 men to defend the people of Tibet against the turbulent Goorkhas, who had plundered one of their chief cities. The Chinese gained several victories, advanced to within a short march of Khatmandeu, and imposed a humiliating peace. This was not the last occasion of China's interference, for in 1856, when the late Jung Bahadur had begun to encroach, the Chinese Amban then declared that unless he promptly desisted, he "would report all to the Emperor, and bring down a large army to recover the Tibetan lands and to invade Nepaul, promising—with an oath repeated seven times—that in such case he would ravage Nepaul, destroy its capital, and carrying off its malik, would send him to the Emperor at Pekin, to be presented to the Emperor in his most angry mood." Even as remarkable a man as Jung Bahadur was impressed by the power of China, and Sir Richard Temple has told us how he used to "feelingly recount the blows inflicted upon Nepaul by Chinese armies." Nor is there the least reason to suppose that the Chinese attach less importance than of yore to the policy of keeping, on the one hand the landmarks of the Empire as far removed from the centre as possible, and on the other of maintaining the buffer States which have separated China from India, and which have served to keep borders held by tribes more or less independent from falling away from their allegiance. The events of the last twenty years have shown that the Chinese attach no abated value to these possessions. In our own day, we have seen three great rebellions repressed within the limits of China proper. We have witnessed them followed by a campaign in the very interior of Central Asia, which, whether we like to sneer at some of the details or not, was triumphant, and triumphant over an opponent who had been considered by capable English officers likely to re-establish a vigorous dominion at the expense of China, and to offer a not ineffectual resistance to the progress of Russia. The effect produced by the campaigns of Tso Tsung Tang was increased by the bold attitude assumed towards Russia in reference to the province of Kuldja, and by the haughty refusal to accept a treaty that defrauded China of a portion of her rights. It is not in face of those events that the statement will be lightly accepted and believed that China is prepared to waive her rights in the States beyond her frontier. The whole lesson impressed upon us by her history is, that time fights on her side; because she has nothing to gain by being precipitate, therefore, her silence must not be construed as signifying an abandonment of her pretensions.

The history of China tells us much with regard to the past, but it may be said that it cannot inform us how the claims which originated at a remote period, and which were asserted by superior resources and determination, are to be made good in the face of the resolute aggression of a great military state like France. It is no use, it may be said, quoting the precedents of Keen Lung's campaigns—even that of the Goorkha overthrow in the passes of the Himalaya—for the simple reason that the French are different from those opponents, and that they seem to be as resolute as they have shown themselves to be formidable. There would be greater force in this objection if it could be assumed that the Tonquin question is one that France will be able to settle in a single campaign. Two years have elapsed since Captain Riviere planted the tricolour on the citadel of Hanoi, and the interval has been taken up with unceasing military operations. Yet the French do not now command the whole country, within even twenty miles of that town. It is not at all clear, therefore, that the old qualities of pertinacity and endurance are not the most important towards effecting the solution of the present difficulty; and in them it is reasonable to believe that China is as well equipped as ever she was. At the same time the dangers of the situation, not merely in Tonquin but wherever the Chinese claims to predominance come into contact with the tendencies of strong Governments to encroach, are aggravated by the uncertainty felt as to the degree of importance attached by China herself to any one of these possessions, which sometimes is little more than sentimental. The wish to respect them is hampered by the doubt on this point, while the designs of those who seek to ignore or dispute them are facilitated. The lessons of Chinese history are almost as instructive in this matter as they are on the subject of how the Empire acquired and retained the prizes of military prowess. The Pekin Government has evidently drawn a very nice distinction, although it declines to reveal the basis on which its judgments are formed, between those matters which are important and to be contended for, and those which are not worth a serious effort to retain. Thus we have seen it relinquish its hold upon Siam, acquiesce for the time in the loss of Loochoo, surrender the vast territory of maritime Manchuria, and facilitate the opening of the kingdom of Corea to all the trading nations of the world. Each one of these events involved an infraction of the rights of China as the paramount power. On the other hand, we have seen the Celestials clinging with tenacity to rights that are certainly of no greater practical value than some of those she has waived, and giving increased meaning to dormant claims, by embarking upon protracted and arduous campaigns. It still remains to be seen under which category the Chinese consider that the question of their invaded rights in Tonquin should be placed, and the balance of peace and war depends on the decision arrived at in Pekin, whether the operations of the French on the Songcoi are to be regarded with the calmness that acquiesced in the loss of maritime Manchuria, or with the indignation that decided the recovery of Kashgar and Kuldja.

While the history of the Empire affords precedents in support of both conclusions, the language of the Tsungli Yamen itself has revealed a certain amount of doubt upon the subject—not indeed with regard to the extent of the Chinese Emperor's rights in Tonquin, but on the point of whether the Empire would be seriously injured or not by the operations of France. There seems to have been a hope that even the loss of the Songcoi Delta might not deprive the southern provinces of Kwangsi and Yunnan of the protecting belt of independent territory which served to supplement the weakness and shortcomings of mandarin rule among turbulent subjects, and on a disturbed frontier. But the much larger form which French operations have assumed in the course of the campaign, both in Annam and in Tonquin, has precluded the idea that the solution of the Red River question will be anything short of the absolute contact of the two countries along a frontier which, so far as China's pretensions go, will be one that is very much curtailed. It is not permissible in this Society to pursue the inquiry any further; but there can be no question that such a climax of affairs is one most calculated to give the fullest weight to the original views of Chinese statesmen on the subject of their feudatories. Did the French only seek to found a second Hongkong at the mouth of the Songcoi, or were they even to be satisfied with a portion of the delta, the Chinese might, perhaps, acquiesce in an arrangement which averted the necessity of strong measures, and which left their relations with the Lolos and other border tribes undisturbed. If the situation be found to admit of a compromise, then possibly they will revert to the policy of concession which has been observed towards the chief foreign powers during the last twenty-five years. But if there be no middle course practicable, then, undoubtedly, the Chinese will revert to that mode of action which is most in accordance with their historical traditons, and with their own predilections.

A study of Chinese history teaches us something more than that the people and Government of the Celestial Empire have the instinct of superiority, and the great gift of governing subject races. It shows that they are not devoid of the power without which great pretensions approach the ridiculous. Notwithstanding their strong partiality for peace, their unconcealed and, let it be said, very foolish contempt for the profession of arms, and their consistently acting on the assumption that the best of all remedies is the one attained without violence—notwithstanding this unequivocal declaration in the interests of peace, the Chinese have engaged in a large number of wars, and of wars, moreover, in which they were uniformly successful, until they came into contact with the superior knowledge and resources of Europe. It is assumed by those who will not take the trouble to inquire into the facts, that the last foreign war with China was one of the simplest affairs possible, that victory was achieved, and the Pekin Government humbled, in a single campaign, and that the Celestials proved themselves contemptible soldiers. The facts were indeed different. During a war which continued for four years, the English naval and military forces, although always possessing a natural and well-deserved superiority, were frequently reduced, after some signal success, to impotency, by the impossibility of reaching any vital spot of this singular empire. The possession of Canton failed to produce any decisive effect at the capital; and when the Peiho forts were carried, and a treaty was concluded at Tientsin, the Chinese employed the twelve months intervening between its signature and its ratification in strengthening those forts, and preparing for a resolute defence of the metropolis. When the English envoy sought to make his way up the river with what seemed to be a sufficient force, he was rudely repulsed; and it required another twelve months to enable a strong expedition to be fitted out and despatched to the North of China. Then the Chinese were vanquished as much by superior strategy as by superior strength; while the unanimous decision of every military authority who went through the campaign and who has left his views on record, from Lord Wolseley downwards, was that the Chinese soldiers fought with great intrepidity, and only required better weapons and more skilful leading to have made a more stubborn and, perhaps, an effectual resistance. In face of their opinions, it would be hard to say that China does not possess the power and resources necessary to engage in war on a large scale. But the indications of history with reference to the present situation, do not cease with the campaign of 1860. We have the long wars with the Taeping rebels to assist our judgment towards a just conclusion. We have the struggle against the Mahomedans in Yunnan on the one hand, and of Kansuh and the Central Asian provinces on the other. There was much in those wars, carried on by Chinese generals and officers, to show that China was moving, and that her military efficiency was far from contemptible. But in each and all of these contests the Chinese acted as if they had no better ally than time, and that the enemies they could not overthrow in a single encounter they might vanquish out of sheer weariness. They afford no exact precedent, therefore, for the collision between China and a European power which would rely upon the celerity of its movements as the surest way of worsting a cumbrous and unwieldy antagonist. But we are, fortunately, provided with a more exact parallel for this higher mode of warfare, in the achievements of that remarkable man Chinese Gordon, who has proved himself, in more than one continent, the last support of enfeebled rulers and embarrassed administrations, and who now seems to have added a new chapter to the "Arabian Nights," by the spectacle of light and confidence which his mere presence has afforded in the midst of the dreary blackness of the Soudan. General Gordon's campaign in the country round Soochow, at the head of Chinese troops of whom a portion were led into action by Chinese officers, went very near to completely demonstrate the fact that a Chinese army might be made as mobile as a European. But it may be said that the excellence of the "ever victorious army" consisted in its foreign leading and in the genius of its commander. Of course, the whole credit of the victories which entailed the dispersion and flight of the rebels along the Grand Canal belongs to General Gordon, but he has himself placed on record his opinion that "Chinese troops, led by Chinese officers, will fight very well," and that, as a matter of internal policy for China, they are to be preferred to placing Europeans and Americans at the head of the national forces. Although the matter does not admit of decisive proof, there is a large quantity of evidence, both in the actual facts of history and in the opinions of those who had direct practical acquaintance with the Chinese as combatants, to show that they possess all the essentials to form an efficient army, and that the shortcomings of military discipline might be compensated for by superior numbers, the advantages of position, and the dogged determination of the people.

There is, consequently, no reason to suppose that there can be any better guide as to what China will do on the present occasion, in her dispute with France, than to ascertain by the light of history what she has done on similar occasions in the past. She has never been oppressed by any great feeling of timidity, although the threats used in her name are sometimes in excess not of her wish but of her sensible perception of what is possible. She has made some progress in military knowledge. She has less reason now to be afraid than at any time since the death of Keen Lung. Her dominions are at peace. There is no other burning question to distract her mind. With England and with Russia she is in accord. She has collected a vast quantity of munitions of war, and she has acquired the nucleus of a disciplined army. When she had none of these things, when, moreover, she was torn to pieces by internal dissension, she presented a bold front to the demands of England and the other nations, and proved herself capable of a protracted, if none the less vain, resistance. Is there much reason to believe from these facts that the Chinese Government, however tardy its action may be, will submit tamely and without a murmur to the infliction of an injury upon interests that it cherishes without the least attempt at concealment? A French writer has very truly called the Chinese "monopolisers," and history tells us that, where they have once been supreme, they are expelled only with the greatest difficulty. Their memory is most retentive, their patience is above proof, and they are not easily diverted from the main point of a dispute to any side-issue. They have, on the other hand, it must be admitted, a way of extricating themselves from situations in which the preservation of peace seems next to impossible, and not merely of adapting themselves to altered circumstances, but of actually extracting personal advantage from a situation that seemed sure to entail their discomfiture. The French may be able to convince the Chinese that the re-arrangement of Tonquin may yet be carried out without injuring their interests; but unless they can and will take the trouble to do so, there can be only one issue for the present complication. Chinese history of recent times contains, no doubt, instances of disagreeable surrender, but it is impossible to find one where the Chinese would have to withdraw more emphatic declarations, or to make greater concessions to an aggressor than in the case of a French conquest of Tonquin. For that very reason if the history of the past furnishes a sure clue to the events of the future, it must be said that China has gone too far to draw back, and that the decisiveness with which her opinions have been expressed betrays the absence of all inclination to retreat, and bow to the decrees of a harsh necessity.

DISCUSSION.

Mr. MARTIN WOOD said that Mr. Boulger had not traced to its root the remarkable tenacity and persistence of the Chinese people and State, as no doubt he could have done. He mentioned that to revive the remembrance of a remarkable article in the *North American Review*, in 1879, by Mr. W. Williams, probably an American missionary, who wrote on the social status of China. His object was to explain the durability of the Chinese State, and he went back to two or three of those revolutions, which showed how the Chinese commonwealth remained through all such changes, with its permanence as a State as assured as ever. All this accorded entirely with the conclusions of Mr. Boulger's paper. According to his recollection, Mr. Williams traced the State durability to the strength of family principle, and referred it to the ancient Hebrew and Biblical history. He explained how this had stood firm through many revolutions and disasters by virtue of the persistence of the family hierarchy. There had been lately some indications of weakness in their material condition, and he should like to ask whether famines and droughts had been more frequent within recent times than formerly, and whether they could be traced to any undue denudation of forests, and the demands of an increasing population.

The CHAIRMAN said there was the one peculiarity about the Chinese, that after a long period of apparent unchangeableness, during the last forty years, there had been a great change in the country, and especially in the military habits of the people. When the first opium war was fought, and our troops went up the coast to occupy Tientsin, they were met by some men with matchlocks, but the majority used bows and arrows and cross-bows, and the artillery was hooped round with iron. The guns in some of the forts were of a pattern which made them look like Armstrongs, but they were made in one casting, and were probably more dangerous to the Chinese than to their enemies. But all that was now changed; they knew the value of a Krupp gun as well as a European; they had Armstrong guns and rifles very similar to those with which the German army were provided. They made their own gunpowder, and they had depositories of ammunition, arms, and warlike materials at different parts of the kingdom. This change had taken place chiefly since the English and French troops marched to Pekin; and the last time he was in China, two or three years ago, he was amazed at the difference in the fortifications. For instance, forts which he first remembered as a series of earth works, with the guns open in the embrasures, were now of the most perfect kind, more nearly resembling our own at Portsmouth. Up the Yang-tsze-kian they had armories where they could cast large guns, had lathes for turning them, and where they could turn out anything required in the shape of warlike implements. These factories were originally established under the supervision of Europeans, but the Chinese had become so apt, that they could now dispense entirely with European assistance. He had no doubt that if, unhappily, war should ensue between the French and Chinese, there would be a very different force to deal with from that which there was at the time when the combined armies marched to Pekin. He would conclude by proposing a cordial vote of thanks to Mr. Boulger, for this very able paper, which had evidently been prepared with more than ordinary care.

Dr. LEITNER, in seconding the motion, remarked that, consciously or unconsciously, some passages in this extremely able paper reminded one of parts of Gibbon, which were not, perhaps, altogether inappropriate, especially that portion in which he spoke of Roman discipline confronting barbarian numbers, This would perhaps sum up the conclusions to which those who did not altogether share Mr. Boulger's views as to the possibility of an encounter between the French and the Chinese, would arrive. But on such a question, the reader of the paper was a greater authority than one like himself, to whom the Chinese fell under the vague head of Turanian, or, in other words, under the convenient algebraical form of x, the unknown. Amongst philologists, there should be a great division made between the known and the unknown families of language; the known being the Semitic and Aryan, and the unknown or Turanian, under which class was put the great mass of information they had yet to obtain. He was afraid that statesmen were very much in the same position, and that a good deal of what they had to do, if not altogether deserving the way in which Mr. Boulger had characterised Chinese Gordon, as "the last support of enfeebled rulers and embarrassed administrators," must certainly, by their own admission, come under the convenient x, or the unknown. In the case of Yarkand, they had, some years ago, an example which ought to be immortalised by those who worshipped red tape. The Chinese Governor of Yarkand had orders not to fight until the Chinese army came to relieve him, but to hold the fortress, though he was surrounded by the troops of Yakub Khush Begi. It seemed ungracious to object to any little circumlocution or difficulty of routine that might be encountered in this country, when they had that splendid example, followed by the most remarkable instance of heroism in the Chinese Governor of Yarkand. When the enemy approached he would not give up the fort, and he would not fight; but he constructed a mine of gunpowder under the Council-room and assembled his Council; and when the first enemy put his head into the room, he quietly dropped the ash from his opium pipe on to the train leading to the mine and blew up the fort. He hoped that "the spectacle of light" given by the fair complexion of General Gordon, and the confidence which he felt in himself, and inspired in others, would cause in the midst of the dreary blackness of the Soudan, not only the pacification of the Soudanese now, but also within the next few months, a satisfactory settlement of the question which would then have to be confronted. The Chinese army going to relieve Yarkand sowed their crops, and reaped them, and ate them, and then advanced next year, and sowed their crops again, and then advanced again to the relief of Yarkand. They certainly drove out, however, when they did come, by their crushing numbers, Yakub Khush Begi, and made an end of the matter. He hoped, therefore, that, in spite of the delays of English redtape, success would crown our efforts as it had those of the Chinese. Mr. Martin Wood had referred to the question of the famines, and asked what steps had been taken for their prevention in more recent times. The Chinese Government appeared to have taken the step of allowing the governors of their outlying Tartar provinces to do what they liked until famine actually occurred, and then, when grave complaints reached the capital, the governor was decapitated. The consequence was that within the last forty or fifty years, famines in Chinese Tartary had been exceedingly rare. He was glad to be the exponent, however feebly, of the gratitude which he was sure all who had heard the paper read must feel to Mr. Boulger.

The motion having been carried,

Mr. Boulger, in reply, said with regard to the material condition of the Chinese, and the question whether famines were more or less frequent than of old, it was hardly possible to give an exact answer. It must be remembered, however, that these famines, of which they had heard so much during the last 20 years, had always followed in the train of rebellion. They had heard of famines decimating the provinces of China, but they were the results of the Mohamedan and Taeping rebellions; there were no famines in the provinces which were not disturbed. Another cause of material injury to China was the periodical inundations of the yellow river, which had always occurred since its course was diverted a thousand years ago. Beyond those two facts, there was really nothing known of the material condition of China to make one suppose that she was less prosperous than she has ever been; the state of her trade, however doubtful it might be for Europeans, was certainly most favourable to the Chinese.

TWELFTH ORDINARY MEETING.

Wednesday, February 27th, 1884; E. A. Cowper, M.Inst.C.E., in the chair.

The following candidates were proposed for election as members of the Society:—

Capper, Robert, Westbrook, Swansea.
Crossley, William J., Glenfield, Altrincham.
Curtis, Richard, Limehurst, Altrincham.
Grindley, John, Millfield, Highgate, N., and Upper North-street, Poplar, E.
Kerr, James, Church, near Accrington.
Kirkpatrick, Andrew J., 179, West George-street, Glasgow.
Lloyd, Frederick James, 4, Lombard-court, Gracechurch-street, E.C.

The following candidates were balloted for and duly elected members of the Society:—

Barker, Richard, Morialta, Forest-hill, S.E.
Binns, Edmund Knowles, The Rosary, 3, Montgomery-road, Sharrow, Sheffield.
Chester, Henry, 2, The Elms, Clapham-common, S.W.
Crossman, Colonel William, R.E., C.M.G., United Service Club, S.W.
Duncan, David John Russell, 32, Queen Victoria-street, E.C.
Habgood, William, 20, Farringdon-street, E.C.
Howard, Frank Geere, Oaklands, Cricklewood, N.W.
Humber, Thomas, Beeston, Notts.
Immisch, Moritz, 119, Torriano-avenue, Camden-town, N.W.
Jármay, Gustav, Winnington-park, Northwich.
Jones, Edward, 145, Strand, W.C., and Holmdale, Wimbledon.
Mills, Percy Batt, Belmont, Chigwell, Essex.
Parkes, Dr. Louis C., 51, Cadogan-square, S.W.
Sharp, Sidney, Millmead, Guildford, Surrey.
Wilson, Miss Lillian, Boston-house, Chiswick.

The paper read was—

INTERNAL CORROSION AND SCALE IN STEAM-BOILERS.

By G. Swinburn King.

In presuming to offer any remarks on corrosion and scale in steam-boilers, I have no thought of instructing eminent engineers and chemists in a matter concerning which it would better become me to listen to instruction from them. But, profiting from that which they have already taught me, my desire is to call renewed attention to an important subject, and to endeavour, in popular language, to interest the philanthropist and the economist, to whom it especially appeals, and to lay before the owners of steam-power, and their superintendent engineers, the results of my researches; pointing out what I believe to be the surest methods of overcoming evils which are known to cause a considerable loss of life, and an enormous annual waste of property.

Further discussion and inquiry may result in the discovery of better methods, but, in the meantime, those that have proved effectual cannot be too widely made known.

A former connection with the Admiralty led me to reflect on the importance of this question, and to take a great interest in it. Since that period I have made personal investigation into the subject in the great shipping ports of London, Liverpool, Cardiff, Hull, and other places; and in the manufacturing centres, such as Warrington and the neighbouring towns.

From an economic point of view, the subject affects the widest interests in this country: the birth-place and home of steam-power. Besides its relation to the Navy and the shipping world generally, it is of vital importance to every owner of factory, mill, or mine; and, as it must ultimately affect the cheapness of production, it should concern every class and every consumer.

Since the days of James Watt, now a century ago, when the giant steam was finally subjugated to the will of man, there has been a constant cry for more power.

In the earliest days of steam as a motive power, boilers were sometimes made of wood and afterwards of stone; and these primitive materials were followed by the adoption of cast iron, generally in a spherical or hemispherical form, as being best calculated to hold in bonds the expansive force. Copper was found to be inferior in tensile strength, and too expensive for the purpose. Cast iron has now been discarded for wrought iron and steel, and the spherical form of boiler has given way to the tubular or cylindrical, with tubular furnaces and flues running through and within it. The Cornish, the Lancashire, the Galloway, and marine boilers are all constructed after this fashion; and the greatest efforts of our ablest engineers have been directed, not in vain, to construct a boiler strong to resist, strong to drive, and strong to meet the cry for more power.

But, from the moment one of these structures is mounted into its position, insidious foes are working, which, sooner or later, will compass its destruction; and among the foremost of these must be placed corrosion and incrustation, or scale. These, while constantly reducing the strength of the boiler, appear to be the most common cause of explosion.

The Boiler Explosions Act came into force on the 12th July, 1882, and from that time to November, 1883, fifty-seven explosions had been reported to the Board of Trade. This Act, however, has only a limited scope, and does not apply to steamships having certificates from the Board of Trade, nor to H.M. ships, &c., nor to boiler explosions on railways, nor to those investigated under the Mines Regulation Act of 1872. The total number of deaths resulting from these particular catastrophes was thirty-nine, and in addition, forty-six persons were injured. Such fatal explosions —happily rare—as that on board the Royal Mail steamer *Severn* last November, by which nine persons lost their lives, are excluded from this return.

Mr. Gray, in his report to the President on the explosions occurring in the twelve months ending July, 1883, states that—

"The prevailing cause of explosion is the unsafe condition of the boilers through age, corrosion, wasting, &c.; and [he adds] a noticeable feature in many cases is the absence of any effort on the part of the steam user to ascertain the condition of the boiler, and, consequently, of any attempt to repair defective plates or fittings."

The report of the Registrar-General for 1881, for England and Wales alone, shows that the total number of deaths in that year, directly attributed to boiler explosions, was 51; but, besides these, no fewer than 652 persons were killed by scalding in various and unstated ways; and though it cannot be stated as a fact, it is fair to assume that at least a proportion of these deaths by scalding, from ungiven causes, arose from boiler explosions. These, it must be remembered, are the bare official returns of the killed. Add to them only an equal number of wounded, and it needs no vivid imagination—no affectation of word-painting on my part—to picture to your minds the greater suffering, unrecorded, of mutilated men and women, of bereaved families, and homes made desolate.

If some of these terrible disasters can be traced to their cause, and a remedy found—if life can be saved—as I am fully convinced it can be, this paper will not have been read in vain. Such is the humanitarian side of the question—but the loss of property, arising from decay, is not indicated by the number of explosions, and is far in excess of that which is thus suddenly occasioned. Every steam user knows the heavy annual outlay necessitated by rapid deterioration of boiler plates and tubes, the amount of fuel wasted by reason of scale encrusting the interior, the injury it inflicts on the boiler, and the labour and expense of chipping it out with the scaling hammer.

Mr. Robert Wilson, in his valuable "Treatise on Steam Boilers," says—

"As a rule steam-boilers explode from one cause alone—over-pressure of steam." "It often happens," he says, "that boilers are too weak for the pressure they are worked at, and no accumulation of pressure beyond this is requisite to bring about their destruction."

A boiler may be unfit to bear its working pressure from four causes, which he enumerates:—(1) Its original design and strength not being understood by those who fix the pressure; (2) the strength, although originally sufficient, having been gradually reduced by wear and tear; (3) by a sudden overtaxing as by unequal contraction; (4) by bad workmanship or material.

I propose to confine my remarks to the second of these causes, and to inquire whether the aggregate of casualties which are attributable to wear and tear cannot be reduced; and whether a remedy cannot be found for the weakening of the various parts of a boiler by corrosion and "pitting," and by the over-heating of furnace plates and tubes, consequent upon the formation of lime scale upon them.

Internal corrosion is a trouble from which few boilers entirely escape; but marine-boilers are the greater sufferers. Land-boilers are subject also to very serious and often rapid decay from external corrosion, but I do not propose to make more than a passing remark on external decay. The principal causes arise from undue exposure to the weather, unscientific mounting on possibly damp brickwork, leakage consequent upon faults of construction, or negligent management on the part of the engineer in charge. These sources of corrosion are commonly known, and the measures necessary to prevent them are now well understood; although it must be admitted they have been often culpably neglected.

Internal corrosion may be divided into ordinary corroding (or rusting) and pitting.

Ordinary corrosion is sometimes uniform through a large part of the boiler, but it is often found in isolated patches, which have been difficult to account for.

Pitting, which is still more capricious in the location of its attack, may be described as a series of small holes, often running into each other, in lines and patches—eaten into the surface of the iron to a depth sometimes reaching a $\frac{1}{4}$ of an inch. Pitting is the more dangerous form of corrosion, and the peril is increased when its ravages are hidden beneath a coating of scale or fur which may have gathered over it. For without great watchfulness this insidious canker may go on unsuspected, until a catastrophe reveals it.

Ordinary corrosion has been commonly accounted for by the presence of acids in the water, but the mysterious ways of pitting have been an enigma to engineers; and although a variety of theories have been advanced to explain its capricious and peculiar methods, none were conclusive until recent scientific investigation discovered the true agency.

It was long suspected that galvanic action, or electricity in some form, had to do with both corrosion and pitting. One theory was that voltaic action was set up between the iron shell and brass tubes, and another that differences in the quality of the iron plates produced the same result. Experiments were made, from time to time, to test these hypotheses, but they seem to have ended, for the most part, in the conclusion that electricity was inoperative either as a cause or a cure. Considered as a cure, it was set aside by some eminent engineers as mere empiricism; but most thoughtful men admitted that the action of electricity, if it really existed, was not understood. New light has since been thrown upon the subject, and altered views now prevail, but I will not anticipate.

There is another form of decay in boilers known as grooving. This also comes under the head of wear and tear. It may be popularly described as a kind of surface cracking of the iron, caused by its expansion and contraction under the influence of differing temperatures. It is attributable generally to the too great rigidity of the part of the boiler affected, and may be looked upon as resulting from faults of construction. It is, therefore, outside the scope of this paper, except in so far as it may be, and frequently is, aggravated by internal corrosion, which fastens upon the cracks and eats them more deeply into the iron.

The hard calcareous scale which is deposited by the water on the internal surfaces of the boiler, may be taken roughly as identical with the fur which forms on the inside of a tea-kettle. It is composed chiefly of salts of lime, and is known by many names in different districts. I have collected a few specimens for inspection, recently taken from both land and marine boilers, which will give a more definite idea to what it really is. (Specimens produced.) On the whole, it is perhaps a greater enemy than internal corrosion, especially in land-boilers, as it brings in its train so many destructive agencies, and involves so many expenses. As of fire, it may be said that it is a good servant but a bad master—for a thin covering of about the substance of a coat of paint is found to protect the iron from rust, and is therefore favoured by all engineers.

Beyond this point, however, it is an unmitigated evil. In the first place, it necessitates a great waste of fuel, varying according to the thickness and character of the incrustation; but the waste of coal may be fairly put down at an average proportion of not less than 100 per cent. The reason is this, that scale is a very efficient non-conductor of heat, and when it is interposed between the furnace and the water, the latter is unable to take up the heat, which, by consequence, goes away unused up the flues. Then again the iron, or other metal, of the furnace and tubes, being no longer protected by contact with the water, becomes red hot, and is burnt and twisted to the imminent danger of the boiler; while a heavy expense is incurred for renewing the plates and tubes so affected.

When the scale is thick and hard, the proper examination of the parts beneath it is impossible until it has been entirely removed. Indeed, if it were not removed, the boiler would become unworkable. Scale, therefore, being so great a foe, has to be periodically chipped away with hammer and chisel; and the process of chipping is so severe that it tends very greatly to wear out the boiler. The cost of chipping is, in itself, a heavy item; and it should be borne in mind that a factory boiler must, during the process, perhaps every six or eight weeks, be put out of work for several days at a time.

Scale will stop the feed pipe, which supplies water to the boiler; or hardening over the fusible plug in the furnace crown, which is intended to melt and give warning when the water is dangerously low, will nullify this precaution; and it has thus caused both collapse and explosion.

To dwell on the nature and detail of all the various deposits that afflict steam-boilers would occupy too much time, and it is not necessary for my purpose; but concerning carbonate of lime, which is often a source of danger, I must offer here a few remarks.

This is deposited as a pulverent body; and under certain conditions, chiefly of neglect on the part of the engineer in charge, will form a hard scale similar to that we have been considering, but by proper attention a great deal of it may be got rid of by blowing down, or emptying the boiler to the extent of a few inches day by day, by the scum cock, while it floats near the surface, or by the blow-off cock when it has settled at the bottom. If, however, this floury deposit is allowed to accumulate, and thicken the water, it will produce priming, which may be described as "boiling over," the same process which is apt to take place in boiling a saucepan of milk, or of water thickened with flour. The water is driven with the steam into the machinery, and may knock off the cover of a cylinder, or blow out the bottom of it. The second great danger which it involves is, that lying in a mass upon the furnace plates, it may prevent the steam from rising, and thus the water being lifted on the top of the deposit by the steam held beneath it, the furnace is left without protection, and is liable to be overheated, and to collapse by the pressure of the steam.

However, these particular dangers may be averted, as already indicated, by due care, without which no scientific appliance is of any avail; and touching this point, I may quote Mr. Michael Reynolds, the author of several excellent engineering works. After inculcating care in various ways, he says, in his practical and significant style:—"Any boiler can be made sensitive and hard to manage. Fire it on no system, feed it with water just as the lead plug is in danger, and fill it to the whistle; and your boiler will one day give a big kick." Many a big kick, it may be added, has been occasioned by want of ordinary attention to well-known rules.

The difficult problems that corrosion and scale have presented to engineers and chemists are evinced in the number of patents that have been taken out for chemical compounds to solve them. Hundreds of these compositions have been put into the market, and the number is still increasing; a proof, perhaps, that no panacea has been discovered; although many preparations are still in use by different engineers. These compounds have in truth become so numerous, that every new one is looked upon as another nostrum, and perhaps by the majority of interested persons it is not credited even with the virtues it may really possess.

The chemical laboratory has been ransacked in vain for an absorbent of oxygen that will stop corrosion, or an alkali that can be applied without the risk of causing priming.

With regard to the inutility of boiler compositions, I cannot do better than quote Mr. Hannay, of Glasgow, of whose invention I shall have to speak later on :—

"Boiler compositions [he says] can be classified under two distinct heads. First, there are compounds of the nature of precipitants, which are intended to render the incrusting material pulverent instead of coherent. But these do not at all prevent corrosion, and the best compouuds only partially prevent incrustation. The second class, called solvents, are chiefly ammonia salts, which form soluble double salts with lime, and so prevent incrustation. They are, however, very dangerous, as they dissociate under high-pressure steam, and act rapidly on iron, thus increasing the corrosion. Besides, in marine-boilers, under great pressure, the presence of even a minute quantity of ammonia salt causes violent 'priming,' that is, sudden ebullition, driving the water of the boiler over into the cylinders of the engine, and sometimes causing the fracture of the cylinder or piston rod. Experiments were made with nearly every possible form of chemical boiler composition, and they were all found wanting."

If further condemnation is required, it will be found in a report of Mr. Lavington Fletcher, of the Manchester Steam Users Association, an engineer of acknowledged and leading authority in such matters. He is reported as saying :—

"The number of anti-incrustation compositions was very numerous. Their component parts were veiled in mystery. Many of them proved injurious to the boilers on actual trial. Some lined the plates with a glutinous coating which, while it had the desired effect of keeping off the scale, unfortunately at the same time kept off the water, in consequence of which the furnace crowns became overheated, strained, and bulged out of shape. The members, therefore, were warned not to adopt any of these boiler compositions without the greatest caution. As the incrustation compositions were costly, blowing out was too often given up when they were used. The practice of neglecting blowing out was strongly objected to, and an explosion that occurred at Bury from that cause was referred to as an illustration."

Mr. J. A. Rowe, an able engineer and officer of the Board of Trade, observes with regard to compositions, that some of them may be useful to prevent the formation of hard deposit, but the "objection to the very best of them is that their acids tend to injure the boiler. . . . The majority of them have passed into oblivion, and those that survive seem doomed."

The superintendent engineer of a Bristol company told me of an instance in which, after careful trial, he had adopted a compound which was strongly recommended. It was used in the boiler of a ship on a voyage to America, and it answered its purpose admirably; but, on the return voyage, the engineer in charge put too much of the fluid into the boiler, and the feed-pipe was consequently stopped. The openings into the water gauges being also stopped, they continued to indicate a sufficiency of water until it had fallen to the level of the furnace crowns. The consequence was, the furnaces burned and collapsed, and the ship was seriously disabled on the high seas.

Some compounds cure one part of the evil, and do not touch others, while some again are extremely dangerous to use in a boiler under steam pressure.

Among the many inquiries directed upon the general subject, some of the most exhaustive and minute have been those instituted by the Admiralty, extending from 1874 to 1880. They were carried out by committees appointed to inquire into the causes of decay in the boilers of H.M. ships. The committees were invested with very abundant powers, and were directed to propose measures tending to increase the durability of boilers.

The results of their labours are contained in very able reports, full of valuable information and practical suggestion; but for the purpose of the present inquiry, they may be briefly summarised as follows :—

1. With regard to a prevailing belief that the presence of particles of copper in a boiler was a source of injury, they state, first, that the quantity carried into the boiler is extremely small; and, second, that no injurious effect of importance can be produced by it.

2. That fatty acids resulting from the use of vegetable and animal oils for lubrication were a source of injury, and they recommend the use of mineral oils.

3. Moist air, or water containing air, are powerful corrosive agents. They recommend increased density in the water, especially in boilers fed from surface condensers, and that the boiler should be emptied as seldom as possible.

The main conclusion, however, at which the committee arrived—the great principle that they asserted and demonstrated—was that galvanic action, induced by the contact of zinc with the iron of the boiler, was the best and only trustworthy remedy for corrosion; and that, so long as the metallic contact was maintained, little or no corrosion would go on.

They adopted a plan of hanging slabs or plates of zinc by iron straps from the stays or rods within the boiler, the zinc being held in a clip in which it was tightly bolted. The theory was perfect, but the weak point in practice was found to be in keeping up electric contact between the two metals. The zinc and the iron not being metallically connected, but only mechanically pressed together, were liable to be so far separated—by the corroding of the surface of the zinc—that the galvanic current was soon weakened and destroyed.

The committee endeavoured to circumvent this difficulty, first, by fixing in each boiler an excessive number of plates, so that (apparently) if electric contact should cease even in many plates, it might chance to be maintained in some; and, secondly, they directed a frequent examination with the view of renewing the contact, and putting in fresh plates in lieu of those destroyed by corrosion.

This system was the best they were able to arrive at, but it could be maintained only at such a cost that, to use the words of the report:—"The expense of the zinc necessary for efficient protection is undoubtedly an important element in determining how far it should be adopted." For besides the expense of fitting, examining, and renewing the excessive number of plates already referred to, the committee go on to say that "the actual waste of zinc is much greater than that due to the protection of the boiler; and it becomes important to ascertain whether that waste cannot be avoided."

With great care, however, this system was found to prevail against the inroads of corrosion; and herein was a distinct advance, although it still left the question of incrustation by lime-scale comparatively untouched. Indeed, it is stated that the scale which formed in some of the boilers in which slabs or plates were used became "harder and more adherent," and it was therefore suggested that the zinc should be periodically removed altogether, for a limited time, in order that a slight corrosion forming under the scale might enable it to be separated more readily from the iron.

Under the Admiralty system, then, it must be presumed that the bad effects arising from scale, such as the burning of the iron, the waste of coal, and the injury caused by severe chipping, are still a source of trouble and expense; and such I believe is the case. I have before me a specimen of the scale which formed in two months in one of H.M. steam vessels. It was recently taken from a boiler treated on the Admiralty method, and considered to be in very good order.

The committee's report attributed this hard scale to the action of the excessive quantity of zinc which was found necessary for protection when used in the form of slabs or plates. This, however, is now shown to have been an erroneous conclusion, the real cause being that the galvanic current set up under the Admiralty system has not sufficient intensity. I hope to explain this point a little more fully later on.

Now, having pointed out where the Admiralty method fails, I must give credit to the inventor, *per contra*, for the large amount of success it has, nevertheless, achieved. Experience teaches us that few inventions cannot be improved upon, and Mr. Weston himself, of whom I am about to speak, would be the last to claim perfection for his particular plan of protecting boilers by means of zinc.

Mr. William Weston is the Admiralty chemist at Portsmouth, and was a member of the Boiler Committee, whose collective labours are worthy of all praise. It is due to him, however, to state that the system of protection finally adopted in the British Navy was initiated and worked out by him, with indefatigable pains and assiduity; and that his method, whatever may be its shortcomings when viewed in the light of later discovery, has worked so well that near half-a-million of money must have been saved to the Navy and the British tax-payer since its introduction.

Before the application of the galvanic principle, it was not an uncommon occurrence for the boilers of H.M. ships to be worn out in one commission, or, at least, to become so unsafe as to render their renewal necessary; and, as a case in point, I may mention the *Bellerophon*, whose boilers had to be renewed, after serving only one commission of three or four years, at a cost of some £30,000.

A man who serves the Queen is content to do his duty, and must often do so without being singled out for praise or reward even for special services; but in this paper I am at liberty to mention the name of Mr. Weston with honour, and to claim for him the personal credit which is his just due.

The mercantile marine has in a great measure followed in the wake of the navy; and zinc is now very largely employed in the fleets of all the large companies. Every possible method of fixing it in the boilers has been adopted, with more or less success. Engineers who understood the principle of its action in forming with the iron a galvanic battery, have sought to secure metallic connection by many mechanical devices, while others, convinced of its efficacy, but not understanding its methods, have even thrown it loose into the boilers, to waste and crumble away to no purpose.

Zinc, indeed, had long been used with the object of depositing any minute particles of copper that might find their way into the boiler. It was useless for this purpose, as the Admiralty inquiry fully proved; but wherever it happened to be connected with the iron, it became protective, by setting up electric action, which would continue for a short time, until oxidisation of the zinc had broken the electric contact.

A superintendent engineer who was using zinc in his boilers, fixed to the iron, told me he did not believe in the galvanic theory, while in practice he was profiting by it; and when I pointed out this fact, and asked him to explain on what other principle the zinc could be protective, he was unable to answer me.

Another engineer to an important company told me he had a theory of his own, that what was called corrosion and pitting was nothing of the kind, but was solely the result of friction from the circulation of water in the boiler. On the other hand, the majority of superintendent engineers who have some knowledge of electricity and chemistry, are quick to appreciate the truth of the now ascertained cause, and the scientific remedy.

Among the numerous methods adopted for fixing the plates in boilers, the plan patented by Mr. Phillips (formerly a member of the Admiralty Committee), was considered one of the best. It consists in attaching a plate of zinc to a stud or peg, 3 or 4 inches long, projecting from the shell of the boiler, the plate being screwed on tightly by a nut, to ensure close contact with the iron. This system, however, is liable to failure, like all other modes of mere mechanical attachment, as I shall be able to show; and the only means whereby it can be made at all successful is by introducing an excessive number of plates, at great expense, and by constantly examining, cleaning, and renewing them. I have known as many as thirty-eight plates fixed in each of six boilers in one ship on this system, and as many as fifty-six in one boiler of a ship of war on the Admiralty system.

Now, it often happens that when one mind is moved to investigate in a particular direction, another, at a distance, is working to the same end; and men unknown to each other are working out the same problem, and arriving at similar conclusions. So it was in the application of zinc to steam boilers. While Mr. Weston was working up, step by step, to his present system, Mr. Hannay, of Glasgow, an electrician and chemist, alone in his laboratory, or watching experiments in steam factory or sea-going ships, was building up fact upon fact, and coming about the same time to the same conclusion in principle. In the application of that principle he made an important advance on other methods.

I will endeavour, as briefly as possible, to narrate his proceedings, and describe his invention. The investigation was commenced for the Allan Line of steamers, from Glasgow, at the request of Messrs. Allan Brothers, who, like all owners of steam power, were deeply interested in the boiler question.

The common theory held at that time was that free oxygen and carbonic acid in the water were the active causes of corrosion, and Mr. Hannay's first experiments were directed to absorb the oxygen by the ordinary methods known to chemists, with the result, however, that corrosion continued. When an alkali was added to absorb the carbonic acid, priming was caused to such an extent as to be dangerous to the safety of the machinery. He may be said to have exhausted chemistry in his endeavour to find a means of stopping the decay; but, although he succeeded in removing every trace of free oxygen and carbonic acid, the corrosion still continued after six months of patient trial. He concluded, therefore, that, while free oxygen and carbonic acid might help to corrode the boilers, they were certainly not the chief causes.

It next occurred to him that certain parts of the boiler more highly heated might, for reasons familiar to science, have their surfaces so altered as to cause them to become electro-negative to the colder parts. This view was particularly impressed upon him from the fact that corrosion so often took place along certain well defined lines, as, for instance, along the sides of the fire tube. Sometimes the corrosion was so deep that there was reason to apprehend collapse of the furnace. The cold blast going to feed the fire kept the part where the corrosion was quite cool, while the flames kept the top very hot.

Starting, then, from these facts, he deduced the theory that thermo-electric currents were set up between the colder and hotter parts of the boiler, and that the colder part, forming the positive pole, corroded by the natural law of galvanic action.

To test this theory, experiments were made with a boiler specially constructed to allow it to be heated in sections, and to stand a pressure of 200 lbs. to the square inch. Two iron plates were fixed in the boiler, one near the top, and the other near the bottom, and both were connected with a galvanometer, so that a current of electricity passing from one plate to the other could be detected and measured. The boiler was heated alternately more strongly at the top or the bottom, with the constant result that whenever the temperature rose above the boiling point, as in a steam-boiler, the cooler plate became positive, and wasted away. Thus the theory was lifted into the region of ascertained fact.

Attempts were made to keep boilers in actual use more uniformly heated, but if corrosion were stopped in some places, it was sure to break out in others.

It appeared, therefore, that the only way to prevent this corrosion was by making the iron all negative by a current stronger than that set up in the iron itself by differences in temperature. The current was estimated and found to be very small; a weak battery was fitted up, and the positive electrode, or wire, passed into the water of the boiler, the negative electrode being soldered to the outside of the boiler.

After six months' trial with this arrangement, it was found that corrosion had entirely ceased.

Two important facts, therefore, were now made clear; natural electric currents, so to speak, caused corrosion, and a stronger artificial current could be made to cure it.

The experimental boiler was then again tried with the same arrangement as before, but it was first filled with dilute acid. The current was kept going for three months, when it was found that the interior of the boiler was still quite free from corrosion, the acid having been powerless to injure it.

The actual natural current between the metals being so very small, it was thought that, instead of a battery, a simple galvanic couple, formed by a mass of zinc within the boiler, properly connected with the iron, might be sufficient to overcome it.

Now, the theory of zinc in contact with iron preventing corrosion may be illustrated thus:—

Take two pieces of metal, one of zinc and one of iron, and immerse them in a solution of water diluted with acid, both will suffer from corrosion; but connect them with a wire, and you make them at once into a galvanic couple. A current of electricity is set up between them—the corrosion is directed entirely upon the zinc, which crumbles away, while the iron is no longer injured. The zinc is the positive, and the iron the negative pole. Now you have only to continue the plate of iron till it extends all round the zinc and encloses it, and you have a perfect illustration of the manner in which an iron boiler, enclosing a block or mass of zinc, is made as a whole into the negative pole of a galvanic couple, and is thenceforward absolutely protected from corrosion. It will also become evident that if the connecting wire be broken, or the contact between the zinc and the iron made imperfect by the intervention of any foreign matter, the galvanic current will cease, and the iron of the boiler will corrode as well as the zinc—just as the two pieces of metal were seen to corrode before they were joined by a wire.

The theory, then, of the protection of iron by contact with a more electro-positive metal being unassailable, and experiment corroborating it, inquiry was next instituted to discover the cause of failure in zinc as ordinarily employed.

It was found that, as zinc had been previously used, no proper arrangements were made for ensuring a true and lasting metallic contact. To show how this fact was demonstrated, and at what pains it was ascertained, a narration of one of the numerous experiments made will be interesting:—A boiler was fitted with rolled zinc plates attached to studs, on Mr. Phillips's principle, as previously described. Every precaution was used to give perfect metallic contact. The stud was filed bright and made slightly conical, the hole in the zinc plate made to fit tightly, and the nut on the stud screwed home so as to drive the plate into thorough contact with the clean iron. An insulated wire was fixed to the plate, and led, through a stuffing box packed with india-rubber. Another wire was soldered to the outside of the stud. When a small battery and a galvanometer were put in circuit, the current passed from the zinc to the stud, and so round again to the battery, proving that the contact was perfect. There were six plates put in on trial altogether, and the result was that, after three days' boiling, two of the plates had become metallically disconnected from the boiler—that is to say, no current could pass through the circuit. After five days, another plate became useless, owing to the same cause. At the end of twelve days, only one plate was in electrical contact with the boiler. The boiler was opened after thirteen days' steaming, and it was found that none of the plates were really used up, but that a layer of oxide of zinc had formed between the plate and the stud, and the zinc was thus rendered useless. It must be remembered that these six plates were all specially fitted, and ought to have acted thoroughly well if anything could. The sixth plate was sent away with the ship again, but only remained active two days. It was eaten through when the boiler was again opened.

By this and other experiments it was proved that no mere mechanical attachment of the zinc will suffice to ensure continued maintenance of the galvanic current, because, no matter how closely the zinc is fitted to the stud, or bolted to the iron, the water creeps in between, and soon destroys the metallic contact.

It was also found that the use of plates was faulty. If they are cast, they split up and fall to pieces in a few days, and if rolled, they are only about a quarter of an inch in thickness, and they soon dissolve away.

To meet the various defects in the use of zinc plates, Mr. Hannay designed a ball of zinc, with a copper conductor cast through the centre of it, the copper being so combined and amalgamated with the zinc at the junction of the two metals, as to form brass, and thus no corrosion could form between them to stop the galvanic current. The zinc is well hammered at a certain temperature, ensuring long existence in an efficient condition.

This ball of zinc is called an "electrogen;" it is fitted in any convenient part of the boiler by a simple device, and a wire from each end of the copper conductor is soldered firmly to to the iron. From this moment the electrogen keeps up an uninterrupted galvanic current, and the whole of the interior of the boiler is absolutely protected from corrosion so long as any of the zinc remains.

It was ascertained, by further experiments, that a very small surface of zinc was sufficient to afford protection for a radius of twenty-five feet from the point of contact, and the spherical form of the zinc was adopted because it would maintain perfect protection with a minimum of waste, the large surface exposed by plates, in proportion to their bulk, being quite unnecessary. Herein, therefore, was the means of avoiding that waste which the Admiralty Committee stated was "much greater than that due to the protection of the boiler," and for which they sought a remedy.

Two electrogens are found in practice sufficient to protect an ordinary "single-ended" marine-boiler in which, by some engineeers, forty or fifty plates would have been considered necessary. The electrogens will last for about six months, while the plates would probably corrode away in as many weeks.

The advantages that Mr. Hannay claims for his system, as compared with any employment of zinc plates, are that it is less expensive and more effectual, and that the protection it affords does not depend upon a chance contact that may be destroyed at any moment. But a further gain, perhaps even greater than these, is that it does not allow scale to form in a boiler at any time to a much greater thickness than that of an egg shell, or a coat of paint.

The zinc ball, with its perfect contact, generates a current of greater intensity than zinc plates mechanically fitted, and the consequence is that a portion of the water is slowly decomposed, and the hydrogen that is evolved at the negative pole, all over the surface of the iron and underneath the scale, forces off the scale in thin flakes by mechanical action, as soon as it becomes thick enough to be impervious to the hydrogen. In this way the scale is kept forming and re-forming, hanging in loose flakes, or falling off as it becomes detached from the iron.

Thus all the evils attending incrustation, which have been before enumerated, are avoided. Fuel is saved, burning of the iron is prevented, and chipping becomes no longer necessary.

The reason why scale becomes more hard and coherent under the zinc-plate method as used in the navy, is that while the galvanic current set up acts in retarding corrosion, it has not sufficient intensity to decompose the water and deposit a layer of hydrogen on the iron; so the scale grows on a firm surface, and is not pushed off by gas evolved beneath it.

When zinc is merely pressed against iron, the two metals really touch each other at minute points only, and thus great resistance is introduced. Resistance in this case means that the current is destroyed to a certain extent as electricity, and converted into heat; just as the resistance of the break destroys the motion of a train and converts it into heat. Then the water creeping in between the two metals, and forming a non-conducting oxide between the two surfaces, increases the resistance, and ultimately prevents the passage of the current altogether.

When resistance is prevented, and the full intensity of the current is allowed to pass from the zinc to the iron, and back through the water, hydrogen is slowly accumulated at the iron surface, yielding protection from corrosion, and, at the same time, loosening and throwing off the scale.

The value of any discovery that will prevent the formation of hard scale in land-boilers can scarcely be over-rated. These boilers in which fresh water is used, do not suffer so much from internal corrosion; but the calcareous scale, which forms in them, has been always a great source of trouble. Compositions have failed, and zinc plates are ineffectual to remove it.

The electrogen, however, seems to have solved the problem; and to make it sufficiently active in fresh water, the homœopathic principle is applied of *similia similibus curantur*. A small quantity of salt, which is the active corrosive agent in sea water, is made, not only to cure the disease of corrosion which it actuates, but to stimulate an electric current which entirely disposes of incrustation.

Sea water contains on an average 32 to 38 parts of salt in 1,000. Mr. Hannay's homœopathic dose is ½ an ounce to a gallon, or 4 parts to a 1,000; and, as no proportion less than 8 times this amount has any effect on iron, no harm can be done to the boiler, even if it were not protected by the zinc. Into brewers' "tanks" and other boilers, the water from which is used for manufacturing purposes, salt, of course, cannot be admitted; but this difficulty is overcome by a simple device, by which the salt is kept separate from the body of the water.

Land-boilers, in many districts, would become quite unworkable through the accumulation of scale, if it were not chipped off every five, six, or eight weeks—of course at considerable expense—the boiler lying idle during the process. With electrogens it has been proved that boilers will work more than twice the usual time without any necessity for opening them, and that then the loose flakes of scale may be cleared out in a short time with a hose and a broom. Meantime, no thick scale being allowed to form, it becomes perfectly harmless; the coal consumed does its full work, and steam is made more freely.

Engineers, who have witnessed the results in several recent trials, have stated their opinion that the discovery will revolutionise the treatment of land-boilers.

In conclusion, a further and valuable addition has been made to the marvellous applications of electricity, which have pre-eminently distinguished the last decade of scientific discovery.

But there is no finality in human invention. More light will dawn, and with it new marvels will arise. It may be that, before another decade has run its course, electricity or atmospheric power will have superseded steam, and the huge iron boiler of to-day will be looked upon as the clumsy expedient of an ignorant generation.

Till then, while the evils we have been considering exist, and are potent for the destruction of life and property, inquiry into their nature and origin is both desirable and necessary, and time will not have been wasted in seeking to discover the most effectual remedies.

A number of models and diagrams, illustrating boiler explosions, were lent for exhibition by Mr. E. B. Martin.

DISCUSSION.

Mr. E. B. MARTIN said he had endeavoured to collect materials to illustrate the subject of boiler explosions, and had published the results of his investigations over a period of twenty-one years. The last time the subject was before the Society, Mr. Walford and other speakers made use of his statistical returns to base their calculations upon. When asked to give the result of his investigations to the Parliamentary Committee in 1870, he arranged all the results of explosions under general heads. First, the faults in boilers due to constructional materials, faults which might be prevented by careful periodical inspection, such, for instance, as corrosion, and faults attributable to want of care on the part of the men. To-night they were dealing with the evils which might be protected against by periodical inspection. By the tables, a total was given of 1,258 explosions, killing or injuring 385 persons; out of that number internal corrosion was the cause in 115 cases, causing the death or injury of 238 people. It should be remembered that those figures represented only a very small portion of the risks of internal corrosion, because thousands of boilers must have been found corroded, and had been renewed before they came to the stage of bursting. Internal corrosion took several forms. One was the corroding of the whole of the interior of the boiler very gradually, and that was a very difficult thing to detect, because there was then no part which could be particularly detected more than the rest. The next case was pitting—a very puzzling kind of corrosion. In pitting, the plate was perfectly sound everywhere except in certain places. The holes were very deep, and larger in the interior than at the front, like those in granite rocks, as if they were scooped out from the inside. Another form was what is called channelling, where it looked as if the plate had been chiselled out with a gouge. That was very seldom seen in the inside of a boiler, unless the boiler had been left without any water in it. Another most formidable form was furrow, where a nick was cut in the edge of the plate. That was because the plate was not only subject to corrosion, but to bending backwards and forwards, when any corrosive action of the water would attack it very fast. That was found chiefly in the tubes of locomotives and in the ends of Cornish boilers; it was owing to the strain at that part of the boiler between the flue and the shell, and if there was not sufficient play that peculiar furrow was produced. Another evil was scale—that was found in every variety. He had found it varying from a substance almost like flannel to quite hard scale, and from an almost impalpable scale to balls as big as one's fist. The scale slipped down in cylindrical boilers, and formed in the bottom a very hard agglomeration. He might also refer to the description of corrosion known by the formation of a "pocket," and that was another form which must be guarded against, if the result of the electrogen was to bring down the scale in flakes to the bottom of the boiler. Then as to the remedy generally suggested for all those evils of internal corrosion, the one he had advocated most strongly was to get better water It was a great pity to use an antidote, and to continue the poison. The author of the paper had pointed out that this could be comparatively easily done. It was better worth while to spend a great deal in doing something with the water itself, than to do anything with the water afterwards in the boiler. Those evils were mostly met with in connection with the use of sea water in sea-going boilers. The introduction of electricity as affecting corrosion and scale was not exactly new. He had tried an apparatus to prevent the deposit of scale, an apparatus with prongs pointing in all directions, which were supposed to collect the electricity of the steam as it was formed, and to convey it away, but he could not find the slightest alteration, though he had tried it month after month. Those who started that idea, he thought, went on a wrong principle, because they began by saying that electricity was formed by the conversion of the steam. They knew that Faraday had said that was not true, and there was no electricity, as far as hey knew, in the formation of steam, but that it was formed very rapidly by the friction of the globules against the edges of the outlet. He had tested this by a model hydro-electric boiler, in which the steam was caused to produce frictional electricity, and the result of his tests showed that it was not the electricity of the steam that had anything to do with the scale forming. It was no good, therefore, to do anything in that direction to prevent it. The author, however, seemed to have started on quite another principle in using galvanism, but from what he had seen in the plates of boilers, he thought it had no effect at all, because, as had been explained, the contact with the outer shell was not made sufficiently good. The author had shown them, however, how to get over that difficulty by the electrogen, and that looked as if it was at least a start on the right principle. Without the test of experience, it was difficult to say whether or not the apparatus would succeed, but there was enough in it to make it well worth while to try its application to land-boilers. There was one danger to be guarded against. When an antidote was put into people's hands to guard against a particular evil, they sometimes would not take the trouble to remove the evil itself, and it was to be hoped people would not, therefore, become careless in getting fresh water, which he thought was the very best of remedies. These were temporary matters after all, for before long they must get their direct power from the fuel that was burnt, so as to make their engines rather fire than steam-engines.

Mr. Loftus Perkins had only the experience of using perfectly pure distilled water in his boilers, and he found that it did not affect the iron at all. When at sea they carried the requisite fresh water with them, and if distilled fresh water were used, boilers would never wear out at all. He found it was no use attempting to distil sea water, the salt was carried over mechanically. Distilled fresh water alone was used in his boilers. Of course he was excluding grease and everything, except pure water. By pure water he meant water distilled a great number of times, and that should be done of course before it was put into the boiler. That was very easily done with proper arrangements. He had had boilers and heating apparatus working 50 years, and they were just as good as the day they were made. In the heating apparatus distilled water was not used, and the result was that there was a very small quantity of sediment which could easily be got rid of.

Mr. King sketched the apparatus which Mr. Hannay suggested could be introduced into Lancashire boilers between the flues. The apparatus might be put any where. A wire came from each end of this electrogen, and was fastened on to the iron where most convenient. That was soldered firmly to the iron of the furnace on both sides, and as long as that contact remained perfect there was a continuous electric current between the whole surface of the iron, wherever the iron was exposed, and the zinc. The electrogen was a ball of zinc, through the middle of which a strong bar of copper passed as a conductor; at each end of the copper was a wire, then the electrogen was dropped into a cup, and the ends fastened on to the iron wherever the greatest amount of intensity of current was required, for instance, under the furnace, where the greatest amount of corrosion took place, would be best.

Mr. Henry Maudslay said the principal subject of the discussion had been land-boilers, with which he had not so much acquaintance as with marine boilers. In the early days of steam navigation, some large copper boilers were made for vessels employed in the Bay of Naples, where they had to lie for some time, and would have been exposed to the corroding action of the water there, which was strongly impregnated with salt and sulphur, and they answered very well. In high-pressure boilers, of course, other difficulties would occur; and in the days when chemical science was not so far advanced, and so much was not known with regard to the antagonism which would occur between the materials used and the impurities contained in various waters, a variety of chemicals were recommended for the purpose of preventing deposit. In the case of locomotives which had to make long journeys, there would be so much difference in the quality of water obtained in various districts, that the whole question became very difficult, and there was quite room for another paper, showing the different conditions which would prevail in marine and locomotive boilers as compared with those of a stationary engine, where the chemical properties of the water used could be exactly ascertained. For instance, the water at Epsom was impregnated with Epsom salts, and though it would seem pure when put into the boiler, the moment it was heated, chemical substances would be deposited, which would have a material effect on the iron. Water from the chalk, and from other sources, would leave deposits of a very different character. It would be very useful if a tabular statement were prepared showing the components of various waters, and their effects on the iron or steel of which the boilers were made. A remedy might then be devised in the shape of some electrical or other apparatus by which those effects could be counteracted.

The Chairman said he could confirm what had been said as to the great difference of water in different parts of the country. In some places it was so bad that it could not be used at all; in one district it contained salt and soda, and in others it was very hard. On some lines the difference was so great, that when an engine got furred up, it was sent to another locality and there got cleaned out.

Mr. Porter said the water at Camden-town Station of the London and North-Western Railway was formerly taken from a deep well, but it struck Mr. Webb that it would be better to get a purer water, and it was now brought from Bushey to Camden-town, and was there treated by Dr. Clarke's process, with the aid of such mechanical means as he had devised for carrying out that system on a large scale; the object being to deprive it of the calcareous matter in solution.

Mr. Wavish asked whether the author considered it was more important to keep up a rapid circulation in the boiler than to use other means. He found that by securing a rapid circulation he could keep the boiler clean, and also get an equalisation of the expansion of the boiler-plates. Of course he was speaking of land-boilers, and he would show the meeting a pipe which had been four years in work, and had never been cleaned. He kept up the circulation by means of a tube from the bottom, supported by vertical bars from the furnace.

The Chairman said there was only a scale of from $\frac{1}{4}$ to $\frac{3}{8}$ of an inch on the pipe exhibited. The Galloway tubes, commonly put into boilers passing up from the bottom, were very useful in promoting the circulation in Lancashire and Cornish boilers, and it was very important to keep them at the same temperature at the bottom as the top. He had known some so badly constructed that, when there was steam up at the top, you could bear your hand in the water at the bottom. The condition of the plates when such was the case could easily be imagined.

Mr. W. Haworth asked what means Mr. Wavish adopted for getting rid of the lime and other deposit in the boiler, which would increase from day to day unless there were some means of blowing it out.

Mr. Wavish said it was blown out occasionally; but it was reduced to such a small quantity that there was very little to take out.

The Chairman remarked that the stone did not go away with the steam, and must fall into the bottom of the boiler. He should imagine that Mr. Wavish was favoured with very pure water.

A Member asked if any means were taken to purify the water before using it.

Mr. Wavish replied in the negative. It was the East London Company's water. The boiler had not been scaled for four years; and he only blew out once in three months.

Mr. Porter remarked that the East London Water Company's engineer, who had six boilers under his management, had adopted the Porter-Clark process for purifying the feed water for those boilers.

Mr. NELSON pointed out that in many steam-boilers, when the water was in ebullition, it was continually rising to the surface, and the deposits which were made were enamelled on by the heat of the boiler. His remedy would be not to let the enemy get in at all. It was not possible to use the scum-blower to advantage, unless it was used continually, and until the boiler was almost emptied, there would not be a particle of sediment run out. Of course that was seldom done, because, if so, steam could never be got up at all. In conclusion, he proposed to show the working of a small model which he had constructed.

Mr. J. J. EASTICK asked how the small quantity of salt spoken of was proposed to be kept from the body of water in the boiler in Hannay's system, and also how, when the pieces of scale were sent round, there could be any water behind them to become decomposed, because he thought the scale would be perfectly dry.

The CHAIRMAN said that the stone formed was sufficiently porous to become damp. He thought the water would get to the plate, although in small quantities; at least that was his own observation.

Mr. LAYCOCK said that a very valuable discovery had been brought before them, its adoption by the Admiralty having led to a very large economy. It was not merely a question as to whether pure water in a particular boiler would give the same result as in others, or would cause no corrosion. They knew, as a matter of fact, that corrosion did exist, and that it was one of the greatest difficulties which had to be contended against. If Mr. Hannay's system was an improvement upon that of the Admiralty, that was a matter which was surely worthy of better attention than had been given to it. He thought an important question such as this should be brought forward at another time, so that the Society might see whether this was a good invention or not.

Mr. A. J. MAGINNIS said with regard to marine boilers, of which he had a number under his superintendence, that he had some time ago tried the "electrogen," and the results at that time were not satisfactory; but he must do Mr. Hannay the justice to say, that the steamers in which they were tried, afterwards passed out of his superintendence. He was only told that no throwing off the scale could be seen. For aught he knew, it may have had the protective qualities of the zinc he had previously used in the boilers. Up to the present time, with everything that chemists and scientific men had brought forward, those who had charge of marine boilers had discovered no better way of keeping down scale than the old method of chipping it away by hand labour. With regard to compounds, one great question to marine boilers was the length of time that vessels were in port. He knew of marine boilers now working continuously in first-class steamers, which had been 14 years in existence carrying high pressure, and those boilers were very recently subjected by the Board of Trade to double the working pressure; he could not, however, say whether zinc was used in them. He was acquainted with some boilers ten years old, in which zinc had been used almost from the first. He had tried the boilers in two steamers, using the compound in one and not in the other, the vessels being in the same trade and using the same water, and he found that he could scale the boiler in which the compound was used in two or three days less time. That result was more particularly observable in the narrower portions of the boilers. One difficulty, however, referred to was that the compounds attacked the iron or steel, as the case might be, of the boilers. He had not been able to try that with boilers carrying 80 lbs. or 90 lbs. pressure, but he had placed some borings, filings, and rivets, and had them suspended for six years in the compound in a cold bottle, and to the present day nothing of the kind could be seen. Time was money to owners in those matters, and £20 or £30 expended in putting a compound into a boiler was a trifle if a steamer was thereby enabled to get away several days sooner than she otherwise would. Vessels had, of course, to sail to all parts of the world, and good scalers could not always be found—even engineers were not always qualified to look after the scaling of boilers. Though desirous of giving credit where credit was due, he thought Mr. Weston was getting more praise than he ought in this matter, because in the mercantile marine, zinc had been used for years before the Admiralty ever thought of it; to his own knowledge it had been used ever since 1867. Metallic connection was the important point to be attended to. Scaling was a most expensive process, and would cost sometimes more than £100 in a foreign port, but still it was money well spent. As to the use of distilled water, new steamers generally made their first run with salt water, for the purpose of getting a coating on the boilers, and preventing the formation of red rust, which would lead to very bad corrosion indeed. He had found plates which had been allowed to get into that condition pitted through and through in three months, where no protective scale had formed on the tubes. With regard to the use of scum-cocks and blow-off cocks, he quite agreed with the Admiralty instructions in doing away with them, but there were occasions when they might be used with advantage, so as to get out the grease and other things which had come in from the machinery, by blowing down the boilers to the level of the furnaces. Another point was to secure the proper circulation of the water from the time the fires were lighted. That was in fact the salvation of boilers, and for that purpose he always took care to connect his boilers with a donkey-engine, and by other means to ensure that the water should flow in continuously at the top of the boilers until they were filled up.

Mr. J. Green said that notwithstanding the expense of rolled zinc, the Admiralty were employing it. He desired to know whether the wires were altogether contained within the boilers or not.

Mr. King said they were entirely inside.

The Chairman said—I quite agree with Mr. King, that England, being the home of the giant steam, thanks to Newcomen, Watt, and Trevithick, we do right in spending some time in thoroughly mastering an apparently slight fault, which really is but a slight fault now that we know what it is; but it may, I think, be taken as a lesson not to try carelessly, and give up rashly, a promising invention, without first thoroughly investigating all points, to see that we are not deceiving ourselves. Thus, if we lose the electrical contact that we need, and do not know it, we ought to thoroughly examine and discover whether all the circumstances really are what we wish for, and whether all contacts are perfect; this Mr. Hannay seems to have done, and, of course, with the immediate result of maintaining the galvanic current between the zinc, now commonly used in marine boilers, and the iron or steel of the boiler. One of the first applications of zinc, as a "protector" of other metals, was that of Sir Humphrey Davy, who put large blocks of zinc into a ship's side, in contact with the copper sheathing used in his time for wooden ships, and with the effect of preserving the copper from corrosion. The result was very curious, as the weeds and barnacles thought it was done for their comfort, and they forthwith clung all over the copper sheathing, which no longer poisoned them off; this, of course, made the ship so foul that the plan had to be abandoned. The true hard scale, spoken of by the author of the paper, composed chiefly of carbonate of lime, is deposited in a neglected boiler in a crystalline form, and if allowed to become very thick, as we see in some samples of "Sunday stone," may ruin a boiler; in fact I have known of a set of tubes being taken out of a ferry boat in one solid mass, with the stone between them; and in some few cases, where the stone was chipped away, there was found to be no boiler-plate left at particular places, so that the stone had been the only boiler-plate for some time at that spot. But these are rare cases of thorough neglect. If a proper composition is regularly added, the carbonate of lime does not deposit in a crystalline condition, but in what chemists call "an amorphous condition," and in such form it falls as mud or fine sand to the bottom of the boiler, where it can be blown out. A boiler thus attended to, and fed with fresh water, does not corrode or scale heavily; this I say from experience of many boilers, and I have never had a blow-up or anything approaching one, or in fact any trouble with any of them. I have known many copper boilers, in past times, and they were very satisfactory, except in first cost; and I have pulled out two old low-pressure copper waggon boilers that had holes in them plugged with wood. I have only a few years since taken down what I believed to be the last low-pressure copper "haystack boiler" in London, and which was in very fair working order; the copper was excellent. It was, of course, replaced by a double-flued high-pressure Cornish boiler. Many years ago, at the request of a friend, I tried a composition containing ammonia, but although it brought off some of the scale, it was very bad for the boilers and for the engine, which it rusted all over, inside and out. Mr. King has spoken of the idea, now exploded, of small particles of copper being carried over from surface condensers. This is a mistake, and the pitting of iron boilers that took place when surface condensers were first introduced, was from the grease and oil then used becoming converted into acid grease, by long boiling with the water at pressure. I mention this because, having put up boilers to work at 220 lbs. per square inch, for the purpose of forming acid grease, I found that $4\frac{1}{2}$ hours was quite sufficient for the purpose. However, for some time now, salt water has been used in marine boilers, and as that is changed from time to time, there is lime enough in the water to neutralise the acid grease if any is formed, and the use of mineral oil in place of vegetable oil has pretty well cured the evil. The author has spoken somewhat of undue expansion and contraction of the metal of a boiler due to unequal heating. Now, in certain cases the strains induced are most severe; for instance, a single-flued Cornish boiler, full of cold water (and particularly if the brickwork is damp and cold), may, if heated quickly, have 20 lbs. pressure of steam in it, and yet have the bottom so cool that a person can bear his hand on it. In such case the top of the boiler, at and above the water line, is longer than the bottom, and the strains are very severe. If several boilers are used in one works, it is easy to arrange a small pipe to take steam from one boiler at work into the bottom of the cold boiler, and thus heat it up fairly. Bad effects are often produced by the mistaken notion of feeding cold water to the bottom of the boiler; this I have known done with a number of Cornish boilers in London, and the boiler repairs were excessive. The right plan was, I think, first suggested by Mr. Lavington Fletcher, viz., to run a long and perforated feed-pipe into the boiler, above the crown of the furnace (so that, if the valve leaked, it would not leave the crown dry), but below the waterline; then the cold water distributed itself amongst the hot water that already contained steam, and no violent cooling of particular plates or of the bottom of the boiler occurred. In conclusion, I think the thanks of the meeting are due to the author for his paper.

The vote of thanks proposed by the Chairman was accorded unanimously.

Mr. King, after thanking the meeting, said in answer to observations made, that the salt was kept from mixing with the water by a contrivance enclosing the "electrogen." As to the doubt of the hydrogen getting underneath the scale, and peeling it off, the best answer was that it actually did so. Whether it got through the cracks or through the pores of the scale, he was unable to add, but he should think it was a little of both. In 99 cases out of 100, this apparatus had been successful in preventing scale from gathering to any thickness beyond that of an egg-shell, which was the thickness engineers liked to have in their boilers. He might add that the chippers, finding their interest going, had sometimes cut the wires and thus stopped the electric current, and at other times these were found not to be properly fitted by the men, and that instead of seeing that they had positive metallic contact, the men had soldered the wires on to rusty iron, thereby, of course, stopping the galvanic current. As to the credit due to Mr. Weston, until he introduced the zinc system into the navy, the boilers were wasting away to a very great extent, and credit was at least due to him, from an economical point of view, for bringing that system into use in the navy.

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION.

The following Sub-Committees have met at the Society of Arts since the meetings recorded in last week's *Journal*:—

School and Education.

Wednesday, February 20th.—Present: Lord Reay, in the chair; Mr. Alfred Bourne; Mr. J. G. Fitch; Rev. T. Graham; Mr. T. E. Heller; Mr. A. C. King; Lieut.-Col. W. R. Lewis, R.A.; Mr. Philip Magnus; Dr. R. J. Mann; Inspector-General F. J. Mouatt, M.D.; Mr. T. Nordenfelt; Mr. W. Woodall, M.P.; Mr. H. Trueman Wood.

India.

Wednesday, February 20th.—Present: Sir Joseph Fayrer, M.D., F.R.S., in the chair; Sir George Birdwood, M.D., C.S.I.; Deputy Surgeon-General N. Chevers, M.D., C.I.E.; Mr. R. A. Dalyell, C.S.I.; Surgeon-General C. A. Gordon, M.D., C.B.; Colonel J. Michael, C.S.I.; Mr. W. G. Pedder; Mr. H. A. Perry; Mr. J. R. Royle; Mr. R. Stewart; Mr. A. Stirling; Surgeon-General Townsend, C.B.; Mr. Frederick Young; Mr. H. T. Wood.

Education Congress.

Tuesday, February 26th.—Present: Mr. B. St. John Ackers; Rev. T. Graham; Mr. Philip Magnus; Rev. T. W. Sharpe.

Laboratory.

Tuesday, February 26th.—Present: Sir Joseph Lister, Bart., F.R.S., in the chair; Mr. W. Watson Cheyne; Dr. W. H. Corfield.

Obituary.

John Hullah, LL.D.—This distinguished musician, who had been for many years intimately connected with the Society of Arts, both as member and examiner, died on February 21st, in the seventy-second year of his age. Throughout a long life of hard work he has figured as one of the most conspicuous and energetic advocates for the extension of musical culture amongst the masses. Born at Worcester, June 27, 1812, John Pyke Hullah came at a very early age to London, which thenceforth became his home. He did not, however, enter upon any course of musical training until 1829, when he became a pupil of William Horseley. Three years later he studied singing under Crivelli, at the Royal Academy of Music, and made his *debût* as a composer in 1836, when his opera, *The Village Coquettes*—the libretto by Charles Dickens—was produced at the St. James's Theatre. The first training school in England was founded by Dr. Kay (afterwards Sir James Kay-Shuttleworth) and Mr. Edward Carleton Tufnell; and Mr. Hullah accepted the post of musical instructor. In 1841 he organised a school at Exeter-hall for the education of schoolmasters of day and Sunday schools, on a system founded upon that of Wilheim. On June 21st, 1847, the first stone of St. Martin's-hall was laid. The building was opened, in an uncompleted state, on February 11th, 1850, and there Mr. Hullah continued to hold his entertainments, until it was destroyed by fire in August, 1860. During the twenty years from the foundation of his class to the destruction of St. Martin's-hall, it is estimated that no fewer than twenty-five thousand vocalists received tuition at Mr. Hullah's hands; and many vocalists of prominence were introduced to the public, amongst whom may be mentioned Mr. Santley, Mr. Lewis Thomas, Miss Palmer, and Madame Lemmens-Sherrington. Mr. Hullah held from time to time many official appointments. From 1844 to 1874 he was Professor of Vocal Music at King's College, and occupied similar posts at Queen's College and Bedford College, London, since their foundation. He was examiner to the Society of Arts in the Theory of Music from 1859, when the examinations were commenced, until the time of his death. In 1876, he suggested the examinations of the Society in the Practice of Music, and these were commenced in 1879 under his superintendence. In March, 1872, he was appointed Inspector of Training Schools for the United Kingdom. In 1875, the University of Edinburgh conferred upon him the honorary degree of LL.D.

General Notes.

Wheat Production in New South Wales.—The development of the wheat-growing industry in New South Wales has been uniformly steady of late years, as shown by the following returns:—

1874	2,273,620	bushels.
1875	2,148,394	,,
1876	1,958,640	,,
1877	2,391,979	,,
1878	2,445,507	,,
1879	3,439,326	,,
1880	3,612,266	,,
1881	3,717,355	,,
1882	3,405,966	,,
1883	4,042,395	,,

It will be seen by these figures that the wheat crop of 1883 was considerably in excess of those of previous years.

Acoustic Indicator for Spindles.—Professor R. Escher, of Zürich, has invented an apparatus for remedying an inconvenience which has been found to exist in the ordinary appliances by means of which the number of spindle-revolutions is indicated. He remarks, in a communication to the *Centralblatt für Textil Industrie*, that by the present system a relatively large expenditure of power is required, while, for various mechanical reasons, the records arrived at cannot, in all cases, be taken as correct. He has found a simple means (by using a spool with glued paper fastened round it, and with four holes cut in the paper at equal distances) of obtaining a distinct musical sound from the pitch of which the exact number of revolutions is found. F (first space in treble clef) represents 2589·4, and an octave higher exactly double (5178·8). The difference between each semitone is graduated; thus, between F and F sharp, there is a difference of 154, while between E and the next F the difference is 290·6. The table annexed to the communication in question is based on the French normal pitch. For the benefit of those whose musical knowledge is defective, the suggestion is made that a pitch-pipe might be constructed, bearing on it the necessary indications of the number or revolutions appertaining to each chromatic interval. By this means it is believed errors would be rendered improbable, it is considered.

Amber.—Natural amber must be regarded as a mineral resin, though probably derived from an extinct coniferous tree. Its ultimate constituents are: carbon 78·82, hydrogen 10·23, and oxygen 10·95; and its specific gravity varies from 1 to 1·1. It becomes negatively electric by friction, and melts at a temperature of 550° to 750° Fahr. Amber is found on the shores of the Baltic and Adriatic seas, and to a smaller extent in Sicily; generally near the surface of the ground, but also at the bottom of the sea. Its yellow tint varies in depth, while it is sometimes transparent and sometimes opaque; but the clouded variety is the more highly esteemed. The demand for this substance, especially in the East, has led to the manufacture of an artificial amber; but the true may be distinguished in many ways from the false, and also from gum copal, which somewhat resembles it. Real amber is never perfectly uniform in tint, as are both artificial amber and copal; it is also harder and less easily scratched or crushed. It is slightly brittle, and breaks with a regular conchoidal fracture Amber may be cut, sawn, filed and polished; but the pieces will not stick together again, as they wil with its substitutes. The warmth of the hand wil cause it to exhale an agreeable aromatic odour, which is not the case with either copal or artificial amber. Finally, amber, covered with grease and held over a flame, may bend, which the other substances will not do.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, eight o'clock:—

March 5.—"The Progress of Electric Lighting." By W. H. Preece, F.R.S. Sir Frederick Abel, C.B., F.R.S., Chairman of Council, will preside.

March 12.—"Water Regulation, in regard to Supply, Floods, Drainage, and Transit." By General Rundall.

March 19.—"The Elephant in Freedom and Captivity." By G. P. Sanderson, Superintendent of Government Elephant-catching Operations in Bengal. Sir Joseph Fayrer, K.C.S.I, M.D., F.R.S., will preside.

March 26.—"Vital Steps in Sanitary Progress." By B. W. Richardson, M.D., F.R.S. Sir Robert Rawlinson, C.B., will preside.

Foreign and Colonial Section.

Tuesday evenings:—

March 18.—"Borneo." By B. Francis Cobb, Vice-President of the Society.

April 1.—"The Rivers Congo and Niger entrances to Mid-Africa." By Robert Capper.

Applied Chemistry and Physics Section.

Thursday evenings:—

March 13.—"The Upper Thames as a Source of Water Supply." By Dr. Percy F. Frankland.

March 27.—"Cupro-Ammonium Solution and its Use in Waterproofing Paper and Vegetable Tissues." By C. R. Alder Wright, F.R.S., D.Sc.

April 24.—"Economic Applications of Sea weed." By Edward C. Stanford, F.C.S.

Indian Section.

Friday evenings:—

March 7.—"The New Bengal Rent Bill." By

W. Seton-Karr. Sir George Campbell, M.P., K.C.S.I., will preside.

March 28.—"Trade Routes in Afghanistan." By Griffin W. Vyse. Lord Aberdare, F.R.S., will preside.

April 25.—"The Existing Law of Landlord and Tenant in India." By W. G. Pedder.

Cantor Lectures.

The Third Course will be on "Building of London Houses." By Robert W. Edis, F.S.A.

Lecture 3. Mar. 3.—Fittings, Planned Furniture, Constructive Decoration.

MEETINGS FOR THE ENSUING WEEK.

Monday, March 3 ... SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. Robert W. Edis, "Building of London Houses." (Lecture III.)

Central Chamber of Agriculture (at the House of the Society of Arts), 2 p.m.

Farmers' Club, Inns of Court Hotel, Holborn, W.C., 4 p.m. Mr. Woodward, "Fruit Farming."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. A. Geikie, "The Origin of the Scenery of the British Isles." (Lecture VI.) 5 p.m. General Monthly Meeting.

Engineers, Westminster Town-hall, S.W., 7½ p.m. Mr. A. C. Engert, "The Defects of Steam-boilers and their Remedy."

Chemical Industry (London Section), Burlington-house, W. 8 p.m. 1. Dr. C. R. A. Wright, "The Manufacture of Cupro-Ammonium and Zinc-Ammonium, and their Technical Adaptation." 2. Mr. S. H. Johnson, "The Filtration of Potable Waters." 3. Paper on "Some Applications of Keiselghur."

British Architects, 9, Conduit-street, W., 8 p.m. General Meeting. Report of Council on award of Medals and Prizes.

Institute of Agriculture, Lecture Theatre, South Kensington Museum, S.W., 8 p.m. Mr. W. B. Tegetmeier, "The Production of Poultry for the Table."

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 7, Adelphi-terrace, W.C., 8 p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. Arthur Severn, "Beach Studies."

Tuesday, March 4...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Gamgee, "Animal Heat." Lecture I.)

Central Chamber of Agriculture (at the House of the Society of Arts), 11 a.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. Sydney W. Barnaby's, "Hydraulic Propulsion."

Pathological, 53, Berners-street, Oxford-street, W., 8½ p.m.

Biblical Archæology, 9, Conduit-street, W., 8 p.m. Dr. S. Louis, "Handicrafts and Artisans mentioned in Talmudical Writings."

Zoological, 11, Hanover-square, W., 8½ p.m. 1. Mr. W. R. Ogilvie Grant, "A Revision of the Fishes of the Genera *Sicydium* and *Lentipes*, with Descriptions of Five New Species." 2. Mr. F. Moore, "Descriptions of New Asiatic Diurnal Lepidoptera, chiefly from Specimens in the Calcutta Museum." 3. Count T. Salvadori, "Note on *Anas capensis*."

Wednesday, March 5...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. W. H. Preece, "The Progress of Electric Lighting."

NOTICES.

CANTOR LECTURES.

The third and last lecture of the course on the "Building of London Houses," was delivered by Mr. Robert W. Edis, F.S.A., on Monday, 3rd inst., when the lecturer treated more particularly of fittings, planned furniture, and constructive decoration.

On the motion of the Chairman, a cordial vote of thanks was accorded to the lecturer for his interesting course of lectures.

Proceedings of the Society.

APPLIED CHEMISTRY & PHYSICS SECTION.

Thursday, February 28th, 1884; W. H. Preece, F.R.S., Vice-President of the Society, in the chair.

The paper read was—

RECENT PROGRESS IN DYNAMO-ELECTRIC MACHINES.

By Professor Silvanus P. Thompson, B.A., D.Sc., M.S.T.E. University College, Bristol.

Fifteen months ago, I had the honour of delivering in this place a course of three Cantor Lectures on "Dynamo-electric Machinery." In the first of those lectures, the endeavour was made to trace out a physical theory of the action of dynamos, and to follow the theory into its bearings upon the construction of such machines. In the second lecture, a large number of actual machines were considered and compared with one another and with the theory; and in the third lecture, the dynamo was considered in its functions as a mechanical motor.

As the present paper may be considered supplementary to the Cantor Lectures, it will be convenient to treat of the features of progress which come to-night under review in a similar order of topics. I, therefore, take up first the theory of the dynamo.

There are, in fact, three distinct theories of the dynamo: (1) a physical theory, dealing with the lines of magnetic force and lines of current in which these quantities are made, without further inquiry into their why or how, the basis of the arguments; (2) an algebraical theory, founded upon the mathematical laws of electric induction and of theoretical mechanics; and (3) a graphical theory, based upon the possibility of representing the action of a dynamo by a so-called "characteristic" curve, in the manner originally devised by Dr. Hopkinson, and subsequently developed by Frölich, Deprez, and others. The last of these three methods, though it has not received any great or striking development during the past year, has proved itself to be the most invaluable aid in the practical construction of dynamo-machines. One has only to refer to the use made of characteristics by Mr. Kapp in his articles on the winding of "compound" dynamos, and, still more recently, by Dr. Hopkinson, in solving certain problems in the electric transmission of energy, to see how invaluable the method is.

In the algebraic theory much progress has been made during the past year; and there certainly was room for it. Monsieur Joubert has published, in the *Journal de Physique* for July, 1883, a long mathematical article, the object of which is to deduce the equations of the dynamo, taking into account not only the action of self-induction in the circuit, but also some of the terms of the second order usually neglected in first approximations. It is a question whether he has not still omitted some terms of quite as great an importance as those retained in the complicated formula deduced by him. But the matter can hardly be discussed in the present paper. Still more recently, Professor Clausius has published in Wiedemann's *Annalen*, for November last, a paper expounding a mathematical theory of dynamo-electric machines far more comprehensive, and, I venture to say, far more true, than any other yet put forward. Without shirking any of the mathematical difficulties presented by the complications of mutual induction between, and self-induction in, the various organs of the machine, and by the admitted incompleteness of all our formula for connecting the magnetism of an electro-magnet with the strength of its exciting current, Prof. Clausius has succeeded in putting the equations into a shape, not only far more satisfactorily from the point of view of completeness, but in framing those equations in a manner that must commend itself to every engineer. The relative simplicity attained by Clausius is, in fact, due to his lavish introduction of a set of arbitrary constants, each one of which having values that must be determined by experiment, for each machine or type of machines. The number of new symbols thus introduced is considerable; and it would be very desirable to find names for the separate constants to be determined. An excellent translation has appeared in the *Philosophical Magazine* of this year, and another is in process of publication in *The Electrician*, in which journal the series of articles on the theory of dynamo-electric machines from the pen of Professor O. J. Lodge is still continued. It cannot be said even yet that the mathematical theory of the dynamo is near completion. A further paper by Professor Clausius is promised; and it remains to be seen whether this article will deal with some of those points in which the graphic method has been so useful in practice, for example, in determining the proper quantities of wire for the coils in "self-regulating" or "compound" machines, and in finding the best shape to give to magnets and pole-pieces.

Turning to the physical theory of the dynamo, there is much to record. Our knowledge of the inductive actions which go on between the field-magnets and armatures of dynamos, has received considerable additions during the past year from the researches of Isenbeck,

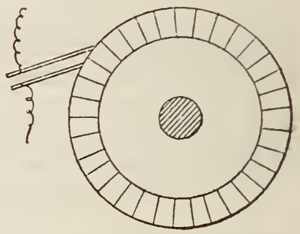
HORIZONTAL DIAGRAM OF POTENTIALS AT COLLECTOR OF GRAMME DYNAMO.

FIG. 3.



METHOD OF EXPERIMENTING AT COLLECTOR OF DYNAMO.

Cunnynghame, Pfaundler, and others. There is a good deal to be said on this head, and I have several new results to announce as the result of my own observations. Let me take as my starting point a matter mentioned in my Cantor Lectures, namely, the distribution of potential round the collector or commutator of a dynamo. Mr. W. M. Mordey, who first drew my attention to the fact that this distribution was irregular in badly designed machines, had devised the following method of observing it. One terminal of a voltmeter was connected to one of the brushes of the dynamo, and the other terminal was joined by a wire to a small metallic brush or spring, which could be pressed against the rotating collector at any desired part of its circumference. I then made the suggestion that these indications might with advantage be plotted out round a circle corresponding to the circumference of the collector. Figs. 1 and 2, which are reproduced rom my Cantor Lectures, serve to show how the potential in a good Gramme machine rises gradually from its lowest to its highest value. The same values as are plotted round the circle in Fig. 1 are plotted out as vertical ordinates upon the level line in Fig. 2. I made the remark at the time that if the magnetic field in which the armature rotated were uniform, this curve would be a true "sinusoid," or curve of sines; and that the steepness of the slope of the curve at different points would enable us to judge of the relative idleness or activity of coils in different parts of the field. About the same time, I developed this method of observation a little further, and used two small metal brushes, at a distance apart equal to the width between the middle of two consecutive bars of the collector of my little Siemens dynamo, for the same purpose.* As the collector rotated, these two little brushes

* Dr. Isenbeck has also independently used a similar arrangement to investigate the induction going on in a Gramme dynamo.

(see Fig. 3 p. 320) gave on the voltmeter an indication which measured exactly the activity of the induction, in that section of the armature which was passing through the particular position in the field corresponding to the position of the contacts. I found, in the case of my Siemens dynamo, that the result was fairly satisfactory, for the difference of potential indicated was almost *nil* at the sections close to the proper brushes of the machine, and was a maximum about half way between. In fact, the differences of potentials was rising most markedly at 90° from the usual brushes, or precisely in the region where (as seen in Fig. 2 p. 320) the slope of the curve of total potential was greatest. One immediate result of Mr. Mordey's observations on the distribution of potential, and of my method of mapping it, may be recorded. I pointed out to Mr. Mordey that in a dynamo where the distribution was faulty, and where the curves of total potential showed irregularities, the fault was due to irregularities in the induction at different parts of the field; and that the remedy must be sought in changing the distribution of the lines of force in the field by altering the shape of the pole pieces. I am able now, after the lapse of fifteen months, to congratulate Mr. Mordey on the entire and complete success with which he has followed out these suggestions. He has entirely cured the Schuckert machine of its vice of sparking. The typical bad diagram given in my Cantor Lectures was taken from a Schuckert machine before it received from his hands the modifications which are so signally successful to-day.

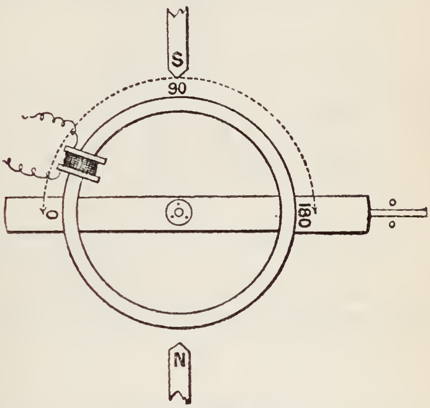
Since the experiments above detailed, I have experimented on my Siemens dynamo in another way. The machine was dismounted, and its field magnets separately excited. Two consecutive bars of the collector were then connected with a reflecting galvanometer having a moderately heavy and slow moving needle. A small lever clamped to the collector allowed the armature to be rotated by hand, through successive angles equal to 10°, there being thirty-six bars to the collector. The deflexions obtained of course measured the intensity of the inductive effect at each position. The result confirmed those obtained by the method of the two wire-brushes.

I mention these methods, which have been used in my laboratory at Bristol, and have not been published before, because they relate strictly to the physical theory of the dynamo as developed in my Cantor Lectures, and also because of their practical application to all dynamos in which any such defect appears. They are also very closely related to the researches of Dr. Isenbeck, which next claim attention.

Dr. Isenbeck described, in the *Electrotechnische Zeitschrift* for last August, a beautiful little apparatus for investigating the induction in the coils of a Gramme ring, and for investigating the influence exerted by pole pieces of different form upon these actions.

Isenbeck's apparatus (Fig. 4) consists of a circular frame of wood placed between the poles of two small bar-magnets of steel, each 25 centimetres long, lying 25 centimetres apart. On the frame, which is pivotted at the centre, is carried a ring of wood or iron, upon which is placed at one point a small coil of fine wire. This corresponds to a single section of the coils of a Pacinotti or of a Gramme ring, of

FIG. 4.



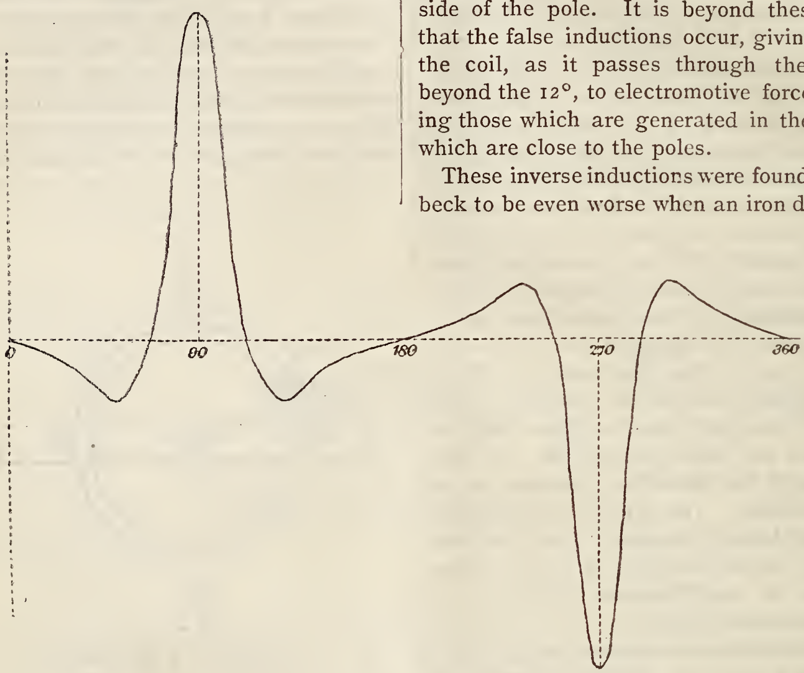
ISENBECK'S APPARATUS.

which the ring of wood or iron constitutes the core. The coil can be adjusted to any desired position on the ring, and the ends communicate with a galvanometer. On vibrating it isochronously with the swing of the needle of the galvanometer, the latter is set in motion by the induced currents, and the deflexion which results shows the relative amount of induction going on in the particular part of the field where the coil is situated. The vibrations of the frame are limited by stops to an angle of 7° 5'. Pole-pieces of soft iron, bent into arcs of about 160° so as to embrace the ring on both sides, but not quite meeting, were constructed to fit upon the poles of the magnets. In some of the experiments a disc of iron was placed internally within the ring; and in some other experiments a magnet was placed inside the ring, with its poles set, so as either to reinforce, or to oppose, the action of the two external poles. In Dr. Isenbeck's hands this apparatus yielded some remarkable results. Using a wooden ring, and poles destitute of polar expansions, he observed a very remarkable inversion in the inductive action to take place at about 25° from the position nearest the poles.

Fig. 4 is a sketch of the main parts of Isenbeck's instrument, and shows the small coil mounted on the wooden ring, and capable of being vibrated to and fro between stops. When vibrated at 0°, or in a position on the diametral line at right angles to the polar diameter, there is no induction in the coil; but as the coil is moved into successive positions round the ring towards the poles, and vibrated there, the induction is observed first to increase, then die away, then begin again in a very powerful way, as it nears the pole, where the rate of cutting the lines of force is a maximum. This powerful induction near the poles is, however, confined to the narrow region within about 12° on each side of the pole. It is beyond these points that the false inductions occur, giving rise in the coil, as it passes through the regions beyond the 12°, to electromotive forces opposing those which are generated in the regions which are close to the poles.

These inverse inductions were found by Isenbeck to be even worse when an iron disc, or an internal opposing magnet, was placed within the ring; but a reinforcing magnet slightly improved matters. Of course such an action in a Gramme armature going on in all the coils, except in those within 12° of the central line of the poles, would be most disastrous to the working of the machine; and the rise of potential round the collector would be anything but regular. In Fig. 5 I have copied out Isenbeck's curve of induction for the consecutive four quadrants. From 0° to 90° the exploring coil is supposed to be vibrated in successive positions from the place where, in the actual dynamo, the negative brush would be, round to a point opposite the S pole of the pointed field-magnet. From 90° to 180° it is passing round to the positive brush; from 180° to 270° it passes to a point opposite the N pole; and from 270° to 360° returns to the negative brush. Now, since the height of this curve, at any point, measures the induction going on in a typical section as it moves through the corresponding region of the field, and since in the actual Pacinotti or Gramme ring the sections are connected all the way round the ring, it follows that the actual potential at any point in the series of sections will be got by adding up the total induced electromotive force up to that point. In other words, we must integrate the curve to obtain the corresponding curve of potential corresponding with the actual state of things round the collector of the machine. Fig. 6 (p. 323) gives the curve as integrated expressly for me from Fig. 5 by the aid of the very ingenious curve integrator of Mr. C. Vernon Boys. The height of the ordinate of this second curve at

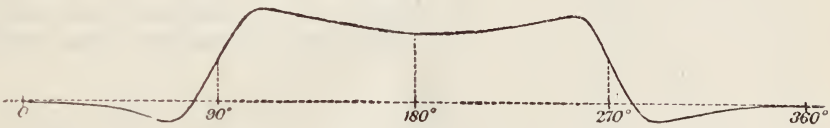
Fig. 5.



any point is proportional to the total area enclosed under the first curve up to the corresponding point. Thus the height at 90° in the second curve, is proportional to the total area up to 90° below the first curve. And it will be noticed that though the induction (first curve, Fig. 5) decreases after 90°, and falls to zero at about 102°, the sum of the potentials (second curve, Fig. 6) goes on increasing up to 102°, where it is a maximum, and after that falls off, because, as the first curve shows, there is from that point onwards till 180° an opposing false induction. If this potential curve were actually observed on any dynamo, we might be sure that we could get a higher electromotive force by moving the brush from 108° to 102°, or to 258°, where the potential is higher. Any dynamo in which the curve of potentials at the commutator presented such irregularities as Fig. 6, would be a very inefficient machine, and would probably spark terribly at the collector. It is evident that the induction in some of the coils is opposing that in some of the adjacent coils.

Two questions naturally arise—Why should such detrimental inductions arise in the ring; and how can they be obviated? The researches of Dr. Isenbeck supply the answer to both points. Dr. Isenbeck has calculated from the laws of magnetic potential the number of lines of force that will be cut at the various points of the path of the ring. He finds that the complicated mathematical expression for this case, when examined, shows negative values for angles between 12° and 90°. The curves of values that satisfy his equations have minima exactly in those regions where his experiments revealed them. This is very satisfactory as far as it goes. But we may deduce a precisely similar conclusion in a much simpler manner, from considering the form and distribution of the lines of magnetic force in the field. These are shown in Fig. 7,

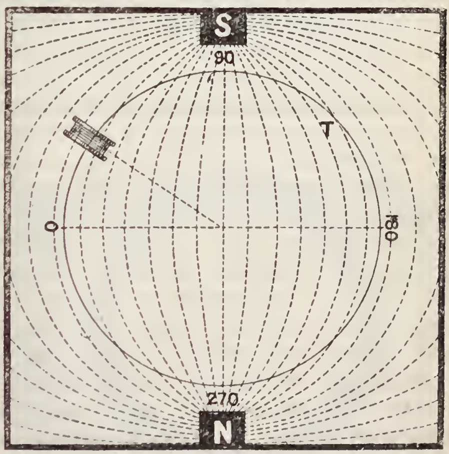
FIG. 6.



together with the exploring coil situated as in Fig. 4 (p. 321). A simple inspection of the figure will show that at 0° a certain number of lines of force would thread themselves through the exploring coil. As the coil moved round toward the S pole, the number would increase at first, then become for an instant stationary, with neither increase or decrease; after that a very rapid decrease would set in, which, as the coil passed the 90° point, would result in their being no lines of force through the coil. But at the very same instant the lines of force would begin to crowd in on the other side of the coil, and the number so threaded through negatively, would increase until the coil turned round to about the position marked T, where the lines of force are nearly tangential to its path, and here the inversion would occur, because, from that point onwards to 180°, the number of lines of force threaded through the coil would decrease. We see then that such inversions in the induction must occur of necessity to a small coil rotating in a magnetic field in which the lines of force are distributed in the curved directions, and with the unequal density which this disposition of the field-magnets presents. The remedy is obvious; arrange a more uniform field, in which the lines of force are more equally distributed, and are straighter.

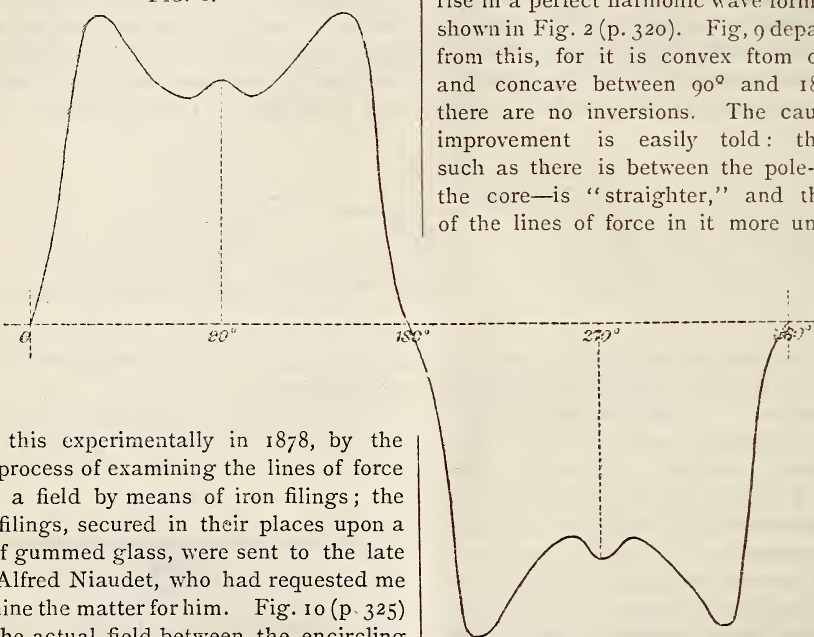
If an iron core be substituted for the wooden core, the useful induction is greater, and the

FIG. 7.



false induction less; there is still an inversion, but it takes place at about 25° from the pole, and is quite trifling in amount. The introduction of iron pole-pieces extending in two nearly semi-circular arcs from the magnets on either side has, if the wooden ring be still kept as a core, the effect of completely changing the induction, so that the curve, instead of showing a maximum at 90° from starting, shows one at about 10°, and another at 170°! If, however, we make the double improvement of using the iron pole-pieces and the iron core at the same time, the effect is at once changed. There are no longer any inversions. though the induction shows some peculiarity still. Fig. 8 shows the curve of induction adapted from Dr. Isenbeck's paper, and Fig. 9 (p. 325), the curve of potential, which I have had integrated from it. Looking at Fig. 8, we see that on starting from 0° induction soon mounts up, and becomes a maximum at about 20°, where the coil is getting well opposite the end of the encircling pole-piece. From this point on, though the induction is somewhat less, it still has a high value, showing a slight momentary increase as the coil passes the pole at 90°, and there is another maximum at about 160°, as the coil passes the other end of the pole-piece. My integrated curve (Fig. 9) tells us what would go on at the collector, if this were the action in the connected set of coils of a Pacinotti or Gramme ring. The potential rises from 0° all the way to close upon 180°. Still this is not perfect. In the perfect case the potential-curve would rise in a perfect harmonic wave form, like that shown in Fig. 2 (p. 320). Fig, 9 departs widely from this, for it is convex ftom 0° to 90°, and concave between 90° and 180°. But there are no inversions. The cause of the improvement is easily told: the field—such as there is between the pole-piece and the core—is "straighter," and the density of the lines of force in it more uniform. I

FIG. 8.

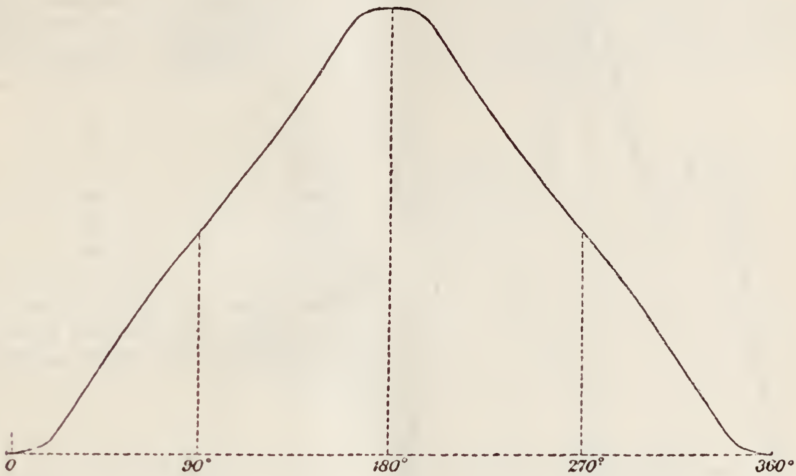


proved this experimentally in 1878, by the simple process of examining the lines of force in such a field by means of iron filings; the actual filings, secured in their places upon a sheet of gummed glass, were sent to the late Mons. Alfred Niaudet, who had requested me to examine the matter for him. Fig. 10 (p. 325) shows the actual field between the encircling pole-pieces and the iron ring. It will be seen that, though nearly straight in the narrow intervening region, they are not equally distributed, being slightly denser opposite the ends of the pole-pieces. One other case examined by Dr. Isenbeck, we will glance at. The effect of introducing within the ring a interior magnet, having its S pole opposite the external S pole, and its N pole opposite the external N pole, was found to assist the action. The induction-curve is represented in Fig. 11 (p. 326). As will be seen, there are two maxima at points a little beyond the ends of the pole-pieces, as before; but in between them there is a still higher maximum, right between the poles. This case also has been integrated on Mr. Boys' machine, and shows the potential curve of Fig. 12 (p. 327). This curve is a still nearer approach to the harmonic wave-form, being concave from 0° to 90°, and convex from 90° to 180°.

I pass from Dr. Isenbeck's researches, and the integrated curves of potential which I have deduced from them, to some further researches of my own, which were undertaken with the view of throwing some light on the question whether the Pacinotti form of armature, with protuding iron teeth, or the Gramme form, in which the iron core is entirely overwound with wire, is the better. It has been assumed without, so far as I am aware, any reason assigned, that the Gramme ring was an improvement on that of Pacinotti. Pacinotti's was of solid iron, with teeth which projected both outwards and inwards, having the coils wound between. Gramme's was made "either out of one piece of iron, or of a bundle of iron wires," and had the coils wound "round the entire surface." Now the question whether the Gramme construction is better than the Pacinotti or not, can readily be tested by experiment. And experiment alone can determine whether it is better to keep a thickness of wire always between pole-pieces and the core, or to intensify the field by giving to the lines of force the powerful reinforcement of protruding teeth of iron. The apparatus I have constructed for determining this point is now before you. It is sketched in Fig. 13 (p. 328).

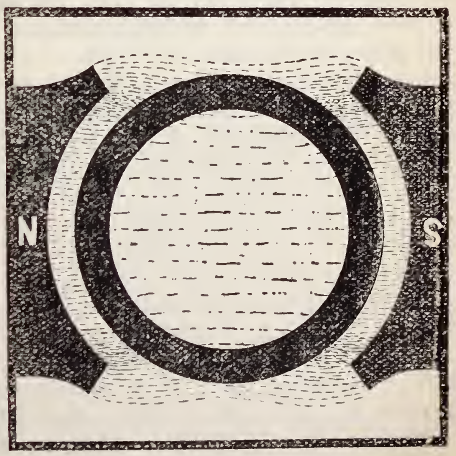
First, there are a couple of magnets set in a frame so as to give us a magnetic field, and there are pole-pieces that can be removed at will; in fact, there are three sets of pole-pieces for experimenting with different forms. Between the poles is set an axis of brass,

FIG. 9.



upon which the armatures can be slid. These armatures are three in number. One is shown in Figs. 14 and 15 (p. 328), and consists of two coils of fine wire wound upon a wooden ring; another armature is exactly like this, but is built up on a ring of iron wire; a third (shown in its place in Fig. 13) is constructed upon a toothed ring made up of a number of plates of ferrotype iron cut out and placed flat upon one another. On each of the armatures are wound two coils at opposite ends of a diameter. The coils contain precisely equal lengths of silk-covered copper wire, cut from one piece. The cross section of the core within each of these coils is in each case a square, of one centimetre in the side, so that the number of turns in each coil is as nearly equal as possible. I can slip any one of these armatures into the field, and connect it with a galvanometer. There is a lever handle screwed to the armature, by means of which it can be moved. I have used two methods of proceeding in order to compare the coils. One of these methods is to turn the armature suddenly through a quarter of a revolution, so that the coils advance from 0° to 90°, when the "throw" of the needle of the galvanometer—which is a slow-beat one—gives me a measure of the total amount of

FIG 10.



IRON RING IN THE MAGNETIC FIELD.

induction in the armature. The results are as follows:—

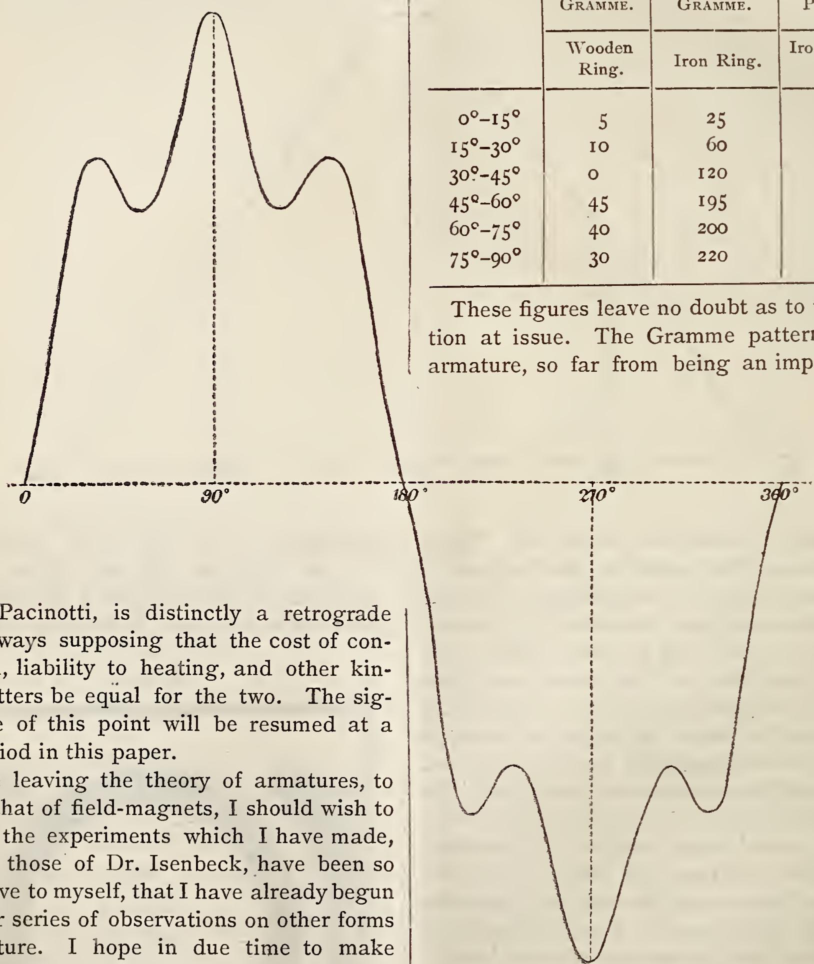
Gramme.	Gramme.	Pacinotti.
Wooden Ring.	Iron Ring	Iron Toothed Ring.
5	24	50

My second method of using these armatures consists in jerking the coils through a distance equal to their own thickness, the coils being successively placed at different positions in the field. The throw of the galvanometer being observed as before. Each of the coils occupies as nearly as possible 15° of angular breadth. Accordingly, I have two stops set, limiting the motion of the handle to that amount, and at the back, there is a graduated circle enabling me to set the armature with the coils in any desired position. If we move the coils by six such jerks, through their own angular breadth each time, then starting at 0°, the sixth jerk will bring us to 90°. I have plotted out in Fig. 16 (p. 329), the three curves thus obtained, and the corresponding numbers are given in the following table:—

	Gramme.	Gramme.	Pacinotti.
	Wooden Ring.	Iron Ring.	Iron Toothed Ring.
0°–15°	5	25	30
15°–30°	10	60	70
30°–45°	0	120	140
45°–60°	45	195	320
60°–75°	40	200	380
75°–90°	30	220	360

These figures leave no doubt as to the question at issue. The Gramme pattern of ring armature, so far from being an improvement on the Pacinotti, is distinctly a retrograde step; always supposing that the cost of construction, liability to heating, and other kindred matters be equal for the two. The significance of this point will be resumed at a later period in this paper.

Fig. 11.



Before leaving the theory of armatures, to pass to that of field-magnets, I should wish to say that the experiments which I have made, and also those of Dr. Isenbeck, have been so instructive to myself, that I have already begun a similar series of observations on other forms of armature. I hope in due time to make known the results of my investigations.

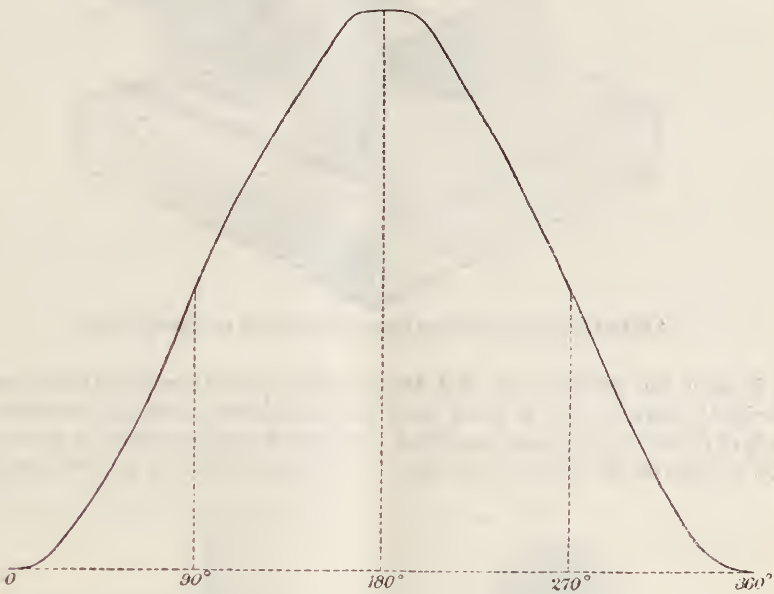
But little advance has been made in theory so far as relates to the field-magnets. The law of saturation of an electro-magnet remains still an empirical law. It is satisfactory, however, that such widely differing authorities as Professor Clausius, M. Marcel Deprez, and Professors Ayrton and Perry, agree in accepting the empirical formula of Fröhlich as a sufficiently accurate expression for the law of saturation.

Some progress has been made in the theory of the lead that must be given to the brushes of the dynamo. Formerly this was ascribed to a sluggishness in the demagnetisation of the iron of the armature; but in 1878, the late

M. Antoine Breguet suggested as a reason the influence of the actual current circulating round the armature coils, which would tend to produce in the iron of the armature a magnetisation at right angles, to that due to the field-magnets.

Breguet showed that there would be a resultant oblique direction of the lines of magnetisation in the field, and therefore, since the "diameter of commutation" is at right-angles to this direction, the brushes also must be displaced through an equal angle. Clausius accepts this view in his recent theory, and adopts for the angle of the resultant field that whose tangent is the ratio of the two magnetising forces due to the field-magnets, and the current in the armature respectively. Professors Ayrton and Perry have also pointed out that there will be an additional displacement of the resultant pole of the armature, consequent upon the self-induction going on in the armature coil between its different sections. In their paper on the government of motors, in which they have brought out this point, they, however, take the view that part of the displacement of the pole is due to the sluggishness of demagnetisation of the iron. I do not think, however, that this can be maintained. No experimental proof has ever been given that there is any such thing as a true magnetic lag; the apparent magnetic sluggishness of thick masses of iron is demonstrably due to internal induced currents; and no one uses solid iron in armature cores for this very reason. Neither has it been shown that thin iron plates or wires, such as are used in armature cores, are slower in demagnetising than magnetising. Indeed, the reverse is probably true; and, until further experimental evidence is forthcoming, I shall assume that there is no magnetic lag in properly laminated iron cores.

Fig. 12.



It may here be pointed out that, assuming as a first approximation that the rule that the tangent of the angle of lead represents the ratio between the magnetising power of the field-magnets and of the armature coils, the lead may be diminished to a very small quantity, by increasing the relative power of the field-magnets, a course which is for many other reasons advisable. All practice confirms the rule that the magnetic moment of the field-magnets ought to be very great as compared with that of the armature. Further than this, there ought to be so much iron in the armature as to be just saturated when the dynamo is working at its greatest activity. If there is less than this, it will become saturated at a certain point, and when any currents greater than this are employed, the lead will alter, for then the magnetic effect due to the current in the armature will be of greater importance, relatively to that due to the field-magnets. For the same reason, the lead will be more constant when the field-magnets are under their saturation point, than when quite saturated. In short, every cause that tends to reduce the lead, makes the lead more constant, and therefore tends to reduce sparking at the brushes. And the best means to secure this is obviously to use an unstinted quantity of iron—and that of the softest kind—both in the field-magnets and in the armature, for then the currents circulating in the armature will have less chance of perturbing the field.

In relation to the magnetisation of field-magnets, it may be pointed out that the "characteristic" curves, now so much used for the study of the action of dynamo machines, which show the rise of the electromotive force of the machine in relation to the corresponding strength of the current, are sometimes assumed, though not quite rightly, to represent the rise of magnetisation of the field-magnets. Now though the magnetisation of the magnet may attain to practical saturation, it does not, under a still more powerful current, show a magnetisation less than saturation. But the characteristics of nearly all series-wound dynamos show—at least, for high speeds—a decided tendency to turn down after attaining a maximum; and for some machines, for ex-

Fig. 14.

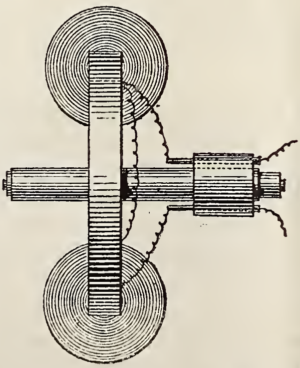

Fig. 15.

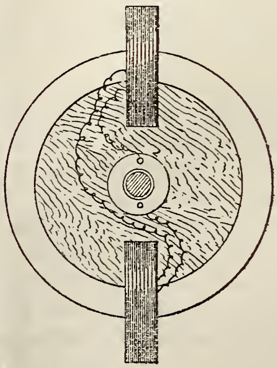
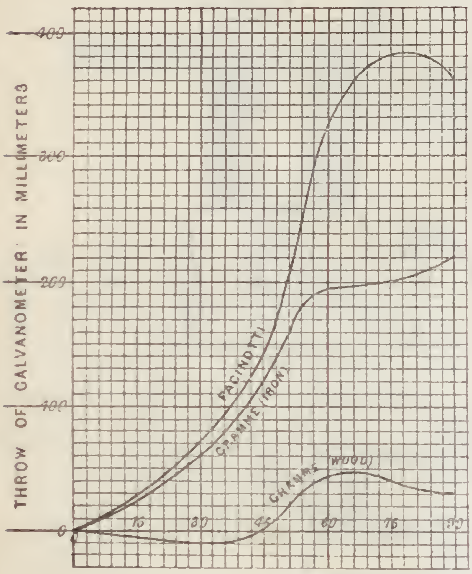


Experimental Armature.

ample, the Brush, this diminution of the electromotive force is very marked. The electromotive force diminishes, but the magnetism of the field-magnets does not. An explanation of this dip in the characteristic has lately been put forward by Dr. Hopkinson, in his lecture on "Electric Lighting," before the Institution of Civil Engineers, attributing this to the reaction of self-induction and mutual induction between the sections of the armature. No doubt this cause contributes to the effect, as all such reactions diminish the effective electromotive force. I am inclined, however, to think that the greater part of the effect is due to the shifting of the effective line of the field in consequence of the iron of the field-

FIG. 16.



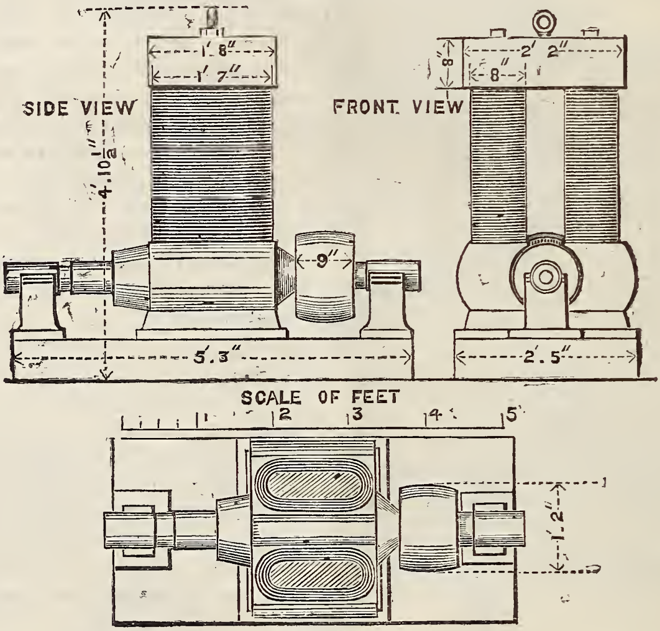
magnets becoming saturated before the armature is so. It is at least significant that in the Brush machine, where the reduction of electromotive force is very great, there is also such a mass of iron in the armature, and so variable a lead at the brushes.

Another point in which theory has for long been ahead of practice, is in the advantage to be gained by working as nearly as possible with closed magnetic circuits; that is to say, with a nearly continuous circuit of iron to conduct the lines of magnetic force round into themselves in closed curves. The enormous importance of this was pointed out so far back as 1878 by Lord Elphinstone and Mr. C. W. Vincent, whose dynamo embodies their idea. Every electrician knows that if a current of electricity has to pass through a circuit, part of which consists of copper, and part of liquids—such as the acid in a battery, or the solution in an electrolytic cell—the resistance of the liquid is, as a rule, much more serious than the resistance of the copper. Even with dilute sulphuric acid the resistance to the flow of the current by a thin stratum is 200,000 times as great as would be offered by an equally thick stratum of copper. And in the analogous case of using a field-magnet to magnetise the iron core of an armature, the stratum of air—or, it may be, of copper wire—in between the two pieces of iron, offers what we may term a relatively enormous resistance to the magnetic induction. If we take the magnetic permeability of iron as 1, then the permeability of air is something like $\frac{1}{20000}$, and that of copper is not very different. Or, in other words, a stratum of air or copper offers about 20,000 times as much resistance to the magnetic induction as if the space were filled up with soft iron. Obviously, then, it would be a gain to diminish as much as possible the gaps between the portions of iron in the circuit. The values of the magnetic permeability for iron, air, and copper, have been known for years, yet this simple deduction from theory has been set at defiance in the vast majority of cases. We have had, a few minutes ago, an experimental proof that the Pacinotti ring, so far from having been "perfected" or "improved" by Gramme, as some very high authorities say, is vastly inferior to it. It will perhaps be intelligible now why Pacinotti's design was essentially right.

I now pass on to the progress recently made in the practical construction of dynamo-electric machines. Thanks to the kindness of several of those by whom this progress has been achieved, I am able to put before you their very latest results.

The Edison dynamo has, during the past eighteen months, received very material improvements at the hands of Dr. Hopkinson, F.R.S. Some of these improvements relate to the field-magnet; others to the armature. Dr. Hopkinson has, in the first place, abolished the use of the multiple field-magnets, which in the Edison "L" "K" and "E" machines were united to common pole-pieces, and instead of using two, three, or more round pillars of iron, each separately wound, he puts an equal mass of iron into one single solid piece of much greater area of cross-section and somewhat shorter length. One such iron mass, usually oval or oblong cross-section, is attached solidly to each pole-piece, and the two aer united at the top by a still heavier yoke of iron. The machines have, consequently, a more squat and compact appearance than before (FIG. 17). It may be remarked, in passing, that the use of multiple pillars of iron used by Edison in the "L," "K," and "E" machines must have been prejudicial, because the currents in those portions of the coils which passed between two adjacent iron pillars must have been opposing each other's magnetising effect. Dr. Hopkinson has also introduced the improvement of winding the magnets with a copper wire of square section, wrapped in insulated tape. This wire packs more closely round the iron cores than an ordinary round wire. In the armature the following change has been made. The iron core in the older Edison machines was made of thin iron disks, separated by paper slipped on over a sleeve of *lignum vitæ;* and held together by six longitudinal bolts passing through holes in the core-plates, and secured by nuts to end plates. These bolts are now removed, and the plates are held together by great washers, running upon screws cut on the axle of the armature. The size of the central hole in the plates has been diminished, thus getting into the interior more iron, and providing a greater cross-section for the

FIG. 17.



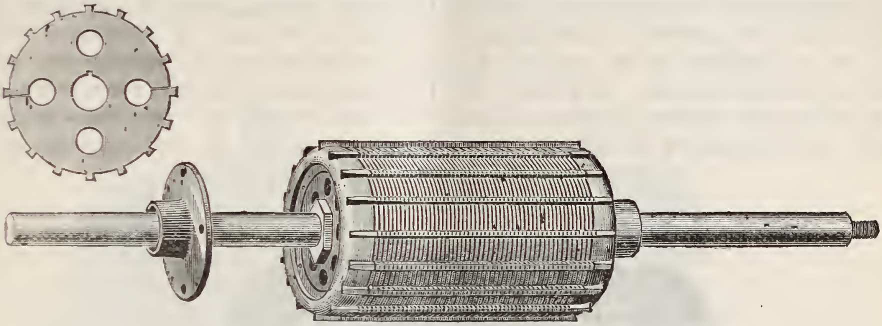
EDISON-HOPKINSON DYNAMO.

magnetic induction. By these improvements, a machine occupying the same ground space, and of about the same weight as one of the older "L" 150-light machines, is able to supply 250 lights, the efficiency being at the same time improved. In the new 250-light machine, the diameter of the armature is 10 inches; its resistance, cold, is 0·02 ohm; that of the magnets is 17 ohms. The characteristic curve of the machine shows that even when doing full duty, the field-magnets are far from being saturated. It will be remarked that, in the older construction, the bolts and their attached end-plates furnished a circuit in which idle currents were constantly running wastefully round, with consequent heating and loss. An Edison 60-light "Z" machine of the older pattern, tested by the committee of the Munich Exhibition, was found to give an efficiency which, if measured by the ratio of external electric work to total electric work, exceeded 87 per cent.; but its commercial efficiency—the ratio of external electric work to the mechanical energy imparted at the belt—was only, at the most, 58·7 per cent. In a recent test made by Mr. Sprague, at Manchester, on an improved dynamo (a 200-light machine), the efficiency of electrical conversion exceeded 94 per cent., and the commercial efficiency 85 per cent.*

The Edison Company states that "the weight and cost of the machines per lamp are greatly reduced," but they add a table from which it appears that the old 250-light machine costs £250, whilst the new 250-light machine costs £265, if made as a fast-speed machine, and £425 if constructed as a slow-speed machine.

The Siemens' machines have not been much altered during the past year; and it is a little difficult to describe the improvements which have been made, as the firm of Siemens Bros. decline, for commercial reasons, to furnish data for publication. Progress has, however, been made by this firm, especially with their compound-wound machines, of which some account has been given by Herr E. Richter, in the *Electrotechnische Zeitschrift*. It appears that three methods of combination have been tried. The shunt and series coils have been wound on different arms of the magnets; they have been wound on separate short frames, and slipped on to the cores side by side; and they have been also wound over one another. In the latest machines, the series coils are wound outside the shunt windings. The regulation judging by the curves given by Herr Richter, is not perfect. The best regulation was from a "*g* D 17" machine, of which two of the magnet limbs were wound with shunt coils of 29 layers of a 1 millimetre wire, and the other two with two layers of a 3·5 millimetre wire. The potential varied from 64 to 69 volts when the number of lamps was reduced from 20 to 9.

Fig. 18.



Core of Weston Armature.

Fig. 19.

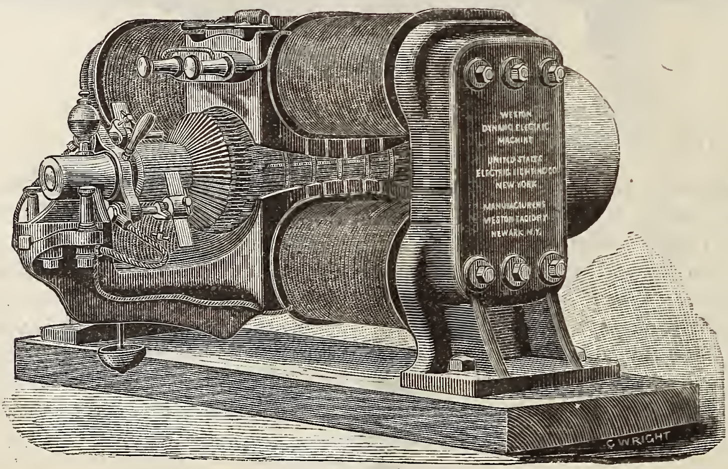
Weston Armature.

The Weston machine has an armature more or less resembling those of the Siemens' machines. The core is built up of disks of iron, of the form shown in Fig. 18, strung together, and presenting projecting teeth all along the surface of the cylinder. Fig. 19 shows the armature when completed. In this machine, as is also evident from Fig, 20 (p. 332), the pole-pieces are laminated, to obviate eddy currents and heating. Recently, Mr. Weston has adopted a method of winding the armature with two circuits, so that an accident to one section shall not completely break down the machine. The latest of the Weston machines show substantial design, and many improvements in detail upon the older forms.

* These values assume the B. A. unit as the true ohm, and are, therefore, probably about 1½ per cent. too high.

The machines of the Gramme type next come in for consideration. In those of the actual Gramme pattern I cannot learn that any important improvement has been made in this country; but in the States, the Fuller Electrical Company, which holds the Gramme and Wood patents, has brought out several improved forms of machine, in which mechanical engineering skill of a high order is apparent. The field-magnets, frames, and pole-pieces are very substantial, the ring is better built than the European types, and the collector bars are prevented from flying to pieces by the addition of an insulated ring shrunk on over their ends. In France, too, the machine has received important modifications at the hands of M. Marcel Deprez. M. Deprez's dynamo has two Gramme rings upon one axle, which lies between the poles of two opposing field-magnets, each of the two-branched, or so-called horseshoe form. These are laid horizontally, so that the north pole of one is opposite the south pole of the other, and *vice versa;* the poles being provided with curved pole-pieces between which the rings revolve. M. Deprez, who has given much attention to the question how to design a machine which, with the least expenditure of electric energy, gives the greatest actual couple at the axle, is of opinion that the horse-shoe form of electro-magnet is the most advantageous. The iron cores and yokes of the field-magnets are very substantial; but the pole-pieces are not very heavy. M.

Fig. 20



Weston Dynamo.

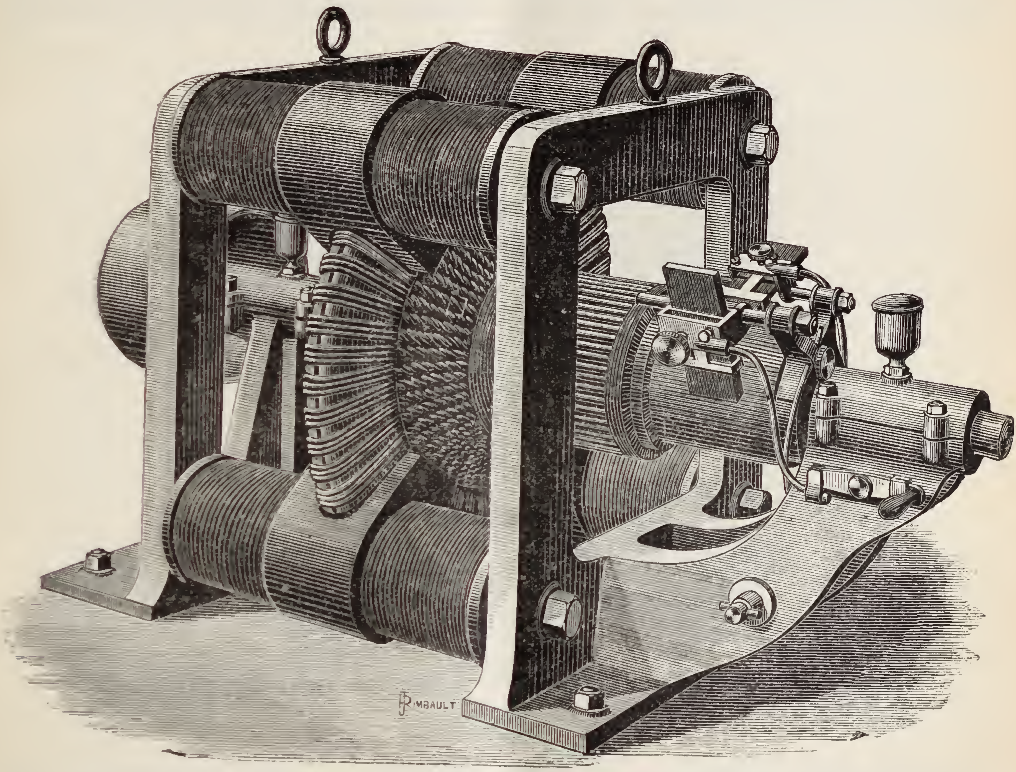
Deprez's machine has a very elaborate system of sectional windings of the field-magnets and a switch-board, enabling him to couple up the connections in various ways. The circuits of the two rings are quite distinct, and each armature has its own collector and brushes. M. Deprez has also constructed other Gramme machines, with armatures of very fine wire, for his experiments on the electric transmission of power.

Another machine, having as an armature an elongated ring somewhat like that of the Maxim dynamo, was shown during last autumn at the Fisheries Exhibition, under the name of the Hockhausen dynamo. The field-magnets of this machine are very strangely disposed, the ring being placed between two straight electro-magnets placed vertically over one another; the upper magnet being held in its place by curved flanking-pieces of iron, which run down the two sides of the machine, and connect the topmost point of the upper magnet with the lowest part of the lower. This arrangement, which strikes the eye as being both mechanically and magnetically bad, is claimed as one of the virtues of the machine, which, in spite of its magnets, appears to be a very good working machine. Its armature is constructed of four separate curved iron frames, upon which the previously wound coils are slipped, and which are then bolted together and secured to strong end-plates. I have not seen any report on the efficiency of this of machine.

We next come to the class of machines in which a flattened Gramme ring is used, and of which the machines of Fein, Schuckert, and Gülcher are the best known types.

Mr. Gülcher has been steadily at work improving his dynamo in its various mechanical and electrical details. In particular, he has devoted attention to the winding of the field-magnets, so as to secure a constant potential at the terminals. After experimenting with various methods of compounding, he finds that the best results are arrived at in the following way:—In his four-pole dynamo there are eight cores to be wound. Each of these receives a shunt coil of fine wire, and outside this a main coil of stout wire. The eight fine wire coils are then joined up in series with one another, and connected as a shunt to the terminals; whilst the eight main circuit coils are joined up in parallel. In proof of the degree of accuracy attained by this method Mr. Gülcher has given me many numerical data from actual tests. All of them show a very fair approximation to a constant potential, and an actually attained constancy for a con-

Fig. 21.



Victoeia (Schuckert-Mordey) Dynamo (4-Pole).

siderable range. For example, a 4-pole machine, intended to give 65 volts, gave that figure exactly, when the external current varied from 30 to 88 ampères; and gave 64 volts at 5 ampères, 63·5 volts at 130 ampères. With one ampère only, the potential was 61·5 volts. Mr. Gülcher adds that, in spite of all possible care in manufacture, very large machines do not give results as satisfactory as those given by machines of somewhat smaller dimensions, though the machines are of identical type, and their parts calculated from the same formulæ. He thinks this, to indicate that to obtain the same ratio of out-put and efficiency to weight, there ought to be a corresponding increase made in the electromotive force of the machine. In other words, the means taken in large machines to keep down the electromotive force to equality with that of the smaller machines are detrimental to the action of the machine.

The Anglo-American Electric Light Corporation has been manufacturing during the past year a dynamo of the flat-ring type, under the patents of Schuckert and Mordey, to which the not very apt name of the "Victoria" dynamo has been given. By the kindness of Mr. F. Wynne, general manager of the Corporation, and of Mr. Mordey, and Mr. P. Sellon, I have been able to learn a great deal about this machine, and to test personally its capabilities. There are two types of the new Schuckert-Mordey dynamo, one having 4, the other 8 poles arranged round the ring. As mentioned earlier in this paper, Mr, Mordey has given great attention to the form of the pole-pieces. These pole-pieces, in the earlier Schuckert machines, consisted of hollow iron shoes or cases which occupied a large angular breadth along the circumference of the ring. Similar hollow polar extensions are still used in the Gülcher machines (see Fig 26 of my Cantor Lectures). Mr Mordey has found my opinion, based upon the diagrams of potential at the collector, to be correct, that these wide-embracing pole-pieces were responsible for false inductions, giving rise to opposing electromotive forces and setting up secondary neutral points at the collectors. He has, therefore, by long extended experiments, arrived at a form of pole-piece which completely obviates these effects. As will be seen from Fig. 21 (p. 333), which represents the 4-pole Victoria dynamo, the pole-pieces, though they embrace the ring through its whole depth, from external

FIG. 22.

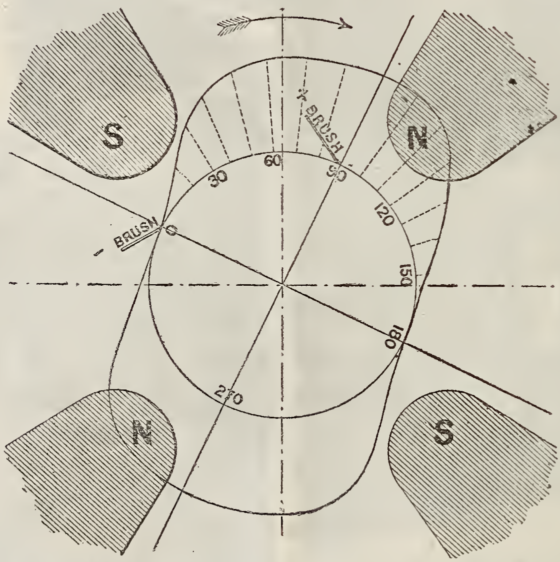


DIAGRAM OF POTENTIALS AT COLLECTOR OF 4-POLE SCHUCKERT-MORDEY DYNAMO.

to internal periphery, are quite narrow, and do not cover more than 30° of angular breadth of the circumference of the armature. They are of cast-iron, and are cast upon the cylindrical cores of soft wrought-iron which receive the coils. It may be mentioned that, in the 4-pole Gülcher machines, the wide box-like pole-pieces are also cast on wrought-iron cores. The armature of the Victoria dynamo resembles in its structure the Pacinotti rather than that the Gramme type. Its core is built up of rings cut from sheet charcoal iron, and Mr. Mordey has taken special pains to ensure that there are no electric circuits made in the bolting together of these cores, each plate being both electrically and magnetically insulated from the adjacent plates. Eddy currents in the core are thus almost entirely obviated. This was far from being the case with some of the earlier machines, in which, as in the Edison machine until Dr. Hopkinson improved it, the bolts holding together the cores constituted an available path for wasteful inductions. The core rings of the Victoria dynamo are toothed, as in the Pacinotti ring, and the wires are wound in the intervening gaps. There is, moreover, ample ventilation in this armature, a point not to be overlooked. Formerly, in a four-pole machine, four brushes were necessary—as in the Gülcher dynamo and the four-

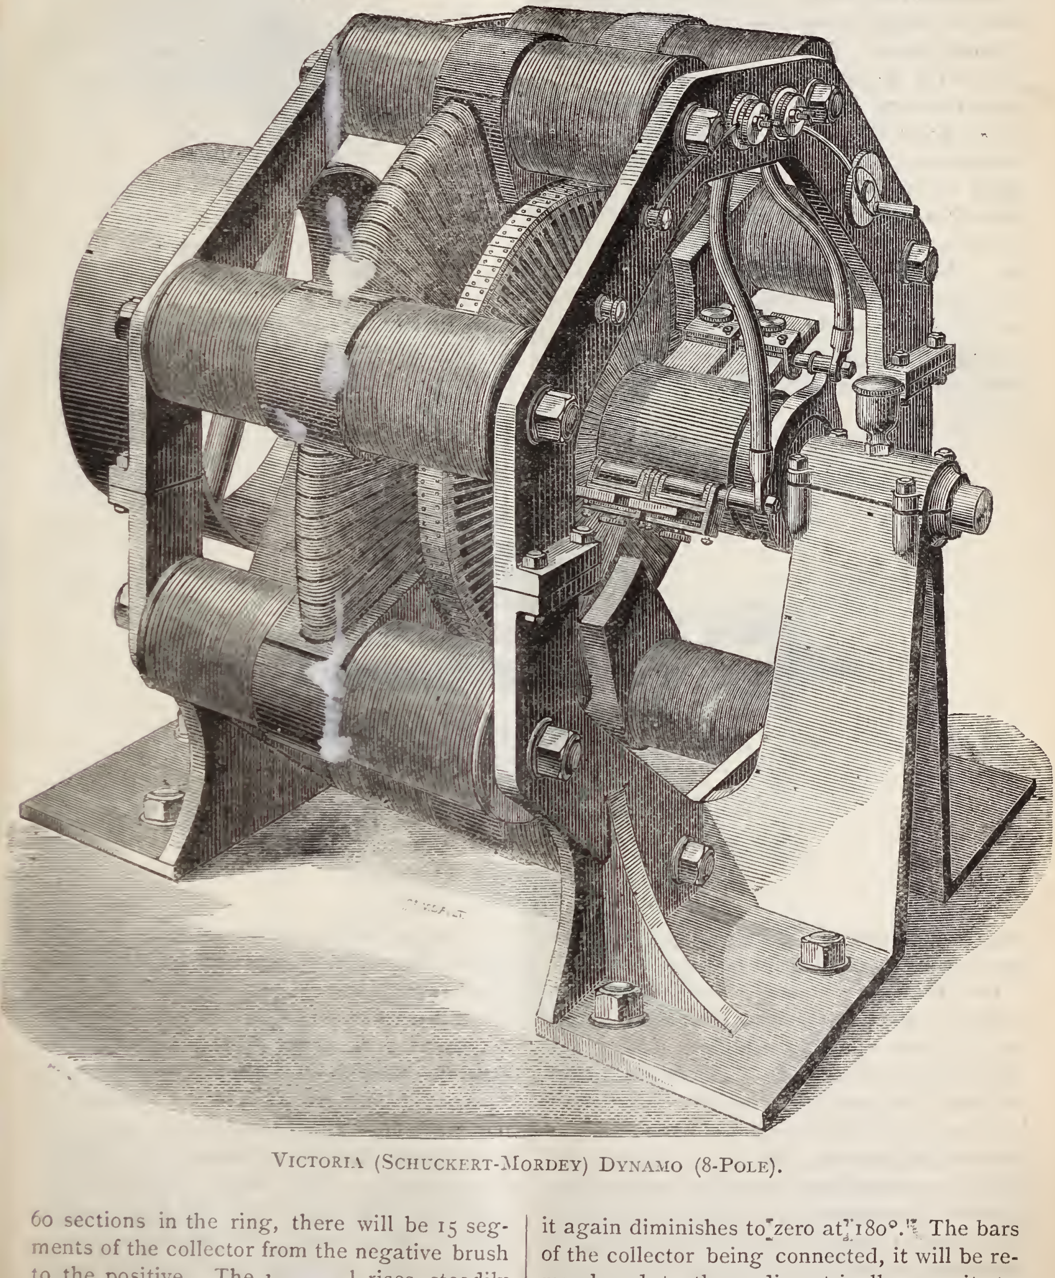
Dec. 4, 1880	Anglo-American Brush Electric Light Corporation	800,000	400,000	£10 shares	Brush and Lane-Fox incandescence	Brush patents purchased from the Anglo-American Company for £40,000 in cash, 10,000 fully paid shares, and 15,900 £4 paid. Share capital reduced to £400,000 = 80,000 £5 shares, Feb. 6th, 1882. 13,701 £5 shares fully paid; 26,999 shares £3 paid.
,, 28, 1880	Siemens and Company	...	400,000	£100 shares, £75 paid	Siemens	Manufacturing and lighting.
Feb. 7, 1881	Swan Electric Light Company	100,000	...	£10 shares	Swan incandescence	Patents purchased from J. W. Swan for £50,000, £25,000 in cash, and 2,500 in fully paid shares. Amalgamated with the Edison Electric Light Company, June 30, 1883 (except as to foreign and colonial patents), under the name of the Edison and Swan United Electric Light Company.
April 1, 1881	Maxim-Weston Electric Light Company	172,500	172,500	£1 shares	Weston-Maxim	Capital increased to £500,000, May 18, 1883.
July 15, 1881	Eastern Electric Light and Power Company	250,000	150,000	£5 shares	Brush-Lane-Fox	India patents. 20,000 shares taken up, upon 20,000 of which £4 was called, and the remainder in full; £123,045 paid, Nov. 14, 1882. Difficulties experienced in carrying out installations, in consequence of the prohibition by the Indian Government of overhead wires.
Aug. 9, 1881	Anglo-Colonial Electric Light Company	8,000	...	£1 shares	Laing	Formed to purchase the Laing patents for England, India, and the Colonies [illegible]
October [illegible] 188[illegible]	North [illegible]					

pole Gramme. Mr. Mordey has reduced the number to two, by the device, firstly, of connecting together those segments of the armature coils which occupy similar positions with respect to the poles; and secondly, of connecting together, by me llic connections, those bars of the collector which are at the same potential. In the four-pole machine opposite bars are thus connected. Two brushes only are then necessary, and these are 90° apart. Fig. 22 (p. 334) gives the actual diagram of the potentials at the collector. There being

FIG. 23.

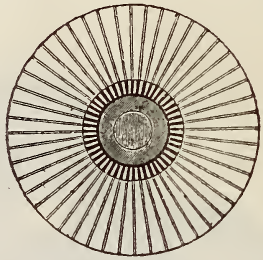


VICTORIA (SCHUCKERT-MORDEY) DYNAMO (8-POLE).

60 sections in the ring, there will be 15 segments of the collector from the negative brush to the positive. The p l rises steadily from the negative brush, nd becomes a maximum at the positive brush, at 90°, whence it again diminishes to zero at 180°. The bars of the collector being connected, it will be remembered, to those diametrically opposite to them, it follows that the potential will rise from 180° to 270°, precisely as it rose from 0° to

90°, and will again fall to zero in passing from 270° to 0°. If the curve from 0° to 180° were plotted again horizontally, we should clearly see how nearly regular the rise and fall is. If from this curve we were to construct another one, in which the heights of the ordinates should correspond to the tangent of the angle of slope of this potential curve—in other words, if we were to differentiate the curve—we should obtain a second curve—the curve of induction. It would show a positive maximum at about 30°, and a negative maximum at about 120°, where the slope up and slope down are steepest in the potential curve. These maxima of induction are situated very nearly opposite the edges of the pole-pieces, on the side toward which the armature is rotating. Apparently the lines of force of the field are the thickest here. In this displacement of the maximum of induction we have, I think, the explanation of the inferiority of the earlier machines with broad polar expansions. In those machines the maximum position of induction was displaced to the very edge of the broad pole-piece, and, therefore, the induction was sudden and irregular. It is a singular result that while

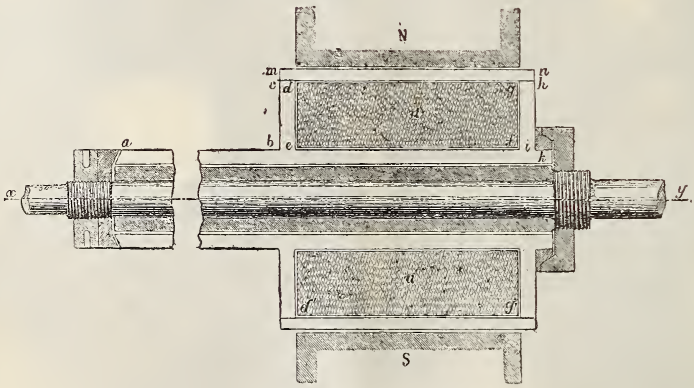
Fig. 24.



Cabella Armature.

in those machines in which the ring armature is extended cylinderwise, there must be wide-embracing pole-pieces, in those in which the

Fig. 25.

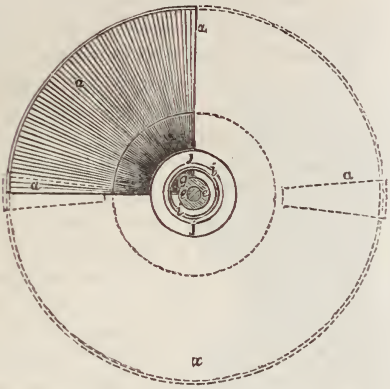


Cabella Armature. Section.

ring is flattened into a disc shape, the pole-pieces must on no account be wide.

The Victoria dynamo is self-regulating, having all the eight field-magnet coils doubly wound, with main circuit coils inside, and shunt coils outside. The characteristic of this machine is wonderfully straight. In a "D^2" machine, wound for a potential of 60 volts, the following values were obtained. Open circuit, 58 volts; 10 ampères, 58·5 volts; 20 ampères, 59 volts; 60 ampères, 59·7 volts; 90 ampères, 59·9 volts; 120 ampères, 60 volts. It will be seen that for small loads the potential drops a little; but it is under these circumstances that the engine speed usually rises slightly in practice, so that the constancy of the potential between the mains is somewhat better than the figures would show. In actual practice, the regulation is marvellous. I have myself opened the circuit of a Victoria dynamo which at the time was feeding 101 lamps, 100 being at a distance, 1 lamp attached to the terminals of the machine. On detaching the main wire from the terminal, the 100 lamps were suddenly extinguished. The solitary lamp on the machine did not even wink, and there was no flash at the brushes. The sparking was so slight it was impossible to tell whether the machine was an open circuit or whether it was doing full work. The lead was the same under all loads. There are not many dynamos that can show a result of this kind. According to measurements made by the Anglo-American Corporation's electricians, who have published

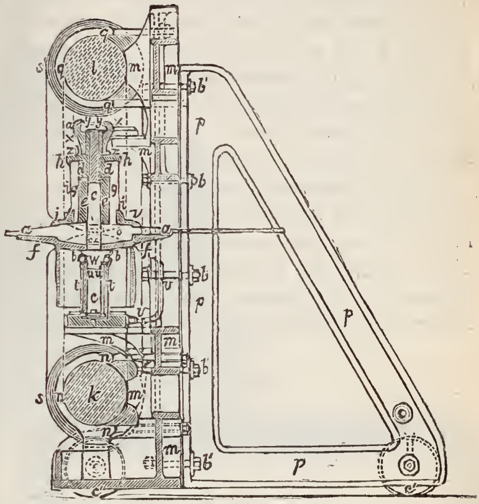
FIG. 26.



ARMATURE OF SIR W. THOMSON'S WHEEL DYNAMO.

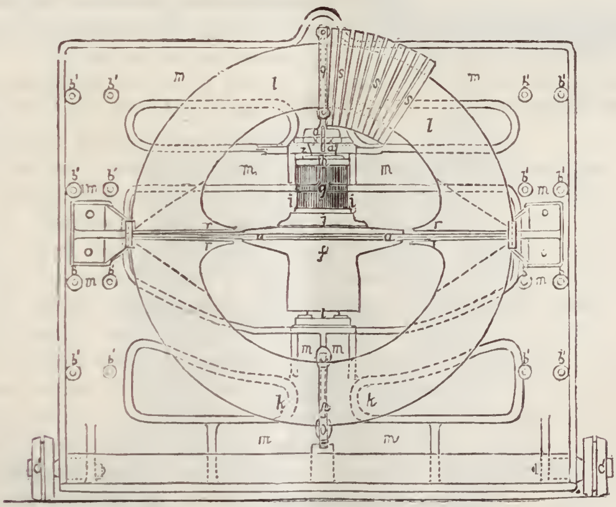
the figures entire, the factor of conversion of this machine is 96·15 per cent., the electrical efficiency 85·68 per cent. These values assume the B.A. unit of resistance as the true ohm, and are, therefore, probably about $1\frac{1}{2}$ per cent. too high. Some of these machines are wound for low speeds for ship lighting. These machines have an electrical activity slightly higher, and an efficiency slightly lower, than the high speed machines. They also have field-magnet cores

FIG. 27.



SIR W. THOMSON'S WHEEL DYNAMO. VERTICAL SECTION.

FIG. 28.



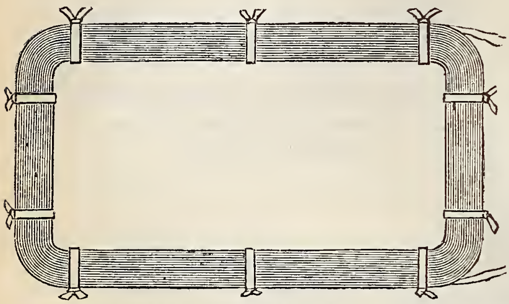
SIR W. THOMSON'S WHEEL DYNAMO. FRONT ELEVATION.

slightly heavier, requiring, therefore, the expenditure of rather more electrical energy in maintaining the field. These remarks refer, of course, to a comparison between machines wound to light an equal number of lamps, and to work at an equal electromotive force.

A larger type of Victoria machine having 8 poles, alternately north and south, set round the ring, has also been constructed by the Anglo-American Corporation. This machine (Fig. 23, p. 335) illuminates 750 incandescent lamps. The ring has 120 sections, there being 15 sections, therefore, between each pole and the adjacent pole of the surrounding set. As each segment of the collector is connected with those situated at 90°, 180°, and 270° distance round the set, only two brushes are required.

A rather singular commentary upon the real superiority of multipolar dynamos having rings of the flattened type, over the more compact ring armatures to which we have been accustomed in the ordinary Gramme machines, is furnished by the announcement within the past month of a new and improved dynamo designed by M. Gramme himself, in which there is a flat-ring armature rotating within a crown of 12 poles. Elaborate illustrations and a detailed description of this latest of dynamos are given in the *Revue Industrielle*, of January 9th, 1884. From this article it appears that in the opinion of M. Gramme the new machine still requires some modifications to make it quite a

Fig. 29.



Parallelogram Coil from the Elphinston-Vincent Armature.

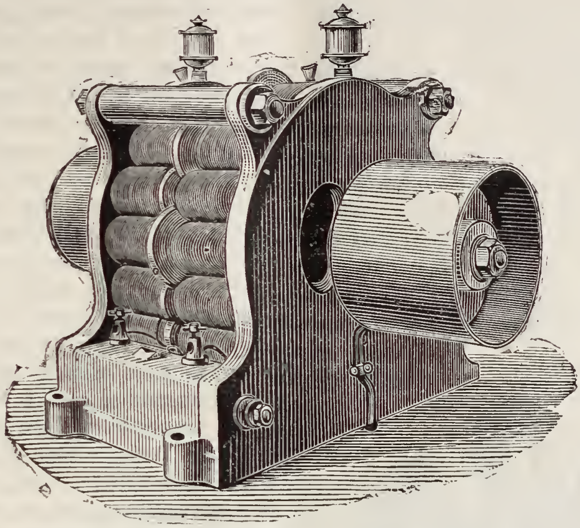
practical machine. A glance at this drawing is quite sufficient to enable one to hazard a guess at the reasons. The pole-pieces are broad, nearly meeting one another. I should confidently predict from such a design the vice of sparking at the brushes and heating of the collector segments. Moreover, there are no fewer than 24 brushes! Think of the friction of 24 brushes, and the labour of making the complicated holders. It appears that in England we are at least a few steps a-head of France in the matter of designing dynamo-machines.

Another 4-pole flat-ring dynamo has been designed by Herr Schuckert, of Nürnberg, and was exhibited at the late Vienna Exhibition. This machine, which had many excellent points in its design, was compound wound, and was calculated to give, at 450 revolutions, a current of 320 ampères at 100 volts.

The present drift toward multipolar dynamos of this type is very significant. There is little difference save in detail between the 4-pole machines of Gülcher, Schuckert, and the newer "Schuckert-Mordey" dynamo, albeit these differences are not unimportant. But all these constructors agree in adopting the flat-ring. The advantage originally claimed for this construction, namely, that it allows less of the total length of wire to remain "idle" on the inner side of the ring, is rather imaginary than real, for the total resistance of the armature is but a small fraction of the whole resistance of the circuit; and it is possible to spread the field so as to make all parts of the wire active without any gain whatever, if, by this spreading, there is no increase on the whole in the total number of lines of force in the field. The real reasons in favour of multipolar flat-ring armatures appear to be the following:—First, their excellent ventilation; second, their freedom from liability to be injured by the flying out of the coils by the tangential inertia (often miscalled centrifugal force) at high speeds; third, their low resistance, due to the fact that the separate sections are cross-connected either at the brushes, or in the ring itself, in parallel arc. To these may be added that, with an equal peripheral speed, the armature rotating between four poles undergoes twice as much induction as when rotating between two poles; since it cuts the lines of force twice as many times in the former case as in the latter.

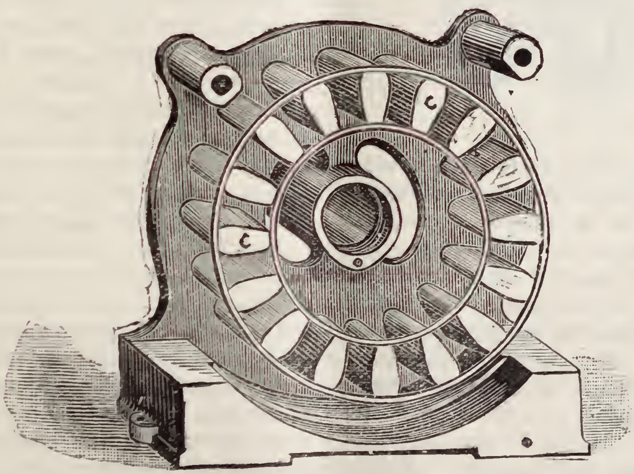
I pass on to the improvements made in the dynamo by Messrs. R. E. Crompton and Co. To describe the course of development which the Bürgin dynamo has undergone in Mr. Crompton's hands would alone occupy a whole evening. The armature of the original machine, as it came from Switzerland, consisted of several rings set side by side on one spindle, these rings being made of iron wire wound upon a square frame, and carrying each four coils. In this form it is described in Professor Adams's Cantor Lectures on "Electric Lighting" in 1881. Mr. Crompton changed the square form to a hexagon having six coils upon it, and increased the number of rings to ten, so that the armature consisted of sixty segments. He then found it advisable to alternate the positions of these, instead of placing them in a regular screw-order on the spindle as shown in most of the published drawings of this well-known machine. The next step was to increase the quantity of iron in the hexagonal cores, and to ascertain by experiment what was the best relative proportion of iron and copper to employ. At the same time, Mr. Crompton and Mr. Kapp introduced their system of "compounding" the windings of the field-magnets. Another change in the armature followed, the rings being made much broader and fewer in number, four massive hexagonal rings, united to a 24-part collector, replacing the ten slighter rings and their 60-part collector. Quite recently Mr. Crompton and Mr. Kapp have again remodelled the style of armature, and have produced a machine which, though it is not yet quite completed, shows what may be done in the way of improvement by careful attention to the best proportions of parts and quality of material. The new dynamo weighs 22 cwts. Its field-magnets are of the very softest Swedish wrought iron, compound-wound. The armature is a single ring of the elongated or cylindrical pattern, and its coils are wound upon an iron core made up of toothed discs of very thin soft iron fixed upon a central spindle, the coil being wound between the teeth as in a Pacinotti ring. In fact, the

FIG. 30.



THE FERRANTI THOUSAND-LIGHT DYNAMO.

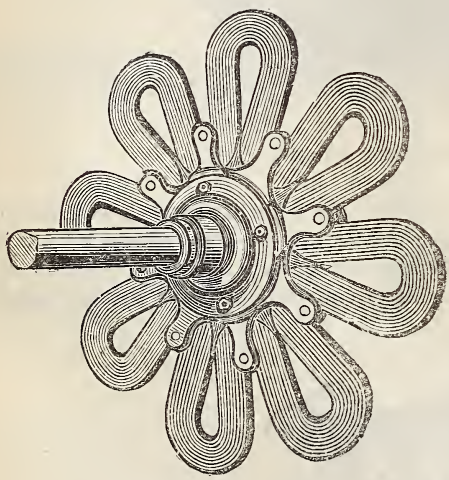
FIG. 31.



HALF-CARCASE OF FERRANTI DYNAMO.

armature may be described as a kind of cross between those of Weston and Pacinotti, having also something in common with the Bürgin armature; at least, so I understand, for though I have, by the kindness of Mr. Crompton, been allowed to see the machine, I have had no opportunity as yet of examining the armature. Mr. Crompton's great aim has been to have as complete a magnetic circuit as possible, and that of the best quality. He has sought to increase the intensity of the field by having plenty of iron in the armature, and bringing that iron as close as possible into proximity with the pole-pieces by means of the projecting teeth. The result is an extraordinary increase in the "output," or, as Sir William Thomson terms it, "activity" (*i.e.*, amount of work done per second) of the machine The machine is

Fig. 32.



Feeranti Armature.

only 3 ft. 4 in. long, 12 in. high, and 2 ft. wide. The armature is 17 in. long, and 8 in. diameter. At 1,000 revolutions per minute it gives 110 ampères at 145 volts, or its "activity" is 15,950 watts; but at this speed it heats too much. The power of the field-magnets is such that, at all speeds, and under all conditions of the external circuit, the intensity of the field overmasters the magnetising action of the currents in the armature coils. There is, therefore, hardly any lead at all at the brushes, and what lead there is, is absolutely constant. There is no sparking at the brushes, and it is impossible to tell by looking at the brushes whether the current is off or on. Mr. Crompton is now constructing another machine of the same general design, but larger, to drive 1,000 Swan amps. This machine, together with its engine, is only about 8 ft. long, 6 ft. high, 2 ft. 4 in. wide, and complete, with its bed-plate, will weigh only about 8 tons.

It may be mentioned that in Messrs. Crompton's compound dynamos, as also in those of the Anglo-American Corporation, the series coils are wound direct upon the iron-cores, and the shunt coils outside them, thus reversing the practice adopted by Messrs. Siemens, and by Mr. Gülcher. It might have been expected that theory would have something to say in determining which practice is preferable. If the shunt coils of thin wire are outside, the prime cost for an equal magnetising effect will probably be greater. If the series coils are outside, the loss by heating in producing an equal magnetic effect will probably be increased. It might have been expected that, as with galvanometer coils, so with the coils of field-magnets, it would be advantageous to get as many of the turns as close as possible to the core, and, therefore, that the thinner wire should be wound on before the thicker. But, on the other hand, it is advisable to keep down the resistance of the series coils, as they will form part of the main circuit; whilst the additional resistance necessitated by winding in coils of larger diameter is not altogether a disadvantage in a shunt coil. If this proves to be the right way of regarding the problem, we shall wind the shunt coils outside those that are in series with the main circuit.

Before leaving the subject of ring-armatures I should like to refer to a form recently devised by Signor B. Cabella, which I think might be recommended to amateur constructors of dynamos as being easily made. The Figs. 24 and 25 (p. 336) show its general arrangements. The armature resembles that of the Edison dynamo in being built up of copper strips. These are separately cut out, and consist each of a straight piece having two arms, and projecting at right angles. A sleeve of insulating material is placed over the axle, and round this these copper pieces are arranged to the number of some 240 or so, having their arms projecting symmetrically round in two radial sets, one near one end and the other near the other. The channel formed thus between the two sets is lined with insulating material, and then entirely filled up with soft iron wire wound round. Then straight strips of copper, eight millimetres broad and two millimetres thick are screwed across the outside (like the bars of the Edison armature) from the ends of one set of radial projections to the ends of the others, forming the parallelogram section. But, in order to connect the ring all round in a continuous circuit, these external strips of copper are connected at their two ends to pieces which project not from the same internal copper strip but from adjacent strips. Thus an external bar will connect the anterior end of the first strip with the posterior end of the second; and so on. Every third strip is carried along the axle and connected to a segment of the collector. This construction is certainly simpler than that of the Edison armature, and might be adapted to many different types of machines. According to Professor Ferrini, one of Cabella's armatures placed between the poles of a 60-light Edison ("Z," old pattern) instead of its ordinary armature, increased its power so that it could be used over 100 lamps.

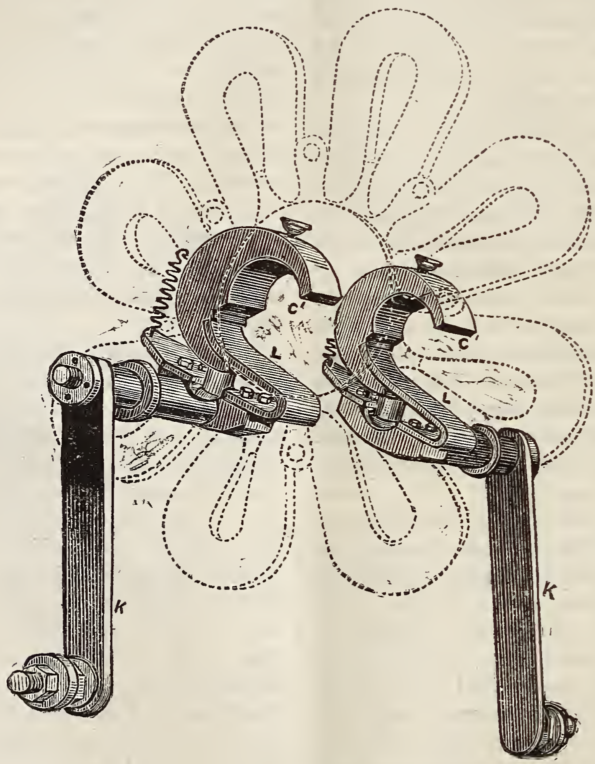
Passing from ring-armatures, I come to another type of machine having disc armatures. The earliest machine of this type was due to the indefatigable Mr. Edison, who built up his disc of radial bars connected at the outer ends by concentric hoops, and at the inner by plates or washers. Each radial bar communicates with the one opposite to it; and the disc thus built up is rotated between the cheeks or pole-pieces of very powerful field-magnets, which very nearly meet, and which therefore yield an enormously powerful field I cannot hear of any of these disc dynamos having yet come into practical use.

Another type of disc-dynamo has been invented by Sir W. Thomson. In this case, the armature is a flat wheel, very like a flattened bicycle wheel. It is shown at *a* in Figs. 26, 27, and 28 (p. 337). The radial arms or spokes of the wheel, in which the currents are induced, are all connected at their external ends to the copper rim, but at their internal ends are carefully insulated and connected each to a segment of a collector or commutator, *g*. As in Edison's disc machine, so also in this, the thin disc rotates between the poles of very powerful field-magnets, which, in the case of Sir W. Thomson's machine, are semicircular in form. Sir W. Thomson also pivots his armature with its axis vertical, and spins it like one of his gyrostats. Unfortunately, the machine has not shown itself to be in practice a success. Its construction necessitates a very high speed, else the electromotive force would be small. If the radial bars, instead of being all joined to one rim, were united by overlapping insulated rims, each one to the one next to that diametrically opposite, and a connection brought round again at the hub to the next but one from that at which the outer rim started, then, applying similar connections all round, the radii would all be connected in circuit, and a much higher electromotive force might be obtained. I am not aware that any disc so connected has yet been tried.

Some improvements have also been made in the Elphinstone-Vincent machine. The sections of the armature of this machine are wound separately in parallelogram forms like that shown in Fig. 29 (p. 338), and the separate sections are then fixed upon the periphery of a papier-maché cylinder which is mounted so as to rotate between powerful field-magnets and internal field-magnets whose poles reinforce the field. In the improved machines the parallelograms of wire are so arranged that the overlapping ends lie outside the ends of the polar surfaces of the field-magnets, which, therefore, can be brought very close to the surface of the rotating cylinder. Amongst other improvements, also, segments of the collector are internally cross-connected, so that only two brushes are needed instead of six as formerly. Several improvements in mechanical details have also been made.

In alternate current machines something has also been done. The Ferranti - Thomson machine, which, at the date of my Cantor lectures, had just made its appearance, has been considerably perfected. By the courtesy of Mr. Hammond, I am enabled to show Figs. 30 to 33 (pp. 339, 340), illustrative of the "1,000-light" dynamo, and of its working parts. Externally, the machine is scarcely charged at all; the driving pulley being a little larger in proportion. Internally, considerable changes have been made, and in these the hand of the experienced mechanical engineer is apparent. The frame-work of the machine is now cast in two halves, which are afterwards bolted together. Fig. 31 (p. 339) shows one-half of the carcase of the machine with its projecting circle of magnet cores, C, which receive the field-magnet coils. The armature, originally a single zigzag piece of copper, has assumed the form shown in Fig. 32 (p. 340), in which it may be seen that the convolutions are multiplied, and are held in their places by bolts through a star-shaped piece of brass which also serves to carry to one of the two collectors the connexion with one of the zigzag copper strip. There are in fact three complete circuits of copper strips in the armature connected in parallel arc. They begin at three of the alternate four bolts of the star-shaped piece, and, folding ound one another, they all eventually unite with a second and inner star-shaped piece, which communicates with the second collector. Each strip makes ten turns round the zigzags, so that there are thirty layers, all well insulatd from one another by strips of vulcanised fibre. This armature is 30 in. in diameter, and a little more than ½ in. thick in the upper convolutions, so that the opposite poles of the field-magnets can be brought very close together, and a very powerful field produced. The entire armature weighs only 96 pounds. The most extraordinary part of the machine is, however, the arrangement adopted for conveying the currents to the external circuit. The axle carries on either side of the armature an insulated collector ring of bronze, to which the afore-mentioned star-shaped pieces are respectively connected. Instead of brushes, solid pieces of metal, shown at *C′ C′*, Fig. 33, are employed to collect the current. These collectors hook on over the collecting rings, and bear against about 180° of the periphery of each ring. They are fixed on universal joints, and

Fig. 33.



Collectors of Ferranti Dynamo.

held by springs from rotating. Copper strips connect them to the terminals of the machine. The arrangements for lubricating the bearings are extremely perfect. The machine requires a speed of 1,400, and weighs 1½ tons. Mr. Ferranti has also designed a slow-speed dynamo to run at 300 revolutions per minute, and feed 500 lamps.

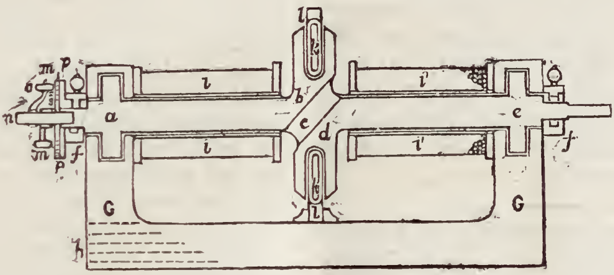
A very large alternate current machine was shown at the late Electrical Exhibition at Vienna, by Messrs. Ganz, of Buda-Pesth. It was capable of furnishing light for 1,200 Swan lamps (20 candle-power each). This dynamo, which in some points resembled Gordon's well known machine, was constructed according to the Mechwart - Zippernowsky system. The thirty-six bobbins of the field-magnet were set concentrically on an iron frame, and rotated within an outer circle of thirty-six armature bobbins. The field-magnet coils were, in fact, the fly-wheel of the high-pressure compound engine which drive the machine and its exciter. The diameter of the rotating part was 2½ metres. A salient feature of this machine is the fact that any one of the coils, either of armature or field-magnets, can be removed from the side of the machine, in case such are needed. The whole fly-wheel can, in this way, be taken down by one man in a few minutes. An electrical efficiency of 85 per cent. is claimed for this machine.

Of one other class of machines—the unipolar dynamo—I had intended to say something. It is a remarkable thing that, though to my knowledge a great deal of attention has been paid lately to machines of this type, no one has yet succeeded in designing a practical unipolar dynamo. There seems to be some hiatus in the theory of this class of machine, for the very singular fact remains that those which are designed in defiance of precautions to avoid wasteful internal eddy currents will work, though badly, and those designed with such precautions will hardly woık at all.

There are two or three other new designs for machines which, at present, can hardly be called anything but curiosities. There is, for example, a design for a dynamo (a drawing of which is given in Fig. 34), by Sir Charles Bright, in which the field-magnet coils and armature stand still, but in which the iron cores and the brushes rotate. There is another design by Professor G. Forbes, in which part of the field-magnets rotate. Mr. C. Lever has designed a machine on somewhat similar principles to the foregoing. I have myself essayed an alternate - current machine, in which both armature and field-magnets stand still, while laminated pole-pieces alone revolve. I hear also of a dynamo designed in the States in which there are no field-magnets only two revolving armatures.

And now I have left myself no time to deal with the third branch of my subject, namely, the dynamo in its functions as a mechanical motor. In this branch also much progress has been made. If time permitted I would speak of the motors designed by Professors Ayrton and Perry, which are successful to a very remarkable degree in yielding a great mechanical power in proportion to their weight. I might have been inclined to say something of the attempts made by the same able electricians to produce a self-governing motor by various devices of centrifugal and periodic governors, and also by using an ingenious differential winding. I might tell you how I have myself worked at the question from a different point of view, and have sought to govern motors so that they shall run at a uniform speed, by devices which will not wait until the speed changes before they act, but by devices depending upon the variations in the load of the machine, in short, upon dynamometric governors instead of centrifugal ones. These things must, however, wait until some more convenient season. Time will only admit of my showing you here, in conclusion, a model designed by Mr. C. Dorman to illustrate the graphic law of efficiency of motors, which I put forward in my Cantor lectures, and which I am happy to learn has since been largely used in many different countries.

FIG. 34.



SIR C. BRIGHT'S SUGGESTED DYNAMO.

To sum up then, it may be observed that in every department under review, the story of the past fifteen months is one of solid progress. It has been, it is true, progress of a quiet and perhaps of a commercial rather than a scientific order, yet, as I have shown you, one in which practice and theory have gone hand in hand. It is true that in some few points theory is a-head of practice, but in a still larger number practice is a-head of theory. It would be a great boon to us if our theoreticians could bring up theory to the level of practice in some of the simplest facts. We do not even know the exact law of the saturation of iron in electro-magnets, and content ourselves with formulæ, which we *know* to be incorrect. Of the laws of induction of magnetism in circuits partly consisting of iron, partly of strata of air, or of copper wire, we know very little. We want some new philosopher to do for the magnetic circuit what Dr. Ohm did for the voltaic circuit fifty years ago. There is ample room for progress yet in theory as well as in practice; and the perfection of theory means the deliverance of practice from arbitrary rules of thumb, and from the blunders of inexperience which have so retarded progress in the past. The history of the past fifteen months, however, gives great encouragement for the future, because it shows how much may be done, even in the face of great commercial depression, by those whose knowledge and experience give them a deliberate faith in the future, and whose efforts are directed toward no uncertain end. A steady development toward the yet far distant goal of perfection is going on unceasingly. The progress of which I am permitted to be the chronicler to-night is progress of the good and substantial kind, that owes nothing to the excited rush of Stock Exchange speculations, and which, not having been nurtured at an unhealthy fever heat, is destined to be of permanent value.

My thanks are due to the publishers of the *Electrician* for permission to reproduce Fig. 17; to the publishers of the *Electrical Review* for Figs. 26 to 29; to Mr. F. Wynne, of the Anglo-American Electric Light Corporation, for Figs. 21 and 23; to Mr. R. Hammond, of the Hammond Electric Light Company, for Figs. 30 to 33; and to Mr. Hugh Watt of the Maxim-Weston Company, for Figs. 18 to 20.

DISCUSSION.

The CHAIRMAN said they were much indebted to Professor Thompson for the extremely clear and able manner in which he had brought forward the progress of dynamo-electric history, and he was very much pleased to find that in that progress he had given the first place to practice, and the second place to theory. He had always found theoretical men rather inclined to look with a certain amount of disdain upon practical men, and to think that practical men knew nothing about their subject unless they followed the dictates of theorists. But a change seemed to be coming over the spirit of the dreams of philosophers, and they were now paying much more attention to the teachings of experience than they used to. Professor Thompson had shown how, during the past 15 months' progress, the lead had been taken by practical men; and he had been rather amused at this, because not much more than a week ago he heard him make similar remarks upon a paper brought before the Royal Society by Professor Hughes, one of the most wonderful experimenters and discoverers of the present day. Professor Hughes succeeded, with pins, bodkins, bonnet wire, match boxes, tin kettles, and similar pieces of apparatus, in extracting from nature some wonderful secrets, and he had brought out some very beautiful instruments, which had been the result of incessant toil and constant experiment in every shape and form. Professor Thompson, at the Royal Society, gave the theory after Professor Hughes had shown his instruments, and at the end of the paper expressed surprise that Professor Hughes' instrument accorded with his theory. This was much what he had told them now, though not quite in the same words, that, after all, experience was the only safe guide in teaching one how to make instruments for real practical work; and theory was a very good servant indeed when it came afterwards, and gave a plain, simple, unvarnished tale, which all could understand, to enable them to understand the peculiar action which had taken place. Professor Thompson had alluded to the theory of the dynamo machine, and divided his theories into three—the physical, the algebraical, and the geometrical; and he was bound to say that his own diagramatical representation of the action of dynamo machines, and of the performance of magnetic fields, were perhaps the most interesting part of his paper. The way in which he had worked out the magnetic field had taught everybody more about this subject than they knew before. But he must say that he objected *in toto* to this application of the term theory to explanations which Professor Thompson had given of the action of the dynamo machines. Theory was neither algebraical, nor geometrical. What Professor Thompson called theory was an explanation—a mode of representing what took place. But a theory was more than that; it was an explanation—a mental picture—of what took place in nature which placed it beyond mere hypothesis. For instance, the theory of light was an explanation of a certain physical action which took place in the universe, which enabled the vibrations of the sun to be represented in our eyes. The theory of heat was something which enable dus to conceive of matter itself vibrating and the space around it also vibrating in unison; but he objected to applying the term theory to either an algebraical or geometrical description of the actions of the dynamo or any other machine. He, and all other electricians, wanted to have some idea conveyed to their minds of what took place in a wire, in iron, and in the space occupied by the iron and the wire, which produced those marvellous results which they saw in the electric light and in the transmission of force, and to this sense he would confine the word theory.

Mr. LIGGINS said he was not qualified to speak on the scientific aspect of the question, but he was much interested in hearing of the progress which had been made during the last sixteen months. He was glad to find that some of the bubble companies were going to the wall, and when some of the systems which had very little merit were out of the way, there would be a chance for some simple and practical method to come into use. One day last week, at the Edgware-road Station, he noticed that the electric arc light was wonderfully steady, and the superintendent informed him that an improvement had just been introduced, which reduced the cost from £200 to £8. That was all he heard about it, for he had not time to inquire further particulars, but he hoped the time was not far distant when the public would derive a benefit from some of these improvements.

Mr. PERCY SELLON then gave some particulars of the Victoria machine. He said that taking an original Schuckert machine, capable of giving 60 incandescence lamps of a certain power, by substituting four poles for two, the mass of which, both in iron and copper, was very little in excess of that in the original two, and using identically the same ring, they obtained 100 lights, and a much better result in the commutator. From the old Schuckert machine they got a very similar diagram to that which had been shown, among those integrated from Isenbeck's as a bad one with false inductions (Fig. 6), the output of the machine being crowded into two bobbins, and on the other side there was a back electromotive force which caused considerable sparking. This was almost entirely removed by the use of four poles, and at the same time the internal resistance was brought down to about one-fourth what it was before. In constructing large dynamos for 500 lights and upwards, they were increasing the number of poles to 6 and 8, and eventually, probably, they would go to 12 for very large machines. The great advantage of this was that when you brought the poles together you had a given number of lines of force crowded into a very much smaller space; the distance of the centres between north and south polarity were much less, and whilst the number of poles increased, the intensity of the field remained the same, and, therefore, a given length of wire and iron, revolving at a certain speed, would give a decidedly higher result. With regard to the system of compound winding, he should say that a great deal of the credit was due to an *employé* of the firm, Mr. C. Watson; and it was applied without any formula or mathematics, and the very first machine constructed without any experiments gave as good a curve as the one shown on the diagram. It gave a difference of potential of only about 3 per cent. when the whole number of lamps was at work, and when the armature was simply working on the shunt. That showed that theory was not always necessary.

Professor THOMPSON, in reply, said that he did not agree with the Chairman's criticism on his use of the word theory. He thought that he had indicated that these three methods were really three aspects of the theory. The number of lines of force which he had been dealing with, might be expressed by a certain length of line, geometrically, or by the symbol n alphabetically, or when viewed optically, by a mere pictorial demonstration. What some people wrote n for, other people indicated by drawing a line in a certain direction. It was only another way of arguing about the things themselves. He wanted them not to ignore those essential considerations which constituted the true theory, and which underlay the mere mere facts of observation. They were approximating to that theory by one process or another; sometimes by algebra; sometimes by geometry; sometimes by diagrams; and it made all the difference between working intelligently and unintelligently, to have a principle to guide one. He had been trying to discover, both from *à priori* considerations, and from the teachings of experience, what the principles were which ought to guide practice; and he thought he might claim to have vindicated the claims of theory. It was quite true that theoretical men had been sometimes loth to allow any consideration to practical men; but on the other hand, practical men would often refuse to have anything to do with theory. The vindication he wanted to put forward was this; in his Cantor lectures and since, he had been working diligently at the curves of potential round the commutator, and to-night he had connected them with the curves of Isenbeck. Part of the improvement he had noticed in the Schückert machine was directly due to the advice he had given Mr. Mordey, and to the world at large, on shaping of the pole-pieces to that form which would give the best result on the commutator in respect to the rise of the curve of potentials. Originally the Schuckert machine had great shoes of iron, as pole-pieces, round it, now they were narrowed and tapered. It was found that where you had pole-pieces on the two sides of an ordinary cylindrical Gramme ring, it was better to have them curved round through a large arc, because it gave a flatter field, and the cutting of the lines of force was more regular. Now they were finding that practice was leading in an exactly opposite direction for flat ring machines with the poles at the sides; the shoes were being cut down into little narrow pole-pieces. Theory had led practice to that; and theory, too, had pointed out the relation between the curve of the potential, and the induction due to the pole-pieces. After theory had indicated the source of error and a possible means of remedy, they had gone on experimentally cutting down the pole-pieces until they got the proper curve on the commutator. He might further claim, as a vindication of theory, that M. Gramme, who had had fourteen years' experience in constructing Gramme machines, and to whom they owed an enormous debt of gratitude, had not yet arrived at the real point which had been reached in England. M. Gramme confessed that this 12-pole machine of his was not yet perfect; and he (Professor Thompson) had little doubt that the reason was that he had great flat pole-pieces nearly meeting each other. He would stake his opinion on the fact that if he had only made the poles narrower, he would have had a better curve of potential, and a machine that did not spark so much. That was the deduction he should draw at once from the potential curve. He claimed that it was entirely admissible to call a generalisation from which deductions of that kind might be drawn, theory; it was theory in the truest sense of the term, because it pointed the way for practice to follow. He did not require to know what electricity was, or what magnetism was in a piece of iron, or what was the ultimate form of the transfer of force across the space between them, before he used the word theory. He regretted that cold water should have been thrown on his attempt to raise the construction and design of dynamo-machines above mere rules of thumb, which were the essence of practice when unenlightened by theory. Practice without theory went on blundering in the dark, and though it was possible to blunder into success it was much more easy to blunder into failure. With regard to the invention which had been mentioned which would reduce the cost from £200 to £8, he need hardly say he should be much interested in further details; he believed it was the first instance on record in which an inventor dared to claim to have reduced the cost more than 50 per cent., that being the usual reduction claimed in the stock phrase of company promoters.

The CHAIRMAN, in proposing a vote of thanks to Professor Thompson, said he did not apply the word "theory" in the sense he objected to. He thought that certain geometrical and algebraical investigations were essential in carrying out any practical question, but he objected to the use of the word "theory" to explain what was really better expressed by the word "principle." Professor Thompson himself used the word "principle," and had detailed the principles that governed the action of the dynamo machines, and it had been in following these principles that such vast improvements had been made. He should like to have heard some description from Professor Thompson of a class of dynamo machine which was now coming into use daily very largely for the production of copper by the deposit of the metal from its salts. This was being done both at Swansea and at Birmingham. Mr. William Elmore, a hard worker in this field, who had works at Blackfriars, was setting up very large works at Swansea for the extraction of copper from impure ores by this method and when next Professor Thompson brought the subject before this Society, as he was sure the Council would insist upon his doing next year, he hoped that he would pay a little attention to those dynamo machines that were met with in other fields besides the production of electric light and the transmission of power. Again, he was rather disappointed to hear him pass by very lightly the performance of the Hockhausen machine, which was certainly the most distinguished feature of the Fisheries Exhibition. He did not think that that machine had received the attention it deserved, or been studied so carefully by Professor Thompson as others. Its performance was simply wonderful, and though he had not yet seen the Victoria machine, his own impression was that of all those he had seen the Hockhausen was decidedly the best. Perhaps Mr. Crompton's was an exception, for he had this advantage over Professor Thompson that he had seen the performance of the Crompton machine. It was certainly a wonderful little thing. You saw before you apparently a lump of iron which was motionless and silent; it appeared motionless because it went so quickly, and it was silent because it was so beautifully made, but with that machine currents of electricity were produced that had increased the output of the form known as the Crompton-Burgin machine exactly 100 per cent. The great lesson to be learnt was this; advance was being constantly made in all these machines, an advance whose future they could scarcely see an end to, and everyday they could perceive how, by the combination of theory and practice, they were developing the power of producing electricity to an extent which no one had dreamed of. What with the improvements such as had been mentioned that evening, with improvements in electric lamps and various other appliances, he did not think there was any chance of that end being reached which gas shareholders were so anxious to see.

The vote of thanks was carried unanimously, and the meeting separated.

THIRTEENTH ORDINARY MEETING.

Wednesday, March 5, 1884; Sir FREDERICK ABEL, C.B., D.C.L., F.R,S., Chairman of Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Allen, Mrs., 18, Ashchurch-park-villas, Shepherd's-bush, W.
Bowick, Thomas, Stafford-lodge, Southend, Bedford.
Davey, Henry, Rupert-lodge, Headingley, Leeds.
Davies, William J., Gunterston-road, West Kensington, W.
Fielden, Edward Brocklehurst, Nutfield Priory, Redhill, Surrey.
Kinglake, Robert Alexander, Rushmere, Wimbledon.
Larnach, Donald, 21, Kensington-palace-gardens, W.
Moseley, Charles, Manchester.
Playster-Steeds, John, Grosvenor-gate, Twickenham.
Rose, Frederick, 28, Page-street, Westminster, S.W.

The following candidates were balloted for and duly elected members of the Society:—

Brown, Henry, B.A., 10, Phillimore-gardens, Kensington, W.
Dewar, Prof. James, M.A., F.R.S., 19, Brookside, Cambridge.
Hogg, Stapleton Cotton, 68, Warwick-square, S.W.
Mitting, Ebenezer Kennard, Rye, Sussex.
Preston, Edward, 35, Cornwall-gardens, South Kensington, S.W.
Rivington, Rev. John Alfred, M.A., 32, Eardley-crescent, West Brompton, S.W.
Smith, Harry Fryer, 13, Albany-st., Regent's-pk., N.W
Venner-Morris, A. A., Ivernolen, Ammanford, R.S.O., Carmarthenshire.

The paper read was—

ON THE PROGRESS OF ELECTRIC LIGHTING.

By William Henry Preece, F.R.S.

At a recent meeting, held in the City, to determine the future of a prominent electric lighting company, the principal speaker is reported to have said*:—"Electric lighting was at present a failure, and the sooner the public were made aware of it, the better for their pockets." This statement (if made) is not only an egregious fallacy, but an absolute untruth. Electric lighting is a most pronounced success. What has proved a disastrous failure is, electrical company-mongering, and electric lighting finance. The money-making world has been too eager to reap the benefit of the patient student, the ingenious inventor, and the observing engineer.

The progress of electric lighting, from a financial point of view, has been disgraced by the commission of every possible crime that commercial immorality could invent, and every foolish act to which insane speculative mania could lay itself open; but from a practical point of view it has been steady and sure. At one time, I contemplated in this paper, entering somewhat largely into the commercial side of the question. I had prepared a list of every company that had been promoted, floated, or wound up, but on further consideration I saw no advantage in crying over spilt milk. The ravenous promoter, the thoughtless investor, the disappointed speculator would care little for what would be said here. The evil that has been done could not be undone. History would soon again repeat itself. If any other fresh invention were to spring up, to threaten the prosperity of some well established interest, stockholders would be frightened, mania would set in, financiers would flourish, and money would freely change pockets.

There is no doubt, however, that the disgraceful financial operations, and remarkable gullibility of the investing public, of the past two years have materially checked the progress of electric lighting by destroying confidence in its success, and thereby withholding the sinews of war by which alone ultimate success can be secured. With millions thrown in the gutter, it is not to be wondered at that investors button up their pockets when the words electric light is mentioned; but leaving aside the question of the gross mismanagement which has allowed immense sums to be squandered, I propose briefly to indicate some of the progress made, both in a scientific and practical sense, and to show that electric lighting is a real true success.

On August 18th, 1882, an Electric Lighting Act, promoted by the Board of Trade, received the Royal Assent and became law. Its effect has been to add considerably to the expenses of those who are struggling against difficulties. Its object was to prevent the possibility of the formation of such a gigantic monopoly as that of water and gas. It has effectually done this, but by strangling the babe. The Act provides that an electric lighting undertaking should be carried out under a provisional order or under a license. The former covered a period of twenty-one years, the latter a period of seven years only. Provisional orders required that those who supplied the electric light, should, within a given time, compulsorily light, for public and private purposes, some portion of the district they wished to supply, while other portions should be lighted only on requisition and by agreement, or failing either, the order was to be withdrawn. These relative areas were to be determined upon jointly by the local authority affected, and the undertakers. The capital to be expended in every separate case was to be allotted, and a certain portion deposited with the Board of Trade, to prove the *bona-fides* of the undertaking.

Very carefully prepared regulations were issued, controlling the mode of supply, and securing the safety of the public. These regulations are sufficiently elastic to be modified with the advance of electrical knowledge, and with the teachings of experience.

Provision is made for the purchase by the local authority of the undertaking, if promoted by a company, at the end of the twenty-one years' period, and restrictions are inserted

* *Electric Review*, February, 16, 1883, p. 139.

preventing the possibility of any claim to monopoly, or to exclusive rights. Moreover, the limitation of profits and the revision of prices are left to be controlled by the fear of competition from rival electric light companies, and from the existence of gas, and by the exercise of public opinion through the medium of the Board of Trade. The tenure of the order is dependent on faithful discharge of its obligations. The Board of Trade remains a species of arbitrator between the public and the undertakers of light. It has effectually checked the establishment of a monopoly, but at what price?

One hundred and six provisional orders were applied for last year, sixty-nine were granted, but at the present moment deposit has not been paid on one single undertaking, and, therefore, not one single installation has been carried out under the provisions of the Act. Of the sixty-nine provisional orders granted, fourteen were given to local authorities themselves, but not one has been carried out.

Ten applications for licenses were received by the Board of Trade, but none were persevered with, and, therefore, none have been granted. No form of license has yet been issued. It is intended that their restrictions shall be less onerous, and their operation shall be more tentative in their character than those of provisional orders. They will be granted for seven years, to be renewable at the end of that period.

Some modification will have to be made in this Act. It is all in the interest of one class, viz., the local authority. The fear of the repetition of the gas and water monopoly has evolved restrictions that render commercial enterprise difficult. No cautious inventor would embark his capital in business which, if successful, will at the end of twenty-one years be confiscated, and, if unsuccessful, will be thrown on his hands, while no local authority will take the bull by the horns and do the work itself while there is the prospect of someone else doing it for them. Ever changing local authorities are very chary of investing ratepayers' money in tentative schemes, and cautious speculators will not risk money in what must be either practical confiscation or doubtful gain. The City of London has gone so far as to ignore the Act, and to invite tenders to light the streets, and to supply houses without any restriction whatever. Other corporations will, perhaps, do the same. Capital can be attracted only by gain. If the gain is to be thickly spread over a few years, the public will suffer. If it be only thinly spread, the capital will not come, and the public will equally suffer. Hence the operation of the present Act is detrimental to the public good.

As regards the scientific progress little has to be said. We had learnt nearly all we wanted to know before electric lighting had entered its practical stage. In reality, the very fact that it had entered its practical age was a proof that it had passed through its infancy of scientific tuition. The conditions that determined its production, the laws that regulated its behaviour, the means that were available for its control, had all been thoroughly investigated and laid down, before practice stepped in to show us what could be done.

Electricity can be produced, currents can be distributed, light can be generated, but we have yet to learn how all this can be supplied economically, profitably, and with safety to person and to property. Practice alone can determine these points, and it is well to make a rapid survey of the extent to which practice has up to now enabled us to solve these points. The future of electric lighting is now in the hands af practical men.

It has been well said that a want has only to be announced to prompt inventive genius at once to supply it. Electric lighting has called for motors of a class not hitherto in demand, and steam, gas, and water engineers have rushed to the front to meet the demand. Nothing can surpass the perfection of this class of apparatus; where everything is excellent, it would be invidious to single out examples. The production of electric currents means the expenditure of power; and when the extent of the installation is known, it is a simple calculation to specify how much horse-power is needed. Some employ a fall of water to urge a turbine, others employ steam, many use gas to obtain the power requisite to convert the energy of mechanical motion into that of electric currents. Gas-engines are being very largely used, and since the expenditure of a given amount of gas as power, will produce more light through the agency of electricity than by direct combustion in air, it is clear that we have here an evidence of the true function of gas. The perfect gas-engine has not yet been produced. Those in use are too noisy, too irregular, and sometimes uncertain, but the advances made are very marked and very encouraging. The hall in which we are is, as you see, brilliantly illuminated by a gas-engine. Those little lamps, though electric glow lamps, are in fact lighted by gas, though the gas itself is consumed in the cellar. The light we enjoy is only a form of the energy which has been brought into this building by the Gas Light and Coke Company. In all cases of electric lighting, electricity is merely the agent which transforms the pent-up energy contained in water, steam, or gas, into that of light. Hence it is that so much of the efficiency of electric lighting apparatus depends upon the instrument called the "dynamo," by which the conversion of this energy is brought about, and here it is that so much inventive skill has been expended, and so much real progress has been made.

The dynamo is the machine by which mechanical energy is converted into electric currents. Rings, or bars of copper-wire, forming a portion of the electric circuit, are forced through a space subject to strong magnetic influence, and the result is the formation of electric currents, whose intensity is dependent primarily on the magnetic strength of this space, and of the velocity with which the wire is made to pass through it, and secondarily, on the dimensions of the conductors, and of the size of the machine. The tendency of recent improvements has been to improve the mechanical details and to increase the out-put of the smaller machines. Thus by increasing the quantity and quality of iron, by better winding, and by rearranging some parts of the machines, Dr. Hopkinson has succeeded in doubling the out-put of the Edison dynamo. Mr. Crompton, by somewhat similar means, and by using the purest iron obtainable, has succeeded in making his Bürgin dynamo light up 210 lamps, instead of 90. Sir William Thomson and Mr. Ferranti have turned out a little machine, which succeeds in lighting up 1,000 lamps by a mass of metal, which two years ago would not have illuminated 100 similar lamps.

Thus we have a process which is still actively going on, by which the economical out-put of a given weight of material is vastly increased.

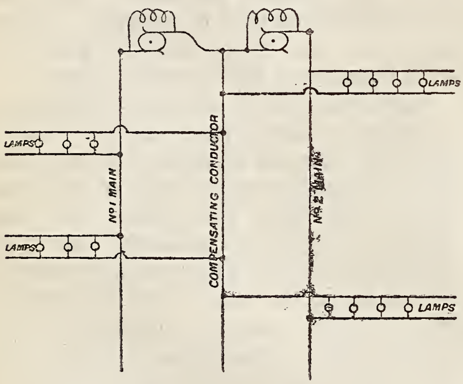
One of the most interesting objects at the Fisheries Exhibition last year was the Hochhausen dynamo, which is one of the most remarkable yet brought into the market. Those who visit the forthcoming Health Exhibition will have an opportunity of inspecting it. The main features of this dynamo are the extreme simplicity and the mechanical accuracy of its parts, the automatic mode of governing, its great adaptability, so that it can be varied at will either to high or low tension, and the remarkably low velocity for such high electromotive force.

The distribution of the currents through conductors is one of the problems that demands the highest skill of the engineer, not alone for the efficient working of the system, but for its economy. It is not sufficient to convert our useful energy into electric currents, we want to distribute them with the least possible waste. Conduction means waste, and this waste can be controlled only by using the purest metal, and by so regulating the electromotive force and dimensions of the conductor as to obtain the maximum effect with the minimum means. It is an exceedingly difficult problem to solve. The metal universally used is copper, but very few people take the precaution to test its purity. Contractors go to the cheapest market, and the result is they get the nastiest material. I know of conductors that give only 70 per cent. of the conductivity that they should give. This means largely increased waste, and greatly enhanced cost of working. Impure copper not only means needless waste, but waste means heat, and, therefore, danger.

But wasted energy may also take the form of leakage, or direct loss of current. This is cured only by good insulation. Good insulation unfortunately means expense; and here again competition has forced too much economy. I have not examined one single case of the failure of an electric light that has not been traceable either to crass ignorance, or to needless economy. Perfectly well insulated copper conductors are within the reach of all who choose to pay for them; but when proper specification, proper inspection, and proper tests are neglected, we must expect, as has too often happened, failure and expense.

A marvellous improvement has been made by Dr. John Hopkinson and by Mr. Edison, independently of each other, by which the weight of copper necessary for central station working has been diminished 60 per cent., and this is due to the use of two dynamos connected in series, and a third, or compensating conductor, placed between them as shown in the accompanying diagram. (See next page.) The weight of copper necessary for a conductor can also be diminished by the use of high tension currents, and this has led to various suggestions by which high tension currents shall be used for charging secondary batteries, and for exciting induction coils, but the use of high tension currents for household purposes is at present regarded as dangerous.

High tension currents are, however, available for public street lighting, and are very satisfactorily employed for this purpose. There is a very senseless crusade being conducted just now in certain quarters against overhead wires. Overhead wires, if properly constructed, are most desirable, especially for electric lighting. It is the terrible abuse of this mode of construction that has caused the present onslaught upon them. They have been erected recklessly, and they disfigure our streets; they are maintained carelessly, and they endanger traffic; they have been run up without method or control, and they have damaged property. But overhead wires can be made absolutely secure, they need not be a disfigurement nor an injury; they are far more readily maintained than underground wires; they facilitate the economy of electric lighting, not only by affording better conductors, but by radiating away



the waste heat generated, and by requiring fewer joints and connecting points.

I do not in the least object to overhead wires through our streets for public lighting, though I strongly object to the cloud of wires that now obstruct the sky line in many of our thoroughfares. When ugly objects form an essential function of utility, it is wonderful how their unsightliness is condoned. Who complains of the ugliness of gas lamp-posts, and what is there in the necessary adjuncts of town life more ungraceful or hideous?

I do not, however, advocate overhead wires for general lighting. The conductors in that case must go underground, and with the great demand for telegraphs, telephones, and electric lighting, it is a pity that our Corporations do not extend that useful system of subways, that has been partially carried out in the City of London, for easy fixing and inspection. The present mode of laying pipes in trenches is not only costly but dangerous, and it has led to many more accidents than have been occasioned by the falling of overhead wires. Our streets are almost always open for either gas, water, telegraphs, or telephones, and the evil is increasing, and will continue to increase, with electric lighting. The cure is proper subways.

The progress made during the past two years in the form and character of lamps, whether arc or glow, has not been very marked. In arc lamps the tendency has been to simplify the working parts, and to increase their steadiness of action. The Crompton, Pilsen, and Fyfe-Main lamps leave little to be desired in this respect. At the Vienna Exhibition, there was a remarkably steady lamp in the French Section, the Abdank lamp, but it has not been seen in England yet. The arc lamp has many serious defects, which circumscribe its value very considerably, but it is eminently adapted for workshops, railway goods yards, and for large spaces where high masts can be fixed.

For general domestic illumination the glow lamp, as made by Swan and Edison, is, in my opinion, the only proper one. At the Munich and Vienna Exhibitions, a remarkable lamp by Cruto, of Turin, was shown. It was said to be a carbon tube of high resistance. It gave very good results, and absorbed a very small current, but it is not in the market yet. At Vienna, the Bernstein lamp attracted much attention. It also was a thin carbon tube made by carbonising a hollow silk ribbon, but it had low resistance, and required much current. It gave a considerably higher candle power than we are accustomed to. For instance, one lamp requiring 5 ampères and 30 volts, gave 60 candles; and another, with 8·5 ampères and 35 volts, gave 100 candles. Its normal efficiency of 2·5 watts per candle was very low, the efficiency of the Swan lamp being 3·5 watts per candle, and that of the Edison 4 watts per candle. Its duration is said to be very great. All glow lamps can be made to give economical results when we use large currents, but, unfortunately, their life is much curtailed by doing so. The filament is disintegrated, and the inside of the glass is, in consequence, covered with a dark deposit. Hence we are obliged to be satisfied with low efficiency to obtain reasonable durability.

The Bernstein lamp is, however, of an inconvenient power, and while it may do for street lighting, and for large spaces it is not adapted, in its present form, for our rooms and offices. It is, therefore, a lamp that is more likely to replace arc lamps than the present glow lamps, as made by Edison and Swan. It has, however, shown us a direction in which economy can be effected, and we may reasonably hope that the workers in this field will soon find a means to improve the present efficiency of the small glow lamps, and thus reduce the cost of working them.

A good many private houses, as well as public establishments, have been recently fitted up, and their experience has developed many difficulties and dangers which have only to be found out to enable them to be overcome. There is no use ignoring the fact that the admission of electric currents into our homes means the admission of a new danger—a danger that is only to be surmounted by the dictates of experience. Careful rules and regulations have been drawn up for the guidance of those who are executing installations, but the true remedy is to employ none but skilful and experienced contractors, and to have premises properly inspected by recognised professional men. Under such guidance electric light leads can be made absolutely harmless and devoid of all danger. The same cannot be said of gas, oil, or candle, for they involve the use of matches, and are always in a condition of potential danger. 2,041 persons in England alone, in 1881, met with violent deaths from burns, scalds, and explosions (not in mines). In one week, not long ago, six deaths from explosions of gas were recorded in the *Times*. Hence, while electricity is certainly accompanied by its own dangers, these dangers can be neutralised, and other infinitely more serious ones can be completely expelled from our houses.

Mr. Killingworth Hedges has devoted a great deal of attention to safety catches, and he certainly has produced the most efficient that are in the market. No electric light lead should be without its safety plug, or cut out. It is a precaution of a cheap and simple character, efficient, and reliable in action. A bar or sheet of lead, or alloy, is inserted in the circuit, which is instantly fused when from any cause the current exceeds its proper amount. It is a nuisance to be left in the dark, which must happen when the safety catch is fused, for the circuit is broken; but one can submit to this when the result is safety gained, or some source of danger eliminated. The remedy is a little barbarous, but it is efficient. A less crude contrivance was shown in Vienna—the invention of Mr. Anderson—but I have not seen it in practice.

It is most desirable that we should have, in every electric light installation, instruments to measure the current flowing and the electric pressure present. Am-meters, or current measures, and volt meters, or pressure indicators, are very numerous. I have always used Sir William Thomson's well-known instruments, but the greatest novelty in this direction are the instruments of Capt. Cardew, R.E., which are exhibited to-night. They indicate current and potential, or pressure, by the expansion of a platinum wire due to the heat generated by the current that flows through it.

Another important economical feature is the proper distribution of light. Trotter's dioptric system is very ingenious and useful. Several are shown.

I scarcely think that the true solution of isolated house lighting will be secured until we can obtain reliable, effective, and economical secondary batteries. Planté's original accumulator, as improved by Faure, Sellon, and Volckmar, has not yet reached that stage of perfection that one would wish to see, but the progress towards this desideratum is steady and promising. Planté has himself made a decided improvement by preparing his lead plates in nitric acid, and the experiments that I have made with his cells, as supplied by Elwell and Parker, of Wolverhampton, are so encouraging that I am about to use a set of them in my own house. A secondary battery has this advantage, that your electricity is stored up to be used when you want it, by day or night, without the constant use of machinery. In ordinary houses, such as mine, there ought not to be required more than one day a week for charging—a day set apart for the purpose like washing day—when sufficient electricity should be stored up for a week's work. I scarcely hope to do this yet, but it is well within the bounds of possibility.

I have indicated to you the direction in which progress has been made. The output of the apparatus has been greatly increased, and, therefore, the capital required for installation reduced, the expenditure on conductors has been considerably diminished, the efficiency of the lamps—especially in their durability—has been improved, and all these steps in advance have the tendency to economise the production of the electric light. But the progress is being continued, and there is vast room for this improvement. Nothing approaching finality has yet been reached.

I see no reason whatever why our public streets should not be as efficiently lighted by electricity as they are now by gas, and for the same price. But the public are not satisfied with the same illumination; they will have more light. They are spoilt by the dazzling splendour of the arc lamp, and they treat with contempt the less showy glow lamp. Nevertheless, the best lighted street in the City of London is Holborn-viaduct. The Thames-embankment and Waterloo-bridge have now been lighted by fifty arc lamps for over five years by the Jablochkoff Company. Blackfriars-bridge, Bridge-street, Ludgate-hill, St. Paul's-churchyard, and Cheapside have been lighted by thirty-eight Brush arc lamps for three years. We are now engaged in a very interesting series of experiments at Wimbledon, to determine the best and most efficient way of lighting public streets, and much value in an economical sense will, it is hoped, accrue from these trials.

It is remarkable how the use of electricity is growing in favour with theatre managers. Supported by the success of the Savoy, the Criterion, and the new Prince's Theatre in London, the Prince's Theatre in Manchester, the Prince of Wales and the Royal Theatres in Birmingham, two theatres in Glasgow, and many others are following Mr. D'Oyley Carte's spirited venture, and who can refrain from wishing that all would follow his example? Cool and pure air, absence of headache, and cheerfulness of mind are experienced at the Savoy, while the reverse is felt elsewhere where gas is used. I have recently examined the estimates for lighting up the Opera house in Vienna, and I have every reason to believe that less than 30s. per lamp per annum will brilliantly illuminate that beautiful house, and give a handsome return to those who have undertaken the contract.

There are many small central stations at work in England, but none on a large scale. At New York there are several. The Edison Company's first station lights 431 houses, and 10,300 lamps, and they are now erecting two new ones for 50,000 and 70,000 lamps, respectively. We have, in London, one at work on the Holborn-viaduct, another at Brixton, and another for 5,700 lamps will shortly be opened at Victoria-station. There are small central stations at Godalming, Chesterfield, and Colchester. The Hammond Company have one at Brighton, which works over an area of seven miles. This company maintains 900 arc lamps, and 5,500 glow lamps in different places in England. There is a central station at the Edgware-road station of the Metropolitan railway, whence Notting-hill-gate, Gower-street, King's-cross, and Aldgate stations are lighted over a length of fifteen miles long. One hundred and fifty-one glow and five arc lamps are illuminated by the distributing system of Goulard and Gibbs. Lord Salisbury, an amateur electrician of no mean type, has established quite a system of his own at Hatfield. The *Times*, ever in the van of progress, has for four years lighted up its printing and compositors' room.

Our new Law Courts are admirably lighted, and some of the judges have said that the electric light is the only good thing in this new Palace of Justice. The House of Commons has gradually been fitted up, and the Colonial Parliament Houses in Cape Town and New South Wales are following the examples. Indeed, restaurants, hotels, and public buildings, are all testifying to the fact that I am so anxious to bring before you, that electric lighting is a decided success, for they are using it. But we want to see it in our homes. An excellent little book on this point has recently been published by Mr. Hammond, which is well worth your perusal. He has given there a table so striking and convincing, that I have had it copied and suspended for your information:—

The following table shows the oxygen consumed, the carbonic acid produced, and the air vitiated, by the combustion of certain bodies burnt so as to give the light of 12 standard sperm candles, each candle burning at the rate of 120 grains per hour:—

Burnt to give light of 12 candles equal to 120 grs. per hour.	Cubic feet of oxygen consumed.	Cubic feet of air consumed.	Cubic feet of carbonic acid produced.	Cubic feet of air vitiated.	Heat produced in lbs. of water raised 10° F.
Cannel Gas......	3·30	16·50	2·01	217·50	195·0
Common Gas ...	5·45	17·25	3·21	348·25	278·6
Sperm Oil.........	4·75	23·75	3·33	356·75	233·5
Benzole............	4·45	22·30	3·54	376·30	232·6
Paraffin	6·81	34·05	4·50	484·05	361·9
Camphine.........	6·65	33·25	4·77	510·25	325·1
Sperm Candles	7·57	37·85	5·77	614·85	351·7
Wax	8·41	42·05	5·90	632·25	383·1
Stearic	8·82	44·10	6·25	669·10	374·7
Tallow	12·00	60·00	8·73	933·00	305·4
Electric Light...	none	none	none	none	13·8

There you see why the electric light is so pure and so healthy. There is no consumption or pollution of air. There is the smallest possible production of heat. There are none of the existing dangers from fire or suffocation, but all is pure, healthy, and safe.

Our homes on the sea—those ocean palaces that render voyages to America and our colonies a pleasant yachting picnic—are being gradually fitted. Over sixty are already so fitted, and all will soon be done. None but those who have tumbled and tossed on the angry ocean in a pitch-dark confined crib for the seemingly never-ending night, can appreciate the peace and comfort of the soft and gentle little glow lamp that is now supplied.

Efforts are being made to introduce primary batteries for the generation of electric-light currents, but not as yet with marked success. Unless the products of combustion can be sold profitably, primary batteries must necessarily be costly, and their constant renewal, and the amount of personal supervision they demand, militates much against their use, but some admirable batteries for small and temporary installations have been brought out, notably that of Mr. Holmes. Our railway trains are being lighted. Very satisfactory experiments are being made on the Brighton, South Western, South Eastern, Metropolitan, Midland, and Great Northern railways, with dynamos, primary and secondary batteries, and there is no doubt whatever of their ultimate success. There is no reason why the energy of the moving train itself should not produce currents of electricity to illuminate every compartment with the light of day.

Exhibitions have been both banes and antidotes. They have had much to do with the cause of the late mania, but they have also encouraged invention, and stirred up emulation. Last year's Fisheries Exhibition did much to educate Londoners to the advantages of the light. This year's Health Exhibition will do more; and I venture to prophecy—a foolish practice, unless you know—that this Exhibition will, as an electric light display, be the best we have ever seen.

There have been a good many failures in electric lighting, as there must be in the introduction of every new enterprise, but every failure can be traced to imperfect apparatus, or to the employment of inexperienced contractors—in fact, to bad engineering. It is not long since that the wiring of a large building was let to one firm, and the lighting to another, with the necessary consequence that the whole thing "burst up," to use an Americanism, on the night of opening.

It is difficult to express any opinion on the economy of the electric light. We have not had the experience of any central lighting station of sufficient magnitude to justify the formation of such opinion. Any comparison between gas and electricity on this basis is unfair, because gas is produced in quantities sufficient to supply hundreds of thousands of lamps, while the largest electric light station yet erected does not light up 10,000 lamps. In New York, the price is the same for electricity as for gas, but then gas costs 12s. per 1,000 cubic feet, as it did in London, in the memory, perhaps, of some present. Nevertheless, the cost of supplying electricity now is far less than was the cost of supplying gas in the early days of its introduction.

But why draw a comparison? People do not compare the cost of gas with that of candles, nor the price of a pheasant with that of a mutton chop. If we want a luxury we must pay for it, and if the price of the luxury is not too great, people will have it. People will have electric light, if it can be supplied to them, not because it is cheap, but because it is safe, healthy, pure, soft, and natural. And, moreover, they will not object to pay any reasonable price for it, whatever may be the price of gas. Gas is most destructive, unhealthy, and objectionable when used for artificial illumination. The proper function of gas is the production of heat, and we see in this room how this production of heat can be utilised to form electric currents which diffuse about us a real luxury—pure light. When the electric light can be supplied, questions of sanitation, ventilation, and decoration will determine its use, and not questions of price. At present, for household purposes, it is a luxury for which we must pay; but the progress made is so rapid, and the room for improvement so great, that the day is not far distant when we shall cease to regard it as a luxury, and shall demand it as a necessity.

[An Appendix, consisting of a Table of the Electric Light Companies, is printed as a Supplement.]

DISCUSSION.

The CHAIRMAN said the paper had quite borne out his expectations, that it would show immense progress to have been made in electric lighting since Mr. Preece read a paper on the same subject some three years ago.

Mr. E. CROMPTON said he could not make a long speech, as he had been suffering all day from a bad headache, arising from a nine hours' argument with a recalcitrant Corporation Committee, who seemed bent on putting wires into a public building of such a size as would have certainly set it on fire; and he was going back again by the 12 o'clock train to try and put the matter right. The paper was a most able and much needed contribution to public knowledge on this subject, for there was no doubt an impression abroad that the electric light was waning, and that it was not the light of the future, but after that evening he hoped such a delusion would vanish. He would endeavour to say a word or two from his own experience; and first of all, with regard to the question of economy, he might say that in the minds of practical men there was no doubt whatever about the economy of the electric light. They knew that the cost of producing it had steadily decreased, and now the cost of producing so much electricity, and using it in lamps, was as easily calculated as the cost of gas, if they were furnished with the data which all gas engineers must have in dealing with gas-works, and that was, the consumption required. If they were to go to any fresh country and compete with gas for lighting a town, with coal at a fair price, they could compete on even terms, and if coal were dear, more easily still. In fact, the dearer the fuel the better for electricity, because the fixed charges, the cost of production and labour, would remain constant for the two, but electricity had the advantage in producing a greater number of units of light per ton of coal consumed. One point which Mr. Preece had forgotten to emphasise was, that in the future they must look less to electric systems and more to the men who carried them out. What had now to be done was the working out practically of the many inventions which had been brought out. Hitherto, the men had been kept in the background, and the systems put in front; but the gentlemen, such as he saw there, who had the foresight to gather around them a staff of young men, whom they had thoroughly trained in all the details of the science, were those who would carry electric lighting to a successful issue in the future. In one sense, as Mr. Preece had said, the electric light was a luxury, but in another it was a necessity, and any man who had once had it in his house, especially if he were the father of a family, would, he was sure, say that it was necessary. Those who had seen children's faces in a nursery after a dull winter's day, when the gas had been lit all the time, and compared them with children in a house blessed with electric lighting, would say that he who was content with gas when he could get electricity was simply poisoning his children. The reason why electric lighting spread so slowly in private houses was the almost insurmountable difficulty in finding a place to put the motive power. They had to put the machinery in cellars, and often part in one cellar and part in another, and the men in charge had to work underground—in fact, such difficulties were never thrown in the way of engineers before, owing to the enormous value of property in towns. These difficulties were so great, that it was wonderful the failures had not been more numerous, and very great credit was due to the sub-engineers—whose names never came forward—who worked out these details.

Mr. GEORGE OFFOR wished to correct one statement in the paper, with regard to licenses under the recent Act. A license for lighting the town of Colchester was being persevered in, and would be granted as soon as certain slight modifications had been arranged between Major Armstrong and the Company. Again, with regard to the danger of distributing of electricity by currents of high tension, that had been got over at Colchester by the engineers in charge, in the following manner. Storage batteries were employed, which were charged in series from a central station by a high tension current; but to avoid the taking of that high tension current into the houses, each stack of batteries was divided into two parts, connected by a rocking switch, by means of which, while one-half the battery was being charged by the high tension current, the other half was in supply, and as soon as the electromotive force was reduced in the supply half to a certain point, it automatically threw the supply half into charge, and the charging half into supply. Under that arrangement, the potential carried into the houses was that of lamps used, and by that means the condition of the Board of Trade, that the potential should never exceed 200 volts, was complied with. This installation at Colchester was of peculiar interest, because it was the first practical attempt to supply electricity on similar lines to those adopted by gas companies. The current being distributed from a central station gave a constant supply, and the consumer had none of those difficulties to which Mr. Crompton had alluded in finding space for the machinery; he was charged so much per thousand, or per lamp per hour, as the case might be. With reference to the great question of economy, he could endorse all that Mr. Preece had said with regard to readiness with which the electric light would be taken irrespective of the price of gas; but from his experience with a small installation of only 2,000 lamps, he found they could compete with gas at the same price. They were able, however, to obtain a higher price very readily, viz., ½d. per lamp of 20 candles per hour, which was equivalent to 5s. per 1,000 feet of gas. The reason they could do so was readily explained. A large linendraper remarked to Major Armstrong that he found his goods very much damaged by gas, and that the saving by electricity in that way alone more than paid for the whole cost. There was an impression abroad that the electric lighting business was played out, simply because certain gambling transactions on the Stock Exchange had brought the shares to a discount; but they knew not only that the means of supplying electricity had marvellously improved, and that the demand for electric lighting was increasing in at least equal proportion.

Mr. HAMMOND agreed with the preceding speakers that such a paper as they had listened to was much needed at the present time. Those engaged in electric lighting had often to listen to most unpleasant remarks, such as had been referred to, and in many cases were plainly told that the whole thing was a swindle; but he maintained that the progress already made had been such as to warrant them in believing that some day electric lighting would triumph over all obstacles, and have as great a future as the railway system, or the water or gas supply. He believed they were on the eve of as great an era in lighting as their forefathers who had stood on the threshold of the railway era. Many people thought the details given in the table to which reference had been made were only of interest to chemists; but on the contrary he was convinced that the public would, ere long, come to the opinion that it was quite as dangerous to take in poison with the air as in their food or water supply. What was the position of England, only twenty years ago, with regard to water? and there was an almost exact analogy between pure water and pure air. Twenty years ago, the people of England were perfectly indifferent as to what water they were drinking, but they then woke up suddenly to the importance of the subject; and when he was a member of the Corporation of Middlesborough, that body, in conjunction with Stockton, were willing to pay £800,000 to secure pure water. What had happened with regard to water would also happen with regard to air. In their houses of business they had to put up with many inconveniences; but when they went home, if they could ensure having the air as pure as that which existed outside, they would be willing to pay something for it. In the case of water, they were now willing to pay any price to secure purity, as in the case he had mentioned, where £800,000 was paid for what a few years before could have been secured for half the money, but it was not then deemed of sufficient importance. Mr. Preece had mentioned the great progress which had been made in the construction of dynamos and lamps, and the question was what had been the great obstacle during the last few years to the progress of electric lighting; for numerous as were the installations at the present time, they had to face this fact, that, with the one exception mentioned by the last speaker, no absolute house to house installation was at present in existence. It was all very well to say you had a machine which would run a thousand lights at a slow speed, and that the lamp was slightly improved; the question put to him by a friend of his was, how soon are you going to supply it in Pembridge-square? He said that he knew where electric lighting was introduced he had not to breathe poisoned air, that it was perfectly under control, and so on, but why was it not offered to the public at large to take advantage of? There were all sorts of reasons advanced. Some said it was the Electric Lighting Act which stood in the way, but he did not believe it. He thought the twenty-one years tenure was quite sufficient. It was not the intention of the framers of the Act, or the Board of Trade, that at the end of that time the property of the company should be confiscated, but that it should be sold at its then value without calculating anything for prospective profits, such as had been demanded hitherto in the case of gas and water companies, and he did not believe such a provision would prevent capitalists investing. Then it was said that the frightful speculation which had occurred was the great bar; and, no doubt, shares in electric lighting companies had been treated like counters in a game at vingt-et-un or écarté; but the great bar after all was something different. They had heard of different kinds of energy, but, after all, the most powerful kind of energy was what Americans called the almighty dollar. There was upwards of 150 millions of money invested in the gas industry; and the shareholders in this industry were to be found in every town throughout the kingdom, and they were all working dead against electric lighting, which they feared might depreciate their property. What encouragement was there to men to put their money into electric lighting? The very same people whose money they wanted for this purpose were gas shareholders. He was lately in Birmingham, and there he was told that they had a million and a-half in gas; that they lived on gas; and what was the use of his coming to them and talking of electric lighting. He told them that they would have to put as much into electric lighting, and why was it not done? The great obstacle was, in this case as in every other, that unless the best work was always put into it, any new thing took years to make its way. It was because every installation had not been a success that people who looked into it said they would wait a bit, and see what better could be done. As a man said to him the other day, he was at some place where all the lights went out. When Mr. Crompton had to spend nine hours in persuading people not to use wires which would burn the place down, they could understand the difficulties which had to be encountered. They had not yet recognised the fact that those who had to do this business must be men who never turn out bad work. He had had to suffer from this cause himself, having, as Mr. Preece had mentioned, to put machinery costing £5,000 to £6,000 into a building which had been fitted up with wires by people who had put up the electric bells. But better views were now beginning to prevail, and when it was generally recognised that good work had to be done in every direction, they would go a-head. He had yet to meet with the mother who, for the sake of cheapness, would give her child food which had a modicum of poison in it, and they would yet live to see the day when there would be as much aversion to breathing poisoned air as there was now to eating poisoned food or drinking impure water.

Mr. Preece said he had omitted one point in his paper, and that was the fittings in the house. He had lately dined with Mr. Tayler Smith, a well-known architect, who had devised such beautiful fittings for his house, that he had induced him to bring some of them there, and he hoped he would explain them.

Mr. TAYLER SMITH said he hardly agreed with Mr. Hammond as to the great obstacle to the general introduction of electric lighting. In his opinion one very great obstacle was that companies did not care to supply a house that only required 20 or 30 lights, they wanted you to have 40, 50, or 60, and charged for the whole when only a part were in use at the same time. In order to avoid paying for the maximum when he only used the minimum, he had arranged all his lights so that they could be removed from one room to another as required, having "shoes," as he termed them, inserted in the skirting of the rooms into which the wires could be readily inserted. He then exhibited and explained various forms of candelabra and bracket lights of very elegant design, all of which were readily detached and placed where required, the most striking and original of all being a hanging light, which could be raised or lowered at pleasure, like a telescopic gaselier. A two-light bracket could be put in the place of a single one, if more light were required, and for reading lamps there was a very ingenious arrangement by which the wire conveying the current was wound on a wheel under the lamp when a short distance only was required, and paid out when the lamp had to be moved to a greater distance from the connection. If any one's foot caught in the wire leading from the socket, it simply slipped out, and was easily replaced. Another very beautiful design was intended for a pianoforte lamp, which threw the light on the music, and not into the eyes of the player.

The CHAIRMAN said the discussion might usefully be continued to much greater length if time permitted, but unfortunately it did not. There was no doubt some truth in what Mr. Hammond had said with regard to the powerful interests which were arrayed against the cause of electric lighting, but it was to be hoped that as the use of gas was rapidly extending in many directions not contemplated until recently, that opposition would by degrees die out. If time allowed him to go into the various uses of electric lighting, he should have had to mention several points which Mr. Preece had omitted; but he hoped that gentleman would bring the subject before them again at no very distant date, and give further details.

Mr. PREECE said, if he had one regret, it was that they had not had an opportunity of hearing something said from the gas companies' point of view. He was a gas shareholder himself, and held a portion of the 150 millions to which Mr. Hammond referred; but he was not at all afraid of his investment, nor of the future of gas, notwithstanding what he had brought forward with regard to the progress of electricity. He believed that the same era which Mr. Hammond anticipated for electric lighting was also awaiting gas as a motive power, and as a store of energy to be used principally for the production of electricity. A very important point had been mentioned by Mr. Crompton, that they must look more to men than to systems, and Mr. Crompton himself was an example of the sort of men who were bringing electric lighting into the front rank. In preparing that paper he had visited Mr. Crompton's factory at Chelmsford, where 250 men were busily employed in the manufacture of these things; and he regretted that he had not been to Colchester, as he should not have made the mistake which Mr. Offer had corrected. He had visited a great many private houses, however; he had breakfasted in Glasgow, and dined in Manchester, under the electric light; but of all the places he had visited none had afforded him so much pleasure as the house of Mr. Tayler Smith, where every detail was carried out in the most perfect manner, as they could judge from the specimens which had been exhibited. On the next occasion he would promise gas a chance, and see what could be said in its favour as against electric lighting.

The CHAIRMAN, in proposing a vote of thanks to Mr. Preece, remarked that one important element in the development of every practical application of science was to find a clear exponent of the subject, who was at the same time honest enough to say frankly all he thought, either for or against the subject he was dealing with, and such a man they had in Mr. Preece.

The vote of thanks was carried unanimously, and the meeting separated.

Miscellaneous.

INTERNATIONAL HEALTH EXHIBITION.

The following Sub-Committees have met at the Society of Arts since the meetings recorded in last week's *Journal*:—

SICK AND AMBULANCE.

Wednesday, February 27th.—Present: Director-General Crawford, A.M.D., in the chair; Surgeon-Major G. J. H. Evatt, M.D., A.M.D.; Mr. John Farley; Inspector-General J. D. Macdonald, M.D., C.B., F.R.S.; Surgeon-General W. A. Mackinnon, C.B., A.M.D.; Dr. J. C. Steele; Mr. J. S. Young.

THE DWELLING HOUSE.—SUB-COMMITTEES A AND B.

Thursday, February 28th. — Present: Captain Douglas Galton, C.B., F.R.S., in the chair; Sir Frederick Abel, C.B., F.R.S.; Dr. Alfred Carpenter; Mr. C. N. Cresswell; Mr. W. Eassie, C.E.; Mr. Rogers Field, C.E.; Dr. E. Frankland, F.R.S.; Mr. G. Godwin, F.R.S.; Mr. Charles Heisch; Mr. Malcolm Morris; Mr. Shirley F. Murphy; Mr. Samuel Osborn; Major-General Sir Richard Pollock, K.C.S.I.; Sir Robert Rawlinson, C.B.; Dr. R. Thorne-Thorne; Mr. Ernest Turner; Mr. Frederick Young; Mr. H. Trueman Wood.

The Library.

Tuesday, March 4th.—Present: Dr. W. Ogle, in the chair; Rev. T. Graham, D.D.; Mr. A. C. King; Mr. C. M. Kennedy; Mr. J. L. Clifford Smith; Mr. D. Williams.

NOTES ON THE REARING OF SILK-PRODUCING BOMBYCES IN 1883,

By Alfred Wailly

(Membre Lauréat de la Société Nationale d'Acclimatation de France).

General remarks.—By referring to my report on the rearings of 1882, which appeared in four numbers of the *Journal of the Society of Arts* (19th and 26th January, and 2nd and 23rd February, 1883), it will be seen that during the very mild winter of 1881-1882, a considerable number of moths emerged from cocoons of Indian wild silkworms. During the last winter only six moths emerged from the 1st to the 16th of January, 1883, after which no more emerged till May. As I have observed, and stated in previous reports, moths from tropical species are apt to emerge during the winter when the weather is mild, while moths of native or northern foreign countries seldom, if ever, emerge before the spring. This irregularity in the emergence of the moths of tropical species is one of the difficulties in the way of their reproduction and acclimatisation; it may take place at any season, though the greater number emerge in the summer and autumn. Hence the necessity, to have a fair chance of success, of having a large number of live cocoons.

I bred, or attempted to breed, in 1883, about the same number of silk-producing bombyces as in previous years, such as *Attacus Pyri*, of Central Europe, *Attacus Cynthia* and *Antheræa Pernyi*, originally imported from North China; *Telea Polyphemus*, *Samia Cecropia*, *Samia Promethea*, *Saturnia Io* and *Actias Luna*, from the United States of North America; *Actias Selene* and *Antheræa Mylitta*, from India. *Attacus Atlas*, as will be seen further on, could not be attempted. I reared, besides the above-named species, a number of lepidoptera, which, as they have no connection at all with sericiculture, cannot find their place here. My notes on the rearings of 1883 being very numerous, covering some 28 pages of my note-book, I shall not reproduce them *in extenso*, as details on most species have already been given in previous reports. Although it is sometimes necessary to repeat former statements, I shall confine myself principally to new facts.

As yet, only a few of my European and American correspondents have sent reports of their success or failure in rearing the various species of silk-producers. Of British correspondents, Mr. John Ball, of Macclesfield, has obtained a very great success in 1882 and 1883 with *Antheræa Pernyi*, *Actias Luna*, and *Actias Selene*, and he wishes me to record it. With respect to the rearing of *A. Pernyi*, in 1882, Mr. Ball says he found this most valuable silkworm as easy to rear as any of the British lepidoptera, and quite hardy, and he succeeded in obtaining two broods during the year. The moths began to emerge from the 1st of May, and the first larvæ hatched on the 16th of the same month; the larvæ spun up from the 20th to the 24th of June. On the first of August a female moth emerged, and on the 3rd a male, from the pairing of which ova were obtained on the 4th, which hatched on the 16th of August. Larvæ formed their cocoons from the 1st to the 7th of October.

Of *Actias Luna* reared in 1882, Mr. Ball says:—With the 24 ova you sent me I obtained 22 larvæ, four of which died in first stage. The other larvæ thrived splendidly; they had hatched on the 15th of June from ova laid on the 2nd of June. The larvæ spun up from the 13th to the 17th of July. From the 18th of August to the 22nd all the moths emerged from the cocoons, and all were fine perfect specimens. In 1882, Mr. Ball was equally successful with this species, the rearing having taken place about one month later.

With respect to *Actias Selene*, Mr. Ball says:—The larvæ from the ova you sent me on the 8th of July, hatched on the 15th of July, spinning up from the 18th to the 19th of August, and the moths emerged from the 21st to the 24th of September. Mr. Ball's rearing of *Selene* in 1882 was also a great success; it took place at the same period, the moths emerging from 21st to 25th of September, all splendid specimens. Both *Luna* and *Selene* were fed exclusively on walnut.

Wild Silkworms.

Of late years, wild silk culture has attracted much attention in various quarters, and there is no doubt that the rearing, on a large scale, for commercial purposes of such silkworms as *Pernyi*, *Cynthia*, *Mylitta* (tussah), *Polyphemus*, *Cecropia*, and others, would be a very profitable enterprise, if these wild silkworms were bred in climates suitable both to the worms and the plants they feed upon. These two indispensable conditions could easily be found. *Attacus Cynthia* is not only acclimatised but naturalised in France, and it can be reared even in England, in the open air, with the greatest success. *A. Pernyi* (oak silkworm) can also be reared in the open air, and it is reared, on a large scale, in Guipuscoa, a north-eastern province of Spain, where two crops of cocoons are obtained every year. *Telea Polyphemus*, introduced by me in this province, thrived equally well, and became acclimatised. Some years ago, I sent large quantities of *Cynthia* and *Peryni* live cocoons to the United States of North America, and both species are now found wild in many parts. The acclimatisation of these wild silkworms is, therefore, an easy matter when a suitable country is chosen.

I lately received from Paris a letter dated 31st October, from a gentleman who, together with some of his friends, intend to entrust a rather considerable capital to one of my correspondents in French Guiana, for the purpose of cultivating on a large scale the *Attacus Aurota*, a wild South American silkworm common in Brazil, the Guianas, and other parts of South America. No doubt, if the project is carried out, the rearing of this species will be easy, and the quantity of cocoons obtained will be enormous, for this silkworm has six generations every year in French Guiana. But I was asked before anything was done respecting that enterprise to give advice, and state what would be the commercial value of the silk, which was a difficult question to answer.

Cocoons, as is well known, are of two sorts: the closed cocoons like those of *Pernyi*, *Yama-Maï*, *Mylitta*, *Polyphemus*, and others, and those cocoons which are naturally open at one end, such as those of *Cynthia*, *Atlas*, *Cecropia*, *Aurota*, &c. The *open* cocoons, and *Aurota* is one of them, remain exactly the same after the moth has emerged, as they were before, and no opinion on the quality of the silk can be formed till these cocoons have been carded. The *closed* cocoons, on the contrary, are cut open (or are apparently *cut)* by the moth when it emerges from it; then the threads can be pulled and the silk examined and appreciated to a very great extent. Such is not the case with the open cocoons, the silk of which cannot be pulled by hand.

For the last ten years my work has been the reproduction, rearing, and study of the various wild silkworms of China, Japan, India, and America, of which I could obtain live cocoons or ova. Many persons in Europe and America, through my exertions, have also been able to rear and study them. But this work has occupied all my leisure hours. I have had, therefore, no time left to study the quality of the silk of the various species. All I know is that the silk of *Pernyi Yama-Maï* and *Mylitta* is valuable, and, if well worked, is almost equal to that of the *Bombyx Mori;* the silk of *Polyphemus* seems equally fine. I had always thought, and I still think, that the silk of these species, with closed cocoons, is superior to the silk of those with open cocoons, and my opinion also was that reeled silk was of more value than carded; but from a letter lately received from Mr. T. Wardle, of Leek, a great authority on such a subject, I see that carded silk is as good as reeled silk, a very important fact to know, as it would make some of the open cocoons as valuable as the closed ones, if the thread obtained by carding were as fine as that obtained by reeling. In his letter of the 5th of November last, on the subject of sericiculture, Mr. T. Wardle says:—"Have you visited No. 71, New Bond-street, London, where all my Tussur (*Mylitta* or *Paphia* of India) developments are? My partner, Mr. Brough, would be glad to explain anything to you. I think, if anyone went to India to collect Tussur cocoons and any other wild silks, that it would pay, and I think any enterprise of that kind would receive some Government encouragement. . . . To cultivate any cocoons would be a good speculation, if they could be produced in sufficient quantity; because, if they cannot be reeled, they can be carded, and, of the two, there is more demand for carded yarn than reeled, and a carded yarn fetches more money than a reeled one."

I twice visited Mr. Wardle's place in New Bond-street, and I examined with the greatest interest the splendid and various articles manufactured with the Tussur silk, and I would recommend all persons taking an interest on this subject to visit the place. A visit to Mr. Wardle's would show of what importance would be the cultivation, on a large scale, of the Tussur and other equally valuable wild silkworms in such countries as would be suitable to them.

The collecting of wild silk cocoons in the forests of India, or other parts, would be profitable to reproduce and rear the various species, but I do not think sufficient quantities of these cocoons could be collected in this way for manufacturing purposes, and for the latter, rearing in the open-air and on trees must be resorted to.

Worms reared in a state of domesticity in warm rooms, or in "*magnaneries*," as the mulberry silkworm, would be liable to the terrible contagious diseases which, for years, have attacked the latter, to such an extent as to make the supply of mulberry silk very much smaller than it used to be. In France, some fifty years ago, one of the most terrible of these diseases (which fortunately has now, it is said, disappeared) was the "*muscardine*," a white vegetable parasite which was developed inside the worm or in the chrysalis. Whilst the *muscardine* preyed on the mulberry silkworms, the other epidemics had disappeared; but, from 1845, two other distinct diseases made their appearance one after the other. The first was the "*pébrine*" (pepper disease), a very ancient affection of the worms, which, when attacked by it, are covered with black spots, and grow smaller and smaller till they die. Later on, a second, very distinct from the first, and a worse disease, made terrible ravages among the worms; this is the "*flacherie*." The *flacherie* is worse than the *pébrine*, because, after all the expense and the labour of rearing the worms, which eat and grow well, showing apparently no signs whatever of disease, they die within a few days before the spinning period; hence, a great loss and disappointment. These contagious diseases may co-exist, but when they are intense, it often happens that one excludes the other, according to the ordinary law of epidemics. These diseases, created by the overcrowding of worms in hot rooms, may also be the consequence of rearing from eggs containing the germ of disease, for, it must be remarked, that a certain number of diseased worms live and procreate in spite of that germ of disease in them. On the contrary, silkworms reared in the open-air, on trees, and in suitable climates, could not be attacked by these contagious diseases. Since the deficiency in the production of mulberry silk, the cultivation in India of the Tussur silkworm has been considered of the highest importance. As yet, it does not seem that the rearing of the Tussur worm has been attempted on a large scale, though, no doubt, it will be so before long.

Major G. Coussmaker published, in 1873, a most useful and interesting pamphlet on "The Tussur Silkworm," and every year, in spite of the difficulties in his way, Major G. Coussmaker reared this valuable silkworm in a state of semi-domestication in the neighbourhood of Poona, with a success which increased every year, as may be seen by reading his annual reports. In his last report to the Secretary of the Bombay Government, dated Poona, 14th February, 1883, previous to his final departure for England, Major Coussmaker, however, says that he regrets he cannot recommend Government to continue these experiments in that part of India, owing to three causes, the principal one being that the climate there was an insurmountable obstacle.

On a visit I paid to Major G. Coussmaker last October, I had the pleasure to converse with him at length on the subject of sericicultnre in India, and I have since read the many letters which were sent to him on the subject by correspondents in various parts of India. A perusal of these letters shows that the rearing of the Tussur silkworm could be successfully carried out on a large scale, if assistance were given to an experienced sericiculturist.

From the knowledge acquired by the reading of numbers of reports and letters, I think that a warm, moist temperature, such as that of Ceylon, is the best for the Tussur and some other wild silkworms.

I have also examined Tussur cocoons sent from Calcutta, Madras, Ceylon, and Bombay, the last having been kindly brought for me by Major Coussmaker. Major Coussmaker complains in his last report of the small size of the Bombay cocoons, as compared with those of other parts of India. Now, those from Ceylon are quite as small, if not smaller, than the Bombay cocoons, but the silk of the Ceylon cocoons, in my opinion, is finer and softer; they are, for the most part of a yellowish white, and similar in shape and texture to the Japanese oak silkworm (*Yama-maï*) cocoons.

In January, 1883, I saw in the offices of the Société d'Acclimatation de France, in Paris, cocoons which had been sent when alive from Cochin-China. These cocoons seemed to me exactly like those of the Ceylon Tussur in size, shape, and colour; but the moths varied in their shades of colour, just as those of the Tussur found in various parts of India. The moths of the Ceylon species, on the contrary, as far as I have observed, are all of the same colour, the male being dark reddish brown, the female bright yellow. An interesting article on the Cochin-China silkworm, which I saw in Paris, written by M. J. Fallou, may be read in the June number, 1883, of the "Bulletin" of the Société d'Acclimatation. The species was at first considered as being *Antheræa mylitta* (the Indian Tussur), but subsequently it was found to be *Antheræa Frithii* (Moore), a species described in the "Proceedings of the Zoological Society," 28th June, 1859.

By comparing the species which I have considered as the Ceylon *A. mylitta* with the other Indian *Mylitta*, an entomologist might be lead to give the Ceylon race a differant name than *Mylitta* as the cocoon is more oval and somewhat different in other respects, and so are the moths to a certain extent.

But, is it not possible that these differences are due to a difference of climate, and that the Ceylon species and *A. Frithii* are only southern species or varieties of *A. mylitta*. At any rate, whether or not the Ceylon silkworm is the same species as the *A. mylitta* of the more northern parts of India, it seems evident that the moist and warm climate of Ceylon is very suitable to the rearing of that species of *Mylitta*. In all probability other species would succeed as well, and the introduction of the more northern *Mylitta* into Ceylon would, in course of time, show whether it is the same as the Ceylon silkworm.

Coming now to the rearing of the *A. mylitta* and other wild silkworms in various parts, and on a large scale, the plan adopted by the Japanese for the rearing of their valuable oak silkworm, *Yama-Maï* and very probably also by the Chinese, who are expert sericulturists, might be followed. Many papers have been written on the culture of the Japanese *Yama-Maï*, two published as far back as 1864, one of which had been translated from the Japanese into Dutch, by Dr. Hoffman, and then from the Dutch into French, by M. F. Blekman, interpreter to the French Legation in Japan. According to the pamphlet translated from the Japanese, the plan adopted for the rearing of the *Yama-Maï* consisted of three different operations. I say "consisted," because the first and second systems of rearing may, perhaps, not be adopted at the present time. Now, let us see what these three systems of rearing the *Yama-Maï* are :—

1. On branches, *en baquets*, in tubs.
2. On branches, *à fleur de terre*, at a level with the ground.
3. On trees, *en libre nature*, in the open air.

A note following these three headings says: The first mode is employed for the rearing of the worms till after the third moult; after that period the second and third modes become applicable.

The first mode of rearing is this: tubs, placed under a shed, are filled with water and covered with lids in which holes have been bored, four, five, or six, according to the size of the tubs. The oak branches which are to feed the worms are plunged through these holes into the water, taking care to plunge the stalks of the branches into the holes which are opposite to one another, using only half of them, and corking or stopping the holes which have not been used, till the foliage has been eaten by the worms, or has become too old or faded. Then fresh branches are introduced into the tubs through the holes left vacant for that purpose. The fresh branches being placed so as to touch the old ones, the worms quit the old branches to go to the fresh ones. If the space is too wide between some parts of the old branches and the new ones, the old branches are cut in small pieces, which are placed, or pinned, on the new branches. A tap is placed at the lower part of the tub, so that the water can be drawn out and renewed every other day, or every day, as the purity of the water is of the utmost importance. This plan of rearing may be adopted till the worms form their cocoons, when the rearings are on a small scale.

COMMERCIAL MUSEUMS.

The above subject has been recently discussed in the *Deutsches Handelsblatt*, in connection with the progress made in the direction indicated by England as well as by other European countries. In France the idea has found an energetic defender in M. Felix Faure, who advocated it in his proposal for the budget of 1884. According to the project of a so-called *Musée Commerciale Consulaire*, it would contain—1. A collection of raw material from foreign countries. 2. A collection of objects which are required in various foreign markets, accompanied by details as to prices, duties, &c. M. Faure's opinion is that private enterprise could not successfully carry out such an idea, and he therefore proposes a museum of this kind to be established at the Ministry of Commerce, and for a committee of manufacturers, exporters, and commission merchants to be formed under the presidency of the Minister. The establishment of such a museum in Paris would be followed by similar museums in other business centres.

In Germany, the formation of a museum of commercial geography was proposed in December, 1881, when (with promises of support from the German Foreign-office and Admiralty), the Central Association for Commercial Geography of Berlin sent out a formal request for co-operation to persons likely to promote the idea either by subscriptions or by exhibits. The responses to this appeal have been numerous and valuable as to the latter portion of the subject, but the funds available are not sufficient to cover the expense of arranging the collections. In Wurtemburg, however, the efforts made have been much more successful, private enterprise having established at Stuttgart a so-called "depôt of export," samples in which every branch of Wurtemburg industry is represented in a systematic manner. A catalogue has been printed, 4,000 copies of which have been distributed amongst various consulates, hotels, &c., in different parts of the world. It is printed in German, French, English, and Spanish. About 450 firms have joined in this enterprise.

The idea thus successfully carried out at Stuttgart has been partially adopted at Vienna, where the Oriental Museum deals with Eastern trade.

Belgium inaugurated a Commercial Museum at Brussels in April, 1883. This is not only a collection of Belgian industrial products, but much care has been taken in suitably classifying the samples, forwarded by Belgian consuls in all parts of the world, for the purpose of illustrating the articles capable of being imported by Belgium from various countries. The Belgian Parliament supplied the necessary funds for this undertaking.

Although not having made such an advance as Belgium in the solution of the question at issue, Italy has made progress of a satisfactory character, the Government having decided to open such institutions at Milan and Turin. The first contributions towards the Museo Commerciale Consolare were exhibited by the Minister of Agriculture at the Milan Exhibition, and at its conclusion, the claims of both Milan and Turin were brought forward in such a prominent manner that the collections were divided. Since then, the various Italian consulates have been invited to furnish articles for exhibition.

SCHOOLS OF ART.

An Exhibition, to illustrate the operations and influence of Schools of Art, will be arranged by the Science and Art Department of the Committee of Council on Education, South Kensington. It will consist of school studies, works of ornamental and decorative art produced from designs by students in schools of art, works of ornamental and decorative art, woodcuts, lithographs, and etchings designed or executed by those who have been students in schools of art.

The following particulars have been issued:—

1. My Lords consider that it will be of advantage to the art education of the country if an exhibition of works of art manufacture designed and executed by students of schools of art, be held during the present year, in connection with and forming part of the International Exhihition at South Kensington.

2. The works will consist of carvings in all materials, furniture, decorations, metal working of all kinds, jewellery, goldsmiths' work, pottery, glass, woven and printed fabrics, &c.

3. All articles exhibited must be the work of past or present students of schools of art, or executed from designs by such students, the works themselves having been executed since the year 1862. The articles must be certified by the manufacturers, by the master of the school of art in which the student has received instruction, or by the student himself. The name of the manufacturer, of the school of art, and of the student will be published.

4. The decision as to the acceptance of any work for exhibition will rest entirely with the committee of selection.

5. The works must be sent to the department on or before 31st March. They must be addressed to the secretary and accompanied by a note (written only on the first and third pages) describing them as they are meant to be inserted in the catalogue. The note should also state the names of the manufacturers,

the designers, and the artisans; the names of the schools of art attended by any of them; and the periods for which they attended. The prices of each article may be given if it be desired.

6. Every possible care will be taken of the works sent for exhibition, but the responsibility for loss or damage in transit, and during the period of the Exhibition, will rest with the exhibitor. By order, W. D. DONNELLY, Col. R.E., Assistant Secretary.

Correspondence.

MR. SWINBURN KING'S PAPER ON BOILER CORROSION.

Mr. J. H. Porter writes with reference to his remarks in the discussion, laying stress upon the fact that the modification of Dr. Clark's process, invented by him and known as the Porter-Clark process, purifies the water before it is pumped into the boiler, thereby carrying out the views of Mr. E. B. Marten, that it was better to improve the water before use than to treat it within the boiler itself. Mr. Porter quotes, from a report of Mr. Lavington Fletcher, a paragraph to the same effect. The number of boilers under the charge of the East London Water Company's engineer is 60, not 6, as given in the report. Mr. J. J. Eastick also writes to say that the view he had intended to put forward in the discussion was that the removal of scale from boiler-plates was effected by the sudden conversion of water into steam behind the scale, rather than by the decomposition of water which had soaked through the scale, and the formation thereby of hydrogen, which is supposed to force off the scale by mechanical action.

General Notes.

EXHIBITION IN URUGUAY. — An Uruguayan National Exhibition is to be opened at Montevideo, on the 19th of April, 1885. It is to be organised by the General Board of Agriculture and Immigration, and will include all sorts of foreign farming apparatus and cattle. Special importance will be attached to woods and forests, and the necessity for their cultivation. Exhibitors must be registered before March 1, 1885.

CHAMBERS OF COMMERCE IN FOREIGN COUNTRIES.—The French Consul at Mexico, M. Coutouly, has reported to his Government the acceptance by the club of French residents, of his proposal for the establishment of a local French Chamber of Commerce. A similar arrangement is projected at Guatemala. It is intended by means of such bodies to afford French agents useful guidance, and to transmit to the Home Government all information affecting French commerce and industry, as well as to elucidate questions bearing on French trade, whether local or general.

NEW TEXTILE PLANTS.—In the French journal *La Ramie*, M. Pailleux calls attention to a Japanese plant named *Kusu (Pueraria Thunbergeana)*, the roots of which contain starch, while the leaves and shoots are used as food. Its fibrous portions are adapted for use in the manufacture of cordage. It is a lofty and hardy plant, attaining within a year a height of from 12 to 25 feet. It yields fruit, and grows upon the most unfruitful dry ground where nothing else would thrive, provided there is a sufficiency of warmth. It requires no care, and can be propagated by seeds or by planting. A plant named *Kappe* was shown at last year's Amsterdam Exhibition. It is indigenous to Java, and when its fibres are carefully prepared they resemble wool, and when curled, at a moderate cost, can be used for stuffing mattresses. It can also be spun and dyed, but the fibrous appearance it retains shows that a radical improvement in the method of treating it has still to be discovered. All who examined the fibre at Amsterdam were satisfied of its contingent importance as a textile material.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, eight o'clock :—

MARCH 12.—"Water Regulation, in regard to Supply, Floods, Drainage, and Transit." By General RUNDALL. THOMAS SALT, M.P., will preside.

MARCH 19.—"The Elephant in Freedom and Captivity." By G. P. SANDERSON, Superintendent of Government Elephant-catching Operations in Bengal. Sir JOSEPH FAYRER, K.C.S.I , M.D., F.R.S., will preside.

MARCH 26.—"Vital Steps in Sanitary Progress." By B. W. RICHARDSON, M.D., F.R.S. Sir ROBERT RAWLINSON, C.B., will preside.

FOREIGN AND COLONIAL SECTION.

Tuesday evenings :—

MARCH 18.—"Borneo." By B. FRANCIS COBB, Vice-President of the Society. Admiral RYDER will preside.

APRIL 1.—"The Rivers Congo and Niger entrances to Mid-Africa." By ROBERT CAPPER.

APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings :—

MARCH 13.—"The Upper Thames as a Source of Water Supply." By Dr. PERCY F. FRANKLAND.

The Rt. Hon. Sir LYON PLAYFAIR, K.C.B, M.P., F.R.S., will preside.

MARCH 27.—"Cupro-Ammonium Solution and its Use in Waterproofing Paper and Vegetable Tissues." By C. R. ALDER WRIGHT, F.R.S., D.Sc.

APRIL 24.—"Economic Applications of Sea weed." By EDWARD C. STANFORD, F.C.S.

INDIAN SECTION.

Friday evenings :—

MARCH 7.—"The New Bengal Rent Bill." By W. SETON-KARR. Sir GEORGE CAMPBELL, M.P., K.C.S.I., will preside.

MARCH 28.—"Trade Routes in Afghanistan." By GRIFFIN W. VYSE. LORD ABERDARE, F.R.S., will preside.

APRIL 25.—"The Existing Law of Landlord and Tenant in India." By W. G. PEDDER.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 10...Geographical, University of London, Burlington-gardens, W., 8½ p.m. 1. Mr. M. Lupton, "Lupton Bey's Notes on the Bahr Ghazal Province, in the Soudan." 2. Mr. E. G. Ravenstein, "The Somal and Galla Countries."

Institute of Agriculture, Lecture Theatre, South Kensington Museum, S.W., 8 p.m. Mr. Bernard Dyer, "Some Scientific Aspects of Cheese-making."

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. F. Harrison, "London as a Historical City."

TUESDAY, MARCH 11...Royal Institution, Albemarle-street, W., 3 p.m. Prof. A. Gamgee, "Animal Heat, its Origin, Distribution, and Regulation." (Lecture II.)

Medical and Chirurgical, 53, Berners-street, Oxford-street, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Adjourned Discussion on Mr. Sydney W. Barnaby's Paper, "Hydraulic-Propulsion."

Photographic, 5a, Pall-mall East, S.W., 8 p.m.

Anthropological, 4, St. Martin's-place, W.C., 8 p.m. 1. Mr. A. L. Lewis, "The Longstone and Other Prehistoric Remains in the Isle of Wight." 2. Admiral F. S. Tremlett, "The Cromlec of Er Lanic." 3. W. J. Knowles, "The Antiquity of Man in Ireland." 4. Mr. H. Prigg, "A Portion of a Human Skull of supposed Palæolithic Age from near Bury St. Edmunds."

Colonial Inst., St. James's Banqueting-hall, Regent-street, W., 8 p.m. Mr. Charles S. Dicken, "The Mineral Wealth of Queensland."

WEDNESDAY, MARCH 12...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Lieut.-General F. H. Rundall, "Water Regulation in Regard to Floods, Drainage, and Transit."

Graphic, University College, W.C., 8 p.m.

Microscopical, King's College, W.C., 8 p.m. 1. Professor Abbe, "The Distance of Distinct Vision." 2. Mr. T. B. Rosseter, "Further Observations on *Stephanoceros Eichhornii*."

Royal Literary Fund, 10, John-street, Adelphi, W.C., 3 p.m. Annual Meeting.

College of Physicians, Pall-mall East, S.W., 5 p.m. (Gulstonian Lectures.) Dr. Clifford Allbutt, "Chapters on Visceral Neuroses." (Lecture II.)

Civil and Mechanical Engineers, 7, Westminster-chambers, S.W., 7 p.m. Mr. A. J. Gale "American Construction."

THURSDAY, MARCH 13...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Chemical and Physical Section.) Dr. Percy F. Frankland, "The Upper Thames as a Source of Water Supply."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

London Institution, Finsbury- circus, E.C., 7 p.m. Prof. E. Pauer, "Romanticism in Music."

Society for the Encouragement of Fine Arts, 9, Conduit-street, W., 8 p.m. Mr. William H. Cope, "Jade—its Peculiarities and Mode of Treatment, Artistic and Mechanical, illustrated by Numerous Specimens."

Parkes Museum of Hygiene, 74A, Margaret-street, Regent-street, W., 5 p.m. Dr. Henry Veale, "Organisation and Management of Field Hospitals."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. Tyndall, "The Older Electricity, its Phenomena and Investigators." (Lecture III.)

Telegraph-Engineers and Electricians, 25, Great George-street, S.W., 8 p.m. Mr. W. H. Massey, "Notes on a Train-lighting Experiment."

Mathematical, 22, Albemarle-street, W., 8 p.m. 1. Professor Larmor, "The Direct Application of the Principle of Least Action to Dynamical Analogues." 2. Professor M. J. M. Hill, "The Closed Funicular Polygons, belonging to a System of Co-planor Forces, having a Single Resultant." 3. Mr. J. W. L. Glaisher, "The Square of Euler's Series." 4. Mr. J. Griffiths, "Further Results of a Theory of Transformation of Elliptic Functions."

FRIDAY, MARCH 14...United Service Inst., Whitehall-yard, 3 p.m. Capt. J. T. Bucknill, "Automatic Artillery Fire."

Royal Institution, Abermarle-street, W., 8 p.m. Weekly Meeting. 9 p.m. Mr. J. N. Langley, "The Physiological Aspect of Mesmerism."

College of Physicians, Pall-mall East, S.W., 5 p.m. (Gulstonian Lectures.) Dr. Clifford Allbutt, "Chapters on Visceral Neuroses." (Lecture III.)

Astronomical, Burlington-house, W., 8 p.m.

Quekett Microscopical Club, University College, W.C., 8 p.m.

Clinical, 53, Berners-street, W., 8½ p.m.

New Shakspere, University College, W.C , 8 p.m. Mr. A. A. Ader, "Shakespeare's Use of Alliteration."

SATURDAY, MARCH 15...Geologists' Association, 2 p.m. Visit to the Natural History Museum under the Direction of Dr. Woodward.

Royal Institution, Albemarle-street, W., 3 p.m. Captain Abney, "Photographic Action considered as the Work of Radiation." (Lecture III.)

CORRECTION.—In the report of the Chairman's remarks in the discussion on Mr. Boulger's paper on "Chinese History" (see ante p. 301), it should have been stated that the fortifications referred to were at Woosung (col. 2, line 4); also for "Tientsin" (col. 1, line 15 from bottom) read *Chusan*.

Journal of the Society of Arts.

No. 1,634. Vol. XXXII.

FRIDAY, MARCH 14, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

SOCIETY OF ARTS PRIZES.

The Council of the Society of Arts are prepared to award the following prizes in connection with the International Health Exhibition :—

John Stock Prize.

Under the John Stock Trust, a Society's Gold Medal or £20, for the best example of sanitary architectural construction, in the following classes of the Exhibition :—

Class 20.—Dwellings, models and designs for the same, and specimens of buildings erected in the grounds. Fittings and accessories for dwelling-houses. Completely-fitted apartments.

Class 28.—Materials for sanitary house construction—roofs, walls, damp-courses, solid floors, damp-proof wall-coverings, cements, &c.

Class 29.—Materials for sanitary house decoration, non-poisonous paints and wall papers, floor coverings, washable decoration, &c.

Class 30.—Objects for internal decoration and use in the dwelling. Fittings and furniture.

Class 32.—Publications and literature, models, pictures, diagrams, &c., relating to Group III.

Shaw Prize.

Under the Shaw Trust, a Society's Gold Medal or £20, for the most deserving exhibit in the following Classes :—

Class 41.—Designs and models for improvements in the arrangement and construction of workshops, especially those in which dangerous or unwholesome processes are conducted.

Class 42.—Apparatus and fittings for preventing or minimising the danger to health or life, from carrying on certain trades. Guards, screens, fans, air-jets, preservative solutions, washes, &c.

Class 43.—Objects for personal use — Mouth-pieces, spectacles, dresses, hoods, &c., for use in certain unhealthy and poisonous trades.

Class 45.—Sanitary construction and inspection of workshops, factories, and mines—(*a*) New inventions or improvements for ameliorating the condition of life of those engaged in unhealthy occupations; (*b*) means of economising human labour in various industrial operations.

North London Exhibition Prize.

Under the North London Exhibition Trust, a Society's Gold Medal or £20, for the best set of specimens illustrating the handicraft teaching in any school in the following Classes :—

Class 49.—Domestic economy and other forms of technical and industrial education for girls — (*a*) Models and apparatus for the teaching of cookery, housework, washing and ironing, needlework and embroidery, dressmaking, artificial flower - making, painting on silk, pottery, &c.; (*b*) specimens of school work.

Class 50.—Handicraft teaching in schools for boys—(*a*) Apparatus and fittings for elementary trade teaching in schools; (*b*) specimens of school work.

Fothergill Prizes.

Under the Fothergill Trust, Two Gold Medals (or two sums of £20), one for the best exhibit in Class 27, and one for the best in Class 26.

Class 27.—Fire prevention apparatus—Extincteurs, portable engines, domestic fire escapes, &c.

Class 26.—Lighting apparatus — (*a*) Electrical apparatus for illumination and domestic use, secondary batteries, electroliers, accumulators, &c.; (*b*) apparatus for lighting by gas, gas producers, gas meters, gas fittings, chandeliers, &c.; (*c*) oil and other lamps; mineral oil, wax and other candles, vegetable and animal oils.

Trevelyan Prizes.

From the Trevelyan Prize Fund, Five Gold Medals (or five sums of £20), for the best exhibit in each of the following Classes :—

Class 2.—Prepared vegetable substances used as food, including tinned, compressed and preserved fruits and vegetables. Bread, cakes, and biscuits of all kinds. Tobacco.

Class 3.—Prepared animal substances used as food in a preserved form—tinned, smoked, salted, compressed and prepared animal foods of all kinds; food produced by insects, such as honey, &c.

Class 6.—Cookery practically demonstrated.—Economical cooking, workmen's and other kitchens, cheap restaurants, bakeries, cafés, foreign cookery, &c.

Class 7.—The chemistry and physiology of food and drink. The detection of adulteration, materials used as adulterants, analyses, food constituents and equivalents, tables, diagrams, &c.

Class 11.—Apparatus and processes for conserving, storing, conveying and distributing fresh food of all kinds.

Each prize will be a Gold Medal, or the sum of £20, at the option of the recipient.

The Council propose to ask the juries in each class to recommend for their consideration either two or three exhibits which they might consider deserving a prize.

ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal for 1884, early in May next. This medal was struck to reward "distinguished merit in promoting Arts, Manufactures, or Commerce," and has been awarded as follows:—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S., "for his great service to Arts, Manufactures, and Commerce, in the creation of the penny postage, and or his other reforms in the postal system of this country, the benefit of which have, however, not been confined to this country, but have extended over the civilised world."

In 1865, to his Imperial Majesty, Napoleon III., "for distinguished merit in promoting, in many ways, by his personal exertions, in the international progress of Arts, Manufactures, and Commerce, the proofs of which are afforded by his judicious patronage of Art, his enlightened commercial policy, and especially, by the abolition of passports in favour of British subjects."

In 1866, to Professor Faraday, D.C.L., F.R.S., for "discoveries in electricity, magnetism, and chemistry, which, in their relation to the industries of the world, have so largely promoted Arts, Manufectures, and Commerce."

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S., "in recognition of their joint labours in establishing the first electric telegraph."

In 1868, to Mr. (now Sir) Joseph Whitworth, LL.D., F.R.S., "for the invention and manufacture of instruments of measure and uniform standards, by which the production of machinery has been brought to a state of perfection hitherto unapproached, to the great advancement of Arts, Manufactures, and Commerce."

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, &c., "for his numerous valuable researches and writings, which have contributed most importantly to the development of food economy and agriculture, to the advancement of chemical science, and to the benefits derived from that science by Arts, Manufactures, and Commerce."

In 1870, to Ferdinand de Lesseps, "for services rendered to Arts, Manufactures, and Commerce, by the realisation of the Suez Canal."

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B., "for his important services in promoting Arts, Manufactures, and Commerce, especially in aiding the establishment and development of International Exhibitions, the development of Science and Art, and the South Kensington Museum."

In 1872, to Mr. (now Sir) Henry Bessemer, F.R.S., "for the eminent services rendered by him to Arts, Manufactures, and Commerce, in developing the manufacture of steel."

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France, "for his chemical researches, especially in reference to saponification, dyeing, agriculture, and natural history, which, for more than half a century have exercised a wide influence on the industrial arts of the world."

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S., "for his researches in connection with the laws of heat, and the practical applications of them to furnaces used in the Arts; and for his improvement in the manufacture of iron; and generally for the services rendered by him in connection with economisation of fuel in its various applications to Manufactures and the Arts."

In 1875, to Michel Chevalier, "the distinguished French statesman, who, by his writings and persistent exertions, extending over many years, has rendered essential service in promoting Arts, Manufactures, and Commerce."

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal, "for eminent services rendered to Commerce by his researches in nautical astronomy, and in magnetism, and by his improvements in the application of the mariner's compass to the navigation of iron ships."

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France, "the distinguished chemist, whose researches have exercised a very material influence on the advancement of the Industrial Arts."

In 1878, to Sir Wm. G. Armstrong, C.B., D.C.L., F.R.S., "because of his distinction as an engineer and as a scientific man, and because by the development of the transmission of power—hydraulically—due to his constant efforts, extending over many years, the manufactures of this country have been greatly aided, and mechanical power beneficially substituted for most laborious and injurious labour."

In 1879, to Sir William Thomson, LL.D., D.C.L., F.R.S., "on account of the signal servicсs rendered to Arts, Manufactures, and Commerce, by his electrical researches, especially with reference to the transmission of telegraphic messages over ocean cables."

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S., "for having established, after most laborious research, the true relation between heat, electricity, and mechanical work, thus affording to the engineer a sure guide in the application of science and industrial pursuits."

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the

University of Berlin, "for eminent services rendered to the industrial arts by his investigations in organic chemistry, and for his successful labours in promoting the cultivation of chemical education and research in England."

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S., "for his researches in connection with fermentation, the preservation of wines, and the propagation of zymotic diseases in silk worms and domestic animals, whereby the arts of wine-making, silk production, and agriculture, have been greatly benefited."

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S., "for the eminent services which, as a botanist and scientific traveller, and a Director of the National Botanical Department, he has rendered to the Arts, Manufactures, and Commerce, by promoting an accurate knowledge of the floras and economic vegetable products of the several colonies and dependencies of the Empire."

The Council invite members of the Society to forward to the Secretary, on or before the 19th of April, the names of such men of high distinction as they may think worthy of this honour.

Proceedings of the Society.

INDIAN SECTION.

Friday, March 7, 1884; Sir GEORGE CAMPBELL, M.P., K.C.S.I., in the chair.

The paper read was—

THE NEW BENGAL RENT BILL.

By W. S. SETON-KARR.

The subject on which I have the honour to address you this evening is wide, important, capable of consideration under various aspects, and certain to lead to much divergence of opinion. It is usual, in similar cases, for the lecturer or speaker to begin by saying that, in his treatment of the question, he will avoid all political controversy. I think it preferable to say that I shall avoid irritating remarks, or disparagement of the motives and opinions of those who have particular views, whether of the rights of the tenantry or of the position and privileges of the Zemindar; for, in truth, it is impossible to treat this subject properly without reference to its political scope and effect. Agriculture is not only a great, but it is the greatest, interest in India. A good system of revenue, rent, and tenure lies at the bottom of all its social advancement. In every one of our numerous annexations, nothing goes on at all until the claims of the Government are laid down with equity and precision. And though revenue in Bengal and Behar has long been settled on a basis accepted and well understood by the people, and although my present paper will deal with rent and occupation rather than with revenue, it is quite obvious that, unless the respective rights and claims of Zemindar and ryot are fairly adjusted, chronic warfare will not cease, and Oriental society, so far from progressing, will be threatened with something not very unlike disintegration and decay.

Now, I apprehend that most of my audience are more or less familiar with the prominent and characteristic features of the Zemindary systems of Bengal, Behar, and a small part of Orissa; therefore only a brief recapitulation of the events which have led to the present state of antagonism will be necessary. When, rather more than a century ago, the Government of the East Indies passed from the speculations of commerce to the responsibilities of empire, its administrators mostly adhered to the various systems—revenue, police, and judicial—established by their predecessors, the Mohammedan viceroys of Bengal. They were eminently cautious and conservative. The revenue was collected from various contracting parties, just as it had been by Nawabs who reigned with absolute power at Dacca or Moorshedabad. A good deal of time has been taken up in discussions whether those responsible for the collection and payment of the Government revenue were hereditary Zemindars, or mere tax collectors and farmers of the public dues. But—as any one familiar with the records and writings of the last century, especially with that storehouse of information, the Fifth Report of the House of Commons, dated 1812, will admit—the first Zemindars were of various classes. There were the heads of ancient houses, some older than the Mogul Empire itself— Bishanpore, Tikari, Bettia, Nuddea, Nattore, and others, with whom it was natural that the ruling power should contract; there were farmers who contended for the privilege of collecting the Government dues and making their own profits; there were some in whose families the office of tax gatherer had a tendency to become hereditary; there were others who contracted one year and defaulted in the next. There were, in short, ancient Rajas, Mohammedan upstarts, wily and supple Hindus, and even adventurous Englishmen of resolution, skill, and knowledge of the native character. But about the time of the great debate on paper between Shore and Lord Cornwallis, and certainly at the epoch of the Decennial Settlement, all the various parties were generally comprehended under the term Zemindars, and in the not, perhaps, scientific phraseology of the Legislature of the day, were sometimes styled landholders or proprietors of land. In considering their attributes, duties, responsibilities, and rights, it is, above all, essential to divest oneself of the idea that a landholder in Bengal corresponds to the English squire or owner in fee simple. Nothing can be further from the truth. And, indeed, this attempted analogy, arising out of loose language, misleading translations, and forcible introduction of the English law of real property, though productive of some confusion and error, has long been abandoned by all but a very few, and forms no part of the Zemindars' case. Doubtless, on the other hand, the Zemindar of Bengal, whether he owns a whole *chuckla*, two or three pergunnahs, or is a Talukdar with only a couple of villages, always enjoys certain rights and privileges which give him much importance, which it is not easy to formulate or define, and which rest partly on legislative enactment, partly on judicial decision, but most on the custom and common law of the country. He is, in one sense, the owner of an estate, but that estate means technically nothing more than a certain area of the land of Bengal on which is assessed a fixed portion of the Government revenue. As responsible for that portion of revenue, the Zemindar has certain clear rights over the whole area. He can establish or induct ryots into any part of it, or he may cultivate the land by his own hired servants. His dues may be collected from the cultivated land, as well as from the swamp and the jungle. He has rights in fishing, in the natural products of the forest, in honey, wax, wild fruits, and timber. He can vary the rent claimable from each cultivator according to the character of the cultivation, and no one ever, in theory at least, disputes the Zemindars' claim to a far higher rate for sugar-cane, tobacco, garden or homestead, than for early or late rice. All lands or plots vacated by ryots, owing to death or desertion, revert, *ipso facto*, to the Zemindar. He can assign the vacant homestead to a new ryot; can establish new villages; found new bazaars, or *hauts;* cut roads, drain swamps, and dig splendid reservoirs. The theory which regulates all these acts of lordship is not, I hold, that the soil belongs to him, but that these successive operations tend either to increase or to diminish the rent-paying power of the land; and as rent must be the basis of land-revenue, no one but the Zemindar has the right to say how fresh land is to be taken up, and by what ryots; under what terms the waste or jungle is to be reclaimed; to what extent the existing acreage of rent may be diminished in order to supply the general community with such solid benefits as a road from one cluster of populous villages to a crowded bazaar; or a tank of pure water, a quarter of a mile in length and some thirty feet in depth. Time prevents me from pursuing this topic further, or proving my position, as I might do, by judicial record, by the testimony of experts, or by the writings and opinions of officials who have made the Zemindary system the study of a life.

A similar brief sketch must be given of the rights and titles of the ryot. It is useless, for any legislative or practical purpose, to inquire at what period, or under what political convulsions, those village communities, so familiar to us elsewhere in India and so admirably illustrated and expounded by Sir Henry Maine, disappeared from off the face of Bengal and Behar. No doubt acute writers may find traces of this system in the tendency of men of one caste, or one religion, to occupy whole villages, or particular *mahallas* or quarters of villages. Fishermen in one tract; outcasts or *chandals* in another; Brahmins in a third; Mussulmans in a fourth—are instances familiar to every district officer. But liability to Government in Bengal and Behar never goes beyond the liability of the Hindu family of cultivators, while undivided in mess and estate, for the rent of their holding. We must take, then, the ryot as an individual, one of a cultivating class, but not one of a coparcenary community. If the Zemindar had his privileges, his prestige, his legal and equitable rights, and his able partisans, the ryot has had also his friends and defenders, the custom of centuries to back him, the practical connection with the soil which revolution could not alter, which high-handed oppression could not terminate, which legislative enactment did not fail to recognise, and which statesmen, from Shore and Cornwallis down to Canning, Grant, Lawrence, Campbell, and Eden, have exerted themselves to maintain and protect. To quote one sentence from the Legislature of 1793, which has been referred to scores of times since this agitation began, the Governor-General, Lord Cornwallis, reserved for himself and his successors the right "to enact such regulations as he may think necessary for the protection and welfare of the dependent Talukdars, ryots, and other cultivators of the soil." A *jotedar*, or proprietary tenant, in early days, depended for security, freedom from annoyance and oppression, no doubt quite as much on the character of the Zemindar and his agents, as on the protection of the English executive authority or the safeguards created in his favour by the law. He was liable, as we have seen, to rates of rent which rose with the character of his produce. His plot might be measured at any time by his Zemindar, who could resort to this operation without recourse to any Court. He might be bullied by the Amin, harassed by collecting agents, called on to contribute extra cesses to the extravagance or necessities of the Zemindar who had lost a big law suit, married an eldest son, dedicated a temple, or received a title from the hands of Government. But no superior landlord dictated to him about the rotation of crops, if such an agricultural operation was thought of, or required him to erect fences or little embankments, and keep them in repair. There were no conditions as to repairs or alterations in buildings. The ryot built his house of bamboo posts, wattles, and thatch of grass or reeds, and carried it off bodily or sold it, if he thought of changing his village. If his holding was too big to manage, or if he rose from the status of a *jotedar* to something resembling a dependent Talukdar, he could sub-let any portion, without asking any one's leave, to cultivating sub-tenants. Indeed, this authority was tacitly recognised in his *potta* or title-deed of occupancy, whereby he bound himself to urge no plea of abatement on account of death or desertion. And while no interference with any one agricultural operation was ever attempted by any Zemindar, the ryot had two safe-guards and two proofs of some distinct proprietorship, which, in this discussion, can never be put aside. In the first place, for nearly one century in Bengal Proper, no enhancement of rent has been possible without resort to the Courts. The judicial rent, so familiar to us from recent Irish legislation, has prevailed more or less in the Lower Provinces since the days of Lord Cornwallis, and long before Act X. A high-handed Zemindar, or a lessee of some thirty villages under such a Zemindar, has doubtless often claimed extra payments, as I have explained, known as *abwabs;* but for the additions to the *jumma*, or rent proper, as it is termed, there is nothing for it but taking the recusant ryot into Court. Sometimes a prominent and wealthy ryot is selected, and sometimes it is necessary for the landholder to dragoon half a village in succession, through three Civil Courts. This fact alone, so patent, so universal, so clearly recognised by every class connected with the land, either as Zemindar, dependent Talukdar, substantial tenant-proprietor, or sub-cultivator, ought to dispose of the last shred of argument in favour of the absolute, unqualified dominion in the land, ever claimed for the superior holder. The second safe-guard is, perhaps, less known and it is very often disputed, but it is none the less capable of satisfactory legal and authoritative proof. It is that the *jote* of the ryot has a distinct marketable value, and is absolutely essential to the performance of certain acts, or to the appropriation of lands to some one specified use. For instance, a rich Zemindar wants a piece of land on which to erect a temple, or a summer or garden house, or a *kucherry* for himself and his agents. If there is a vacant plot within his Zemindary, he can appropriate it to this object. But if there is none such vacant or suitable, the Zemindar is compelled by custom having the force of law, to get a piece of land by assignment from one of his own ryots. And any district officer conversant with his business and the people will give you scores of instances of this practice. I will go further, and say that it is not only usual for a Zemindar to become his own ryot as it were, or to take an assignment of land from one of his own tenants for a practical, beneficent, or philanthropic purpose; but it is quite as common for a Zemindar, for purposes of annoyance or revenge, to gain a footing in the Zemindary of a rival by an exactly similar process. If a ryot is unable to stand the oppression of his own Zemindar, he often surrenders his holding to the neighbouring Zemindar, who will be quite able and willing to fight the ryot's battle for him; and I have known instances in which an able and unscrupulous landowner, having gained a footing in the estate of a rival in this way, has ended by purchasing, annexing, or in some way, legal or illegal, appropriating all the similar and all the superior rights, and ousting his rival from the complete estate. Ryotty tenures, again, are often put up to public auction, in execution of decrees, and sold for what they are worth. They are also disposed of privately, though I own that the power of a ryot to sell or convey away his tenure, without first obtaining the leave of the Zemindar, is constantly called in question, and is just one of those points on which much diversity of opinion exists in different localities. But still, as a fact, the sale does often take place, whether the power to sell be recognised or denied; and at any rate the ryot, it has been legally settled as a rule, holds by custom and not by contract. His rent cannot be varied except by formal suit and judicial decision. His *jote* is something so tangible, so valuable, so necessary for those who wish to deal practically with the soil, that it becomes an object for competing Zemindars, and is recognised as a separate asset under the decrees of Courts.

Such is just an outline of the position of Zemindar and ryot since the legislation of 1793, and I have not time to support and illustrate my position by a review of the various laws, limiting, expounding, or defining the power of the Zemindar between that legislation and the era of Lord Canning, to show how the recovery of rent was facilitated to the Zemindar, in 1799, by power to distrain crops, with certain reservations to the ryot, and to bring summary suits before the Revenue authorities; to explain why Zemindar was, for years, prevented from giving leases of large tracts for more than certain periods; to show how the partition of estates, under the Hindu law of inheritance, had to be jealously watched and circumscribed, in order to prevent detriment and loss to the Government revenue; or to enter on the vast and fertile subject of the resumption of invalid rent-free tenures, which caused such agitation between the years 1828 and 1840.

It is sufficient to say that while the interests of the ryots was often obscured and neglected, they were never wholly lost sight of before the law of 1859, which, in spite of the distraction caused by the Sepoy revolt, the Government of Lord Canning found time to pass, and which, for some years at least, was deemed to have secured the position of the ryot, and to have redeemed the pledges recorded by Lord Cornwallis in 1793. To three important provisions of that celebrated statute I need only just allude. It recognised the permanent occupancy of a ryot who had cultivated land for twelve years, and secured him or his successors against eviction. It protected him from judicial enhancement, unless he was paying a less rent than the same class of ryots in his neighbourhood, or unless the productive powers of the soil had been increased otherwise than by his agency, or unless he held more land than his deeds could cover; and it supplied him with other securities against oppression and extortion, while it defined more strictly the acknowledged position and superior claims of the Zemindar. For some years things went much better. The ryot began to understand what the law gave him. The well-known rent case of the High Court of 1865 still further elucidated the Act. But, about the year 1873 matters altered. Agrarian disturbances, as they are called, were frequent. In some places Zemindars could not collect their lawful dues. In others their extra cesses were intolerable. Ryots learned the art of combination. It became clear, after divers attempts to cope with the difficulty, that something must be attempted on a larger scale. A Rent Commission, composed of some very able gentlemen, English and native, was appointed. Their labours resulted in a report. The report was followed by an exhaustive correspondence of the Government of Bengal, and by the draft of a new rent law, which was followed by another draft from the hand of Mr. Ilbert, the legal member of council; and this brings me, not *per saltum* but by short steps, to the important part of my address, the Tenancy Bill for Bengal. Some previous acquaintance with my whole subject, the perusal and reperusal of the Fifth Report of the House of Commons, a careful study of the recent Blue-books published by the Government of Bengal and the Government of India, to say nothing of a large quantity of independent literature, in magazines, and reviews, and unpublished documents, have quite satisfied me that Lord Ripon's Government had no option in the matter. It was not a case of deferring legislation to some distant season, or for hoping that the agricultural agitation would subside owing to the spread of education, the weight of judicial decisions, the increased power of an active executive, or any other plausible reason for putting off till to-morrow which ought to be done to-day. Very likely the draft Act has excited active opposition, has offended the feelings of a powerful class, and may call forth, even from those most qualified to judge fairly, a wide diversity of opinion. But after nine years of disturbance, copious reports, and the concurrent testimony of some of the ablest administrators, there was nothing for it but fresh legislation. A Government which has always boasted of its anxiety for the welfare of the speechless part of the native community, would have failed in its first duty, had it not tried to grapple with this intricate, this controverted problem, the rents and tenures of Bengal and Behar.

So now to the specific measures proposed for the relief of the ryot, and, to a certain extent also, in the interest of the Zemindar. I have sometimes thought whether the Bill, with its seventeen chapters, two hundred and thirty sections, besides schedules and appendices, might not be too comprehensive; whether the object in view could not have been obtained by re-casting and improving Act X of 1859. Intelligent natives are perplexed and harassed by our ceaseless flow of legislation. I remember a Bengal Zemindar of large estates and conspicuous ability, whose outlay for stamps used in litigation and agricultural business averaged £7,000 per annum, telling me that he and his agents were perfectly bewildered by supplementary, amending, and explanatory laws. The scope and object of one, and its main sections and clauses, had only just been mastered, when they were ruthlessly swept away. Yet when I recollect that the Rent Commissioners, the late Lieutenant-Governor of Bengal, and the Viceroy and his Council are all in favour of one new comprehensive enactment, I waive my own objections, even though I am aware that the new Bill consigns to oblivion many of the best known Regulations and Acts well understood by the Zemindar, not too complicated for the tenantry, and endeared by long practice to the official mind. The main subjects dealt with by the new Bill are:—

1. The distinction between land known as *khamar*, or *nij*, and that known as ryotty; or, in loose English language, the land cultivated by the superior landlord as a home-farm, and the land given over to ryots who pay him rent. In the times of the Tudors the *khamar* would have been known as demesne lands.*

2. The limitation on the power of the Zemindar to enhance his ryot's rent.

3. The acquisition and the incidence of the right of occupancy by ryots.

4. The treatment of sub-ryots, or other ryots not hitherto having an occupancy right.

5. The framing of tables of Pergunnah rates all over the country, to serve as a guide to the Civil Courts or to supersede or anticipate their action altogether.

6. The sale of ryotty or occupancy holdings, or sub-tenures.

There are divers other provisions for the issue of processes, the payment of rent at proper times of the year, the distraint of standing crops, the correct keeping of accounts, the delivery of receipts for rent, and the powers of the Courts, which, however important, are not so radical or essential. I have only time to allude to these latter in one lump.

The distinctions between *khamar* or home-farm and ryotty land has long been familar to all residents in the interior. Indigo planters, in most factories, have always had a quantity of the former land, which they cultivated with their own servants, bullocks, and ploughs. Many of the Zemindars do the same. According to my experience, the cultivation of the *khamar* land was generally slovenly; the various operations of ploughing, harrowing, weeding, and watching, was carelessly performed; and the result was far inferior, as regards the crop, to what would be attained by a Kaivert, a Kopali, a Pode, a Teor, or any one of the Hindu agricultural castes. Still, variety in cultivation and tenure has not been without its uses. There is always a chance that some energetic Talukdar, or it may be an Englishman, may arise and set the fashion of a more careful agriculture; that he might try new kinds of produce, or get greater returns from such valuable crops as *pan*, sugar-cane, tobacco, jute, and others. I cannot say that I recollect more than two or three instances of this improved or model cultivation on the part of Bengali Zemindars. But still it is not desirable to exclude the possibility of the appearance, among the Zemindars and Talukdars of Bengal, of some wealthy magnate, who, like Lord Tennyson's agricultural Baronet, should be—

> "A breeder of fat oxen and fat sheep,
> A pamphleteer on guano and on grain,
> A patron of some thirty charities."

I see no great harm in the provision for effecting a survey and register of these *khamar* lands in the collectorate. The plan was once proposed by Sir J. P. Grant. I myself introduced a Bill for the purpose, in the year 1861, and I note especially that, in Behar, Zemindars, for some years past, have been in the habit of converting large stretches of ryotty into *khamar*, and annexing them to the indigo factories. But I gathered from one of the discussions on this subject that it was proposed to compel the Zemindar who became possessed of a ryotty tenure, vacated for some cause or other, to settle some other tenant upon the land. He (the Zemindar) was

* See an excellent article on this subject in the *Quarterly Review* for January last.

not allowed to use it for his home farm, or to convert it into a garden, or otherwise to keep it for his own enjoyment. Whatever may be the danger against which the authorities wish to guard, I sincerely trust that no such compulsory clause will be inserted or retained. Let the occupancy, hereditary, *khoodkhast*, *chapparband*, or *kadimi* ryots have what security of tenure you think fit, but avoid these despotic and obligatory clauses. Tyrannical or unfair appropriation of ryotty lands by wholesale ought to be met in divers other ways. And even in Behar, where this plea of wholesale usurpation is most pleaded as a reason, it is stated that three-fourths of the land are still held under occupancy tenures. If land does revert to the Zemindars by death, flight, or failure of heirs, as I have always maintained it must do by the common law of the country, the Zemindar ought to be left to deal with each plot as he thinks fit. There should be no legal interference with what has long been recognised as an hereditary privilege of the superior landlord. Otherwise, for a small object in favour of the ryot, you present the Zemindar with a tangible grievance. Mr. Ilbert says distinctly, in his reasons and objects, "that the existing stock of *khamar* land cannot hereafter be increased." But suppose large tracts to be laid desolate and drained of inhabitants, by an epidemic, a famine, or an inundation, or the jungle and swamp to be reclaimable, surely it is not politic or equitable to say that no Zemindar or landlord shall appropriate any portion of such tract for his own *khamar* land and cultivate it, if he likes, as what we should call a home farm.

The next point is the limitation of the Zemindar's power of enhancing rent, and I will consider this in connection with the equally important matter of the preparation of tables of Pergunnah rates. As usual, in our Anglo-Indian administration, the venue and jurisdiction of suits for rent and enhancement has been repeatedly shifted. Sometimes the duty has been divided between the Revenue and the Civil Courts, that is between the Courts of the Collector and his deputies, and those of the Native Subordinate and the English Civil Judges. But, in truth, Courts of any kind, however admirable, are not the best sort of machinery for ascertaining generally the qualities of the soil, the varieties of the produce, and the increase in the productive powers of the land, whether due to the ability of the cultivator or to great social or economic causes. The best plan for the ascertainment of the customary or local rate would be to entrust the inquiry to a Revenue or a special Commission. I have seen it stated that Pergunnah rates are not now ascertainable. Within my own experience of twenty years ago, they were not only ascertainable but ascertained. In the districts with which I was practically most familiar, Jessore, Pubna, and the Twenty-four Pergunnahs, and other metropolitan districts, these rates varied slightly in each Pergunnah, were perfectly well known, and could be got at with comparatively little trouble. Major Ralph Smith got them in his report on the Twenty-four Pergunnahs, and so has Mr. W. W. Hunter. I cannot but think that resolute and intelligent officers, conversant with the people and going about the country in camp and on circuit, could easily make out tables of rates for rice, garden, homestead, sugar-cane, jute, &c., in several of the largest districts. And even if they did not exist everywhere, or were fluctuating and uncertain, it would be quite possible to take districts in which they had not been obliterated as guides and types for the others. Many a retired civilian, when he reads of these agrarian quarrels, would, I believe, wish himself thirty years younger, in order that he might have the chance of spending the cold season on such a special duty. Also I entirely approve of the provisions whereby a ryot, subjected to a suit for enhancement, shall not be liable to be sued again on the same account for a period of ten, twenty, or even thirty years. It is intolerable to think that a substantial tenant-proprietor, to whom, as a class, is owing all the wealth and diversity of cultivation in Bengal, should, after going through an ordeal of two or three Courts in the year 1884, be again subjected to the same annoying and expensive process, at the caprice of the Zemindar and his agents, in the year 1887. It is also perfectly equitable and proper to fix a reasonable rate of enhancement beyond which no Court shall go. In the end this will save all parties a deal of trouble, and the Pergunnah rates would be guides and aids to the Civil Courts.

The subject of Permanent occupancy is a more difficult, a more perplexing, and yet a very essential part of the Rent Law. The law of 1859 fixed twelve years as the period which entitled a ryot to consider himself immovable as long as he paid his rent. I shall not stop to discuss at length whether the legislators of that day conferred a new status on the twelve-year tenant, or only stereotyped the already existing customs and ideas. My own deliberate opinion is, that Act X, in this respect, was in full conformity with the experience and the just expectations of a large class of ryots, and with a correct appreciation of revenue, rent, agriculture, and social life. But it has been found that Zemindars and their agents have resorted to various expedients in order to defeat this law. They shift their tenants from one plot to another just before the twelve years expire. They get the ryot to contract himself out of his rights, and they resort to various artifices well known to collectors and magistrates. It was at one time proposed to reduce the limit still more in favour of the tenants, by cutting it down to three years. But at present it is proposed to retain the older and higher limit, and to stipulate that any resident ryot holding any plot or plots in any village, whether he has been shifted or not, shall acquire this occupancy right. I could wish that the Government of India had adopted the test of distance suggested by the Government of Bengal, and required the plots so held to be within two miles, or one *kos*, of the ryot's residence. With regard to other ryots and to sub-tenants — that is to say, the ryots of the ryot—I agree with a remark of one of the district officers consulted, that the less we try and legislate for this particular class the better. The object of the paternal care of the Government should be the well-known *jotedar* or tenant proprietor, who resides in his ancestral home, who owns a tract of fifty, thirty, or twenty acres, and who occasionally, by holding an entire village, rises almost to the dignity of a sub-tenure. Let him sub-let his land to the cultivating or labouring classes who are variously termed *shikmi*, *korfa* or *koljana* tenants. Let such come and go, like the men in Lord Tennyson's "Brook," as in a fluctuating and populous community is natural and right. If they manage to acquire occupancy rights under the broad law which you are about to lay down, they will do so by the action of national causes, which you ought not either to hinder or to accelerate. I should despair of providing for all contingencies, or embracing all classes and all agricultural rights by a code which would be in advance of the needs or capacities of the community.

Lastly, comes the free sale of these occupancy rights, to whomsoever they may belong. Less has been made of this part of the subject in the report of such sterling ability than might have been expected. I mean by this, that I find little or no mention in this voluminous official literature of the practice whereby an over-reaching Zemindar buys up the *jote* or tenant-right within his own estate, or in that of his adversary. It is true that the practice and legality of such sales is constantly questioned and discussed; but my own conclusion is that, whether the Zemindar liked it or not, whether he was too weak or too careless to interfere effectively, tenures were sold by private bargain, were made over by private arrangement, were put up to auction by Civil Courts, and possessed a sort of marketable value all over the country. It is not necessary to say more on this head, than that the Nazir of any Civil Court puts up to public auction every day the *jumma* of Thakur Dass Mandal, in the village of Gharibpur, being ten rupees nine *annas* and four *pie*, at the suit and decree of Baboo Kalachand Dutt. But while the draft Act proposes to recognise this practice authoritatively, it takes no notice of the other practice I have alluded to, by which a powerful Zemindar buys up two or three *jummas* or *jotes* in a neighbouring Zemindary, and ends, as I said at the commencement of the lecture, in getting a firm grip of the whole estate. Neither does it cope with that prominent and glaring evil so familiar to district officers, namely, the acquirement of the tenure by a powerful litigant in the name of some one else, usually a dependent or mere man of straw. It is called *benami* in Bengal and *ism-farzi* in Upper India. It is productive of more confusion, antagonism, and annoyance than any other bad agrarian device that I can recall. Admistrators have deplored it. Civil Courts have tolerated it. Legislators have tried to grapple with it. The remedy that I have always proposed is, that no person should be entitled to plead in any Court of the country, or in pursuance or defence of any right whatever, that he is the real and legal owner of what is put forward ostensibly in another's name. He ought to be bound to register his own purchase or possession in his own name.

The above are the main provisions of the Bill to which I think it desirable to draw your attention, and to some of which I should be prepared to give support. There are others which I think uncalled for and unpolitic. It was a mistake, as one of the native members of the Viceroy's Council pointed out, to drag into the Bill such a phrase as "compensation for disturbance or for improvements." These are terms drawn from the Irish Land Act, and the very phrase, "compensation for improvement," seems to me to be based on a very erroneous apprehension of the relations to each other of the rent payer and the rent receiver. Nothing in all this long history is better understood practically in Bengal then the course of agriculture, the foundation of new villages, the draining of swamps, the reclamation of lands covered with brushwood, grass, and jungle. All provisions for the landlords requiring improvement, and calling on the ryots to make them, are quite foreign to the state of rural society. As I have said already, the landlord may be left to drain the morass, to cut the canal that lets out the water of the great Hanspukria mere, to build the temple, to make the bathing ghaut, and to establish the new bazaar. The ryot, with his own plough and his own capital, plants his date garden, turns the swamp into rice land, and the rice field into garden land, without the aid of the legislature or the Zemindar.

I do not wish to apply harsh terms to those who drafted or amended this part of the Bill on its original lines; but the sections 126 to 132 really, to my mind, evince a complete ignorance of the kind of improvements on a large scale which a Zemindar has been in the habit of encouraging or carrying out himself, and of the uses to which the substantial ryot puts his ploughs and his two or three pairs of bullocks, his manual labour by *dao* and *kodali*, on the house and the land which he is accustomed to call his own. Neither do the authors of these provisions appear to have dreamt of the delicate questions which will infallibly arise out of the proviso that a ryot may make certain improvements, and if he refuses, that the Zemindar may come in and make them himself. It is easy to imagine cases in which the opening of a Mahommedan burial-ground, the building of a Mahommedan mosque, the erection of a Hindoo temple or a serai, might afford endless opportunities of collision between Zemindars and ryots of opposite religions. The common law and practice of the country is quite sufficient to meet these contingencies, and both parties may be perfectly well left to make their own arrangements on all these matters, subject, as a last resort, to the ordinary tribunals. These schemes, which seem designed to foster village fights, caste rivalries, and endless litigation, can only be compared to Cloud-Cuckoo city in the play so well illustrated recently by a body of Cambridge undergraduates, out of which indistinct atmosphere they ought never to have emerged.

In discussing the Permanent Settlement of Bengal, we are somewhat apt to lose sight of the fact that this Permanent Settlement was extended, in the year 1795, to the important province of Benares. Yet we do not hear in that quarter of these disturbances, or of the necessity for the revision of Regulations I. and II. of that year. I have no practical knowledge of the working of the system in Benares; and, in reference to the laws in question, I perceive that the Bengal Settlement was introduced there with certain modifications. The rights of the village Zemindars, who, of course, are very different persons from the large Zemindars of Bengal, were ascertained and defined. Some of them, when dispossessed, were reinstated. The Puttidars, or co-parceners, descended from the same common stock, were allowed to establish their rights. Care was evidently taken that the more powerful Talukdars, corresponding to the Zemindars of Bengal, should not override the rights of the village proprietors; and, somehow, difficulties were obviated or anticipated. This may have been owing to the greater experience of the British authorities; or to the sturdier character of the ryots in Benares, Ghazipore, and Juanpore; or, as I have heard from a civilian of great Revenue experience, now deceased, owing to the fact that the Resident at Benares, Mr. Jonathan Duncan or his successor, went in, under the Perpetual Settlement, as it were, and secured the rights of the inferior proprietors, or to some other cause. But there is the fact that we have no disturbances in Benares; and I do not exactly see why what has been done for the tenant in one province may not be done in another.

I understand, however, that the present Lieut.-Governor of Bengal is in favour of a general cadastral survey and record of all holdings whatever, all over the Lower Provinces. To this I would reply that this greater proposal comes too late; that it would only be accomplished by an enormous and an incommensurate expenditure; that it would excite violent passions, and probably cause grave outrages in many districts; and that the object contemplated ought to be attainable by other less expensive and less harassing modes. In short, if I could offer a word of advice to intending legislators on this tremendous subject, it would be couched in the following terms:—"Beware of attempting too much, or trusting that all difficulties will disappear before the serried array of sections and clauses. The more minute your provisions, the greater the opportunities for craft and cunning to evade the law, or turn what is meant for the ryot's advantage to his detriment and loss. It is the story of the old usurer in Horace:—

> "Scribe decem a Nerio: non est satis, adde Cicutæ
> Nodosi tabulas centum: mille adde catenas;
> Effugiet tamen hæc . . . . vincula Proteus."

I purposely omit the offensive epithet that would complete the line. Grapple, I would say, with the most prominent of the evils brought to light in this interminable discussion. Make Zemindars register their *khamar* or *nij* lands, but allow the same to be increased or diminished by natural causes, and without interference or compulsion; surround the substantial tenant-proprietor, who has done so much at his own expense for higher cultivation, with all reasonable security for his possession, and guarantee him against vexatious enhancement at recurring intervals. Leave the sub-ryots entirely alone. Do not attempt to prescribe to either Zemindar or *jotedar* the limits or the terms of their respective improvements, whether affecting the course of agriculture, or the erection of houses, or the general convenience of the community. Be satisfied with legislation on broad lines and on existing customs, and give to Magistrates, not Collectors, a power to award a summary and reasonable compensation to any ryot who has been forced to pay extra harassing cesses, however dignified by precedent or tradition. But take nothing from the Zemindar of manorial right, equitable privilege, or ancient custom, which the Perpetual Settlement gave him, or which, however feudal in it its character, is not absolutely inconsistent with the well-being of a proprietary class of tenants. Remember that the Zemindary system of Bengal, at various times, has stood a severe strain, and has not failed. In the trying time of the Mutiny, the revolted Sepoys in Eastern and Central Bengal melted away before the impassive demeanour and, in some cases, the active loyalty of the Zemindars; and the same class in times of scarcity and famine, have not been unmindful of their duty to a starving an enfeebled population. Record the Pergunnah Rates, and be not discouraged by any assertions that such cannot be traced. If in any one district they are difficult of ascertainment, then let the State step in and create the precedent which its officers cannot find. By this and similar means may this long standing controversy be mitigated, if not concluded, and the proposed legislation, shorn of its excrescences, tempered by reason, and possibly aided by compromise, may be accepted as a relief or a boon by the Zemindar, while it will conduce at the same time to the consolidation of a valuable class of existing peasant proprietors, as well as to the honour and credit of the British name in India."

DISCUSSION.

Rajah Rampal Sing said he had heard the paper with much pleasure; but, although it was very able and instructive, he feared those who were not well acquainted with the circumstances of India, and especially of Bengal, would not thoroughly understand the subject. He had the honour of representing the poor tenants of Bengal, and would endeavour to put their case before the meeting. It was the case in India, as all over the world, that the conquerors of the country had secured the land to themselves, and the tenants' interests were but little considered. He was not speaking in any way as a party man, for he was himself a landlord, having about 200,000 people on his estates, and he would therefore be affected by the new law; but he knew that unless the poorer people were protected, India could never prosper. He maintained that the passing of this Bill was not in any way inconsistent with the terms of the Settlement made by Lord Cornwallis, because he reserved to himself and his successors the right of making improvements or alterations if it should be found necessary, and since the state of India had improved, the terms of the Settlement might properly be changed. The tenants of Bengal had, at present, in reality no rights; the landlords exercised almost despotic power, and rack-rented them to an extent. By passing this law, the Government would not only secure the comfort of the tenants, but also the interest of the landlords, because, selfish as they were, they ignored their own interests. The tenants, at present, having no security, had no inducement to improve the land, and if there seemed no likelihood of a good crop, they would go away, and thus the landlord, in the end, suffered loss. With a permanent occupancy the land would be improved, and the landlord would be sure of getting his rent.

Mr. Robert Cust had been very much pleased with the paper, particularly as he knew that Mr. Seton-Karr had not only had a quarter of a century's experience amongst the people whose condition he had described, but had also conscientiously perused all the papers connected with the subject. He was glad to say that he agreed with the conclusions he had arrived at, and coming from the North-West Provinces he, perhaps, looked at the question more impartially, as an outsider. It was perfectly true that this Bill had not been introduced unnecessarily. In some respects the Zemindars, perhaps, were hardly used, in limiting their demesne land, but, on the whole, he must say he was an uncompromising advocate of the tenant; and should not be worthy of being a disciple of Lord Lawrence if he were not. His own training and experience had brought him to the firm conviction that the welfare of India depended on the Government supporting the masses, who cultivated the land. It was rather remarkable that, in Benares, there had always been quiet and contentment, while in Behar, an adjoining province, there had been so much trouble, the two provinces being almost precisely similar both in the character of the population and in the soil, and both being under the permanent Settlement. The Benares Settlement was made by Jonathan Duncan, two years after the Settlement of Bengal, and was almost identical with it. The reason for the difference was simply this; that forty years after that Settlement the Government of the North-West Provinces went boldly in and made a sub-settlement, by which not only the rights of the superior landlord, but also of the occupying tenants, were safe-guarded; and that was found to be good for both landlord and tenant. He could see no solution for the difficulty in Bengal except by doing something of the same kind; half the expense to be paid by the landlords, and half by the State. He said this all the more freely because he was sorry to see that in Calcutta two parties who had recently been in open controversy with each other on another question were now united in opposing this measure. He would remind his hearers that, when Herod and Pilate became friends, it was to do an act of injustice.

Mr. LETHBRIDGE said he had followed the paper closely, and had learnt much from it, and with most of the conclusions he agreed, but on others he ventured, with some diffidence, to differ from Mr. Seton-Karr. He had said that in his opinion Lord Ripon's Government had no option but to proceed with this legislation, and he expected to hear some very good reasons for that statement, but the only one adduced was, that there had been nine years' disturbance, with copious official reports, together with the opinions of some of the superior officers of the Government. With regard to the nine years' disturbance, he had, during part of that time, been resident in the centre of Bengal, and since he left the Kishnagur district, he carefully followed the current politics of every part of the province. He was acquainted with the incident of the Pugna riots and some other disturbances, but so far as the whole of one part of Bengal was concerned, he believed it was acknowledged by everyone acquainted with the province that, so far from disturbances having occurred through the oppression of the ryot by the Zemindar, the fact was quite the contrary, and the Zemindars had not been able to obtain their own rights from the ryots. He did not think there was anything which could be called a serious disturbance ever heard of in that part of Bengal. In Behar, which was generally supposed to call for this legislation most strongly, for a considerable part of the nine years referred to, a large quantity of land had been under the direct management of the Government, owing to long minorities, and it was stated by the Zemindars, especially the Maharajah of Durbungah, after the estate had been many years under the management of the Government, that whatever had grown up in the course of time to which objection might be taken, they had been started or followed by the Government officials who had charge of the land. The early part of the paper, which was purely historical, seemed to be mainly of academical interest, as connected with the Land Bill, and the most important part contained in it was the statement that a great mistake was often made in supposing the rights of the Zemindar corresponded in any degree to the rights of an English freeholder. He was not prepared to dispute that, because there were certain rights which attached to a landowner in England which a Zemindar had possibly never possessed; but on the other hand, there were rights which had been possessed before the permanent settlement by the Bengal Zemindar, that no English landowner ever possessed since the feudal times. Up to the permanent settlement, the Zemindar had rights of police, and could try offenders summarily. That was quite sufficient to show that these rights were not coterminous, but it did not follow that one right was not as great as another, and it seemed to him that the historical rights of the Bengal Zemindar were as large, if not larger, than those of any landowner in England. With regard to the rights of the ryot, there was very little said from which anyone need dissent. Mr. Seton-Karr had swept away the fallacy, which had been put forward of late, that there was any trace to be discovered in Bengal of the old village system, and, therefore, it was absurd to talk of going back to the rights of the ryot, or any other persons' rights at the time when that village system existed. He was glad to hear the reader of the paper deal with such force with the monstrous proposals of the present Government with regard to the khamar rights of the landlord. It seemed to be interfering almost with the fundamental notions of property of any sort, to tell the nominal owner of land that he could not take land into his own hands and cultivate it. That he should have his khamar surveyed at his own cost seemed to him to be grossly unjust in every way.

Sir JAMES CAIRD said he would not have presumed to take any part in the discussion, seeing so many gentlemen of much greater experience of India present, but he was glad to bear testimony to the great value of the paper, and he thoroughly agreed with Mr. Seton-Karr that the question had come to the front in such a fashion as to be impossible to be resisted. When in India, as a member of the Famine Commission, he found when they came to Bengal that at that time this question was of most pressing importance. They made many inquiries on the subject, and came to the conclusion that legislation was necessary. He was also glad to hear from Mr. Seton-Karr that the Cornwallis Settlement not only gave certain rights to the Zemindar, but reserved the power to the Government at any time when necessary to protect the rights of the ryot. What was the cause of this question coming to the front so prominently? It was simply that in the rich provinces of Bengal, where the population had increased so greatly, and where five-sixths of the people were entirely dependent on the land, the competition for land had become so excessive, and the temptation, therefore, to raise rent upon the small cultivator was so great, that it had been necessary for the Government to come forward to protect the interests of the cultivators. He regretted to hear that Mr. Seton-Karr thought it desirable to except the sub-tenants, the very men who it seemed to him were most helpless, and that he reserved his sympathies for those who were better able to take care of themselves. What a picture did Mr. Seton-Karr draw of the Zemindar? He described them to be bad cultivators—the crops they produced were not comparable to those of the small tenants who surrounded them, and yet he seemed surprised that any law should be passed to prevent these men having greater facilities for acquiring an additional extent of land. He did not see why any man who could afford it should not buy land, but it was undesirable for India, where people were pressing on the means of subsistence, that the land should fall into the hands of those who had proved unable to make a good use of it. The excessive pressure of the population of Bengal should be considered; about fifty millions out of the total of sixty, were entirely depeudent on the cultivation of the land, and of those fifty millions nearly two-thirds occupied from two to three acres a-piece. They were the very smallest cultivators, the very people over whom he was sorry to say Mr. Seton-Karr had not extended the ægis of his protection. He trusted that all-important point would be kept in view. A few nights ago he had the pleasure of sitting next to M. Clemenceau, and on inquiring about the small occupying owners in France, he was glad to hear that, notwithstanding the law of sub-division of land there, the plots were not becoming too small, because very often the cultivating occupier had as a neighbour an owner who was not a cultivator, and from whom he hired the land, and by great thrift and frugality acquired the means of gradually buying out his neighbour, and in that way keeping a workable extent of land. The result was, as M Clemenceau assured him, that these small cultivating owners were doing well. He should be glad to see something of the same system adopted in India—to see the small men there becoming owners of their own land, and independent of the Zemindar altogether.

Mr. Maclean said this was a very difficult subject, and he having no practical acquaintance with Bengal, should not have ventured to address the meeting, but for one circumstance. He had taken considerable interest in the subject, having had to discuss Indian affairs for many years past, and he thought one of the great evils with regard to Bengal was this, that for the last 25 years, to his own knowledge, the Zemindar had been perpetually worried by fresh legislation. Now a great attempt was to be made apparently to pass one comprehensive measure, and he did hope that something would be done to settle the respectlve interests of the Zemindar and ryots once for all. The provision which Sir James Caird had referred to, which allowed the Government to interfere from time to time for the protection of the ryots, might be a good one, but it might have its mischievous side also if Government felt itself justified in upsetting every settlement made after five or ten years, and in harassing and doing occasional injustice to the Zemindar. The Zemindars had been eminently loyal, and had always stood by the Government of India, and their rights ought to be respected, the tenants' rights being duly provided for too.

Mr. Charles Campbell said it was a great pleasure to an old Bengaller, like himself, to hear Mr. Seton-Karr descant in his vivid manner on Bengal things. With regard, however, to the statement that the Zemindar of the permanent settlement was not intended to be made into a prproietor like an English squire, he must join issue. Nothing could be clearer to his mind, from the regulations of 1793, and the recorded opinions of Lord Cornwallis, Mr. Shore and many others, that the Zemindar was constituted the full and actual proprietor of the soil (as much and in many things far more than any Yorkshire or Leicestershire squire), so far as such proprietorship did not interfere with the rights of certain tenantry, which rights were clearly specified at the time, but, unfortunately, were never registered or recorded. Mr. Seton-Karr assumed that this Bill was urgently required, but, in his opinion, it was in many of its main points as uncalled for, unjust, and impolitic measure as was ever conceived. What could be more unjust to the Zemindar or useless to a ryot than to give a ryot who had acquired a right of occupancy under the proposed statute, power to sell that right to any one he pleased. As to the jotedar of Jessore, whom Mr. Seton-Karr and he (Mr. Campbell) knew well, he could look after himself very well, and did not need assistance. What was much more wanted was fair protection for the petty cultivating ryots, who were as 1,000 to 1 as compared with the big jotedars. Further, the Bill contained provisions for the Board of Revenue to declare what was to be looked upon as the staple produce of each locality; and it was suggested that there should be a roving kind of commission to fix ratcs for rent in every locality, after consideration of what is known as the Pergunnah rate. In his (Mr. Campbell's) opinion there was no such thing as a Pergunnah rate in actual practical operation. The only possible test of a fair rent in Bengal was what the neighbours willingly paid and throve under. By Act X of 1859 it had been found totally impossible for the Courts to fix fair and equitable rents with reference to the fluctuating values of produce. In parts of Bengal land was often cultivated on the half-and-half system; the cultivating ryot carrying out at his own expense the entire cultivation, and dividing the produce on the spot with the superior ryot (who sometimes did, and sometimes did not, provide the seed). If it were intended to provide against famines by new-fangled legislation, he (Mr. Campbell) considered the Zemindars should at least have some compensation for the confiscation of their guaranteed rights.

Mr. Seton-Karr, in reply, said he had benefited very much by the remarks of his critics. Mr. Charles Campbell, he thought, rather forgot what the *barga* system really was. One man had the plough and bullocks and the other had the land, and then they divided the produce in half. He had cultivated land on that system himself. He gave the land and the ryot gave the plough and bullocks, and they stood over the crop and divided it between them, the ox treading it out at the same time, according to the Scripture, not being muzzled when he did it. As had been said by Sir James Caird, there might be some difficulty in ascertaining to what particular class the ryot belonged; but he thought the best thing was not to encumber legislation with a vast number of minute provisions, because if they attempted too much, they would probably fail in everything. It had been said, with some point, that he had not given sufficient reasons for the Bill being brought forward, but he thought the reasons were so patent to anyone, who had read the reports of Sir Ashley Eden, Sir George Campbell, Mr. Rivers Thompson, and all the best officers in Bengal, that something must be done, that it was unnecessary to dilate upon them. He could have given reasons for half-an-hour, but to those who would take the trouble to read the Blue-books, he thought there was very little room for argument on this point. He was very glad to hear the way in which his attempts at description of the system had been received, and should carry away with him for future guidance many useful hints from what had been said.

The Chairman, in proposing a vote of thanks to Mr. Seton-Karr, said the greater part of his remarks had his hearty concurrence, though some points had been raised by Sir James Caird and other speakers, with respect to which he should be more inclined to agree with them. He believed there was no man connected with India who had a more intimate knowledge of Central Bengal than Mr. Seton-Karr, but in Behar, perhaps, more even than in Bengal, was there a crying necessity for legislation. The commission appointed to inquire into the subject there, which comprised men of various classes, not only officials but Zemindars and indigo planters, came unanimously to the conclusion that legislation was absolutely indispensable. There was scarcely a ryot in Behar who could prove and maintain the rights conferred upon him by the Act of 1859. As regards the general question, he was glad justice had been done to the great Settlement of 1793. As had been shown, that was a Settlement not only in favour of the Zemindar, but also of the ryot; and for his part, he believed that great as the loss to the Revenue might be from a permanent Settlement, on the other hand, the advantage was so great, that there was a great deal to be said in its favour, provided that it was for the advantage of the people, and not of one class only, amounting to the withdrawal of Government protection for the great mass of the people. He must admit, without going into details of the Bill, he was much inclined to think with Mr. Seton-Karr and others that this Bill was a great deal over-loaded with detail. No doubt there was a great deal to be said in favour of combining into one Act the whole law on a complicated subject; but, on the other hand, those who had to deal with legislation were apt to find great difficulty in combining codification with an amendment of the law. He had read that Bill with a great deal of care, and while there was a great deal of codification, amendment, and elaboration of old principles, he thought the only really important new principle in it was one which for his part he might have wished the Bill had been confined to, namely, that the right given by the Act of 1859 to twelve year tenants should also be given to those who, from circumstances, had not held the same land continuously, but had been chopped and changed about by superior powers. That was the essential feature. and if that reform had been effected, perhaps the codification and other amendments might have come afterwards. With regard to the sub-ryots, he was inclined to agree with those who differed from Mr. Seton-Karr, if he understood him aright, that he would leave them unprotected altogether. With regard to the unlimited right of sale, a great deal was to be said on both sides. Imprudent people having rights to which they were unaccustomed, might be tempted to make an improvident use of them. There was one point on which he must express his difference from Mr. Seton-Karr, and that was with regard to the survey; he thoroughly admitted the difficulties, the magnitude, and the expense of the undertaking, but after a wide experience of different provinces he came to the conclusion that you could not expect to settle the question permanently until there was a survey and record of rights. It was the want of that survey, and record of rights which had caused the Settlement of 1793 to fail, and made the Settlement of 1859 fail. The only other point he need refer to was the statement in the paper as to the assistance given by the Zemindars of Eastern Bengal at the time of the Mutiny.

Mr. Seton-Karr said he only spoke of their passive demeanour.

The Chairman said his impression was that the ryots were not only passive but very active in Eastern Bengal in defeating the Sepoys. It was very much by a popular movement that they were defeated. That showed the immense advantage of settled ryots who had well ascertained rights to protect. A great deal was said about the ryots of Eastern Bengal, who were extremely well off, and had been able to hold their own, and that was the fact. They were mostly Mohammedan, and that was a democratic religion; it got rid of the worship and tyranny of caste; that might have something to do with it. At any rate that prosperous population in Eastern Bengal was almost entirely a Mohammedan population, perhaps the greatest in the world, and the British Government had been able to hold that country for 100 years with a single sepoy regiment, because the people were contented and prosperous. That was a striking example of the advantage of a well-satisfied peasantry. There was no fear of Mohammedan or any other fanaticism so long as justice was done to the people.

The vote of thanks was carried unanimously to the reader of the paper.

FOURTEENTH ORDINARY MEETING.

Wednesday, March 12, 1884; THOMAS SALT, M.P., in the chair.

The following candidates were proposed for election as members of the Society:—

Bratty, William, Sandford-street, Manchester.
Byrne, Charles Pitt, B.A., 52, Bedford-gardens, Campden-hill, W.
Fletcher, Thomas, United Telephone Company, Oxford-court, Cannon-street, E.C.
Francis, E. G., 59, Fulham Palace-road, S.W.
Griffith, R. W. S., Eyeworth-lodge, Lyndhurst, Hants.
Johnson, Samuel H., West Ham-hall, Forest-gate, E.
Johnson, George Stillingfleet, 11, Savile-row, W.
Lethbridge, Roper, C.I.E., 19, Clanricarde-gardens, W.
Nightingale, E. W., 139, Denmark-road, Camberwell, S.E.
Rawes, Francis Bristow, Bowbridge Works, Newark-on-Trent, and 13, Brunswick-ter., Newark-on-Trent.
Smith, Surgeon-Major Samuel, Wyndham-house, Kingsdown Parade, Bristol.

The following candidates were balloted for and duly elected members of the Society:—

Capper, Robert, Westbrook, Swansea.
Crossley, William J., Glenfield, Altrincham.
Curtis, Richard, Limehurst, Altrincham.
Grindley, John, Millfield, Highgate, N., and Upper North-street, Poplar, E.
Kerr, James, Church, near Accrington.
Kirkpatrick, Andrew J., 179, West George-street, Glasgow.
Lloyd, Frederick James, 4, Lombard-court, Gracechurch-street, E.C.

The paper read was—

A SYSTEM OF NATIONAL WATER REGULATION NECESSARY IN REGARD TO SUPPLY, FLOODS, DRAINAGE, AND TRANSIT.

By LIEUT.-GENERAL RUNDALL, R.E., C.S.I.

Six years ago, H.R.H. the Prince of Wales, in his capacity of President of this Society, called the attention of the Council to the all-important necessity of securing a supply of pure water to the population of the United Kingdom, pointing out that while the great cities and populous towns were taking steps to permanently improve their supply, the smaller towns and villages were still dependent on sources wholly inadequate for health and comfort, and his Royal Highness added, that great public good would arise from an open discussion of the question in the Society's rooms. His Royal Highness rendered a great service to the country in thus removing the subject from the limits of merely local considerations, with which it had hitherto been treated, and placing it on the broad platform of a national question of the first importance. The records of the Society show how thoroughly the Prince's proposals were taken up, and the subject discussed from all points of view, and especially the administrative one; it is therefore all the more regrettable that no practical result has as yet followed the several Conferences held by the Society, and that the nation seems as far from deriving any benefit from the adoption of a comprehensive policy as it was previous to his Royal Highness's suggestion.

One cannot but be struck, after a perusal of the interesting and highly instructive papers and discussions recorded in the Society's *Journal*, how much the question of Water Supply is mixed up with the general hydrographic conditions of the country, so much so as to render it difficult, if not practically impossible, to devise a comprehensive scheme independently of them. While, however, there is almost a unanimous consensus of opinion as to the necessity for dealing with the subject on a national basis, there is some divergence as to the most desirable method of administration, and considerably greater difference as to the engineering arrangements, both leading to the inevitable conclusion that there must be some duly recognised authority capable of reconciling such differences, and controlling definitely the lines which a national scheme should follow. The constitution of such authority, however, is a point which will be reverted to afterwards, and it is merely alluded to now, as mainly suggestive of the title which the writer has given to this paper.

After the startling theories which have been of late so prominently propounded, as to the Land being the common property of the nation, the writer somewhat hesitates to pronounce on what may, at first sight, seem to be a parallel assertion, viz., that the Water of a country is really and truly National property. Falling from the heavens, it comes as a gift, not to individuals, but to the country at large; and in proportion as it may be controlled or otherwise, it proves to be either an element of unmixed good or an instrument of positive evil. It can, in no sense or instance, be deemed a "fixture," for in whatever circumstances it is found, it is ever liable to variation, increasing or diminishing by circumstances or phenomena which no human being can control. The rainfall is allowed by the proprietors of the uplands, in which it is in excess, to run off unchecked, regardless of the interests of proprietors lower down, to whom that superabundance carries absolute injury; while in other parts of the kingdom the population are at the same time in actual want of one of the absolute necessaries of existence, and by whom it is procurable only at great trouble and expense. If water is to be regarded as inalienable private property, the question arises, is the owner of such property responsible for only a definite proportion of the volume which falls within the limit of his estate, and to just as much as he finds it convenient to acknowledge an ownership, and is he at liberty to let the rest of it disperse itself wherever it can find a passage regardless of consequences? Again, who will undertake to define the principle on which a given proportion of the whole volume of a river rolling on towards the sea belongs to the respective riparian proprietors, or would those proprietors themselves care to admit any responsibility for mischief resulting from want of due control of their relative proportions, even supposing they could be defined?

In large rivers it is obviously impossible, but if principle is involved, then such principle cannot in equity be overridden by the fortuitous circumstance of the varying size of a river allowing itself to be controlled, and so admitting an exclusive appropriation of its waters. It is doubtful whether there has ever been hitherto such a recognition of its property by the national Legislature, or whether the principle has ever been admitted; the tendency has rather been to recognise the opposite principle, that its waters belong to any and everybody else but the nation itself. The remarks of such an authority as Mr. G. J. Symons, F.R.S., in his paper read at the Society's Congress, are much to the purpose when he observes, "Existing Private Bill legislation is creating rights of very doubtful expediency, granting absolute water rights over large tracts of land to the first company or companies that ask for them;" while one of the conclusions enumerated in the epitome of his views entirely goes to support those of the writer of this paper, viz., "That it would be much better if the entire administration of streams was under a single direction, seeing to all questions of drainage, sewerage, canalisation, motive power, and supply."

That Water is one of the main sources of our wealth seems hardly to have come home to us as a nation. Attention has been concentrated on our mineral, manufacturing, and agricultural resources, but not a single one of these can get on without the help of water. As an insular nation, water is the mainstay of our defences, carrying the symbols of the power on which we mainly rely for protection against foreign aggression; it is the one element of our commercial prosperity whose value no rival can diminish, or of whose possession no enemy can deprive us, so long, as a nation, we are careful to maintain the supremacy of the flag which, "for 1,000 years, has braved the battle and the breeze."

As a manufacturing nation, water is an element which enters essentially into almost every industry, either as a component part, an ingredient, an auxiliary, or a motive power. Whether it be the huge engines which move the millions of spindles of our peaceful industries, or the hundreds of machines which in our public dockyards or in private factories forge the instruments of war, all would be motionless and powerless but for the water from which the steam power is derived.

As an agricultural nation, water is indispensable, for if the heavens be as brass, the earth will be as iron; neither can seed be sown, or harvest reaped, while the cattle may wander in vain for pasture. True, it is seldom that such an extreme experience is encountered in England, and our lands, as a rule, suffer more from excess than lack of moisture; nevertheless, for agricultural operations, the due regulation of water is essential, for there are many tracts where water is only procurable on farms with much difficulty and expense. Surely, the evident deduction from the above considerations must be, that water ought to be looked upon in the light of National property, and if so, its conservancy, or rather its regulation, should be dealt with on a National basis.

Hitherto it has been customary to discuss each branch of water management separately, as though it were entirely distinct and unconnected with either of the others. It has either assumed the shape of a Conference on Water Supply, or a Commission on Drainage, a Bill for Protection from Floods, or a Select Committee on Canals. As long as these several branches of the water question are thus dealt with independently, so long will there be not only a succession of isolated and often unsatisfactory results, but there must necessarily be a prolongation of unremedied evils. The object of this paper is to draw attention to the value of its water to the nation at large, and to point out that the real and only effectual way of dealing with the several problems connected with it, is to take up the subject of its Regulation as a whole, and to deal with it on a comprehensive basis.

Not only is it impossible to separate the question of water supply from that of drainage, as was remarked by a member of the Congress, but both are intimately connected with that of protection from floods; and in the proper management of this last will be found the solution of one of the supposed difficulties to the extension of inland canal navigation, the necessity for which is every day becoming more and more evident, if England is to hold her own in the keen competition with foreign markets. The experience of a lifetime in dealing with the water question in its several phases, enables the writer to pronounce confidently on both its administrative and engineering features, and, it will be hoped, prove his excuse for any seeming dogmatism which may occur in his remarks.

The term Water Regulation embraces the four cardinal divisions specified in the title to this paper, and signifies the management of the water supply of any country on a recognised comprehensive principle, so that any one branch of it may not be pursued at the expense of the others, and that while individual and local considerations receive due attention, the interests of the country at large may not be lost sight of. The necessity for a comprehensive treatment of the water question in the United Kingdom, is made evident by a consideration of the distribution of its rainfall, the peculiarity and the great inequality of which is probably known only to the few who have made it a special study. The admirable chart attached to the Sixth Report of the River Pollution Commission of 1868 shows that, roughly speaking, a line drawn from Berwick down the centre of England to the Isle of Wight, separates the country into two nearly equal main divisions of small and large rainfall. In the Eastern half, it will be observed, the rainfall varies between 20 and 30 inches, the greater part being less than 25 inches; while the Western half fluctuates between 30 and 50 inches, including some tracts on the extreme west where the variation is from 50 to 70 inches, and certain isolated patches, such as the highlands of Wales, the lake district, and Dartmoor, in which the rain exceeds 75 inches. The same inequality is evident also in Scotland and Ireland, each of those portions of the United Kingdom being similarly nearly equally divided.

Turning to the hydrographical chart, however, it will be seen that the line of water partings does not coincide with that of the rainfall, and that for the most part the sources of the principal rivers in England and Scotland are situated within the limit of greater rainfall. Those running to the East Coast have for the most part a much longer course than those discharging on the west, with the exception of the Severn, and the areas served by them are fully twice as great. *There*, therefore, is an illustration on a large scale of Mr. Symons' remark, of a great rainfall with a sparse population on the one side of the kingdom, with those conditions reversed on the other. Curiously, however, the same arrangement does not obtain in Ireland, the main rivers there having the longest course to the west of the island. These conditions govern the flood discharges of the respective rivers. Those following to the Eastern Coast, though gathering from a much larger catchment basin, do not discharge a relatively greater flood volume, but maintain it for a longer period, while those running to the West Coast precipitate their floods with greater rapidity, and therefore in a shorter time.

Again, the Eastern rivers, occupying a larger area of catchment basin, have to serve a larger population with much less rainfall. It is stated by various authorities that not more than one-third of the rainfall on those districts is carried off by the rivers. If so, there is not more than 8 inches a year available, on an average, for all purposes; and if the navigable course of the rivers is to be maintained, it would be impolitic to draw off, during the low season, any portion of their volume for the domestic supply of towns and villages, let alone that required for manufacturing and other purposes. According to the statistics given in Mr. F. Toplis's essay, to which the Society awarded a silver medal in 1879, the population contained in the eastern district, measuring 34,000 square miles, amounts to over 16,500,000, leaving 8,750,000 for the 24,000 square miles comprised in the western district. The relative proportion of rainfall is thus in inverse ratio to the area and population. In arranging, therefore, for the distribution of the water, it would clearly be but equitable that those parts of the country which have the superabundant rainfall should, if need so require, supply those where it is scanty. But such equitable apportionment of the national property could only be effected by some systematic regulation of the water supply, for unless measures are taken to store the surplus in those districts where and when it falls, the greater portion will, as for instance in the lake district, owing to the character of its geological formation, pass off unutilised in the form of floods to the sea. That such regulation should be in the form of storage, is almost self-evident, for, as water is a valuable commodity, and every year becoming more so, it is better policy to construct a class of works which will eventually contribute towards the cost of regulation, by conserving the water for after distribution to the various purposes for which it can be utilised, than a series of works which serve only for protective purposes, and have no direct recuperative value.

It has been asserted on the highest authority that the average rainfall of the United Kingdom has been diminishing during the past half century. If such be the case, it would add a very cogent reason for storing a portion of the superabundant rainfall; but though this statement has been called in question, and reliance is not always to be placed on averages, yet, in dealing with water supply, it is an axiom that, in estimating the quantity of water available, the minimum and not the average rainfall should form the basis of calculation. An inspection of the registers for the east of England shows that four years out of every seventeen are years of scanty rain, in which not more than fifteen to eighteen inches fall.

Again, it was stated by Mr. (now Sir Robert) Rawlinson, in the discussion on the paper read by Mr. Bailey Denton before this Society, in the year 1867, that after a most careful series of observations carried on for many years, out of an average of 25 inches of rain falling in the Thames basin, four-fifths of the entire quantity could not be accounted for by measurement in any way, leading to the conclusion that 20 out of the 25 inches passed again into the atmosphere. Now, if such conclusion be correct, it is evident how seriously, in a year of minimum rainfall, the navigability of the Thames must be affected, and how jealously any abstraction of its volume should be guarded against.

Although the quantity required for the supply of towns and villages in the United Kingdom is but a small percentage of the average rainfall, yet a very large proportion of it is needed to maintain a uniform and effective depth in its navigable rivers. The state of the Thames itself affords an apt example. The navigable channel above Chiswick is notoriously becoming so deteriorated year by year, that the proposal has been seriously put forward of erecting a weir across it in the neighbourhood of Isleworth; and though the deterioration may possibly be due partly to the deepening of the reaches from Battersea downwards, causing a prolongation of the ebb tide, and so lowering the low water level in the upper tidal reaches, yet, were the surplus floods of the Thames stored in sufficient quantity when they occurred, such a regulated volume could be afterwards discharged during the summer months as would suffice to counterbalance this condition, and by restoring or further raising the low water level, preserve the full uniform depth necessary for maintaining the navigation in the highest possible efficiency. Probably, the interest of the outlay in storage might be partly met by the additional tolls leviable on vessels of greater draught and tonnage. But this is a point which the Thames Conservancy Board may have already considered. The volume of the extreme floods in the Thames near Teddington has been roughly estimated to be 20,000 feet per second; but the volume which the river can safely carry off in the lower part of its course has not been stated, nor the length of time for which such a discharge was maintained. Assuming, however, that it is capable of discharging three-fourths of that volume harmlessly, it would only be necessary to provide storage for restraining the remaining fourth for the specific number of hours during which the flood remains at its extreme height. One day's flow of 5,000 cubic feet per second would amount to 432,000,000 cubic feet, and could be stored in one or more reservoirs, aggregating seven-ninths of a square mile in area, with an average depth of twenty feet. For the number of hours over twenty-four that the Thames may run with a maximum discharge, that area of storage would have to be proportionately increased. Data recording the duration of a flood in the Thames at its maximum discharge are not available, but it is doubtful if it ever reaches three consecutive days, and if so, the expense of constructing storage for that quantity could not be excessive.

The aggregate amount of storage then required to retard a maximum flood depends on the number of hours during which such a flood remains above the volume that it can carry off harmlessly. As soon as it falls materially below that volume, assumed in the case of the Thames to be 15,000 cubic feet per second, then the retarding reservoirs may, if necessary, commence to discharge their contents. Such discharge could easily be regulated by standard gauges at various ruling stations on the main river and its tributaries, especially if those stations were connected by telegraph or better by telephones, and the reservoirs could be emptied and made ready against the approach of the next flood. With reference to the expense of such storage, it may be stated that Mr. Toplis, in his essay already alluded to, calculates that the population of the Thames catchment basin will require a supply of 150 million gallons, equal to 24 millions cubic feet daily. To furnish that quantity for twelve months would require an available storage, exclusive of loss by evaporation and absorption, of 8,760 million cubic feet, or more than six times the amount assumed above as necessary to retard the excess or injurious proportion of a seventy-two hours' maximum flood in the Thames. If these data and figures be respectively correct, they show that there exists a fair prospect of a moderate outlay on storage, as one of the remedial measures against floods, if properly regulated, being amply repaid by the subsequent distribution of the stored water for domestic purposes only. But if the question of maintaining an effective navigation throughout the dry period of the year be considered, it will be found that a still further portion of the floods may be profitably retained for subsequent discharge. The low water volume of the Thames is stated, in Mr. Denton's paper, to be 450,000,000 gallons daily, equal to 833 cubic feet per second, and that this amount is liable to be further diminished by abstraction by some of the metropolis water companies by one-third. Now let it be assumed that the summer flow, by being doubled, would make the river channel so efficient as to admit of a large class of vessels navigating it; 850 cubic feet per second would amount to 3,060,000 cubic feet, or 113,333 cubic yards per hour, or 2,720,000 per day, or say 272,000,000 for 100 days, the extreme period, probably, that there would be any necessity for augmenting the summer volume, being also six times the quantity required to be stored for the retardation of a three days' maximum flood. From hence it will be seen in what ways, and to what extent, the after distribution of flood water is capable of being profitably utilised, leading to a possible solution of the vexed question as to who is to pay for works for the prevention of floods, and rendering unnecessary the distinction made in the Floods Prevention Bill of lowlands, midlands, and uplands, and avoiding the contentions which are pretty certain to arise therefrom.

Without claiming actual accuracy for the figures, the following may be assumed as a rough approximation of the expense of storage, and a possible saleable value of the water. Supposing the population of the Thames catchment basin to require, as above stated, the storage of 8,760,000,000 cubic feet, or 324,000,000 cubic yards, the cost, according to various data for storing on a large scale, appearing to average 2,700 cubic feet, or 100 cubic yards per £1, would be £3,240,000. Taking 5 per cent. thereon to cover interest at 3½ per cent. and 1½ per cent. for sinking fund, and 2 per cent. for working expenses, or 7 per cent. in all, the yearly income must be £227,000. This would enable the stored water to be sold at the rate of 12,000 gallons for a shilling, or one penny per 1,000 gallons, to companies and corporations undertaking the detailed distribution. Or, to illustrate it more popularly, the quantity of water requisite for a household of ten people, consuming 200 gallons per day —73,000 gallons annually—may be provided for 6s. a year. To this has, of course, to be added interest on the capital cost of distribution, its working expenses, and management; but any householder is capable of calculating, from the rates which he now pays, whether the difference between an annual payment of 6s., or the rate of 1d. per 1,000 gallons, and his total water rate does not leave an extraordinarily large margin for covering the expenses of distribution and its management, &c. The charge usually made has been till lately at the rate of 1s. per 1,000 gallons when sold in small quantities by meter, and 6d. per 1,000 gallons for trade purposes—at least such are the prices given in evidence before the Rivers Pollution Committee by Mr. Gott, the borough engineer of Bradford, though in the instance of one very large consumer, who paid between £600 and £700 a year for his water, a charge of only 2¾d. per 1,000 gallons was levied.

The subject of Supply having been so elaborately treated by the Royal Commission of 1868, and subsequent Conferences, it is scarcely possible or necessary to add anything to the information that has already been collated. But a summary of the leading points, and of the general principles which should govern the water supply to cities, towns, and the country as a whole, may be here conveniently and briefly stated.

The two essential principles in the supply of so important a necessary of life are—

First, that the cost should be kept as low as possible, in order that the poorer classes may be supplied at the lowest possible rates, and the quantity should be practically unlimited. It is evident, if economy in construction be secured, then there will be less difficulty in obtaining an unlimited supply.

Secondly, if practicable, the supply should be taken from the sources available within the watershed of the district, whose towns and villages have to be supplied—for in a country like England, where the chief cities and towns are pretty evenly distributed, the presumption is, that the available supply will be wanted, and can be utilised, within its own area. But as is apparent from the unequal distribution of the rainfall, such an arrangement is not always practicable, and there may be cases, certainly, in which it may also not be desirable, as, for example, in the instance suggested by Mr. Symons, of "a large population in one district with very small rainfall, and a large rainfall in another district in which there is only a very small population, and so an arrangement by which one could be brought to the other may prove the most desirable." Otherwise it would seem, at first sight, to be more economical to draw the supply from the sources near at hand rather than from a distance, provided always that the water be of good quality. Whatever may be the difference of opinion as to the propriety of utilising stored water for supplying the population of towns, the preponderance of evidence is in favour of this method. When, however, the supply of towns and cities is treated as an entirely separate subject, and carried out by a small section of the community, with reference only to local requirements and irrespective of all other considerations, irreparable injury is likely to be inflicted by rendering impossible in the future improvements which would confer the greatest amount of benefit to a much larger section, who are not at the time aware of the sacrifice their interests may be sustaining.

It has been customary, hitherto, to look only to present requirements, and to leave the future to provide for itself; but it was justly pointed out at the Congress, by Mr. Symons, that in any national water supply scheme the arrangements should be sufficiently elastic for four times the existing population. The metropolis itself is a notable illustration of the wisdom of this remark, for, owing to its rapid growth, it is now suffering for want of such elasticity in the arrangements of many of its private water companies, and, in the contests now pending with the City authorities, a forcible instance is supplied of the need of systematic regulation of the national water resources, under some competent directing authority.

From the storage of water in connection with supply, to its utility as one means towards the prevention of floods, the transition is natural. For some years past, as the season for floods periodically recurs, the necessity of undertaking preventive measures forces itself on public attention. Not only has the subject been largely discussed, but much information has been collected by the various committees appointed from time to time, and remedial suggestions have been proposed at the meetings of several scientific and engineering societies. While opinions may have differed as to the best method of dealing with the problems which have presented themselves for solution in the cases of rivers of different types, there seems to be an almost universal agreement as to the absolute necessity for altering or improving the existing administrative management. A conspicuous instance where the evils of isolated and divided control have been made apparent, may be cited in the results which have attended the various schemes for the improvement of the drainage of the Fen districts. In a paper read before the Institute of Civil Engineers, in 1882, Mr. Wheeler stated that "upwards of £2,000,000 of money had been expended thereon, but all the engineering works were in an unsatisfactory condition, owing to the divided jurisdiction." No doubt, as long as the design and execution of remedial measures have to be discussed and decided by several local controlling authorities, so long will it be impossible to effect any comprehensive treatment of the evils to be remedied; much less will it be possible to attempt a combination of objects, such as would embrace works for the benefit not of local interest only but of those of the country generally.

Of course no absolute rule can be laid down as to the kind of works best adapted for the prevention of damage from floods. As has been shown above, the rivers of the east and west coasts differ in their condition materially, and so naturally require to be treated differently; but the writer is himself unable to agree in the view which he is aware is largely held by many engineers, that works for the regulation of floods should commence at the mouth of a river, and be proceeded with upwards along its whole length. He is of opinion that, realising the valuable property which a country possesses in its waters, the regulation of floods should be begun rather at their source than at their exit, so that a portion of the full value of that property may be reaped, instead of allowing it to be all wasted fruitlessly in the ocean. He does not mean thereby that the mouths also of rivers do not require improvements, but only that it is the wrong end to begin at; for this reason that the mouths of rivers are not to be improved by a regulation of their flood, but by that of their tidal volumes. Keeping in view the necessity in all river improvements of maintaining a provision for town supply, navigation, and water power, it would seem, *primâ facie*, that rather than endeavour to get rid of surplus water very rapidly, it would be more to the purpose to retain as much as could be profitably stored, and to discharge it after the flood seasons in such quantities, and at such times, as would supply the wants of the community dependent thereon. That, as regards the navigation in the Fen districts, such a course would have been beneficial, seems to be evident from the state in which those navigations now are. From the description given in Mr. Wheeler's paper already referred to, it appears they have been allowed to go to ruin, and shoals and weeds so choke the channels, that the rivers are less capable of discharging the drainage of the country than when left in their natural state, and constant floods consequently occur.

The canalisation of those rivers of course dates far back to a time when local wants received more attention than those of the general community; but as there can be no question as to the great advantage of maintaining water carriage in those districts, for the conveyance of not only such bulky articles of low value as are needed by an agricultural community, but also those which have to be carried to the manufacturing towns in the neighbourhood, it is evident that, in any comprehensive scheme for the prevention or regulation of floods that may in future be designed for the Fen districts, the restoration and maintenance of those old navigations should find a place. Their case furnishes an appropriate illustration of the need and value of some central authority, capable of dealing with the important duty of water regulation. As it does not come within the scope of this paper to go into engineering details, I will not attempt a discussion of any of the many suggested methods of dealing with floods, my object being rather to point to the connection which they have with the other branches of the water question, and of the necessity of considering, in any of the proposed remedies, the bearing which they may have as regards the supply, drainage, and especially the navigation of the rivers. It may, however, be useful to glance at some of the main causes of floods.

A good deal of stress has been laid on the improved plan of drainage now pursued in connection with a higher system of agriculture, contributing to a more rapid discharge of rain falling on the land. Much more importance has been ascribed to this than it merits, for subsoil drainage is oftener necessary in the low than in the higher lands of a river, and the quantity conveyed by such drainage is both small and carried off much more slowly than the surface drainage; so that probably, in most cases, much of the latter has passed off before the subsoil drainage can reach its outfall into the river.

The relative volume, height, and duration of floods depends principally on the configuration of the catchment basin and its extent. If it is somewhat circular in shape, with the sources of its tributaries nearly equidistant from the main river, and heavy storms are pretty evenly distributed over them all, both in point of time and quantity, then the various affluents will probably reach the main stream nearly simultaneously, and so precipitating their respective volumes at the same time, must necessarily choke the course of the main stream, and give it a greater duty than it can possibly perform. The floods, consequently, rising above the banks, must spread themselves over the country, to the injury generally of the growing crops, and sometimes to the stacks of harvested crops. If, on the other hand, the catchment basin be long and narrow, the rainfall will probably not occur simultaneously at the sources of all the feeders, and, therefore, the arrival of their respective volumes at the course of the main stream will be successive, and not simultaneous. Not only does the peculiarity of the configuration of the basin govern the engineering measures to be adopted, but they will depend also on the character of the river itself. For instance, the rivers in the Fen district having a small fall, with beds on a high level, and so partaking of a quasi-deltaic character, require different treatment from rivers like the Irwell and the Severn, which run in troughs with a steep slope. Nevertheless, whatever accessory works, such as marginal embankments, cut-offs, &c., may be needed in either case, still the general principle of retaining a portion of excessive floods for after distribution, rather than allowing all the water to run uselessly to the sea, will hold good in both engineering and financial aspects.

It may not be out of place here to notice a remark made in an article on "Floods," by a writer in the January number of the *Nineteenth Century*, to the effect that—

"Agriculturists are becoming more and more convinced that if English agriculture is to have any chance of commercial success, capital outlay must be conducted with extreme prudence and even parsimony; but that this truth is naturally more slow in reaching the minds of engineers and professional men, whose attention is directed to great works and professional fame rather than to economy and local rates. That if certain proposals made by eminent engineers had found their way into the Statute Book, there would have been opened for ratepayers an endless vista of taxation, and for the profession a prosperity second only to that enjoyed in Egypt in the best days of Ismael."

I think I may, in the name of all my brother engineers present or absent say, in reply, that the skill and fame of an engineer is measured by his ability to overcome the greatest obstacles by the simplest means and at the least expense, and that in most instances, and notably in so vast a subject as the water question, the best, surest, and most economical results are attained where operations are carried out on a large scale than on a small one; and that, therefore, the proposals which the writer states alarmed the House of Lords Committee were put forward for the purpose, not of advancing professional fame, but of securing the greatest good to the greatest number, and at the smallest cost to each individual concerned.

Proceeding now to the next branch of the subject, Drainage, it is scarcely necessary to point out how intimately it is connected with that of floods, at least that portion of it which comes under the title of Surface Drainage. The swamping of land may arise either from absence of slope not allowing the rainfall to run off sufficiently quickly, or from the overflow of surcharged rivers incapable of carrying off the accumulated waters of closely succeeding storms. Under the term drainage, however, is included also the removal of water from over saturated subsoil, and the waste water and sewerage of towns and villages. The two last do not, however, fall quite within the scope of the term drainage as intended in this paper, but yet they are in a measure connected with the general subject, inasmuch as it has become a serious question as to how the drainage of towns and villages is to be disposed of. The practice of allowing it to run into the rivers is becoming too serious a nuisance for the community to tolerate any longer. The opposition which the proposed Thames Valley sewerage scheme has created is an instance in point, for it is not without reason that grave apprehensions are entertained by the dwellers on its banks of the results, in a sanitary aspect; and that the inhabitants of the metropolis and suburbs view with alarm the prospect of a possibly irreparable pollution of the river which is their principal and favourite recreation resort. It would be impossible for such questionable schemes ever to be seriously entertained if they had to be submitted to a central authority charged with the duty of regulating the waters of the kingdom in the interests of the whole community. For the rectification of lands swamped by the overflow of rivers, it is evident that if such portions of excessive floods over and above what the natural channel of the river is capable of carrying off be retarded, a remedy will at once have been found; while for such low-lying lands as need the additional protection of marginal embankments, parallel drains carrying off the rainfall to a lower level will probably be found sufficiently efficacious. If such contributions to the river injuriously affect the flood volume, it will be owing to the sectional capacity of its bed having become deteriorated by neglect. The restoration of the entire river's regimen in such a case will evidently be necessary; but if left to be dealt with by the parties interested only in the particular tract of land to be drained, nothing but the local and immediate end to be gained would be attempted, without the slightest reference to the injury or inconvenience entailed on others. So, likewise, the conveyance of water from supersaturated soils would be locally dealt with, regardless of the effect that might be produced on neighbouring lands; or, possibly, as great an evil would ensue by the neglect of the proprietors to take measures for the removal of the surplus water, which, as in the Report on the Public Health Act of 1875 Amendment Bill, the committee justly observe, "impedes production, lowers the temperature, not only of the surface from which the surplus moisture is taken, but of the adjacent districts, and by the damp and chill lessens the vigor of human as well as vegetable life." Such instances, again, demonstrate how, for want of regulation, the water which falls from the heavens for man's benefit is, by his neglect, allowed to become a source of positive evil. A proper regulation of Floods thus reacts on the management of Drainage, and a due control of Drainage works will prevent unnecessary contamination of rivers which have to furnish the population with a Supply for domestic purposes. Treated singly, the few may be benefited at the expense of the many; but if these questions are dealt with as a whole, it is perfectly certain that those charged with securing the interests of the entire community will not lose sight of the needs of individuals. It, therefore, behoves the nation to take care that all legislation, in which it is proposed to deal with the waters of this country, is shaped not on the narrow limits of parochial or municipal needs, but on the broad, connected, and comprehensive basis of national requirements.

But when this has been accomplished, and the treatment of Supply, Floods, and Drainage, not singly but relatively, has been secured, there still remains a fourth, and by no means the least important, branch of the water question to be dealt with, and that is Transit by inland navigation. Unhappily for the interests of the kingdom, Water carriage, which has been truly called the National mode of transport, has been lost sight of ever since the discovery of railways as a means of locomotion, a neglect which could scarcely have occurred had there been any central authority to watch over the regulation of the water property of the country. Happily, the commercial community are beginning to awake from the fascination which the railways have till lately kept all classes spell-bound, and to see that, while the advantages they have conferred, and are still conferring, are unquestionably very great, yet the limit of economy in transport has not been reached, and that the United Kingdom has still not only to learn, but to adopt, a mode of carriage which will admit of its produce and manufactures being carried at such reduced rates as will enable it to hold its own successfully in competition with foreign countries, which are now rapidly supplanting British products in the markets of the world. It would be more correct to say that the nation has to *resume* rather than to learn the use of water carriage, for it needs only to study the history of inland navigation, and to look upon the works carried out by the eminent fathers of English engineering to perceive the important part that canals were wont to play, not only in the internal commerce of the country, but in the conveyance of its products to the coast for shipment to the rest of the world. A great authority, Mr. David Stevenson, commenced his treatise on inland navigation with the following words:—"That railways have entirely superseded, and will in future prevent the extension of canal or water carriage as a means of ordinary transport must at once be conceded." Judging from results as they exist at present, it must be confessed that Mr. Stevenson's opinion seems to have been justified. But the question arises, why should this supersession of canals have ever taken place? The answer usually given is that the railway is a much more perfect and superior machine; that canals cannot be depended upon, but are liable to interruption at one season from a deficiency of water, and at another from accumulation of ice, while the very limited speed at which boats can be propelled precludes them from meeting the needs of the present day, which insists on rapidity in transport. That a railway is a more complicated contrivance may be granted, but not that it is a more perfect one, for it may be asked what constitutes perfection in a carrying machine? To have one's goods conveyed with the greatest safety, at the least expense, and in a reasonable time, would seem to meet the idea of perfection; but it is averred that in the present day speed is an essential element, and one which is unattainable on canals. It may be conceded that *relatively* with railways a *high* speed is not economically attainable; but it is a fact, not generally known to those who are accustomed to see goods trains flashing past railway stations, that that speed is no criterion as to the actual time occupied by those very trains between terminus and terminus, and that the average rate at which goods are conveyed on lines not furnished with a separate "way" does not much exceed five miles per hour; so that speed in the delivery of goods being an essential requirement of transport in the present day has not been realised on even the majority of railways. There is no reason why all the existing canals should not also be adapted for steam traffic, at a sufficient speed for the class of goods for which water carriage is most suitable. Where, as in the case of the Aire and Calder Canal, intelligence, energy, and skill have been brought to bear on the subject, the cost of transport has been reduced to a figure which it is impossible for railways even to approach. The evidence given before the Select Committee on Canals last session contains a mass of valuable information on the capabilities of water carriage which will doubtless open the eyes of the public. Mr. Bartholomew, the engineer and manager of the Aire and Calder Canal, told the committee that for merchandise traffic, at speeds of from 4½ to 6 miles per hour, the cost of haulage, including depreciation and repairs, is only 1-34th of a penny per ton per mile! What has been accomplished on that canal may be done on any other. Though it does not necessarily follow that all the arrangements in the Aire and Calder would be applicable to the canal system throughout Great Britain, yet it is quite certain that, if similar pains were taken with each main line of navigation, the result in the reduction of cost of transport would be a great gain to the public as well as to the shareholders in such lines.

As regards the other objections, the want of water is one which would be very easily overcome, if the suggestion made above of storing some of the excess flood waters of rivers were carried out, while, as regards interruption to traffic during the winter months, it not unfrequently happens that when canals are blocked with ice, railways are choked with snowdrifts.

On the other hand, the advantages that canals have over railways are—

1. They admit of any class of goods being carried in the manner and at the speed which proves to be most economical and suitable for it, without the slightest interference with any other class.

2. The landing or shipment of cargo is not necessarily confined to certain fixed stations, as is obligatory on railways, but boats can stop at any point on their journey to load and unload, and discharge their cargoes direct over the ship's side.

3. The dead weight to be moved in proportion to the load is much less.

4. The capacity for traffic is practically unlimited, provided the locks are properly designed.

5. There is no obligation for maintaining enormous or expensive plant or establishments, as all that can and would be provided by separate agencies and distinct capital. Thus a large outlay in first cost and subsequent maintenance of rolling stock is avoided.

6. An almost total absence of risk, and the reduction of damage to cargo in transit, and consequently of insurance to a minimum.

Whatever advantage there may be in the capabilities of railways as regards speed, there can be no question that safety and cheapness are best secured by canals. It is no argument to point to the relative amount of traffic at present existing on the two methods of conveyance; for, in their existing conditions, no more common ground of comparison exists than between a perfectly modelled and furnished mail steamer of one of the great ocean companies and an antiquated model of a coal barge on the Thames. For, besides the defects in construction, the present system of canals labours under the following drawbacks—

1. A total absence of unity of management; for example (as stated before the committee by Mr. Lloyd, the manager of the Warwick canals), on one of the routes from London to Liverpool there are nine different canals and navigations. On another there are nine, and on a third ten different companies.

2. A want of uniformity of gauge in the locks, and in the canals themselves.

3. With few exceptions they are not capable of being worked by steam.

4. An unequal system of tolls.

5. Last, but not least, the fact of so many links in the communication being in the hands of the railways paralysing any unity of action, and rendering any scheme of amalgamation between the several lines impossible.

In thus prominently urging on the nation the expediency of re-establishing its ancient water lines on the most improved principles, that is n enlarging their sections and locks to a uniform gauge on the main lines, and adapting them to steam traffic, remodelling the boats, readjusting the tolls, and reforming the administration generally, the writer believes that the interests both of the public and of those to whom the canals may belong, will be equally materially advanced. As he explained in the memorandum which he had the honour to lay before the Select Committee—

"What is needed is not a ruinous competition amongst carrying companies in order to provide accommodation for the trade of the country, but an intelligent distribution of the traffic amongst the different modes of conveyance best suited to it. The re-establishment of water carriage on an effective basis in England need not, and would not, interfere (except beneficially) with the financial results of railways, for it would not only relieve them from the bulk of their least renumerative class of traffic, but set them free to provide larger and more convenient accommodation for passenger traffic, as well as for the extensive class of light and valuable manufactured goods. It would also greatly tend to diminish the number of accidents and liabilities to heavy compensation arising therefrom, would lessen the wear and tear of both "way" and rolling stock, would enable them to contract their overgrown establishments, and so, by reducing the per-centage of working expenses, tend to increase rather than diminish the dividends."

The canal system of Great Britain, as represented on the map, shows that all the main arterial lines are occupied; but, unhappily, even those lines are in the hands of different proprietors, and, more unhappily still, important links of those lines are, as before observed, in the hands of railway companies, as will be evident by an inspection of the map on which the railway owned or controlled canals are marked in red. A statement, handed to the Select Committee by Mr. Calcraft, Assistant Secretary to the Railway Department of the Board of Trade, shows that out of a total of 3,029 miles of canal in the United Kingdom, no less than 1,436 miles are either owned or controlled by railway companies. It is easy to understand, therefore, the difficulty with which water carriage has to contend, and something of the hopelessness with which canal companies view any endeavour to resuscitate the traffic which has been taken away from them. Though unquestionably much of the blame rests on themselves, for yielding so readily to the chains the railways have forged for them, yet the Legislature of that day cannot be acquitted for having omitted to insist on maintaining the independence of the canals, and to prohibit their purchase by railway companies. An attempt has certainly since been made to remedy that omission, by the establishment of the Railway and Canal Commission, but it has been found absolutely necessary in other countries to keep the two classes of communications perfectly distinct. According to M. Krantz, the member of the National Assembly appointed to inquire into railways and other means of communication, experience in France shows "that canals require the aid of a special director, who will both look after their interests and effectively protect them. Nothing but constant trouble results from a united direction of railways and canals." Equally so will it be to attempt to amalgamate their supervision in England or in any other country in the world.

Although it may be considered a digression foreign to the immediate title of this paper, it is impossible not to point to a lamentable instance of the impolicy of a nation neglecting to improve and maintain the waterways bountifully provided for it by nature, notably the Government of Egypt (not the present either *de facto* or *de jure* Government), but the rulers within the present century, who have failed to recognise the value of the grand highway which runs through the length of that kingdom. Had some of the outlay which has been expended on the railways running parallel to the Nile been devoted to removing or overcoming the obstacles on the river itself, and to the establishment of an effective steam flotilla, the Government could have dispatched an efficient force which would have nipped the insurrection of the Madhi in the bud, have avoided the necessity of Hicks army's march across the waterless desert, and have given that gallant commander a base from which his operations could have been conducted, without losing touch of army head-quarters at Cairo. It has been said that had the railway between Berber and Suakim been made when General Gordon recommended it, the late misfortunes would never have befallen the Egyptian Government, but it does not require much intuition to perceive that a horde of fanatical semi-savages, such as have lately swept across the country, would have made short work of a railway whose whole length of 250 miles it would have been impossible to defend, whereas such a river as the Nile would of itself defy any human attempts to interfere with its course, let alone the ease with which the principal points of its course could be defended by a comparatively small force, assisted by a flotilla of gun boats. The Nile would thus have done for Egypt what the

Yangtze Kiang did for China, in enabling General Gordon first to stem the tide of, and then to secure the final triumph over the great rebellion.

But to return to the Canals of the United Kingdom. Owing to the unaccountable general absence of reliable returns of canal traffic, it is not possible to arrive at an idea of the total weight of goods travelling over the entire water system at the present time; but it is quite certain that it is nothing like what would be conveyed, were the canals adapted to modern requirements, and the cost and charges reduced to the low figure at which it has been shown they can be worked. On the Leeds and Liverpool Canal the traffic in 1880 amounted to nearly 2,250,000 tons, and that Canal paid a dividend of 21 per cent. last year. There is no question that, in two particulars, land carriage cannot compete with water, and those are in cheapness and capacity. Perhaps it is owing to the distances in England being so small, compared with those encountered on the Continent and India, that the necessity for economical conveyance has, till recently, not been so much felt; but of late years, since the pressure of competition has been so great, manufacturers and traders have been led to look into the question, and have discovered that, in respect of cost of transport, they are working at a great disadvantage in comparison with foreign countries. Railway companies having practically ceased to be competitive, and having arrived at mutual understandings as regards passenger fares and goods rates, while the supervision of the Legislature has been insufficient to check such combinations, the public have had no remedy, and have been obliged to submit to whatever has been demanded; and hence have arisen those anomalies in rates which gave rise to the late Commission of Inquiry. The same thing practically would happen with canal or any other carrying companies, if they had the opportunity of coalescing either amongst themselves or with the railways, just as has happened on the Bridgewater Canal betweeen Manchester and Liverpool. What canals are capable of effecting in the way of cheapness is evidenced by the results attained on the Aire and Calder, where, as before observed, the cost of haulage has been reduced to 1-34th of a penny per ton per mile, at speeds of four and a half to six miles per hour. It is quite within the mark, then, to assume that a charge of 1-10th of a penny would suffice to cover all the other expenses, and yield a handsome rate of interest besides. At such a charge it is almost impossible to calculate the dimensions the traffic might not reach, for it would set in motion all kinds of articles of low value which now never move, because the cost of carriage is prohibitory. Hence it follows that much of the traffic that would seek the canals would not materially interfere with the present traffic on railways, for it would mainly consist of a class of goods which cannot afford to pay railway freight. The question, therefore, arises, Is it wise or politic for the nation to relinquish the enormous advantages it possesses in its existing system of canals, which originally so contributed to its wealth, and to refrain from undertaking their improvement up to the standard of modern requirements? No one can read the evidence placed before the Select Committee, and fail to see what the trading community and what the country itself is losing, by not following the example of all the continental nations, in putting their water ways into the highest possible state of efficiency, especially when the cost of doing so would amount to so small a sum in comparison with that which has been invested in the railway system.

The capital cost of the 4,000 miles of British canals has been variously estimated, at a mileage rate of £3,500 to £5,000, to stand at from £14,000,000 to £20,000,000 sterling, while the improvements of the main lines is variously calculated at from £5,000 to of £12,000 per mile more. If two of the principal lines were first taken in hand, one running north to Liverpool, and the other to Bristol from London, the metropolis and ports would then be connected with the districts yielding the three great products of coal, salt, and iron, and with the three great manufacturing industries, in cotton, pottery, and hardware. Along these two lines there would also be moved much of not only agricultural produce, but of farming requirements in general. It cannot be doubted that if the charge for carriage were reduced to one-tenth of a penny per mile, or from 2s. to 3s. a ton between London and Liverpool, and Bristol, the traffic would be enormous, and every class of the community, both producer and consumer, would greatly benefit thereby. This is not a question of theory, but deduction from actual facts, which are taking place at this time, and which are furnished by the experience of a properly designed and well administered canal like the Aire and Calder. Mr. J. Spencer Watson, of Blackwall, laid before the Select Committee a paper showing the relative cost of canal transport between London and Liverpool as it is, and as it might be with improved boats and steam tugs. The present cost of carriage in 50 ton boats is 10s. per ton, the future cost he estimates at from 2s. 6d. to 3s. per ton, both exclusive of tolls, and capable of further reduction if the carrier owned his own plant. The tolls between London and Preston Brook, 220 miles, are 5s. 2d., or at the rate of one-third of a penny per ton per mile, while on the remaining 20 miles of railway controlled canal to Liverpool the toll is 7s. 6d., thus obliging the canal carriers to charge 20s. to 22s. per ton, instead of from 8s. to 10s. Is it not, then, for the interests of the public generally that this matter should be taken in hand without delay, and endeavours made to repurchase the canals from the railways, and to remove the obstacles in divided interests and management which at present hinder these lines of communication from being placed under unity of control, whether as a private or a State enterprise. Surely if Water Regulation is a National duty, in no point could it be of greater importance than in the conservancy of its waterways, in protecting its internal lines of communication, and in the adoption of measures for the removal of the alleged obstacles, administrative and physical, before alluded to.

A universal revival of the Water Carrying trade throughout the country will give a great stimulus to many manufacturing industries. It would tend to enhance the value of all land bordering the canal banks; it would in its own direction, just as the railways have done in theirs, afford a vast increase of regular and well ordered employment to that portion of the population which is willing to work but cannot procure any, and would assist the exertions of those philanthropists whose sympathies have been lately stirred by the revelations contained in the "Bitter Cry of Outcast London," and similar pamphlets, by helping a large mass of the labouring classes to earn the means of paying for better accommodation, which, perhaps after all, is the first practical step towards securing the erection of a better class of dwellings. "God helps those who help themselves" is a trite saying not devoid of truth; so, if the aid of the Legislature is to be called in to devise a remedy for the evil of overcrowded habitations, could it be more usefully turned than in the direction of helping the poor to help themselves: and could this be better accomplished than by fostering a revival of an old industry, which used formerly to afford employment to a large mass of the working classes? That industry, if resumed on a scale commensurate with modern requirements, would not only again furnish a fair subsistence to greatly increased numbers, but, by the very nature of its business, necessitate the location of the work-people so employed in the neighbourhood of the suburban stations, where the mass of its particular traffic must needs be concentrated, and would thus probably contribute materially towards the desired object of relieving the present congestion in the heart of the Metropolis. But whether conducive to that end or not there can be no doubt that a restoration of the Canal System on a footing commensurate with modern requirements, will decidedly contribute towards ameliorating the state of the "Canal Population" itself, whose low social condition Mr. Smith, of Coalville, has not been content with only graphically and sympathetically describing, but has practically done his best to improve, by unceasing self-denying labour amongst them.

Having thus attempted to show the interdependence of the several branches of the Water question, and the consequent necessity for dealing with the Water property of the nation on a comprehensive basis as a whole, it remains to consider the administrative part of the subject, and the organisation by which it may be carried out.

The opinion expressed by some of the highest authorities, the recommendations of Parliamentary Committees, the resolutions passed at the Conferences of this Society, and the discussions held at other kindred institutions, are almost unanimous in the conclusion that the only way to secure the greatest good for the greatest number, will be by placing the Water Administration under a single direction, capable of judging of all questions on Supply, Flood, Drainage, and Transit. The recommendations contained in the Report of the Select Committee on the Public Health Act Amendment Bill, 1875, though referring more particularly to the water arrangements of the metropolis, are so thoroughly applicable to those of the whole kingdom, that they form a fitting conclusion to this paper:—

"It is," the committee observe, "essential to an economical as well as efficient sanitary improvement, that combined works should be carried out under one management. The less the extent of executive agency, the greater will be the concentration of responsibility and chances of early and successful execution. That the abandonment of water supply to private companies involves disregard of the public interest on important points, wherever the promise of trading profit does not arise, or when the continuance of such profit may be threatened, for example, first, in the item of cheap supply, and, secondly, in the case of possessors of rights on property who would, for public purposes, have conceded them at reasonable rates, but who consider themselves justified in acting on widely different principles, in dealing with the companies as the latter do with the public; that is, in exacting payment from them, not according to the service or value, but according to their necessities. Hence three or four times the market value of land or other property is obtained, one potent means of extortion being the expense of the procedure for obtaining private acts, and the threat of opposition if the terms are not complied with. By the execution of these works, however, as public works, the expense of which is defrayed by equal rates, and the necessity for immediate outlay obviated by a distribution of charges, all risks are saved to the capitalist and consumer; the middle or higher classes are relieved from undue burthens, and the charges may at once be lowered for all parties."

The Committee's general recommendations for the works of the metropolis are equally applicable for those of the whole kingdom, as advocated in this paper, viz., that:—

"Their execution will be best effected by unity of design and direction in the hands of a very few competent paid officers, giving their whole time and attention to the objects to be attained until they are accomplished. That the most effective and real responsibility will be secured to the great body of ratepayers as well as to every resident, not by attempting to fix responsibility on a multitude of fluctuating parochial (and it may be added), or municipal bodies, but by making it direct through the Government to Parliament."

The Committee conclude with observing—

"That the proper execution of the works will be best guaranteed, the responsibility of the persons charged with their execution best ensured, and the interests of the poorer classes of the population best guarded, by the control of Parliament."

There is one other point, only incidentally alluded to in the above remarks, that calls loudly for reform, and that is the expenses which all schemes for improvement seem obliged to incur before they can obtain Parliamentary sanction. It appears monstrous, for instance, that such an important scheme as the Manchester ship canal should have to incur an expenditure of £100,000 before it can obtain the necessary Act. Many deserving schemes are thus at the outset weighted with a large unremunerative outlay, and many, especially navigation improvements, it is said, cannot be brought forward, through the Companies being unable to encounter the Parliamentary and other expenses necessary to overcome needless opposition and obstruction.

The appointment of a permanent Water Commission, similar to the Railway Commission, whose time now is apparently fully and almost entirely occupied with railway matters, would probably prove the best central controlling authority. Its members should be appointed either permanently or for a definite number of years, and might consist of three, or, perhaps better, of five officers, seeing that the schemes to be brought before it embrace engineering, sanitary, legal, agricultural, and financial considerations. To it may be confided all the subsidiary arrangements as to local supervision, the composition and responsibilities of conservancy bodies, and the limits of their respective authorities, in fact the settlement of all administrative details; the Commission itself to be responsible to the nation through Parliament, to whom it should annually render an account of its stewardship.

There remains yet the financial portion of the subject to be considered. It appears to be the opinion of most of the eminent authorities who have expressed themselves on the point, that the method which would be attended with the most economy, would be for the Government to manage the financial arrangements. In the discussion on national water supply at the Congress held by the Society, Sir Henry Cole observed that "the general financial principles to govern the scheme should be the work of the Government. The capital required might be a hundred million pounds or more, but what was that, looking to the cost of railways, with so important a matter as pure water?" Without contemplating, however, such large expenditure, it would, doubtless, be practicable to raise a Government Water Loan at a low rate of interest, as has been done for the purchase of the telegraphs, or as was proposed to be lent to the Suez Canal Company, for the purpose of advances on reasonable security to such companies or corporations as may desire to carry out improvements to a scheme of supply or navigation approved by the Commissioners. Amongst other financial proposals, it has been suggested that the requisite capital might be raised on the guarantee of a penny income-tax. Though such a proposal would doubtless be met with strenuous opposition, yet it is tolerably certain that the taxpayers would be more than repaid by the great reduction in cost that would ensue in the single item of coal. The Continental system of executing public works by State agency is not one that commends itself to this country, the tendency of public opinion being to deprecate anything like State interference, but there is a difference between the State being the actual proprietor of the works, or the agency by which they are carried out, and its undertaking merely the financial operation of raising the requisite funds for their construction. At the same time, there is unquestionably also a difference between Water projects and schemes like railways involving merely the one element of carriage. In the former, sanitary, agricultural, and domestic, as well as public interests are involved, and, as experience has proved, such interests are better not left to the ministration of private associations. Therefore, doubtless, it is that so many influential advocates are to be found for Water schemes being undertaken by the Government for the nation.

From whatever point of view then the water question is regarded, whether as schemes for the Supply of a necessary of life for every household in the kingdom; or as a source of benefit or injury to property, according as Floods are regulated or unrestrained, or Drainage perfected or neglected; or as Navigation works for securing the cheapest possible conveyance of some of the most necessary articles of domestic consumption, and of the largest items of its internal trade, an end which the country is now anxiously seeking, there can be no hesitation in pronouncing it—in amplification of His Royal Highness's recommendation—an essentially National one; to be dealt with no longer by municipal or other local authorities, but to be treated as a vast imperial question of the greatest importance, demanding a combination of the highest talent and largest experience that are available for its solution.

APPENDIX.

SELECT COMMITTEE ON CANALS, 1883.—PAPER HANDED IN BY MR. J. S. WATSON, JUNE 14, 1883.

Statement of Cost of Canal Transport between London and Liverpool, if effected with three Boats (84 ft. by 12 ft. by 6 ft. 3 in. draft) carrying 120 tons each, and towed by similar-sized Steam Barge carrying 90 tons (450 in all), exclusive of Canal Tolls.

Time for Journey 5 days, with 2 days to load, 2 days to unload, and 1 spare day, say 10 days.

Total Cost of New 120-ton Barges.	Hire of Barges, the Owners doing Repairs.		£ s. d.
£620 each	£100 per annum	= 6s. 8d. per day for each barge for 300 days } 6s. 8d. per day + 10 days + 4 barges	13 6 8
	Wages	9s. per day for each barge — 9s. per day + 10 days + 4 barges	18 0 0
	Haulage, 18 horse-power; none fitted in steam barge.		
First cost of Machinery, New.	Hire of Machinery.		
£600	£120 per annum	= 8s. per day...... 8s. per day + 10 days £4 0 0	
	Wages of engine-drivers	10s. per day......10s. per day + 10 days 5 0 0	
	Coals, oil, &c.	5 days steaming 3 0 0	
			12 0 0
	Expenses incidental	Say 1s. per day + 10 days + 4 barges	2 0 0
	Nett cost* of transport, if the carrier paid hire rates for all his plant		45 6 8
	Profit, say 25 per cent		11 6 8
		Cost of transport of 450 tons would be	£56 13 4

This is equal to 2s. 6½d. per ton, and might fairly be reckoned at 3s. per ton exclusive of the canal tolls.

* The nett cost would be somewhat less if the carrier owned his own plant.

Cost of Canal Transport as now carried on between London and Preston Brook (for Liverpool) in two 25-ton Canal Boats, exclusive of Canal Tolls.

Time for Journey 8 days, with 1 day to load, and 1 day to unload, and 2 spare days, say 12 days.

Total Cost of New 25-ton Boats.	Hire of Boat, Owners doing Repairs.		£	s.	d.
£120	£30 per annum	= 2s. per day for 300 working days } 2s. per day + 12 days + 2 boats	2	8	0
	Wages	8s. per day per boat — 8s. per day + 12 days + 2 boats	9	12	0
	Haulage one horse to each boat.				
	Horse hire	2s. 6d. per day } 6s. per day + 12 days + 2 boats	7	4	0
	Horse keep and expenses	3s. 6d. per day...			
	Expenses, incidental	8d. per day per boat — 8d. per day + 12 days + 2 boats	0	16	0
	Nett cost, if the carrier paid hire rates		20	0	0
	Profit, say, 25 per cent		5	0	0
		Actual cost at present time for 50 ton	£25	0	0 = { 10s. per ton exclusive of tolls.

The present tolls charged on iron work from London to Preston Brook are, for 220 miles ...... 15s. 2d. per ton.
And at Preston Brook trans-shipment into larger craft is necessary, for which the Bridgewater Navigation Company charge for 20 miles ...... 7s. 6d. ,,

The actual rate is about 20s. to 22s. per ton ...... 22s. 8d. ,,

STATEMENT OF ABSTRACT LENGTHS OF CANALS, INDEPENDENT AND OWNED BY RAILWAY COMPANIES IN THE UNITED KINGDOM,

Presented by Mr. Calcraft, Assist.-Sec. Board of Trade, Railway Department, to the Canals Committee.

	England.	Scotland.	Ireland.	Great Britain and Ireland.
	Miles.	Miles.	Miles.	Miles.
Owned or controlled by Railway Companies ...	1,259½	85	92	1,436½
Owned by other than Railway Companies ...	1,428½	—	164	1,592½
Grand total				3,029

These lengths are exclusive of the Rivers Thames, Severn, Wye, Humber, Wear, and Tyne in England; Clyde, Forth, Tay, and the Caledonian Ship Canal in Scotland; and the Shannon and other Navigations in Ireland.

SUMMARY OF CANALS AND NAVIGATIONS IN ENGLAND AND WALES,

According to the statement presented to the Canals Committee by Mr. E. J. Lloyd, General Manager of the Warwick Canal.

	Miles.
Public Trusts	927¼
Independent Canals	1,445¼
Guaranteed and owned by Railways	1,333
Derelict	188½
Ownership not known	36¾
Converted into Railways	119¾
Total	4,050½

DISCUSSION.

Sir ROBERT RAWLINSON, C.B., being called upon to open the discussion, said he was sorry to say he could not endorse a good deal which had been put forward, and, at the same time, he was loth to throw out any disparaging remarks at the beginning of the discussion. With regard to the regulation of floods, however, there was a mistake, in one respect, in the figures adduced, as to the method of dealing with floods in the Thames. The writer stated, on some authority, that the flood was to the dry weather flow as about 24 to 1, viz., 20,000 cubic feet in flood to 833 feet in dry weather; but the fact was the Thames rose from 10 to 12 feet in flood, and the first few inches of that rise would give more than that difference. This would show what an enormous fallacy was involved in the figures given. In the drainage area of Lancashire and Yorkshire, where water supplies had been carried out, the dry weather flow was about half a cubic foot per second per 1,000 acres, whilst the flood flow was from 500 up to 600 times that amount. He had had the question of regulating floods in the Thames under consideration before, and had noticed that it had been treated of in magazine articles by writers who knew nothing whatever about it. Mr. Ruskin some time since recommended compensating reservoirs to regulate the floods in Italian rivers, but if he knew as much about floods as he said he knew about pictures, he would never have hazarded any such remarks. Reservoirs might be made for any purpose, and he did not disparage them for the purpose of canals or water supply, but as to making compensation reservoirs to regulate or diminish river floods, all the capital in the country would not do it. Such reservoirs must be either full or empty; if they were full they would be of no use, as they would hold no more water, and if they were empty, probably two days' very heavy rain would fill them. In a small area he had under his own control, where the dry weather flow was about 250,000 gallons per day for months continuously, the flood flow was in one day upwards of 90,000,000 gallons. What size then must be the compensating reservoirs for such a district? Where would you find the sites or the money necessary to make compensating reservoirs for the Thames? Last week he went down to inspect the water supply recently formed for the town of Leeds; not quite finished. The reservoir were about the finest he had ever seen; they were in the Valley of the Wharfe, three in number, one below the other; they cost from £150,000 to £200,000 each, and were capable of impounding 20,000,000 gallons per day. Out of that they were obliged to send 6,000,000 for compensation, leaving 14,000,000 for Leeds, and at one point they had pumping power by which they could raise 6,000,000 more if required. Those works, with the necessary distributing apparatus, had cost some £1,500,000, the population being about 320,000, or about £5 per head. The metropolitan water supply took each day about 150,000,000 gallons of water from the Thames, the Lea, and the chalk springs, equal to about one-third the dry weather flow of the Thames; but the quantity actually taken from that river was about 80,000,000 gallons. The various works were valued by Mr. Smith for the late Government at £33,000,000, but the present Government repudiated the bargain, and denounced it as a job. As an engineer, having some knowledge of the value of waterworks, he said it was not a job; he believed it was as honest a valuation as ever was made, by as able a man as ever undertook such a task, and that London would never again have so good a bargain offered it. He made this remark because the subject must come up again. He quite agreed with General Rundall, that the utilisation of water should, in many respects, be both national and municipal. Water should not be dealt with like sugar, butter, or beer; it should not be dealt out so as to produce the largest dividend, but should be so stored that it could be utilised by the community at the cheapest cost, and that all surplus might be used for public purposes at prime cost. Dwellers in London knew what a condition the streets and footways were in after two or three small falls of rain; but if the water-supply were in the hands of the municipality, every public footway might be washed with water, not costing more than ½d. per 1,000 gallons, instead of 6d. or 8d., as was charged by the companies now; and they would then be made as clean as they were after a heavy thunder storm, every week, and every day, if necessary. All the great municipal bodies were acquiring the water supply in the same way as London would have to do, if any municipal body were established which could have the control of it. They would have to pay a fair and honest price for it; not a confiscating price. That price would necessarily be large, but it would not be dear, if in future they had no more dividends to pay, but only the interest on the capital, which a community like London could borrow at 3¼ per cent. The companies were now paying 8, 10, and 12 per cent., hence the great value they put on their works; and as the works extended, that interest went on in the same ratio on a larger capital. If the municipality had the works, they would only have to pay the cost of management, and by consolidation, from £50,000 to £100,000 a year might be saved in management. It was just the same with regard to gas; Manchester, Birmingham, and Leeds had acquired the gas. Leeds gave a large price for the existing works, but they now supplied gas at 1s. 10d. per 1,000 ft., and made a surplus. In Birmingham there was not a man in the Corporation who dared to face the large expenditure involved in purchasing the water and gas works until Mr. Chamberlain became mayor, the idea being that it would saddle the town with an enormous debt, forgetting that when you bought a paying property you were not incurring a debt, but acquiring an estate. In 1852, he valued the Birmingham Waterworks, and they could then have been bought for some £350,000, but they were afraid of it. When Mr. Chamberlain became mayor he showed them that they had been losing about £7,000 a-year by not having bought them, and they then gave some £1,250,000. They had been considerably enlarged, the result being that the water was cheaper and better in quality, and was distributed over a wider area, and produced an income which more than paid the interest on the capital, and maintained the works in efficiency. With regard to the purport of the paper, he had no hesitation in saying that, if the question of utilising and storing water, and putting it to the most beneficial uses, were taken up as it was in France, enormous benefit might accrue; but he did not think the railways were going to be injured, or much of their traffic taken away. Still, there was a great deal of traffic which it was not all necessary should go at railway speed, and which might be carried by canals, and it was worth considering how far that could be done. He must repeat, however, that the idea of preventing floods by storage reservoirs was one that no engineer acquainted with the subject would dream of.

Mr. Martin Wood expressed his satisfaction that this large and pressing question of inland water transit had been brought forward. One of the foibles of Englishmen was to run too much in one groove at a time, and that had been the case with railways. The canals were too much cramped and subordinated to the railways, and if that state of things could be altered, it would have a very beneficial effect on our national industries. When we considered what was being done on the continent, we should see the importance of more attention being given to the question of water transit.

Mr. Liggins said there was no doubt that all large cities required a larger water supply, and more wholesome water for domestic purposes, as well as for cleansing the streets. But he did not like the idea of great impounding tanks being formed at the source of the River Thames; for instance, one of the most important adjuncts to navigation was a proper scour in the rivers to keep the channels clear, and he knew there were many men of the highest authority who were uneasy with regard to the shallow waters in some parts of the mouth of the Thames, which were more and more impeding navigation. To curtail the flood outlet would, to his mind, be a great mistake. The rural population higher up the river, as a rule, got their water from ponds and wells practically for nothing, and if these expensive works were carried out, it would necessitate the imposition of local rates, which would be strenuously resisted. When the Metropolitan Board, and the best engineering science of the day told them that a sufficient supply could be obtained from the chalk, he should hesitate to support an extension of the supply from the Thames. He had never heard a more unpractical scheme in his life than that for going back to canals for inland goods traffic. Thirty years ago he had to bring a large steam boiler from a Midland town to London for shipment to the West Indies, and it was frozen up in the canal between London and Birmingham for seven weeks, causing great delay and inconvenience to the ship which was to take it out. A railway company received goods in any town on one day, and, as a rule, delivered them next day at the dock; and the rates were nearly the same from all towns to any port in the neighbourhood of London. The canal companies did not appear to think so very much of the future before them, for there was a Bill lately in Parliament for converting the Regent's Canal into a railway. The metropolis wanted a good supply of pure water, and he did not think the public would long desire to continue the present system under which private companies had a monopoly. He hoped engineers would turn their attention to the question of obtaining a better supply of water from chalk.

The Chairman, in moving a vote of thanks to General Rundall, said he could not profess to follow him into the details of his paper, but he might say a word or two on a very important subject. The development of the water transit of the country was one of the main points treated of, and this was certainly a matter of great interest to the whole trading community. Although it was perfectly true that the railways were, and must remain, the dominant carrying power, still the question arose whether the best use was being made of the waterways which existed throughout the country. This was a question raised in the paper, and it was deserving of serious consideration. No doubt a great deal of the water communication had fallen practically into disuse, still, there were many instances in which canals were carrying a good deal of traffic, and earning very fair profits by so doing. The Bill for dealing with the Regent's Canal was not quite what it had been described by Mr. Liggins. It was a Bill to enable a company to purchase the Regent's Canal, and lay down a railway by the side of it, because the roadway of the canal afforded the cheapest and most easy means of laying down a railway in that direction; but the Bill contained a very stringent clause for keeping the water-way open, and of a certain specified depth, because that canal happened to be a most important outlet to the internal communication of the country. General Rundall also referred to the question of floods, which affected another most important national interest, that of agriculture. The question was one of enormous difficulty, and he should have been glad if Sir Robert Rawlinson had gone more fully into it. As a Member of Parliament, his attention had often been called to this subject, which was one of very great difficulty, both in an economic and legislative sense, and he was rather disposed to think, though he spoke with some hesitation, that it was one which must be dealt with in a broad and general way. It had more than once been referred to Parliamentary Committees, but it required such a large grasp of a difficult and scientific subject, that he feared such a body was hardly competent to deal with it. What was really wanted was a strong board of men thoroughly conversant with water matters, and having powers to deal either with the whole country, or with very large areas. One other question had been dealt with, perhaps most important of all, because it effected not only the commercial and agricultural interests, but almost every person in the country, and that was the water supply of large towns. He had been extremely pleased to hear what was said by the reader of the paper, and also by other speakers, with regard to the importance of giving to towns a supply of water in such a way that no interest was concerned in making a profit out of it; the great necessity being a plentiful supply of pure water at prime cost. He remembered the negociations which went on with regard to the purchase of the water companies of London, some years ago; he knew Mr. Smith, and was glad of the opportunity of bearing testimony to the great zeal and ability which he had displayed in the matter, and he feared that the labour he incurred in endeavours to carry out that most difficult negotiation, and his disappointment at its failure, contributed very much to his death shortly afterwards. He remembered his mentioning to him one point which it was very material to bear in mind in any negotiation of this kind, that if all the companies around London were united under one management, that fact alone would effect an enormous saving. Mr. Smith told him, when talking the matter over, that the moment he accomplished this union, although the price given might appear larger, there would be a saving in the cost of management of at least £50,000 a-year. He believed that was underestimating the figure, and Sir R. Rawlinson had put it much higher. But it was not merely the saving of money which was involved; the most important point was the power of drawing water from the most valuable and purest source, as well as the convenience of management. He greatly regretted that, owing to some misunderstanding in the mind of the public, and possibly also to a certain amount of party feeling, the negotiation broke down, and he should only be too glad if an opportunity occurred for its renewal, either on the terms then arranged, or, if possible, on more favourable ones, because he felt that it was of the utmost importance that the water supply should not be in the hands of private companies, but of a public body who would supply it at prime cost. But whilst saying that, he must guard himself against any suggestion that property should be taken without proper compensation. In dealing with private property it was of the greatest importance, not to the rich man only, but still more to the poor man, that rights of property should be most rigidly respected. If these companies had Parliamentary rights on which individuals and trustees had invested money, and the public were going to deal with the matter, those rights must be respected. The last point on which he would say a word was the suggestion that the canal or water system should be bought up and managed by the Government. He thought they were a long way from any scheme of that sort, and he had great doubts whether Government management was beneficial, except in certain exceptional cases. He thought Government interfered too much with private matters, and that, on the whole, most matters were much better left in the hands of private enterprise.

The vote of thanks having been carried,

Lieut.-General RUNDALL, in reply, said it was only right that a paper publicly brought forward should be freely criticised, and he was very glad that his paper had elicited so much discussion. Sir Robert Rawlinson, however, had slightly mistaken his figures. What he said was that the flood-water was 20,000 cubic feet, and that 5,000 cubic feet might be brought under regulation. Of course, every engineer had his own ideas about these matters, and, perhaps, as Sir Robert Rawlinson was so great an authority, it would not be proper to call his dictum in question; but he would not, perhaps, have made his concluding remark if he had been aware that he (Lieut-General Rundall) had been an engineer for thirty years, and had had under his control the reservoirs of the whole Empire of India, those reservoirs not being measured by acres but by square miles, so that he did know something about reservoir engineering. He had also had the charge of rivers of the greatest magnitude. With regard to other matters, such as the re-establishment of canal navigation, they could only be decided by a consideration of facts which actually existed, and as he had given those facts in the paper, he would not go over the ground again.

Miscellaneous.

PREPARATION OF TAPIOCA.

By JAMES COLLINS.

The tapioca plant (*Manihot utillissima*, Pohl), a euphorbiaceous plant, is too well known to need a description here. The late Dr. Seemann informed me that he had heard from Chinese that the peculiar lumpy form in which we receive tapioca was owing to the action of a peculiar kind of wood used in the preparation of the starch. In the case of India-rubber, in a certain part of South America, the addition of the juice of *Calonyction speciosum*, brings about the more speedy coalescence of the particles of rubber, and salt water or lime juice is used in the East for the preparation of India-rubber and gutta-percha. In India too, the capsules of *Puneeria coagulans* are used in the making of cheese instead of rennet, and thus the product does not interfere with the religious observances of certain castes. The common wood sorrel of the country, *Oxalis acetosella*, acts also as rennet, and in Jersey the leaves of the ash are used to prepare curdled milk and cheeses.

In the case of tapioca, however, I told Dr. Seemann that I believed the agglomeration and alteration was owing to the starch being partially changed into dextrine. This I have since proved to be the case. Whilst in the East I endeavoured to clear up the matter. In the case of gambier, I only saw part of its preparation in Malacca, where I was on sick leave. It was near a gambier plantation, and I saw two or three Chinese coolies just boiling down in the open air, the freshly gathered plant in a large copper, or "quallie," over an improvised fireplace. Their stirring apparatus consisted of two or three different kinds of wood, and a long-handled iron shovel, somewhat of the same shape as that used by bakers. The latter seemed to be most prized. Either from reticence or because the coolies understood but little Malay, I could not ascertain whether any particular wood was used or prized. In the case of the preparation of sago, although whilst in Singapore I purposely rode and drove several miles out into the country on various occasions, I never saw the whole of the process of preparing granulated sago, yet what I did see left me no grounds to believe that any particular wood was used, and I was assured by European planters and native operators that various woods were used, but none for any particular quality, and iron stirrers were much preferred.

As to tapioca, whilst in Malacca, I saw the whole process, from the fresh root stock to the finished product in the process of packing for market. I ascertained that there were two or three large tapioca plantations some miles up country, and a friend kindly offered to make arrangements for my visiting them. We visited two or three plantations, but as they were all conducted on the same principle, it will suffice to describe the largest and best. It belonged to a wealthy Chinese, and the factory was well and substantially built of stone and brick. The first thing we noticed was a large horizontal engine with a European engineer in charge. We were soon ushered into the presence of the owner, and received with that courtly ceremony for which the well educated Celestial is remarkable. Refreshments were quickly served, consisting of tea, tiger's milk, *i.e.*, cocoa-nut milk with a dash of brandy, various fruits, cigars, &c., and had to learn, if we did not know before, that an Eastern must not be hurried. At last we proceeded to the manufactory. Here above our heads, and in every direction, were driving bands, streams of water flowing in every direction, glowing fires, and a hive of Chinese—a loin cloth, and that of the scantiest dimensions, alone saving them from being quite naked.

Taking our station at the far end, we saw droves of Chinese arriving from the fields with baskets slung on poles filled with the fresh tapioca root stocks. These were at once taken by others to large tubs, fed with a constant stream of water, and the root stocks cleansed from adhering mud, and then passed on to the "paring" table. Here the dark outer coat was peeled off, just as one might peel a turnip, and all discoloured or bad parts removed. Next, the cleaned root stocks were passed on to a machine furnished with knives, and sliced, then passed on to a pulping machine. After being thus treated, the pulp was removed in cane baskets to the strainers. These strainers were large wooden frames, with calico bottoms, and were fed from the pulp baskets, Above these strainers were tanks giving off a powerful stream of water impinging on the pulp, and the strainers had a motion communicated to them by a shaft exactly like that given by hand in sifting. As the starch became washed out, it was received into inclined troughs, and allowed, whilst in suspension, to run into settling "vats." Here, after well stirring, the starch was allowed to settle, and the water drawn off, and fresh being pumped in till the starch became clean and white. In this part of the building, which was on a lower plane than the rest, the smell of hydrocyanic acid was by no means faint. When the starch had undergone this washing, and had been strained, whilst still moist, it was removed to the drying department.

The machinery we have mentioned occupied the central line of the building, and on either side, next the wall, was the drying apparatus. On the one side tapioca flour was prepared, and on the other the granular form of it. The flour was prepared by spreading the wet starch on a long iron table or slab, heated slightly by fires placed underneath, and constantly stirred and turned over with iron shovels to prevent agglutination, and ensure equal drying. The granulation was performed as follows:—There were a long range of quallies, or small iron shallow pans, slightly tilted forward on ledges of brickwork, and heated with a wood fire. Each operator had a qualie and fire to himself. Taking up a quantity of damp starch, he stirred it round and round with his iron shovel, and the heat being greater than in the former case, as it became stirred about, became agglutinated together in small masses, and became coated with dextrine. We could not but admire the dexterity with which it was done; how well the open fires were managed, so that no more heat than was necessary was communicated. The "bullet" tapioca we also saw made; it is done by pressing the starch through perforated plates and "cooking" in "quallies." No wood was used in stirring, and when I asked why, I was told that only those who could not afford iron used wood.

Notes on Books.

THE PATENTS, DESIGNS, AND TRADE MARKS ACT. With Notes, &c, by Roger W. Wallace. London: Maxwell, 1884.

To the text of the Act, Mr. Wallace has added a full commentary, in the form of notes to the various sections; he has also prefixed a general introduction, in which are given a summary of the principal changes effected by the new Act, a brief account of the origin of the Law of Patents, and some notes on the principles on which the law is based. There is also, before the text is reached, a table of the steps to be taken in order to obtain a grant of letters patent. The notes are for the most part explanatory or illustrative, but are in some cases critical, as when the author points out that the permission of opposition after the publication of the specification will encourage fraudulent opposition; or shows that the privileges granted to inventors as against the Crown are less valuable than they appear at first sight. In passing, it may be noted that Mr. Wallace has overlooked the fact that the examination as to sufficiency of description is to be confined to the provisional specification. From his remarks (p. 24, and again pp. 18 and 19), he does not seem to have appreciated this. On the whole, the author's comments are favourable to the Act, and he evidently expects that the results of its working will be beneficial to the inventor, especially if the Board of Trade hereafter exercise their powers of reducing the fees for the later stages. Several new points are taken. The fact that there are no references to the Channel Islands in the Act does not seem to have attracted any previous comment. Nobody appears to have noticed that the portions of clauses in which they were mentioned were, in deference to the susceptibilities of their governing bodies, quietly dropped out at one of the stages. It might be fair subject for inquiry. What is now the state of the Patent Law in those islands? Besides the Act itself, the rules issued under its authority by the Board of Trade and by the law officers are given, and, indeed, they occupy almost exactly the same space as the Act and the notes upon it—half the book, in fact, if the sixty pages of introduction be left out of reckoning. In conclusion, it may be noted that Mr. Wallace gives due credit to the Society of Arts for its efforts to promote a reform of the law.

General Notes.

Australian Saddlery.—In New South Wales the number of saddlery and harness manufacturers is 231, against 123 in 1875, the returns for 1874 being defective. The New South Wales imports of saddlery and harness during 1882 were:—Great Britain, 1,660 packages; Victoria, 1,765 packages; South Australia, 155 packages; Queensland, 57 packages; New Zealand, 5 packages; United States, 154 packages; New Caledonia, 1 package; and Germany, 11 packages. The total value of these imports was £81,631, of which the British manufactured goods amounted to £55,355.

Lace-making in Ireland.—Mr. Alan S. Cole delivered lately two lectures on lace-making and Irish lace, in the Lecture Theatre of the Royal Dublin Society. He said that the Science and Art Department had given him its directions to proceed to Ireland, in compliance with a request which had been made to it last year by members of Parliament representing Irish constituencies. As might be remembered, exhibitions of Irish embroidery, lace, crochet, and similar work were held last year in Cork and London. They demonstrated in a conspicuous manner that Ireland possessed an unusual talent for producing such works. But whilst that talent was strongly developed, the absence of correctly drawn patterns, and indeed of a supply of new patterns, was as strongly proclaimed. Without some effort to counteract that poverty in design, the workmanship, however good, must gradually cease to have any value of itself. An effort had therefore to be made. It was, however, only in its infancy, and required all the snpport and tending which could be given to it. The first symptom of the seriousness with which that effort was being put forward might, he thought, be seen in the applications for help which were sent by different schools and convents to the Science and Art Department. The influence of the Dublin School of Art and Needlework would, no doubt, extend in time to the numerous art needle-workers scattered throughout the country. The lecturer then passed on to the art of lace-making by hand, which, he said, had, for upwards of a quarter of a century, been struggling in Ireland. Having described in detail the characteristics and the process of making needle point, and pillow laces, he proceeded to deal with the subject of machine-made lace. Contrasting hand-made lace with lace manufactured by the aid of machinery, he remarked that thousands of yards of lace could be made in a day by a single machine, whereas but a foot or two of simple patterned narrow lace could be made in a day by a single lace worker. But, then, hand-made lace was attended by the advantage that the worker could introduce a plait or particular loop which the machine could not accomplish.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, eight o'clock:—

March 19.—"The Elephant in Freedom and Captivity." By G. P. Sanderson, Superintendent of Government Elephant-catching Operations in Bengal. Sir Joseph Fayrer, K.C.S.I, M.D., F.R.S., will preside.

March 26.—"Vital Steps in Sanitary Progress." By B. W. Richardson, M.D., F.R.S. Sir Robert Rawlinson, C.B., will preside.

Foreign and Colonial Section.

Tuesday evenings:—

March 18.—"Borneo." By B. Francis Cobb, Vice-President of the Society. Admiral Ryder will preside.

APRIL 1.—"The Rivers Congo and Niger entrances to Mid-Africa." By ROBERT CAPPER.

APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings:—

MARCH 27.—"Cupro-Ammonium Solution and its Use in Waterproofing Paper and Vegetable Tissues." By C. R. ALDER WRIGHT, F.R.S., D.Sc. Prof. W. J. RUSSELL, Ph.D., F.R.S., will preside.

APRIL 24.—"Economic Applications of Sea-weed." By EDWARD C. STANFORD, F.C.S.

INDIAN SECTION.

Friday evenings:—

MARCH 28.—"Trade Routes in Afghanistan." By GRIFFIN W. VYSE. LORD ABERDARE, F.R.S., will preside.

APRIL 25.—"The Existing Law of Landlord and Tenant in India." By W. G. PEDDER.

CANTOR LECTURES.

The Fourth Course will be on "The Alloys used for Coinage." By Prof. W. CHANDLER ROBERTS, F.R.S., Chemist of the Royal Mint.

LECTURES I. and II. March 17, 24.—Gradual Development of the Processes of Coining. The Composition and "Standards of Fineness" of the Alloys used for Coinage in Ancient and Modern Times.

LECTURE III. March 31.—Methods by which Accuracy of Weight and "Fineness" of the Alloys is ensured.

LECTURE IV. April 7.—Questions connected with the liability to Reduction in Weight and various Coins by Wear during Circulation.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 17...SOCIETY OF ARTS, John-street, Aldelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. W. Chandler Roberts, "The Alloys Used for Coinage." (Lecture I.)

National Indian Association, Exeter-hall, Strand, W.C., 4 p.m. Annual meeting.

Institute of Agriculture, Lecture Theatre, South Kensington Museum, S.W., 8 p.m. Mr. H. Woods, "Ensilage—its Influence upon British Agriculture."

Medical, 11, Chandos-street, W., 8½ p.m.

Asiatic, 22, Albemarle-street, W., 4 p.m.

Victoria Institute, 7, Adelphi-terrace, W.C., 8 p.m. Paper on "Evolution."

TUESDAY, MARCH 18...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Foreign and Colonial Section.) Mr. B. Francis Cobb, "Borneo."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. A. Gamgee, "Animal Heat, its Origin, Distribution, and Regulation." (Lecture III.)

Civil Engineers, 25, Great George-street, Westminster, S.W., 8 p.m. Mr. James A. Longridge, "Wire-gun Construction."

Statistical, Royal School of Mines, Jermyn-street, S.W., 7¾ p.m. Mr. G. B. Longstaff, "The recent Decline in the English Death-rate, considered in connection with the Causes of Death."

Pathological, 53, Berners-street, Oxford-street, W., 8½ p.m.

East India Association, the Council Room, Exeter-hall, Strand, W.C., 3 p.m. Mr. A. K. Connell, "Indian Pauperism, Free Trade, and Railways."

Zoological, 11, Hanover-square, W., 8½ p.m.

WEDNESDAY, MARCH 19...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. G. P. Sanderson, "The Elephant in Freedom and Captivity."

Meteorological, 25, Great George-street, S.W., 7 p.m. 1. Mr. Robert H. Scott, "Brief Notes on the History of Thermometers." 2. Annual Exhibition of Thermometers and other new Meteorological Instruments.

Geological, Burlington-house, W., 8 p.m.

Archæological Association, 32, Sackville-street, W., 8 p.m. Mr. Thomas Morgan, "Review of the evidences and theories relative to Cæsar's Landing Place."

College of Physicians, Pall-mall East, S.W., 5 p.m. (Croonian Lectures.) Dr. H. Jackson, "Evolution and Dissolution of the Nervous System." (Lecture I.)

THURSDAY, MARCH 20...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. Greenwood Pim, "Hairs occurring on the Stamens in Plants." 2. Mr. A. W. Waters, "Closure of Cyclostomatous Bryozoa." 3. Mr. C. B. Plowright, "Life History of *Æcidium bellidis.*" 4. Mr. F. Kitton, "Diatomaceæ, from Island of Socotra."

Chemical, Burlington-house, W., 8 p.m. 1. Dr. Gladstone, F.R.S., and Mr. Tribe, "Note on the Preparation of Marsh Gas." 2. Mr. R. Meldola, "The Action of Dibrom-a-napthol upon Amines."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. Tyndall, "The Older Electricity, its Phenomena and Investigators." (Lecture IV.)

Historical, 11, Chandos-street, W., 8 p.m.

Numismatic, 4, St. Martin's-place, W., 7 p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Special Meeting.) Mr. A. C. Kirk, "Compressed-Air and other Refrigerating Machinery."

FRIDAY, MARCH 21...United Service Inst., Whitehall-yard, 3 p.m. Colonel Sir Charles B. Nugent, "Imperial Defence—Part I. Home Defence."

Royal Institution, Abermarle-street, W., 8 p.m. Weekly Meeting. 9 p.m. Mr. Matthew Arnold, "Emerson."

College of Physicians, Pall-mall East, S.W., 5 p.m. (Croonian Lectures.) Dr. H. Jackson, "Evolution and Dissolution of the Nervous System." (Lecture II.)

Philological, University College, W.C., 8 p.m. Mr. Thomas Powell, "The Keltic Derivations in Prof. Skeat's Dictionary of English Etymology."

Medical Officers of Health, 1, Adam-street, Adelphi, W.C., 7½ p.m.

SATURDAY, MARCH 22....Physical, Science Schools, South Kensington, S.W., 3 p.m. 1. Prof. S. P. Thompson, D.Sc., and Mr. Colman C. Starling, "Hall's Phenomena." 2. Mr. H. Tomlinson, "Hall's Phenomena." 3. Prof. S. P. Thompson, "Some Propositions in Electromagnetics."

Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Captain Abney, "Photographic Action considered as the Work of Radiation." (Lecture IV.)

Journal of the Society of Arts.

No. 1,635. Vol. XXXII.

FRIDAY, MARCH 21, 1884.

All communications for the Society should be addressed to Secretary, John-street, Adelphi, London, W.C.

NOTICES.

APPLIED CHEMISTRY & PHYSICS SECTION.

The discussion on Dr. Percy F. Frankland's paper, "The Upper Thames as a Source of Water Supply," read on Thursday, March 13th, was adjourned until to-night, 21st inst., at 8 p.m. The paper, with the whole of the discussion, will be printed in the next number of the *Journal.*

CANTOR LECTURES.

The first lecture of the course "On the Alloys Used for Coinage," was delivered on Monday evening, the 17th, by Prof. W. Chandler Roberts, F.R.S., of the Royal Mint. He pointed out that although the gold coinage of this country is estimated to consist of no less than 700 tons of an alloy of gold and copper, information as to the nature and composition of the alloys used for coinage is far from being widely diffused. The views of many people on this important subject may still be expressed by the words of William Stafford, one of the earliest of English political economists, who writing in 1581, makes a knight "confesse that he could not perceave what hinderance it should be to the realm to have this metal more than that, for our coyne," provided it "be stricken with the Prince's scale." The operations of a modern Mint are chiefly remarkable for the extreme care and accuracy with which they are conducted, and, this being the case, it was considered advisable to devote the present lecture to tracing the steps by which the machinery and appliances now in use have been arrived at. It is, however, very difficult to describe the history of the mechanical side of coining chronologically, because the progress has been by no means continuous, as certain types of machines have survived persistently in some countries, and have been abandoned in others, often to be again introduced with or without modification. Illustrations of this fact were then given. The methods adopted by the Greeks in striking coins, and the casting of coins as conducted in late Roman times were indicated, while more recent plans were illustrated by cutting discs of metal, by means of an appliance formerly used in the Mint in the Tower of London, and by striking them by a press devised in the Paris Mint, early in the present century.

Professor Roberts said it had often been contended that art had suffered serious loss by the replacement of the old hand-struck money by coins struck by machinery. It was, therefore, not a little remarkable that the artists who were connected with mints appear to have been the very people to insist on the introduction of mechanical improvements. For instance—to take only the comparatively well-known names from those mentioned—Benvenuto Cellini described, in 1586, the screw press which, in a form modified to enable it to be worked by steam-power, has only just been abandoned in the Mint in this country. Leonardo da Vinci, as Dr. Richter has recently shown, devised in 1515, for use in the Mint at Rome, a method of cutting out discs of metal for coinage, which was a great advance on the crude methods employed in the 16th century. Briot, Engraver-General of the Paris Mint, invented a machine, used in this country in the reign of Charles I., which depends upon a principle definitely adopted in the new lever-coining presses now at work; and his pupil, Simon, the best engraver England ever had, employed an elaborate mechanical contrivance, which enabled him to produce one of the most beautiful coins known.

In order to meet the objection that the artistic side of minting was hardly within the province of the chemist, Professor Roberts quoted Biringuccio, one of the greatest of the early metallurgists, whose advice to the Mint master, written in 1540, might be briefly stated as follows :—"If the coins are very accurate as regards 'standards of fineness,' but small profits can be made ; while, if too much base metal is introduced, the execrations of the people will follow ; but especial care should be devoted to the preparations of the dies for striking artistic coins, so as to give the people pleasure in things they are obliged to use."

SOCIETY OF ARTS PRIZES.

The Council of the Society of Arts are prepared to award the following prizes in connection with the International Health Exhibition:—

Under the *John Stock Trust*, a Society's Gold Medal or £20, for the best example of sanitary architectural construction, Classes 20, 28, 29, 30, 32 of the Exhibition.

Under the *Shaw Trust*, a Society's Gold Medal or £20, for the most deserving exhibit in Classes 41, 42, 43, and 45 (relating to Industrial Hygiene).

Under the *North London Exhibition Trust*, a Society's Gold Medal or £20, for the best set of specimens illustrating the handicraft teaching in any school—Classes 49 and 50.

Under the *Fothergill Trust*, Two Gold Medals (or two sums of £20), one for the best exhibit in Class 27 (Fire Prevention Apparatus), and one for the best exhibit in Class 26 (Lighting Apparatus).

From the *Trevelyan Prize Fund*, Five Gold Medals (or five sums of £20), for the best exhibit in each of the following Classes:—2, 3, 6, 7, and 11 (all comprised within Group 1, "Food").

A full list of these Classes was given in last week's *Journal*.

Each prize will be a Gold Medal, or the sum of £20, at the option of the recipient.

The Council propose to ask the juries in each class to recommend for their consideration either two or three exhibits which they might consider deserving a prize.

ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal for 1884, early in May next. This medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce." The following is a list of those to whom the medal has already been awarded:—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S.

In 1865, to his Imperial Majesty, Napoleon III.

In 1866, to Professor Michael Faraday, D.C.L., F.R.S.

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S.

In 1868, to Mr. (now Sir) Joseph Whitworth, LL.D., F.R.S.

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, &c.

In 1870, to M. Ferdinand de Lesseps.

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B.

In 1872, to Mr. (now Sir) Henry Bessemer, F.R.S.

In 1873, to M. Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France.

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S.

In 1875, to M. Michel Chevalier.

In 1876, to Sir George B. Airy, K.C.B., F.R.S.

In 1877, to M. Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France.

In 1878, to Sir Wm. G. Armstrong, C.B., D.C.L., F.R.S.

In 1879, to Sir William Thomson, LL.D., D.C.L., F.R.S.

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S.

In 1881, to Professor August Wilhelm Hofmann, M.D., LL.D., F.R.S.

In 1882, to M. Louis Pasteur, Member of the Institute of France, For. Memb. R.S.

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S.

A full list of the services for which the medals were awarded was given in the last number of the *Journal*.

The Council invite members of the Society to forward to the Secretary, on or before the 19th of April, the names of such men of high distinction as they may think worthy of this honour.

Proceedings of the Society.

FOREIGN & COLONIAL SECTION.

Tuesday, March 18, 1884; ADMIRAL RYDER in the chair.

The paper read was—

BORNEO.

BY B. FRANCIS COBB,
Vice-President of the Society.

Away in the far East lies that grand cluster of islands known as the Indian or Eastern Archipelago, and chief among this group is the island of Borneo, the subject of the paper to-night. It is one of the largest islands in fact, except Australia, the largest in the world. Its coast line is upwards of 3,000 miles, its length is 850, and its greatest breadth is 600 miles. On the west are Sumatra and the Straits of Singapore, on the north the China seas, on the east the Straits of Macassar, the island and sea of Celebes, on the south is the Java Sea and the island of Java. The equator cuts through nearly the centre of the island, and the 115 degree of west longitude would do the same from north to south. It lies in the direct tract between Singapore and Hong-Kong, and breaks the long steaming distance of 1,300 miles. Recent surveys of the coast determine nearly 300,000 square miles as the area of the island.

The history of Borneo, like that of Australia, is modern; the earliest record dates from 1706, when the English occupied temporarily a small island on the north coast and again in 1763, they took possession of Balambangan, which was abandoned chiefly from the difficulty of withstanding piratical attacks. In 1812, and, again in 1813, expeditions were sent against "Sambas," but nothing appears to have come of them, and probably the only Englishman who in those days really appreciated the value of the Eastern archipelago was Sir Stamford Raffles. In 1776, the Dutch established a factory in Pontianak, and, in conjunction with the Sultan, made war with Sunadana, and were granted certain portions of the south coast. After being driven out by the English expedition of 1813, they returned in 1818, and have remained ever since in the south part of the island, Poutianak and Banjermassin being their principal stations, and the present residences of the Governors.

To the Dutch now belong the greater part of the island. From Cape Datse, on the second parallel of north latitude on the west coast, round to the fourth parallel on the east coast, the Dutch have a country through which flows no less than twenty-two rivers, besides numerous branches, many of which, such as those of the Barito or Banjermassin river, the Mahakkam or Samarinda river, the Kapolas or Poutianak rivers, are large rivers in themselves, besides having tributaries. Altogether the country is admirably watered.

Carl Bock, who was the commissioner of the Dutch Government, in speaking of the Kohi country, through which passes the Mahakkan river, says:—

"A short distance above Samarinda we came upon an unexpected symptom of future commercial activity, in the shape of a coal mine, which is occasionally resorted to by Dutch steamers, but is worked principally for the purpose of supplying the steam yacht belonging to the Sultan of Kortir."

This mine is not a hundred yards from the river. Another coal mine at Pelarving is worked by the Sultan, who sells the produce to the Dutch Government. Speaking again of a higher portion of this river, but where the flood tide still flowed, the same gentleman writes:—"Along the banks were frequent outcrops of coal strata," and he speculates upon the time when "smoky collieries would send their long track of black smoke across the clear blue sky." He also speaks of the large size of the many tributaries that he passed on his journey from Samarinda on the east-coast to Bangermassin on the south.

The influence of the Dutch is slowly making itself felt; but it is not too much to say that some of the native Dyak tribes of the interior, through which traverse the rivers Mahakkam and Barito, are still, as they have been since the island was known, and as Carl Bock found them recently, not only head-hunters but cannibals, and unless these peculiar habits be arrested by the authority of the white man, these tribes, if left to themselves, must become extinct. A chief of the Tring Dyaks informed this gentleman that his people did not eat human flesh every day, that was reserved for feasts, and on these occasions the brains, hands, and knees were considered the epicure's parts, and reserved for the chiefs.

English ideas of Borneo may really be said to date from 1839, when Sir James Brooke visited the island, and by his own personal energy and perseverance succeeded in founding Sarawak. With the aid of Admiral Keppel, he annihilated the dangerous piratical fleets that infested those seas, and only those who at that time passed through the Malay Straits in sailing vessels can thoroughly appreciate the great and good work that was then performed. The piratical proas were the terror of single merchantmen, and unless a becalmed ship could make an early successful shot or two from her usually insufficient guns, it fared hardly with the crews, for the pirates dashed in and boarded the ship. The fate of many a missing trader has been discovered by the chronometers, sextants, and such things from the ship being sold in Singapore some years after. Now, Rajah Brooke's peaceful settlement of over 30,000 square miles has, by the justice of its administration, succeeded in establishing perfect confidence of the natives towards their rulers, has turned a series of battle-fields into cultivated land, and Sarawak is a happy and prosperous settlement, with a population of over 240,000. A recent writer was so struck with what he saw there that he says:—

"The history of the English Rajahs of Sarawak is well worthy of study by politicians and statesmen; and it opens up the great question whether the future of the human race might not be benefited by the extension of the system here inaugurated, of the free government of small semi-barbarous states under trained and educated English gentlemen, untrammeled by the cramping influence of official subordination, and unburthened by the dead weight of a complex governmental organisation, and an elaborate system of loyal and official precedents."

The steady progress of Sarawak is shown by the increased population as well as by the exports of products and imports of European manufactures.

Passing along the coast from Sarawak in a north-easterly direction, we come upon the lands and territories of the independent Sultan of Brunei, of which Mr. William Crocker, a gentleman who has spent some fourteen years in Sarawak, writes:—

"It is much to be regretted that whilst Sarawak has much advanced, whilst the people under her rule are contented and happy, the subjects of the adjacent State of Brunei are still growing under misrule and oppression. Of this I could adduce overwhelming evidence, showing how the wretched inhabitants are ground down by the exactions of petty chiefs and princes."

Beyond this territory, both to the north and to the east of it, lies the new settlement, colony, or territory of British North Borneo, held under the charter of the British North Borneo Company, a territory comprising some 25,000 square miles, and, when taken possession of, inhabited by a population of about 100,000 souls. This to us must be the most interesting portion of the whole island, for here we find another instance of how great things may grow out of small ones; and the settlement of North Borneo under the government of a British company, working under a Royal Charter, having for its object the development of the natural resources of its soil, and the amelioration of the lot of its people, may be considered as one of the the most remarkable events of the present generation. The first idea of making a settlement under the management and control of white men appears to have occurred to Mr. Alexander Dalrymple, who was in the East India Company's service, and, as long ago as 1766, obtained a grant of North Borneo for the Company. Strange to say, the plan of the country he sent home was very like the present concession to the North Borneo Company. The East India Company paid but little attention to its new acquisition, and gradually it appears to have dropped out of sight.

In 1865, the American Consul at Brunei obtained from the Sultan concessions of territory of a similar nature to those now held by the North Borneo Company. The Consul endeavoured to form the American Trading Company of Borneo, and to this company, represented by Mr. Torrey as president, and some Chinese merchants in Hong-Kong, the lessee transferred his leases. The American company commenced operations on the coast, imported Chinese workmen and coolies from Hong-Kong, and formed a settlement on the Kimanis River on the north-west coast; but, from want of capital, the company did not flourish, and the settlement had to be broken up, the Chinese having to be returned to China. Shortly after, Mr. Torrey, as president of the moribund company, went with Baron Overbeck to Brunei, and assisted in obtaining from the Sultan fresh grants in favor of a new association, represented by Baron Overbeck on behalf of Mr. Alfred Dent, from which emanated the British North Borneo Company. The following year, viz., 1878, another grant was obtained from the Sultan of Sooloo.

Mr. Consul General Treacher, writing to Lord Derby from Labuan, thus reports on the transaction:—

"Concessions have been obtained by Messrs. Overbeck and Dent, from the Sultan, which includes the whole northern portion of Borneo from the River Sulaman on the west to the River Sibuco on the east. The new lessees thus become possessed of all the best harbours in Borneo, and which command, to some extent, the route to China. Not only does this portion of Borneo contain the best harbours, but it also possesses the best soil, and is richest in natural productions, such as birds' nests, camphor, gutta-percha, sago, &c., besides valuable minerals, the existence of coal being known."

There are in all five distinct leases or concessions—three from the Sultan of Brunei, another from his Prime Minister, or Pangeran, Tumongong, and one from the Sultan of Sooloo. These grants have been executed in the fullest and most formal manner. In order to convey to the inhabitants information of the grants, the Sultans deputed a high officer to accompany the representative of the company on a voyage round the coast. At each of the places touched at, these officers assembled the chiefs and people, and read to them a solemn proclamation announcing the grants, and exhorting them to obey the new authorities. Two years now elapsed before the charter was granted by the British Government. In the meantime, the agents and residents of the company had been acquiring the confidence of the natives, as well as a knowledge of the country, and establishing the elements of civilised government. Their success was most remarkable; their presence was everywhere welcomed, and their authority gladly admitted. Supported by no physical force, by personal influence they succeeded in evoking comparative order out of chaos, and in establishing a degree of security for life and property unknown before in North Borneo.

In 1880, Admiral Hall, then Commander-in-Chief on the China station, reported to the Admiralty that, in his recent visit to Usakan and Sandakan, he was very favourably impressed with the influence for good manifestly possessed by the agents of the company over the natives, and suggests that it would add to the prosperity of the people if the political aspect of the question would permit of H.M. Government recognising their status. Again, Vice-Admiral Coote, writing from the *Iron Duke* to the Admiralty, uses almost similar words. He says:—

"I was very favourably impressed with the influence for good manifestly possessed by them over the natives. These people apparently look up to the agents as their lawfully constituted governors, and seem most willing to be led by them into the paths of industry and commercial enterprise. Should the political aspect of the question permit of H.M. Government recognising, at an early date, their status in the country, I am of opinion that it would add materially to the prosperity and security of the people, to the development of the country, and open up new markets for our home and colonial produce."

Commander Johnstone, of H.M.S *Egeria*, reports later as follows:—

"The new settlement of Elopura, at Sandakan, appears to me to be very promising. The Chinese are laying out money, and the place has made advance since our last visit, two months ago. The administration appears to be very well carried on, and the Government to be popular with the natives."

Mr. Walters, the mineral explorer, in a long report, in which he frequently refers to the great satisfaction of the natives at the new Government, and to the disappointment evinced by others that the Government had not been extended to them also, concludes thus:—

"Permit me to conclude by saying that this noble enterprise has the best wishes of thousands in the far East, filling as it does this blank in one of the largest islands in the world, and opening up to civilisation and commerce a country hitherto the seat of piracy, slavery, and blood-shed."

A gentleman connected with the enterprise from the first, Mr. W. B. Pryer, and whose history during the last few years may be said to be an epitome of the history of North Borneo, has reported from time to time, and I will avail myself of that gentleman's reports and correspondence, for the purpose of showing what the results of the colonisation by the company has been. Mr. Pryer, writing to his Excellency the Governor of Labuan, from Elopura, in June, 1880, says:—

"When I arrived here in 1878, I found the only place in this bay to be a small village, hidden away in an obscure corner, in the far end of the bay. The entrance was frequently blockaded by pirates, and the reason for the small trade with surrounding islands was the danger to navigation caused by them. The important river of Kinabatangan was blocked by a jealous and suspicious chief. The coast line was in the hands of the rapacious Sulus, by whom the Bajows of the foreshore were ground down and oppressed in every way. The Indians of the forest, the Boolydoopies, were forced to yield to their exactions to such an extent that but very few years more would have witnessed the extermination of large sections of them; they had all but abandoned their fields and orchards. Of the Dyaks of the interior virtually nothing was known. As for trade, the little coasting steamer called at intervals of two or three months, but neither brought nor took away cargo, except birds' nests from one locality alone. Slavery was rampant, slave-boats containing cargoes of unfortunate starved wretches in such a state that it turned one's stomach to look at them, covered with sores, bruises, and ulcers, and many of whom certainly died, were frequently to be seen here or in the Kinabatangan; robbery was rife; there was no security for either life or property. Slaves were treated in the most atrocious manner, being frequently cut down or flogged, and mashed green chillies rubbed into the wounds. The rich soil of the country was entirely uncultivated, as the proceeds would certainly have been taken by the most powerful man when ripe—and, in fact, it is difficult to say in what way matters could have been in a more deplorable condition.

"Now, Elopura, placed on a commanding and carefully selected site at the entrance of the harbour, monthly gains in population and importance. Over a dozen Chinese traders do an increasing trade with all the rivers on the coast. The Kinabatangan opened for traffic, sends away 10,000 bundles of rattans, besides other produce monthly. I have communicated with the chiefs of the interior, who are anxious to receive the new Government, and send their goods and produce down for sale on a safe and free market. The Bajows of the foreshore, freed from their oppressors, offer to place themselves and their kreeses at my disposal for any emergency. The Boolydoopies, able to cultivate their crops in peace now, have wide, and every season increased, paddy fields. Slaves and slave boats are things of the past. The cost of food is less than half what it was. Crime is simply unknown. The Chinese do not even fence their kitchen gardens. The now hard working Sulus are clearing away the forest for farms, with the knowledge that they can sit down in their houses without fear of being kidnapped in the middle of the night and sold as slaves, or their crops taken by some one else. As for the pirates, the natives finding a strong helping hand behind them, and H.M.S. *Kestrel* in the harbour, put such pressure on them that they moved off bag and baggage to Palawan, and are seen no more."

A year later, in 1881, Mr. Pryer informs Mr. Dent that Panglima Mohardee, of Sibutu Island, wished to place himself, his people, and his island under the company's rule, and Mr. Pryer concludes his report by, "I beg to disclaim beforehand any connection in any way with this demand, or that it was in the remotest way instigated by me:" and the summing up a report on the east coast of North Borneo, which had been three years under Mr. Pryer's administration, is as follows:—

"The little money which has been spent from time to time in freeing slaves and the like, has not been thrown away. The various conflicting interests of Sulu and Dyak, Bajow and Booloodoopy, Chinaman and Malay, trader and artisan, fisherman, and coolie, have all been consulted and cared for, with the result that European planters can start planting to-morrow with as much security as though in an English country, instead of in a country which, three years ago, was impassable by small parties, owing to the fear of head hunters or tribal feuds, and on whose coasts it required a small fleet to move together to keep off the pirates."

In the Parliamentary Blue-book, C. 3,108, relating to the Charter of the North Borneo Company, and other matters connected therewith, will be found on pp. 117 and 119, the reports of acting Consul-General, W. H. Treacher, to Lord Derby, and following these Lord Salisbury's instructions, and the Consul's replies, showing how the Spanish gunboat compelled the Sultan of Sulu to sign a treaty, and demanded the same of the Sandakan Sulus of North Borneo, and how they refused, and it will be seen that, but for the energy of Mr. Alfred Dent, and his representative Baron Overbeck, the opportunity of founding this settlement would have been lost. Mr. Treacher subsequently became governor of the new colony under the company, and in his official report of December, 1882, a good deal of extraordinary information is given in such a matter of fact way, that it requires a knowledge of the fact that, but a few years ago, Elopura, Kudat, and the other stations were not even in existence, to appreciate as a fact what reads like a page from a romance. He gives the stations their respective populations and how composed, which being only to December, 1882, are now all largely increased, and then the sources of revenue to the company, viz.:—

1. Land sales.
2. Quit rents on town and suburban lots, and on agricultural lands.
3. Licenses, or rights to farm the sales of certain things such as spirits, opium, &c.
4. Royalties of 10 per cent. *ad valorem* on birds' nests, gutta-percha, beeswax, rattans, camphor, and other natural products collected and exported from the company's territory.
5. Import duties on spirits, wines, beers, tobaccos, &c.
6. The Government share of the birds' nests caves at Gomanton, near Sandakan.
7. Poll tax on certain villages in Papae transferred by the Rajahs of Brunei.
8. Inland tax of 2 dols. upon strangers entering the colony to export jungle produce.
9. Profit on sale of copper coinage.
10. Local house tax.

North Borneo, when taken possession of, was very sparsely inhabited; and a large revenue was, therefore, not to be expected, until a population had been attracted to turn to account the wealth locked up in the primeval jungle, and to till and cultivate the vast tracts of virgin soil, which the absence of any large native population leaves for the use of European and Chinese planters.

Not only may the above sources of revenue be reasonably expected to increase year by year with the growth of the population, but new ones will, from time to time, be added to the list. The following may be noted as additional sources of revenue in the future:—Spirit farms and pawn farms on the system in force in the Straits Settlements, tobacco farms, stamp duties, postage, circulation of notes, salt tax, rents of public markets at the principal stations, land rents from the native paddy lands, imposed as in Perak and the other protected states of the Malay Peninsula, lease of mineral rights, development of mother-of-pearl fishery in Marudu Bay and the adjacent islands, and of a trade in timber, firewood and charcoal. As the Chinese population increases, it will probably be found imperative to follow the example of the protected Malay States, and take steps to establish a control over gambling, to which the Chinese are passionately addicted.

The opening up of several birds' nests caves known to exist up the Kinabatangan river, is another assured source of revenue in the future, and Mr. Resident Pryer estimates that in three years he will be drawing a nett income of 20,000 dols. a year from birds' nests. The value of the guano of the Gomanton and other caves has not yet been ascertained; but, even should it not prove remunerative to export to Europe, there will be a large local demand when the plantations already commenced are thoroughly opened. The Gomanton Caves alone are estimated to contain at least 25,000 tons of guano, and the average price of samples sent to London for analysis was put at £7 per ton.

As one might naturally expect, the land sales formed the principal source of revenue during the first six months, and Governor Treacher reports as follows on the east coast or Sandakan district:—Sales, 95,000 acres, producing 59,733 dols.; 20,000 acres more had been sold to the Australian Sugar Company, represented by Mr. de Lissa, but these were not to be paid for until 1888. In the same district, from the 1st January to 31st March, 1883; the sales were 32,713 acres, producing 21,610 dols.

One of the steamers of the Eastern and Australian line, running between Hong Kong and the Australian ports, visited Elopura on her way north, having among the passengers on board Mr. de Lissa. This gentleman had had large experience of sugar growing in Mauritius, and in the northern territory of South Australia. He was struck with the suitability of the soil in Sandakan Bay for the cultivation of sugar, with the central position of Elopura, in steam communication with Australia, the Straits Settlements, and China, and with the facilities for obtaining cheap and good Chinese labour direct from the latter country. He therefore applied for 20,000 acres of land in the Bay, which, with the approval of the Court of Directors, were granted to him on more favourable terms than those laid down in the published Land Regulations, his case being treated under Clause 18 of those Regulations, which provide that "special arrangements may be made in the case of companies or persons wishing to take large tracts of land." This land is now being surveyed and cleared, and one square mile has been set aside for a settlement of Swatow sugar cultivators, with whom arrangements are being made for immigrating to this country under Government supervision.

The Melbourne *Australasian* of the 29th December last states that a company was formed in Melbourne for the purpose of taking up large tracts of land in North Borneo, recently granted under charter from the British Government to the North Borneo Company. They instructed Mr. William Reece, who has had considerable experience as a sugar planter in Fiji and elsewhere, to select their land, and he has just returned to Melbourne, after having fulfilled their commission. He left in March, and proceeded to Sandakan Bay, North Borneo, *viâ* Hong-Kong. He found that Sandakan was a pretty large town, with a population of about 5,000 Chinese, 100 European, and 3,000 Malays. He stayed a few days there, and then started southwards, in which direction he intended selecting the territory. Most of the journeying was by water, and as the rivers were numerous and large, he found no difficulty in speedily obtaining a comprehensive idea of the country. He travelled in a house boat, with a small party, and in his trip up the rivers and into the interior, by land when necessary, he found the natives very friendly. They are particularly cordial in their relations with Englishmen, and Mr. Reece was surprised to find how quickly they tell to what nation a foreigner belonged. The Dutch and Spaniards are not favourably regarded, because of the bad reputation they have gained in connection with their occupation of other parts of the island; but the natives feel that they have some assurance that they will be differently treated by England. The land taken up for the Australian Company is not more than 160 miles from Sandakan at the farthest, and comprises in all 100,000 acres. Mr. Reece speaks highly of the growing capabilities of the soil, both there and at other places which he visited. "I have never seen," he says, "products grow so fast anywhere. I saw coffee plants in full bearing in fourteen months, although in other places two years generally elapse before the berries can be used. Sugar-cane can be got ready for the mill within ten months. The climate is a grand one, the temperature being pretty even all the year round. The average annual rainfall is about 120 inches. The timber is some of the finest I have seen. I measured some of the trees, which were from eight feet to twelve feet diameter, and 120 feet in height before a branch appeared." The land seemed to be suitable for sugar, coffee, tobacco, and cocoa plantations, and to that use the company intend putting it. They will hold it under an agreement with the British North Borneo Company, which provides, among other things, that unless they occupy it within eighteen months of the completion of the contract the right will be forfeited. The rivers upon which Mr. Reece travelled were the Dawata, Tabarnak, Tagayan, Sagama, Kinabatangan, and Discovery, each of which has some relation to the enterprise he had in hand. The harbours generally he found to be very good. The company, in accordance with their agreement, will take early steps to occupy and cultivate their land.

It is interesting to read Governor Treacher's report on the imports and exports of the first six months of his reign, but these are limited to the Sandakan district; the reports from the west coast not being returned in time to be included. In forwarding these returns to the governor, Mr. Pryer, the "resident," remarks:—

"The most noticeable feature about it (export trade) is the increase in the export of birds' nests from 23,078 dols. in 1881, to 32,433 dols. in 1882, and this, notwithstanding that many of the Melapi collectors died of cholera, whereby the collection was delayed, and a lot of the nests spoilt. The fact is, that as the country is opened up, fresh caves are worked, and a permanent export of a valuable product from fresh districts is secured to the country. There is a noticeable increase in the export of all sea produce, the quantity of trepang being nearly three times as large as in the previous or any other year, while sharks' fin, mother-o'pearl shell, and sea-weed are brought to market here in increasing quantities from the islands of the adjacent seas. In gutta there is a falling off; the districts in which it is collected are undoubtedly growing more and more remote. Imports show a heavy increase, no less than 120,083 dols. value having entered the district this year in excess of last."

At present we have no inland officers, with the exception of Mr. Hewett in the Kinabatangan, so that the returns give but a slight idea of what the trade of the territory would be, were the inland districts, with their stores of gutta, rubber, rattans, camphor, beeswax, birds' nests, &c., thoroughly opened to the traders. In the course of a few years, we may confidently expect to see the tropical products of the plantations now being commenced figuring in our Returns of Exports, and perhaps also coal and other minerals.

Return of East Coast Imports for the Half-year ended 31st December, 1882.

	dols.
Arms	129·00
Cloth	24,863·82
Crockery	1,585·55
Hardware	8,588·58
Machinery	2,298·80
Oil	2,846·05
Opium	4,070·00
Provisions	8,433·16
Rice and flour	18,794·25
Salt	275·26
Spirits	1,627·07
Sugar	2,098·43
Sundries	21,893·63
Treasure	35,000·00
Tobacco	2,531.15
Total	135,034·75

Return of East Coast Exports for the Half-year ended 31st December, 1882.

	dols.
Birds' nests	10,292·00
Beeswax	42·00
Camphor	664·50
Copra (dried cocoa-nuts)	(not returned)
Gutta and rubber	25,768·62
Mother-o'-pearl shell	1,178·90
Rattans	13,092·48
Seed pearls	70·97
Seaweed (edible Agar-agar)	657·60
Sharks' fins	454·45
Sundries	576·52
Trepang (Bêche de Mér)	4,621·26
Total	57,419·30

It will be seen that the principal imports are cloth and rice. The natives, having the natural productions of their forests and seas ready to hand and easily collected, do not grow sufficient rice for their own use, but prefer to purchase it from the Chinese traders by barter. The exports at present are all natural productions of forest or sea. The principal are gutta-percha and rubber, birds' nests, and rattans. Agar-agar (edible seaweed) appears for the first time in the list of exports.

I must now give you section 11 of Governor Treacher's report, because it deals with the

"Armed forces." "The forces on the east coast consist of one European inspector, 16 native non-commissioned officers and corporals, and 78 privates. On the west coast four native officers and 32 privates." The Governor gives the particulars of the forces, and concludes thus:—"As this force is the standing army of the country, I do not consider it efficient either in number of the men, or quality of officers. An officer of higher rank should be command of the force." Section 12 of the same report is as follows:—"XII. Forts and Armaments"—"There are no forts in the territory. Six brass 12 lbs. howitzers are mounted at Kudat, three at Elopura, and three at Gaya, for saluting purposes."

In the discussion which occurred in the House of Commons at the time of the granting the charter, one of the speakers likened the enterprise to that of the French in Tunis. A more unfortunate comparison could scarcely have been made. The French in North Africa are there by the sole right of battle, fire, and the sword. The company, on the other hand, are established in North Borneo with the free assent, goodwill, and assistance of the inhabitants without a blow having been struck or threatened, and so far from there being any danger of collision with the natives, the difficulty will be to prevent the tribes outside the limitations of the company's territory rebelling against their own Rajahs, and throwing themselves upon the company. When Mr. Dent visited the settlement last year, a deputation of chiefs, from the Membakut and Bangawan rivers, waited upon him and Governor Treacher, and begged that their rivers might be taken over by the company. They had to be informed that their country belonged to the Sultan of Brunei, and that the company could not interfere beyond its boundaries. It was difficult to make these chiefs understand why the company's officers could not come to them also, and take control of the rivers, and relieve them from the tyrannical control of the native Rajahs. A greater contrast to the French rule in Algeria could not possibly be shown.

It must not be supposed, however, that because peaceful, the enterprise was free from anxiety, troubles, and cares; only the patient and indomitable courage, combined with great consideration for the natives, and firmness with the tribal chiefs, as shown by the officers of the Company, could have brought about such results. Mr. Dent, speaking at a farewell dinner given to him, at Sandakan, alluding to the many difficulties overcome, says:—

"While we were working at home, there were friends besides who undertook the still more difficult task of maintaining the position in North Borneo, pending the decision of Her Majesty's Government; and where should we now be if we had not left behind us men with such energy, pluck, perseverance, and patience as we know to be personified in the Resident of Sandakan, Mr. Pryer, who was landed at the Old Settlement, twelve miles down the Bay, in 1877, and has never left the country since. That real work has been done by the company's officers is manifest on all sides, and that a great strain in connection therewith has been put upon the residents, heads of departments, and indeed every officer of the district, I am well aware."

And Mr. Pryer, while modestly disclaiming too much praise, says:—

"I cannot in justice refrain from referring to the steady, faithful, and loyal way in which I have been seconded from the first by the natives, more particularly the Bajaus and Sulus; to their ready sympathy in times of trial, which has not been unfrequent in the old days, and to their quick appreciation and co-operation in all my projects at a time when I was almost alone in the land.

"With regard to the essential supply of labour, we look to China, whose thousands are already beginning to pour into our country, but our crops will be of no use if we cannot find a market for them. No doubt we can raise unlimited quantities of tobacco, of pepper, cocoa, sugar, rice, sago, coffee Liberica and Arabica, and other products, but of what good are they if we cannot find markets of easy and cheap access? These queries were answered in the hour the *Tannadice*, last August, steamed into our harbour, being but five hours off her course on the highway between Hongkong and Australia. As we can raise unlimited quantities of produce, so can China and Australia consume them, and we are here a port of call, between such large ports of consumption as Brisbane, Sydney, Melbourne, Adelaide, Singapore, and Hongkong."

Peace has her victories as well as war, and the bloodless victory of North Borneo, the victory of high civilisation and patient moral courage over what, but a few years ago, was one of the most debased of savage barbarisms, is one that will, when history records these events, shed a halo round the names of the brave gentleman who inaugurated and carried out the rescue and salvation of the tribes that were rapidly exterminating one another, and who planted peace, order, and a civilised rule, where death, treachery, murder, and slavery only were known.

Years hence, when the settlement shall have grown in population and importance, the names of Alfred Dent, Pryer, Treacher, Witti, Hutton, and others, shall live in the affectionate remembrance, and become household words among the natives and settlers of North Borneo.

DISCUSSION.

Sir Rutherford Alcock, K.C.B., thought that North Borneo would, one day, be a colony of great national importance. English people had great interest in these eastern seas, though they did not all know to what extent this interest really runs. Besides having a trade to the amount of forty millions sterling with China, from which a revenue of seven millions went to India, and was very essential to the finances of the Government of that country, and to the 240 millions of inhabitants, while four millions of revenue were derived in this country from the import of tea. The island of Borneo seemed to be the only place which had escaped the Spaniards and the Dutch, who had asserted possession over the whole Eastern Archipelago, and although there were sources of unknown wealth, with every possible inducement for colonisation, neither Spain nor Holland seemed to have the means of making great colonies of their setclements. The Dutch had made a garden of Java, and worked marvels there; and the Spaniards had done a great deal with Manilla, but the whole of Borneo had been left in a state of wilderness and jungle. When Mr. Dent, in the first instance, devoted his attention to it, it was really no man's land, that is to say, it was jungle, occupied by a very sparse number of natives, who did very little in the way of cultivation, though a good deal in the way of head-hunting. As this country projected right into the fair-way of our trade between India and China, an interval of 1,300 miles between Singapore and HongKong, it struck him some years ago as being a matter of national importance that they should have a port there, and he could see no reason why they should not occupy the place. It had been the destiny of Great Britain to colonise more extensively than any other State in the world, and the time was not far distant when the English tongue would be predominant over the whole face of the globe. As these possessions might hereafter afford homes to the overgrowing population of England, it was a matter of the greatest importance that they should be taken in hand. It was in vain for Englishmen to try to limit their responsibility, as it was their destiny to expand. Another reason for taking possession of this island was to be found in the fact that it was important for England, in the event of war, to have good harbours of refuge, and these harbours already existed at Borneo, and the natives were eager that England should take them. If they were taken by another State which happened to be neutral in any war that occurred, England would not be able to blockade them, and might suffer great loss. There was no annexation in a sense which politically could be objected to; the North Borneo Company merely required a charter which would secure them from molestation outside, they undertaking, in return, to find the capital with which to develop the resources of the country. No doubt, when they had spent a few millions in building up a great colony, England would be very glad to take it over. The colony was as yet in its infancy, but since the formation of the company, two years ago, the revenue of the place had increased to £13,000, and the population had also increased considerably. No doubt it would take some time before the company was a paying concern, but that it would pay was undoubted in his opinion Already a syndicate of Australian capitalists had taken up 96,000 acres of land, and sugar and coffee factories would soon be established. Although he might not live to see it, he had no doubt that Borneo would be a great colony, and one of immense national importance.

Mr. Hyde Clarke said that after the very able paper which had been read by Mr. Cobb, and the remarks of Sir Rutherford Alcock, it would be presumptuous on his part to detain the meeting with many observations. His connection with Borneo dated many years back, and he had always thought, in common with the ideas which had influenced Sir Rutherford, that it was a matter of great importance to England to take possession of as large a portion of Borneo as possible. Any one who had followed the history of those archipelagoes, and watched what the Dutch, Spaniards, and Portuguese had been doing, must feel that the relations of those islands should be put on a proper footing. They had been told what was the condition of South Borneo under the Hollanders; and as to the northen part, the condition had been very much the same, without any profession of government on the part of the Spaniards; so that it was evident, from what had been already done, that action had been introduced by the Company, healthy not only to England, but to all other nations. The policy heretofore had been one of monopoly, one of exclusion of all other nations from any participation in trade, and consequently the participation by any one in raising the condition of the natives; but that would now be entirely altered, and North Borneo would be thrown open, as India was, to the exertions of the whole of the world; and it would inevitably follow that those influences, which had been already applied to the benefit of the native tribes, would be carried to a still higher degree. He was sure that, in a short time, they would see such a development of civilisation, of wealth and of commerce in Borneo, as would make it a very valuable possession to our Empire, and a source of safety and security to the whole of our Indies, and by no means one of danger. Having watched the exertions of those eminent men who promoted the Borneo Company, he was able fully to appreciate the difficulties which they had to encounter, more particularly with the respective Governments of this country, on whose part there had been a natural timidity in acceeding to the application of the company, from fear of complications with foreign powers. Everyone knew the feeling which was excited in Spain when the charter was given to the company; and, therefore, to have reached this stage it must be evident that there had been very great exertion and perseverance in laying the foundation of what would, at no very distant date, be one of the greatest colonies of the Empire.

Mr. Liggins said that Rajah Brooke, and those who worked with him in founding this colony, had had a hard fight, not against the natives of this beautiful island, but against the Government of England; and it was most disheartening to find that whenever any attempt was made to increase the trade of England, the Government did their utmost to stifle it. The Government had thrown a wet blanket on the desire of the Australians to possess a neighbouring island, which might, at some future date, be a source of considerable danger to them, and it was very disheartening that an attempt to do good should be neutralised by our Government. He thought the paper which had been read might bring home to the minds of the leaders of the Government that there was a necessity for an altered state of things at home. It was the duty of Englishmen to assist their countrymen, no matter where they were located; and in Borneo the commerce could be increased by assisting the Borneo Company, in addition to which the passage to China would be rendered more safe and secure in the event of war breaking out.

Admiral Mayne observed that Colonel Gordon had pointed out the necessity for having a harbour and a naval station at Borneo, and there would be no difficulty in this being accomplished, as there were several excellent harbours round the coast, one being quite equal to that of Sydney. At Labuan, an ample supply of coal could be obtained for any number of ships. He believed that hereafter Borneo would be the depôt for trade between China and Australia. The Australians had already taken 100,000 acres of land, and a service of ships had been started from Singapore and Hong Kong, so that before very long, Borneo would be a most flourishing and prosperous colony.

The Chairman said that, having visited Borneo, he could fully confirm all that had been said about the colony by Sir Rutherford Alcock. He thought it would be most desirable to establish a coaling station at this point, as the supply at Labuan could not be depended on, and it was well known that many men of war could only carry coal sufficient for a run of 1000 miles. For war purposes they must have frequent coal depôts. The last link of the chain at present stopped at Hong Kong, so that if there was one at North Borneo it would be invaluable in the event of war as an ample supply could not be relied on at Labuan. He fully concurred in what had been said by previous speakers as to the importance of developing this colony. In conclusion, he begged to propose a hearty vote of thanks to Mr. Cobb for his valuable paper.

The vote of thanks having been unanimously passed,

Mr. B. F. Cobb said he much regretted that the time at his disposal was so limited that he had found it impossible to touch upon all the matters connected with so large a subject as Borneo. With regard to the influence which civilisation had had upon the natives, he might say that, whereas at one time head-hunting formed part of the religion of the Dyaks—none of their festivals or ceremonies being complete without a certain number of human heads, and no one being reckoned a warrior until he had obtained some heads—the adjacent tribes now got out of the difficulty by obtaining either the heads of monkeys or pigs; and there was, no doubt, that in time, as they became more civilised, the custom of having heads of any kind at the different ceremonies would be entirely abolished.

FIFTEENTH ORDINARY MEETING.

Wednesday, March 19, 1884; Sir Joseph Fayrer, K.C.S.I., M.D., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Christie, John, Clevedon-lodge, St. Margaret's, Twickenham.
Howard, Walter, Oaklands, Cricklewood, N.W.
Ince, Francis, St. Fagan's, 17, Fitzjohn's-avenue, Hampstead, N.W.
Kent, Arthur, 11, Wigmore-street, W.
Langton, Henry Currer, Docklands, Ingatestone, Essex.
Trench, George, Standard-house, Faversham, Kent.

The following candidates were balloted for and duly elected members of the Society:—

Allen, Mrs., 18, Ashchurch-park-villas, Shepherd's-bush, W.
Bowick, Thomas, Stafford-lodge, Southend, Bedford.
Davey, Henry, Rupert-lodge, Headingley, Leeds.
Davies, William J., 59, Gunterstone-road, West Kensington, S.W.
Fielden, Edward Brocklehurst, Nutfield Priory, Redhill, Surrey.
Kinglake, Robert Alexander, Rushmere, Wimbledon.
Larnach, Donald, 21, Kensington-palace-gardens, W.
Moseley, Charles, Manchester.
Playster-Steeds, John, Grosvenor-gate, Twickenham.
Rose, Frederick, 28, Page-street, Westminster, S.W.

The paper read was—

THE ASIATIC ELEPHANT IN FREEDOM AND CAPTIVITY.

By G. P. Sanderson,
Superintendent of Government Elephant-catching Operations in Bengal.

Whilst the popular interest felt in the elephant is, perhaps, greater than that attaching to any other wild animal, I think it may be safely said that regarding none, tame or wild, do more fallacious impressions exist.

The peculiar opportunities which have been afforded me during fifteen out of nearly twenty years spent in India, of observing the elephant in its wild and domesticated states—opportunities which it has been at once my duty as a public servant, and my delight as a sportsman, to make the most of—have induced me to believe that what I may be able to tell you to-night, regarding some of the most interesting features of the Asiatic elephant, may be acceptable to you, as being facts, and perhaps be of some small service to the cause of natural history. I will first commence with a few remarks on the elephant's intelligence.

The elephant's size and staid appearance, its gentleness, and the ease with which it performs various services with its trunk, have given rise to the exalted idea of its intellect that prevails among those not intimately acquainted with it. And its being but little known in Europe, whilst what is known of it justly makes it a favourite, leads to tales of its intelligence being not only welcomed with pleasure, but accepted without investigation. Many elephant stories are intended for the amusement of little folk; but in a sober inquiry into the mental capacity of the animal, they must not be accepted as facts.

The opinion is generally held by those who have had the best opportunities of observing the elephant, that the popular estimate of its intelligence is a greatly exaggerated one; that, instead of being an exceptionally wise animal, its sagacity is of a very mediocre description. The truth of this opinion no one who has lived amongst elephants can doubt. It is a significant fact that the natives of India never speak of the elephant as a peculiarly intelligent animal, and it does not figure in their ancient literature for its wisdom, as do the fox, the crow, and the monkey.

One of the strongest features in the domesticated elephant's character is its obedience. It may also be readily taught, as it has a large share of the ordinary cultivable intelligence common, in a greater or less degree, to all animals. But its reasoning faculties are undoubtedly far below those of the dog, and possibly of other animals; and in matters beyond the range of its daily experience it evinces no special discernment. Whilst fairly quick at comprehending anything sought to be taught to it, the elephant is decidedly wanting in originality. To begin with, the elephant displays less intelligence in its natural state than most wild animals. Whole herds are driven into ill-concealed enclosures, which no other forest creatures could be got to enter; and though these enclosures are made immensely strong, and are generally capable of resisting the efforts of any single elephant, they would not for a moment withstand the combined attack of even two or three, much less of a whole herd. But elephants never thus combine to free themselves. I have frequently seen fifty or sixty crowded into a stockade only thirty yards in diameter, the palisades of which would have been of no more account than corn-stalks before the rush of three or four of them, but no such rush has been made. More significant still, I have, on several occasions, seen a single elephant in a herd, by a bold dash, burst through the palisade and effect its escape, but I never yet saw any other elephant follow, and the hunters have at once repaired the breach.

When a herd of wild elephants is secured within a stockade, or *kheddah*, the mahouts ride trained elephants amongst the wild ones without fear, though any one of the wild ones might, by a movement of its trunk, dislodge the men. This they never do. Single elephants are caught by being bound to trees by men under cover of a couple of tame elephants, the wild one being ignorant of what is going on until he finds himself secured. Escaped elephants are retaken without trouble; even experience does not bring them wisdom. Almost yearly, one or two tame elephants of the hunting establishment at Dacca are lost in the jungles by straying, or other accident, whilst engaged in the capture of their fellows. As an example, in December, 1878, an elephant which had been captured three years, and partially trained to hunting, took fright at the fires and guns used in driving a herd, and ran away. Her mahout fell off, and nothing more was seen of her until March last, when we re-captured her after four and a-half years absence, in a herd of twenty-one elephants, 100 miles from where she was lost. She had a calf at heel. When pricked with a spear, and ordered to kneel, she did so promptly, and in three days she, and another reclaimed runaway, were employed in the capture of their fellows. Whilst such facts testify to the docility of the elephant, they tell heavily against its intelligence.

Though possessed of a proboscis which is capable of guarding it against such dangers, the wild elephant readily falls into pits dug in its path; whilst its fellows flee in terror, making no effort to assist the fallen one, as they might easily do by kicking in the earth around the pit. It commonly happens that a young elephant falls into a pit, in which case the mother will remain until the hunters come, without doing anything to assist her offspring, not even feeding it by throwing in a few branches.

In its domesticated state one of the elephant's chief characteristics is, as before stated, its obedience; and it does many things, at the slightest hint from its mahout which much impress the on-looker unacquainted with the craft of elephant-guidance. The driver's knees are placed behind an elephant's ears as he sits on it, and it is by means of a push, pressure, and other motions, that his directions are communicated, as with the pressure of the leg with trained horses in a circus. It would be as reasonable, however, to credit performing dogs which spell out replies to questions with knowing what they are saying, as elephants with appreciating the objects to be gained by much which they do under the direction of their riders.

Then as to the stories regarding the elephant's reasoning powers, what an improbable one is that of the elephant and the tailor, wherein the animal, on being pricked with a needle instead of being fed with sweetmeats as usual, is represented as having deliberately gone to a pond, filled its trunk with dirty water, and returned and squirted it over the tailor and his work. This story accredits the elephant with appreciating the fact that throwing dirty water over his work would be the peculiar manner in which to annoy the tailor! How has he acquired the knowledge of the incongruity of the two things, dirty water and clean linen? He delights in water himself, and would, therefore, be unlikely to imagine it objectionable to another. If the elephant were possessed of the amount of discernment with which he is commonly credited, is it reasonable to suppose that he would continue to labour for man instead of turning into the nearest jungle? We commonly use elephants to carry provisions for the hunting parties through the same forests wherein they were disporting themselves as wild animals less than a year ago. That they thus submit must be regarded as more creditable to their good dispositions than to their good sense.

All who have had to deal with elephants will agree that their good qualities cannot be exaggerated; that their vices are few, and only occur in exceptional animals; that they are neither treacherous nor retentive of an injury; and that they are obedient, gentle, and patient beyond all other domestic animals. But it is no traducement of the elephant to say that it is, in many things, a decidedly stupid animal.

Another matter upon which much misapprehension exists is the height to which elephants grow. We hear and read of Indian elephants 12, 15, even 20 feet high! As a matter of fact, 10 feet in males, and 8 feet 6 inches in females (vertical height at the shoulders, measured as a horse), is very rarely attained, and is not exceeded by one animal in 500. As bearing on this subject, I may quote the following from the "English Cyclopœdia." The Mr. Corse referred to therein was a gentleman thoroughly conservant with the Indian elephant. A valuable paper of his on the subject was read before the Royal Society in 1799.

"During the war with Tippoo Sultan, of the 150 elephants under Captain Sandys, not one was 10 feet high, and only a few males $9\frac{1}{2}$ feet high. Mr. Corse was very particular in ascertaining the height of the elephants used at Madras, and with the army under Marquis Cornwallis, where there were both Bengal and Ceylon elephants, and he was assured that those of Ceylon were neither higher nor superior to those of Bengal."

* * * * * * *

"The Madras elephants have been said to be from 17 to 20 feet high. Now let us see how dimensions shrink before the severity of measurement. Mr. Corse heard from several gentlemen who had been at Dacca that the Nabob there had an elephant 14 feet high. Mr. Corse was desirous to measure him, especially as he had seen the elephant frequently at a former time, and then supposed him to be 12 feet high. He accordingly went to Dacca. At first he sent for the mahout or driver, who, without hesitation, informed him that the elephant was from 12 to 14 cubits—that is from 15 to 18 feet high. Mr. Corse measured the elephant exactly, and was rather surprised to find that the animal did not exceed 10 feet in height."

In my own experience, I have had some amusing instances of the difficulty of getting at absolute fact in this matter. I have for some years made a point of ascertaining the height of all the largest elephants I have heard of in India. Five years ago, I inserted a request for information on this subject in all the chief newspapers of India. Accounts of 11 and 12 feet elephants poured in, but none stood the test of inquiry. To make it worth any one's while to establish such dimensions, I offered to give an order upon any gunmaker for the best double-barrelled rifle, and all accessories, to any gentleman who could produce evidence of an elephant even 11 feet high. This was never done, and I only found one elephant above 10 feet. This magnificent animal belongs to the Maharajah of Nahun-Sirmoor, in the Punjaub, and measures 10 feet $7\frac{1}{2}$ inches in vertical height at the withers. I made a journey of 100 miles in a palanquin to measure him with my own hands. He is the only elephant over 10 feet in height that I have ever seen, amongst many thousands, and he must be regarded as not less phenomenal than a human being of 8 feet.

In connection with this subject, I may mention that twice round an elephant's fore-foot is his height, within an inch or two; more frequently it is exactly so. Out of many hundreds of elephants of all ages which I have measured, I have only once found the variation to be as much as five inches.

There is, at present, in the Indian Museum in Calcutta, the skeleton of a male Indian elephant which Dr. Anderson, the Superintendent, informed me he thought must have stood about $11\frac{1}{2}$ feet when alive. But this estimate is based entirely on the height of the skeleton as at present set up, which may be, and in my humble opinion is, too great. I, unfortunately, have not got my note-book, which contains the height of the skeleton, with me in London. The elephant to which this skeleton belonged was shot whilst wild, and, therefore, could not have been measured, when on the ground, with any approach to accuracy. It was undoubtedly an exceptionally large animal, but was not over 10 feet, in my opinion, based upon the following consideration. There is now in the British Museum, in South Kensington, a skeleton which I lately brought to England of an elephant which died in June, 1883, at Dacca. I measured this elephant most accurately before his death; his height was 9 ft. 10 in. at the shoulder. Now, his femur bone measures over all 3 ft. $11\frac{3}{4}$ in., and is only an inch shorter than that of the skeleton in the Indian Museum in Calcutta. This seems to me to be a reliable ground of comparison between the two, and to be fatal to the claim advanced for the Calcutta Museum elephant of being 20 inches taller than one with a femur bone only 1 inch shorter.

In June, 1878, I measured the since famous African elephant, Jumbo. He was then 10ft. 5in. at the withers, and being about 17 years old, was still growing. I have been unable to ascertain his exact height, measured in the foregoing manner, when he left England for America in 1882. His height was then taken to the top of his back, with his fore and hind feet brought near together. This would tend to arch his back very considerably. He measured 11 ft. 6 in. in this way; but as his forefoot, planted firmly on the ground, measured 5 ft. 6in., his height at withers was probably about 11 ft. According to Sir Samuel Baker, who has seen large numbers of both Asiatic and African elephants in their native wilds, the Africans, male and female, average about one foot higher than the Asiatic. The case of Jumbo appears to confirm this to a great extent, as regards male elephants; but I have never seen African females even as large as Asiatic females. Of course in captivity we do not see one African to 1,000 Asiatics (taking India into account), so the comparison is unfavourable to the Africans.

Much misapprehension prevails regarding the uses and powers of the elephant's trunk. This organ is chiefly used by the animal to procure its food, and to convey it, and water, to its mouth; also to warn it of danger, by the senses of smell and touch. It is a delicate and sensitive organ, and is never used for rough work. In any dangerous situation, the elephant at once guards it by curling it up. The idea that he can use it for any purpose, from picking up a needle to dragging a piece of ordnance from a bog is, like many others connected with the elephant, founded entirely upon imagination. An elephant might manage the former feat, though I doubt it (I have never seen elephants raise coins and such small articles otherwise than by suction); the latter he would not attempt. Elephants engaged in such work as dragging timber invariably take the rope between their teeth; they never attempt to pull a heavy weight with the trunk. An elephant is powerful enough to extricate a cannon from a difficult situation, but he does it by pushing with his head or feet, or in harness, never by lifting or drawing with the trunk. Elephants do not push with the forehead, or region above the eyes, but with the base of the trunk or snout, about one foot below the eyes.

I may here mention that I have seen many instances of very severe injury to their trunks amongst wild elephants. These were evidently caused by the sharp edges of split bamboos whilst the animals were feeding. Some have had from a few inches to a foot of the member totally useless, merely hanging by a little muscle, both nostrils having been cut through.

The age to which the elephant lives is, as must ever be the case with denizens of the forest, uncertain. The general native opinion is that they attain 120 years in exceptional cases (they have been known to reach this age in captivity), but more usually to 80 years. Under the more favourable conditions of a natural life the elephant must attain a much greater age than in captivity. I think it by no means improbable, looking to their peculiar dentition and other circumstances, that elephants live to 150 or 200 years, but this view is, of course, to a great extent a supposition.

One of the most remarkable facts in connection with wild elephants is the extreme rarity of any remains of dead ones being found in the jungles. This circumstance is so marked as to have given rise to the belief amongst some wild tribes that wild elephants never die; whilst others believe that there is a place, unseen by human eye, to which they retire to end their days. The latter belief is untenable, as there are no parts of the forests of India that are not well known to, and occasionally visited by, the wild tribes who nhabit them.

In my own wanderings for many years through elephant jungles I have only seen the remains of one female elephant that had died in giving birth to a calf, and of one elephant drowned in a mountain torrent. Not only have I never seen the remains of an elephant that had died a natural death, but I never met anyone amongst the jungle tribes, or professional elephant hunters, who had.

Sir Emerson Tennant says in his work on Ceylon:—"The natives generally assert that the body of a dead elephant is seldom or never to be discovered in the woods. And certain it is that frequenters of the forest with whom I have conversed, whether Europeans or Singhalese, are consistent in their assurances that they have never found the remains of one elephant that had died a natural death. A European gentleman, who for 36 years without intermission had been living in the jungle, ascending to the summits of mountains in the prosecution of trigonometrical surveys, and penetrating the valleys in tracing roads and opening means of communication—one, too, who had made the habits of wild elephants a subject of constant observation and study—has often expressed to me his astonishment that, after seeing many thousands of living elephants in all possible situations, he had never yet found a single skeleton of a dead one, except those which had fallen by the rifle. The Singhalese have a superstition in relation to the close of life in the elephant; they believe that, on feeling the approach of dissolution. he repairs to a solitary valley, and there resigns himself to death."

This quotation from Sir Emerson Tennant shows the similarity of opinion between the natives of Ceylon and of India. But the belief of a universal sepulchre is untenable on many grounds. It may be believed that, in annually capturing large numbers of elephants, the hunters of the Dacca establishment penetrate the most retired parts of the jungles of Assam, Chittagong, and elsewhere; but though many men have grown grey in the service, I have not met one who has seen a dead elephant's remains, except at a time when an epidemic disease decimated the herds in Chittagong. Jungle fires seldom penetrate the large forests; thus their bones cannot be burned. Monsoon rains do not destroy them for some years, as is proved by the bones of elephants that have been shot, and which may be seen many years later. It may be thought that aged, weak elephants are sometimes unable to extricate themselves from morasses or the soft beds of rivers where they go to take their last drink, and that their remains are swallowed up therein. This possibly may occur occasionally, but there are many elephant jungles where no quicksands or bogs exist. In Mysore, for instance, a province where wild elephants abound, and which I know intimately, the jungle streams are small, and their beds are uniformly rocky. If elephants died in these, their bodies would be floated down through inhabited country where they could not escape observation. But this has never, to my knowledge, occurred. It is probable that the longevity of elephants may account to a great extent for their remains rarely being seen. If elephants live for 200 years, the annual deaths from natural causes would only amount to 5 per 1,000. This figure would, no doubt, be exceeded in reality, as elephants are liable to be killed by each other, and to die by various accidents. Though the number that die annually is thus, probably, much less than might be supposed, the mystery of what becomes of the remains of those that do die is still entirely unexplained.

Herds of elephants usually consist of from 30 to 50 individuals, but much larger numbers, even upwards of 100, are by no means uncommon. A herd is alway led by a female, never by a male. In localities where fodder is scarce, a large herd usually divides into parties of from 10 to 20. These remain at some little distance from each other, but all take part in any common movement, such as a march into another tract of forest. These separate parties are family groups, consisting of old elephants with their children and grand-children. It thus happens that, though the gregarious instincts of elephants prompt them to form large gatherings, if circumstances necessitate it a herd breaks up under several leaders. Cases frequently occur when they are being hunted; each party will then take measures for its individual safety. It cannot be said that a large herd has any supreme leader. Tuskers never interest themselves in the movement of their herds; they wander much alone, either to visit cultivation where the females, encumbered with young ones, hesitate to follow, or from a love of solitude. Single elephants found wandering in the forests are usually young males, animals debarred from much intimate association with the herds by stronger rivals; but they usually keep within a few miles of their companions. These wandering tuskers are only biding their time until they are able to meet all comers in a herd. The necessity for the females regulating the movements of a herd is evident, as they must accomodate the length and time of their marches, and the localities in which they rest and feed at different hours, to the requirements of their young ones.

Elephant calves usually stand exactly 36 in. at the shoulder when born, and weigh about 200 lbs. They live entirely upon milk for five or six months, when they begin to eat tender grass. Their chief support, however, is still milk for some months. I have known three cases of elephants having two calves at a birth. It cannot be said that the female elephant evinces any special attachment to her offspring, whilst the belief that all the females of a herd show affection for each other's calves is certainly erroneous; were such the case it would preclude the belief in any marked love for her own young. During the catching of elephants many cases occur in which young ones, after losing their mothers by death or separation, are refused assistance by the other females, and are buffeted about as outcasts. When a calf is born, the mother and the herd usually remain in that place for two days. The calf is then capable of marching. Even at this tender age calves are no encumbrance to the herd's movement; the youngest climb hills, and cross rivers, assisted by their dams. In swimming, very young calves are supported by their mother's trunks, and are held in front of them. When they are a few months old, they scramble on to their mother's shoulders, and hold on with their fore-legs, or they swim alone. Though a few calves are born at other seasons, the largest number make their appearance in September, October, and November.

The elephant is full grown, but is not fully mature, at about 25 years of age. At this period it may be compared to a human being of 18; and it does not attain its full strength and vigour before 35 years. Female elephants give birth to their first calf at from 13 to 16 years of age, when they are still palpably immature themselves. Only the male Indian elephant has tusks; the female is provided with short tushes, or downward prongs, in the upper jaw; they are seldom more than 4 in. in length. On the continent of India, *mucknas*, or male elephants without tusks, are decidedly rare. The absence of tusks appears to be a merely accidental circumstance. But in Ceylon male elephants with tusks are still more uncommon. Sir Samuel Baker says that not more than one in 300 is provided with them. It is difficult to imagine what can cause the vital difference of tusks and no tusks between the elephants of the continent and of Ceylon, as they are of the same species, and the climate, and their food, may be said to be identical. Elephants occasionally lose one, sometimes both tusks, in accidents in the jungle, and some have only one tusk from birth. The latter are known as *gunéshas*, and are reverenced by Hindoos if the tusk retained be the right hand one. Elephants never shed their tusks. Jerdon and others, following Mr. Corse, are undoubtedly in error in saying this occurs between the first and second years of the young elephant's existence or at any other time. The skulls of fœtal elephants exhibit milk tusks, but these never make their appearance; they are absorbed, and the tusk that cuts the gum is the permanent one. Nor are tusks lost by accident ever renewed.

The records of many hundreds of elephants, captured by the Dacca establishment, show that there are about 43 male elephants to 100 females; and one *muckna*, or tuskless male, in every 10 males.

Elephants are exceedingly inoffensive and retiring in their habits. They are very timid in their wild state, and withdraw at once from the intrusion of man. They usually drink after sunrise, and before sunset. They prefer the water of the small tributary streams to that of the larger rivers of the jungles they may be inhabiting; for what reason I have never been able to ascertain. Elephants seldom bathe after the sun is down, except in very warm weather. They swim remarkably well, as is proved by the fact that large numbers are annually sent across the tideway of the combined Ganges and Bramhapootra, between Dacca and Barrackpore, and they are sometimes six consecutive hours without touching bottom. I have seen an elephant swim a river 300 yards wide with his hind legs tied together. Elephants are sometimes drowned, apparently by being attacked with cramp, or by a fit.

The only pace of the elephant is the walk, capable of being increased to a fast shuffle of about fifteen miles an hour for a very short distance. The elephant can neither trot, canter, or gallop, nor can it make the smallest spring either in vertical height or in horizontal distance. A trench 8 ft. wide and 8 ft. deep is quite impassable to an elephant.

It has been satisfactorily settled that there is no such creature as a really white elephant, the so-called albinoes of the Kings of Burmah and Siam being merely elephants of a somewhat dirty cream colour, and in some cases even elephants with only an unusual amount of the flesh-coloured blotchings on the face, ears, and neck, common in some degree to all elephants. I need not advert here to Mr. Barnum's so-called white elephant further than to say that he is the commonest of common elephants, to be seen every day in India, and does not possess a single peculiarity of any description to justify the statements regarding his colour and special character, which preceded, and even followed, his arrival in England.

I will now pass to the modes of capturing and training the elephant. Elephants are not bred in captivity in India, as by the time the young ones would be of a useful age, 15 years, they would have cost more than would suffice to capture a number of mature wild ones. Elephants are, however, bred extensively in a semi-wild state in Burmah and in Siam, where fodder is very plentiful. With the exception of such elephants as come from Burmah, almost every elephant seen in India has been wild at one time.

The following are the methods of taking wild elephants. For single elephants, pit-falls; running down and noosing from trained elephants' backs; or tying the animal's legs together under cover of trained females, usually called decoys. When a whole herd is the object of pursuit, a salt-lick, or sometimes a pool in the jungles, is surrounded by a stockade. Men are constantly on the watch, and the gate is closed when a herd has entered. But the most certain plan is that followed by Government, namely, the surrounding a herd, wherever found in the forest, by a large circle of men, and the building a stockade, into which it is driven. This method will be described further on. With regard to the other plans mentioned, the pit-fall is an old native method, and is now prohibited in British territory on account of its cruelty. It may be imagined that an immense majority of the elephants that fell into pits from 15 to 18 feet deep sustained permanent injury, if they were not killed outright, as often happened. The native hunters seldom took the the trouble to put boughs into the pits to break the force of an elephant's fall. If an elephant was seen to be injured, it was left to die as it fell. I have known four elephants to fall into the same pit together, one only of which was got out alive.

The pits were arranged with great ingenuity by the hunters. Sometimes an uncovered one would be left in view, in avoiding which an elephant fell into a covered one alongside. Or several were dug in close proximity, in which others might be taken when fleeing in terror upon the fall of one of their number. Through the carelessness of the hunters, who only visited the pits occasionally, elephants were frequently starved to death before they were discovered.

The plan of enclosing elephants in salt-licks, or places to which elephants, in common with all wild animals, resort at certain seasons to eat the earth impregnated with soda, used formerly to be much in vogue in Assam. It also led to much cruelty. Natives could seldom procure a sufficient number of tame elephants to deal with a large herd, should one be enclosed; and in former days scores of elephants died in enclosures from want of food during the delay that occurred in sending for tame elephants. Several of these salt-licks are perfect Golgothas to this day. Such reckless waste of elephant life has now, however, been put a stop to.

Running elephants down, and noosing them from the backs of tame elephants, is very rough and dangerous, but highly exciting, sport. It is far from an economical method of taking them, as the wear and tear of the tame elephants is very great. It is conducted as follows:—Three or four fast tame elephants are equipped with a rope each, at one end of which there is a noose, the other being secured round their bodies. On some, the noose is on the near side, on others, the off. Each elephant has three riders—the mahout on its neck to guide it; the nooser, kneeling on a small pad on its back, holding the noose in his hands; and a spare man seated behind, whose duty it is to hammer it unmercifully with a spiked mallet. This urges an elephant to a much greater pace than any use of the driver's goad will, though that inducement is by no means omitted.

Thus equipped, the elephants approach a herd of wild ones. Sometimes a musket is fired to terrify them, and the chase commences through or over everything, the men saving themselves from being swept off as best they can. Where the ground is favourable, the tame elephants endeavour to range up on opposite sides of a fleeing wild one, of moderate size and strength, when the nooses are cast, and generally encircle its neck. If this is effected, the tame elephants are checked; but the choking of the wild one, or fatal accidents to the tame ones or their riders, by being pulled over, or dragged into ravines, or by being attacked by other elephants, are not unusual accompaniments to this rough work.

Hand-noosing is practised only in Ceylon, where several hunters on foot manage, with wonderful skill and activity, to noose the hind legs of an elephant when running away, and to secure the trailing ends of the ropes to trees as it passes.

The largest male elephants cannot be captured by the above plans; and from their habit of frequently absenting themselves from their companions, they are seldom caught with the herd by the stockade or kheddah plan. They are the most valuable beasts, and are usually caught in the following manner, or some modification of it. Four or five steady females, ridden by their mahouts, who partly conceal themselves with a dark-coloured blanket as they lie on their elephants' necks, are taken to the jungle where the solitary male is known to be, and are there allowed to graze like wild ones, and gradually to approach the male, if he does not take the initiative. Some wild males make off at once, probably scenting the riders, but many abandon themselves without reserve to the society of the females. These keep in constant attendance on the male, sometimes for two days and nights. When the male seems inclined to sleep soundly, usually soon after sunrise, the females stand close around him, and a couple of mahouts on foot tie his hind legs together, and bind him to a tree, if one be near; or they withdraw the tame elephants, and after the male has tired himself out, by dragging his legs after him in his flight, he is fastened to some tree as he passes it. In a day or two cables are got round his neck, and he is marched off.

I may here say that the term decoy, often used in reference to elephants engaged in the capture of others, is entirely misleading, as they use no arts to divert the wild one's attention, as has been constantly asserted, but act entirely at the command of their riders. The statement that one elephant will assist in binding another, except in as far as it will hand up the end of a rope, or pull one when ordered to do so, is entirely incorrect.

The Government kheddah plan is the most certain and economical method of taking wild elephants. As many as 118 have been secured in one drive by this means. A Government hunting party consists of 370 men, trained to the work. They are generally from Chittagong, the natives of that district being unrivalled in the craft. There is a large surplus labouring population in Chittagong, and there is no difficulty in raising one or two kheddah parties during December, January, and February, when there are no agricultural operations on hand. The men receive two and a-half months' pay at Rs. 7 (or about 15s.) per mensem, and they also have free rations.

A kheddah party of 370 men having been collected, it marches to the hunting grounds, sometimes 200 miles distant, where a base camp is ready, and where the establishment of tame elephants, generally from 100 to 150, has been collected, together with the stores, tools, and ropes required for the operations. Muskets and rations having been delivered to the men, and religious ceremonies for success having been performed, the hunters enter the jungle. The trackers of the party have probably already marked down a herd, whereupon the hunters approach to within a mile, and then divide under two experienced leaders, one half filing off to the right, and the other to the left, their object being to enclose the herd in a large circle by meeting beyond it. A man is left at every 30 yards or so along the lines, according to the nature of the ground. The skill with which this movement is effected is very remarkable, as the ground is usually quite unknown to the hunters, and the difficulty of crossing streams and hills, of forcing their way through dense jungle where no path exists, and of gaining the point they are making for without a compass, is considerable.

The circle, when completed, is often five or six miles in circumference. A large one, with men posted fifty yards apart or so, is more efficient in keeping in a herd than a smaller one with men much closer. Unless plenty of room be allowed to the elephants, they are liable to break through the cordon of guards; but it is a maxim in elephant catching that, the circle having once been formed, a herd can only escape through accident or great carelessness. It usually takes three or four hours to surround elephants. In a couple of hours the hunters run up a thin fence of split bamboos round the enclosure, and clear a path for communication between each others posts. Their chief duty then is to see that the elephants do not break out of the circle. The animals seldom give trouble during the day; at night large fires are kept up, and shouts and shots are used to drive them back should they approach. The bamboo fencing serves to show the chief hunters, who patrol the circle at intervals, where the elephants have broken out should they escape, so that the particular men who are to blame can be detected. This investment of the elephants may have to be maintained for a week, sometimes for a month, if the elephants cannot be secured in the first attempts.

The elephants usually give some little trouble for the first two nights, but their conservative nature then seems to lead them to believe that there are set bounds to their wanderings; and unless fodder or water becomes scarce, they seldom try to force the guards. A small herd always gives more trouble than a large one. The former may only be a wandering party from some large body of elephants not far away; it then shows a strong desire to break through to join its companions. A small herd, too, probably has no calves with it, which is a great disadvantage, as it is then restless and quick in its movements. And a herd of a dozen elephants or so may be well in command of one courageous leader; whereas, in a large gathering, timid animals preponderate so greatly that a panic is easily established, and elephants that might otherwise behave boldly become infected with the general fear.

One or two of the males of a herd frequently pass in and out of the circle; and I have known several cases in which a portion of a herd has been absent when their companions were surrounded, and has been admitted by the guards by withdrawing at the point where it wished to pass in. Sometimes, but not often, men are killed at their posts by the elephants.

On the day following the investment of the herd, the construction of the kheddah, or small enclosure into which the elephants are to be driven, is commenced. It is situated on one of their chief paths (within the circle) and is constructed with the trunks of young trees, about 6 in. in diameter, and 12 ft. high, arranged in a circle of from 20 to 50 yards across. Inside, round the foot of the palisades, a trench 6 ft. wide and 4 ft. deep is dug, the earth from this being thrown up into a bank on the inner side. The trench and bank of loose earth usually deter elephants from attacking the stockade, or should they do so, prevent their employing their full force against it. The palisades are lashed together with canes, and are strongly supported by cross beams and forked supports behind, the whole structure being designed to support outward pressure only. Were elephants to pull the palisades inwards, they would yield at once, but they never use their trunks for this purpose. An entrance of 4 yards in width is left for the ingress of the herd, and a gate, studded inside with sharp spikes, is either slung from the trees overhead, or is made in two leaves, and is pushed to upon the entrance of the herd, by men stationed behind it.

A stockade of 40 yards in diameter accommodates 100 elephants easily. To guide the elephants into it, two lines of strong palisades are run out from the gate along each side of the path by which the herd is to approach. These guiding wings diverge to perhaps 60 yards across at their commencement, which may be 100 yards or so from the gate. When the whole is completed, the new woodwork is hidden with leaves and branches. The stockade is usually completed in three or four days. The hunters consider Friday the most lucky day for driving, and they make extraordinary efforts to get the stockade ready by that day if possible. The work of the stockade is done by one-half the hunters being taken from the large circle from morning till evening daily, as a weak cordon of guards suffices to keep the elephants in during the day.

All being in readiness for driving, a number of men are taken from the original circle, and a smaller interior surround is formed by commencing at the guiding wings of the kheddah, and posting the men until the elephants are again closed. The original circle is, of course, still maintained, in case of the elephants breaking through the inner one. If the herd be in two or three detachments, as frequently happens, these are quietly driven together, and the whole are then moved forward towards the kheddah. Should they show an inclination to break to the right or left, the men deter them by striking their axes against the trees. When the elephants gain the funnel-shaped approach to the stockade, the men close in from behind, and from the sides, and urge them on with shots and shouts. If the herd suspects danger, and breaks back through the beaters, fatal accidents not uncommonly occur. Sometimes a herd declines altogether to go in the direction of the stockade, owing to their having the wind from that quarter. In such a case a new stockade may have to be constructed, and if that does not succeed, others also. In this way elephants are sometimes kept in a surround for a month.

Supposing the herd to have been got within the wings near the gate, a line of dry grass and bamboos arranged beforehand is fired, and their retreat is cut off. They then sometimes attack the guiding palisades, but men with spears and muskets receive them here. I have seen two cases in which the elephants forced the palisades, and killed men behind them. Tame elephants are used, if possible, to assist at this stage of driving, chiefly as a protection to the men on foot, who run behind them should any elephant turn and charge. There is much less danger of this occurring in dealing with large herds than with small ones, as should a single elephant charge out of a large herd, it is rarely supported, and it quickly rejoins its companions. But a determined leader of a handful of elephants is liable to be followed at once by the rest. When an elephant chases the men, they betake themselves to the shelter of tree trunks, bamboo clumps, or long grass, and it is astonishing how they frequently escape uninjured. I have known many cases of men standing against a tree, or hiding in tufts of long grass, within a couple of yards of elephants that were pausing in indecision, without being discovered, though the elephants were evidently aware of their close proximity, as they kicked up the ground in anger, and then made off. In such cases the slightest movement would have led to the hunters being instantly trampled to death. Men are frequently killed, of course, but they are almost always young hands who are learning. I saw one such make a narrow escape a few years ago; he ran from an elephant and climbed a tree; the elephant butted the trunk, and the man fell down, but his pursuer was so astonished at the sight that she fled at once.

Sometimes drives are conducted by torchlight, and these seldom fail, owing to the elephant's fear of fire. The scenes on these occasions are exciting beyond description. The elephants in rushing along tear down large branches of trees that are connected with the undergrowth by climbing-plants, and even sometimes upset dry trees bodily in their passage. The cries of the young, and the deep, thunder-like growls of the elders of the herd, the continued crashing of the jungle, and the shots and incessant cries of the men, form, with the unnatural light of the fires and of torches moving through the forest paths, a scene that cannot fade from the memory of anyone who has witnessed it.

When a herd has been driven into the stockade, the gate is closed and barricaded, and men with firebrands and spears repel any attacks upon it or the palisades. But the trench is usually sufficient to deter the elephants from crossing it. On the same, or following, day, ten or twelve tame elephants are admitted with a mahout and rope-tier upon each, and it is a very remarkable fact that the wild ones very rarely attempt to dislodge the riders, as they easily might. They naturally fail to comprehend anything so foreign to their experience as a man upon an elephant's back. I never knew a case, except one that happened to myself, of any rider being attacked by a wild elephant. The mahouts separate the wild elephants one by one from their companions, when their hind legs are tied by men who slip to the ground for the purpose. A rope is then secured round each captive's neck, and to its hind legs, and it is led out and picketed in the forest near.

If two well matched rival tuskers happen to be impounded in one stockade, they sometimes fight to the death, seemingly regardless of their novel position. If not well matched, the more powerful one bullies the weaker one incessantly. On one occasion, when a herd of forty-eight elephants had been impounded, a scene of this kind occurred, one elephant following and fighting with another almost continuously for two days and nights. The smaller elephant retaliated on others weaker than himself, and between them the pair killed four young elephants and a large *muckna*. They caused such commotion that the tame elephants could not be admitted. At last the larger tusker forced the smaller one across the trench, and against the palisades. The latter commenced to break his way out; and though muskets were fired into his face, and spears and digging tools, made red-hot for the occasion, were applied to his trunk and head, the inducement behind was so strong that the counter efforts of the men were unavailing, and he made his way through the palisade, and went off into the jungle. This was at 2 a.m., and was a sufficiently exciting scene. No other elephants attempted to follow, and the gap was quickly repaired.

Amongst these forty-eight elephants was one that had escaped about twelve years ago, judging from the ages of her three calves. We first observed the fact of her being an escaped elephant by seeing old rope marks on her legs. When the tame elephants entered the stockade, two ranged alongside this one, and on being pricked with a spear, and told to kneel, she obeyed at once. She was ridden alone a few days afterwards.

The number of wild elephants that can be taken care of is, at the most, 50 per cent. more than the tame ones. As each capture is concluded, the wild elephants are marched out of the jungle into open country, for if kept in the forest, they continue to be excited by jungle sights and sounds, and to struggle for liberty, whilst flies are much more troublesome to their wounds in the jungle than in the plains. Each batch of new elephants requires a number of tame ones to be detached in charge of it; thus the hunting operations are limited by the number of the latter.

When a sufficient number of elephants has been taken, the hunters are dismissed, and all elephants under 7 ft. in height are sold to merchants who follow the kheddah parties for the purpose of purchasing such. Those above 7 ft. are retained for Government service, except some males and old females, which are also disposed of. Not more than 30 per cent. of the elephants captured are young and strong females, thoroughly suitable for Government service. The selected wild elephants are now divided into gangs of twenties, with a proportion of tame ones in charge. These escort the wild ones, bring their fodder, and lead them to water daily. The march from the jungle commences about the end of February, and the elephants reach the depôt at Dacca in May. They are then put into training, and by November are quite steady, and are drafted for military service.

New elephants are trained as follows:—They are first tied between two trees, and are rubbed down by a number of men with long bamboos, to an accompaniment of the most extravagant eulogies of the animal, sung and shouted at it at the top of their voices. The animal, of course, lashes out furiously at first; but in a few days it ceases to act on the offensive, or, as native say, "*Shurum lugta hai*," "It becomes ashamed of itself," and it then stands with its trunk curled up, shrinking from the men. Ropes are now tied round its body, and it is mounted at its picket for several days. It is then taken out for exercise, secured between two tame elephants. The ropes still remain round its body to enable the mahout to hold on should the elephant try to shake him off. A man precedes it with a spear to teach it to halt when ordered to do so; whilst as the tame elephants wheel to the right or left the mahout presses its neck with his knees, and taps it on the head with a small stick, to train it to turn in the required direction. To teach an elephant to kneel, it is taken into water five feet deep when the sun is hot, and upon being pricked on the back with a pointed stick it soon lies down, partly to avoid the pain, partly from inclination for a bath. By taking it into shallow water daily, it is soon taught to kneel even on land.

Elephants are taught to pick up anything from the ground by a rope, with a piece of wood attached, being dangled over their foreheads, near to the ground. The wood strikes against their trunk and forefeet, and to avoid the discomfort the elephant soon takes it in his trunk, and carries it. It eventually learns to do this without a rope being attached to the object.

I have only time to add a few facts regarding the financial results of elephant catching by the Government establishment at Dacca. Referring only to the official year ended 31st March, 1883, the expenditure upon the hunting establishment for twelve months was* £12,948, and the receipts by surplus elephants sold, and the value of those retained, £19,492, showing a profit of £6,544. Of this amount, £4,000 was surplus from the preceding year.

During the past five years the annual average number of elephants captured during our short working season, from December to February, has been 154. The greatest number in any single year was 252 in seven weeks in 1882, and 199 in a similar period in 1883. A ready sale is effected amongst the native landowners, and others who are fond of keeping elephants, of all those not required by Government.

The belief that wild elephants have decreased in India is not an uncommon one, and may have arisen from the fact of laws having been passed in late years for their protection. Also, from their undoubted decrease some years ago in Ceylon. But the case of that island is not analogous to that of the continent. In Ceylon, elephants have always been made a peculiar object of pursuit by large numbers of sportsmen, and by paid native hunters, whilst their range is not without its limits. To show the numbers that have been destroyed there, I may quote the official statistics between 1845 and 1859, which show that during those fifteen years rewards were paid for 5,194 elephants killed in, I believe, only a part of the island. Similar destruction has gone on for years, until rewards were abolished some years ago. But elephants are again becoming numerous, and are again allowed to be shot.

But on the Continent of India the number shot by European sportsmen has always been small, and it was only for a few years that natives were induced to turn their attention to killing them by a reward given for their destruction in the Madras Presidency. This was soon withdrawn, and the representations of humane officials having further led to the curtailment of the wasteful methods of trapping them practised by native hunters, the wild elephant now enjoys perfect immunity throughout the Western Ghats, and those boundless forests extending for hundreds of miles along the foot of the Himalayas into Burmah and Siam. The number annually caught by the Government hunting establishment at Dacca (the only one at present in India), and by licensed native hunters, is, comparatively speaking, very small; and there is no doubt that all the forest ground that can be legitimately allowed to the wild elephant is as fully occupied at present as is desirable. The elephant-catching records of the past fifty years attest the fact that there is no diminution in the numbers now obtained in Bengal, whilst in Southern India elephants have become so numerous of late years that they are annually appearing in places where they had never been heard of before.

In the Billigarungun Hills, an isolated range of 300 square miles on the borders of Mysore, wild elephants first made their appearance about the beginning of this century, having strayed from the forests at the foot of the Neilgherry range, across an intervening strip of some thirty miles of civilised country. Prior to that time the Sholagas, a wild tribe that inhabit the Billigarungun hills, but which has now dwindled down to a handful of savages, were a numerous people; traces of their former extensive cultivation, even of orange groves, gardens, and iron-smelting furnaces, still exist, together with lakes on the summit of the hills, for the convenience of the cattle which used to be driven thither from the neighbouring low country for pasturage during the hot weather. The Sholagas were almost destroyed by three successive visitations of small-pox, a disease which is always exceedingly fatal amongst hill people in India; their lands relapsed into the densest forest; and wild elephants and bison now abound where probably not one was to be found a century ago. The case of these hills is an interesting instance of a large tract of country in India having relapsed into a wilderness in recent times.

To give an idea of the numbers of wild elephants in some forests, I may say that during the past five years, between 1878 and 1883, 1,066 wild elephants have been captured by the Dacca hunting establishment in a tract of country about fifty miles long by twenty miles broad, in the Garo-hills in Assam, whilst fully as many more were met with during the hunting operations. Of course these elephants do not confine themselves to that tract alone, but wander into other parts of the hills. There are immense tracts of forest in India similarly well-stocked with wild elephants.

I am sure it will be regarded as a matter for hearty congratulation by all, that so grand, interesting, useful, and harmless an animal as is the elephant is in no danger of becoming extinct in India. Though small portions of its haunts have been cleared for tea or coffee cultivation, the present forest area of the country will, probably, never be practically

* Taking the rupee at 2s., for convenience.

reduced, for reasons connected with the timber supply and climate; and as long as its haunts remain, the elephant must flourish under due regulations for its protection.

DISCUSSION.

Mr. A. D. BARTLETT said he had had many years' experience of elephants, but only amongst those in captivity. He had had to do with probably the largest one ever seen in Europe, viz., Jumbo. When he came to the Zoological Gardens he was about four feet high, and weighed 700 lbs.; at first he was troublesome, but after a very short time became perfectly manageable, and grew very rapidly. This was to be attributed to his good living, and his constant bath in warm weather; in seventeen years he had grown from four feet to eleven feet in height. During the last few years of his stay he began to display, during a certain period of the year, a very troublesome disposition, and terrified everyone who came near him, except his keeper, Scott, who had extraordinary control over him. Scott was a very curious man himself, and it was with the greatest difficulty he could be induced to allow another man to assist him in the management of the huge animal. But it was feared that on some occasion, if Scott fell ill, or were injured by the elephant, he would be entirely unmanageable, for no other man dared go near him in his house, though when out at exercise he was perfectly quiet. At night, however, he used to tear about, and almost shake the house down, and became such a source of trouble that the Council decided to part with him. He was glad to say that he had recently heard from Mr. Barnum that Jumbo had increased one ton in weight, and was the father of two little infants, and he believed it was Mr. Barnum's intention to send over here a female elephant which was expected to give birth to another descendant of Jumbo's in November next.

Admiral RYDER asked if Mr. Sanderson could give any information with regard to the worship of elephants in Siam.

Mr. WEDDERBURN MAXWELL was very glad to hear that the cruel system of taking elephants in pits was condemned, and hoped it would be put an end to throughout India. Having lived in a district adjoining the scene of Mr. Sanderson's operations, he could confirm all he had said, and thanked him for the very graphic and accurate description he had given of the mode of capture.

Dr. GARSON asked if some further information could be given as to the length and weight of the tusks.

Mr. MARTIN WOOD said Mr. Sanderson had assured them that the number of elephants in India was not likely to decrease; but they all knew that in Africa the animal was being mercilessly destroyed, and he should like to ask if any means could be suggested by which the pitiless warfare against this noble beast could be checked.

Mr. CHRISTY said this last point was of great importance. He frequently had inquiries from Africa whether it was possible to organise a body of retired officers, or others, who would go Africa and assist the planters and Europeans there in devising some means of capturing and taming elephants. They had even gone so far as to authorise the purchase of some Indian elephants for the purpose, if necessary, but up to the present he had not heard of any practical measures being taken, though the matter had been much discussed in the *Field* and other papers.

Mr. KLENCK was sorry to hear that there was so much sacrifice of human life in the capturing of elephants. He would also emphasise the remark of a speaker with regard to the cruelty of catching elephants in pitfalls.

Mr. ANDREW CASSELS thought most persons present were afraid to expose their ignorance on this subject, by making any remarks in the presence of two such authorities as the Chairman and Mr. Sanderson; but he must say that one of his illusions had been removed that evening, for up to then he had always looked upon the elephant as a very sagacious animal.

The CHAIRMAN said this was a subject on which he could talk for a long time, though he certainly could not claim to be an authority, and knew very little compared to Mr. Sanderson. As he had listened to the graphic description of the elephants rushing through the primeval forests in the sub-Himalayan districts, he could not help his thoughts reverting from those regions to the valley of the Thames in the time long past, when the very ground upon which they were then met was the *habitat* of elephants far larger than any of those whose dimensions Mr. Sanderson very rightly expressed such doubts about. Most people knew that the Thames valley was, at one time, the habitation of probably two species of elephants, whose remains were constantly dug up in the marshes. Only so recently as 1846, one of those enormous creatures, the *elephas primigenius*, which was by some supposed to be the ancestor of the modern elephant, was turned up in Siberia, by the action of the water, in a good state of preservation. He was 13 ft. in height and 15 ft. in length, with enormous tusks, and covered with a long coating of hair, with a thick matting of wool underneath, showing him to be adapted to a cold climate. The African and Indian elephants were the only remaining examples of a great race which had passed away, though the remains of eight or ten different forms were still occasionally found in certain parts of India, showing clearly marked resemblances to the present type. A question had been asked about the African elephant and its capabilities of domestication, and if anything could be done to stop its wholesale destruction. It would be very difficult to suggest anything in that direction; but he might say that, some years ago, the idea did occur to him and others that these animals might be caught and utilised, and he suggested then that Mr. Sanderson should be asked to go from India with a select number of men trained by himself in elephant catching, taking a certain number of elephants with them, and there set up an elephant catching establishment. Had that been done, he felt convinced that long ere this there would have been a number of useful working elephants in Africa. The African elephant was just as capable of being tamed and trained as the Indian, though there were certain differences between them which might be of some practical importance. For instance, he did not know how a mahout could sit on the neck of an African elephant, on account of the immense size of its ears, but there might be other means of driving it. It was quite ascertained, however, that the African elephant was as docile, intelligent, and as capable of doing good work as the Indian, and there was no reason why he should not be utilised in the same way. There was very little doubt that the elephants mentioned in the classic authors, as being employed in the Punic and other wars of Hannibal, and those slaughtered in the amphitheatres at Rome, were of the African species, as was shown by medals and drawings, though these were not always perhaps perfectly reliable in details, such as in the size of the ears and shape of the cranium. He hoped the suggestion made, some years ago, by Mr. Sclater and others, as well as by himself, would eventually bear fruit. Certainly such a scheme could be placed in no better hands than those of Mr. Sanderson, for there was no one living who knew more about elephants; and, if a mission of this kind were entrusted to him, within a few years he felt sure he would produce as good a stud of elephants in Africa as could be got in India. He did not know that he should agree with him in all he said, but where he did not, he should defer to his opinion. He confessed he put the animal's intelligence somewhat higher than Mr. Sanderson did, but perhaps this was because Mr. Sanderson had seen them more in the wild state, and might not have seen so much of their after training; but he had certainly seen from time to time instances of intelligence which went beyond what Mr. Sanderson had described. If the elephant fell short of the intelligence of the dog, it certainly came very near to it, and he could not call the elephant a stupid animal. He should have liked to know something more about the growth of the animal, and when it attained full maturity. He did not think this was yet known and appreciated in India, and he believed that if the *mukhna*, now in the Zoological Gardens, or his female companion, were presented to an ordinary mahout, he would put their ages considerably beyond 15 or 16, which was the undoubted age, because their birthdays were known. He had known them for many years, having come over in the same ship with them in 1876, when they were quite small; but they were now both over 8 ft., and in India such a sized elephant would generally be put down as 20 or 25. He had a certain amount of experience of these animals, from having kept them, known them well, and been known by them. The last elephant he had was a very good one, staunch, faithful, unintimidated in the presence of tigers or any other wild animal, and was about 30 years old, or possibly a little more, when he lost her, with other property, at the time of the mutiny. Several years afterwards, when he returned to India, he happened to go up into Oude, and in making a journey, part of it had to be accomplished on elephants. When he got out of his carriage to mount the elephant she recognised him immediately, before he recognised her, and he thought that certainly showed a greater amount of intelligence than could be expected from a stupid animal. Another important question was, how to tell the age of an elephant. By looking in his mouth you could tell approximately, but probably not within three or four years. Mr. Sanderson had mentioned an important fact, which was not yet generally acknowledged, that the tusks of an elephant, which did not represent canine teeth, but incisors, were not deciduous, but came once for all, and remained. Comparative anatomists said that these teeth had a deciduous form at first, that they grew for a year or a year and a-half, and were then shed and replaced by the permanent tusks. Mr. Sanderson said this was not so, and though this had yet to be verified, he (the Chairman) thought he might be right. That there was a deciduous tooth which was followed by the permanent one he had no doubt, but apparently it was not shed, but absorbed, which would explain the matter. If they looked into a large elephant's mouth they would see two enormous teeth, double teeth, but not generally more than two, and if they looked into the mouth of one of the elephants in the Gardens now, they would probably see in front of one the fragments of another double tooth. The fact was that the elephant had six molar teeth on each side in the lower jaw, three of which represented the deciduous, and three the permanent teeth; one grew behind the other, and pushed it forward. The first three were lost in the first nine years. At about the 20th to 25th year the fourth tooth was lost, and for the rest of its life the animal depended on the two last. Knowing this, you might, up to a certain period, estimate approximately the age. Again the mahouts said they could tell the age of an elephant partly by the general appearance, but what they depended most upon was a fold in the upper part of the ear; however he doubted if they were not frequently out some years. Then there were questions as to the kind and amount of food the animal required, and the best means of keeping it in health. It was laid down in the commissariat of India that, for an elephant at sea, there was required daily, 150 lbs. of hay, 20 lbs. to 30 lbs. of flour, a certain amount of rice, 4 oz. to 6 oz. of salt, and 30 or 40 pails of water. The amount consumed by Jumbo was a truss and a-half of hay, two of straw, 2 lbs. of rice, 1 bushel of bran, 1 peck of oats, 7 lbs. of biscuit, grass or green food as much as he could get, and 10 pails of water; so that an elephant was a costly animal to keep. Yet he remembered the time when you could keep one in India, including the mahout and grass cutter, for thirty or forty rupees a month. It would cost more than twice as much now. As to the value of elephants, their price was perfectly arbitrary and conventional. You might pay almost any sum for a good tusker or even a good *mukhna*, which was a male with very small tusks like those of a female. If they wanted to see fine specimens of well formed elephants, they could not do better than examine those in the Zoological Gardens, both of which had been carefully selected by men of extremely good judgment and knowledge of the animal. The larger, though the younger one, was a perfectly beautiful elephant, and was selected especially by the late Jung Bahadoor, who was a great lover of elephants; on the table was a picture of a very fine tusker which belonged to him, and was considered the finest in India. With regard to ivory and the size of tusks, he had copied some figures on the subject, stating that some African tusks weighed 100lbs. each, and one pair weighed 325lbs. It was also stated that the best ivory came from Siam, though why that should be better than the Indian he did not know, as it was the same species. The ivory of the mammoth was even yet exported in tons from Siberia, but whether after being exposed for so many centuries to the weather and water it was of as good quality as the modern ivory, he could not say. He concluded by proposing a vote of thanks to Mr. Sanderson, which was carried unanimously.
