ORIGINAL LECTURES.

LECTURES ON
CHEMICAL AND MECHANICAL DISEASES AND THEIR RELATIONSHIP.

By H. BENCE JONES, A.M., M.D., F.R.S.

Preface.

On the Conservation and Correlation of Force in the Body.

The hypothesis of the constancy of the amount of force in the universe tends so much to promote experimental inquiry in every direction that for this, if for no other reason, it deserves and will obtain the utmost consideration.

No sooner was the relationship between the different forces of nature perceived than it was applied to the explanation of all machines, whether natural or artificial.

To the sun, which gives only the 2,300,000,000th part of its heating power to our earth, was traced the greater part of the energy of our planet, controlled and modified in each part by the daily and annual motions in space.

For the working of each mechanical, chemical, or electrical machine—for example, a mill, a steam-engine, or a telegraph—a source of power is necessary, and also provision for the application, direction, and control of that power.

The steam-engine will, perhaps, make the correlation of the forces and the controlling power most clear. The prime force is the chemical attraction of oxygen for hydrogen and carbon. The force is latent until the particles of matter are brought sufficiently close to enable them to act the one on the other. Hence comes heat, and from the heat mechanical motion, and this resolves itself again into the agent from which it was produced. In addition to the main spring there is a regulating spring, a directing agency which gives or takes away oxygen or fuel, and by proper contrivances controls the motion of the machine.

In plants and in animals the same laws of the indestructibility and the correlation of force offer a new and vast field for experimental investigation into the relationships of the agencies that are in action; and promise to unfold much, though possibly not all, of the mystery that is comprehended under the word "life."

In the course of clinical lectures which I gave each year to the pupils whilst I was Physician of St. George's Hospital, I constantly dwelt on the relations and differences between chemical and mechanical diseases.

Whenever I was able I pointed out a chemical or molecular disease running its course with scarcely any mechanical or massive disease resulting from it; but much more frequently I had to show how the molecular gave rise to the massive disease, how this again reacted on the chemical changes in the body, and these in consequence produced still greater mechanical results, until ultimately the motions of the diaphragm or heart were stopped, or the patient was restored to a healthy state.

Thus, whenever a good case of diabetes was in the wards, I dwelt on the chemical nature of the disease and on the absence of mechanical symptoms; whilst in a case of gall-stone or renal-stone, I dwelt on the chemical error which led to the formation of the stone; and then I pointed out the more serious mechanical disease resulting from the impaction, and then the wrong chemistry that this mechanical disease produced, the jaundice or uræmia, chemical diseases of the blood and textures, far more dangerous than the primary chemical complaint.

If a case of uncomplicated apoplexy was admitted, I pointed out how the escape of blood in the brain caused mechanical pressure; whence came altered chemical actions of nutrition and oxidation (inflammation) set up to repair the injury and to restore the brain to a healthy state.

Or, if a case of chorea from fright was in the House, I dwelt on the resemblance of the symptoms to the effect of the electric shock, and I showed how the mechanical motion caused abnormal chemistry of secretion and nutrition, and sometimes led, even, to the stoppage of the heart.

Some of my lectures on Chemical Diseases were almost identical with some of my lectures on Animal Chemistry; and as a new edition of these has long been asked for, instead of reprinting them with the alterations which the progress of chemistry requires, I shall endeavour to give an outline of a far more extensive application of chemistry to Medicine. I shall do this by taking a few examples of errors of deficiency or of excess in the two great chemical processes of oxidation and nutrition, which, acting and reacting the one on the other, are always taking place in each particle of the human body during life. Thus, oxidation depends on the nutrition of the blood-globules, the heart, and the blood-vessels which admit of the diffusion of the oxygen and the fuel into each portion of the extravascular structures; whilst nutrition depends on oxidation directly by transformation of force, and indirectly by the heat causing a relaxation of the vessels, and thus permitting an increased flow of nutritive substances to the parts.

I am far from supposing that animal chemistry at the present time is sufficiently advanced to admit of the classification of all diseases according to the altered chemical actions that are taking place in the body, and I shall not in the present course of lectures be able to give even a general view of the numberless variations that are already known to occur in the chemical processes of oxidation and nutrition.

But I shall endeavour to show, by a few striking examples, that the theory of the conservation of force opens a vast field of experimental inquiry, not only as regards the origin and connexion of the actions which constitute disease, but also as regards the actions of the remedies by which those diseases are modified or removed.

It must be remembered that animal chemistry is only one hundred years old. The chemical actions of health, as in respiration, digestion, nutrition, secretion, are far from being thoroughly made out, although day by day our knowledge is advancing.

In proof of this I may take the first grand chemical action going on in the body—oxidation. How little of this do we know at present. Pettenkoffer's experiments on respiration in health and in disease will probably give us for the first time accurate information on the amount of oxygen consumed by man in different circumstances. How this oxidation takes place. Whether the oxygen is made into the denser ozone (whose energy is to that of ordinary oxygen as common phosphorus to the allotropic red phosphorus). Whether Schoenbein's views are correct—that every substance capable of being oxidised first makes the ordinary oxygen into ozone, and that this enters into combination, first slightly (still preserving its properties), and then firmly (when the ozone loses its characteristic). Whether antozone exists, and by combining with ozone forms ordinary oxygen. These are questions which show how our knowledge is advancing, while they also show how much remains to be done before the chemistry of oxidation in the body can be thoroughly understood.

One two-thousandth part of ozone in the air is said to cause dangerous engorgement of the lungs, and even smaller doses long continued cause bronchitis and pneumonia. The blood of animals killed by ozone is found very rich in fibrin, and its dark colour shows that it has undergone active oxidation.

Professor Stokes thinks that cruorine (hæmatoglobulin) takes no part directly in oxidation, but that it so exalts the energy of the oxygen that it enables it in and out of the body to do what it could not do in its ordinary condition. However, the most energetic oxidations occur outside the capillaries, where no cruorine exists. Still, further, the modification of oxidation by the presence of substances in the blood and outside the capillaries is one of the problems of animal chemistry which M. Pasteur's work on fermentations out of the body is beginning to solve. The resemblance of inflammation to ordinary combustion has long been recognised, and we are beginning now to see that fevers bear the same relation to inflammations that fermentations do to combustions; and it is becoming clear that a vast class of diseases will be proved to be errors of chemical action—interferences caused either by want of regulation, or by the introduction from without, or by the generation within, the body of substances that increase, diminish, or change the oxidation which is necessary for the working of the body.

Most probably among these simple errors of oxidation the following diseases will be found:—Diabetes, acidity, oxalic acid, uric acid, uric oxide, cystine, fatty degeneration, gout, rheumatism, inflammation; and among fermentations, eruptive fevers, continued fevers, intermittent fevers, small-pox, syphilis, pyæmia, glanders, hydrophobia, plague.

If, instead of oxidation, I take assimilation, or the great chemical problem of nutrition on which the repair of the body depends, it is easy to show that still more difficult questions await solution.

The quantitative and qualitative errors in the chemical com-

position of the different structures of the body are just beginning to be investigated, though but little at present is known of the causes on which these errors depend. The excess or deficiency in the supply of nutritive material—the wrong quality of the matter supplied—the wrong chemistry in the act of assimilation in the different textures—the excess or deficiency of chemical action in the removal of the used organs; these constitute a multitude of chemical diseases, some of which at present are known as hypertrophy, atrophy, and degeneration, and all of which chemistry will some day almost, if not altogether, explain.

In the following lectures I have separated for the sake of clearness the errors of chemistry in the repair of the body from the errors of chemistry in the oxidising action in the body; but a close relationship between these actions exists. Assimilation in great measure depends on the temperature of the body; a few degrees more or less within may produce, as regards nutrition and oxidation, very different results; even the supply of nutriment to any part depends partly on the chemical action going on in that part, and by oxidation the used organs are made soluble or volatile to facilitate their removal from the body.

How far chemistry now is from dealing with these complex problems, or even with the more simple chemical questions of the conversion of food into blood, and blood into textures, may be seen in the fact that the chemical action of simple substances, as arsenic, copper, mercury, lead, zinc, etc., on the blood and textures of the organs is not yet worked out.

Wherever it is possible, I shall point out how excess or deficiency of molecular action produces mechanical disease, and in my last lecture I shall rapidly prove that the converse relationship exists: for massive diseases or injuries give rise to secondary chemical diseases—that is, to excess or deficiency, or altered molecular actions which again react on the original mechanical wrong, whereby the secondary chemical actions are exalted or depressed.

I am far from thinking that all the actions that take place in the body are directly chemical or mechanical. He would be but a poor Physician who overlooked the influence of the nervous system either in the origin, the progress, or the treatment of every disease. The supply of oxygen and nutriment to every part is so immediately under the control of the nerves that act on the heart and capillaries, that the chemical processes of oxidation and nutrition can be accelerated or retarded by the action of the nerves quite as decidedly as by any direct chemical or mechanical action.

The progress of animal electricity will probably make clear the connection between nervous, electric, and chemical force. Then the large class of diseases which arise from the disturbances in the regulators of the chemical and mechanical actions in the body will be as clear as the errors in the chemical and mechanical actions which form the subject of this course of lectures.

We are just ceasing to regard the nervous force as the origin of all the power in the body. Instead of making it a creator of force, we are beginning to regard it as the liberator and restrainer of the force in the body; in other words, as the regulator, through the blood-vessels, of the extent and degree of oxidation and nutrition that occurs in the human machine.

Taking the various parts of the nervous system separately, there are—1st, central organs; 2ndly, conducting organs, transmitting impressions at the rate of twenty-eight or twenty-nine yards a second; 3rdly, sense organs; and 4thly, peripheral working organs; and it is in these that the regulating power is made manifest. For example, mechanical, chemical, electrical irritation of the vagus stops the heart's action. Irritation of the sympathetic or division of the vagi increase the frequency of the heart's contraction. The ganglia of the heart seem to differ in their action. Experiments show that some have a liberating action, an automatic rythmic action; while other ganglia have a restraining action. Another example is seen in the vaso-motor nerves. Both Bernard and Schiff consider that these are of two kinds—the one set closing the vessels and the other set of nerves opening them. When closed, the blood is stopped; there is paleness and coldness, and no effusion of parenchymatous fluid: when opened, there is increased flow of blood, redness, and higher temperature, and increased exudation from the capillaries. In other words, the mechanical and thermal actions in the body are regulated by the nervous force acting on the blood-vessels.

The difference between muscular and nervous action is that between the horse and his rider, the gun and the gunner, the steam-engine and the driver; and it would not be more wrong to attribute all the force in these machines to the action of the spur and bit, the trigger, or the lever, than to attribute the force of the body to nervous action.

The finger of the engineer liberates the power stored up in the boiler; and the nerves unlock forces, already latent in the muscles. But besides those forces which result in the mechanical and other motions of the formed body, there are others to which the body owes its form, and which manifest themselves most wonderfully in the first stages of the embryo's existence. Animal form lies latent in the almost formless first animal cell. It is the power resident in this latter which determines the cycle through which the matter it draws towards it is to run. Whence those powers of the germ ultimately arise, our knowledge is at present insufficient to determine.

In the last century Physiology and Medicine have been chiefly occupied with the determination of the structure of the organs of the body in health and disease, in tracing the microscopical variations in the form and substance of the different parts of the body; the grand principle of the indestructibility of force, which in these latter days has been propounded, will probably cause the next century to be fully occupied with the problem of the metamorphosis of force in the body in health and in disease.

We have ceased to look on the human machine as a creator of vital or nervous force, and we are beginning to regard it as a converter of latent into active force.

In the body the force is latent in the elements, oxygen, hydrogen, carbon, nitrogen, sulphur, phosphorus, etc. The amount in each element may be measured by the heat produced in combustion or by the mechanical work that can be done by that heat. Thus, in the combustion of one gramme of hydrogen, the caloric equals 34462 units—a unit being the quantity of heat that raises 1 gramme of water from 0° to 1° C.—whilst in the combustion of one gramme of carbon the caloric equals only 8080 units, the mechanical work can be calculated from the fact that the mechanical equivalent of each unit of heat is equal to 430 grammetres—(that is, the work of raising 430 grammes one metre high). Hence the work that can be done by one gramme of hydrogen is 14,818,660 grammetres, and by one gramme of carbon 3,474,400 grammetres. As the number of units of heat produced in the body daily amounts to many millions, it is convenient to make the unit 1000 times greater, namely, the heat required to raise one kilogramme water from 0° to 1° C. The mechanical equivalent then becomes 430 kilogrammetres.

Mr. Joule makes the mechanical equivalent of heat 772 foot pounds—that is, the quantity of heat required to raise one pound of water one degree of Fahrenheit is equal to the heat produced by one pound of water falling 772 feet; and it would raise a pound weight 772 feet high, or 772 lbs. one foot high. As yet, distant approximations only can be made to the amount of force that daily goes into the body in the food and oxygen. As with the matter, so with the force of the food: the quantity that goes in is balanced by the quantity that comes out in any given time, provided the force and matter in the body at the beginning and end of the time is constant.

M. Barral has given an approximate estimate of the different amounts of force lost in different ways. From 1 to 2 per cent. of power is given out in heat of the urine and fæces; from 4 to 8 per cent. in the heat of the breath; from 20 to 30 per cent. in evaporation of water from the surface; and from 60 to 75 per cent. in conduction and radiation, and in mechanical work.

Force enters the body latent in the food. It consists of the affinities, as yet unsatisfied, which subsist between the constituents of the food and the respired oxygen. In the body, these affinities come into active play, producing heat, mechanical motion, and all those other actions, internal and external, to the sum of which we give the name of life.

Death is the stoppage of this conversion in consequence of the latent force not being developed into active force, either through some arrest of action in the heart, lungs, or brain, or by some direct interference with the chemical actions in the ultimate molecules of the organs.

When the number of centuries during which natural knowledge has been studied shall have approximated to the number already spent on classical knowledge, we may expect that the changes in the matter and force in the body in health and in disease will be so well known that even mental diseases will be more thoroughly understood than the simplest of those chemical diseases which, as far as our present knowledge admits, I shall endeavour to make clear to you in this course of lectures.

There remains only one subject more to which I must allude.

In my clinical lectures I tried to point out clearly the difference and relationship between the chemical and mechanical treatment of disease, to show that sometimes only chemical remedies are wanted; in other cases, more especially in Surgery, that mechanical treatment alone need be used; but that most frequently both chemical and mechanical actions are simultaneously wanted, and that these react potently on one another. For example, medicine with rest will do what medicine without rest will not; or diet and exercise may do together what either separately could not effect. The mode of action of mechanical remedies is at present much more comprehensible than that of chemical remedies. Motion increases chemical action and rest checks it. When the blood is carried through a muscle at rest the quantity of oxygen remaining in the blood is nearly $7\frac{1}{2}$ per cent., but if the muscle is in motion then the quantity of oxygen is reduced to $1\frac{3}{10}$ per cent. In other words, when motion takes place there is much more chemical action than when the muscle is at rest.

Motion acts in two ways upon chemical action—1st, directly by conversion of force, and, 2nd, indirectly by bringing the molecules more closely into contact, so that the latent energy can be changed into active force. This is chiefly effected by the circulation bringing fresh and larger amounts of oxygen in contact with the hydrogen and carbon, phosphorus and sulphur of the textures.

Rest lessens the supply of oxygen, lessens the pressure in the capillaries; the mixture and contact of molecules in the textures, and thus diminishes chemical action. Heat and cold act both chemically and mechanically in promoting or checking chemical action.

Heat acts directly by conversion of force; it also acts by dilating the capillaries, and thus permitting freeer circulation, and the consequent increased chemical action.

Cold acts directly by stopping chemical action, and indirectly by constricting the capillaries, and thus hindering the circulation and preventing the contact of the oxygen with the combustible and nutritive substances.

Food acts both chemically and mechanically,—chemically, 1st, by furnishing latent force, and, 2nd, material for the formation of the organs by which that force is made active. It acts mechanically by the solid parts increasing chemical action in the stomach, and by the fluid parts adding to the mass of liquid in the blood and by the dissolved solids that pass into the blood, adding to its specific gravity, and thus altering the osmotic actions throughout the system.

Food may be divided into water, salts, carbonaceous and nitrogeneous matters. The water and salts do not take a direct part in oxidation and nutrition, but they are indispensable indirectly to the chemical actions by dissolving the active substances and bringing them into sufficiently close contact for the action to take place. Both carbonaceous and nitrogenous aliments can be acted on by oxygen, and can thus change their latent into active force.

Hydrogen, carbon, and nitrogen, sulphur, phosphorus, iron, and lime, enter into the composition of the organs by which the conversion of latent into active force is effected. Ultimately, more or less completely, these elements are themselves acted on by the oxygen, and thus no distinction exists between respiratory and plastic food. Professor Liebig's division of food, however, gave the first impulse towards the clear comprehension of the two great chemical actions that take place in each particle of the body, and which constitute the mainspring of those forces which are summed up in the word "life."

Royal College of Surgeons.—We strongly recommend the Members of the College to pay a visit and inspect the large additions about to be made to the Hunterian Museum, and which will be exhibited until Thursday next in the Theatre of the College. To those interested in the anatomy and diseases of the eye, there is a very extensive collection made by Dr. Bader, of Guy's Hospital. Those gentlemen interested in the ear will see a most extraordinary collection purchased by the College of Dr. Hubrich, of Munich. Dr. Bell Pettigrew exhibits a very interesting and valuable series of preparations illustrating the anatomy of the bladder. There are also some valuable donations made by several members of the Council of special importance to Ethnologists. It is to be hoped that the Members will see the importance of aiding and assisting the Council in adding to their unrivalled collection.

COURSE OF

LECTURES

ON THE URINE AND DISEASES OF THE URINARY ORGANS. (a)

By GEORGE HARLEY, M.D., F.R.C.P.,

Professor in University College, and Assistant-Physician to University College Hospital.

Lecture X.

DIABETES MELLITUS—GLUCOSURIA—SACCHARINE URINE—ITS NATURE AND RATIONAL TREATMENT.

In no department of experimental research have results of greater value to the clinical Physician been recently obtained than in that connected with the study of animal saccharine matter. Within the last few years, indeed (since 1848), an entire revolution has taken place in our ideas of the physiology and pathology of diabetes; and although we have still much to learn before we can completely unravel the skein of laws regulating the formation and destruction of sugar in the animal economy, we have, nevertheless, reason to congratulate ourselves upon that which has already been achieved, and be sanguine in our expectations of what science may yet accomplish.

Before entering upon the consideration of this important era, which dawned within my own time, and whose gradual development I have not only watched as an interested spectator, but occasionally assisted as a conscientious actor, it will be advisable for me briefly to scan the earlier literature of diabetes, in order that you may better appreciate the advances that have been recently made, and comprehend in what respect the views of its pathology about to be given essentially differ from those of my predecessors and contemporaries.

From time immemorial, cases of emaciation, accompanied by an inordinate thirst and voracious appetite, had been observed, and in consequence of the patients so affected being at the same time troubled with an excessive elimination of urine, ancient Physicians gave to the disease the name of Diabetes (δια, through; βαινω, I go). It was not, however, until 1674 that the urine was discovered to possess, in some cases, a sweet taste, the honour of which discovery belongs to an English Physician named Thomas Willis. From this time henceforth the disease was divided into two classes, one of which received the name of Diabetes insipidus (without sugar), the other that of Diabetes mellitus (with sugar).

In 1774, exactly one hundred years after the date just alluded to, Mathew Dobson, a Physician practising in Liverpool, discovered that the blood as well as the urine in diabetes contains sugar, and from this observation he justly concluded that the saccharine matter found in the urine is not formed in, but only excreted by, the kidneys.

In 1778, Cowley succeeded in separating the sugar from the urine in a free state. (I may here remark that Bartholdi, so early as 1619, called attention to the presence of saccharine matter in milk; but this is, of course, a point entirely unconnected with diabetes.)

In 1796, John Rollo, Surgeon-General to the Royal Artillery, made the first important observation regarding the treatment of diabetes by discovering that an animal diet not only reduces the quantity of urine, but even diminishes the amount of sugar daily eliminated.

The next two steps were made by foreigners.

In 1815, M. Chevreul ascertained that the saccharine matter met with in diabetic urine differs from ordinary cane sugar, and closely resembles that of the grape.

In 1825, another important step was gained by Tiedemann and Gmelin discovering that starch is transformed into sugar during its passage along the alimentary canal.

In 1837, the next observation of interest was made by M'Gregor, of Glasgow, who found sugar in the vomited matters of diabetic patients—an observation which seemed to confirm Rollo's idea that the disease arises from the gastric juice turning vegetable food into sugar; and from that time till the present animal diet was consequently considered our sheet anchor.

We now arrive at an entirely new phase in the literature of diabetes, in which the teachings of the sick chamber gave place to those of the laboratory.

(a) This Course of Lectures which we are now publishing has been, with certain modifications, annually delivered to Medical Practitioner during the last eight years.—Ed. *Med. Times and Gaz.*

In 1848 the physiological world seemed as if struck by a thunderbolt when Bernard proclaimed that animals, as well as vegetables, had a sugar-creating power. Until then all the saccharine matter met with in the human body, whether in health or in disease, was supposed to originate in the transformation of vegetable substances. And now, for the first time, were we made alive to the startling fact that men, like sugar-canes, possess within themselves a saccharine manufactory. The liver being daily and hourly as actively engaged in fabricating sugar as in secreting bile.

Like all great discoveries, the rays of this one were not limited to its own field of inquiry, but broadly reflected over the various departments of scientific Medicine. By it new ideas were awakened, new discoveries made, and even at the present hour the impetus it gave to original research is still alike perceptible in the laboratory, in the dead-house, and in the clinical ward. In connexion with the subject of diabetes alone, the following may be reckoned as a few of the more important discoveries to which it led :—

In 1849 Bernard discovered that the disease can be artificially communicated to animals by pricking the floor of the fourth cerebral ventricle.

In 1853 I discovered that diabetes may be artificially induced in animals by exciting the liver through means of stimulants, such as alcohol, directly introduced into the portal circulation. An observation which explains the well-known fact that diabetes is a much more common disease in spirit-drinking than other countries.

In 1855 Bernard discovered that the formation of sugar in the liver cannot be regarded in the light of a "vital" process, as it goes on, not only after the death of the animal, but even after the removal of the liver from the body.

In 1856-7, Chauveau and myself gained another piece of ground by ascertaining that the sugar normally present in the circulation is not burned off in the lungs, as hitherto supposed, but disappears from the blood in its transit through the capillaries of the general circulation. The function of the saccharine matter most probably being to nourish the body.

In 1857, Bernard made the additional discovery, that before albuminous substances are converted into sugar, they first pass through the transitional stage of glucogene (animal starch).

Lastly, in 1859-60, Brücke and Jones ascertained, by careful experiment, that traces of sugar are even to be detected in normal urine—an observation which, we shall afterwards see, has an important bearing on the pathology of diabetes ; for, as I stated in a previous lecture, it may be regarded as a fundamental law that in disease neither new substances nor new functions are created. Morbid phenomena being merely the result of a change in the quantity and quality of normally existing agents and agencies.

Chemistry.

Although every one knows, or at least imagines he knows, a good deal about the nature and properties of sugar, I shall venture to say a few words upon the subject ; for the more extensive our knowledge, the easier will be the comprehension of this hitherto-regarded inexplicable disease. And on the present occasion it is the more necessary for me to do so, seeing that I differ from my predecessors and contemporaries in believing that there are at least two distinct forms of the disease, requiring diametrically opposite lines of treatment—an opinion which I shall presently show is as much in accordance with the teachings of the bedside as of those of the laboratory.

The term "sugar" is applied to a great variety of substances, the common essential character being their sweet taste. Chemists have, however, drawn broad distinctions between the different forms of saccharine matters, the properties of which are exceedingly varied. But for the sake of convenience they have been divided into two great classes—a *first* and a *second*—according to the manner in which they are acted upon by acids and alkalies.

To the first class, of which *cane sugar* is the type, are given all those that are easily crystallised, and which when boiled with an alkali are not decomposed, but enter into combination with it to form a saccharate of the alkali.

To the second class, of which *grape sugar* is the type, are awarded those which are not easily crystallised, and which when boiled with an alkali are transformed into the acids of molasses—glucic and melassic acids.

When acted upon by acids, on the other hand, an equally remarkable feature of distinction is observable in these two classes of sugar ; for while sugars of the second class remain apparently unaffected, sugars of the first (cane) are rapidly transformed into those of the second class (grape).

These changes are easily illustrated. If, for example, I boil a little sugar candy (a sugar of the first class) with potash, no apparent change is visible ; whereas, if before boiling it with potash I heat the solution of sugar candy in a test tube along with a couple of drops of hydrochloric acid, on adding the potash, the whole liquid becomes of a dark brown colour in consequence of the grape sugar (a sugar of the second class) which was formed by the action of the hydrochloric acid upon the cane sugar being instantly decomposed by the potash into the acids of molasses (glucic and melassic).

Just as the vegetable kingdom furnishes us with the two great types of sugar, *cane* and *grape*, so the animal kingdom yields to us their representatives in the form of milk and liver sugar ; milk sugar being the analogue of cane, liver sugar of grape. For example, the sugar of milk is readily crystallised, is unaffected by alkalies, but easily transformed into liver sugar by the action of acids. Liver sugar, on the other hand, is crystallised with difficulty, unaffected by acids, but rapidly decomposed by alkalies. (b)

Even the relative distribution of the two classes of sugar in the vegetable and animal kingdom is nearly identical ; for just as in the vegetable world the sugars of the second greatly preponderate over those of the first class, so in the animal economy, while the second class sugar is to be encountered in the blood, the liver, and the urine, that of the first class is limited to the mammary secretion alone.

Tests for Saccharine Urine.—A great variety have been proposed, but I shall only enumerate those possessing a real practical value.

1st. Specific Gravity.—Saccharine urine is generally, though not always, of a high specific gravity, averaging from 1020 to 1040. The specific gravity may be much higher, or much less, even independently of the amount of sugar it contains. For in diabetic urine there is generally a large excess of urea, which greatly adds to its specific gravity ; and occasionally, on the other hand, the disease is accompanied with an albuminuria sufficient to reduce the specific gravity even to below the normal standard. The specific gravity itself is therefore no criterion of the amount of sugar contained in any given specimen of urine.

2nd. Potash Test.—To a drachm of urine in a test-tube add an equal bulk of a solution of potash of the specific gravity of 1060. Heat the upper half of the liquid in the flame of the lamp until it boils ; then mark the change. If sugar be present, the upper boiled portion of the liquid changes colour, and becomes yellow or brown, in proportion to the amount of saccharine matter in the liquid. The browning being due to the transformation of the sugar into glucic and melassic acids. The lower cold half of the liquid, on the other hand, by remaining unaffected serves as a standard of comparison.

3rd. Copper Test.—To a drachm of urine add half a drachm of the potash solution. Shake the mixture and *afterwards* add a few drops of a solution of sulphate of copper(c) ; just sufficient to produce a pale blue tint when the whole is agitated. Boil the liquid from the bottom, and if sugar be present the blue colour will disappear, and a yellow or red precipitate form, according to the amount of sugar present in the urine.

The chemical steps of this process are as follows :—When sulphate of copper (SO_3CuO) is added to a solution of caustic potash (KaO), the sulphuric acid combines with the potash to form a soluble sulphate, and the oxide of copper separates in the form of a gelatinous precipitate, which, however, in consequence of the presence of organic matter remains suspended in the urine.

$$SO_3CuO + KaO = SO_3KaO + CuO.$$

The next stage in the process is produced by the heat causing the sugar to oxidise itself at the expense of the oxide of copper ; whereby the yellow suboxide is thrown down.

$$\text{Sugar} + \begin{cases} CuO \\ CuO \end{cases} = \text{Sugar O} + \begin{cases} Cu \\ Cu \end{cases} O$$

If much sugar be present, and the boiling is continued

(b) By combining liver sugar with chloride of sodium (common salt), Berthelot and De Luca have succeeded in obtaining large, colourless, transparent crystals, the watery solution of which ferments with yeast, and reduces the oxide of copper. The composition of the crystals, as ascertained by analysis, is represented by the accompanying formula—$2C_{12}H_{12}O_{12}, 2HO + NaCl$. The authors conclude therefrom that liver sugar is not only exactly the same as that found in diabetic urine, but that it is also identical with the sugar of the grape.—*Compt.-Rend.*, vol. xlix., p. 213.

(c) The most convenient strength I find is ten grains to the ounce of water.

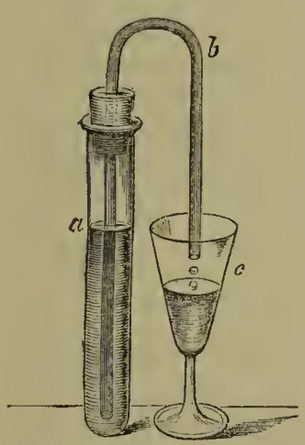
sufficiently long, all the oxygen is withdrawn from the copper, and the red metal is precipitated on the bottom and sides of the test-tube.

N.B.—Should the urine contain albumen, the albumen must be separated by the aid of heat and acetic acid before applying the copper test. Otherwise, on adding the sulphate of copper to the urine + the potash, a purple instead of a blue liquid will be obtained; and, on boiling, no reduction of the copper will occur unless a large excess of sugar be present, the liquid merely changing its tint from a purple to a mauve, and from a mauve to a red colour.

When the urine contains bile pigment, or is otherwise high coloured, and the sugar is present in small quantity only, it is necessary to decolourise the urine before adding the reagents. For this purpose, put an ounce or two of urine into a six-ounce bottle along with a tablespoonful of animal charcoal and a small pinch of carbonate of soda. Shake the mixture well for a few minutes, and then filter. A perfectly colourless liquid will thus be obtained, and greatly facilitate the application of both the copper and potash tests.

A great deal has been said about the fallacies likely to arise from the presence of uric acid, cotton fibres, chloroform, etc., in the urine. All I can say is, that during a fifteen years' experience I have never encountered them. In all cases of doubt, however, in addition to the potash and copper, I invariably apply the fermentation test.

Fig. 24.



4th. Fermentation Test. — The easiest way of applying this to urine is to employ an apparatus like that represented in the accompanying woodcut.

A test-tube, of about six inches long and three-quarters of an inch in diameter, is to be fitted with a piece of ordinary small glass tubing bent to the shape of a syphon in the flame of the spirit-lamp by means of a piece of cork. When ready, the tube is filled brimfull of urine, to which a few drops of baker's yeast have been added. The syphon is next fixed in the tube by means of the well-fitting cork, and the free end allowed to dip into a glass conveniently placed to receive the liquid as it is driven out of the tube by the carbonic acid generated during the process of fermentation. Each equivalent of sugar is transformed into one of alcohol and four of carbonic acid gas, so that every seventeen cubic centimetres of carbonic acid evolved is equivalent to one grain of sugar decomposed.

During the fermentation process the apparatus must be kept in a moderately warm room.

When diabetic urine is set aside for a few days it frequently ferments spontaneously, and the liquid becomes filled with Torulæ, or sugar fungi, which can be readily recognised with the microscope. They consist, like the common yeast plant, of a number of spores strung together in short rows like beads. The sporules of torulæ are, however, smaller than those of yeast, their relative size being represented in Fig. 25.

Fig. 25.

Fig. 25.—*a*. Sporules of Torula cervisiæ from diabetic urine. *b*. Spores from baker's yeast.

(To be continued.)

Pryce *v.* Bowen. — We learn on inquiry that Mr. Evan Thomas, jun., to whom we referred last week in the above case, completed the full curriculum for the Membership of the College of Surgeons, at the Edinburgh Infirmary, and at the University College, London, and that he was not admitted to examination after only *three months' study*, as his answers when in the witness-box, as reported in the *Liverpool Mercury*, led the public to suppose.

ORIGINAL COMMUNICATIONS.

ON THE POSITION OF THE UTERUS.

By Dr. M. CLAUDIUS,

Professor of Anatomy at the University of Marburg.

If we seek an answer in literature to the question regarding the position of the uterus, we obtain everywhere a definite one. Anatomists, gynæcologists, obstetricians, and Surgeons alike in Germany, England, and France, express themselves with rare concurrence to the effect—that the uterus in its normal position is surrounded before and behind by the intestines; in other words, that the Douglasian space is filled up with loops of intestines. In older anatomical works this is in general not directly asserted, but simply implied; for instance, in the frequently-recurring statement that the uterus and broad ligaments form a transverse septum through the small pelvis, and such like. In recently published works, on the contrary, there are the most definite statements on this point. Any observations or reasons on which this opinion rests are in the majority of cases not communicated, the fact alone being set forth as undoubted and generally believed.

On the contrary, the investigation on living persons with healthy uterus, and on the dead subject, furnishes totally different results. In the case of the former, the finger introduced into the rectum always feels the probe lying in the uterus, without intestinal loops being noticeable between. And in the dead subject the uterus with the broad ligaments and ovaries is observed in by far the greater number of cases lying as close to the posterior wall of the pelvis as the lungs are to the ribs. The rectum generally passes close behind the left border of the corpus uteri, swerves, however, also sometimes considerably towards the left, more rarely towards the right, so that the uterus lies in the middle line. The broad ligaments cling so very close to the posterior wall of the pelvis, that in the case of sagittal sections (through frozen corpses) which pass between the uterus and ovary nothing of them is noticeable at first inspection, and it is only discovered after more careful examination that a thin double flap of peritonæum lies against the wall of the pelvis, in whose upper end the section of the tube is visible. The ovary lies more laterally,—its long axis horizontal or generally a little raised at the outer end—in a shallow cavity, the fossa ovarii, which is hollowed out in the tissue, that fills up at the upper border of the musc. pyriformis the hole intended for the vasa and nerv. glutæus superior. The anterior side of the ovary is completely covered by the ala vespertilionis, so that the intestines do not come in contact with it at any point. The Fallopian tube takes its course close above the upper border of the ovary, and then curves downward behind its outer end, so that the infundibulum is enclosed in the lateral half of the fossa ovarii between its base and the posterior side of the ovary. This at least I observed in a case in which there seemed to be nothing abnormal.

The main points of the above description rest on examinations of 88 subjects, 36 of which were sections of frozen corpses represented in Pirogoff's "Anatomia Topographica," while 4 were in Le Gendre's "Anatomie Chirurgicale Homalographique." I have to thank the friendly exertions of Dr. Füngel, Director of the Hospital at Hamburgh, for 38 cases. Lastly, I myself have examined 9 subjects, 5 of which were sections of frozen corpses. 10 cases must be excluded from this number, because the uteri showed evident traces of disease or malformation. But of the remaining 78 cases the genital organs lay 70 times close upon the posterior wall of the pelvis, whereas in 8 cases loops of intestines lay embedded in the Douglasian space.

The last-mentioned cases are, in my opinion, likewise of a pathological nature. The uterus is, then, only in its normal position when along with the broad ligaments it touches the posterior wall of the pelvis and the rectum. In my opinion, it is always a case of anteversio, anteflexio, or antefractio uteri when intestinal loops are present in the Douglasian space. This opinion is founded principally upon two reasons.

Firstly, because in this manner alone the uterus can obtain a safe position in the pelvis. This argument will probably be much attacked. We find in all authors this alone impressed, that the uterus is very moveable, but that is no reason why we should suppose it is capable of movement. To be sure, it is undoubted that the uterus can easily be moved by violent

treatment through moving of the neighbouring parts, but nevertheless certain that it rests in the healthy female quite unmoved in the pelvis. This is sufficiently proved by repeated explorations *per rectum et per vaginam*. If we except the rectum, which during filling and emptying moves the uterus gently forwards and backwards, there are no causes of disturbance at all. The above statement is sometimes grounded on erroneous observations. If a softened vaginal portion may be moved easily in all directions by the finger introduced into the vagina, it is concluded from this that the uterus makes the contrary movements between the intestines in the pelvis, and therefore forms a double-armed lever, whose hypomochlion lies in the bottom of the pelvis, fascia pelvis, and muse. levator ani. It is easy to comprehend that this is impossible. For not only would every considerable movement of the uterus—by which the intestinal loops changing their position would be forced out of the space above the bladder into the Douglasian space, and *vice versa*—cause great violent twitching of the broad ligaments, such as no living being could bear, even although we assume the mobility of the intestinal loops to be very considerable, but also, on account of the round ligaments, the lateral flexures would be much sooner limited than the forward movements, which is not the case. Certainly the body of the uterus can only be moved by the finger, introduced into the vagina through the raising of the bottom of the pelvis. To be sure, this appears to possess in different individuals a very varying resistance. From the rectum the uterus may be pressed as far forwards as the anterior wall of the rectum, and the point of fixture of the uterus yield. It is true that by means of the uterine probe the uterus can be moved forward and towards both sides, but this violent treatment has nothing to do with the solution of the question, whether the healthy uterus ever changes its position during life? No circumstance speaks to the affirmation of this question, while the examination of healthy individuals and of corpses necessitates the admission that the uterus has a seat as well protected against the intestines as the liver has. The unvarying position of the vaginal portion and its resistance in healthy women to the pressure of the finger can only have their cause in the steadiness of the body of the uterus in the small pelvis. Nor is the uterus more affected by the emptying bladder.(a) The plicæ vesico-uterinæ and the tissue lying beneath are, according to examinations on recently killed animals, so lax and yielding that the uterus cannot be drawn by them forward against the intestinal loops. Moreover, experiments on corpses, undertaken with all necessary caution, prove that the bladder can be filled and emptied without the uterus being moved in the least.

The uterus is mainly held in its position by the round ligaments. After these have reached the lateral wall of the pelvis, having left the inguinal canal, and continuing along the posterior wall of the pelvis, in a curve concave forwards and downwards, they attach themselves firmly to the uterus, below the insertion of the Fallopian tubes. In this position they are tense, and permit of a lateral motion of the uterus as far only as their own substance may be stretched. Of themselves alone they would be unable to fix the uterus, because they would cut through between the intestinal loops. This is hindered by means of the broad ligaments, whose use consists in this, that they form broad folds about the round ligaments, by means of which these gain resistance against the intestines. This apparatus can only then be effectual when the broad ligaments touch the posterior wall of the pelvis with their whole surface. If there are intestines in the Douglasian space, the uterus is moved forward, and the round ligaments lose their tension; the uterus is therefore no longer fixed, either laterally, forwards, or backwards. It will be moved to all directions by the intestines, whose state of repletion alters several times daily. If the intestines in the Douglasian space are being filled, while those lying above the bladder are being emptied, the uterus will be anteverted, but in the contrary pressed backward, along with which laterally inflexions generally will be combined. If the intestines are being filled on the one side before on the other side behind the broad ligaments, the uterus must necessarily be turned on its axis. All these movements must be accompanied by distensions of the broad ligaments; and thus the many complaints of those affected with anteversio uteri are rendered comprehensible.

It is easy to understand that as long as the uterus retains its normal rigidity, intestines can never enter the Douglasian space. The pressure which is exercised on its whole anterior surface by the intestines has the result of retaining it in close contact with the rectum, and must completely overcome the gentle pressure that is exerted by parts of single loops of intestines on the superior opening of the Douglasian space. The intestines cannot enter at the side of the uterus, behind the Fallopian tubes, on account of the narrowness of these, just as little as on the borders of the omentum majus. It is not impossible that single loops of intestines, which have passed into the Douglasian space, can be expelled out of it by the overpowering pressure of the filled portions of the alimentary tube, as soon as the former have become more moveable by being emptied.

During pregnancy the uterus touches the posterior wall of the pelvis, as far as the promontorium, and remains there during the involution post partum (b) (see the sections of Pirogoff, l.c.).

The uterus can maintain its position against the intestines only as long as it retains its normal rigidity. As soon as its tissue is relaxed, and therefore the pressure on the under part of the anterior surface is not more continued as far as the upper border, it is possible for the intestines to inflect it from above forward and backwards. These physical conclusions confirm the statement of pathological anatomists, that softening of the tissue of the uterus is the principal cause, in the most cases, of deviatio uteri.

According to the aforesaid, the apparatus of the uterine ligaments is only then useful and effectual when the uterus reclines against an unyielding surface and loses instantly its whole meaning, if intestines are behind it.

The second reason for my opinion seems to be of still greater weight. If intestines lie behind the uterus they will generally touch the ovarium and the infundibulum of the Fallopian tubes. The fimbriæ are so moveable, light, and tender, that it is impossible to conceive their lying safe between the intestines, both as regards their structure and position. They will be removed from the ovary, and the tender fringes covered with ciliated epithelium will be destroyed. We can understand this if we think of the lumps into which the omentum majus is rolled up, if it chances to come between the intestines. There would be no longer the possibility of the entrance of an ovum into the infundibulum. But simply the contact of the ovary with intestines would render the conveyance of a discharged ovum in the infundibulum impossible. Through their changes of form and position the ovary, which is held fast at one end by its ligament, would be tugged up and down, and be thus removed from the infundibulum. The discharged ova must fall into the furrows which run in the most different directions between the close-lying intestines, and through their peristaltic movements be conducted anywhere but into the infundibulum.

If, on the contrary, the ovary with the lateral half of its posterior side resting on the infundibulum lies in its fossa, protected in front by the ala vespertilionis against every touch, the entrance of an ovum into the infundibulum is conceivable. The ova expelled from the follicles are forced by the pressure exerted on the anterior side of the ovary into the canals, which lie upon the upper and lower borders of the ovary, as the pressure there must be less. The canal of the upper border, threesided in a transverse section, is formed by the passage of the ala vespertilionis from the ovary to the posterior wall of the pelvis; those of the under border are small slits before and behind the ligamentum ovarii. They are stretched a little by the liquor folliculi, and the supposition that a stream is excited in them by the ciliated tissue, powerful enough to conduct the liquid with the excessively slippery ovulum into the infundibulum, has nothing absurd in it. It is possible that the pulsation of the branches of the art. hypogastrica, which have their origin directly below the ovary, assists the

(a) I take the freedom of adding a remark on the state of the bladder in corpses, which, as far as I know, is not yet regarded in pathology. The emptied bladder is contracted in the corpses of animals, and very seldom in young human corpses, into a thick walled ball, with a small round lumen. In ordinary dissecting-room-corpses a totally different condition is met with. If in these the bladder is empty the upper half, covered by the peritonæum, and therefore exposed directly to the pressure of the intestines, appears cup-like fitted into the lower, so that the lumen represents a semicircle, open above, by every perpendicular section, passing through the orificium urethræ. Paralysis of the detrusor urinæ appears to be the cause, and the lessening of the energy in the urinal stream in old age leads to the same conclusion. Perhaps the more intimate knowledge of this state of things may be useful for the treatment of many bladder affections. (See Pirogoff fascic, iii., A.)

(b) It is not stated in Le Gendre's work whether the represented pelves were frozen while still connected with the trunks, or after being cut away. In the latter case the drawings would be of no use in determining the position of the uterus.

passage of the ova. We may expect that the special examination of the uterus *in situ* will shed a light upon this process. The examination of the epithelium in the fossa ovarii of a person who has died suddenly during ovulation is very desirable, as, perhaps, ciliated epithelium is developed there on the peritonæum during this time (as in frogs).

It is easy to comprehend from the above that sterility must, as a rule, be united with anteversio uteri. An intestinal loop, indeed, may lie behind the uterus, and still the situs ovarii be quite normal, as I have observed in one case. On the other hand, Dr. Füngel has informed me that in two cases where the situs uteri was normal, he saw the infundibulum hanging down before the ovary between the intestines,—an anomaly which likewise must entail sterility. Sections of female corpses of the rapidly-disappearing savage tribes in America and Australia would be interesting, since it is not impossible that epidemical deviations of the uterus are the cause of the sterility of the females.

The comparative anatomy and the history of development show us likewise the female genital apparatus in close contact with the rectum and the posterior wall of the pelvis. In the first months of fœtal life it is impossible for intestinal loops to enter into the Douglasian space on account of their thickness. In the most Mammalia the central portion of the uterus bicornis touches the rectum.

I lastly take the liberty of calling the attention to some conclusions immediately connected with the aforesaid. If a gynæcologist(c) says, "through its great mobility the uterus can be brought by double manual exploration into every situation, and every change of position can be caused artificially; indeed, a soft uterus can be inflected"—the moral thereof needs not to be explained. But the uterine probe might, in the hands of a careless Physician, become the most dangerous instrument. If the handle of the probe lying in the uterus is but gently moved backwards, the intestines must fall into the Douglasian space, and the consequences thereof will certainly be mischievous.

RUPTURE OF THE BLADDER—EXTRAVASATION OF URINE—DEATH ON THE THIRD DAY—CORONER'S INQUEST.

By C. GAFFNEY, Esq., M.R.C.S., &c.

On Friday, the 18th November, 1864, at 8 o'clock p.m., I was requested to visit a man who had met with an accident, whilst engaged in his ordinary avocations, which were those of an agricultural labourer. From evidence given subsequently to his decease at the coroner's inquest, it seems that he was filling a barn with barley from a neighbouring stack in company with two other men, and that having completed his task for the night he threw down his fork (a height of some ten feet) which stuck fast in the ground, and he himself followed, letting himself down by means of a beam which supported the roof of the barn: however, when near the ground he made a spring at the rest, and jumped on to the handle of the fork behind him, which entered the rectum, passing through his trousers, and penetrated the bowel to a depth of ten inches. His agony was extreme, and his companions having endeavoured to relieve him to the best of their power conveyed him home, and had him removed to bed, where I saw him. His condition was one of collapse, the features were shrunken and pale, the pulse feeble, and the extremities cold. He had vomited everything which had been given him since the occurrence of the accident; however, having given him a little cold brandy and water, he managed to get it down, and I then proceeded to examine the wound.

It was seated at the anus, the orifice of which was permanently open to the extent of half an inch in diameter. Its edges were jagged and contused, and there was a good deal of discolouration and echymosis for some distance around. Blood was flowing from it in small quantity. Having examined it first with a probe, and then with my finger, I could discover no aperture of communication with the bladder posteriorly, and on examining the bladder anteriorly I found it full of urine, and on passing the catheter I drew off about a pint of urine tinged with blood, which afforded considerable relief. Having ordered a tablespoonful of brandy in a little cold water every hour, and bottles of hot water to the feet, I administered fifteen minims of laudanum and left him, warm fomentations having been laid to the wound.

November 19.—Much worse; has passed a very restless night. Pulse much more frequent and weaker; the skin was hot. Sordes had begun to collect on the teeth and gums, the tongue was dry, and his general condition was much changed for the worse.

State of the Wound.—This looked very unhealthy. Urine mixed with feculent matter was flowing through it. I once more endeavoured to detect the opening into the bladder, but failed in my attempt. Having re-introduced the catheter, which I retained in the bladder by means of tapes, and having carefully sponged the wound, I ordered the brandy to be repeated every half hour, and took my leave.

20th.—Having expressed a very unfavourable prognosis to his relatives on the preceding night, I this morning called in a neighbouring Practitioner of eminence to consult with me, as to the further steps to be adopted in the case. Having carefully examined the wound, he decided that the only thing to be done was to allow the urine free exit through the wound, and to this end recommended the wound to be injected with warm water twice or three times a day, which advice was carefully attended to. Having substituted beef tea for the brandy in the intervals, and having recommended small doses of opium every four hours, no further suggestions were offered, and we took our leave. At 1 p.m. I again visited him, and having injected some warm water into the wound he expressed himself comforted; but occasional delirium having set in, I dared not administer the opium, and finding there was nothing more that I could do, I took my departure, and was informed of his sudden decease one hour after I had left him, the contents of the bowels having been discharged by the mouth when at the point of departure.

By an oversight a post-mortem was not made, which is the more to be regretted as the case presented features of great interest. Still, such as it is, I trust it will not be unacceptable to some of your readers, as exemplifying a great fact embodied in this principle, that a wound may be of trifling extent, and yet the consequences may be very serious and rapidly fatal, and if it leads to a more careful and thorough investigation of wounds of all kinds, however trifling they may seem on a mere cursory examination, I shall be abundantly repaid for my time and trouble in compiling this case.

Buntingford, Herts.

DISLOCATION OF THE HUMERUS, WITH OTHER INJURIES—COMMINUTED FRACTURE OF THE CORACOID PROCESS.

By E. L. HUSSEY,
Surgeon to the Radcliffe Infirmary, Oxford.

A mason's labourer, aged 22, slipped his footing on a scaffolding in the early daylight of a winter's morning, December 1, 1864, and fell from a great height on his left side among a pile of loose bricks. He was picked up insensible, and taken at once to the Radcliffe Infirmary, Oxford.

Among other injuries of very severe character (from which he did not rally), his left humerus was dislocated inwards and forwards, the head of the bone being below the clavicle. The dislocation was reduced immediately without difficulty by the House-Surgeon (Mr. Winkfield).

From the report of his fellow workmen and the appearance of the body, it seemed that the man had fallen on his left side with the elbow drawn back and the forearm flexed on the humerus, the elbow receiving the shock of the weight of his body as he fell.

Upon examination after death, it appeared that the coracoid process was broken completely off from the scapula. Two separate pieces were found, drawn apart by the muscular fibres attached to them—one downwards on to the ribs, the other inwards toward the humerus, below the rent in the capsule. There was not time to allow of making a careful dissection, so as to see whether the muscular fibres attached to the fragments of bone were in truth, what I thought them to be, those of the pectoralis minor in one case, and the coracobrachialis and biceps in the other. These two pieces of bone, when put together, do not form the complete process as it exists in the skeleton. A small piece of bone at the base and side is wanting. This escaped detection in the hasty examination, which was the only one I had the opportunity of making.

Oxford.

REPORTS OF HOSPITAL PRACTICE
IN
MEDICINE AND SURGERY.

KING'S COLLEGE HOSPITAL.

TABULATED ACCOUNT OF TEN DEATHS FROM PYÆMIA, FOLLOWING OPERATION OR INJURY, OF THE YEAR 1864—JAN. 1 TO DEC. 31.

No.	Name and Age.	Disease or Injury.	Operation (if any) and Date.	Date of Commencement of Symptoms.	Remarks.
1	M. W., 47; admitted May 18	Erysipelas of leg and necrosis of femur, following fracture of patella	Amputation in middle third of thigh, June 18	June 20 . .	Shivering and thirst; tongue foul and moist; dark, thin, grumous discharge from wound; free perspiration; pulse went up to 133; death June 27. Brandy to 8 oz., ammonia, chloric ether, quinine, and iron. Post-mortem.—None. This case was accompanied with pneumonia.
2	T. R., 35, male; admitted Feb. 6	Inflammation of knee from fall	Amputation of thigh in middle third, May 30	June 12, 11 days after	Healthy discharge from wound ceased about June 13. Shivering, vomiting, quick pulse, thin brown discharge from wound. Involuntary discharge of urine and fœces June 20. Death June 20. Brandy, wine, ammonia, and chloric ether. Post-mortem.—None.
3	W. P., 46, male; admitted April 27	Injury to ankle-joint; formerly fracture just above joint	Amputation below knee, May 7	May 18 . .	Shiverings, lasting for about four hours at a time; some signs of suppuration on right wrist-joint. May 22, abscess formed in knee-joint; healthy secretions ceased; disposition of flaps to unite; foul thin discharge; end of femur ulcerated completely through the stump; death May 31. Brandy, ammonia, imperial drink. No post-mortem.
4	J. S., 54, male; admitted April 15	Necrosis of os calcis	Chopart's amputation, July 13, 1864	July 30, 17 days after operation	Originally in Medical wards with low fever; suppuration in right foot set in, followed by necrosis. The stump suppurated freely at first; at the commencement of the symptoms the discharge became thinned and dark-coloured; suppuration in the knee came on about August 5, and extended amongst the adductors; shivering, dry tongue, quick pulse, delirium, death August 26. Brandy, ammonia, beef-tea. Post-mortem.—None.
5	M. H., 26, female; admitted Oct. 6	Injury to knee of 17 years' standing; contraction from abscess	Excision of knee-joint, Oct. 29	November 9	Rigors and diarrhœa commenced November 9; brown, moist tongue; unhealthy watery discharge from wound; hectic; breath sweet; pulse fluctuated to 145; death November 22. Brandy, ammonia, beef-tea, opiates. No post-mortem.
6	P. S., 29, male; admitted June 25	Suppuration of hand following blow	Pus evacuated .	July 1 . .	Rigors, lessening of healthy discharge, tongue brown and moist; delirium July 15; diarrhœa, vomiting, coarse crepitation, stertorous breathing, incontinence of urine; sloughing of nates; pulse fluctuated to 152; respiration 64; death July 26. Tr. ferri. mur. quin. disulp.; brandy to 24 oz.; opiates. Post-mortem.—None allowed.
7	J. P., 54, male; admitted Sept. 9	Necrosis of left femur	Abscesses connected with dead bone, opened Sept. 14	In a very low state on admission	Accompanied with pneumonia and jaundice, shivering, bilious purging, discharge of foul brown pus from wound; death September 21. Brandy, ammonia. Post-mortem.—None.
8	J. L., 25, male; admitted Feb. 17	Strumous disease of shoulder-joint	None . . .	Feb. 24 . .	Delirium, shivering, pus in urine, quick pulse, coma, and death September 29. Post-mortem.—Pleuritic adhesions of both lungs; tubercle and cavities in both. Heart healthy. Great quantity of fluid in both ventricles of brain. A small quantity of grumous pus in shoulder-joint; articular cartilages gone.
9	A. B., 46, female; admitted Jan. 14	Fractured femur, and abrasion over elbow-joint	None (fracture put up)	January 21 .	Erysipelas commenced about elbow and extended up the arm. The symptoms, shivering, quick pulse, etc., commenced soon after the erysipelas set in; great pain on surface of body when touched; coma; death January 31. Collodion and oil to arm, sprinkled with flour. Brandy, ammonia, iron. No post-mortem.
10	S. S., 30, female; admitted Aug. 5	Stricture of rectum	Stricture divided, Aug. 10	August 12 .	Shiverings; symptoms of peritonitis August 12; vomiting; death August 20. Post-mortem.—Peritonitis; pus in uterine veins; walls of rectum very much thickened and ulcerated. Brandy to 24 oz.; ammonia; fomentations to abdomen.

CENTRAL LONDON OPHTHALMIC HOSPITAL.

THREE CASES OF GLAUCOMA—IRIDO-CHOROIDITIS—IRIDECTOMY—RESULT—REMARKS.

(Under the care of Mr. HULME.)

Case 1.—Catherine B., aged 44, married, dark hair, brown irides, a thin, sallow-looking woman, always accustomed to wear spectacles (24 convex) from the age of 21, complains that the sight of the right eye began to fail her in the middle of the month of October, 1864, haloes round the flame of a candle, accompanied with pain over the right brow and along the corresponding nasal side of the orbit, etc., etc., for which she did not apply for Medical relief till Tuesday, December 6. During the week previously she had been suffering great pain, the sight had almost entirely gone, and when she presented herself at the Hospital she had all the symptoms of an acute attack of glaucoma—pain, dilated pupil, extreme tension of globe, etc. She could just distinguish the shades of fingers, but could not count them. The field of vision was much contracted in the upper and inner segments. She was admitted on the evening of December 8, and on the morning of the 9th Mr. Hulme, assisted by Mr. Aldridge, who administered chloroform, performed iridectomy, the upper section, removing about one-sixth of the iris. There was no bleeding; the iris prolapsed well through the sclerotico-corneal aperture.

On the 10th the relief from pain was complete, not the slightest bad symptom. On the 12th the eye was examined. The section had healed. She counts fingers easily. On the 17th she left the Hospital, and on December 23 she reads No. 4 at six inches without glasses; with 24 convex she reads No. 2 (pearl) type. The plane of the iris of the operated eye is now vertical; that of the left eye is bulged forwards; this pupil, however, is more contracted, sluggish in action, and there is a shade of increased tension in the globe.

Case 2.—Mrs. B., aged 53. About a year ago the vision of the left eye began to fail. The sight, to use her own expression, "came and went." She has for years used convex glasses, and has increased their power twice. She complains of haloes, etc. The sight of the right eye has been lost for several years; she can just distinguish light from darkness with it. She had the first attack of pain six months ago. The sight got much worse, and glasses only assisted her periodically. About a week before Christmas, 1863, she was laid up in bed with acute pain in the globe, but did not apply at the Hospital till January 1, 1864. The sight was then rapidly failing, the pain continuous, the patient much depressed. The appearances then noted were—pupil dilated, lens and vitreous clear, cupping of the optic disc, increased tension of globe; can barely distinguish the shade of the hand before her. The iridectomy was made outwards, about one-sixth of the iris removed. The relief from pain was immediate. The section healed well. Five days afterwards counted fingers at two feet distance.

She left the Hospital early, and I saw her on February 5, and she then read No. 10 Jæger, and with No. 12 convex reads No. 4.

Case 3.—James W., aged 57, married; pale, sallow-looking man; steward of a steamer. Has worn glasses for the last twelve years. In January, 1864, the sight of the left eye failed him, after an attack of severe pain. He applied two or three days after at the Hospital, and came under Mr. Aldridge's care, with all the marked symptoms of acute glaucoma. In March I assisted Mr. Aldridge in operating under chloroform, who performed an upper iridectomy. With this eye he now can read No. 2 Jæger with 10 convex. In May, 1864, the sight of the right eye began to fail. He went to sea, and could not apply at the Hospital. He was attacked by pain and loss of sight, for which he was leeched. The pain was relieved, and the sight partially returned; but he was always troubled with temporary obscurations, haloes round the candle-flame, and dull circumorbital pains. He applied at the Hospital again December 16, 1864. During Mr. Aldridge's absence he came under my care. The notes are—considerable tension of globe; pain; loss of vision, so far as not to be able to count fingers; muddy iris, but not dilated; leaden-coloured sclerotic; ciliary injection; slight venous congestion.

Ophthalmoscopic examination shows adhesion of the iris at its lower margin; circular pigmentary deposit on the capsule of the lens, with a hazy centre. The optic disc is with difficulty distinguishable; it shows venous congestion, and a patch of bright white sclerotic is seen at the lower and outer part of the fundus.

He was admitted on December 18, and Mr. Hulme operated under chloroform on the 20th; upper section, one-sixth of iris removed.

December 21.—Perfectly free from pain.

December 23. — Can count fingers. Discharged from Hospital.

December 26.—Can make out No. 20 Jæger; with 6 convex, makes out No. 19 at six inches; tension healthy; remains under treatment. Iodide of potassium ter. die.

December 31.—Reads No. 14 with 6 convex.

January 4.—Makes out No. 16 without any glass, and with No. 6 makes out No. 12 Jæger.

Mr. Hulme made a few remarks to the class on the instructive points which these three cases afforded. In the first case, the immediate relief to pain and the rapid restoration to sight, with the perfect absence of any untoward symptom, was very satisfactory. But he wished the gentlemen to notice the bulging forward of the iris of the left eye, which, with the decided degree of extra tension that was present, was a suspicious sign of the recurrence of the disease in the sound eye, although the sight was at present comparatively unimpaired. This case, therefore, required close watching. In case two, the iridectomy was made outwards, the globe being small, tense, deep sunk in the orbit, with an overhanging brow; yet the results as regards vision could not be considered otherwise than good. Case three was an especially well-marked instance of the good effects of early operation, the restoration of sight in the left eye being very perfect, while the insidious form of iritis of the right eye, almost unattended to by the patient, had been slowly doing its destructive work till the attack of glaucoma supervening on the irido-choroiditis showed at last to the patient himself the necessity of again seeking relief by operative interference. Time and treatment are only now required before the permanent improvement to vision in the right eye can be fairly ascertained. Mr. Hulme always keeps the eye closed for three or four days after the operation with a broad strip of adhesive plaster transversely across the upper lid. At present he has not had to regret a cystoid cicatrix as a consequence of the incision.

SAMARITAN HOSPITAL.

CASE OF OVARIOTOMY.

(Under the care of Mr. SPENCER WELLS.)

At page 568 of our last volume we gave the result of Mr. S. Wells's whole experience of ovariotomy in the Samaritan Hospital,—namely, 57 cases, with 41 recoveries and 16 deaths. The following interesting case (with two others which will be reported in a future number) has occurred since our last report:—

Semi-Solid Ovarian Tumour—Never Tapped—Ovariotomy—Recovery.

On the 25th of August, 1864, an unmarried woman, thirty-four years of age, a book-stitcher by trade, consulted Mr. Wells about a swelling in the abdomen, which had been pronounced by Dr. Barnes to be a tumour only removable by operation. The patient was considerably emaciated. The extremities were warm, and there was no œdema nor varicosity of veins about the legs. The mammary areolæ were not deeply coloured; the follicles were large; and in the left mamma was a nodule the size of a walnut. The digestive organs were in tolerably good order, although flatulence was a troublesome symptom. Sleep was disturbed, and rheumatic pains were complained of in the limbs and shoulders. There was an occasional cough, getting worse at night, and a little expectoration of thick mucus. The breathing was shallow and tubular, especially on the right side, but there was no appreciable dulness. The pulse was 110, and the heart's tones normal. The quantity of urine was diminished, and there was occasional retention even for two days at a time. The abdomen was manifestly distended. The girth at the umbilical level was 35 inches, the distance from the umbilicus to the ensiform cartilage 8½ inches, to the pubic symphisis 7½ inches, and to each ilium 9½ inches. The upper margin of the spleen reached to the seventh or eighth rib; its lower margin could not be traced. The liver was not displaced upwards; its lower margin could not be defined. A tumour filled the abdomen, reaching up to within two inches of the ensiform cartilage, and occupying the entire abdominal cavity

with the exeeption of the right iliae region. Fluetuation was not well marked in the tumour; whieh, however, had an elastic feeling, highly suggestive of the presence of very viseid fluid. There was eonsiderable tenderness, especially over the left ilium. All over the tumour, arterial impulse was well marked. In the left iliac regions and elsewhere there was a bellows-murmur synchronous with the radial pulse. The eatamenia, which had first appeared at the age of seventeen, had always been profuse. There was no leueorrhœa. On examining per vaginam, the hymen was found to be entire. The anterior wall of the vagina, towards the right side, was somewhat depressed by a very hard rounded tumour not tender on pressure. The uterus was far back and almost out of reaeh; the eervix felt soft.

The patient said that her father had died of heart disease, and that her mother and six brothers and sisters were all alive and well. She had been born at Stepney, where she had spent her youth, and she had no idea what brought on her disease. Two years previous to Mr. Wells seeing her she had observed a swelling in the abdomen, whieh she persisted in saying had "begun aeross the ehest, and gradually grown downwards." At first the symptoms were not alarming, eonsisting of pain in the right groin and a bearing down of the uterus, with darting pain in the left breast. The tumour did not increase mueh in size, but the symptoms beeame aggravated. Palpitation, dyspnœa, burning heat in abdomen, and pain in the back, along with oeeasional attacks of dysuria, were sufficiently distressing, and oeeasionally became so urgent as to confine the patient to her bed. It was just after recovering from one of those attaeks that she came to Mr. Wells. He was on the eve of leaving town, preseribed some iron, and Dr. Ritchie saw her for him on September 8, when she eomplained of being unable to see well at night, blue flames often dancing before her eyes. The pupils were dilated, and the retinæ were very pale; the blood-vessels, however, were well injected. The patient thought that the iron was inereasing her appetite; she was told to continue it, and to take some wine daily. On September 15 she was mueh in the same state. The blood was examined mieroseopieally by Dr. Ritchie, and found not to eontain any exeess of white eorpuseles. The red ones, however, instead of running into rolls, showed a tendency to eohesion by their margins. Beeberine was ordered. On the 22nd, menstruation began. Fluetuation was felt in the right upper angle of the tumour, whieh appeared to be softening. The stomaeh was displaced upwards, and the transverse eolon eould be traced beneath the lower margin of the liver. On the 29th the abdomen was measured, and found not to have altered in the slightest from the previous measurements.

She was first admitted to the Samaritan Hospital, Oetober 8, 1864. There was still menorrhagia and dysmenorrhœa, but no clots passed. The girth was 36½ inches, the measurement from sternum to pubes 16 inches, and from ilium to ilium 18½ inehes. The right lumbar region was resonant, the left dull. The tumour was much in the same state as before. Some doubt having been expressed by different gentlemen who saw the patient, as to the nature of the tumour, Mr. Wells wrote in the Hospital case-book, on Oetober 28, as follows:—"I found a large semi-solid ovarian tumour. The uterus is pushed backwards, and the fundus flexed to the right." She was quite willing to have ovariotomy performed; but the general health not being in a very satisfactory state, she was sent to the Convalescent Institution at Walton. She returned, and was re-admitted to the Samaritan Hospital on November 25—having eeased to menstruate on the 19th. On the 28th Mr. Wells entered in the ease-book, "Uterus still pushed backwards by the tumour in front of it, whieh appears to be unattached. It is *certainly* not attaehed to the abdominal wall, and *possibly* not between uterus and bladder; but this is not certain."

Mr. Wells performed ovariotomy upon November 30—Dr. Lawrenee, R.N.; Dr. Griffith, of Peckham; and Mr. Savory, of Stoke Newington, being among the visitors. Chloroform was given by Dr. Parson. At first a small ineision was made below the umbilicus, a cyst was tapped, and two or three pints of fluid escaped; then two or three other cysts were tapped inside the first, but very little diminution in the size of the tumour could be effected. The ineision was therefore enlarged, till it extended from three inches above to six inehes below the umbilicus. There were no adhesions, but there were a few ounces of ascitic fluid in the peritoneal cavity. The pedicle was about two inches long, and as broad as three fingers. It sprang from the left side of the uterus. The operator secured it with a medium-sized elamp, which was made to fix by a screw on its arc. As he feared this might slip, he tightened a wire-rope, by means of a small écraseur, round the pediele below the clamp, and left the instrument on. Beneath this again he tied the pedicle with a strong silken ligature. Hæmorrhage was only superficial, and was easily restrained by compression. The right ovary was found to be healthy, and the wound was elosed with eight deep and six superficial sutures of silk. The operation was peculiar only in the smallness of the size of the cysts, leading to the necessity of a large incision, and from the extra precautions which were taken to keep the pediele from slipping on aceount of the eonstruetion of the clamp. The quantity of fluid colleeted after the operation was five or six quarts, and about as much was spilt. The tumour weighed about fifteen pounds.

The patient reeovered well from the chloroform, but required some opium. Six hours after operation Mr. Wells took away the eompressing apparatus of the écraseur, leaving the wire-rope on. On the second and third days the patient was very well, but required eight grains of opium on the second day; in other words, twenty minims of laudanum were injeeted eight times. On the fourth day, the wound being well united, he removed the stitches. On the seventh day the elamp was hanging by a mere shred of dead tissue; and as there was some neuralgic pain in the right hip, he removed the clamp. There was a little dyspnœa, a symptom whieh had been also previously observed. Acetate of ammonia was given freely, and apparently with benefit. The bowels acted freely on the tenth day, after an injection of warm water. There was some escape of pus for a few days from three or four of the suture traeks, but convaleseence progressed very favourably, and she left the Hospital in very good health on January 3, 1865.

METROPOLITAN FREE HOSPITAL.

RHEUMATIC BRONCHITIS.

It will be granted that in referenee to treatment that it is a matter of very great importance to study the nature of tissue changes in disease. It is more important to know that eertain thoraeic symptoms depend on rheumatism even than to diagnose the exact position of the pulmonary disease. In Dr. Laycoek's lectures, published a few years ago in this journal, mueh attention was paid to this subject. If the views of Dr. Jones be correct, we have, in certain cases of bronchitis, more rational grounds for treatment. We can treat rheumatism by general remedies, as by the iodide of potassium and alkalies, with more hope than a more or less local disease like bronchitis, by expeetorants or other empirieal measures. We may refer to some eases recorded in our Hospital Reports by Dr. Sutton a few months ago, illustrating, in a very definite manner, the relations of rheumatism to eertain local affeetions.

We must, however, keep in mind that rheumatism and ehronic bronchitis are very common diseases, and their eoexistence does not by any means imply a relation. Besides, it is a eommon and a useful praetiee to give iodide of potassium in ehronic bronchitis, espeeially with emphysema, whether it be attended by rheumatism or not. Moreover, in Dr. Jones's second case the treatment was too complieated to enable us to judge what share the iodide had in the cure. The two eases here related can, then, only be considered as a text for remarks embodying the more general experience of a Hospital Physieian on an interesting subject. We report Dr. Jones's remarks, in order that he may speak for himself.

Acute Rheumatic Bronehitis.

(Under the care of Dr. JAMES JONES.)

A. E., aged 20, was admitted into Gurney ward with acute rheumatic arthritis, sharp fever, scanty high-coloured urine eopiously depositing pink lithates. There was also much dyspnœa and eough, with all the physieal signs of capillary bronchitis throughout both lungs, but no earditie complication. The dyspnœa was generally most severe at night. She was treated with alkalies in large doses and morphia: the joints were enveloped in cotton wool. Under this treatment both the arthritic and bronchial affections steadily and *pari passu* subsided, and in three weeks she was able to leave her bed.

Chronic Rheumatic Bronchitis.

M. R., a man of middle age, was admitted an out-patient with cough, dyspnœa, and ehronic arthritic rheumatism.

There is nothing in the physical signs to distinguish his case from one of idiopathie chronic bronehitis, but the symptoms run a somewhat peeuliar eourse. The dyspnœa and cough suddenly subside, and as suddenly beeome aggravated without any apparent cause. The ehest symptoms do not appear to be in any way influenced by the state of the arthritie affeetion, but seem to run an independent course. Under the use of iodide of potassium, biearbonate of potass, compound tineture of camphor, and deeoction of senega, both the bronchial and arthritic inflammation were greatly diminished. The patient declares that no medicine he had ever before taken did so much good to his eough and breathing.

Dr. James Jones in commenting on these cases observed that the influence of chronic eonstitutional diseases in the production of bronchitis or the effect of constitutional diathesis in modifying bronehial inflammation, were subjeets of great importanee, and afford a field for inquiry which had been but little explored. As a part of this very extensive subjeet, he would direct attention to a form of bronehitis not by any means uneommon, yet requiring a special mode of treatment—the rheumatic. His attention was drawn to this form of disease by the large number of eases of chronic bronchitis in rheumatic subjects to be found amongst the out-patients, espeeially during the winter months, and the mode of treatment whieh afforded them the greatest amount of relief. In this disease clinieal Medicine demonstrates what pathology suggests—from their eomplex anatomieal constituents—that the bronchi must be liable to rheumatie inflammation. There appear to be two forms of this disease—the one purely rheumatic, of which the first case affords an example; the other of a mixed eharacter, produeed by the modifying influence of rheumatism, or the rheumatie diathesis on ordinary bronchitis exemplified by the seeond ease. The majority of eases of rheumatic bronehitis exist in the ehronic form. The physical signs give no clue to its nature, as they are identieal with the corresponding idiopathic form. But the irregularity of its course, the seeming eaprice whieh rules its exaeerbations and its subsidenees, and its amenability to those remedies whieh are found useful in relieving the arthritie rheumatism will enable us to differentiate between it and the idiopathic disease. Like arthritie rheumatism, it is often aggravated by the warmth of the bed, the dyspnœa beeoming so severe as somewhat to mimic a paroxysm of spasmodic asthma, being, like it also, relieved by a eopious expectoration. Dr. Jones has not yet had any opportunity of determining the nature of the structural lesion, or whether it differed anatomieally from that which aeeompanied the idiopathic disease. The treatment which he had found successful consisted of a combination of the alkalies and opium in the acute form, with the addition of iodide of potassium and senega in the ehronie; an underdress of flannel, and the use of a respirator, as a protection against those atmospherie ehanges whieh exercise so great an influence over rheumatism.

THE LONDON HOSPITAL.

THE BLISTER TREATMENT OF ACUTE RHEUMATISM.

(Case under the care of Dr. DAVIES.)

The Profession will welcome any new and reasonable therapeutical means in the treatment of a disease so eommon and so dire in its effects as acute rheumatism. Few diseases add so largely and in so many ways to the mass of human suffering. Although it rarely kills, it frequently incapacitates the patient for aetive life, and, besides, it is the parent of many other definite diseases—as ehorea and paralysis. In itself, or so far as the patient knows, it is a mere question of a few weeks' severe pain. Although in great distress and helpless, he is nearly eertain to get through it. And at one time, before its connexion with heart affeetion was known, it was not thought by Medical men to be a very serious disease. No treatment, however, can be worthy of the name which does not tend to keep off eardiac complication. To do this ought to be the great object of all treatment, and any plan that falls short of it, however much it may relieve the patient's suffering, is a failure. In spite of all that has been done in the treatment of this disease, we are eontinually meeting with cases of heart disease in the out-patients' department of our large Hospitals.

Now, most Physicians are agreed that one important way of preventing cardiac complication is to cure our patient quickly. To do this many plans have been urged, and the most reeent is that brought forward by Dr. Davies—viz., by free blistering. We think that by far the most important statement in his paper is—"In no ease when the heart was sound at the time of admission did any organic lesion develop itself." We may just add, however, that there are few diseases about which there are more flatly contradietory opinions as to the results of any particular method of treatment than acute rheumatism. Thus the alkaline treatment is mueh relied on by many Physicians, but at Guy's Hospital we see cases treated by Dr. Gull by a plaeebo, *e.g.*, a little extract of taraxacum and water. This Physician avers that this no-treatment, or rather no-drug treatment, is quite as good as the alkaline method. He speaks from experience, as he has earefully tried both. The patient gets well, he believes, as soon, and the heart is as seldom attacked, under one as under the other. Dr. Davies' plan seems to us to be a medium betwixt drug treatment and what we may eall treatment by time. We shall give next week particulars of two cases under the care of Dr. Greenhow, followed by remarks by that Physieian, in which it will be seen that the results were favourable. Dr. Davies' plan has been tried with sueeess in other Hospitals, and we shall shortly report a ease treated by Dr. Jeaffreson, in St. Bartholomew's. Many eases have been treated in the London Hospital since Dr. Davies' paper appeared, and we now give the following example:—

The most striking feature in Dr. Davies's method of treatment is, that it is absolutely and entirely local. In the eases he relates no drugs, except an oecasional purgative, were given. Wherever a joint was inflamed, there a blister was put on. The blisters are to be applied quite round the affe.ted limb; not on, but near to, the inflamed joint. When a large joint like the knee is affeeted, the blisters should be two inehes wide. They should be put on, he says, at "the very height of the inflammatory stage, when the loeal pains are the most severe and the eonstitutional disturbance the greatest." Poultices should be afterwards applied to prevent flow of serum. In one ease nearly 300 square inches of blisters were applied. It may be thought that, as regards pain, the remedy is worse than the disease, but the eontrary is the fact. The patients like the blister treatment, and it has never eaused strangury in any of Dr. Davies's eases, exeept to a trifling extent in one ease.

This seems at first sight a strange way of treating a blood disease like acute rheumatism, but, as Dr. Davies shows, under this treatment the urine will become neutral or even alkaline. So, then, the treatment, although local, produees that eondition of the urine whieh is generally aimed at in the eommon treatment by alkalies. Dr. Davies uses local means, as he thinks the poison loeates itself in the inflamed joints. He believes, indeed, that the blood is not loaded with the *materies morbi*, but that it is deposited in eertain tissues which have temporarily an affinity for it. Instead, then, of giving alkalies to *neutralise* the "aeid poison," he thinks we should try to *eliminate* it by blisters applied near the points where it is then aeeumulated. Whether Dr. Davies's theory of the action of his remedy be eorrect or not, the practiee seems to have been very sueeessful, and is deserving of careful trial in our Hospitals. It is purely a question of fact. Does the blister treatment shorten the duration of acute rheumatism and prevent heart eomplication? If further experienee shows that it does aeeomplish these two important objects, Dr. Davies may be congratulated on having inereased the powers of usefulness of our Profession in no small degree.

The followiug case is supplied to us by Mr. J. E. Adams, Assistant-Resident Medical Officer to the Hospital:—

Ann S., aged 25, married, was admitted November 30, for aeute rheumatism. It had begun eight days before, and was her first attack. Her health had usually been good, but lately she had been weak—*i.e.*, since her eonfinement three months before.

When admitted she had all the eonstitutional symptoms well marked. Her tongue was furred, there was great thirst, complete anorexia, she eould not sleep, her pulse was 108, and temperature 100°; seeretions acid. There was intense pain in both shoulders, both hips, in the left wrist, hand, knee, and ankle, and they were hot and swollen. There was also a very soft systolie murmur audible at the apex of the heart.

Blisters were at once applied to all the affeeted joints, ten in number; and no medicine was given beyond an opiate at night.

The next day there was very little pain in the blistered joints, but the hand was now affected. The constitutional

*

symptoms were about the same, but there was slight strangury. Two blisters were ordered for the right hand.

The next day there were no rheumatic pains, the pulse was diminished in frequency, tongue cleaning, but there was little sleep, and the appetite had not returned. The sweat was still slightly acid; urine and saliva neutral; strangury very slight.

Two days later the pulse was reduced to 80; temperature 99°. She had passed a comfortable night, and the appetite was returning.

From this time she improved steadily (having only once a little pain in the left elbow, but no constitutional disturbance) and left the Hospital on December 20, perfectly well, the condition of the heart being the same as on admission.

Medical Times and Gazette.

SATURDAY, JANUARY 7.

ANNUS MEDICUS, 1864.

Last week we said a few words on the arrangements we had made on behalf of our readers this year; now we proceed to take a brief glance at the principal Professional events of the year which has just closed. And first we offer our hearty thanks to the many valued contributors and correspondents who have aided and lightened our labours, and enabled us to give our subscribers two volumes of no slight or passing value.

Of our own work we will not speak; we have endeavoured always to uphold the dignity and honour of the Profession, and to advocate its best interests, and we trust that we have laboured not unacceptably, nor without success. But though we say no more than this of our editorial work, it is the merest justice to own that we feel some pride and satisfaction in pointing to the valuable matter the labours of others have enabled us to publish. Such lectures as those of Drs. Simpson, Garrod, Priestley, and Harley, and of Messrs. Paget, Fergusson, Helmholtz, and Huxley, and essays like those of Peacock, Hare, Haughton, Althaus, Laycock, Wharton Jones, John Wood, and others, form, together with the "Medical History of England," the discussion on "Hospital Mortality," and other communications contained in our columns, volumes of no mere temporary interest and worth, but such as, we believe, will be judged a valuable and solid addition to Medical literature.

One of the most, if not the most, prominent topics of Professional interest during the year has been the management, or rather the mismanagement, of the Army Medical Services. This subject has been so frequently and fully treated of in our pages, and is so well understood by the Profession, that there is no need to go into details here. It is sufficient to state that by the Royal Warrant of 1858, by admission into the service through a well-conducted, special competitive examination, and under the able direction of the late Mr. Alexander, the British Army Medical Service was rendered highly popular, and as highly efficient. But this desirable state of things having been attained, the Horse Guards then, for some mysterious reasons, adopted, and have persistently maintained, towards it a course of conduct apparently calculated, and certainly most effectually tending, to utterly destroy it. They took upon themselves to annul the best provisions of the Royal Warrant, and by means of broken faith, and ill-kept promises, and the constant infliction of indignities, slights, and general and petty annoyances of every kind, they contrived to excite in the service an amount of disgust and discontent unparalleled for degree and extent, and in the Profession at large such a feeling that it became impossible to recruit the service, though its portals were enlarged to admit the waifs and strays of the schools. The authorities were at last driven to tout for the services of the unsuccessful hacks of the Profession as "Acting Assistant-Surgeons." The terms of engagement offered were such as no one would venture to propose to a respectable servant, such, viz., as discharge at the pleasure of the Director-General, without notice or compensation; but it is said that the Director-General received 300 applications: very few indeed have, however, been gazetted as accepted. This deplorable condition of the service was warmly and actively noticed by the Medical Press and the Profession, and began to attract the attention of Parliament and the public, and it seemed probable that a more just, generous, and gentlemanly course of conduct would be forced on the Horse Guards; but unfortunately the probability of improvement was mistaken for a certainty, and the younger members of the Profession were induced to enter for the last examination in such increased number as excited much clapping of the wings and defiant crowing at head-quarters; and the day of amendment is postponed. That it must come, however, we do not doubt; for though military authorities may complacently declare themselves satisfied with third-class men, we very much doubt whether John Bull will be content to trust the health of his expensive army to such hands. If some large and liberal measure of reform be not soon granted, the gentlemen who lately entered the service will have only themselves to thank for the delay; and, if they are worth anything, it will not be long ere they bitterly rue having "taken the shilling," for they will find themselves only tolerated by their "brother officers" instead of having definite rank and position as officers and gentlemen; they will get scant pay and more scanty allowances; almost no leave when they have health to enjoy it, and very insufficient and grudgingly-granted sick-leave, however much they may need it; and they will be doomed to constant exile, while the home work is done by the Director-General's hack Assistant-Surgeons.

Why the Horse Guards should thus treat the Medical Department is inexplicable. Was it found that the Medical officers, when first-class men, were too superior in general knowledge and intellectual training to the "combatant" officers? Did the Horse Guards find them too enlightened in their views on military hygiene, and all matters bearing on the health and physical well-being of the soldiers, and too firm and importunate in maintaining such views against leather-stock and pipe-clay colonels? If we wrong the military authorities by suggesting such grounds for their treatment of Medical officers, the fault is theirs; for while they put forth only such an absurd and groundless reason as that the Medical officers aim at military command, we are forced to suppose that their real motives are such as they are ashamed and unwilling to avow. Some slight concessions have been wrung from the authorities, as that the orderly officer for the day, as well as a Medical officer, should be present at the branding of soldiers.

The Indian Medical Service, after a lengthened experience of neglect and ill-treatment, seems to be entering on a brighter era. Our readers will remember that towards the end of the last session of Parliament the Secretary of State for India brought in a bill giving him the power of appointing Medical officers to the Indian army at his will and pleasure, alleging, as a reason, that the competitive system had broken down, for he could not get anything like the number of officers he required; and, at the same time, he declared, as an inducement to trust

him, that had he sent out a new warrant which would remove all discontent and make the service popular. Thanks to the efforts of the press, and to Mr. Pope Hennessy, the Bill was defeated. By-and-by the terms of the Warrant became known, and it is difficult to say whether they excited most astonishment or indignation, for it appeared that Sir Charles Wood's cure for discontent was an universal lowering of the pay of the Medical officers. The whole press of India agreed in denouncing the Warrant in the strongest terms, and the Governor-General suspended its operation. It is hard to conceive how Sir C. Wood could have for a moment really imagined that it could be acceptable. He has, however, had the good grace and good sense to follow it by another new Warrant, the terms of which appear really liberal and satisfactory, and which will, if as good as they at first sight appear, render the Indian Medical Service attractive and efficient. We are obliged to speak of it thus conditionally, and to await the verdict of India on it, for, after what preceded it, we cannot but think of the favourite Parliamentary quotation,—"*Timeo Danaos, et dona ferentes.*" We are, however, at present inclined to think that Sir Charles Wood will not be disappointed in the hope that the last new Warrant, if faithfully carried out, will "diffuse a spirit of satisfaction and contentment among the officers now in the service, and secure for the future a certain supply of Medical officers of good social position, liberal education, and Professional ability for Her Majesty's Service in India."

In Parliament no Act was passed directly affecting the Profession. The public voice, indeed, accuses it of having done very little for good or evil, but get through the Session; but, at any rate, one Act of considerable value, and making a decided advance in intelligent legislation for the public health, was passed, viz., "The Contagious Diseases Act."

That such a Bill was passed gives life and strength to the hope that Parliament may next Session see its way to the enactment of some measure to protect the public against the vile quacks of the "Henery" and "Scott" species. That they can be quite silenced is, we suppose, impossible; but surely it might be made illegal for them to use the Post-office to scatter abroad their filthy pamphlets; and those dens of pruriency and impurity, the "Kahn Museum" and the like, with their "lectures," might be closed. Is it too much to hope that the public press, which boasts, not altogether without reason, of its disinterestedness, purity, and power, may soon be awakened to the scandal and disgrace of making itself the vehicle of the disgusting and lying advertisements of these harpies? The *Times* and some few other journals are without reproach in this matter; would that the daily and weekly press, as a body, would follow their example!

In the House of Commons a charge of inhumanity towards one of his patients was brought against Dr. Flynn, of the Clonmel Lunatic Asylum; but he was eloquently and successfully defended by Sir R. Peel, who declared, *inter alia*, that "the Lunatic Asylums of Ireland were better conducted than any Asylums in other parts of the world, and the Clonmel Asylum, under the superintendence of Dr. Flynn, was a model institution."

In our own little Parliament, as in that of the nation, the members were most diligent in helping one another to do—nothing, but talk; the cause for passing a Session thus being, perhaps, the same for both—their age. The one was in its first, the other in its second childhood. This, not expected at one time to live through the Session, and, at any rate, drawing near the close of its "natural life," was, naturally, garrulous and prosy—"rest and be thankful" its motto; that, meeting for its first Session, as naturally chattered and prattled away, heedless of the flight of time. Had it really been the first meeting of the Medical Council, we might be well content with the results; but for the work of the first Session of its second Parliament, so to speak, of the sixth year of its existence, why—the less said the better. We can hardly hope that that much-enduring class of men, the public reporters, admitted for the first time to its debates, carried away any very high idea of its dignity or usefulness. We much fear their most abiding impression would be one of loquacity rather than of eloquence.

Our new Parliament contains, however, some new and able Members, and the flux of talk this Session may lessen the verbal pressure for the future; so we still will hope for acts as well as words next Session. We are sure that Dr. Burrows is no lover of a merely expectant mode of treatment; and we trust that he will succeed in infusing some of his own energy and business habits into the body over which he so ably presides.

The British Pharmacopœia was published, and we have heard of its being used.

In the Court of the Queen's Bench, Mr. Sargeant, whose name had been struck out of the Medical Register because, "owing to a change of residence," he had not replied within six months to the usual annual letter from the Registrar, obtained a rule absolute for a Mandamus to the General Council of Medical Registration to hear and determine on his application to be registered *de novo*.

Vice-Chancellor Sir J. Stuart directed proposals to be laid before him at Chambers for a scheme for carrying into effect the trusts of the late Mr. A. Morley's will, as to the sum of £50,000 bequeathed by him for founding a convalescent Hospital in connection with St. George's Hospital. We believe that land has been bought for this purpose.

The Lord Chancellor has finally decided, on appeal, that the Donation Governors of St. Thomas's Hospital have the power of selecting the new site for that charity. The choice of the Stangate site therefore holds good.

In the Criminal Courts several members of the Profession have appeared as defendants; but we are happy in having to record only one very flagrant instance of injustice by jury; we refer to the case of Smithyman *v.* Wilson, *vide* vol. ii., p. 198—an action for negligence and want of skill in the treatment of dislocation of the shoulder. The jury gave a verdict for the plaintiff, with £50 damages. The Judge afterwards remarked—"There was clearly upon the evidence no want of skill, and that, I think, the jury may be taken to have found;" but "though there was no want of skill, and the shoulder had been in the first instance properly set, there might have been possibly some little inattention subsequently." For which possibly "little inattention" Mr. Wilson was thus most heavily punished.

In most, if not all, of the other cases the Profession was protected by the good sense of the jury; and we must add that in very few, if in any, would an action have been brought but for some indiscretion, to use a very mild term, and want of true brotherly feeling on the part of members of our Profession. This is a deplorable admission, but such cases as Regina *v.* Goss, Wright *v.* Davies, and Pryce *v.* Bowen, are glaring proofs of its truth. While such things happen, and not exceptionally, does the boast of brotherhood deserve to be estimated as anything more than hypocrisy—the homage paid to a virtue conspicuous among us only by its absence?

Mr. Wilkins was indicted by the Commissioners of Lunacy for an infringement of the lunacy laws, by taking into his house without a license a single lunatic patient; there was no disputing the fact that he had, though we believe unwittingly, sinned against the law, and he was found guilty and bound over to come up later for judgment. We think that under the circumstances the infliction of a mere nominal fine would have met all the requirements of the case, but the judge before whom he finally appeared fined him £50; a druggist who was convicted of having assumed the title of and practised as a Surgeon, was fined by a magistrate one shilling, "to vindicate the law" his worship said. We do not know whether the difference in the amount of fine was due to a Judge's higher appreciation of the majesty of the law than to a Magistrate's, or to the higher position of the defendant in Mr. Wilkins' instance; if the latter, we could

have very well borne to do without such a compliment. At any rate, the Profession will in future remember better the lunacy laws.

The election of Fellows into the Council of the College of Surgeons caused no little excitement, and, as has been the case each year of late, great efforts were made to put in new men. Considerable reward has attended the efforts of the Fellows to break up the old routine system, but they will never meet with more than partial success till the provincial Fellows obtain the right of voting by proxy. Till then the election will remain *de facto* in the hands of the London Hospital Surgeons, and provincial Surgeons, and men of *only* a high scientific reputation, like Messrs. Turner and Gulliver, will have hardly any chance of success. The daring spirit of innovation, the tendency to intrude on the calm repose of officialism and routine, to meddle with the sanctities of time-honoured customs, and to stir up solemn and venerable stagnancies have troubled even the still waters of a Fellowship election at the sister College in Pall-mall. The election of Members to the dignity of the Fellowship has hitherto been a sacred mystery; why some most able and worthy Physicians were year after year passed over, and why others were chosen, was among the things that no Fellow, or, at least, no Member, could understand, and few dared to question. The only clear and certain claim to promotion was apparently the possession of an Oxford or Cambridge degree. But this year, it is rumoured, some "greatly daring" Fellow ventured to inquire why some Member or Members had not been recommended for the Fellowship? and so much dissatisfaction was felt with the nomination-list of the Council, that it was proposed to black-ball all the nominees, and half of them actually were black-balled; a result much to be regretted, for it seems to cast a special slur on the sufferers, all of whom were well worthy of the honour of the Fellowship; it would have been much better, and have had a less personal aspect, to have black-balled the entire list. But the dissentient Fellows were novices in the work of reform, and will doubtless manage better next time. That they will have another opportunity is pretty certain, for we understand that the Council, having been requested by the College to consider whether some better mode of electing Fellows could be devised, have reported in the negative—they think no change desirable. We venture to differ from them entirely: the present mode of election is certainly far from satisfactory. No well-wisher to the College or the Profession would wish the Fellowship made too common or too easy of attainment; but the College has, by its institution of the new order of Licentiates, considerably lowered the public value of the Membership, and ought, we think, in justice to the Members, to admit in a more generous and just spirit their claims to the Fellowship.

A Committee of the College is engaged in inquiring into the condition of the Army and Navy Medical Services. Their report, as well as that of the Committee on Leprosy, which has been sitting for a considerable time, are eagerly looked for by the Profession.

When we turn from considering the active work of the Profession during the year to look down the, alas! lengthy, list of "names once heard, but heard no more," the feeling of sorrow and the sense of loss are excited in very different degrees and extent by the various names that appear. Some, as Drs. Este, Carlyon, Boott, and Headlam, had been able, after long lives of successful labour, to retire from the toils and anxieties of practice, and enjoy a few years of rest and honoured old age before departing hence; and others, as Dr. Osborne, and Messrs. Smyly and Stone, had lived not far short of the three score and ten years of the Psalmist; had lived for "use, and name, and fame;" had had time to gather the harvest, and to "eat the labour of their hands." We grieve for the loss of wisdom, experience, and faithful counsel, and for the breaking up of old friendships; but all these men had had their reward. Others, like Mr. Langley, had scarcely entered into the battle ere it was over for them; for such the sorrow cannot be wide-spread, for their worth and promise, however great, were known to but few. The death of such men as Hardwick, Kirkes, M'Dowell, Miller, Price, and others of like age, excite much more widely-spread and deeper feelings of sorrow and sympathy. In the prime of life, and the full vigour of intellect, having borne the heat and burden of the day, having nobly fought their way to the front, their lives already rich in performance as well as in promise, they actually grasped victory and success, but had no time to taste of their sweets. Of some, the names will live especially for the honour and glory which surrounded their deaths. Who amongst us will ever forget Herbert Llewellyn, the hero of the *Alabama?* His school has honoured itself by erecting memorials to his fame; but his "*monumentum ære perennius*" is the record of his heroism, which will live in the memories of the Profession, and will make his name a household word as long as British Surgery lasts. Not less honourable, though less dramatic, were the deaths of Clarke, Milroy, Gallagher, and their comrades who fell in the field of pestilence in the Bermudas. We at home are, however, touched most acutely, perhaps, when men in civil practice, like ourselves, endowed with every mental qualification for eminence, and rapidly conquering success, suddenly fall from some bodily weakness. We are shocked and surprised, as well as grieved, for they were running only the same daily risks that we ourselves encounter; and we are too apt to forget that for success in any arduous profession, physical strength is as necessary as intellectual power. Of such men lost to us in the past year, the most prominent in London were Dr. Kirkes and Mr. Price.

Mr. Price, gifted with all the qualities that are needed to make a great Surgeon, popular and singularly winning in manner, full of energy, and of a most happy and sanguine disposition, had already acquired a brilliant reputation as an operator, when, at the early age of twenty-eight, he was forced by failing health to resign all hopes of a London career, and, after a long and painful illness, borne with unmurmuring cheerfulness, he died, in November last, at Ventnor. Dr. Kirkes was less brilliantly endowed by Nature, but when, after an illness of less than a week, he was lost to the Profession, by his excellent abilities, his untiring industry and perseverance, and the knowledge and learning that made him equal to every opportunity, he had raised himself to a position rarely indeed attained at his age. Only forty-one when he died, he was Physician to St. Bartholomew's, and joint Lecturer on Medicine in the school of that great Hospital; and he has left behind him works which will long connect his name with the advance of Medical science. Remarkably quiet, unpretending, and gentle of demeanour, and modest in his estimation of his own value, he was of sterling worth and truth, and leaves a pregnant example of a life of rare purity and unswerving high purpose. "*Multis ille bonis flebilis occidit.*" As was said of Mr. Price in the memoir of him which appeared in our pages, it can be most truly said of Dr. Kirkes, that he left "on his part not an enemy behind him, and for friends all who knew him."

THE WEEK.

THE "MEDICAL TIMES AND GAZETTE" FOR THE PRESENT YEAR.

Whilst sketching our programme last week, we omitted to state, in the hurry of composition, that the Medical History of England, by Dr. B. W. Richardson, would be continued during the present year. Our readers will be taken in turn to Bath, Oxford, Nottingham, and Leamington, so we give those good old towns, and all in them whom it may concern, fair warning—

> "If there's a hole in a' their coats,
> We rede them tent it:
> A chield's amang them takin' notes,
> And faith he'll prent it."

We have also the gratification of announcing that during the present year, in addition to the contributions already promised,

Clinical Lectures and Original Papers by the following distinguished Physicians and Surgeons will appear in our columns:—Professor J. Y. Simpson, of Edinburgh; Professor Paget, of St. Bartholomew's; Mr. John Adams, of the London Hospital; and Professors Lionel Beale and Priestley, of King's College.

THE PATHOLOGICAL SOCIETY.

The Pathological Society is the best answer to the men, and there are many such amongst us, who disbelieve in the value of conjoined efforts in the furtherance of science. No doubt the great strides in the progress of all sciences have been the result of individual and unaided work; but individual effort is stimulated and encouraged by a knowledge that others are working in the same direction, under the same auspices, and that every result, by whomsoever gained, will be made public to the whole scientific world without favour or delay. This is the assurance the Pathological Society offers to its members, and this is the secret of its success. Every fact, by whomsoever contributed, finds there a due appreciation, and a specimen shown or a case related before the Society can never be lost or forgotten.

The Report of the past year shows a condition of things of which the founders of the Society and all its officers, past and present, may well be proud. The last Report stated that "the Society was at that moment constituted by a larger number of members than at any previous period of its existence;" but its flourishing condition at that time was only the augury of its present state, for the present Report tells us "that more new members have joined in the past session than in any other of which a record has been preserved;" and not only is the number of names enrolled increased, but the meetings are larger and the specimens exhibited more numerous than at any former period. The finances of the Society seem to be wisely managed, for notwithstanding that the Royal Medical and Chirurgical Society have raised their rent, and the expense of a yearly volume such as the *Transactions* is no small sum, they still have a balance in hand, and by investing life subscriptions and composition fees they have become possessors of funded property to the amount of £308.

We have pointed out what we believe to be one great secret of the success of the Pathological Society—viz., that each man who works for it is certain that his work done will meet with fair appreciation and reward—that it will not be burked by committees or "forgotten" by secretaries. But there is another reason for its striking success which will be acknowledged by every one who has attended its meetings—we refer to the singular good fortune which has attended it in the choice of its officers. We need not speak of its past Presidents, numbering as it does such names as those of Watson, Williams, Fergusson, and other leaders of the Profession; but we feel that more than a passing tribute is due to the President and Medical Secretary who have just retired and to the Surgical Secretary who continues in office. Mr. Prescott Hewett's tenure of the President's chair will not soon be forgotten by the Fellows of the Society. Seldom has the occupation of office been signalised by more talent, extensive knowledge, diligent devotion to the interests of the Society, or by more urbanity and kindness. In quitting the chair, Mr. Hewett, on the part of himself and Mr. T. Holmes, the Surgical Secretary, presented the Society with all that was wanting to give full value to its publications—a complete index to all the volumes of *Transactions*, the labour being contributed by Mr. Holmes, the expense by Mr. Hewett. We congratulate the Society on the most valuable gift it has received, and every student of pathological science, who will find his labours lightened by Messrs. Hewitt and Holmes' liberality. The retiring Medical Secretary, Dr. Bristowe, has so thoroughly identified himself with the work of the Society in past years, and his co-operation and individual labour are of such high value, that we most heartily second the hope expressed in the Report, "that, although they have lost Dr. Bristowe's services as Secretary, the Society may still have his co-operation in other offices." We strongly recommend all who are interested in the real progress of Medicine, who have grasped the truth that facts are of everlasting value, whilst theories are only valuable in proportion as they are built on facts, to join the Pathological Society. Under its able new President, Dr. Peacock, it is, we may safely prophecy, entering on a new stage, in which it will even outstrip its former progress—extraordinary as that has been.

THE CASE OF TIMOTHY DALEY.

It is a matter of no small congratulation that the Poor-law Board have been requested by the guardians of the Holborn Union to institute an official investigation into the real merits of this case. Never was one in which, for the sake both of the individual actors and of the public and Profession, a full and impartial inquiry was more needed. If Mr. Norton, by any wilful neglect, either directly or indirectly, accelerated the death of Daley, by all means let the blame be laid where it is due. Nothing can extenuate inhumanity, and not one word should be urged to mitigate its penalties. But whilst there really exists no clear or convincing proof that Mr. Norton is guilty, we think there is good ground to complain of the unhesitating tone in which he has been condemned by the daily and weekly press. The article from the *Spectator*, which was copied in the *Times* of Tuesday last, would have done credit to the author of "Never too late to Mend" and "Hard Cash." We have rarely seen in any newspaper of respectability, even in a "sensation" leader, such a total disregard of evidence, such unsupported assertion, and such an evident and strong bias against an accused person. The writer starts by assuming the entire truth of the story of the prosecution and the utter falsity of that of the defence. He has recourse to all sorts of expedients to heighten the picture of the poor man's sufferings, and the popular indignation against Mr. Norton. According to the *Spectator*, Daley was not only powerful and muscular, but of *handsome* form. Mr. Norton's daily visit and examination of the bed sores on alternate days, to which he deposed, are construed into "a glance" from the Surgeon "four days in seven;" and the public are twice informed that a pauper patient dying with bed sores is as much killed by the parish Surgeon as though the sores had been made by deliberate blows. As we stated last week, we do not constitute ourselves advocates of Mr. Norton. Let his conduct be thoroughly sifted, and let him be judged by the result. But we do protest against a Surgeon's character being scribbled away by an irresponsible writer, who probably never saw nor heard of a bed sore before he "got up" his article, and who knows nothing of the difficulties and crosses which beset a Poor-law Surgeon in the discharge of his duties. We await the verdict of the Poor-law Board, which we have no doubt will be an impartial one; but in the meanwhile we reproduce Mr. Norton's own statement of the case, published in the *Times* of Saturday, only adding that if he can substantiate what he alleges, he will go very far to clear his character of all suspicion of inhumanity or neglect of duty:—

"*To the Editor of The Times.*

"Sir,—As the Medical Officer of the Holborn Union, will you permit me to say a few words respecting the inquiry into causes which led to the death of Timothy Daley, and the comments upon the inquest which appeared in your paper of Thursday last? I do not for a moment wish this letter to be considered in the light of a defence; that I reserve for the inquiry which will be instituted by the Poor-law Board.

"I am, however, anxious to vindicate my character and Professional reputation to some extent by pointing out certain facts of the case which have either not been reported or have been misrepresented by the witnesses examined. It may be asked why if I had evidence which could disprove the allega-

tions brought against me I did not bring it forward at the inquiry? To this I reply that up to the time of the inquest I had no idea that it would take the form of what I may almost term 'a prosecution.' I had, therefore, no professional adviser to cope with the clever Practitioner engaged against me (although I am indebted to Mr. James for the assistance he rendered me). Moreover, I was told the evidence of two witnesses I was anxious to call was not needed.

"1. Daley is described as being at the time he was admitted into the Holborn Union a strong, muscular man, whereas the evidence of Mr. Lathbury, the Surgeon who saw him on the two days previous to his admittance, proves that he was in a low, weak state, thin and emaciated, and in a condition in which bed sores were likely to occur.

"2. With regard to the length of the bed, it cannot surely be maintained that a man of 5ft. 9in. in height could be cramped in a bed 6ft. long.

"3. With respect to changing the poultices; three witnesses were examined (and two more were present, but not called) who distinctly asserted that the poultices were changed never less than twice, and more frequently three times a-day. As to my Professional care of Daley, the testimony of the nurses proved that I saw him every day, and examined the sores every two or three days, which was as often as I thought necessary, the painful state of his joints causing him extreme agony.

"4. As to the bed sores, in contradiction to Mr. Lowne's assertion that they ought not to have occurred, Dr. Andrews stated, in reply to Mr. James, that if a patient, in addition to rheumatic fever, was in a low, weak, typhoid state, in all probability it would be totally impossible to prevent bed sores.

"5. The man was in the Infirmary six weeks, yet he made no complaint whatever, although a committee visits the wards every week for the express purpose of seeing that the patients receive proper attention and treatment.

"6. A point is made against me on account of my not having signed the dietary cards. Now, these cards were introduced by me to enable the patients to ascertain that they were receiving the diet ordered, poor people being generally suspicious of the treatment they receive in workhouses. These tickets were written by my authority, and when new ones were needed they were copied by a clerk, I invariably satisfying myself that they were correct. There are no regulations concerning them.

"I trust you will kindly give insertion to this letter, which I venture to think does away with much that has been advanced against me. I have been in practice fourteen years, ten of which I have been Medical officer to the Holborn Union Workhouse, during which period I have had many thousands of patients under my charge, yet no complaints have been made against me. I feel it, therefore, a grievous hardship that a charge should be brought against me of which I am entirely innocent.

"Fortunately, the verdict of a coroner's jury does not settle the matter; I have a court of appeal, and I trust you will give the same publicity to the investigation which will be instituted by the Poor-law Board as you have to the inquiry which took place on Tuesday last.

"I remain, yours obediently, "JOHN NORTON."

FROM ABROAD.—RETENTION OF URINE FROM ATONY—ETHER AS AN ANÆSTHETIC—VACCINATION FROM THE COW.

M. FOUCHER detailed to the Academy of Medicine the results of his application of pulverised fluids in the treatment of retention of urine from inertia of the bladder and of vesical catarrh. Such inertia or atony of the bladder is, he observes, a frequent, and sometimes the sole, cause of retention of urine in the aged. It is true that there may be also prostatic obstruction, but this in many cases would be insufficient to induce retention unless atony were also present. When atony forms the chief or sole cause of retention, the urine, on the catheter being passed, flows out unaccompanied by any jet. When the retention is due to the obstruction at the neck of the bladder alone, a jet ensues upon catheterism. Where the bladder is imperfectly emptied in consequence of inertia of the organ, vesical catarrh is a common occurrence, and this, when considerable, adds to the atony of the organ. The two conditions are, in fact, intimately connected with each other, reciprocally influencing one another, each alternately playing the part of cause and effect. As a means of restoring the contractile power to the walls of the bladder and modifying the chronic inflammatory action of its lining, M. Foucher strongly recommends the "capillary intravesical douche," and the injection of "pulverised liquids." The first of these is effected by means of a catheter with a capillary orifice, and to which is attached one of Luer's pulverizators. A small but energetic jet strikes against the walls of the bladder, inducing a marked sensation of cold. In simple inertia this will restore the contractile powers of the organ. But when vesical catarrh, in its varied degrees, is present, a wider diffusion of pulverised liquids is required, for which purpose M. Foucher has had a double catheter specially constructed, which, attached to Luer's pulverizator, effectually irrigates the whole interior of the organ. Either simple water, tar water, infusion of buchu, or other substances, according to the exigency of the case, may be employed, the operation causing no pain, but merely a sense of cold in the hypogastric region. Its success is prompt and satisfactory, some instances of this being adduced in the paper.

M. Regnauld, communicating to the Academy an account of the means of obtaining sulphuric ether in a state of complete chemical purity, questioned M. Gosselin upon the results of any trials he may have made with this pure ether. M. Gosselin replied that he had felt little disposed to abandon the use of chloroform in favour of ordinary sulphuric ether, which induces so much agitation during its administration as to render the production of anæsthesia by its agency difficult. M. Regnauld, however, having supplied him with some ether chemically pure—that is, containing no alcohol,—after trying experiments with it on animals, he administered it to seventeen patients about to undergo operations. He found that the anæsthetic effects of this ether are far more rapidly produced than is the case with ordinary ether, while they are also more certain. There is no stage of agitation, and only from four to eight minutes are required to produce absolute insensibility. In these respects M. Gosselin considers that this chemically pure ether occupies the same rank as chloroform, and that it should therefore be preferred to that agent, as no fatal result has ever occurred from its employment even in its impure condition. (The Surgeons of Lyons have long since renounced chloroform in favour of ether.)

Dr. Lanois, a young Physician of enthusiastic temperament, having listened to the recital at the Lyons Congress of the Neapolitan mode of vaccination, repaired to Naples to thoroughly study the subject under M. Negri, the successor of Galbiati, who has now the management of the enterprise in that city. Highly satisfied with what he observed, he brought back with him to France a heifer vaccinated with all the precaution which M. Negri deemed necessary. The cow, firmly tied, is thrown down on its left side, and its body so flexed as to render the abdominal region supple. A portion of the surface of the right inguinal and hypogastric region, from one to two square decimetres in size, is carefully shaved, and then, by means of a strong lancet with cutting edges and a rounded point, slight scarifications, from six to ten millimetres in length and ten to fifteen millimetres from each other, are traced in a parallel line. Other lines of scarifications are also made, so that there may be about sixty or seventy ranged over the entire surface. They are not made deep, and within the lips of each is deposited the vaccine virus collected on the flat side of a knife from the pustule already produced on another cow. The inguinal region is deemed the most fitting place for the vaccination as the epidermis is very thin there and the skin is mobile, while the part is protected from dirt, friction, and atmospheric influence. From the heifer brought over by M. Lanois, children and another heifer were vaccinated at Lyons, the pustules whence the virus was taken being at their fourth day only since inoculation. Indeed, M. Negri vaccinates from pustules only seventy-two hours old; and he does not open the pustule in the ordinary way from the exterior, but entirely removes it, and even a portion of the dermis situated below it.

It is of great importance that this portion of the dermis should be well scraped away from the excised pustule, so as to expose the virus in its purest condition. To do this effectually requires practice; but the efficacy of the vaccination much depends upon it. All the vaccinations made at Lyons were as successful as those observed at Naples. In a paper which M. Lanois has laid before the Academy, he states that the results of the observations which he made at Naples exhibit the following advantages of the practice:—The possibility of a constant transmission of virus from cow to cow, at all seasons of the year, in sufficient quantities to meet the demands of large establishments; the regeneration and not the impoverishment of the virus by this transmission; the easy practice of the vaccinations; the innocuousness of the course of the eruption; and the certainty of the prophylaxis.

Dr. Philippeaux, from whose paper in No. 51 of the *Gazette Hebdomadaire* we have derived some of the above facts, in reply to the question why this practice, if so good, has not become generalised during half a century, points out that vested interests have stood in its way. Thus, while Ferdinand had his own children vaccinated from the cow, he compelled his subjects to have theirs vaccinated in the ordinary mode at the national establishments; and even members of the Vaccine Committee, who opposed the introduction of the vaccination from the cow, resorted to it for their own relatives. Then, again, it is a more expensive process than the ordinary one, for many heifers have to be kept on hand, so that one may be vaccinated every eight or ten days. In order to acquire the necessary facility and a complete knowledge of this mode of vaccinating, it is necessary that the Practitioner should, like M. Negri, make it a special occupation.

REPORT ON CHEAP WINE.—NO. VIII.

(By our Special Empirical Commissioner.)

(Continued from page 682, Vol. II., 1864.)

Italian, Greek, Hungarian, and Austrian Wines.

As this article may fall into the hands of readers who have not seen any of the foregoing ones, I take the liberty of repeating in these lines the basis of my argument.

The wines in commonest use—that is, port and sherry—are fortified by the addition of large doses of spirit. This not only makes them less wholesome, but it also makes them dear, because to be drinkable with pleasure and safety, they must be kept many years in wood and bottle. Moreover, all sorts of port and sherry have become scarce, and have risen enormously in price. Again, the town is flooded with a lot of the fictitious stuff, chiefly manufactured at Hambro', which is made to look like sherry or port, but which is not *wine* at all, but spirits and water only, coloured and flavoured. If cheapness be an object, or if disguised spirits be really preferred to wine, various compounds of spirits, fruit, sugar, and water, hot or cold, can be prepared to suit every purse and every palate, and to suit common sense also; for it is not common sense to tickle the ear with the name of sherry, and the eye with the sight of a wine-decanter, whilst the liquid is but spirits in disguise; still less to pay even eighteenpence for a bottle of Hambro' sherry, whilst the same amount of spirit may be had in its native purity for eightpence. The hypocrisy of every-day life, too, is much to be wondered at which palms off adulterated spirits as sherry because cheap, but sneers at pure wine if that be cheap. Defrauded, too, by long wars and mischievous legislation, of access to the pure, cheap, and abundant wines of our neighbour, France, our population has been bred up to estimate the brandied wines of Spain and Portugal as the true types, and to look on wine as a dram to be sipped, instead of a beverage to be drank. Hence, natural wine was, before the increased intercourse with France of the last ten years, and the reduction of the duty, a thing quite unknown to the mass of the people. "Claret" and "Hock" were introduced at the tables of the rich as great luxuries; but they were also often used by the vulgar rich in a way which showed that they were part of the apparatus of ostentation and not of enjoyment, just like the heavy silver dishes and hired flunkeys. These delicate wines were often sipped with sweetmeats; they were chilled and even *iced*, instead of being gently warmed; and then of course were condemned as sour, cold, and poor, by persons who had no knowledge of wine-flavour as distinct from alcoholic strength, and who, perhaps, would not have been able to taste it even had they known of its existence. Five years ago a friend of mine died, and as I knew that he had some good wine, I attended the sale of his effects at Reed's, in Great Marlborough-street. There was some very indifferent sherry which he had lately bought, and which the Israelites who haunt auction-rooms bought up greedily at 10s. a dozen more than he gave for it; there was also some superb claret worth 84s. per dozen. It was amusing to see the wry faces which these Jew brokers made at this, and how they spat it out of their mouths; not one of them bid for it, whilst the wine-merchant who had supplied it, and I, bought it in alternate lots at 30s.

People cannot be expected to change the habits of their lives in a hurry, nor yet all at once to relish pure, natural, unbrandied wine after having for years reviled it as sour, cold, and poor. There is a good deal of the *subjective*, however, in our habits of gustation. People will say they relish, and will pretend to relish, and at last may end by really liking, almost anything if they think it a mark of fashion to do so. We want to have people taught what wine really is, how to taste it, and how to discriminate pure wine flavour from the hot fumes of disguised spirits, and then the relish will follow the knowledge.

In describing the cheap wines of Bordeaux and Burgundy I was treading on well-known ground. They have long been familiar to the more refined part of our population. Up to the time of the vine disease they were produced in large quantities; the *brands* or qualities are well known, and any man who fixes what price he likes to give can readily suit himself by applying to almost any wine merchant. Not so with the wines of Italy, Greece, Hungary, and Austria. They have as yet been sent in no great quantity, they are little known even to wine merchants, and are kept in stock by but few. My knowledge of Italian wines is entirely derived from specimens furnished by Messrs. H. B. Fearon, 94, Holborn-hill. Greek wines I only know through Mr. Denman, of Abchurch-lane, City, and Piccadilly. The Hungarian have rather a wider reputation, for I have often met with it at the houses of patients, who have procured them from Mr. Denman, or from Mr. F. Andres, 12, Mark-lane, or Max Gregor, 7, Mincing-lane, or M. Azémar, 40, Mark-lane, or some few others whose names have escaped me.

White Capri (*Vino Bianco di Capri*) is a wine that I have referred to before. It was recommended to me early in 1863 by a well-known Physician, and I procured some from Fearons'; afterwards I got some of the same wine at almost double the price from E. Brun, of Dean-street, and as this went bad I dropped it. I have, however, lately again procured some from Fearons', who have continued to sell it, and find no fault with its power of keeping. It is, as I said before, a remarkably useful wine. Its percentage of proof spirit is 21·8. It is of a light cowslip colour; fragrant, not acid, not rough; brisk, as if slightly ærated; has nothing in it to offend any one; not hot, nor yet cold, and seems capitally adapted for young innocent people at their Christmas merrymaking. With such wine at sixteenpence per bottle there cannot be the slightest excuse for poisoning poor unsuspecting boys and girls with Hambro' sherry.

Besides this, I drank in the summer of 1863 a red *Montepuleiano*, from Tuscany, at 14s. per dozen, and noted it as astringent, clean, light, dry, and wholesome. Also a red *Chianti Broglio* at the same price, which I noted as peculiar tasting, astringent, subacid, and wholesome. Also a red *Barbera*, a Piedmontese wine, at 20s., a peculiarly-flavoured, fuller-bodied, rough wine; and a *sparkling Vino d'Asti* at 24s., strong, sweetish, unstable, not to be recommended so far as one specimen was a test. I believe that now not all these wines are in the market, but I have got fresh specimens of Chianti and of Barbera, of which this is the description:—

Chianti, 14s., peculiarly and full coloured, alcoholic strength = 19·8 per cent. of proof spirit; *Barbera*, 20s., also peculiarly full coloured; alcoholic strength = 25 per cent. In each great and peculiar astringency. Compared with good specimens of Bordeaux of equal price, less acid, more astringent, more body and substance. Large quantities are consumed by Italians in London; little by others. The taste might seem unusual and startling at first, yet there is no reason why any

one who desires a rough red wine to drink with water might not try these, and might possibly relish them.

The Greek wines, which, as I said, I only know through Denman, appear of almost perplexing number, and I believe it would be good policy for the vendor to eliminate some of the less important, and fix the public attention on fewer varieties. I first procured these wines in the spring of 1863, and find the following note of *Red Mount Hymettus*, 16s. :— "Clean, tasting rough; fair body, not too acid or sweet, something of a resinous flavour—satisfactory." I have lately studied them with considerable care, and, to say the least, am convinced that they will form no inconsiderable portion of the future wine of this country, so soon as the middle classes, to whom cheapness is essential, learn to look out for a decided *wine flavour*—that is, for the taste and smell of the grape, more or less modified by fermentation, instead of the taste of spirits. Nay more, the specimens I have tasted of some of those wines which have had age in bottle, led me to believe them so capable of developing flavours of peculiar marked character, that they will be sought out for their own intrinsic excellence, cheapness apart.

In order to classify them, we may divide them into dry and sweet. Of the dry there are the *White Mount Hymettus*, *White Keffesia*, *St. Elie*, and *Thera*, which are white; the *Red Mount Hymettus*, *Red Keffesia*, and *Santorin*.

Of sweet wines the *Como* and *Bontza*, which may be compared to port, the *Caliste* and *Vinsanto*, which are more or less sweet, luscious wines, full of flavour, and suitable, not for dinner, but to drink with cake and sweetmeats, or to give as occasional restoratives to the convalescent. Certainly sweet wines have their place in the economy of nature, and agree well with sweet dishes, and they suit the active digestions of children and some old persons.

The *St. Elie* at 24s.; alcoholic strength = 25. A light-coloured, firm, dry wine; not too acid; clean and appetizing. An older specimen, which had some age, in bottle, was a delicious, firm, well-flavoured wine, admirably adapted for dinner. There seems great promise about it.

The White Mount Hymettus, 16s., and White Keffesia, 20s., as I am informed, differ merely in age; and it seems a pity to multiply names. Alcoholic strength, about 21. The White Mount Hymettus is a very cheap wine. It must be recollected that most, if not all, in the market is very new; yet it has abundance of wine *taste;* whereas some that is older has perfectly astonished me by its firm, dry, clean character, and the abundance of peculiar wine flavour of a Tokay sort which it seems capable of developing.

The *Thera* at 20s.; alcoholic strength = 25. This is a wine which I have only tasted new, from the cask, of a darkish sherry colour, full bodied, and very capable of taking the place of "dinner sherry." Comparing this wine with a cheap fictitious wine of equal price, it is instructive to notice the fulness of wine taste and absence of spirit taste. The taste is peculiar; but this wine seems to have great potentiality of developing flavour in bottle. As it is, how superior to cheap sherry!

The Red Mount Hymettus, 16s., or the older Red Keffesia, 20s., are also wines of great usefulness and great promise when age shall have matured them. The alcoholic strength is about 21. Full bodied, dry, markedly astringent, not acid, they are much more satisfying than pure Bordeaux of equal price.

The Santorin at 20s. has been described in a former article: a very useful wine, the colour and dryness of light port, with little alcohol.

The *Como* of 1861, also described in a former article, is a wine which seems to have been artificially fortified to imitate Port. It is one of the false steps which wine-growers took a few years ago, when, instead of trusting to the excellence of their produce, and having faith that anything good in itself will be liked, though its flavour may be new or *sui generis*, they tried to imitate port or sherry. This Como is a good imitation of new port. Price 28s.

Como of 1862, price 28s.; said to be natural unbrandied wine, is extraordinary stuff, and deserves the attention of Hospital and Dispensary Committees. Its alcoholic strength is 30 (it paid shilling duty only); its specific gravity, 1020; and it is intensely sweet, full bodied, rough, and grapy.

Bontza of 1862, price 24s.; also a natural wine; specific gravity, 1015; alcoholic strength, 25; sweet; decidedly rough; like young port; nothing unpleasant. These wines evidently want age, and must come up for judgment two years hence. It is hardly fair to speak of them now. But I believe that the wine trade of Greece will hereafter be largely developed; that some of these wines are well worth laying down; and that the existence of them is a great boon to the middle classes. In the St. Elie and Hymettus we have pure wine, that seems able to maintain itself without brandy, and yet is not too thin for the English palate.

(To be continued.)

REVIEWS.

The Plurality of the Human Race. By Georges Pouchet. Translated and edited from the Second Edition by Hugh J. C. Beavan, F.R.G.S. London: Longman and Co. 1864. (Anthropological Society.)

Monsieur Pouchet argues forcibly for the doctrine that man is an integral part of the vertebrate series, and not separated from other animals by an impassable gulf, moral or physical. The psychological differences between some men and some animals are not greater than those between men of different races. Different races of men differ in structure, in moral and intellectual qualities, as much as species of animals do. The differences between races of men are *specific*, in whatever sense that word is used of animals. Such are the main points argued in this very interesting treatise, which the Anthropological Society has laid before its members.

A Manual of Practical Hygiene, prepared especially for Use in the Medical Service of the Army. By Edmund A. Parkes, M.D., F.R.S., Professor of Military Hygiene in the Army Medical School, Examiner in Medicine in the University of London, etc. Pp. 612. London: John Churchill and Sons.

One might fairly conclude from the above title that the work was of interest to the military Surgeon alone, but its perusal has convinced us that it is equally suited to their civil brethren, who will find in it much that they would be unable to acquire elsewhere, except after a course of extended reading. The laws of health and the general management of the healthy, although noticed by Celsus—whose advice, by the bye, is in many cases of a very questionable character—Galen, and others, have been to a great extent left unheeded by our Profession as unworthy of consideration; but during the last few years attention has been aroused to our duty on this point, and we thoroughly recognise the fact that he who would practise his Profession with benefit to his patients and with credit to himself must be prepared to avail himself largely of those hygienic rules which tend to produce *mens sana in corpore sano*.

The utter disregard of these rules is confined to no class; high, low, town, country, alike vie with each other in breaking the commonest laws which Nature has laid down as necessary to the well-being of our bodies. If we enter a place of public amusement we are stifled by the heat, poisoned by carbonic acid, or else sit in such a whirlwind that a severe cold is the ordinary penalty for the evening's enjoyment. You are called to see a Dispensary patient, and passing up stairs you find a small room with five or six people in it. The patient is lying on a bed, saturated with perspiration; and as one of the persons in the room is probably a child, a strongly-marked urinous smell pervades everything. In the country you enter a neat-looking cottage early in the morning, and the odours which greet you render a speedy retreat advisable. While we have been looking at the dark side of the picture, we must not forget that the present age has seen at least a beginning of improvement in our sanitary arrangements. The vast drainage systems, the sums of money expended in procuring a plentiful supply of pure water, the legislative enactments made to secure us from the various forms of adulteration from which even the staff of life was not free, and such like precautions have done much to ameliorate the public health; but all the good in this direction cannot be accomplished until the mass of the people are taught that they are responsible for much of the disease to which they are liable by their neglect of common prudence in the management of their homes.

The purity of water, the quality of milk, the adulteration of bread, arrowroot, coffee, etc., are questions which will often be put to every Practitioner. Dr. Parkes's book will afford him the means of giving a decisive and correct opinion: the methods pointed out for this purpose are clear and succinct, and such as every Medical man should be prepared to carry out.

The chemical and physiological effects of food and drink

are ably stated; while those of exercise on the lungs, heart, and skin, as well as on the nervous, muscular, digestive, and eliminative systems are traced with the skill of an experienced observer.

The chapter on Meteorology contains a great deal of useful information. The plates scattered throughout the book add greatly to its value, among which we may notice the various starches from wheat, barley, oats, etc., and representations of tea, coffee, chicory, and cocoa.

We have seldom read a more useful book, or one which we can more conscientiously recommend to our readers.

Acupressure, a New Method of Arresting Surgical Hæmorrhage, and of Accelerating the Healing of Wounds. By James Y. Simpson, M.D., F.R.S.E., Professor of Medicine and Midwifery in the University of Edinburgh, and Physician-Accoucheur to the Queen for Scotland. With Illustrations. Edinburgh: Adam and Charles Black. 1864. Pp. 576.

This handsome and most interesting volume contains, in their fullest form, those doctrines respecting new and improved methods of sealing arteries and hastening the cure of wounds, which were given to the Profession by Professor Simpson in the *Medical Times and Gazette* of 1864, and of which earlier indications are to be found in our volume for 1860, February 11. Dr. Simpson shows that the two great sources of danger in surgical operations are: 1st, hæmorrhage; 2nd, pyæmia—in other words, chemical changes beginning in an open wound and propagated over the whole system. Now, unfortunately, the means in present use for arresting hæmorrhage not only keep wounds open, and so prolong the patient's danger from extraneous sources of infection, but they themselves cause sloughing, however slight, and hence create chemical decomposition within the wounds. Dr. Simpson traces the history of the modes adopted for checking bleeding, with plates of the Surgery of the seventeenth century, and shows that, 150 years ago or less, Surgeons talked with as much complacency of frizzling the wounds, which they afterwards kept open with digestives, as we now do of strangulating tissues by ligatures which keep up suppuration perforce, spite of our theoretical notions of "union by first intention." Then comes the question, how long must an artery be obstructed in order that it may be sealed by a firm clot? and what means have we of obstructing arteries, and of withdrawing our pressure so soon as our end is accomplished? Modern investigations have shown that this may often be attained in a very short time. The *details* no doubt require that further completion which can be attained only by use; but Dr. Simpson has shown the *prineiple*. The ligature must be given up; and if England refuses the boon, it is some consolation to know that it is gratefully accepted by Surgeons at Madagascar; and that there is every hope that the man who has invented the chief means of enabling patients to leave the operating theatre without pain may have the proud satisfaction of enabling them to go to their bed with less risk of decimation by Hospital disease.

Lectures on Public Health Delivered at the Royal College of Surgeons. By E. D. Mapother, M.D., Professor of Hygiene, Medical Officer of Health City of Dublin, and Surgeon to St. Vincent's Hospital. With twenty woodcuts. Dublin: Fannin. London: Hardwicke. 1864.

A Manual of Physiology and of the Prineiples of Disease. With 150 illustrations, and a glossary, questions, etc. (By the same author.) Dublin: Fannin. London: Longman.

Professor Mapother has evidently, in a high degree, the faculty of representing complex subjects in the clearest and shortest possible language. The Lectures on Public Health relate to air, water, food, cleanliness, soil and malaria, climate and vital statistics, and form a manual of the subject which deserves to be circulated as a text-book in national and other schools, and to be adopted by societies which have the function of enlightening the people on matters relating to health. The second work, of which we announce a second edition, is more ambitious, but not so likely to be useful to the whole educated public. It is an attempt at an epitome of physiology, physiological and structural anatomy, and general pathology, in a very small book of 550 pages. It may be convenient for gentlemen preparing for examination, for whom it seems specially intended, but it is far too short for a good text-book for general use either by Medical tudents or the public.

An Elementary Atlas of Comparative Anatomy, in Twelve Plates. The objects selected and arranged by Professor Huxley, F.R.S., and drawn on stone by B. Waterhouse Hawkins. London: Williams and Norgate. 1864. 4to.

This very useful atlas is intended to assist the student of comparative anatomy. It gives, in twelve plates, a comparative view of similar parts in the skeletons of such animals as are most easily accessible. Thus, it begins with the skulls of the dog, horse, sheep, pig, man, the apes, hare, guinea-pig, fœtal chicken, tortoise, turtle, tench, and carp. These occupy the first three plates. In the next we have the skulls of the reptilia, fishes, and amphibia contrasted; and in the fifth the skulls of the six orders of fishes, the examplars being pike, lepidosteus, sturgeon, shark, chimœra, mudfish, and lamprey. Then follows the vertebræ, tails, and hyoid apparatus; lastly, the extremities. All the homologous bones are marked by letters or symbols, so as to be readily identified, and the figures are so arranged as to facilitate comparison.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

December 12.

I find from the published reports in our local newspapers that during the week ending December 3, 77 deaths occurred from typhus fever, being 64 above the average; whilst, at our Workhouse Hospital, out of 1207 cases under treatment, 377 were fever, to which disease alone 36 out of the 65 deaths that occurred are to be credited. Under the class "fever," I presume the exanthemata are to be included, and the varieties of continued fever. Small-pox has been prevalent for some time past, and several deaths have occurred from it. Figures speak for themselves, and show plainly the necessity for strict investigation. The selection of the Special Commissioner was a happy one,—a gentleman who has conducted similar inquiries, and by his relationship with the London Fever Hospital been brought into daily contact with the various forms of the disease that has been so prevalent amongst us. Considering this, and the readiness with which everybody in office and out of office here came forward to give information gleaned by actual observation, we may look forward with much interest to the publication of Dr. Buchanan's report. If he can fix on the cause, and demonstrate it to the satisfaction of our corporate officials, they will not be long in applying the remedy. Dr. Trench, our Medical Officer of Health (if I understand him rightly from his published speeches), believes that indigence is the "*fons et origo mali*," bad ventilation and intemperance assisting in the propagation of the disease. Dr. Shearer, one of the District Medical Officers, has prepared and circulated a careful report on the prevalence of fever in his own district—Toxteth-park. Dr. Shearer shows by a map that the fever raged first in the streets parallel to the river Mersey, and which were unpierced by any cross streets or openings; and secondly in those courts entered by a narrow passage, and blocked up at the other end by rows of privies and ashpits arranged behind the houses of contiguous streets. With regard to the first case, he asserts that no free current of air can pass through them, "rearing their compact bulk like so many solid veils or screens, mutually warding off, instead of opening towards and inviting, the atmospheric influences from the river." And as to the courts, there can be no current through them, and all that the entrance of air can do is to stir up and waft from house to house the pestilential odours arising from the previously-mentioned nuisances. Dr. Shearer's pamphlet is worth perusal by those interested in fever. The observations extend over a year, from October, 1863, to 1864, the type of the disease being nearly exclusively typhus. Mr. Steele gives us a paper on the epidemic at our next Medical meeting, and doubtless it will elicit a warm discussion. From what I have said you will see that the subject of fever is being pretty well ventilated here at present. There are very few evils that are not productive of some amount of good: familiarity with a disease ought to render us more proof against its attacks, for it was not till small-pox had consumed more victims than armies, that the immortal Jenner, guided by the hand of scientific inquiry, plucked the destroying weapon from his foe and used it for his own defence. Two cases of "bone-pegging" have occurred here according to the plan recommended by Mr. Bickersteth, and practised so far with success in the treatment of un-united fractures. The first was done

by Mr. Hakes, at the Northern Hospital, on a boy aged 14. Five months after fracture of the thigh, there being no attempt at repair, Mr. Hakes scraped the ends of the bone with a tenotomy knife, and failing to excite union, he resorted to this new operation. I saw the case six weeks after the operation, the two dull heads were firmly fixed through both portions of the fractured bone, and had caused no uneasiness whatever. The second case was by Mr. Bickersteth, at the Infirmary. The patient was not a good subject for any operative interference, and the introduction of the dull heads caused more action than has hitherto been met with. This was also for fractured thigh.

Doubtless we shall hear further of these cases, as, before this operation will be generally acknowledged and practised by operating Surgeons, the cases where it has been tried must from time to time be brought before the Profession. Mr. Nash, the House Surgeon at the Infirmary, related to me a rather unusual injury to the eye, or rather eye-ball, that occurred the other day—complete dislocation—from a fall on a saucepan-handle. The whole ball completely protruded, the eyelids being closed firmly behind it, the muscles being not torn but on the stretch; the optic nerve could be seen uninjured. Some difficulty was experienced in effecting reduction in consequence of contraction of the eyelids. In a very short time the eye recovered from the concussion to the nerve, and the patient has recovered without a bad symptom.

At the last meeting of the Medical Society Dr. Turnbull read a paper on "Chorea;" alluding to sulphate of aniline, a remedial agent for this disease that he had introduced, he remarked that he had found it exceedingly useful in obstinate cases that had resisted ordinary treatment. Mr. Batty, after fifty years' connexion with our School of Medicine, has resigned, and in consequence of his long-continued and arduous labours has been elected an honorary member of the School, being the first lecturer who has received this distinction. Dr. Grimsdale succeeds Mr. Batty in the Midwifery chair, Dr. Gee taking Diseases of Children, and Dr. Rawdon Pathology. I saw in the hands of Mr. Hewitt, the Surgical instrument maker, a few days ago, a green elastic catheter, originally the property of Napoleon I.; it was taken from his carriage, I believe, at the burning of Moscow, and is now in the possession of Mr. Sharp, Surgeon, at Warrington, who has a well-authenticated history of it. I just mention what I heard of it, thinking it might interest some of your readers. I regret to say that I hear rumours of some trials that are to take place involving the reputation of Medical men; one has advanced as far as So-and-so *versus* So-and-so; others still in their infancy. Numerous examples have shown us now what hollow affairs these generally turn out, and we know that for these annoyances we have frequently not solely to thank our patients. In every large town, and in some small ones too, there are to be found those who dare not for an instant show themselves before a public tribunal and subject themselves to the scrutiny of a severe cross-examination, but are only too ready (*sub rosâ*) to suggest such doubts in the mind of a patient as would ultimately lead to a respectable Practitioner being subjected to a painful and expensive prosecution—Professional jackals, devouring by night the refuse rejected by those that would scorn to touch anything calculated to pollute or stain. We should deeply regret to see further instances humiliating to a long-honoured Profession repeated again similar to those enacted before the public at Chester and also in this town in connection with a public institution. To expose ignorant and presumptive *soi disant* Doctors, and to defend the skilful, though may-be unsuccessful Surgeon, are duties alike incumbent upon us; but to connect unsuccess in all instances with unskilfulness is to assert that the sciences of Medicine and Surgery are certain in their results, and are not influenced by those mysterious workings of Nature which can be best understood by men of extended experience and observation.

Tragical Occurrence at the Berlin Charité Hospital.—In one of the wards of the Berlin Charité there were four patients, all suffering from delirium, and all fastened down in their beds. While they were all apparently asleep, the nurse left the ward for some temporary purpose, when one of these patients, who had apparently well-nigh recovered, managed to loosen the ligatures which fastened him, and springing out of bed, seized a stool, with which he frantically attacked the three other poor wretches tied down in their beds. One of these he killed on the spot, another died in half-an-hour, and the third remains in a hopeless state.

GENERAL CORRESPONDENCE.

PRYCE *v.* BOWEN.

Letter from Mr. Edward Lund.

[To the Editor of the Medical Times and Gazette.]

Sir,—I regret very much that I have been mixed up with the case of Pryce *v.* Bowen, tried at the last Liverpool assizes, and commented on in the *Medical Times and Gazette* of Saturday last. The facts were simply as follow:—The solicitor for the plaintiff called upon me about ten days before the trial and read over to me, before I saw the plaintiff, her own declaration of the manner in which she stated the defendant had treated the arm from the time of the accident until he ceased to attend her, at the end of six weeks; and he asked me to give an abstract opinion on the merits of the case, whether I considered such treatment had been correct, and if it could have had any influence on the issue of the case. I then examined the patient, and gave it as my opinion that in no respect was the defendant liable except as to the treatment during the first nine days after the accident, and then only on the question as to the position in which, according to the plaintiff's statement, the arm had been retained during that time. I was then served with a subpœna to attend the assizes if the case went into court, but in no way had I anything to do with any other witnesses; nor did I know that Evan Thomas, the "bone-setter," would be brought forward until I saw him in the witness-box on the day of the trial, for it had been concealed from me that he was to be in any way connected with this case.

If you will permit me to go into further detail next week, I hope I shall be able to make it plain to you, and to every member of the Profession, that the report which appeared in the Liverpool papers has not truthfully, though doubtless inadvertently, represented the views and opinions that were expressed by me in court, but for which I must wait until I can obtain an authentic copy of the short-hand writer's notes of the evidence taken at the trial, for which I have made application. I am, &c.

Manchester, January 3. Edward Lund.

DEATH FROM CHLOROFORM.

Letter from Mr. J. Usher Huxley.

[To the Editor of the Medical Times and Gazette.]

Sir,—Enclosed are notes of a sad case of death by chloroform which occurred at this Hospital on the 1st of the month.

I subjoin a brief notice of another case which happened here about three years ago, but which was not reported in the Medical papers. I am, &c.

J. Usher Huxley, M.B., House-Surgeon.

Devon and Exeter Hospital, November 4.

W. L., a healthy-looking young man, aged 24, was admitted into the Devon and Exeter Hospital on September 26, suffering from a severe injury to the right foot. A heavy piece of timber falling on it had fractured the metacarpal bone of the great toe, and deeply lacerated the structures of the inner side and sole. The case went on well, and after the separation of some rather extensive sloughs, healthy granulations filled up the greater part of the chasm. The distal end of the fractured metacarpal bone, however, though evidently dead, remained firmly fixed, and considerably hindered the progress of the wound. The man was therefore told that he must either be contented to remain in bed several weeks longer while the bone spontaneously separated, or must submit to a slight operation for its removal. He chose the latter, on condition that he might have chloroform. The heart was examined, and nothing being found to contraindicate the employment of an anæsthetic his wish was acceded to.

On November 1, at 10 a.m., the patient was carried to the operating-room. Two of the Hospital Surgeons and the House-Surgeon were present: three pupils and two nurses were also in attendance. Forty minims (measured) of chloroform were placed in a Snow's portable inhaler, and the inhalation was commenced, the external valve being at first turned aside and afterwards gradually closed. The man breathed calmly and showed no symptoms of annoyance or distress, and in about a minute began to smile, talk, and move his head slightly. The pulse, which was kept throughout, beat quite steadily for from two to three minutes, when it

suddenly became imperceptible; there was no congestion or other change of the countenance, the pupils were not dilated, and the breathing was as yet quite natural; the inhaler, to which no fresh charge of chloroform had been added, was, however, immediately removed. In the course of a few seconds the respiration became deep and sobbing, and the tongue was protruded between the teeth; no return of the pulse could be felt. The only approach to spasm or convulsion was that for a few seconds the teeth were firmly clenched; this quickly passed off, and the tongue was again protruded. The time during which the respirations continued, unaided, after the pulse had ceased may be put down at fully a minute, and not until still later did the face become congested or the pupils dilate.

The cold douche, ammonia, brandy, galvanism, and forceps for the tongue (as always at this Hospital) were at hand in the operating-room. The first was applied directly the pulse was missed, and in the shortest possible space of time brandy was injected into the rectum, solution of ammonia on lint was applied to the nostrils, and galvanic shocks were passed (with due intermissions) through the cardiac region, whilst friction was applied to the extremities. The forceps were not needed, as the tongue did not fall back.

Immediately the breathing began to flag, artificial respiration by the "Sylvester method" was commenced, and this was steadily carried on for upwards of half an hour. The galvanism was applied at intervals for a like period. No trace of reaction occurred. It should be stated that the inhaler had not been used for any other case that morning, so that it contained absolutely no chloroform but the 40 minims.

Autopsy Six Hours after Death.—Body muscular, well-nourished. Thorax.—Pericardium natural; surfaces of right pleura everywhere firmly adherent; both lungs healthy in structure, the right more congested than the left. On removing the heart (all its orifices having been previously secured), the ventricles were found firmly contracted and empty; the auricles contained some blood, the right in larger proportion. In these and in the large veins the blood was mostly, but not wholly, uncoagulated. All the valves of the heart were perfectly healthy. The muscular substance was firm, of good colour, and without the slightest appearance of fatty or other degeneration. On microscopical examination, the ultimate fibres were found free from oil-globules, and the striæ were well marked. The walls of the left ventricle were slightly hypertrophied without dilatation. The whole organ, washed free from blood, but with a portion of the large vessels adhering, weighed 14½ ounces. Aorta healthy; no appearance of clots in the pulmonary artery. Abdomen.—Stomach moderately filled with food. Spleen natural; weight 11 ozs. Liver large, congested; weight 5 lbs. 12 ozs. Kidneys, large and much congested; weight, the right, 9¼ ozs., the left, 9¾ ozs. Both liver and kidneys were firm to the knife, and the surface of the sections looked smooth and rather glistening, so that there was a question as to albumenoid (amyloid) degeneration; but there was no semi-transparent, glue-infiltrated appearance of the cut surfaces and edges, and no reaction, characteristic of amyloid change, took place when solution of iodine was applied. Under the microscope, too, both the arteries and cells of the hepatic and renal structures appeared perfectly natural. After being allowed to remain for some hours (covered over to prevent evaporation), it was found that a quantity of blood had drained from the cut surfaces, and that the liver had assumed the ordinary size, while the kidneys were much reduced in bulk. Sections now freshly made showed perfectly natural surfaces. Head (examined last).—The brain and its membranes were perfectly healthy, and not at all congested; blood, however, had probably drained away from the divided veins of the neck. Some urine drawn off from the bladder after the examination contained a trace of albumen, and a flocculent deposit consisting solely of epithelium.

At the inquest held on this case the jury returned a verdict of "Homicide by misadventure," and wholly exculpated the Medical officers from blame in the matter.

The following case, which occurred in this Hospital about three years ago, is subjoined as it was not reported in any Medical journal nor sent to the Chloroform Committee:—

R. G., a very healthy-looking man, aged 33, wished to have chloroform to avoid the pain attending cauterisation of a sloughing sore on the penis. One drachm of chloroform by measure was placed in the inhaler, and inhalation commenced. The patient soon became very restless, holding his breath, and trying to avoid the vapour (which was, however, much diluted), so that the larger portion of the chloroform was wasted. He was allowed to sit up to spit, and then a second (measured) drachm was put into the instrument; but again he grew turbulent, and struggled so violently that it was found difficult to watch the pulse continuously, though every effort was made to do so. Suddenly he sank back motionless, with widely dilated pupils, and no trace of pulse to be felt. The inhaler was instantly removed from his face, and he continued to draw deep gasping breaths for half a minute. Cold splashing was applied, and artificial respiration by the "Marshall Hall method" was resorted to without the smallest delay. Ammonia was applied to the nostrils, and subsequently a brandy injection was given, while galvanism and friction were assiduously employed. Pressure over the cardiac region (as suggested by Dr. Brown-Séquard in his lectures at the College of Physicians) was also tried. The artificial breathing was afterwards continued by the "Sylvester method" for upwards of an hour. No sign of returning animation occurred.

At the post-mortem examination, the heart was found to be of a normal size, the ventricles were partially dilated, and both contained fluid blood. There was no valvular disease. The muscular structure was firm, of good colour and without trace of fatty degeneration. The brain, lungs, and abdominal organs were all carefully examined, but no sign of disease was found, nor was there marked congestion of any organ.

THE ABORIGINES OF AUSTRALIA.

Letter from Dr. J. A. Baesjou.

[To the Editor of the Medical Times and Gazette.]

Sir,—In the *Medical Times and Gazette* of February 20, 1864, I perceived an account of a paper, by Mr. A. Oldfield, "On the Ethnology of Australia," at a meeting of the Ethnological Society on February 9, 1864.

As several observations made by that gentleman were not conformable to my experience of the Aborigines here, I brought it under the notice of Mrs. Carnfield, the lady of our late resident magistrate, who has had an experience of many years with the natives, and proved herself a real benefactress to these poor creatures.

I take the liberty to request that you will forward the enclosed letter, and also do me the favour, if space allows, to insert the same in the *Medical Times and Gazette* in the "General Correspondence."

I am, &c.,
J. A. Baesjou,
Government Medical Officer.

Albany, King George's Sound, W. A., May 30.

"Albany, King George's Sound, Western Australia,
May 27, 1864.

"Sir,—My attention has been called by Dr. Baesjou to a paper on the ethnology of Australia, read at a meeting of the Ethnological Society on February 9, 1864.

"It has suggested to me that as I have had the experience of twelve years among native and half-caste children, and have been upwards of twenty-five years in Western Australia, some few words from me would not be unacceptable to your society.

"Ever since I have been in the colony I have had the strong conviction that we ought not to take possession of their country without trying to do something for the natives, and therefore I have been interested in all that has occurred to them consequent on our presence among them. But it was not until June, 1852, that I made an attempt to civilise a few of the children of this place. I commenced on my own account with one little Aboriginal girl. Since then I have had, with the sanction and by the support of Government, forty-one children under my charge, not more than twenty-four at one time. Twelve of the whole number have died, but nine of them were ill when admitted. Several were infants; one was only three weeks old. The mothers of these had died. Three boys and four girls from the school are in service, and four of my first pupils are married, three to Englishmen and one to a converted native at the Moravian mission station in Victoria. There are eighteen children at present in the school, and in no respect are they behind European village school children. The eldest of these we have trained so as for her to become a teacher in the school. She is a very intelligent girl, especially fond of reading. She is often found hidden in some corner with a story book, such as *Chambers' Miscellany*, the *Leisure Hour*, *Sunday at Home*, etc., etc., which she reads with avidity.

Since Christmas last she has played the harmonium in church (a fine instrument with two keyboards), and when the Bishop of Perth and the Colonial Secretary were here last month they expressed their surprise at her performance. She has great pleasure in a game of chess, and is quite interested to learn as much as she can when any one plays with her who understands it better than she does.

"It has often been said that do what you will with the natives they will go back to the bush and forget all they have learnt. Our children have had every opportunity to return if they had liked to do so, as their parents and friends come to see them whenever they choose.

"This institution has fully proved that the natives are capable of being raised importantly in the scale of humanity, but it requires extensive and persevering efforts to accomplish this end with the whole population of natives. If such efforts were made, the succeeding generation or generations of them would afford a happy reward to those who used them.

"There are both Aboriginal and half-caste children in the school, and in conduct, manners, and progress in learning they will bear comparison with European children having only their advantages.

"His Lordship the Bishop of Perth, Dr. Baesjou, and our clergyman can be referred to if necessary.

"I am, Sir, your obedient servant,

"A. Carnfield.

"The Secretary of the Ethnological Society."

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

Tuesday, December 20.

Mr. Prescott Hewett, President, in the Chair.

Dr. Morell Mackenzie brought before the Society

TWO LITTLE CHILDREN, FROM WHOM HE HAD REMOVED LARYNGEAL EXCRESCENCES.

The first case was a child aged 4 years, who for two years had suffered from loss of voice, stridulous breathing, and occasional attacks of threatened suffocation. On examining the patient with the laryngoscope, an oblong tumour, about half an inch long and a quarter of an inch wide, was seen to be attached just above the anterior insertion of the vocal cords. After a consultation with Mr. Mason, who also examined the case with the laryngoscope, Dr. Mackenzie removed the growth with his laryngeal forceps. After this growth had been taken away, numerous excrescences were seen below, and some of these had since been removed. The base of the growth could still be seen. In this case the respiration had become easy, but the voice was still suppressed. In the second case—that of a child aged 6 years—there had also been loss of voice for two years. The patient had been under several Medical men, and, among others, under Dr. Martyn, of Knightsbridge, who used the laryngoscope, and recognised the nature of the disease. Finding numerous excrescences on the true and false cords, before operating Dr. Mackenzie had a consultation with Mr. Mason. Since the growths had been removed the voice had become loud and distinctly phonetic, though it was still a little hoarse. He had brought these cases before the Society whilst they were still under treatment, as the bases of the tumours could still be seen, and as he wished to show with what facility operations on the larynx could be performed. These were the youngest children from whom excrescences had been removed either in this country or abroad. The fragments removed in each case were exhibited, and also drawings showing their previous position in the larynx. Dr. Mackenzie also showed the forceps with which the growths had been removed.

Several members examined the children with the laryngoscope.

Mr. Mason said he could corroborate Dr. Mackenzie's statements, as he had examined the children with the laryngoscope both before and after the operations.

CURED SPINA BIFIDA.

Dr. Playfair then exhibited a patient who had had spina bifida. When first seen a year before, there was a large tense swelling. It was smooth and covered with vessels. The mother objected to its being punctured. Now there is no tumour, but in the position of it the skin is curiously folded, strikingly like the convolutions of the brain.

The President, after remarking on the great interest of the specimens, suggested that a drawing of the appearances should be made for the Society's *Transactions*.

Mr. Brooke suggested that a photograph would give a better idea of what was to be seen.

Dr. Cayley then showed a specimen of

DISEASED SUPRA-RENAL CAPSULE.

There was a yellow tumour in one part of the cortex, but in the rest of its extent the capsule was nearly normal. There had been no bronzing of the skin.

Dr. Greenhow said that although there was disease of the capsule in this case, it must be kept in mind that it was not disease of the kind found in Addison's disease.

At a previous meeting, Dr. Dickinson brought forward some

PREPARATIONS AND DRAWINGS TO ILLUSTRATE A CASE OF ADDISON'S DISEASE, WHICH WAS ALMOST TYPICAL IN ITS CHARACTER.

The patient was a woman, Sarah D., 39 years of age, who died in St. George's Hospital, under the care of Dr. Pitman. She had been losing strength for eighteen weeks, and had been growing dark for twelve. The colour of the skin when she came into the Hospital was most striking, and the hair had become darker than it used to be. She had repeated vomiting, and at last sank. Death was preceded by slight convulsions. When the body was examined it was seen that the tint was generally that of a Mulatto, though some variety was found. The face was darker than the shoulders, the colour shading off like a sunburn. There was a dark patch above each patella, but the darkest places were the buttocks, and the front surfaces of the thighs near the groins. The hair was dark brown, short, and curly. There were indications of whiskers and monstache. The supra-renal capsules were produced; they were both increased in size, the left weighed three-quarters of an ounce, and was adherent to the surrounding structures. It was hard, nodular on the surface, and of a light buff colour. On section, it had much the appearance of a fibro-plastic tumour. The centre was different from the rest: it was soft, yellowish, and not unlike crude tubercle. Under the microscope the outer part was found to consist of an aggregation of cells, large, and various in shape. Some were spindle-shaped, some spear-headed, others rounded or polygonal; almost all were nucleated. The central part contained oil-globules and imperfectly-formed pus. On the whole the structure was something *sui generis;* it had some points of resemblance to a fibro-plastic tumour, and some to a malignant formation, but it was clearly distinct from both these forms of disease. It was far removed in its characters from tubercle. The right supra-renal body was only a third as heavy, but was similar in all other respects. Under the peritoneum in many places small growths were seen, of the size of mustard-seeds, or smaller, which were firm, grey, and semi-transparent, and had the same microscopical structure as belonged to the supra-renal bodies. All the other organs were natural excepting the lungs, in which one or two isolated crude tubercles were found. Thin sections of the discoloured skin were made after freezing in ice and salt, and the disposition of the pigment was found to be precisely such as is represented by Mr. Hutchinson in the 8th volume of the *Transactions*. The colouring-matter was limited to the single layer of epithelial cells which is in contact with the papillæ. In the section, the deepest row of cells was the only place where any pigment existed. The row of cells in contact with these was, like all the rest of the cuticle, perfectly free from colour. For the purpose of comparison, sections were made in the same way from the skin of a Hindoo, which was coloured to about the same depth. Here a great difference was found in the disposal of the pigment, which, instead of being limited to the deepest layer of cells, was most marked there, and gradually diminished towards the surface, so that all the cuticle was more or less tinted. The difference was so decided that it would have been easy to say from the microscopic appearances whether the specimen was obtained from a case of supra-renal bronzing or from an inhabitant of the tropics. It was suggested that the difference might be due to the fact that in one case the colouring was congenital, and the deep layer of cells which first received the colour had had sufficient time to become superficial, so that the active epithelial growth had become more or less tinted; while, in the other case, the colour was due to a comparatively recent cause, and enough time had not been allowed to take the brown cells to the surface in the natural progress of epithelial growth.

Mr. Henry Smith showed

PARTS REMAINING AFTER A SUCCESSFUL REMOVAL OF THE ELBOW JOINT.

A little boy was operated on three years ago, when he was five years old. He had been under observation until three weeks ago, when he died from disease of the spine. During the last two years he had been able to use the arm quite well; in fact, as well as the other. The lower part of the humerus, part of the radius, and ulna were removed, and in the specimen the triceps was to be seen attached to the ulna, and the biceps to the head of the radius. The bones were fastened together by dense fibrous tissue. The motions of the *ci-devant* joint were free, and there was no disease.

Mr. Hulke said it would be interesting to hear more exactly the condition of the ends of the bones. If the biceps were attached to the head of the radius, the excision could only have been partial.

Mr. Henry Smith said that he could give no information as to the condition of the ends of the bones than was to be seen in the specimen. No doubt very little of the radius had been removed, but a resection would be complete, however little was removed. A similar objection had been made to some of the cases operated on by Mr. Jones, of Jersey. It was said that some of his cases of excision of the knee were not complete, as scarcely any of the bones were removed. But Mr. Jones remarked that the excision would be complete if the thinnest slice were taken away.

Mr. Holmes exhibited

THE URINARY ORGANS AND TESTES FROM THE BODY OF A MALE INFANT WHO DIED AT THE AGE OF SEVEN DAYS FROM THE CONSEQUENCES OF A MALFORMATION OF THE BLADDER.

As the parts had only been removed from the body a few hours, there had been no time to make an accurate dissection, and the specimen will therefore be exhibited and more fully described at a future meeting; but it was thought desirable to exhibit it when quite fresh, in order to call the Society's attention to the peculiar shape of the bladder and the singular appearance of its lining membrane. The bladder consisted of two distinct sacs, each about the size of an orange, communicating with each other by a round hole about half an inch in diameter. One of these was the true bladder, containing the openings of the urethra and ureters, all of which were quite unobstructed. The parietes of this sac were very thick, and studded with red projections like nævi. The other sac was thin, and appeared to contain little, if any, muscular tissue. There had been no retention of urine during life. The testes were retained in the abdomen. There was considerable deficiency of the muscular parietes of the abdomen, though the skin was perfect, and there was a nævus occupying the region of the pubes. Further particulars will appear in the report of a future meeting.

CORDÆ TENDINÆ OF DISEASED MITRAL VALVE RUPTURED DURING VIOLENT VOMITING.

Dr. Peacock exhibited the heart of a female aged 21, who died recently at the Victoria Park Hospital. She had been an in-patient of the Hospital in 1851, labouring under cardiac symptoms, the sequence of an attack of rheumatic fever two years before. She had not been under any Medical care for some time, and was in her usual health, when she was taken in a cab from her home in Artillery-street, Bishopsgate-street, to the Victoria Park Hospital to be examined for admission. The motion of the cab was very uneasy, and shortly after leaving home she vomited violently; she was then attacked with difficulty of breathing and faintness, and when she reached the Hospital, a distance of scarcely a mile and a-half, she was pulseless at the wrist, and apparently dying. When seen by Dr. Peacock, a few minutes after her arrival, she had in some degree rallied; the pulse was feebly to be felt at the wrist, but she was too weak to be carefully examined, and the loud tracheal rhonchus rendered it difficult to hear the cardiac sounds. It was, however, thought that there was a feeble systolic murmur at the apex of the heart. She was removed to bed, but died in a few hours. On examination after death the pericardium was found to be entirely attached by old and firm cellular adhesions. The heart when deprived of the adherent pericardium and freed from coagula, weighed 20¼ oz. av. (the healthy range for males being 9 to 11 oz.) There was considerable dilatation of the left ventricle, but the walls were not increased in thickness, measuring from ·1776 to ·3996 of an English inch (the healthy average in males being ·541 of an English inch). The aortic aperture was somewhat contracted, measuring 2·93 of an English inch (average in males 3·145), and the ventricular surfaces of the valves were considerably thickened, while the crescentic edges were free. The left auriculo-ventricular aperture was slightly diminished in capacity, admitting only a ball measuring 3·996 of an English in circumference (the healthy average in males being 4·02 of an English inch.) The mitral valve was considerably thickened and indurated, and the cordæ tendineæ of the free fold of the posterior columna carnea were entirely torn from their attachments, so that the valve was entirely loose, and must have admitted of free regurgitation. The walls of the right ventricle were somewhat thickened, measuring ·1776 of an English inch (healthy average ·1666 of an English inch). The right auriculo-ventricular aperture was slightly constructed, measuring 3·996 of an English inch (healthy average 4·791 of an English inch), and the tricuspid valves were thickened and firmer than natural. The lungs were much congested, and the bronchi contained bloody mucus.

Dr. Peacock remarked there could be little doubt that the tendinous cords had been torn from their attachments during the violent vomiting soon after the girl entered the cab, for her mother expressly stated that she did not suffer at all seriously when she left home, and that she had not the slightest idea that there was any risk in taking her to the Hospital. Though cases of rupture of the valves or their attachments, when diseased, were of more common occurrence than such injuries to healthy valves, yet all such cases were very rare. The case did not throw light upon the question of the effect of universal adhesion of the pericardium to the heart upon the functions and nutrition of that organ, for there was considerable disease, both of the aortic and mitral valves, which would explain the great increase of weight. He had, however, seen specimens in which the pericardium had been universally attached, and evidently inflammation of old date, in which the size and weight of the heart did not exceed the healthy average.

Mr. Teevan exhibited

SECTIONS OF DIFFERENT SKULLS SHOWING THE INCORRECTNESS OF CALLING THE INNER TABLE OF THE SKULL THE "TABULA VITREA."

Mr. Teevan observed that in nearly all anatomical and Surgical works it was stated the inner table of the skull was more brittle than the other; and hence had been named the *lamina, vel tabula, vitrea*. The two facts which had given rise to the above supposition were—firstly, when a foreign body penetrates the skull from without, the inner table will always be found more injured than the external; and, secondly, fracture of the internal table alone, without any injury to the external table, sometimes occurs from violence applied externally. He remarked, the above did not happen because the inner table was more brittle, but depended on other causes. The reason why the inner table of the skull is found more damaged than the outer when a bullet enters is because the aperture of exit is always larger than the aperture of entry when a foreign body passes completely through any part of the skull; it matters not what the direction may be. One of the specimens was a section of a skull, in which both parietal bones had been perforated by the same bullet, showing an aperture of entry in the inner table of the right parietal bone the same size and form as an aperture of entry in the external plate of the left parietal. Three other specimens were calvaria, in which Mr. Teevan had produced fracture of the external table without any fracture of the internal table by striking from within. He then explained the causation of the above, and also why an aperture of exit is always larger than an aperture of entry.

Mr. Brooke suggested that the difference depended on the form of the striking body. A cylindrical, flat-headed bullet would make a hole with apertures much more parallel; and the same was borne out by experiments at Shoeburyness.

Mr. Teevan had tried the experiments with bullets shaped as Mr. Brooke had suggested, and had witnessed the experiments at Shoeburyness, and had found no reason to alter his views.

Mr. Balmanno Squire showed a coloured photograph of a patient the subject of

PITYRIASIS VERSICOLOR.

It showed well the variegated hue of the disease, there being no less than four tints. This patient's case showed what he had often observed, but what he believed had not been noticed before—viz., that pityriasis versicolor attacks only the front and back of the body.

Mr. Thomas Windsor, of Manchester, showed specimens from

TWO CASES OF BLACK CATARACT.

As we believe these are the first cases recorded in this country in which the *whole* lens was *perfectly* black, we give the case in a little detail. On September 28, 1864, Mr. Windsor was consulted by a gentleman, aged 48, who had received a blow on the left eye sixteen years ago; severe inflammation followed, a cataract of the usual white colour formed, and in the course of two years the sight was gradually lost. Eighteen months ago he suddenly found that he could again see objects, even newspaper print, and that the cataract had disappeared. Next day there occurred a very violent inflammation, and the sight was again entirely lost. From that time he has been incessantly tormented by severe stabbing pains in the eye and over the left side of the head, and repeated attacks of internal ophthalmia. There was, when Mr. Windsor saw him, no conjunctival congestion, the cornea was clear, the pupil of medium size, but immovable. Perception of light was entirely lost, and it was considered unnecessary to make an ophthalmoscopic examination. From the symptoms and previous history, Mr. Windsor judged that the lens had undergone calcareous degeneration, and had then become displaced, and that it now irritated the eye like a foreign body; as he had already undergone much useless treatment before Mr. Windsor saw him, he at once enucleated the globe. No particular symptoms followed, and in a few days he was perfectly well. On making an equatorial section of the globe, the vitreous was found to be quite fluid, the choroid was much atrophied, and the lens was floating hither and thither at the bottom of the vitreous space. The iris appeared at parts much thinned. The lens was of a jet-black colour by reflected, and of a deep blood-red by transmitted light, though its equatorial margin for perhaps half a line was whitish; it felt very hard and heavy, was of medium size, and appeared to be still in its capsule. No trace could could be found of any effusion of blood. Both the lens and eye were placed in dilute spirit. The former is now only about half its original size, and its colour has, I think, slightly changed. The next case was that of a labourer, aged 35, admitted into the Manchester Eye Hospital in October last. Last July his left eye was struck by a piece of coal; there was when Mr. Windsor saw him some conjunctival injection. The pupil was large and motionless, the iris muddy and tremulous, and there was a small round hole in its outer portion; in the centre of the pupil there was a piece of capsule of a dirty yellow colour, the rest of the space was filled by a perfectly black lens; the tension of the eyeball was somewhat increased, the perception of light was moderate; he saw movements of a hand to two and a-half feet. In a few days Mr. Windsor made a good-sized iridectomy at the inner side. Further examination having satisfied him that the thickness of the lens was considerably diminished, on November 15 he made a flap of a little less than half the cornea and extracted the lens. No accident followed, but the sight was very imperfect, owing to haziness of the vitreous humour. The lens was placed in glycerine, and appears to have undergone no change.

Mr. Hulke, at the request of Mr. Windsor, was asked to examine and report on the specimen.

Mr. Francis Mason showed

A PHOTOGRAPH OF EXTENSIVE COLLOID DISEASE OF THE INTESTINES.

The photograph was brought forward chiefly to illustrate the value of photography in the record of pathological appearances. It showed very clearly the intestines here and there united together by masses of disease.

Dr. Harley then showed a specimen of

URINE FROM A CASE OF INTERMITTING HÆMATURIA.

The patient, sent by Dr. Wilson Fox, said that whenever he was cold he passed bloody urine. He brought with him two specimens, one clear and the other dark. Dr. Harley then gave details of the history of the case, and said that he should have regarded it with great doubt if he had not had under his care a Medical man who had had exactly the same symptoms. There were no blood corpuscles in the urine, but abundance of the colouring matter of the blood and much albumen. The Medical man took mercurials and quinine, and got quite well.

Dr. Martyn showed a specimen of

PLUGGING OF THE PULMONARY ARTERY.

The patient had had rheumatic fever, and was going on as well as usual for several days, and seemed to be recovering. One night she became restless; was said to have had a fit. She said she felt as if choking, and her breathing was laboured and she was pulseless. Her breath was cold, and her nose and cheeks were cold, and the nose and ears became white. She was quite sensible, and complained much of want of air. Auscultation showed, however, that there were loud respiratory murmurs audible throughout the lungs. Ammonia, brandy, and coffee was given, but with no avail. She at last insisted on being laid on her side, after which she gasped and died. Both pulmonary arteries were found to be occluded by a considerable coagulum, but the clot on the right side was more recent.

Dr. Frederick Robinson exhibited a specimen of

FATTY HEART, ASSOCIATED WITH GREAT DILATATION AND THINNESS OF RIGHT AURICLE AND VENTRICLE, TOGETHER WITH WARTY VEGETATIONS DEPOSITED AT THE BASE OF MITRAL VALVE.

The appearance of the diseased auricle was almost melanotic (externally) owing to weakened circulation. Both lungs were completely filled with miliary tubercles, not the smallest portion of the parenchyma being crepitant. The diseased organs were taken from a delicate young soldier in the Fusilier Guards, aged eighteen, who was admitted into Hospital on November 1. He complained only of slight sore throat; was free from pyrexia; and did not complain of cough, dyspnœa, or any chest symptom. He soon recovered from the throat affection, but remained in a cachectic state—well enough, however, to go out of doors for exercise. He was about to be sent to the country for change of air, when he was found in a state of collapse on the morning of his intended departure (December 6). The extreme lividity of the face resembled much the condition met with in cyanosis. The heart sounds were very feeble, and extended over the chest, which was abnormally resonant; a slight systolic murmur was audible below the nipple; and bronchial respiration everywhere, mixed with large crepitation. He survived the seizure but twenty-four hours. The points of interest in the case Dr. Robinson considered to be the faulty state of the pulmonary circulatory system, defective oxygenation of the blood arising from the abnormal condition of the right side of the heart, in connection with tuberculosis. He had never met with a case in which the lung tissue had been so completely displaced by tubercle. The patient might be considered as almost suddenly asphyxiated in consequence, a slight exposure (possibly) to cold in taking exercise sufficing to cause the sudden and fatal issue.

METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

SATURDAY, DECEMBER 17.

Mr. Erasmus Wilson read a paper

ON PREVENTIVE MEDICINE AS ILLUSTRATED IN THE PROPER USE OF FOOD.

Mr. President and Gentlemen,—I feel that some apology is due from me to this meeting in presenting myself before an association of experienced men as an expositor of a department of science of which they are the special representatives; and I ask you to receive as my apology for so doing the commands of your chairman, whose invitation I have ventured to accept. The subject of preventible disease is so vast that an attempt to deal with it as a whole must necessarily lead to confusion; I have, therefore, selected for my dissertation this evening only one twig from the great bundle of branches which constitute the facts of this interesting science. The subject which I shall endeavour to illustrate is contained in the following propositions:—Firstly, That good and sufficient food is necessary to health; and, secondly, that insufficient and inferior food is a fertile source of disease. And, as a deduction from these propositions, applicable to your particular study, I will venture to add, That good and sufficient food is an element of the first importance in the prevention of disease. By food we are to understand that kind of aliment which best conduces to nutrition, growth, and strength; which is capable of producing the most complete development and highest amount of power of the human being; which, in one word, creates health; for in health we have the only trustworthy antagonist of disease. The art and the science of the Physician are alike vain, in his combat with disease, unless he can bring about health; and his first and chief aim is to restore health, being fully assured that if he can succeed in renovating health, disease must be extin-

guished. So, the end and aim of existence of the officer of health may be said to be, to develope the means by which health may be made to occupy the ascendant in the human economy. We have one grand example before us, in which Nature prepares the food of the human being with her own hand, and administers that food at stated periods and according to a prescribed rule. We may ask, What is that food? What are those periods? What is that rule?

The food is milk; the first food of the newly-born man; an animal food. The periods are determined by the sense of appetite or want; and the rule which determines these periods is the space of time occupied in digestion and assimilation. If we examine this food we shall find that it is composed of a variety of principles; if we regard the periods we shall find that they present a perfect regularity of time; if we examine the rule we shall find that it has its origin in the necessities of the animal economy. And we may fairly deduce from our inquiry the three following laws:—

The food of man must possess a variety of composition, in which the animal principle should predominate. The food of man must be repeated at regular intervals, such intervals during the waking hours being not less than three in number. And, thirdly, looking to the fact that the desire for food originates in the necessities of the individual, that the food should be uniformly nutritious. Let me put these propositions in a different manner:—

Man requires variety in his food.

His meals must be regular.

Every meal should be equally nutritious.

Looking to the milk as the food of the infant man, we see the importance which attaches to the perfect purity of the milk, its sufficient quantity, and its regularity of supply; in other words, of a healthy mother—of a mother to whom the nourishment of the future man is a primary and not a secondary purpose of life—of a mother whose instincts harmonise with those laws of nature which govern her infant and should equally govern herself.

But let us take the reverse of these propositions: an unhealthy mother; unwholesome milk; irregularity of exhibition of that milk. I need hardly say that the results must be an unhealthy, weakly child; or, in other words, a fractious, crying child, the subject of vomiting, colic, convulsions, painful dentition, scrofula, rickets, tabes, etc. Is not this preventible disease?

Let me illustrate the subject a little further by reference to my own practice. Eczema is not infrequent in infants; it is apt to commence at the end of the second month, and it sometimes lays the foundation of a life of suffering. Now, eczema in infants is, in every instance, an aberration from the laws of health in the composition and in the supply of the mother's milk. Sometimes the source fails, and is to be made up artificially; and we all know the extreme difficulty of supplying infants with a proper substitute for their natural diet, of rearing them "by hand," as it is popularly termed. In this endeavour we cannot attain either the just variety of composition or the ever-ready supply.

But, as preventive medicine is especially interested in remote predisposing causes, let me adduce a few illustrations. A lady was called upon to give a dinner party a few weeks after her confinement; the excitement of that dinner party cost her infant an eczema. We might go further, and say that the lady transgressed a law of nature, and was punished in her offspring. A young mother hurried from the metropolis to the seaside in the month of November to attend the sick couch of a parent; she was chilled by her journey, her infant was six weeks old; the following day the child was seized with eczema. A lady, recently confined, was worried by a lawsuit; the source of her milk dried up, and remained lost for three days; a similar occurrence took place a few weeks later, and the child was visited with eczema. A poor woman a neighbour of my own was confined in the upper story of her house, her husband was dying in the room below. We might ask: Could the child escape under such circumstances? No: it was covered a few days after its birth with eczema. Within the last week a young woman brought her babe to me covered with eczema from head to foot. The colloquy which took place between myself and the parent was as follows:—"How old is your child?" "Four months." "How long has he had this eruption?" "Since he was three weeks old." "What occurred immediately before the appearance of the disease in your child to cause you annoyance?" "I was vexed by my servant." "And what since?" "I have been vexed to see my poor child in this miserable state." "Have you sufficient milk for him?" "No: I think I must begin to feed him." "By all means do so; that is your only chance of rearing him at all." I could multiply cases of this nature almost indefinitely were it necessary; their relation to the subject before us is self-evident, and I adduce them only as examples of causes disturbing the healthy composition of the milk, and consequently engendering disease in the child.

* * * * * *

But a period comes when milk is no longer the diet of children, and when custom, originating, as we have seen, in Nature's promptings, has determined the necessity of three meals in the day. The infant demands more than three meals, and makes no distinction between the day and the night. The day of the infant is a day of twenty-four hours; the day of childhood, as of the remainder of life, has a duration of twelve to sixteen hours. The three meals at present under consideration are the morning meal, the mid-day meal, the evening meal. These meals represent the wants of the body arising during the intervening interval. The morning meal is intended to supply the moderate waste of the night, the mid-day meal the active waste of the morning, the evening meal the active waste of the afternoon. The amount of the three periods of waste is pretty equal; the amount of the supply should be equivalent to that of the waste.

I am desirous of impressing upon my hearers my opinion and firm conviction that food is not only a necessity, but in civilised life a threefold necessity, and that the three meals should each represent the third of the nourishment of the day, and be so apportioned as to comprehend an equal amount of variety and an equal amount of nourishment. In the primitive life of the labouring class this law is fully appreciated, and is acted upon to the full extent of their means. With the exception of a somewhat more bulky mid-day meal, the morning meal and the evening meal do not far diverge from the standard of the mid-day repast.

But the educated classes are apt to fancy that they possess a knowledge superior to that of Nature, and the result is a perversion of the law of nourishment that leads to the development of debility and disease. A careful, well-meaning mother, from purest ignorance—another expression for superior knowledge, the "little" knowledge that is so proverbially dangerous—will tell you that she conforms to the law of Nature in providing for her children three meals in the day. She will describe those meals as breakfast, dinner, and tea, and you will find the composition of those meals to be as follows:—A vegetable breakfast, namely, bread and butter, with tea and a little milk; a dinner half animal and half vegetable; and a "tea," vegetable like the breakfast. Here, then, we find education bringing about a total change in the diet of man. Born an animal feeder, he is quickly transformed into a vegetable feeder; that is, more than two-thirds of his diet is vegetable and the remaining third only animal, the exact opposite of that which I consider should be the standard diet of children, namely, one-third vegetable and two-thirds animal.

My deduction from these premises is, that children are almost universally under-fed, and that the majority of the diseases of children arise from the debility of constitution induced by this habit of under-feeding. If I am right in this view, preventive medicine may do much in the prevention of disease by correcting an error so widely spread.

The diet of children of all ages should be, a substantial breakfast, with animal food in some shape; a substantial dinner of meat, vegetables, and cereal pudding; and a substantial supper, also consisting, in part, of animal food. The drink may be milk, tea, cocoa, and, possibly, beer. I would call this the diet of health; a diet capable of making a strong body and also a strong mind; and a diet capable of preventing disease. Compare it for an instant with the milk-and-water and bread-and-butter diet of some establishments; the meagre dinner of meat, and the miserable grouting of rice and amylaceous pulp. Rice and amylaceous food should have no place in the diet of health, but should be reserved for the sick room.

Born in prejudice and matured in prejudice, it is the struggle of a lifetime to throw off the trammels of prejudice. We are apt to attach a peculiar signification to the terms which we are in the habit of employing. Ask a person what he usually takes for breakfast, and he will pretty certainly begin his enumeration with the word "tea," the mere drink of the meal; it is, in truth, with him a mere break-fast, instead of being, as it ought to be, a substantial morning meal. The

dinner of labour is the luncheon of fashion; then follows the mildly alkaline and stimulating drink that is termed "the tea;" and last of all comes the supper, the late dinner of fashionable life. We have, therefore, before us a succession of three meals and an intermediate drink, but the drink precedes the last meal; and, therefore, the orderly matron, who is more attentive to her 1, 2, 3 than she is to the intention of the daily fare, prescribes for her children breakfast, dinner, and tea—two slops and a meal. But let her, in good English phrase, call the children's meals breakfast, dinner, and supper, and then we immediately obtain two dinners and one slop, the breakfast—an obvious improvement. I have secured to many a child a reasonable evening meal by suggesting to the mother the mere use of the word "supper" as the name of the third meal. No human being could call bread and butter and tea by the hearty name of supper.

Assuming that the amount and richness of the supply of food should be determined by the offices which it has to perform, there is no period of life when more food is required than in childhood and youth. The hard-worked labourer in a long summer's day scarcely exhausts a greater quantity of nutritious matter than a growing boy of ten or twelve years of age; in the labourer the consumption is waste; in the growing boy it is bestowed in the construction of the body, in developing and building up the future man. And it is no uncommon thing to find that although the general construction of the body has been fairly performed, there is some one organ of the economy that has fared less well than the rest, and that part not uncommonly the skin; hence the origin of acne, of the ringworms, *et hoc genus omne*.

If it be admitted that food is the source of the elements of which the body is composed, what kind of body can be expected in the case of a deficient supply of food, whether that deficiency proceed from actual want or from some perverse theory of refinement founded on a false conception of the nature and objects of food and of its direct convertibility into the flesh and blood of man? Parents are too apt to take their own stomachs as the standard of diet of their children: a cup of tea and a slice of toast suffices for them, so it must suffice for the little ones. I knew a lady who brought up her children on mutton alone, because she herself could digest nothing but mutton. Her children were a feeble, puny, sheepish race, always in the Doctor's hands. A mother, in anticipation of the full meal at seven o'clock, can afford a light lunch; but she unfortunately concludes that, because a light midday meal is good for her, a spare dinner is equally proper for her children. She has heard somewhere that suppers are heavy and interfere with sleep; so, the children must be content with their tea, and go supperless to bed. Parents have rights over their children, but not the right of feeding them in such a manner as to make them the subject of disease. Such parents become the authors of a puny and degenerate race, and are unintentionally traitors to their country.

If the two periods of life already adverted to be important in their influence on the future man—namely, the period of infancy, ranging from birth to the age of two years, and the period of childhood, ranging from two years to seven years—the next two periods—namely, those of boyhood and youth—are equally so. While the food of the infant and the food of the child are abundant and regular, the food of the boy and the food of the youth should be the same. Both are occupied in the great business of growing life; on both are dependent the future man, for his strength and for his manhood.

Boyhood and youth have besides other duties to perform—namely, cultivation of the mind or education; and then the question arises whether these two important processes are equally provided for in the training of our youth. To be well instructed mentally, they must be properly fed physically; and at no period of life are the three ample meals of mingled animal and vegetable food so necessary. There must be no putting off of the stomach with bread-and-butter and slop as the effigies of two of the three meals of the day; but a generous intermingling of all the elements that constitute a sound and nutritious diet.

It is notorious that the importance of a substantial regimen is not sufficiently recognised in scholastic establishments; and the consequence to the pupils is debility and disease, a constant appeal to the Doctor for tonics *vice* food, a frequent outbreak of ringworm, and, worse than all, the development of scrofulous tubercle, and the laying of a foundation for future organic disease and morbid life, or premature death.

Ringworm is essentially a disease of defective nutrition; and those even, who, looking no deeper than the surface, believe the ringworm to be the growth of a plant in the horny covering of the skin and actively contagious by means of its seeds, are the first to admit that the seeds are incapable of vegetation without the presence of a morbid soil, of an unhealthy condition of the skin and of the economy favouring their development and growth.

In all these examples, as it appears to me, the one most pressing want is food, abundant and regular; and could we secure this necessity of our nature to all our fellow-creatures, one-half of the whole of the disease which pervades the world would be spared.

I must not be supposed to undervalue light, and air, and cleanliness, and exercise, the kindred of food; but if it were my commission to improve the human race; to produce finer, stronger, and better men; to extinguish disease; I should begin with food; and if it were my duty to lay down rules for the prevention of disease, I should, in the first instance, endeavour to secure the co-operation and influence of man's first and best friend—his stomach.

MEDICAL NEWS.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—Candidates admitted from July 1 to December, 1864:—

Charles Garland, Armagh; Brinsley M. Walton, Hurstpierpoint, Sussex; W. S. M. Price, Carmarthen; W. R. Thomas, 14, Church-street, Sheffield; Thos. Elmes, Limerick; Rowan Purdon, Tralee; John A. Byrne, Dublin; Nicholas J. Butler, Jordanstown; Wm. R. Macauley, Blackrock; John Snow Cunningham, Rathgar; Richard James Tyrrell, Dublin; Robert Francis Buchanan, Westport; Wm. S. B. Hamlyn, Plymouth; Joseph Allison, Barrow-on-Furness; George Bedford Saunders, Dublin; James M. Hannan, Staff Surgeon; Isaac Hoysted, Assistant-Surgeon 8th Regiment; Wm. Dyas, P. and O. Comp. Service; James Charles Broadbent, Hadlow, Kent; Henry Wade Battersby, Killarney; John S. Greene, Dublin; Thos. Henry Pickering, Dublin; Ed. Turner Thompson, Dublin; Chas. Stennet Redmond, Atley; Joseph Burne, Booterstown; Richard F. Tobin, Waterford; Andrew Rd. Cowell, Dublin; Wm. Henry Sexton, Dalkey; Shewbridge John Connor, Carlow.

APOTHECARIES' HALL. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, December 29, 1864:—

Frederick Chabot, 245, Camberwell-road; Tregenna Biddulph Goss, 24, Newington-place; Henry Mortimer Hawkins, St. Mary's-road, Peckham; Henry Harris, Finchley.

The following gentleman, also on the same day, passed his First Examination:—

John Loam, London Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

LINGEN, CHARLES, F.R.C.S. Eng., has been elected Surgeon Extraordinary to the Hereford Infirmary.

LUDLOW, EBENEZER, M.B., has been appointed Assistant-House-Surgeon to the Bristol Royal Infirmary.

TURNER, THOMAS, M.R.C.S. Eng., has been elected Surgeon to the Hereford Infirmary.

DEATHS.

HUMPAGE, EDWARD, M.R.C.S. Eng., at Cotham, Bristol, on December 22, aged 61.

LAWSON, WILLIAM, L.S.A., at 28, Howland-street, Fitzroy-square, W., on December 17, aged 64.

MOORE, EDWARD DENNIS, M.R.C.S. Eng., at Walsall, Staffordshire, fourth son of the late Brigadier-General George Moore, Colonel, 59th Regiment Bengal Army, on December 24, aged 31.

SCOTT, JOHN J., Staff-Surgeon, of Emaroo, Co. Tyrone, at Up Park Camp, Jamaica, on October 30, aged 34.

THOMSON, DAVID P., M.D., at Wakenaam, British Guiana, of yellow fever, on December 6, aged 43, one of Her Majesty's Justices of the Peace for the Colony, and Coroner, formerly of Liverpool.

YOUNG, EPAPHRODITUS, M.D. Edin., at Boswell House, Croydon, on January 2, late of Clapham-common.

THE CARUS PRIZE FOUNDATION.—Several friends of the veteran zoologist, Carl Gustav Carus, have determined to raise during his Presidency of the Imperial Leopoldino-Carolinian Academy, sufficient funds to found either a travelling fellowship or a prize for the reward of works distinguishable for their novelty or importance. The King of Saxony has placed his name at the head of what is already a considerable list of subscribers; but as it is believed that the

naturalists of various countries will gladly co-operate, a Committee has been formed (Dr. Berthold Seeman being the member for London), which will receive additional subscriptions.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

E. S.—Mr. John Wood, Montague-place, W.C.

Mr. J. Clarke.—The paper has been received, and is intended for publication.

An Old Subscriber, Liverpool.—Sir Hans Sloane (an Irishman) was the first Physician upon whom an hereditary title of honour had ever been conferred. George the First created him a Baronet; he was also the first Medical President of the Royal Society.

A Guy's Student.—The Harveian Oration, in memory of the discoverer of the circulation of the blood, is delivered annually (Midsummer-day) at the Royal College of Physicians. It is the Hunterian oration, in memory of John Hunter, which is delivered *biennially* at the College of Surgeons on February 14.

Mrs. Walker and Family, of Crick, near Rugby.

The following subscription has been received at the office of the *Medical Times and Gazette*:—Dr. Paterson, Partick, £1.

The Griffin Testimonial Fund.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The following subscriptions have been further received on behalf of the above fund:—Messrs. Davies and Hancome, Gower, 5s.; J. T. Tallent, Esq., Hingham, 10s.; Dr. R. Anson, Cambridge, 10s. 6d.; W. S. Barker, Esq., Thingoe, 10s.; A. S. Vandenbergh, Esq., Bethnal-green, £1 1s. Amount previously announced, £108 19s. 6d. Received at *Lancet* Office, £6 14s.

I am, &c.

Robert Fowler, M.D., Treasurer and Hon. Sec.

145, Bishopsgate-street Without, January 4.

Pryce *v.* Bowen.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I should esteem it a great favour if you would insert in this week's *Medical Times and Gazette* the following subscriptions for Dr. Bowen to assist him in defraying the legal expenses incurred by the late trial of "Pryce *v.* Bowen," and so oblige.

I am, &c.

H. D. Scholfield, M D., Treasurer.

14, Hamilton-square, Birkenhead, January 3.

Subscriptions for Dr. Bowen.

Dr. Scholfield, £5; G. Walker, Esq., £5; J. Godden, £5; Dr. Ricketts, £3 3s.; Dr. Downing, £2 2s.; Dr. Lambert, £2 2s.; Dr. Craig, £2 2s.; Dr. Spratly, £1 1s.; S. Edgar, Esq., £2 2s.; — Daniels, £2 2s.; M. Jennett, £1; E. L. Jacob, £1 1s.; — Lamb, 10s. 6d.

Received at the office of the *Medical Times and Gazette*:—Dr. Clapton, £1 1s.; Dr. Sydney Jones, £1 1s.

Consanguineous Marriages.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I am obliged to "A. R." for the references which he has given me, but the papers he names do not contain all I want. As this is a subject of some practical interest, I hope you will not allow it to drop without eliciting some information as to what opinion is held about it by those best qualified to judge, and whether the "warm debates" of "learned bodies" alluded to in the circular to the prefects have resulted in any conclusion that may be regarded as final, and if so, what it is. Possibly the discussion in the French Academy is not yet finished, but postponed pending the result of the circular.

I am, &c.

January 1, 1865. X.

The Birkenhead Case.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir.—It is not my intention to offer any opinion on this case, beyond stating my firm belief that Dr. Bowen treated Mr. Price according to the most scientific rules of Surgery; and the only oversight he committed was, that when vesications and sloughing of the skin commenced he did not ask some of his friends to see the case along with him—a proceeding which every young Surgeon is fully justified in, for his own safety and reputation.

As the case now stands, and in the absence of Mr. Lund's own statement, I also agree with you that, after having heard Mrs. Price, he might have communicated with Dr. Bowen before giving any opinion; and it is the greatest paradox to me that he did not do so.

I flatter myself that I know Mr. Lund well, or, at least, I ought to do. I was in the Manchester Hospital for three years, and out of that time I was Dissector for Demonstrations and clerk to that gentleman for over eighteen months. This brought me into constant contact with him; and during the whole of that time his conduct was that of the most perfect gentleman.

Judge, then, Sir, of my feelings when I read the letter signed "G.," in your journal of last week, in which the writer says: "Such a fellow (for he does not deserve the name of man or gentleman) should be scouted from the Profession."

Let me tell "G." that he is condemning an unheard person; that he is also condemning a man whom I believe to be as incapable of the charge laid against him as either he or any other gentleman can possibly be.

Hundreds of young Physicians and Surgeons, who have received their anatomical knowledge from Mr. Lund, will, like myself, rush to the rescue of his character. With Horace I may say:—

"Absentim qui rodit amicum
Qui non defendit alio culpante.
Hic niger est hunc tu Romane caveto."

I am, &c.,

James Leach, M.D.

Clough Cottage, near Oldham, January 4, 1865.

Resection of the Knee-joint at the Cape of Good Hope Naval Hospital.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—A letter received by the last mail from Dr. Stirling, Staff-Surgeon R.N., in charge of the Naval Hospital at the Cape, informs me that he had performed the operation of resection of the knee-joint on a warrant officer with complete success. The healing process appears to have gone on very rapidly, and at the date of the letter the patient was up and moving about.

The particulars of this case, with other capital operations which Dr. Stirling has had to perform during his short tenure of office at the Cape Hospital, will be found in due time among the records at Somerset House for 1864.

I very much fear that my friend's modesty will prevent him giving the details of this case to the public, although there is no one more competent to do so than he is. I would, therefore, beg to solicit a corner in your journal for this notice of the case, because the result of resection, as applied to the knee-joint, is still *sub judice*, and every case is valuable; and because, as I believe, this is the very first operation of the kind that has ever been performed in a naval Hospital.

I am, &c.,

Wm. Loney, F.R.C.S.

Army and Navy Club, January 2, 1865.

Incision of the Os Uteri in Rigidity.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I shall feel obliged if some of your experienced obstetric readers will favour me with the results of any cases where they have incised the os uteri in cases of rigidity which resist other means of procuring dilatation.

I had a case lately in which, though the labour lasted for three days, the os was only dilated about the size of a florin, and extremely rigid. Having held a consultation with a senior Practitioner, he was of opinion that any incision made in the os would be converted into a large rent during the process of extraction of the child, and that the os would dilate after opening the head by using traction. We accordingly delivered by the crotchet, and I ascertained that the os uteri was lacerated after the delivery.

I write this in order to elicit the opinions of some of the seniors of the Profession for guidance in a similar case, as I cannot find any directions in the writings of Ramsbotham and Churchill as to how the operation should be performed, and, indeed, they seem rather averse to the operation. I should think that four small incisions on opposite sides of the os would be preferable to forcible efforts at extraction.

I am, &c.

Obstetricus.

Management of the Third Stage of Labour.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The letter from your correspondent "Celer et Audax," in your number of the 24th ult., escaped my notice until it was too late to send a reply in this week's impression. I really think it would be a very useless controversy to discuss the claim to priority in describing the great importance of uterine pressure in the management of the placental stage of labour. I can assure "Celer et Audax" that I have no desire to contend for such a right. I distinctly stated in my paper that I had no doubt many would say that the principle advanced was, after all, no novelty; but I maintained, and I still repeat it, that this teaching is not definitely described and insisted on in our obstetric manuals. The capability of pressing off the placenta by judicious manipulation alone, without any traction on the funis whatever, is certainly not laid down; nor is it, I believe, understood or practised as it should be. I am convinced that there is a certain knack in the performance, which is only to be acquired by experience, if we would be almost universally successful in this manœuvre. I cannot agree with your correspondent as to the propriety of extracting the placenta instantly after the child is born—unless, indeed, it is clearly indicated from hæmorrhage, etc. Surely ten minutes is not too long to allow the poor sufferer to rest after the agonies of the expulsive efforts are ended? There are many little details in my paper which may not be uninteresting to "Celer et Audax;" and if he will kindly send me his card I shall have much pleasure in forwarding him a copy, should the dissertation be printed *in extenso*. I entirely endorse the opinion of Mr. Stedman (whose letter appears in your journal this week), that the teaching of the Dublin school, with regard to the arrangement of the Medical Attendant's hands during the birth, is greatly superior to any other school that I am acquainted with.

I am, &c.,

Henry E. Eastlake.

48, Welbeck-street, Cavendish-square, W., January 2, 1865.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Will you kindly allow me space for a word or two in reply to Dr. Greenwood and Mr. Stedman, both of whom assure me that "pressure on the fundus uteri and early extraction of the placenta" are not novelties? Although I am greatly gratified to see the testimony of two such veterans in favour of a practice which I, as a precocious youngster, have ventured to think my own, I should have felt better pleased had their letters appeared when I first wrote in August last. Never having seen or heard of such a practice being inculcated in text-books, or by writers on "Midwifery," and having found it so successful in my own practice, I was induced to suggest its adoption; and I was greatly surprised to find, three months afterwards, Dr. Eastlake propounding the same ideas (in a more elaborate form) at the Obstetrical Society, and being congratulated on bringing the subject so prominently before the Profession: hence my letter of December 24. I have been influenced solely by a desire to contribute my unit towards the advancement of our present knowledge; and I shall most willingly waive my claim to priority, merely remarking that it seems somewhat singular that a practice adopted twenty years ago at the Rotunda Holpital, Dublin, is only mentioned in Dr. Churchill's manual, under the head of "Treatment of Post-partum Hæmorrhage," instead of being regarded as a *sine qua non* in the management of natural labour.

I am, &c.,

January 2, 1865. "Celer et Audax."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The communications on this question by your several correspondents cannot be otherwise than deeply interesting to all of us who practise Midwifery, and if the assertions of these gentlemen be conclusive as to their habit of handling the fundus uteri and removing the placenta without adhesion or hæmorrhage, then many of us are taught a lesson which it were well we had been taught before. One thing seems omitted to be said—how long it may be necessary to keep the hand in that position for its pur-

pose. Having had in a long experience much Midwifery, I cannot help thinking these gentlemen have been very lucky as well as wise, for I certainly have on many occasions, notwithstanding keeping my hand over the uterus on the birth of the child, found a feebly contracting uterus, with relaxed abdominal muscles, exhaustion, and flow of blood on the separation of the placenta—all requiring further measures than such manipulation so infallibly successful in the practice of your correspondents.

In many delicate women, whose blood possesses little fibrin, hæmorrhage is most prone to occur under any and all circumstances, and especially when the *vis nervosa* is below par, with weak muscular fibre. Labour being a natural process, I believe many Practitioners leave too much to Nature; but at the same time Nature is not to be treated as an ignorant and helpless doer of her own work, as Mr. Figg and a few others seem to assert. In many cases it has appeared to me that when the uterus has cast the placenta into the vagina, and it is allowed to remain a time with the abdomen properly swathed so as to support the muscles and compress the uterus, it has been a block or impediment to more loss of blood. The "Celer et Audax" plan may be all very well, but I cannot allow it the infallibility which seems to be claimed for it. There can be no objection, however, to its adoption, and I thankfully accept all information so far as not to make it, when its magic may not be prompt, the plea of hasty interference. I am, &c. AN OLD PRACTITIONER.

THE REPORT ON THE HEALTH OF THE NAVY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the Statistical Report of the Health of the Navy for 1861, just published, the compiler has improved upon preceding reports by the addition of the names of the Medical officers employed during the period afloat. He evidently took a hint from the Army Statistical Report, but has failed to make his as perfect in this and other particulars. By comparing the two, you will observe that to the Army Report is appended a complete list of the Medical officers of that branch of the public service in order of seniority, including amongst its ranks that of Surgeon-Major; while to the Naval Report is appended simply the names of those officers who happened to have been employed in ships, or attached to ships for service, with marines, etc., during the period, without any distinction according to seniority, or any recognition of the rank of Staff-Surgeon—a rank corresponding with that of Surgeon-Major in the army. This is a grave error on the part of the compiler, and one he should correct in future reports; and I will tell you why. The Naval Warrant regulating the status of Medical officers, like the Army Warrant, states that there shall be four grades of Medical officers—viz., "Inspector-General, Deputy-Inspector-General, Surgeon, and Assistant-Surgeon"—and in another clause it directs that "Surgeons after twenty years' service on full-pay, ten of which must be in the rank of Surgeon, shall be styled Staff-Surgeons." The naval Staff-Surgeon, like the army Surgeon-Major, takes rank with Lieut.-Colonels, and gets higher pay than the Surgeons in either service, who only rank with Majors; but, from the date of the Warrant until the present, the Admiralty have never acknowledged the rank of Staff-Surgeon in the Navy-List beyond prefixing the letters S.S. to the name. The Army Office gazette their men to the rank of Surgeon-Major. Why should not the Admiralty gazette Staff-Surgeons? I, therefore, think that in a publication so purely professional a complete list of officers on the active list might have been given with with advantage. It would go far to force the Admiralty to a proper recognition of the Warrant, and do more good than may appear at first sight. You will also not fail to observe that the recommendations or suggestions of army Medical officers tending to promote or to preserve the health of the soldier are fully and fearlessly quoted at full length, whether they have met with attention from commanding officers or otherwise: whereas, in the Naval Report there is a remarkable reticence on this point whenever recommendations have been disregarded. If you should think it worth your while to review this Blue Book in the columns of your journal, I would suggest that you advise the publication of the names of all Medical officers on the active list on all future occasions after the enclosed model.

November 21, 1864. I am, &c. W.

ROYAL INSTITUTION, 3 p.m. Prof. Frankland, "On the Chemistry of a Coal"—(Juvenile Lectures).

9. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Dr. B. W. Richardson, "On Inhalation in the Treatment of Disease."

10. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ETHNOLOGICAL SOCIETY OF LONDON, 8 p.m. M. Khamkof, "Contributions to the Natural History of the Iranians." Sir Woodbine Parish, "On the Artificial Eyes of certain Peruvian Mummies." The Duc de Rousillon, "On the Scythians." Mr. Wallace, "On Civilisation in North Celebes."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Mr. Furneaux Jordan, "On Eczema of the Eyelids, Conjunctiva, and Cornea." Mr. Desvignes, "On Subcutaneous Injection of Quinine in Ague." Dr. Dobell, "On 'Winter Cough.'"

11. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

HUNTERIAN SOCIETY, 8 p.m. Dr. Peacock, "On Some of the Forms of Epidemic Disease recently Prevalent."

MICROSCOPICAL SOCIETY, 8 p.m. H. J. Slack, "On the Vinegar Plant."

12. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

13. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

ORIGINAL LECTURES.

CLINICAL LECTURE ON THE USE OF PERCHLORIDE OF IRON IN SOME CHRONIC DISEASES.

DELIVERED AT

King's College Hospital.

By LIONEL S. BEALE, M.B., F.R.S.

Fellow of the Royal College of Physicians; Physician to King's College Hospital; Professor of Physiology and of General and Morbid Anatomy in King's College, London.

I PROPOSE to-day to ask your attention to a very simple plan of treatment useful in certain forms of urinary diseases which often last for a very considerable period of time, and frequently resist the effects of various remedies administered for their relief. Many of the remarks I feel called upon to make are applicable not only to the particular cases under our immediate consideration, but to affections of other organs.

It is of the utmost importance you should observe for yourselves the course of the cases in the wards, and watch carefully the changes which take place in the patient's state while he is under treatment, for by careful observation alone can you hope to gain that practical knowledge which will give you confidence in diagnosing morbid conditions, or the experience which will enable you to suggest the plan of treatment most appropriate, and which affords the best prospect of being of service. We are not able to give precise written directions which would enable any one to suggest at once the exact treatment which should be adopted in each individual case of disease that may arise. A vast number of collateral matters must be considered, besides the disease itself, and these will differ in each individual patient; so that in the conduct of the case much must depend upon the judgment of the Practitioner, and good judgment can only be acquired by long-continued observation of very many different cases. This is one reason why our clinical observation is so much more useful to us in practice, and so much more to be relied upon than mere book knowledge.

I suppose there is not one branch of natural knowledge more difficult of investigation than therapeutics. Although Practitioners not unfrequently exhibit the utmost confidence in a particular remedy, and patients attribute to it the most wonderful powers, and appeal to its effects upon their own organisms in support of their assertions, it very often happens that after more careful observation it is discovered that the only virtue of the famous remedy is that it is harmless. Hundreds of new remedies are introduced, advertised into popularity, and found by experience to be useless. Practitioners apologise to themselves for using them on the ground that in a particular case very many other things have been tried in vain. Patients are so desirous to try anything new that they often consult one Practitioner after another in the hope of hearing of some new medicine they have not tried before. Thus it comes to pass that we really know very little of the action of many of the remedies we employ, and medicine profits but little by the life's work of hundreds and thousands of Practitioners.

I have often impressed upon you the importance of studying carefully every case before you attempt to advise as to its conduct, or to prescribe medicines, so that you may ascertain what actions are at fault, and consider how the general conditions under which the sick man lives may be modified so as to favour his recovery.

You must not, for example, when you find a quantity of pus in the urine say "Here is pus in the urine; what is good for pus in the urine?" but you must try to find out where the pus is formed, and consider what conditions favour or interfere with its formation. In fact, you must investigate fully the nature of the whole case, and you must think over the physiological and pathological changes which are going on. A Physician is not a mere physic-giver, but one whose business it is to relieve suffering and place sick people in a condition most favourable for their recovery. So that there are cases which may be well treated without a particle of medicine, in which if medicine alone were given, without any change of food and drink, air, clothing, &c., the treatment would be bad treatment indeed.

In prescribing I always employ the most simple remedies, and give them in the simplest form. I prescribe as few different medicines as possible, and avoid changing the remedy unless it is really necessary to do so. In this way every case may add something to our experience, and may teach something to every one who watches it. You will probably have remarked that I very seldom order a new remedy, and for years past I have persisted in prescribing some of the very simplest preparations in the Pharmacopœia, the value of which is undoubted. And I feel quite sure that we have yet very much to learn with regard to the action of some, even of the simplest and most common remedies, as, for instance, acids and alkalies.

For the last six years with very few exceptions the only preparation of iron that I have used is the tincture of perchloride of iron, and I propose to allude to certain classes of cases in which this remedy has proved of value. I have given it almost always in infusion of quassia. The mixture is one known to all Practitioners and commonly prescribed, but in many cases I am sure it is not continued for a sufficient length of time to produce benefit. I used the acid solution of the perchloride of iron in solution in water for many years when I was attending in the out-patient department, and I came to the conclusion that this much cheaper preparation was just as valuable as the more costly tincture. The composition of this "solution" is the same as that of the tincture, except that water is used instead of spirit. It has been in constant use in our Hospital for the last eight or nine years.

There is one other question to be considered with reference to the action of this remedy—namely, whether the benefit is due solely to the iron salt, or partly to this and partly to the free hydrochloric acid present. I am so satisfied of the advantage of the free acid that I often add to the mixture a little free hydrochloric acid. A little chloric ether or the spirit of chloroform of the British Pharmacopœia may be added; and in some cases, especially when the bladder is irritable, you will find the advantage of prescribing at the same time a little tincture of henbane. You may give these medicines in the following doses, omitting the spirits of chloroform or henbane as you think best:—

℞. Brit. Pharm.
Tr. Ferri Perchlor., ♏x. to ʒss.
Acid Hydrochlor. dil., ♏x. to ʒss.
Tr. Hyoscyami, ♏x. to ʒss.
Sp. Chloroform, ʒss.
Inf. Quassiæ ad, ʒj. to ʒjss.
M. To be taken twice a-day, at 11 and 4 o'clock.

Among the most obstinate and tedious cases which come under our care are those which depend upon chronic structural change in the kidneys. There is no remedy under which the condition of the patient improves so steadily as iron. Nor is it in one form only of the affection that iron is found to be of benefit. Iron may be given with the greatest advantage in that distressing form of fatty degeneration which occurs in young persons, as well as in the various forms of chronic contraction met with at a later period of life and under very different circumstances. I feel sure that in certain instances where the renal affection has not very far advanced the long-continued use of iron, combined with judicious management, may do more than improve the condition of the patient or retard the progress of the malady. It not unfrequently happens that a patient quite recovers, although albuminous urine has been passed during many months.

I would caution you against the inference that fat cells or even casts containing oil in the urine are necessarily indicative of the existence of fatty degeneration of the kidney, that must terminate fatally in a short time. I have shown that many small casts filled with oil and cells containing oil are formed in the follicles about the membranous portion of the urethra.(a) These are very likely to be mistaken for casts of the uriniferous tubes. Not unfrequently such bodies are found in urine containing pus and a *little albumen*, which might tend still further to mislead the Practitioner as to the nature of the case. It should be borne in mind that in fatty degeneration of the kidney there is almost invariably present a large quantity of albumen; but the Practitioner should always avoid committing himself to any positive diagnosis in a case of chronic renal disease until he has watched the course of the case for a short time.

In our Hospital we have unfortunately a far greater number of cases of chronic renal diseases than we desire for clinical study. It is seldom that there are not three or four

(a) "Urine, Urinary Deposits, and Calculi," page 309. "The Microscope in Medicine," fig. 216.

cases in each Medical ward. We have, however, the advantage of being able to watch carefully the course of many different examples of a most important class of cases, and are often enabled to study a case of chronic renal disease in various stages from its first commencement in an acute attack to its termination in recovery or death.

I have often had occasion to draw attention to cases of acute dropsy, which progress very favourably up to a certain point. By our purgatives and sudorifics all the acute symptoms are relieved, and perhaps very quickly so; but still there remains some anasarca, and still albumen in small quantity exists in the urine, and after the lapse of a month or six weeks the patient is no better than he was after the first fortnight. Now, it is useless to persevere in purgatives, dry cupping over the kidneys, hot-air baths, and various kinds of sudorifics. These remedies may even cause the dropsy to increase rather than diminish. The patient, already pallid, becomes more so, while the albumen continues to escape in the urine. A generous diet, with large doses of iron, will do much at this period of the affection. You may begin with twenty drops of the tincture of perchloride of iron in infusion of quassia two or three times a day, and gradually increase the dose to a drachm. Sometimes within a week manifest improvement has taken place, the fluid effused in the areolar tissue is absorbed, the quantity of albumen in the urine is diminished, the pale, pasty appearance of the face gives place to a ruddy complexion, the patient gains in strength, and in the course of a few weeks completely recovers.

I do not suppose that the benefit results merely from the addition of iron to the blood. There can, I think, be little doubt that the improvement is due to several circumstances. The state of the digestive process is altered, and the appetite is increased. The quassia and the free acid no doubt improve the action of the stomach, as well as the iron, but where digestion is very weak, you may give three or four grains of pigs' pepsin at dinner. I conceive that the reabsorption of fluid from the areolar tissue is brought about by the improved state of the blood. When the blood is poor the serum more readily permeates the walls of the capillary vessels, and if you keep the blood in a poor state by low diet, purgatives, and the like, the anasarca may increase rather than diminish. Not only so, but, as is well known, anasarca may be produced in a healthy person by depletion, low diet, etc. One of the worst cases of general anasarca I ever saw was that of a poor woman who had had a polypus of the uterus, which she would not permit to be removed, and from which hæmorrhage had been going on for months. After she had at last consented to its removal, the dropsy gradually disappeared, and, by the help of iron and good living she slowly got perfectly well.

But it does not always happen that by the use of iron, the dropsy, in a case of albuminous urine following acute dropsy, entirely disappears. Sometimes the patient remains in *statu quo* for weeks. In too many instances this results from a state of chronic change in the organ which we cannot cure. I have, however, found in several cases the greatest advantage result from the administration of alcohol at this period of the disease. In some cases in which the dropsy has continued for two months or more after the acute symptoms had entirely passed off, and perhaps for five or six weeks after the patient had been taking the iron, I have given four ounces of brandy or half a pint of wine in the twenty-four hours, and from the time this plan was commenced the case has steadily progressed towards complete recovery. You might at first be disposed to doubt the propriety of giving alcohol in chronic renal diseases, upon the ground that alcohol will produce chronic renal disease, and some consider that alcohol, as alcohol, reaches the kidney in a state of sufficient concentration to damage its structure directly; but of this there is the greatest doubt. Chronic disease both of the liver and kidney is induced by many other conditions besides spirit drinking. I think over-eating, and eating enormous quantities at one single meal, has given rise to quite as many cases of these conditions as alcohol, and therefore it is probable that the action of alcohol upon the renal tissues, like food, is indirect. But be this as it may, much benefit often results from the use of alcohol cautiously given in the course of chronic kidney disease.

We have learned that many cases of chronic renal disease which years ago would have been regarded as almost certainly fatal, recover, while others become so chronic that with ordinary caution the patients live for years, and it is often difficult to persuade them that they are not perfectly well. Albumen, however, still passes away in the urine, and so long as this continues the patient must be very careful to avoid taking cold. Not that he should be kept constantly indoors, for this is not the way to avoid "catching cold," and there can be no doubt that in chronic renal disease free oxidation is of the utmost importance. Even in the winter such patients should go out as much as possible, being well protected by warm clothing. Probably a thick woollen or wash-leather suit next the skin is the best protective in these cases. The general health should be carefully attended to in all cases of chronic renal disease. We should consider every point in connexion with the patient's daily life, with the view of keeping him in a good state of health, bearing in mind that it is almost invariably necessary to explain to the patient and his friends that confinement in hot ill-ventilated rooms is not the way to prevent persons from catching cold. The patient should be made to persist steadily with the tincture of perchloride of iron. You may modify the mixture I have suggested in very many ways, nevertheless still insisting upon the importance of the iron being continued twice or three times a-day for many months.

I might have supported the remarks I have made by giving several cases treated upon this plan, but as not two of them would be alike in all particulars, I prefer rather to draw only a general, and, it may be, a rough and not very decisive or convincing, inference than to follow the method sometimes adopted in such inquiries, of tabulating a great number of dissimilar cases and showing how many recovered in proportion to the number treated. Although this plan appears very precise, there are so many disturbing circumstances, that if employed I believe it is scarcely possible to arrive at the truth with reference to the value of different methods of treatment. Many would differ from me in this opinion, no doubt, but I feel convinced that the inquirer learns more with regard to the action of remedies by watching very closely and carefully a few cases than by putting down in different columns hundreds of cases treated upon one plan, and hundreds treated upon another, and hundreds not treated at all, and comparing the results. Some persons having done this, and finding that the number of deaths and recoveries under several different plans of treatment and under no treatment at all were about the same, have considered that the only legitimate inference to be deduced was that the treatment did nothing, and that it was therefore as well to adopt no treatment at all—an inference neither justified by the premises nor supported by evidence of other kinds. Statistics applied to such inquiries in the present imperfect state of knowledge are more likely to promote scepticism and retard the progress of Medicine than to advance therapeutics.

COURSE OF

LECTURES

ON THE URINE AND DISEASES OF THE URINARY ORGANS. (a)

By GEORGE HARLEY, M.D., F.R.C.P.,

Professor in University College, and Assistant-Physician to University College Hospital.

Lecture X.

DIABETES MELLITUS—GLUCOSURIA—SACCHARINE URINE—ITS NATURE AND RATIONAL TREATMENT.

(Continued from page 5.)

Quantitative Analysis.—At one time the quantitative determination of sugar was a long and tedious process, but now by adopting the following method I find it both quick and easy. Three solutions must be retained in readiness:—

1st. A standard solution of sulphate of copper, made by dissolving 34·63 grammes (536·76 grains) of dry sulphate of copper in 1000 c. c. (32·26 oz.) of distilled water. 1 c. c. of this solution represents 0·005 gramme of dry diabetic sugar.

2nd. A solution of caustic potash of the specific gravity of 1060.

3rd. A saturated solution of the bitartrate of potash.

The object of keeping these solutions separate, instead of combining them as is usually done, is in order to avoid the danger of the spontaneous reduction of the oxide of copper, which invariably takes place sooner or later in all the ordinary standard solutions. Having the solutions at hand, place before you two porcelain capsules, each containing an ounce of

(a) This Course of Lectures which we are now publishing has been, with certain modifications, annually delivered to Medical Practitioners during the last eight years.—Ed. *Med. Times and Gaz.*

distilled water; to which add 20 c. c. (measured in glass A, Fig. 8) of each of the solutions, first adding the copper, then the bitartrate, and lastly the caustic potash. Next take the measure B, Fig. 4, and pour into it 10 c. c. of urine, and dilute with 90 c. c. of water. The mixture will thus amount to 100 c. c.

The succeeding step is to put one of the capsules over the spirit lamp, and as soon as its contents begin to boil add, drop by drop, the diluted urine until the blue colour of the liquid entirely disappears. Then place it aside in order that the reduced copper may fall to the bottom, and allow you to judge by the depth of colour of the supernatant liquid if much of the oxide of copper still remains to be precipitated. While this is going on, boil the contents of the second capsule after adding to it an amount of dilute urine equal to that which was employed in the first experiment; and should the supernatant liquid in the first capsule turn out to be still blue, add, in addition to the amount already used, 5 c. c. of dilute urine. After boiling for a few minutes, place it aside in order that its reduced copper may fall down, and repeat the same thing with the other capsule until the exact quantity of dilute urine required to reduce the 20 c. c. of standard copper solution be ascertained. So soon as that is accomplished, all that is required in order to find out the quantity of sugar eliminated by the patient in twenty-four hours is to divide the total number of c. c. of urine passed by the number of c. c. of dilute urine required to reduce the 20 c. c. of copper solution.

Suppose, for example, the patient passed, as in case now before me, 3720 c. c. of urine in twenty-four hours, and 26 c. c. of dilute urine were required to reduce the oxide of copper, the 3720 divided by 26 would give the number of grammes of sugar contained in the twenty-four hours' urine.

$3720 \times 26 = 143$ grammes in the 24 hours' urine.

Those who have not the means of making a quantitative analysis in the way described may adopt the simpler, though less exact, method proposed by Dr. William Roberts. The following is the mode of procedure:—

1. Four ounces of urine are placed in a twelve-ounce phial, with a lump of German yeast of the size of a small walnut.
2. This is loosely corked, or covered with a slip of glass, and placed in a warm place to ferment.
3. A companion phial filled with the same urine—say a three-ounce phial—is tightly corked, and placed beside the fermenting phial.
4. In about twenty-two hours, when fermentation has ceased, the two phials are removed, and placed in some cooler part of the room.
5. Two hours after—that is, about twenty-four hours from the commencement of the experiment—the contents of the phials are separately poured into cylindrical glasses, and the density of each observed.
6. The difference between the two specific gravities is thus ascertained, and every degree of "density lost" indicates one grain of sugar per fluid ounce of the urine.

Crystals of diabetic sugar may be prepared by simply evaporating a few drops of urine to dryness on a glass slide. But this is only possible when the urine is very rich in sugar, and contains but little urea, and other salts. The most characteristic form of crystal is that of the rhomboidal prism occasionally arranged in arborescent tufts, as represented in the accompanying drawing (Fig. 26), which was kindly made for me by Mr. T. R. Loy, one of the gentlemen attending my practical class. Such crystals are in general called diabetic

FIG. 26.

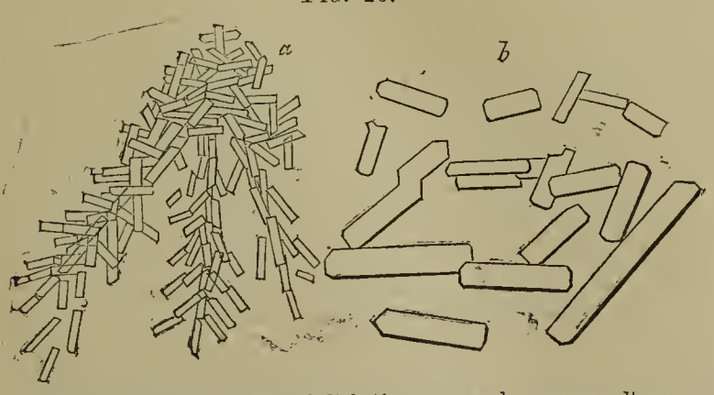

FIG. 26.—Compound crystals of diabetic sugar and common salt, spontaneously formed in concentrated human urine. *a* As seen under a low power. *b*. Highly magnified.

sugar; but I believe them to be a combination of sugar and chloride of sodium, for except in the presence of chloride of sodium diabetic sugar never assumes a so regularly prismatic form of crystallisation. Gibb says that when diabetic urine contains a larger proportion of salts, the sugar crystallises in little circular masses, with minute crystals projecting from the surface. The masses appear to be made up of an aggregation of flat plates of sugar, and, when examined on a dark ground, resemble lumps of the well-known barley-sugar.

Physiology.

If we desire to be philosophical as well as practical, it is necessary that we should thoroughly understand the origin and destruction of the sugar met with in the animal economy. I shall, therefore, now proceed to the consideration of the *physiology* of diabetes.

That sugar is a normal constituent of the human frame is easily shown by withdrawing an ounce of blood from a healthy man in full digestion, and allowing it to fall drop by drop into a couple of ounces of boiling water faintly acidulated with acetic acid. By so doing all the albuminous matters are so firmly coagulated, that on filtration a perfectly colourless liquid is obtained, and on applying to it the copper, potash, and fermentation tests, the existence of sugar can be demonstrated with facility. Should the patient have had a mixed meal, a great part of the sugar found in his blood will have been directly obtained from the food. This opinion is opposed to the view of Bernard, who on finding that animals have the power of making sugar out of albuminous substances, fell into the error of supposing that all the saccharine matter met with in the human body must of necessity be the product of the liver. The results of my experiments on animals have led me to an entirely opposite conclusion in as far as the omnivora and herbivora are concerned. This opinion I arrived at from finding abundance of saccharine matter in the blood of the portal vein and chyle of the thoracic duct of a dog, three hours after he had partaken of a quantity of horse-flesh, to which had been added a couple of ounces of soft sugar.

Even in those cases where the patient has had a mixed diet, without, however, having partaken of any sugar in a free state, I still maintain that a great part of the saccharine matter met with in the blood is the direct product of the food, for the following reason:—All vegetable foods, such as bread, turnips, carrots, potatoes, etc., contain a large quantity of starch, which starch during its passage along the alimentary canal is all, or nearly all, converted into sugar through the agency of the digestive juices, especially of the saliva and pancreatic fluids.

The transformation of amylaceous matters into glucose during their sojourn in the alimentary canal is not the result of accident, but the sequence of an unalterable law, which is equally in force in or out of the body, so long as the physical conditions necessary for its action are in operation. Thus, if an ounce of boiled arrowroot, in a test-tube, be mixed with a little saliva, or have added to it half a dozen drops of pancreatic juice, all the starch contained in the arrowroot will infallibly be changed into sugar in the course of a few minutes. And for this operation the intervention of no other agency than that of a temperature equal to that of the human body is required. A precisely similar change occurs in the animal organism, and the sugar thus formed is absorbed by the mesenteric veins and lacteals, and of necessity forms part of that met with in the circulation.

As regards carnivora, on the other hand, Bernard's assertion is strictly correct, as the result of the following experiment will prove. The experiment was most carefully performed some years ago by Professor Sharpey and myself, with the view of ascertaining not only if sugar exists in the blood of carnivora, but if sugar is actually present in the blood of the healthy animal at the moment of its withdrawal from the circulation.

From the femoral artery of a dog fed solely, during four days, on boiled flesh, perfectly devoid of sugar, one and a-half ounces of blood were allowed to flow directly into boiling water, acidulated with acetic acid, and when the clear filtrate from this blood was tested, it gave unmistakable evidence of sugar, which sugar must have been formed in the animal's body, seeing that not a particle of saccharine matter was introduced with the food. It is quite unnecessary for me to cite another experiment in order to prove that the animal organism has a sugar-creating power, for Nature has herself supplied the proofs. Is sugar not a constant ingredient of the normal milk of the flesh-eater, as well as of the vegetable

feeder? Most assuredly it is. If the animal body cannot form sugar, from whence does the milk of the carnivora receive its supply? For example, where does the sugar found in the milk of the polar bear come from if it is not manufactured by some organ or other in the animal's own body? Not only does the polar bear live on animal diet, but on the flesh of animals, such as the walrus and seal, whose chief food is fish, which fish, in their turn, are not usually supposed to live upon vegetable matter. As regards this point, I am even inclined to go a step further than Bernard, and not only assert that the carnivorous animal has the power of forming sugar out of albuminous substances, but that even in the case of the herbivorous animal the sugar met with in its milk is not directly obtained from the digestive canal. This, I think, is proven by two facts.

1st. Milk sugar possesses certain special characters which distinguish it from all vegetable sugars.

2nd. Milk sugar, although abundantly present in milk, has not yet been detected in the circulation. The natural conclusion, therefore, is, that it is formed by the mammary gland.

Consequently, it is perfectly clear that there must be at least one organ in the body capable of forming sugar.

Now comes the question—In what organ of the body is the sugar formed which is met with in the general circulation of the carnivora? Answer—The liver. Why the liver? Because, in the case of the carnivora, the blood proceeding to the liver is devoid of sugar, while that coming from it is rich in saccharine matter—richer, indeed, than the blood of any other organ of the body. As Bernard may be considered in the light of an interested party, and I have already cited some of my own experiments, I shall now quote three from an entirely independent observer—Schmidt, of Dorpat; (b) the results of which are as follows :—

	Percentage of sugar in Portal vein.	Hepatic vein.
1st dog (on animal diet) . .	0·00	0·93
2nd ,, ,, . .	0·00	0·99
3rd ,, (fasting during two days) .	0·00	0·51

These results I have again and again confirmed, so that there is not the slightest doubt left in my mind regarding their validity, and I believe that they furnish us with the key to the well-known fact that some diabetic patients, even when totally restricted to animal diet, still pass a large quantity of sugar.

Having now ascertained that the healthy blood always contains sugar, and that when the saccharine matter is not obtained from without, the body manufactures it for itself, the next point is to determine if sugar be absolutely essential to life, and what use or uses it is put to in the animal organism.

We must begin by finding out if the quantity of sugar in the blood is always the same, or if it be liable to variations, and to what extent.

From the results of a series of experiments made many years ago, I came to the conclusion that the amount of sugar present in the arterial blood of healthy animals is subject to great fluctuations, varying from an almost inappreciable quantity, after long fasting, up to 0·24 per cent. during the time of full digestion. In the hepatic vein the amount, Bernard says, may even be as much as 2 per cent.

The quantity of sugar present in the general circulation seems to follow a definite law, for it goes on gradually increasing as digestion advances, and as gradually diminishing as we approach the period for the next meal,—the maximum being reached four or five hours after food, the minimum during fasting. Saccharine matter does not entirely disappear, however, from the circulation till after prolonged fasting. Chauveau found as much as 0·05 per cent. in the blood of a dog, and 0·09 per cent. in that of a horse kept during three entire days without food. In these cases, as the animals were of course forced to live on their own tissues, the sugar formed by their livers must have been made out of some one or other of the constituents of the blood.

The rise and fall in the amount of sugar in the circulation, according to the state of the digestion, is clearly the key to another often-observed pathological fact—namely, that in all cases of diabetes the amount of sugar in the urine is subject to great fluctuations during the course of the day; while it furthermore explains why in some slight cases of diabetes sugar is only to be found in the urine a few hours after a meal.

(To be continued.)

ORIGINAL COMMUNICATIONS.

CASE OF AMPUTATION OF THE THIGH—ACUPRESSURE—RECOVERY.

By WILLIAM KEITH, M.D.,
Senior Surgeon Royal Infirmary of Aberdeen, and Lecturer on Clinical Surgery to the University.

Mary M., aged 29, married, admitted into the Royal Infirmary, Aberdeen, on October 17, 1864, with complete disorganisation of the knee-joint, abscesses burrowing in the thigh in all directions, and communicating with the joint. Had been ill for three years, and was in a very exhausted condition. Having somewhat recruited by November 16, by absolute rest and a generous diet, the limb was removed at the upper third of the thigh; and having previously warned my clinical class to watch the case as one in which I meant fairly to test the value of acupressure and wire stitching as proposed by Dr. Simpson, I secured all the arteries—six in number—that required it, by long pins passed under the artery a little way above its open mouth, looped over with wire, and a twist given to the wire round the pin, the tail ends coming out alongside of the pin, exactly as Dr. Simpson planned at the outset of this movement. The faces of the flaps were brought into apposition and secured by eight wire stitches, and the edge of the wound hindered from crusting by a small strip of moist lint laid over the wound.

November 17.—The blood ooze from the wound was most trifling.

November 20.—Four days in. Two of the pins and wire loops were removed; no bleeding whatever.

November 21.—Three of the remaining four pins were to-day withdrawn; a mere drop of blood following as the wire loops came out. The patient going on most favourably; though weak, yet cheerful, sleeping soundly and eating well.

November 23.—Seven days after insertion. The pin controlling the femoral artery was withdrawn, not a drop of blood following.

December 4.—The wound is at this date quite cicatrised, and now only are the eight wire stitches removed, eighteen days after insertion, having caused neither heat, redness, nor suppuration. At no period during the healing process was there ever beyond a teaspoonful of pus seen within the twenty-four hours, and that evidently from the lips of the wound. As she had to travel a distance to her home, she was detained in hospital, only to be fed up until December 21, when she left as sound as a bell. It was unquestionably one of the most satisfactory recoveries I have ever had after amputation of the thigh.

CHILD-CROWING—THE MOST EFFECTIVE REMEDY EXPOSURE TO DRY, COLD WINDS.

By J. ROBERTON, Surgeon, Manchester.

Having a number of years ago given an account of this complaint. with a history of twenty-two cases, I am, notwithstanding, induced (owing to the timidity of parents, as well as of some of my Professional brethren, to have infants exposed in cold spring weather) to furnish additional evidence with regard to the innocence of my principal means of cure.

It may be said, and with truth, that various authors among their remedies for this disease recommend change of air. It is not, however, mere change of locality that I advise, but the free exposure of the infant out of doors, for many hours daily, to a dry, cold, atmosphere; and if the air be dry, the colder the better. The following, from the pen of the late Dr. Marshall Hall, is worthy of attention; and I refer to his opinion regarding atmospheric exposure in child-crowing on account of his acknowledged eminence both as a writer and a practical Physician :—

"The baneful influence," says he, "of the north-east wind, and the curative influence of change of air, and especially of the sea breezes, are not less marked in this affection than in whooping-cough." Again: "All inclemencies of the weather being avoided—for heat, cold, and the north-easterly winds are alike injurious—the child should be much in the open air."

The five following cases, selected out of a number in which

I have been consulted since the publication of my paper above referred to,(a) and all of which have been treated on the same principle, are instructive, especially as showing, contrary to Dr. Marshall Hall's opinion, that easterly and northerly winds are not injurious but curative. Were these winds injurious it would indeed be unfortunate, since, owing to causes I cannot account for, every instance of child-crowing that I have seen has commenced in the winter or spring, as the following list of cases (of which I possess notes) proves:—In November there was one, in December four, January seven, February eleven, March thirteen, and in April four; in all forty cases.

In the way of preparation for change of air the following particulars demand attention:—

1st. Careful scarification of the gums, so as to make and keep bare the tips of the advancing teeth.

2nd. Correction of the alvine secretions, which are nearly always of a pale colour, by small doses of mercury with chalk shaken up in a little syrup.

3rd. Free sponging of the body every morning with cold water.

4th. Warm clothing, suitable to the season of the year.

5th. If the child is in part or altogether handfed, careful attention to the diet; since excess of food is found to aggravate the crowing and other symptoms.

Case 1, January, 1856.—E. H., a girl twelve months old, with only two lower incisors cut, and suffering from the gums over the upper incisors, had crowing spasms very frequently, and while in them was stiff and struggled severely. The thumbs were turned into the palms of the hands, and there was blueness always remaining under the eyes and round the mouth and nose. Was taken in January to Alderley, but the weather being damp and close, she grew rapidly worse while there, having as many as thirty-two attacks of crowing in the twenty-four hours. At the end of a week she was brought back to Manchester, and then taken without delay to the shore below Liverpool. There the weather was found to be intensely cold, and a strong and bitter east wind blowing. Sometimes the nurse who carried baby about could hardly stand with her in her arms, so strong was the wind. Baby was a month at the shore, being out in all weathers for about six or seven hours a-day. From the end of the first week there was evident improvement, and by the end of the third week the crowing spasms had ceased, nor has she ever suffered from a return of them. She was sponged with cold water night and morning; had careful attention paid to the diet, especially as to the quantity she ate; and before the two upper front teeth (which caused her much suffering) came through, her gums had been lanced eleven times. She is now a strong healthy child.

Case 2.—February, 1856.—H. P., a boy ten months old, had for some weeks been feverish and starting in consequence of cutting his side teeth; the gums were frequently scarified, giving relief at the time. About a week before "crowing" was heard he had two convulsions, and for some days was seriously ill. "One morning," as the mother wrote me, "on going up early to his room the nurse drew my attention to his hands—the thumbs were drawn into the palms; and when dressing him I found his feet were also drawn, so much so that I was unable to put on his boots. The nurse told me she had been alarmed by the child making a peculiar noise as though struggling for breath. I remarked also a blueness about the mouth and nose, which made me fear he had been convulsed during the night. I had heard you describe the symptoms of "crowing inspiration," and therefore lost no time in sending for you. Your order was to take him off without delay to Blackpool or Fleetwood. On account, however, of the severity of the weather, and his having a cough, I sent him with his nurse to Southport. In a day or two I went to see him, and found him very little better: his hands and feet were not so much drawn, but the "crowing" was more frequent. On my reporting this, you considered Southport not sufficiently bracing, and you wished me to take him to the bleak shore at Fleetwood, which I accordingly did. There had been a heavy fall of snow, and a north-east wind prevailed more or less the whole time we were at Fleetwood. Every day, wet or fine, he was wrapped up warmly and drawn out in a perambulator from morning till evening. He improved daily; the fits of "crowing" became gradually fewer and less severe, and at the end of three weeks he returned home perfectly well.

(a) "On the Treatment of Laryngismus Stridulus, or Child-Crowing." Page 502 of "Physiology and Diseases of Women, and on Midwifery," published in 1851

Case 3.—January 11, 1857.—Visited Mr. W.'s baby, a male, aged fourteen months, suffering from the incisor teeth, and from fits of crowing with clenching of the thumbs. The gums were scarified, the bowels regulated, care enjoined as to diet, and it was intimated that he must be removed immediately to the sea side. In about a couple of days an attack of crowing terminated in convulsions, and as the child's grandfather happened to live near Disley, at the foot of the hills, the family, with my approval, had him carried thither. On reaching Disley, as the nurse was lifting him from the carriage, he had crowing followed by convulsions. The weather was dry, the cold intense, and the country deep under snow; nevertheless, he was carried daily to the top of a neighbouring hill, and afterwards in a perambulator was wheeled about in the snow most of the day, greatly to the surprise of the country people, who thought the nurse must be out of her mind. A man said, "Are ye mad, lass? ye'll kill that child." She replied, "The Doctor has ordered him to be carried on the hills." "I don't care about Doctors," said he, "ye'll kill him." The crowing was rapidly mitigated, and I was assured by the babe's aunt, who accompanied the nurse, that the crowing and other symptoms had disappeared by the end of a week.

Case 4.—February 4, 1857.—Was consulted regarding a fine, vigorous, male infant, aged 11 months, suffering from the incisor and bicuspid teeth, with crowing and drawing of the thumbs. After dividing the gums, minding the bowels, the diet, and the clothing, I advised a removal to the sea side. The baby's mother, however, having occasion to visit a relative, about ten or twelve miles north of this, in the country, took him thither for change, but with little or no benefit, and on her return, the crowing being frequent and of alarming violence, I advised his being taken forthwith to the dry breezy shore of Blackpool. His mother wrote me from Ulverston as follows:—"We have come here after a month at Blackpool, and I am thankful to be able to give you a satisfactory report. You will remember that the day we last brought baby to you his thumbs were in; we went that afternoon to Blackpool, and before night the thumbs were out, and have only been in once since for part of a day, which was about the tenth day after we got there. We were not able to carry out your system fully for the first ten days, on account of a sharp cough, the weather being at the time most severe, but as soon as the cough moderated we had him out all weathers—for the first week from five to seven hours daily, the second week from seven to eight hours, and for the last week he has been out between ten and eleven hours each day. We took him out both when sleeping and waking, in hard frost, in the bitterest east wind, in a north westerly wind that I could scarcely stand against with him in my arms, in hail-storms and in snow, and yet he never suffered from cold, but on the contrary benefited visibly in health, whilst the crowing gradually diminished. We wrapt him up well certainly, and in that inclement weather he was the only one of the party to come in warm. I have strictly followed your directions; the diet is plain, and the meals given with regularity; the bowels are in order, and he ails nothing but the occasional crowing, which has now ceased to be alarming. His eye teeth and four double teeth are coming, yet it is wonderful how little they affect his health and spirits; he has twelve teeth through, and is now 13½ months old." On returning from Ulverston after two or three weeks, the crowing and the other symptoms had ceased.

Case 5.—January, 1861.—This I attended with my friend Mr. Mellor. The narrative is chiefly from the pen of the little patient's mother. "My baby (a girl aged five months) had her first attack of crowing when at Southport, near the end of January, 1861; but, not knowing anything of the nature of the complaint, it did not alarm me until the attacks, on our return home in February, became frequent and severe. One Sunday the crowing recurred every fifteen or twenty minutes, and early next morning the gums were freely lanced; yet still the paroxysms continued frequent. In the course of the following night they altered in character, for baby with the crowing had twitching of the face, and the feet and hands were drawn. This state of things lasted only for a short time; but still, after each attack, the toes and thumbs were drawn in, and remained so for about an hour, leaving her painfully restless. Baby had now to be hand-fed, and took the bottle well. On Tuesday, by your advice, we set out in an open carriage for Kersal Moor; but before going far she had a convulsion, and we had to turn back. The same afternoon she had a most distressing attack; for, after a crow, the

features were drawn, the eyes and mouth firmly closed, and she lay as if dead. After a short interval, however, she sobbed, and by degrees became sensible. On one occasion I stood with my watch in my hand, when baby remained in the apparently lifeless condition I have mentioned for three minutes. On each of the two following days we drove in an open carriage to Kersal Moor; and the last of these alarming attacks occurred at the inn there. On Friday morning we left for Buxton, in Derbyshire. The day was bright, but cold; yet she was out all day. After this she passed a better night, having no attack till early morning, when there was one of a comparatively mild character. We remained at Buxton till the end of March. The weather was very stormy and windy, the wind generally from the north-west. The hills around were capped with snow, and the ground also occasionally was covered with snow; yet, unless a downfall prevented us, baby was out four hours every day; and if she could not be taken out, the hall door of the inn was kept open and she carried about in the hall. Sometimes we took a drive in an open carriage; and twice went half way to the Cat and Fiddle, said to be the highest inhabited house in England. Here I may remark that although the weather at Buxton was bitterly cold, baby never took the least cold, but steadily improved. When we returned home at the end of the month the complaint was gone, save an occasional catching of the breath. In April, 1862, when she was nearly twenty months, the crowing returned during the cutting of the eye teeth; but this time it occurred only in the night—about four times nightly. She had her gums lanced, and was sent to the shore at Southport; after arriving there she had no return."

I have, in conclusion, to observe that in the numerous cases of stridulous crowing that have come under my notice, painful dentition has been the sole cause. I have never seen or heard of one instance of the disease before or after dentition —always during the teething period; and the opinion advanced by some that child-crowing is owing to morbid enlargement of the glands of the neck, or of the thoracic absorbent glands, has no support from facts.

SUDDEN DEATH, SUPPOSED TO HAVE BEEN CAUSED BY TAKING BATTLE'S VERMIN KILLER.

By WILLIAM STEDMAN, Esq., M.R.C.S. Eng.

On the 29th November, 1864, I was sent for to see M. A. S., aged about 30 years. I found her lying on the floor of her bedroom, dead. Her features presented perfect calmness, the eyelids were partially closed, the lips livid, the fingers and toes quite flaccid.

Rumours of poisoning having arisen, I was desired to make a post-mortem examination in time for the inquest on the 1st December:—

From the evidence adduced, it appeared that on the day of her death she sent a little boy who was passing her door for twopennyworth of vermin poison at about 11·25 a.m.: the boy returned without it, not being able to get so small a quantity; the deceased went next door, borrowed a penny from her neighbour, and again sent the boy, who returned with the poison, "a 3d. packet of Battle's Vermin Killer," gave it to the woman and left the house. In the course of a few minutes a little boy living in the same house wanted to speak to the woman, found her in the bedroom, and she asked him "Are my lips black?" "Is my tongue black?" The boy took no notice of the remark, because, as he says, "she had had fits before." In a few minutes he went up again to the woman, found her leaning on the table, speechless and motionless (doubtless dead). He ran for a neighbour, who came in, and being alarmed fetched her husband, who returned with her, laid the deceased on the floor, and came for me. I arrived exactly at 12·10, and found her dead.

No trace whatever of the poison has been found on the premises; neither cup, nor glass, nor any other vessel in which she could have mixed it, was to be seen. One glass only was found down stairs which was not clean, but from which, without washing it, some gin was taken by one of the layers out, who found no injurious effects from it.

Another witness stated that he was about to be married to the deceased; that he had been to sea; that he had at different times given her money to the amount of £12, and that he was about to receive from her a sum of money to go to Portsmouth to buy tools on the day following that of her death; that on examining her pockets, etc., no money could be found, and none had been paid into the savings bank as had been expected.

I then gave evidence as to the results of the post-mortem examination (in which I was assisted by Mr. Bannister) which were as follow:—

External appearances quite natural, without any sign of spasmodic rigidity. Lungs healthy in structure and very much congested. Heart rather large, pale, and flabby. Stomach contained a small quantity of thick fluid, the stomach itself presenting appearances of slight congestion, which may have resulted from chronic indigestion. Liver and intestines healthy. The head was not examined, as our attention was more particularly directed to the stomach. I gave as the cause of death, failure of heart's action and congestion of lungs.

Having given this opinion, and explained to the jury that I did so in the absence of analysis, and the coroner not thinking the latter necessary, as there was nothing criminal in the case, the jury were evidently dissatisfied, and could not agree as to the verdict, there being such strong evidence of the tracing the poison to the deceased, and of the supposed motive for her having committed the act, viz., that the money which ought to have been forthcoming had been made away with: they deliberated for some time, and ultimately found a verdict of "death from natural causes," although I am satisfied that every one of them, and indeed every one in the room, with the exception of myself, believed her to have taken the poison.

Under these circumstances I, the next day, sent the stomach with its contents to London, and through the kindness of my friend, Dr. Gervis, of St. Thomas's-street, and Dr. Bernays, the Lecturer on Chemistry at St. Thomas's Hospital, they were carefully analysed by the latter gentleman with this result,—that no trace whatever of strychnine, arsenic, or any ordinary poison was to be found; but that in the opinion of Dr. Bernays, the stomach presented appearances of having belonged to an intemperate person.

Now, I conceive this to be a very interesting case, both in a pathological and a Medico-legal point of view.

First, as to the poison and its acknowledged action.

The active principle of this poison, "Battle's vermin-killer," doubtless is strychnine, and according to Dr. Letheby, who analysed a packet of it in the year 1861, contains 23 per cent., or about three grains in each packet: although Mr. White, from whom the packet in question was purchased, tells me that it contains 10 per cent., or from one and a-half to two grains in each packet.

As to its action:—From all that I can glean from authors and experiments of the present day, strychnine taken in poisonous doses never fails to produce tetanic spasms; and although half a grain has been known to kill in five minutes, the same symptoms presented themselves, and indeed, for the last forty years the effects have been the same, Orfila, in his "Traité des Poisons," 1818, giving the following description of the action of those poisons containing it:—

He says—"Ils doivent être regardés comme des excitans de la moelle épiniére, sur laquelle ils portent leur action en déterminant le tétanos, l'immobilité du thorax, et par consequent, l'asphyxie, à laquelle les animaux succombent."

"Quellque soit la surface du corps avec laquelle ils aient eté mis en contact d'une maniére convenable ils sont absorbés, portés dans le torrent de la circulation, et l'absorption parait s'opérer par l'interméde des veines, comme M. Magendie l'a observé le premier."

"Leur action est trés prompte lorsqu'on les injecte dans le pléure, le peritoine, ou la veine jugulaire; elle l'est moins lorsqu'on les applique à l'extérieur, ou lorsqu'on les injecte dans les artères éloignées du cœurs; les effets tardent encore plus à se manifester lorsqu'on les applique sur les surfaces muqueuses.

"Aucun de ces poisons ne produit l'inflammation des tissus sur les quels on l'applique."

Now, in this case, the poison was sent for twice, at a distance of 100 yards from the house, received by the woman, and death had taken place in the course of thirty minutes, and not a trace of rigidity was to be seen on the body immediately after death.

Then, with respect to the motive of the poor woman to destroy herself, it is true that the man may have given her the money, but it is much more likely that he had received it back again, as he was known to have been drinking about a great

deal, and his own sister told me she was quite sure that the poor thing would not spend her brother's money.

Great stress was laid on the remarks, "Are my lips black?" "Is my tongue black?" These were very likely remarks to have come from a woman who had been subject to what is termed "fits," who had doubtless been subject to hysteria, and might have had fainting fits; and why should she ask "Are my lips black?" when the poison supposed to have been taken was not black, but light blue? And she could not suppose that the colour would be changed by contact with her lips.

The post-mortem appearances were quite sufficient, independently of poison, to account for death by syncopic asphyxia; and, although there is nothing in these appearances opposed to the possibility of death from strychnia, the results of the analysis, conducted not by any inefficient manipulator, but by one of the first toxicologists in London, are to my mind quite conclusive, especially as a sufficient cause of death existed in the condition of the heart.

It is true that she was a poor woman, without any friends, and who would not be missed at all by the world in general, and but very little by her own class of life; still, it is equally true, that under any circumstances, and in any position of society, the awful crime of suicide is a very dreadful one, and one which is regarded with natural horror by every right-minded person; and therefore I say, that without some positive proof of poison having been taken, it is equally cruel and unjustifiable in any person to cast such a stain on another who may have died suddenly, and, as in this case, because the poison was traced to the deceased and could not be found afterwards. It is impossible to say what was done with it, but after the results of the analysis it is quite clear it was not in the stomach.

It has been suggested, but I think without much reasoning, that the poison acted at once on the deceased, because she had a weak heart; if this were so, how is it that the poison was not detected? Death having taken place so suddenly, it must have remained in the stomach, and therefore must have been found.

Looking at the case in all its points, I think it a very interesting one; and although it would take a great deal to convince me that strychnine can produce such sudden action, without tetanic spasms, still everything is possible; and should strychnine be possessed of more deadly properties than at present it has the credit of, it is a most fearful thing to know that in so short a space of time, and without leaving a trace behind, lives may be destroyed by a 3d. packet of vermin powder, which may be procured by any little boy who may be sent for it; and it would certainly become the duty of the Legislature to place some check on the indiscriminate sale of such a frightful means of death.

Havant.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

NORTHAMPTON GENERAL INFIRMARY.

FIBRO-PLASTIC TUMOUR OF THE ANTRUM — EXCISION OF THE SUPERIOR MAXILLA — RECOVERY.

(Under the care of Mr. MASH.)

For the notes of the following interesting case we are indebted to Mr. Buszard, Resident Medical Officer to the Infirmary:—

Ann H., aged 24, a domestic servant, was admitted January 30, 1863, with a tumour of the upper jaw.

History.—She has never been strong, and has had several rheumatic attacks, which have left their traces in considerable disfigurement of the finger joints. The right knee-joint is also partially anchylosed from previous chronic inflammation. For the last ten months the tumour in the jaw has been slowly growing, but without occasioning any very severe pain.

Position and Appearance of the Tumour.—Viewed externally the tumour formed a smooth globular swelling over the left superior maxilla, causing a considerable prominence of the cheek on that side. On looking into the mouth, the tumour was seen to spring from the left upper alveolar ridge (the molars were lost), and to project across the roof of the mouth towards the opposite side. The upper surface of the projecting portion was covered by the tense mucous membrane of the gum, but the under surface was ulcerated and sloughy, though firm, and without any disposition to bleed. The premolar teeth were loose, and embedded in the substance of the growth, the site of which was plainly indicated by the easy passage of a probe from the gum into the antrum. There was no enlargement of the submaxillary glands.

When admitted the patient was in a very anæmic state, with a furred tongue, bad appetite, and feeble pulse, but after a course of tonics and generous diet she improved considerably, and on March 28, eight weeks after admission, she was considered well enough to submit to the operation proposed, viz., excision of the left superior maxillary bone.

Chloroform having been administered, to complete insensibility, the operation was performed in the following manner: The left central incisor having been removed, a semi-lunar incision was made commencing a little below the external angular process of the frontal bone, and extending across the cheek into the angle of the mouth, the dissection being carried gradually from the skin to the mucous membrane, so as to allow of each artery being secured as soon as divided, and to prevent the escape of blood into the mouth. A second incision was then made from the upper edge of the nasal process of the superior maxilla along the side of the nose, round the ala, and into the mouth through the centre of the upper lip, and the flap thus formed dissected up. The alveolar border and palatine process were next sawn through by means of a narrow saw introduced into the nostril, and a notch was then made in the bone with the saw immediately below the orbit, as this was not encroached upon by the tumour, and the cut continued through the malar bone, the nasal process being divided by pliers. The operation was speedily brought to a close by seizing the superior maxilla with forceps and drawing it steadily forwards, a few touches of the knife facilitating its removal. A small portion of the tumour which extended deeply required scooping out with the handle of the knife. There was but little hæmorrhage, and only one bleeding-point required a touch with the actual cautery. Some strips of lint were laid in the cavity, and the flap having been brought down and retained *in situ* by a few interrupted sutures and strips of plaster, the patient was removed to bed and ordered ♏ xv. of Battley's liq. opii sed. Milk and beef-tea in small quantities occasionally.

In the evening she was tolerably comfortable; pulse 110; liq. opii sed., ♏ xxv.

29th.—Patient twice sick during the night. Slept a little at intervals. Pulse 118. Slight swelling of cheek. Ordered—ice and milk, one ounce of brandy with arrowroot. Rep. haust sed., hâc hocte.

30th.—An erysipelatous blush has appeared on the face, and there is slight oozing of pus from the incisions. The mouth was well syringed and cleaned with warm water, the lint removed from beneath the cheek and replaced by fresh; the external dressings were likewise reapplied, and warm water dressing laid over the face. Eight ounces of port wine and strong beef-tea ordered.

31st.—Erysipelas has spread over the forehead, and both sides of the face, which is much swollen. Pulse 130, feeble. Pus thin and serous. All the sutures were removed, and the cheek supported by a few strips of plaster, warm water dressing over all the inflamed surface. To relieve the fetor and unpleasant taste caused by the escape of pus into the mouth, it was ordered to be well washed out with a dilute solution of permanganate of potash two or three times daily. The bowels not having been relieved since the operation, an enema of castor oil and barley water was ordered to be given.

April 2.—The parts present a more favourable appearance this morning; the erysipelatous inflammation is subsiding. The incision in the lip and a portion of that through the cheek have united. The pus is more healthy in character. Pulse 120. The patient has derived great comfort from the use of the permanganate of potash lotion; it has certainly greatly diminished the fetor of the breath.

5th.—Progressing favourably. All inflammation has disappeared; the appetite is returning. An egg pudding was ordered.

On the 7th she was able to eat some chicken, and on the 9th she was put on the ordinary diet of the Hospital, with a pint of porter instead of wine.

From this date recovery was uninterrupted; the external wound was soundly healed by the end of the month, and she was discharged cured on May 21. There was but very slight

deformity of the face, except that caused by the cicatrix across the cheek. When seen four and a-half months after discharge, she continued quite well, and there was no appearance of any return of the disease. She continues well to the present time.

The tumour examined microscopically was found to be of the fibro-plastic variety, consisting for the most part of nucleated elongating fibre cells, with intervening fibrous tissue.

GUY'S HOSPITAL.

DISEASE OF THE HIP-JOINT—LARDACEOUS DISEASE OF THE LIVER—PYÆMIA.

(Under the care of Mr. COOPER FORSTER.)

The following case shows the relations of visceral affections to disease which at first is local. It points to the necessity of bridging over the practice of Medicine and Surgery. Whilst a Surgeon is treating a patient for disease of bone he may be dying, not directly of exhausting discharges, or worn out by pain, but of lardaceous disease of his viscera. We have heard it remarked by an eminent Pathologist that not unfrequently the visceral disease is discovered for the first time on the post-mortem table. As a rule, lardaceous disease is connected with diseased bone or with syphilis; but, as in Dr. Greenhow's case, there is no such cause. Not unfrequently the hip-joint is the part diseased, and this probably produces the visceral disease, because it keeps the patient in bed, and is altogether more serious than disease of one of the smaller joints. Not long ago, however, we saw in Guy's Hospital, at the same time, two cases of lardaceous disease, in one of which the hip, and in the other the elbow, was affected. Curiously, the patients were brothers. In all cases of disease of joints, or of disease of bone, we ought at least to examine the urine. Indeed, Dr. Wilks says that he had observed that albuminous urine was very frequently found in cases of disease of bone before he noticed the more particular relations of lardaceous disease of the kidney. The following cases are unfortunately meagre, but they show, in outline at least, the relations we have mentioned. They are copied from the records of post-mortem at Guy's Hospital. The first of the cases has a particular interest as showing the occurrence of pyæmic abscesses in a liver previously diseased. The patient was cut off by pyæmia whilst dying of lardaceous disease.

John T., aged 26, was admitted under the care of Mr. Forster, November 19, and died December 23. He was admitted with suppurative disease of the hip-joint, and was at the same time in a very bad state of health.

Autopsy by Dr. Wilks.—The left hip-joint was quite disorganised, and the bones necrosed. On attempting to remove the head from the acetabulum it was found that it was loose in the socket, but whether the separation had occurred before death was difficult to say. The head and neck of the bone were black and carious, and the former separated into a number of small portions. The acetabulum was also black, and decaying. Suppuration existed all around, and a large abscess in the thigh had extended upwards beneath Poupart's ligament, along the psoas as high as the kidney. Except minute cretaceous deposit in the apex of one lung, the lungs were healthy. The liver was lardaceous throughout to an extreme degree, but scarcely above the ordinary size, although heavier. It also contained numerous abscesses in its substance. They were recent, and evidently of pyæmic character, having their origin in the abscess connected with the hip, which nearly reached the liver. The spleen was healthy. The kidneys were pale, soft, and coarse. There was no reaction with iodine, but they did not appear healthy.

SYPHILITIC CACHEXIA—LARDACEOUS KIDNEYS—DEATH FROM INJURY.

(Under the care of Mr. HILTON.)

Thomas J., aged 50, was admitted, under the care of Mr. Hilton, on October 16, and died December 12. This patient was run over, the wheel passing over the abdomen. He was a cachectic man, and suffered from the results of syphilis, and had sores on his legs. His urine was highly albuminous. Some peritonitis followed the injury, but from this he recovered, but died afterwards from gradual exhaustion.

Autopsy by Dr. Wilks.—The body was cachectic-looking, and showed results of syphilis. There was a depression on the head, where there had been caries of the bone, and the nose was sunken, and flattened, and seamed. There were sores on the legs, and the tibiæ were enlarged. These were old pleural. The lungs were puckered in several parts. At the lower edge and front part of the upper lobe of the right lung a tumour could be felt, about the size of a marble. When cut through, it was found to consist of a hollow case, consisting of some cretaceous matter, and it was filled with a gelatinous matter, looking like coiled-up hydatid membrane. The coils of intestine in the lower part of the abdomen were closely adherent to each other and to the abdominal wall. The liver was firm and of a dark colour, but gave no reaction with iodine. The spleen was rather larger than usual, and very firm. Its sections showed it lardaceous throughout. The kidneys were very firm and wax-like, showing an extreme form of lardaceous disease, and giving the reaction with iodine. The testes were structurally destroyed, and consisted of tough masses of fibrous tissue.

MIDDLESEX HOSPITAL.

CASE OF LARDACEOUS DISEASE OF THE LIVER, SPLEEN, AND KIDNEYS.

(Under the care of Dr. GREENHOW.)

The chief interest of the following case lies in the fact of the apparently spontaneous origin of the degenerative disease, unassociated with either necrosis, constitutional syphilis, or phthisis, one or other of which diseases almost invariably precede it.

T. A., aged 33, baker, admitted as an out-patient June 17, 1864. A thin man, of pallid complexion, but not otherwise of unhealthy aspect. Had never had jaundice, nor, indeed, any other disease before his present illness, his health having always been perfectly good until a fortnight before he presented himself at the Hospital. Had been first attacked with pain and swelling of the left leg, but at the time of his admission was suffering from considerable anasarca of both legs as high as the knees. Heart sounds normal; respiration puerile and harsh in the upper part of both lungs, was scarcely heard below the point of the scapula on either side posteriorly or below the fifth rib anteriorly. Crepitation was heard over a very limited portion of the right lung just above the angle of the scapula, but there was neither cough nor expectoration. Pulse quiet, skin cool, tongue clean but injected; appetite good; bowels regular, once a day, but loose; urine sp. gr. 1010, contained a large amount of albumen, but scarcely any casts.

A tumour was found in the abdomen, extending from the right to the left side, so as to occupy both hypochondria. This tumour appeared to be perfectly smooth; was quite free from tenderness; had never been the seat of pain or discomfort; and, indeed, the patient was unaware of its existence until it was discovered during the examination at the Hospital. Chest resonant to the fourth intercostal space. Absolute dulness on percussion from the fourth rib on right and the fifth on left side anteriorly, downwards, to a line drawn about an inch above and parallel to the umbilicus, where there was perfect resonance from side to side. There was a manifest projection of the tumour in the epigastric region, pressing the front of the xyphoid cartilage forwards and upwards. The tumour had a slightly elastic feeling, especially in the projecting portion. The abdomen measured thirty-five and a-half inches just above the umbilicus, and thirty-six and a-half inches midway between the umbilicus and the xyphoid cartilage. Abdomen everywhere resonant, excepting over the tumour, and the resonance, from an inch above the umbilicus downwards, was equally noticeable in the recumbent and in the upright position. No ascitic fluid could be detected on the most careful examination.

During the next two months the anasarca extended upwards to the thighs and lower part of the trunk, but the upper part of the body and the face remained unaffected. Towards the end of this period ascites supervened, the pulse became quickened, the strength of the patient began to fail, and he was admitted into the Hospital on August 19.

August 20.—Girth at umbilicus, 39½ inches; midway between umbilicus and xyphoid cartilage, and also at xyphoid cartilage, 38½ inches. Extent of tumour much as before. There is still a definite projection in the epigastric region, very well defined at upper margin, but less defined than formerly at side and lower margins. On right side near margin of false ribs is an ovoid projection less hard than carcinomatous tubercles usually are, and with a somewhat elastic feeling. There is fluctuation from side to side in lower part of abdomen. Considerable œdema of scrotum, penis, and lower extremities; œdema of back as high as angles of

scapulæ ; crepitation in base of both lungs, respiration harsh and sonorous ; heart-sounds normal ; pulse 100 ; veins of neck, especially left jugular, distended ; abdomen traversed by large veins ; tongue injected, tender, and denuded of epithelium ; bowels open twice daily, rather loose. Urine amber-coloured ; sp. gr., 1012 ; about three pints in twenty-four hours ; albuminous, but less so than prior to admission.

September 23.—Ascites has increased ; girth at umbilicus is now 41 inches ; patient has cough, and expectorates thick transparent mucus containing streaks and sometimes small clots of blood ; complains of sore throat ; fauces and tongue extremely red ; no appetite ; has nausea and retching ; pulse 100 ; bowels and urine as before.

October 6.—Girth at umbilicus forty-three inches. Has constant vomiting and retching, can keep nothing on his stomach ; tongue very red, and covered with slimy mucus ; teeth and lips covered with sordes ; pulse 112 ; bowels loose ; urine, sp. gr. 1010, about a pint and a-half in twenty-four hours ; contains less albumen.

He gradually sank, and died October 12.

Post-mortem Examination.—Body much emaciated ; lower extremities and scrotum very œdematous ; no œdema of trunk or arms ; pleuræ and lungs normal ; peritoneal cavity distended with clear serous fluid. Liver firmly adherent to the diaphragm, and enormously enlarged ; the enlargement affected both sides equally. The lateral lobes were prolonged upwards, pushing up the diaphragm on either side to a level with the upper border of the fourth rib. Projecting somewhat from the centre of the upper surface of the liver was a smooth, round enlargement about three inches in diameter. The surface of the liver elsewhere was somewhat lobulated, but smooth ; the capsule was much thickened. There was a deep hollow in the under surface of the left lobe, in which the enlarged spleen was contained ; and the right kidney was partly embedded in a similar depression in the right lobe. The substance of the liver was very firm, and on section presented a well-marked, glistening, lardaceous appearance. The enlargement on the upper surface did not differ in appearance from the rest of the liver. On the application of iodine the whole organ became deeply coloured. At the surface of the posterior border of the left lobe was a yellow somewhat cheesy mass the size of a small walnut, and near it were several other smaller ones ; here and there in the substance of the liver were portions passing from the surface into the interior of an almost white colour and somewhat fibrous appearance ; these gave the same reaction of colour with iodine as the rest of the liver. The glands in the transverse fissure and small omentum were large, firm, and, on section, presented a lardaceous appearance ; they also became deeply coloured on the application of iodine. The liver weighed 11 lbs. 8½ oz. ; it measured from anterior to posterior border on each side 12 inches, along the anterior border 10 inches, and in depth 5 inches. The spleen measured 7 inches from above downwards, and weighed 17½ oz ; its substance was of a dark colour, and rather soft, not presenting to the eye an amyloid character, and at first gave no characteristic reaction with iodine, but on examining with the microscope pieces which had been lying for some hours in a glycerine solution of iodine the smaller arteries were found deeply coloured and their walls thickened. Some of the cells of the pulp were also coloured and enlarged, others had their normal aspect. The kidneys were both very much enlarged, capsules non-adherent, surfaces smooth and pale ; on section the organs were found very firm, the cortices much increased in depth and of a glistening waxy appearance ; on applying tincture of iodine, the malpighian corpuscles and the small vessels became deeply coloured, there was also some general colouring of the substance of the cortex. Right kidney weighed 11 oz. ; left kidney 12 oz. Stomach and intestines normal.

ST. GEORGE'S HOSPITAL.

CASES OF CONTINUED FEVER EXHIBITING SOMEWHAT UNUSUAL PHENOMENA—SPINAL SYMPTOMS—CLINICAL REMARKS.

(Under the care of Dr. OGLE.)

During the autumn of last year many cases of "fever" were admitted into St. George's Hospital ; and during the space of the week beginning October 19 more cases of this disease were admitted than had been brought in for several years previously in the same period of time.

The following cases were treated by Dr. Ogle, and to him we are indebted for the details and interesting remarks on their peculiarities. The cases are very important in many ways :—

The patients were mostly from Chelsea or the neighbourhood, and reminded one very strongly of what used to be admitted in former years under the name of "spotted fever." It was, in many cases, very difficult to decide whether they should be termed typhus or typhoïd, the "rash" on the skin being so undetermined and irregular, both in character and mode and time of appearance. For the most part the surface of the skin was noticeable as being very rough, owing to enlarged papillæ. In several of the cases the urine contained a considerable amount of albumen, and in some this fact, coupled with the occurrence of "head symptoms" of a certain kind, rendered it difficult for some time to be quite certain that the case was not one of disease of the kidney, with accompanying cerebral symptoms. In one instance, that of a woman, Anne G., aged 23, this was pre-eminently the case, and rendered more so, perhaps, from the comparatively and persistently low temperature of the surface of the limbs and trunk of the body, and from the alleged fact that before the beginning of her feverishness she had been delirious for nearly two weeks, and for three weeks had suffered from defective memory, owing, as it was said, to her having been frightened by a man-servant at the house where she was a housemaid. In her case the urine contained traces of blood as well as albumen, much lithate of soda, and a few faint granular casts of renal tubes.

After her admission a certain degree of vomiting was experienced. The pupils of the eyes were, however, not noticed as being affected, and she answered questions rationally up to two days before death. At no time was any pain complained of.

On close inquiry, it turned out that in the immediate neighbourhood of the house where she had lived several drains had been opened shortly before her illness, to the annoyance of the inhabitants. Before death the evacuations were passed involuntarily, but there never was decided diarrhœa ; there was also considerable tympanitis.

On post-mortem examination, it was found that there was no disease of the brain or of the lungs, but manifest congestion of the kidneys, and obvious ulceration of the lining of the small intestines.

But the peculiarity which Dr. Ogle noticed especially on reviewing the entire list of fever cases which came under his care was the frequency of the occurrence of what are termed spinal symptoms, as contradistinguished from cerebral symptoms. This was in very many cases manifested quite at the commencement of the case by the existence of intense pain at the lower part of the back, very much reminding one of the complaint so often made by patients in the early stages of small-pox. It was in several cases declared by the great sensitiveness of the skin of the body, which was perfectly hyperæsthetic. This was so much the case in one woman, Susannah J., aged 28 (admitted on the ninth day of the fever), who was throughout remarkably deaf, and who had been much neglected, that she could not bear to be touched in any part of the front of the chest ; so that Dr. Ogle had the greatest difficulty in stethoscoping her. She was also remarkable for extreme pains in the legs, which were quite free from swelling, etc., in any part ; and she had a conspicuous red line along the gums. She quite recovered. In another patient, a girl, aged about 19, the illness had begun with such acute pains about the knees and ankles that she was sent into the Hospital by a Medical man as suffering from acute rheumatic fever. In a boy, Augustus F., aged 15, the pain for several days was acute in the middle of the dorsal region, especially on pressure ; the other parts of the spine, and also the flanks, were quite free from pain. This boy always for many days complained of feeling giddiness in the head whenever he closed the eyes voluntarily.

In one man from Westminster, Thomas S., aged 40, who died four days after admission, and who had been much neglected, having well-marked maculæ in the skin, there was, when first taken in, so much irregular spasmodic movement of the limb that he was thought at first sight to be suffering from choreic symptoms. In his case the urine contained much albumen.

But the case in which most of all the spinal symptoms were developed was that of Anne W., aged 18, from Chelsea, a short, fair, and well-made girl, who, eight days after admission, complained much of pain over the region of the bladder, although at that time her aspect and pulse were much improving. Two days later she could not be kept quiet, and sat up picking the bedclothes, and often trying to get out of bed. In the evening the head was noticed as being drawn back in a singular way ; and on the day after, the muscles of the neck were remarkably rigid, and the head was so far and so

firmly drawn back that breathing and swallowing were very greatly interfered with. Still the picking of the bedclothes went on. During this time the whole surface of the skin was exceedingly sensitive to the touch. She died three days after the extreme restlessness and the tetanic state of the muscles set in; but unfortunately post-mortem examination could not be obtained. This woman lost a brother and some other relation by fever about the same time; but in them there was no manifestation of the spasmodic state of the muscles.

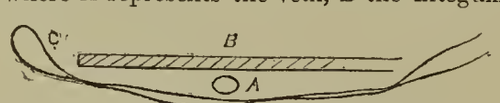
In almost all the fever cases alluded to, Dr. Ogle began with wine from the first, and trusted chiefly to it and to salines with an excess of the sesquicarbonate of ammonia, and to ice applied in bladders to the head. In one or two cases he tried Dr. Graves' plan of applying warm applications to the head, but found this was not appreciated by the patient as were cold applications. During the very week following the admission of these cases of fever, in which derangement of spinal functions was so conspicuous, the work of Dr. Fritz on the spinal symptoms observed in typhoïd fever came into Dr. Ogle's hands fortuitously.(a) In this work the author enumerates the numerous symptoms indicative of derangement of the spinal cord and medulla oblongata, especially in epidemic attacks, observed in this disease, among others mentioning rigidity of the muscles of the neck and such as might be termed tetanic. These spinal symptoms he has encountered among young women and infants and anæmic people, and describes them as generally continuing to the middle or end of the first week. After death but little alteration in the spinal cord can be recognised. The prognosis is always serious. The work is divided into eight chapters, and on the whole treats of its subject very completely.

As indicative of the severity of the epidemic at Chelsea at the time of the year in which Dr. Ogle's cases occurred, we may mention that one of the patients, who died with pneumonia on the fourth day after admission, had a brother in the Hospital with fever at the same time as himself, had lost his mother with the same, and had had one sister, also his brother's wife, and one of his own children all down with fever, but they had recovered.

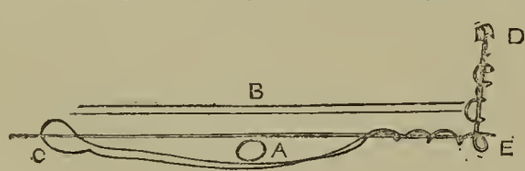
KING'S COLLEGE HOSPITAL.

A new and ingenious method of subcutaneous ligature of varicose veins has lately been introduced at this Hospital by Mr. John Wood, by which a regulated degree of pressure may be applied to the vessel under operation.

The method of proceeding is as follows:—A portion of the integument with the vein to be tied is pinched up in the fingers, and an ordinary needle armed with a thin wire suture is passed under the vein, and the needle then withdrawn, leaving a loop of wire in the wound, as in the following diagram, where *A* represents the vein, *B* the integument, and



C the wire. The integument is again pinched up, this time leaving out the vein, and one of the rectangular pins, used by Mr. Wood in his hernia operations, only with a straight point, passed in over the vein through the passage of the first needle and through the loop of wire—thus, where D repre-



sents the hernia needle. The wire is then pulled tight by its free extremity, and twisted round the end of the needle. Then, by rotating the needle by means of its arm (D E), it is evident that the vein must be occluded by the mutual pressure of the needle and the wire, and that consequently any required degree of pressure may be brought to bear upon it by rotation of the arm (D E). The point of the needle is then cut off.

The advantages of this operation are, besides the fact of being able to regulate the pressure, the ease with which the needle and wire may be withdrawn, which is not the case with the twisted suture in common use, as it often sticks so tightly as to cause great irritation; for this can be withdrawn by merely untwisting the wire and pulling out the needle. Also an equal amount of pressure is applied to both sides of the vein, and there is less irritation than in the twisted-suture operation.

Several cases have been under treatment lately, among which we may mention the case of a man who had his internal saphena tied at one of the London Hospitals, and he came to King's College Hospital with the vein pervious. A month afterwards Mr. Wood tied the vein by this method, and it was occluded in a short time (about three weeks); and there have been others equally successful.

Medical Times and Gazette.

SATURDAY, JANUARY 14.

THE NEW INDIAN MEDICAL WARRANT.

We publish to-day in our columns a letter from "An Indian Surgeon" on the new Indian Medical Warrant, and we confess to a feeling of disappointment as to its tenor, as we had hoped that Sir Charles Wood's new scheme would have been found to remedy fully the injustices under which the Indian Medical officers have so long laboured; but we fear that a spirit of discontent, generated by the persistence through years of disregard in official quarters to real grievances, has become chronic in the Indian service, and that time alone will effect "a perfect cure." It would be far beyond our limits to analyse the document *in extenso*: we shall therefore content ourselves, in the first place, with entering a caveat against the opinions advanced in it being those held by the service at large: as far, at least, as we have been able to ascertain, by communication with other Indian Medical Officers at present at home; and in the second place we shall offer a few remarks on certain passages which appear to us to call for special comment.

The "Indian Surgeon" first complains of the right reserved by Government of making alterations in rules and regulations of the service. When, it may be asked, was it otherwise? Certainly not under the old Company. Has our correspondent been long enough in the service to remember the time when the Court of Directors instituted an organic change in the term of service of its Medical officers by substituting a system of pensions according to length of service, in place of that for rank, which had previously been in force? Would he have a service like the laws of the Medes and Persians, which altereth not? No such thing as a "covenant," to use the expression in its integrity, has ever existed between Government and its Medical officers; the rules and regulations of the service always have been, and always must remain, subject to such alterations as "the powers that be" may from time to time deem advisable. On this point we cannot admit that there is valid cause for complaint.

In connection with this point, our correspondent complains that the services of a Medical officer may legally be dispensed

with at a moment's notice. True; but the same objection applied to the Court of Directors, who, when occasion required, exercised this right without scruple. The "Indian Surgeon" may, perhaps, remember, not many years since, an instance of the services of a Medical officer of the Madras Establishment being summarily dispensed with, he having been guilty of an act which, though not cognisable by a court-martial, was clearly derogatory to his character as an officer and a gentleman. A man entering the service need not be under the slightest apprehension as to this power being exercised, so long as he conducts himself with even ordinary propriety. Pressure from without, to say nothing of a sense of justice, will always prevent any injurious operation of this right.

Urgent complaint is made of the withdrawal of the charge of European troops. This, it must be admitted, is a hardship, but it was a necessary consequence of the transfer of the whole of the European troops to the British force. The Medical officers of the latter service would have had a legitimate grievance had these corps been left in charge of the local Indian Service,—a wholly separate service under the new constitution of things. It is only the *military* European charges which are withdrawn; all the civil and other European charges at the Presidencies remain intact.

Again, complaints are urged on the score that the pay of Surgeons-Major of twenty years', and Surgeons of fifteen years', standing at full batta stations is reduced, the former to the extent of £5 12s., and the latter £2 10s. per month; but the fact is ignored that these self-same grades at half-batta stations receive, under the new Warrant, an increase per month of £14 16s. and £12 6s. respectively. We cite this example particularly to illustrate the spirit in which we conceive the whole letter to have been written. Why should the unfavourable side alone have been held up, the favourable points being either ignored altogether, or passed over with a slighting remark?

We are surprised to find complaint made with regard to the Deputy-Inspectorships (the real prizes of the service) being conferred on merit by selection, in place of the old system of seniority, under which any dolt, whose sole recommendation perhaps was that his bodily health and animal spirits had enabled him to resist climatorial influences, was placed over his superiors in every respect excepting the accidental one of having a few years', or few months' perhaps, longer service. We have always been told that the seniority system was one of the evils of the Indian Service; talent, energy, and other good qualifications being regarded as subordinate to length of residence in India, and we believe that the change in this system, if carried out in its integrity, will exercise a beneficial influence instead of a prejudicial one, as anticipated by our correspondent.

With regard to the abolition of the Medical Funds, we have, in a former number, expressed our opinion that the step was injudicious. At the same time, we may remark that these funds have long since become little else than insurance offices, and on the increased rate of pay under the new Warrant, without deduction for these funds, the prudent Medical officer may obtain very nearly as great, if not greater, advantages by effecting an insurance in some of the many good mutual insurance companies now existing in all the large presidency towns of India. Still, we agree with our correspondent in thinking the abolition of these funds a mistake, to say the least of it.

We are at a loss to understand the complaint with regard to the abolition of Staff salaries, as by Section 27 of the Warrant of November 7th the said Staff allowances are distinctly and specifically admitted.

We could offer many other remarks on other parts of the "Indian Surgeon's" letter, but we forbear for the present. We trust that we have said enough to show that some of his statements at least must be received *cum grano salis*, and that, whilst he has magnified the evils, he has not given due weight to the good points of the new Warrant.

MODERN SYPHILOGRAPHERS.—No. V.

THE NON-CONFORMABLE TYPE OF CASES OF SYPHILITIC DISEASE.

In the more mixed, varied, and anomalous forms we can generally draw trustworthy conclusions if we make our diagnosis from a consideration of the whole of the symptoms, instead of resting it upon the presence or absence of any one of them.

"The initial lesion in constitutional syphilis is a sore, indurated as a rule, generally solitary, involving only a part of the thickness of the tissue upon which it is seated, with sloping and not abrupt perpendicular edges, indolent and chronic in its nature, yielding a scanty discharge, serous or epithelio-purulent rather than purulent, not auto-inoculable, following a longer period of incubation than the non-infecting sore, and attended with an induration of multiple glands, symmetrically placed, and without tendency upon their part to suppurate."

This is commonly followed, within three months, by some one or more of those manifestations of constitutional disease which we have before enumerated, provided no specific treatment has been pursued and the patient has not been labouring under another general disease. We will now consider those cases which are not conformable to this general law.

Induration of the chancre, as we have said already, has been made too much of. Its *positive* evidence is reliable, but the *negative* not so.

Among the poor, the dissipated, and military classes the sources of infection may be manifold, and on this account a combination or co-existence of venereal diseases must often be present. There is no valid reason why a man should not contract a gonorrhœa, chancroid, and syphilis at the same time, or at different times within very short intervals. In practice this is found to be the case:—A man is suffering perhaps from multiple, soft auto-inoculable sores with or without an acute bubo in one groin, and, as these sores heal, one of them takes on a definite and specific induration, and the inguinal glands become indurated in a chain on one side, with an abscess and some indurated glands on the other—or no induration may appear in the sores, but it may affect the cicatrix, or the inguinal glands only—or there may be a solitary and very superficial erosion, inflamed and discharging pus, and induration may appear subsequently beneath this, or the sore may very quickly heal, and the inguinal glands enlarge subsequently. Again, the physiological properties of tissue modify the morbid process, as we perceive when the syphilitic virus falls upon the mucous membrane covering vascular and spongy tissues, as the glans penis of the male, and the vulva of the female, in whom the typical indurated chancre is relatively very rare; or, again, a soft sore (chancroid), involving the areolar tissue, may be attended with a large amount of peripheral swelling and hardness from the amount of effusion attending the inflammatory action, and so it will simulate an indurated chancre; or the induration proper to the chancre may be present in, but concealed by this inflammatory effusion. Now, these are not mere refinements—no spurious varieties which depend upon a love of hair-splitting; but they are drawn from actual observation. Can we explain them, and can we reconcile the great differences which exist between the observations of equally accurate and truthful inquirers? We think modern syphilography has gone a great way to doing so.

It is allowed on all hands that the induration is very varied in its degree, duration, and time of appearance; and by many of the best syphilographers (Bassereau and Sigmund in particular) it is confessed, that induration is not *proper* and *essential* to *every* true *chancre*, and that constitutional infection may be manifested where the primary lesion has been an erosion of so trifling a kind as to have escaped detection, and to have left no trace of cicatrix; but in these cases the state of the inguinal glands will be the test, for *there* will the swelling and induration almost invariably be found. How are we to explain the occurrence of syphilitic manifestations after sores which appear to possess the characters and conform to the

*

type of soft sores? In the first place, we must eliminate all those cases wherein syphilitic phenomena appear *consecutive* to the healing of a soft, non-infecting sore, but are not the *product of it*. For example, a man contracts a true syphilitic lesion (chancre) in January, which heals; and in February, say, he contracts multiple soft sores, during the treatment for which the manifestations of the infection engendered by the first, appear. But there is no great improbability in the assumption, that the fluids from a prostitute may be the vehicle of more than one virus; and if these fluids fall upon an abraded mucous membrane, *there* will the primary lesion be situated.

Let us suppose—what is in the highest degree probable—that a previously syphilised female labours under the soft ulcers (chancroid), then, she may give the two diseases to one person at the same time; and in this way ulcers may appear within a few days, which pursue the course of soft sores until near their termination, when one of them (or a fresh abrasion in their neighbourhood) assumes the characters of the true syphilitic sore, at the date at which the virus should manifest itself—viz., from one to four weeks after contagion. By this twofold infection two separate affections may occur, and pursue their usual courses in close proximity one to another, or they may even occupy the same locality.

Suppose, further, that an abrasion on the male organ is inoculated with the *pus* of a true chancre, it may be that we get a bastard form of sore—inflamed, pus discharging erosion merely—which will, in time, assume specific anatomical characters. The condition, as well as the kind of the fluids, which are the vehicles of the virus, appear to exercise some influence upon the form and character of the lesions they beget; thus, inoculation with the products of secondary lesions or with the blood of a syphilitic patient, is generally preceded by a rather longer incubation, before the appearance of the papule which becomes a raised tubercle.(a) Mr. Henry Lee has shown that the infecting indurated chancre is not capable of being auto-inoculated, unless it first be made to yield pus by inflammation, when its fluids may give positive results. And, we presume, most Hospital Surgeons have seen a few cases in which the constant contact of a gonorrhœal pus with fissures or abrasions on the prepuce has given rise to irritation, inflammation, or even ulceration of a non-specific character.

The *sores* upon the *external skin of the dorsum of the penis* very frequently prove of the infecting character, although much modified in form; and this fact is becoming generally recognised. An oval, raised, indolent elevation, feeling like a piece of cloth in the tissues; a large erosion with irregular edges and ulcerating in a slow and progressive manner; an inflamed-looking patch with some peripheral hardness, perhaps, and having on its surface a thin, dry, tenacious scab,—these may, one and all, be true chancres and the precursors to general syphilitic manifestations. When these lesions heal, a minute knot of induration, like a millet seed, may be often found in the cicatrix. A brownish discoloration, from pigmental deposit, marks the scar, which tint is, in turn, replaced by a patch of whitish hue.

In these cases, too, we may fail to find the enlargement of the inguinal glands, but, in its stead, a knotted cord-like induration of a lymphatic vessel can sometimes be traced.

Bubocs.—The enlargement and induration of the inguinal glands separately and in a chain are the ordinary concomitants of the true chancre, and it is allowed on all hands that constitutional syphilis does not commonly follow suppurating buboes; though occasionally it does! Now, the number of examples of a double infection (the mixed, twofold, hybrid sores of which we have spoken) witnessed in a given number of cases of all venereal ulcers, corresponds very closely with the number of those exceptional cases in which "secondaries" do follow an open bubo. Mr. Henry Lee's statistics at the Lock Hospital (b) coincide remarkably, he says, with the results of the experimental observations of M. Rollet and Fournier into the subject of this twofold inoculation.

There are, however, other causes for the suppuration of the groin of a syphilitic patient,—1. Conditions of constitution—strumous and lymphatic subjects. 2. Causes of local irritation. In these an *accidental* inflammation and suppuration may affect the lesion of the genitals, and the lymphatics may take up the purulent fluids, become poisoned, and an adenitis of the groin may follow, exactly in the same way as an inflammation of the absorbents may follow an inflamed toe or finger, and an abscess of the axilla or groin ensues. 3. A slight amount of suppuration over an inguinal gland, with a recrudescence (a "breaking out") at the site of the chancre, may coincide with the appearance of secondary manifestations.

By whichever of these modes the abscess takes place, it is an exceptional, *accidental* and not an *essential* phenomenon, and the presence of enlargement and induration in the chancre or the remaining inguinal glands, one or both, will generally suffice to determine the diagnosis.

Secondaries after Gonorrhœa.—Swediaur, Hunter, and Wallace have described such cases, and they do occasionally occur, or, more properly speaking, they seem to occur.

Inoculation does not assist us here, for the soft sore (chancroid) is alone auto-inoculable. In some cases intra-urethral chancre may be seen at or near the meatus, but occasionally no such lesion can be discovered. One of the explanations now offered is, that the vaginal fluid from a constitutionally syphilised woman may have syphilitic properties engrafted upon it, and the syphilitic process may run its course as a part and parcel of the gonorrhœal inflammation, with the exciting cause of which it is associated, the evidence of any induration being lost in the swollen state of the urethral mucous membrane.

The *bubon d'emblée* is extremely rare, and it is allied to those cases in which symptoms of constitutional syphilis have been said to appear after no *observed* primary or initial lesion. These occurrences cannot be determined very positively, because the primary lesion may have been very trifling, and escaped the notice of the patient when it did exist. Still, the doctrine of physiological absorption of Hunter—viz., the direct absorption of a virus without any abrasion or ulcer, may be a fact of rare occurrence. Cases of such are mentioned by Ricord, Diday, Lane, Erichsen, and others, and it certainly does occasionally happen that very puzzling cases turn up in practice, such as Mr. Wilson, for instance, describes. Dr. Durkee, in his able and very practical treatise upon these diseases, has a chapter headed "Secondary Symptoms without Primary;" but the instances he cites are open to the same objections, and the wording should run, "without any *observed* primary symptoms."(c) We think Mr. Ceely proved that vaccine virus long maintained in contact with the healthy skin has, in a few rare instances, been absorbed. Does this never happen on the skin of the penis in persons of dirty habits?

As we have said, the result of experiment is parallel with that of our ordinary observation, that a primary lesion of some sort follows at the point of application of the syphilitic virus. We may leave the doctrine an open question, however, for the

(a) The question occurs here, Does a similar period of incubation always ensue, whatever be the source of the virus and its vehicle? The French Commission, in their report to the Academy of Medicine on the contagiousness of secondary syphilitic lesions, state, that the length of the period of incubation was characteristic. We strongly suspect that the activity of the virus diminishes according as it is obtained from the primary or later lesions, and that the period of incubation will be shorter where the source of contagion has been the pus from an indurated chancre and, possibly, the resulting infection may also be more severe. If we remember aright, M. Diday has advanced something of this kind.

(b) See "Lectures on Syphilis." By Mr. H. Lee. 1863. Churchill.

(c) Of late there has been such an accession of information on the subjects treated of in these papers, and the books have come from so many different quarters—Continental and American—that we dare scarcely venture upon any long analyses and reviews for fear that our readers should imagine we are suffering from a violent attack of "syphilomania." Dr. Durkee's is the work of a practical man evidently, and the subjects are treated in a plain, shrewd manner, and from the author's own point of view. It is not an exhaustive treatise, for some of the doctrines and disputes of modern syphilographers are not entered upon; but the book is a good one, and the therapeutics are laid down with discrimination. Mr. Langston Parker's well-known and very practical treatise [Syphilitic Diseases, Fourth Edition,] contains similar instances.

present. One thing is clear, that the rarity of these occurrences renders its determination of little practical moment.

We have already traced the stages and evolution of the syphilitic phenomena in the human frame, and it remains for us to notice very briefly the deviations from the ordinary course, and see if we can trace the causes of these. Generally, within six or eight weeks after the primary disease, secondary manifestations appear, but to this there are some exceptions.

Mercury, it is conceded by all, influences the regular progression of the disease—for the worse, as some think. The mineral occasionally appears to protract the interval between the chancre lesion and the appearance of the secondaries. That is the general opinion, and it is in accordance with our own experience. Here and there, perhaps, an indurated chancre specifically treated is not followed by any secondary manifestations, within the periods, at least, during which the case has been observed. These are exceptional instances certainly. For better or worse, however, mercury administered for the early initial stage does often modify the subsequent course of the disease. On this subject we shall enlarge hereafter; but let it be remarked that the non-appearance of the *ordinary* syphilitic manifestations is no *certain proof* that a cure has been effected.

We have witnessed cases of this kind:—The chancre spreads, and becomes affected with a slow and persistent, though slight, amount of ulceration; or a chronic ulceration appears at the site of a syphilitic lesion, or an ulcer, wound, open bubo (the latter the product, perhaps, of a later and different process) takes on an indolent and peculiar form of inflammation or ulceration—it may be of the serpiginous character,—and during this localised process either no manifestations or very modified manifestations of the syphilitic infection appear. It cannot be doubted, we think, that the persistence, condition, and character of these ulcerations depend upon the presence of a syphilitic element in the system, and we have come to regard these localised processes as acting on the general course of the disease much in the same way as syphilisation does—viz., by their derivative and depurating effects. Be the explanation what it may, the fact remains, that the usual and general manifestations are often not developed in the ordinary way in such cases.

The presence of other diseased actions.—Upon this head there is a lack of that amount of positive facts which we could desire. That a syphilitic patient may become the subject of one of the exanthemata we have occasionally witnessed. In a few cases, wherein the subject of a primary infecting chancre was attacked with rheumatic fever or variola, the manifestations of secondary syphilis did not appear until the patient was convalescent or had completely recovered.

Whilst upon this subject we must remark upon the curious latency of syphilis in the system. Most Medical writers cite instances of this. In some cases, after very variable but lengthened periods of this latency, syphilitic manifestations may appear coincident with, or consecutive to attacks of other diseases. Whatever tends to lower the general health and affect the nutrition of the body may awaken the slumbering germs of syphilis into activity; and, in this way, other diseased actions may prove the exciting causes of syphilitic manifestations, and modify the character and course of these by the intermixture. We may refer the reader to our remarks upon the pathology of syphilis, and to Dr. Aitken's volumes, for further information on this head. In some few cases the evolution of syphilitic symptoms is very irregular, and the disease does not follow the ordinary stages. Sometimes affections of the periosteum and testicle co-exist with a squamous syphilide; sometimes no "secondary" manifestations seem to appear, but those of the tertiary stage succeed the primary, after a more or less extended interval. In a few rare cases, where mercury has been used, no secondaries are observed, but the patient remains out of health for some time, and constitutional symptoms of the secondary or tertiary type appear or are combined.

The influence of climate has not attracted that attention which it deserved. It has not escaped the notice of Mr. Henry Lee, Mr. Gascoyen, and Dr. Marston. The depression, anæmia, and ill-health engendered by tropical heat, malarial poisons, and climatic agencies render the proper administration of mercury difficult or impossible, as can be readily enough imagined, for syphilis is in itself a most debilitating and blood-lowering poison. The dampness and inclemency of northern climes also exert a baneful influence. Such is the general feeling of our English Surgeons, and we know that syphilitic affections are severe in the north of Europe. Extremes of temperature are, therefore, alike prejudicial. It is not that syphilis is more *frequent* in hot than cold climates, for the reverse is the fact, perhaps; but the manifestations of the disease are more chronic, more mixed with other morbid agencies, and less within the control of remedies.

THE WEEK.

THE MEDICAL TRIAL AT THE HOLBORN WORKHOUSE.

We have before stated that we have no doubt that the Poor-law Commissioners will arrive at a right judgment in the case of Timothy Daly; but we must say that, were we placed in Mr. Norton's position, we should prefer being tried by a properly constituted court of justice, where the rules of evidence would be strictly observed, and not by the irregular process which is now being pursued at the Holborn Workhouse. Until the proceedings are terminated, and the verdict is published, we must reserve our comments. We would only draw attention to the fact that, besides the Commissioner, Mr. Ferrall, another gentleman—a Dr. Carr, of whose real position and authority we know nothing—is constituted an assessor in the case. We have always advocated the appointment of Medical assessors in our Superior Courts of Law, whose duty should be to assist the judge with their counsel on doubtful points of Medical evidence. We have, therefore, not one word to say against the principle involved in the presence of a Medical assessor in Daly's case. We think, however, that such a gentleman should be directly appointed by the Poor-law Commissioners, and that his previous reputation and scientific standing should be such as to insure the entire confidence of the Profession and the public. Dr. Carr may possess all these qualifications, but if so we are unfortunately uninformed as to the fact. That gentleman's idea of what constitutes evidence seems to be rather of a vague character; for we find him asking one of the Medical witnesses how he reconciles certain *facts* with other facts to which he had deposed; as if facts were things of such a nature that they could be altered to suit other facts at pleasure. In reference to Mr. Norton, it appears that his place of dining and mode of spending the evening are circumstances bearing on the manner in which he attended his workhouse patients; for these particulars were extracted from him in cross-examination. The loose character of the proceedings appears to us to be much more in accordance with those of a French court of justice than with the precedents of our English law courts. All sorts of irrelevant matters are introduced, and a large portion of the Medical evidence taken is founded on mere surmise, and should be allowed no real weight in the judgment which is to follow.

FROM ABROAD.—CONTESTED ELECTION AT THE ACADÉMIE DE MÉDECINE—HYPODERMIC INJECTIONS—PHYSICAL INCAPACITY NOT A GROUND FOR NULLITY OF MARRIAGE IN FRANCE.

The election at the Académie de Médecine, which took place last week, was attended by some unusual circumstances. A member of the Section of Veterinary Medicine had to be supplied, and the Section sent in its classed list of candidates—viz., 1, M. Sanson; 2, MM. Colin and Lecoq (*ex æquo*); and 3, MM. Goubaux and Leblanc, jun. (*ex æquo*). As an almost invariable rule, the Academy elects the candidate placed first

on the list by the Section; but on the present occasion it has refused to do so, and has chosen M. Colin, placed second. His position was, however, hotly contested, and was not determined until the ballot had been taken a third time, his final numbers being forty-seven of seventy-two votes present. This decision has given rise to lively discussions and many conjectures, M. Sanson having been rejected, according to some, owing to his intimate connexion with the periodical and critical press, held in bad odour by many of the Academicians, and especially by their Secretary (after the too common manner of secretaries), M. Dubois. Others again, and among these M. Guerin, of the *Gazette Medicale*, a very competent judge, and himself an Academician, attribute the action of the Academy to higher motives, in preferring a man of great scientific reputation to a mere veterinary Practitioner, of however considerable a reputation. M. Colin must be regarded as the man of science *par excellence*, being the author of distinguished works, and a most laborious cultivator of his Profession in its scientific aspects. The Academy had offered for its choice a critical writer, a scientific dignitary in the shape of an Inspector of Veterinary Schools, a *savant*, a Professor of Alfort and a consummate veterinary Practitioner. "The choice of this illustrious body has fallen upon the *savant*—that is, the anatomist, physiologist, zoologist, pathologist, and experimenter; he who has known how to embrace and connect by new ties the different branches of Comparative Medicine. In our opinion it is an act of high justice, and an encouragement to progress." Another writer, M. Brochin, throws out an observation which is not without its applicability to the elections into our own scientific bodies, which are almost invariably made in compliance with the recommendations of councils or committees. Doubtless the best and only course, as a general rule, but one that yet may have its dangers of favouritism and cliquism:—

"This is not," says M. Brochin, "the first time the Academy has revised the recommendations of its Sections. Does this mean that they do not offer all the conditions and guarantees for a suitable appreciation? No one would surely maintain such a paradox, and we should seek in vain elsewhere for a more complete competence. But who will venture to affirm that scientific qualifications always alone weigh in the balance, and that a feeling of partiality never slides in its weight when the appreciation has to be made of the respective merits of *savants*, among whom our daily relations must necessarily create different affections, and give rise to preferences from which we know not how, and cannot always guard ourselves? Similar motives, it will be said, may also sometimes actuate Academical majorities as well as the small number of members who compose the Sections; but while this cannot be denied, it must be admitted that the chances of partiality are diminished by reason of the greater numbers."

M. Georges, at the Paris Society of Practical Medicine, gives an account of numerous experiments he had made of injecting poisonous substances into the cellular tissue, with the view of showing the far greater safety and certainty of the hypodermic method as a means of administering medicinally highly-poisonous substances. He injected quantities of codeine, atropine, and especially strychnine, which would surely cause death in the absence of precautions for preventing the too rapid introduction of the poisons. These injections were practised without danger in the dog's paw, the passage of the poison into the veins being checked by the forcible application of a ligature around the paw. To render the experiment still more striking, he resolved to employ injections of the most dangerous of poisons, curare, and M. Claude Bernard conducted them for him. A solution containing about five centigrammes of curare, and sufficient to kill more than fifty dogs of the size of the one operated upon, was injected into the paw, and in twenty minutes the animal fell on its side. The paw was now firmly tied, and at the end of about twenty minutes the animal arose. Whenever the ligature was loosened he again fell down, sometimes at the end of ten minutes, and sometimes in a shorter period, and in this way it became possible to dose with complete certainty, according to the effect desired to be produced, the quantity of poison to be absorbed. Next day the dog was found on his three paws, only suffering from the swelling caused in the fourth by the injection. The ligature was removed, and he was soon all right. The same experiment performed on another dog was followed by the same results, the animal being caused to fall or rise at the end of five, ten, or fifteen minutes, accordingly as the paw was tied or untied. This dog, however, next morning, on the removal of the ligature, fell down again, all the poison not having had time to become eliminated by the urine, so that it was necessary to reapply the ligature. M. Georges points out the superiority of the endermic method when we have to administer powerful substances, as we may apportion the dose with an exactitude, according to the tolerance of the disease and idiosyncracy of the patient, quite unattainable when administered internally.

In reference to a case of absence of the uterus and vagina related at the same Society, in which marriage had been contracted, M. Legrand du Saulle observed that an opinion prevailed that such a marriage is null and void. This is a complete error, no provision existing in the French code for annulling a marriage on this or other ground. He is of opinion that, however hard this may seem in certain very exceptional cases, it is sound legislation which prohibits impotence and sterility to be regarded as reasons for nullity of marriage. Were such admitted, the most scandalous trials would arise, and all kinds of physical imperfections would be alleged on the part of husbands or wives desirous of separation. Physical impotence once admitted as a plea, nervous impotence would follow, and where to set the limit would be a matter of difficulty. The difficulty of deciding in these cases would be often very great, in the face of a division of opinion and contradictory scientific statements. Up to the end of the seventeenth century a legal tribunal for exploring these cases, termed a *congressus juridicus*, existed, experts being appointed who supervised the copulation of the inculpated parties, and reported upon the results. Such a tribunal could only give rise to scandalous immorality, leading, as it did, to problematical and fraudulent results? According to the Prussian law, the physical impossibility of attaining the legal end of marriage is a ground for divorce; as are, indeed, bodily infirmities which give rise to disgust and repugnance, and which render sexual intercourse well nigh impossible. The judges charged with the duty of interpreting and applying these legal dispositions entertain very unwillingly the demands for the rupture of the matrimonial tie on these grounds; so that during Casper's prolonged and conspicuous career, very few cases of this kind came under his cognizance.

REPORT ON CHEAP WINE.—NO. IX.

(By our Special Empirical Commissioner.)

(Continued from page 18.)

Greek and Hungarian Wines, continued.—Special Use of Greek Wine—Sweet Wines—Cyprus and Visanto—Hungarian Wine—Wine Advertisements—False Philosophy applied to True Wine: "No Life without Brimstone!" etc., etc. (a)

Comparing Greek wines with Bordeaux of equal price, we get much more for our money. There is more *body* in them, using the word body to imply fulness and rotundity of taste, and what satisfies the stomach, and alcoholic strength also, apart from flavour. Persons who might think Bordeaux thin and sour might be satisfied with Mount Hymettus; on the other hand, a person who delights in light Bordeaux might think the Hymettus coarse, unless he got some of the older and more mature kind. Wine flavour, I need scarcely repeat, is a product of time, and time adds greatly to the cost of wine, so that in cheap wine we regard not so much present flavour as firmness and soundness, and capacity of keeping till flavour shall be generated.

(a) *Erratum.*—In my paper on the use of Bordeaux wine in the exanthemata, instead of "mix one *pint* of puro Bordeaux," read "mix one *part* of pure Bordoaux," etc.

It follows that the persons to whom we should recommend Greek wines especially are those who are hardly weaned from brandied wine, and who require something full-bodied. I find the Red Hymettus much relished by a patient in an advanced stage of phthisis, who says he really prefers port, but that it makes him too hot and thirsty, whereas the Hymettus quenches his thirst, and gives him "support" besides. A second patient, who has had a narrow escape from puerperal fever, says it agrees well, and has checked diarrhœa. The former patient can afford what he likes; the latter, if she had not the Greek wine, would have been condemned to South African port. These wines, I repeat, should be chosen by those who want something full and round, and who desire purity and wholesomeness as well as cheapness. At the same time let me say that I have presented some of the older Hymettus, especially the white, to fastidious persons, who find it not only irreproachable for a wine of its class, but having promise of high and peculiar merit.

Of the sweet wines I have not much to say, as they are not a class of wine that suits me. The Visanto is a very full-flavoured wine, of very high specific gravity and little alcoholic strength. The Cyprus is marvellously high-flavoured and sweet, and other wines, as the Lacryma Christi, Calliste, etc., partake of these qualities in a lesser degree. Can a patient digest sugar, and does he require it? If so, these wines, with cake or bread, would make a good light refection. They would suit bridesmaids; possibly nursing mothers, children recovering from illness, etc.

Before going into the subject of the Hungarian wines, which I am glad to know are daily rising in estimation with my Professional brethren and with the public, let me say three words on some of the advertisements and other documents by which their virtues and excellences are heralded. Some Medical men sneer at all *advertisers*, and talk of advertising wine merchants in the same tone in which we might speak of advertising Surgeons. This is absurd. Medicine is a Profession, practised for the good of the community, every member of which diffuses the secrets of his skill amongst his brethren, and relies on their support and his own character and prudence to obtain the *clientelle* which rarely fails a man of merit. But with regard to wine, or books, or watches, or coals, there is no reason and no custom to hinder a man from making known to the world that he has something new to sell, which they would desire to buy so soon as they heard of it. Any one who reflects on the great multiplication of our means of health and enjoyment which these wines give us, will not only thank the men who have advertised new kinds of wine, but would welcome the notice of fresh importations from China or Peru. So I neither object to advertising nor to anything which the wine merchant chooses to say in praise of his wines. If he exaggerates, he is sure to be found out and to disgust his customers; but that is his business. What I complain of is, that whatever is foolish or demi-semi-quackish in these advertisements is sure to be contributed by a Medical pen, and to be based on some of those baseless hypotheses which make every age of physic ridiculous to the succeeding one.

Wine, like every other part of the apparatus of life, teaches the true Physician his constant dependence upon observation, and how little he can venture on *à priori* speculation. It would have been impossible for any one, before experiment, to deduce from the composition of wine anything like the truth with regard to its effects on the human body. Neither is it possible, antecedent to experiment, to fix on any particular ingredient and deduce the qualities of the wine from that.

Yet such, I am sorry to say, is the attempt which some modern iatro-chemists have made. They have beguiled honourable wine merchants, and have bespattered admirable wines with baseless rationalistical pseudo-chemical *commenta*, which concentrate into one example all the errors of fact and of reasoning with which Medical theorists can be reproached.

The principal offender is Dr. W. Kletzinsky, author of a paper on "Wine in its Dietetic Relations, and the Intrinsic Worth of Wines, especially as regards the Quantity of Phosphate they Contain." This paper was originally published in a Medical journal at Vienna, in 1855, and has been translated and reproduced by M. Barthélemy de Szemere, in his otherwise interesting and sensible "Notes on Hungarian Wines."(b)

In this pamphlet we find the following (extraordinary?) specimens of Medical fact and reasoning, which have been accepted as gospel by unsuspicious wine merchants, and have been made the subject of scores of advertisements in all forms:—

"1. Malaga wine, it is said, contains a large quantity of phosphate of ammonia and magnesia. So, we may add, does urine. 2. This phosphate, it is alleged, exercises great nutritive powers on the bones, muscles, and nerves; hence Malaga wine is officially acknowledged to be the wine for convalescents! 3. The quantity of phosphate is the best test of the goodness of wine; better than the extractive or the alcohol! 4. Then follows a table, giving the alleged quantity of phosphoric acid per 1000 in various wines, by which it seems that Tokay has 5, Menes (Hungarian) $4\frac{1}{2}$, Malaga 4, Madeira $3\frac{3}{4}$, Szegszard and Buda (Hungarian), *and Sherry*, each $3\frac{3}{4}$; *Cape* $2\frac{1}{8}$, Château Lafitte 2, and so on in a descending scale. I only give a few extracts, as time and space are too valuable to be wasted. 5thly. Dr. Kletzinsky makes an abrupt jump. Having asserted that the Hungarian wine is rich in *phosphoric acid*, he goes on to describe it as *rich in phosphorus!* Then he indulges in a poetical rhapsody on *the phosphor*, as he calls it:—"Without phosphor no nerve can form itself, which, like a telegraph," etc., etc. "Without phosphor no muscular fibril could weave itself that palpitates," etc., etc. "Without phosphor there would be no unison," etc., etc. Then he announces the startling proposition—

"*No life without phosphor,*"

with which readers of wine advertisements are familiar enough. Then comes a letter from the illustrious Liebig, who is made to say "that *the Hungarian wines have over other wines a particular restorative virtue*, which is to be attributed to the phosphoric acid which they contain."

Now, as members of our Profession have set up all this nonsense, it will not be out of the scope of a Medical journal to knock it down, and to show to the very eminent and honourable wine merchants who quote it that it really is unworthy of their wine and of themselves.

In the first place, the secret attraction of this pseudo-chemical *commentum*, as an advertisement for the public eye, lies in the juggle by which the word *phosphor*, or *phosphorus*, is artfully substituted for *phosphoric acid*, as if it were equivalent or synonymous therewith. When the public read of *phosphorus* in wine, they have a dim vision of something of mysterious virtues, which is alleged to be an element of the brain, and to be burned in the process of thinking, and which is supposed to exist in truffles, new-laid eggs, oysters, and other stimulating eatables, and which may make them shine in the dark as it does itself. They do not know really that phosphorus is just as distinct from a compound of phosphoric acid as a stick of brimstone is from Glauber's salts or plaster-of-Paris. The one a combustible simple body; the other an earthy or saline substance, in which not only no sensible trace of the original element is to be detected, but in which, by virtue of combination, all those original properties are of necessity extinguished.

On this point let us hear Liebig:—

"Many writers maintain that flesh and bread contain phosphorus, that milk and eggs contain a phosphorised fat like brain, and that the origin and consequently the activity of the matter of the brain is connected with this phosphorised fat. Hence no excess of phosphorus can be supposed, for example, to exist in thinkers (because they consume much phosphorus), and it is a certain truth that there is *no thought without phosphorus!* But there is no evidence known to science tending to prove that the food of man and animals contains phosphorus as such, in a form analogous to that in which sulphur occurs in it. No one has ever yet detected phosphorus in any fat of the body, of the brain, or of the food, in any other form than that of *phosphoric acid*."

Thus much about the *phosphor* hypothesis, of which I need say no more, but wait till some one proves the existence of phosphorus in wine in an unoxidised form.

In the next place, as for the hypothesis that the goodness of wine is to be determined neither by the alcohol, nor by the extractive, but by the phosphate, the best commentary on it is furnished by the fact that Cape Wine is put above Château Lafitte, and the best punishment for the author would be to condemn him to drink Cape for his natural life. It is not difficult to account for the phosphate in Cape wine.(c) Further, the various combinations of phosphoric acid with lime, magnesia, soda, etc., are of all bodies the most insipid and unstimulating. They abound in all eatables, on which man can live; they are clearly essential to the composition of

(b) Pamphlet, Paris, E. Brière, 257, Rue Saint Honoré. 1861.

(c) I was at dinner one day, sitting next to the late Archdeacon ——, from the Cape. I asked him the reason of the earthy taste in Cape wine. He said, "My dear sir, if you ever were at the Cape, and were to see the black fellows and their families in the vineyard at the vintage season, and how they make the wine, you would think *earthy* a very mild term indeed to be applied to it."

the mechanical framework of animals and vegetables, whether hard or soft; a man who eats bread or potatoes takes them in largely, and they are always as a matter of necessity in a state of flux, being daily taken in and given out, as common salt is. If further, we examine this wine list, we shall see that it is impossible that the quantity of phosphate can be the secret of the alleged restorative virtues of Malaga or of Tokay. These are wines of which we drink very small quantities, whilst we take copious draughts of the others. A man who drinks a pint of claret, containing the ratio of two of phosphate, would necessarily get more of it than one who drank an eighth of a pint of Tokay with its ratio of five of phosphate. Further, we have not heard what the French and Rhinelanders have to say about the phosphate in their own wines. Depend on it, if the character of their wines were to hang upon a chemical analysis, their patriotic chemists would be sharp-sighted enough to find every needful ingredient in the needful quantity. Moreover, although phosphoric acid and its salts (as of iron) are mild and digestible, like those of vegetable acids, still there is no evidence whatever that they possess any special power of feeding or sustaining the nervous system. I know of cases in which phosphates of all sorts were given abundantly, and the nervous system unaffected. Moreover, I would suggest whether abundance of phosphate might not be dangerous to the nervous system, and cause the accumulation of calcareous particles in the brain. I do not believe it myself, but one hypothesis is as good as another.

Lastly, to use the words of Dr. L. Beale,(d)—"When a long train of theories is constructed, the truth of which entirely depends on the accuracy and correct interpretation of the experimental results from which it starts, it behoves us to examine rigorously into the nature of their foundation." And Dr. Beale clearly can find no solid foundation for any hypothesis of the connexion of phosphates with nervous action.

The other day a wine merchant wrote to me recommending some wine, and saying that he had been assured by an eminent Physician that it had peculiar virtues, and that those virtues depended on a large quantity of sulphur. Certainly life is more dependent on unoxidised sulphur than on unoxidised phosphorus. Chemists have good ground for believing that sulphur is largely taken in certain elements of food, and largely oxidised; and I humbly suggest to any wine merchant who wants a new advertising dodge, to lay emphasis on the fact that his wines contain brimstone, and that there is *No Life without Brimstone*. Such an announcement would be valuable in a certain part of the Britannic isles, and would indicate a very agreeable method of taking a necessary medicine.

My time and your readers' will not have been wasted if I shall have succeeded in disenchanting them of that rationalistic myth of the connexion of salts of phosphoric acid with the nervous system. We must go on with the Hungarian and Austrian wines next week; meanwhile, if we ought to be ashamed of recommending wine because of a hazy notion that it is "rich in phosphates," there is another kind of evidence which is quite trustworthy. A patient who is well off, a good judge of wine, and free to choose what he likes, writes to me that the wine that suits him best is Max Gregor's Hungarian Carlowitz. This is the evidence which the empirical philosopher seeks for, and which, instead of the shifting sands of rationalism, stands on the solid rock of fact.

(To be continued.)

REVIEWS.

A Treatise on Pharmacy, designed as a Text-book for the Student, and as a Guide for the Physician and Pharmaceutist; containing the Officinal and many Unofficinal Formulæ, and numerous Examples of Extemporaneous Prescriptions. By Edward Parrish, Graduate in Pharmacy, etc., etc. Third Edition, with 238 illustrations. Philadelphia: Blanchard and Lea. 1864. 8vo, pp. 848.

This work, as a matter of necessity, contains much that is common to works of its class,—such as the account of the chemical and medical properties of known drugs, and the elements of such branches of natural history as are concerned therewith. Its peculiarity and its value to the English reader will be its suggestiveness, by means of the view which it gives of American pharmacy, drugs, and modes of prescribing. There is no doubt but that the Americans are a singularly ingenious people, possessing great power of creating modifications of mechanical forces; they are also little tied down to routine, fertile in new combinations of old drugs, and possessed of a great magazine of new ones in the almost inexhaustible botanical stores of their broad continent. Hence the English pharmaceutist should possess this book, not merely to know how drugs are manipulated over the water, but likewise what drugs are available. Moreover, the list of drugs in this work is limited only by our knowledge of the three kingdoms of nature, and not by the laws of any Pharmacopœia.

The work begins with an account of implements and processes,—bottles, scales, weights, etc. Next comes galenical pharmacy—that is, an account of every process, and its results, applicable to plants, and every part thereof. This part contains a summary of those numerous vegetable preparations (of which podophyllin is one well-known instance) introduced by the secret manufacturers of drugs and vegetable extracts, who call themselves *eclectics*. Then we have inorganic pharmacy; next organic chemistry in its relations to pharmacy; then extemporaneous pharmacy, including a treatise on prescriptions (with some account of the *language* used in prescriptions, which more than ever induces us to write the *signatura* in English), and on the art of prescribing, with a long list of prescriptions, of all sorts of drugs, in all forms. Any Medical Practitioner who desires to spend an evening profitably may do so in turning over the leaves of Parrish's Pharmacy, and gathering fresh hints and notions on the materia medica. We must add that there is a good deal of information also about perfumery, sweetmeats, and the management and diet of the sick-room.

Elements of Materia Medica; containing the Chemistry and Natural History of Drugs, their Effects, Doses, and Adulterations. By Dr. W. Frazer, Lecturer on Materia Medica to the Carmichael School of Medicine. Second Edition. London: Churchill and Sons. 1864. Pp. 453.

The word edition has come to bear a very different meaning when used in reference to general literature and to that of the natural and allied sciences. For instance, when we talk of a new edition of a history by Macaulay or Hallam, or of a poem by Tennyson, we understand the reproduction of the same work, with no change beyond, perhaps, the addition of a few notes or the alteration of a preface. But the announcement of a new edition of Lyell's Geology or of Graham's Chemistry would convey a very different idea. The advance of the physical sciences is so rapid, that a scientific library, like the organised body, must be constantly in a state of removal and deposition, or in ten or twenty years its materials will be found to have grown *effete* and comparatively useless. In no instance is this more true than in the literature of the sciences from which that of Materia Medica draws its sustenance, and it is only reasonable that growth in the primary trunks should be followed by corresponding vigour and change in the offshoot.

Accordingly, in his preface, Dr. Frazer tells us that "in consequence of the numerous changes which have taken place in Materia Medica," the pages of the work before us have been entirely re-written. In what those changes consist he leaves to be found out by the study of the book itself. In the space of a short review we cannot refer to a tithe of them, but we may indicate some of the heads under which they may be ranged. First, there is the change of nomenclature—partly due to newer, if not more satisfactory, generalisations of the facts of chemistry, and partly due to the whims of the compilers of the new Pharmacopœia. To the former we offer no objection. Pharmaceutical chemistry is only one of the many applications of chemistry to the arts; there is little, if anything, special about it, and its scientific character should be maintained by identifying its terms with those of the parent science. We cannot, however, look equally complacently on the alterations introduced by the committee of the Medical Council. Why *quina* was so bad a term that it was necessary to convert it into *quinia*; why *liquor sodæ chloratæ* was to be preferred to *liquor sodæ chlorinatæ*; or why *tiglii oleum* was discarded for *crotonis oleum* we are at some loss to understand. We can only account for these and other transformations by recollecting that a new Pharmacopœia without an arbitrary alteration of nomenclature might be held to cast a permanent reflection on the ingenuity of its compilers. Another and still more important class of changes may be referred to improvements in chemical processes, and a more exact knowledge of the sources whence drugs are obtained. The general introduction of the process of percolation in the preparation of tinctures, and the improved modes of prepa-

(d) "Urine, Urinary Deposits, etc." London: 1864. P. 187.

ring extracts, may be cited as instances of the former, whilst our more exact, although still imperfect, knowledge of the different species of Cinchona yielding the varieties of bark is one of the latter. A third class of changes comprehends newly discovered remedies. There can be no doubt that within the last ten years valuable additions have been made both to the chemical and botanical divisions of Materia Medica; amongst the former we may instance the introduction of carbolic acid, sulphurous acid, and the sulphites, of the salts of lithia and cerium, and of many new preparations of the metals and alkaloids. For the latter we have chiefly to thank our transatlantic cousins; many of their supposed discoveries, such as that of Sarracenia Purpurea, are doubtless worthless, but it is probably as true that in Veratrum Viride, Podophylline, Leptandrin, and several others, we have obtained useful means of combatting morbid conditions.

Such are some of the heads under which a list of changes in the Materia Medica might be ranged. It is well-deserved praise when we say that they are all faithfully reflected in the work before us. In it Dr. Frazer follows the "natural history arrangement," which is far preferable to any founded on imperfect theories of therapeutic action or abstract physiological views. Thus, the whole of the chemical Materia Medica is ranged under the four heads—Inorganic Substances, Compounds of Cyanogen, Alcoholic and Ethereal Preparations, and Hydrocarbons. The pharmaceutical preparations are placed under the description of each substance. In like manner the vegetable and animal medicinal substances fall under the natural orders from which they are obtained. The work concludes with a supplementary list of agents in which many of the newest additions to the Materia Medica, and some of the older ones which have perhaps undeservedly fallen into disuse, are briefly noticed. The style of the book is just what that of such a treatise should be—perfectly clear and correct, but stripped of everything like redundancy or ornament. The chemical directions and botanical descriptions are thoroughly up to the science of the present day. The only criticisms we have to offer are two. The first, that the doses of some substances and preparations appear to us rather large—an error, by the way, we have had to point out in other works of the same class; the second, that by neglecting to use the symbols ordered in the British Pharmacopœia, and retaining the old Galenical symbols in connexion with the British Pharmacopœia preparations, Dr. Frazer, to his English readers at least, has appeared to make no distinction between the troy and avoirdupois ounce. These, however, are small faults, and cannot be held to detract from the real value of the work, which it is not easy to overrate.

Monographie de l'Erythroxylon Coca. Par L. A. Gosse (de Genève). Bruxelles. 8vo, pp. 144.

Coca, so well known to certain South American tribes from immemorial time, belongs to the same class of agents as tea, coffee, maté, and other substances having a similar action in the body. This action appears to depend on a power they possess in retarding oxygenation of the tissues, hindering their retrograde metamorphosis, as it is sometimes expressed. It is doubtless this property which, in the absence of food, makes them sustaining to the body,—a fact which common experience amply proves. The coca shrub may be seen growing in the tropical part of the Crystal Palace, and its properties have been well explained by the late Professor Johnson in his admirable book, "The Chemistry of Common Life." In the work before us, Dr. Gosse has treated some parts of the subject in an exhaustive manner. He has with great industry culled from all sides a mass of interesting information concerning the history, the culture, and properties of the leaf; but it is no doubt due to want of opportunity that no experiments are detailed as to the effects of coca in his own person or experience. He had at disposal only a small quantity of the leaves, and these by no means fresh. We ourselves having been much interested in the matter found that large doses of a very strong infusion produced very trifling effects, and we are constrained to believe that the leaves lose their virtue either through the effects of the sea voyage, or else from being too long kept. The investigation is, however, well worth pursuing, as there is little doubt of the medicinal value of coca. Meantime we heartily recommend Dr. Gosse's monograph to all those who take an interest in this curious subject.

Briton Medical and General Life Association.—Dr. E. H. Sieveking, Physician to their Royal Highnesses the Prince and Princess of Wales, has been elected a Director of this Association.

GENERAL CORRESPONDENCE.

THE NEW INDIAN MEDICAL WARRANT.

[To the Editor of the Medical Times and Gazette.]

Sir,—You have acted wisely and well in not allowing yourself to be carried away by any exaggerated estimate of the new Indian Medical scheme, and in abstaining from forming an opinion upon its merits until it shall have been subjected to an examination in India. As some time must, however, elapse ere this can occur, I shall, with your permission, offer for the information of the Profession a few remarks upon the documents recently issued by the India Office.

The documents referred to are three in number,—

1. Regulations for the Examination of Candidates for the Appointment of Assistant-Surgeon in Her Majesty's Indian Medical Service.

2. Memorandum regarding the Position of Medical Officers hereafter appointed to Her Majesty's Indian Forces.

3. Despatch from Secretary for India to the Governor-General.—Date November 7, 1864.

Within this current year the Indian Medical Service will have existed under three distinct codes of regulations:—

1. The old constitution, which has been in operation from time immemorial.

2. The scheme of Sir Charles Wood of June 15, which has created so loud an outcry of wrong and injury amongst the Profession in India.

3. The scheme which has just been sent to India by Sir C. Wood in his despatch of November 7; and with this latter code I now propose chiefly to deal.

1. The memorandum commences with this statement,—"The regulations are those in force at the present time. They are subject to any alteration that may be determined on." There is, therefore, now to be no covenant between the India Office and those young Medical men who take service under it, detailing or implying obligations, and creating rights on both parts, and such as existed under the administration of the East India Company. It will thus be now perfectly competent and legal for the Secretary for India to act towards those men who take service under him in this new scheme according to the pleasure of his own will, no one being able to make him afraid. He may legally dispense with the services of any officer at a moment's notice, place him on half pay, or make any possible alteration in the rate of his pay and allowances, position, pension, &c. In fact, all who take Indian service under this condition bind themselves hand and foot to the pleasure or caprice of a Secretary for India—they have no guarantee for anything.

2. The Medical charge of all European troops is henceforth withdrawn from Indian Medical officers. Up to this time there have been under their charge three regiments of European dragoons, four brigades of horse artillery, about fifteen or sixteen battalions of foot artillery, and various scattered companies and detachments. The foregoing charges were considered the prizes of the service, and eagerly desired by all men attached to their Profession and willing to work. For several years after entering the service Assistant-Surgeons were employed with these troops, and they thus acquired most interesting and valuable experience in the diseases of Europeans in India. It was this that mainly made them efficient Medical officers, and of these troops they hoped to assume Medical charge as they advanced in the service. The military duties of Indian Medical officers are now to be restricted entirely to charge of native troops. This is a heavy blow and sore discouragement to the service.

3. The second section of the memorandum refers to grades of Medical officers; these are the same as those in the British army, but minus the Director-Generalship.

4. The third section refers to "pay and allowances when in India;" this I shall endeavour to examine carefully, noting what these are henceforward to be, and what they have been, under the two previous codes, which have both been in operation during the current year.

As regards the administrative division of the Medical Department, the Inspector-General is to receive 2500 rupees per mensem, and the Deputy Inspectors-General 1800 rupees per mensem. I regret I have not at present before me any pay tables showing the exact rate at which these officers have hitherto been paid. I therefore speak open to correction; but I have the strongest impression that the rate for Inspectors is

by several hundreds of rupees per month less than it used to be in Bengal; while that for Deputy-Inspectors seems to have there (*i. e.*, in Bengal) undergone no alteration—in fact, few Medical officers know accurately the pay of these higher grades; the number of those holding them is very small, and, according to Para. 16 of Sir C. Wood's despatch, it is henceforward to be made smaller still.

The Inspectors-General are generally men advanced in years, some who have survived most of their contemporaries. They occupy the position of the old Medical Boards. To what age it is necessary to live in India so as to render the attainment to this dignity and pay possible in the case of a Medical officer, I do not know; but this I know, that the late Governor-General, Lord Dalhousie, when speaking to an acquaintance of my own, of the then Bengal Medical Board, said, "I believe there are some gentlemen in it who must have come out in the time of Warren Hastings."

With reference to the Deputy-Inspectors, I have examined the "India Register" of July, 1864, and I find that the juniors of that grade are in Bengal, Madras, and Bombay, officers of 25—28, and 26 years' service respectively.

Not one man in twenty or thirty, I should say, lives long enough, or is able to remain in India long enough to reach these grades, or, rather, to be selected for them; for, be it remembered, an officer does not succeed to them by seniority; consequently, any hopes of these must be so very slender that they cannot operate as an inducement for any young Medical man to choose an Indian career.

5. I come next to the pay of the executive Medical officers mentioned in the memorandum.

By the Warrant of June 15, which has been, and is being still, so bitterly complained of in India, the pay of a Surgeon-Major on full batta, and of twenty-five years' service, was 1093 rupees per month.

By Warrant of November 7 it is reduced to 1000 rupees per month—in this grade of officers a loss has thus been inflicted of 93 rupees per month.

By June Warrant, as above, the pay of Surgeon-Major of twenty years' service, on full batta, was 1956 rupees per month.

By Warrant of November it is reduced to 1000 rupees; in this grade of officers a loss has thus been inflicted of 56 rupees per month.

By Warrant of June a Surgeon of fifteen years' service, on full batta, was paid 825 rupees per month.

By Warrant of November his pay is reduced to 800 rupees, so officers of this grade now lose 25 rupees per month.

An Assistant-Surgeon of ten years' service had for Medical charge of a corps under the old system 556 rupees per month. He is now to receive 600 rupees per month; such officers therefore now gain 44 rupees per month.

Assistant-Surgeons (in charge) above five years' service, who formerly received 421 rupees per month, are now to receive 600 rupees; these consequently gain 179 rupees per month.

Assistant-Surgeons under five years, who formerly received 421 rupees per month for charge of a corps, are now to receive 450 rupees; these, therefore, gain 29 rupees per month.

It will be observed that in considering the new scale of pay I have taken the employed rates; and this, because the unemployed rates are of little importance. Under the new scheme the Medical Department is to be reduced in numbers, and under its new organisation there will be no occasion for any others than those of charge of native troops or civil stations. Further, the only occasions on which Medical officers are unemployed are the few weeks after they arrive in India, or the few weeks before they leave it; or on those very rare occasions on which they have opportunities of getting leave of absence.

6. Before leaving the subject of pay and allowances in India, I must mention that the great outcry which has been raised against the Warrant of June 15 by the Medical Service, the public, and the unanimous voice of the Indian press, proceeded from the fact that that Warrant withdrew from the Medical Service the staff salaries which they had, like other branches of the service, been in the habit of receiving from time immemorial.

Staff salaries, or certain allowances in addition to the pay of their rank, have always been a distinguishing feature of the Indian service. They were not only distinctly laid down in pay and audit regulations, but while permanently fixed for the staff corps at revised rates, in a general order by the Government of India, date October 13, 1863, another order was issued on October 29 of the same year, which not only gave higher staff salaries than formerly to certain regimental officers, but actually conferred staff salaries on all regimental officers whatsoever. I subjoin extracts in proof:—

Cavalry Regiments—Staff Salary.	Rupees per month.
Commandant . .	700
Second in command .	300
Sen. squadron officer .	210
Jun. do. do. .	180
Adjutant . . .	250
Doing duty officer .	150

Infantry Regiments—Staff Salary.	Rupees per month.
Commandant . .	600
Sen. wing commandant .	270
Jun. do. do. .	230
Adjutant . . .	200
Quartermaster . .	150
Doing duty officer .	100

Every officer, whatever his rank, is entitled to the pay of his rank, and also to the staff salary of the position he fills. For example, the commandant may be a lieutenant-colonel, or a major, or a captain; but whatever he be, he receives, in addition to the pay of that rank, 700 rupees for a cavalry regiment and 600 rupees for an infantry corps: in like manner do all the other officers. Formerly, also, Surgeons in charge of corps received staff salaries of 300 rupees a month; Assistant-Surgeons of upwards of ten years' service, a similar sum; and Assistant-Surgeons under ten years' service, 165 rupees per month. To all Medical officers in charge of European troops, "head money" at the rate of 25 rupees per 100 men was also paid; and for Medical charge of native troops, extra to the charge of the corps to which he was posted, the Medical officer received 12½ rupees per 100 men. By Warrant of June 15 the allowances were entirely abolished, and they have not been restored by Warrant of November. To show how seriously this may affect Medical officers, I shall cite a personal instance. I had occasion for months to afford Medical aid to a native regiment and to a European company of artillery whose lines and Hospital were situated three miles from my own house and Hospital. The whole of the morning was taken up with my own work. In the evening, after visiting my own Hospital, I had to start off for the Hospitals of the native regiment and of the artillery. There I had to prescribe for all the sick, and attend to all the papers, reports, and public documents of each of these two Hospitals. I had thus great extra duty involving much anxiety and responsibility; but I had allowances for this, which I felt to be some equivalent. Now-a-days, however, I should be obliged to perform all this duty, not only without receiving a farthing for it, but most likely I should be considerably out of pocket by it; for when it rained I had to hire a conveyance for the journey. Extra duty is constantly falling on the hands of the Medical officers; and as the distances in cantonments are great in India, much time is often occupied in going from one to the other.

If the complaints which have deluged the Indian and British Medical press since the Warrant of June 15 were true, then whatsoever injury was caused by the abolition of staff salary and head money has not only not been repaired, but it must have been intensified by the Warrant of November, which, in the case of Surgeons-Major and Surgeons, has inflicted a further loss, varying from 93 to 25 rupees per month. In such circumstances, how any person of sound mind could hope (as in para. 47 of the Despatch) "that the result will be at once to diffuse a spirit of satisfaction and contentment" among the officers now in the service, utterly baffles my comprehension.

7. The fourth section of the memorandum refers to furlough; and here matters are left as they were. Most intelligent Medical officers in India have long been of opinion that a furlough ought to be granted after every seven years' residence in a tropical climate, and that such a measure would be beneficial not only to the officer, but to the State; but no furlough is to be given for ten years. Ten years! Let us think of them. What has happened, and what may happen, in ten years anywhere? Let me tell what has happened in India. A very considerable time before I had served ten years in India, of thirteen men of my season, seven were under the sod of India, or had been buried in the depths of its ocean waters. How few can hope to live to claim this furlough!

8. The regulations as to leave on Medical certificate remain as they were.

9. The fifth section refers to furlough pay. This also stands as it was. Officers of the British army serving in India have long been paid according to this scale when they returned to England on furlough or sick leave, and Indian Medical officers were entitled to it for many years before it was given them.

10. The sixth section refers to retiring pensions, and requires to be very carefully scrutinised. In order to clear up the subject, I place in juxtaposition the old and new rates.

Table I.—Old Retiring Pensions.

	Per annum. £ s. d.
After 17 yrs.' service	191 12 6
„ 21 „	250 0 0
„ 25 „	300 0 0
„ 29 „	365 0 0
„ 32 „	500 0 0
„ 35 „	700 0 0

Table II.—New Retiring Pensions.

	Per annum. £ s. d.
After 17 yrs.' service	220 0 0
„ 21 „	292 0 0
„ 24 „	365 0 0
„ 27 „	456 0 0
„ 30 „	550 0 0

For comparison I append two other scales of pension :—

Table III.—Rates of Full Pensions allowed to all Officers of the Indian Army.

Colonel . .	£456 5 0 per annum
Lieut.-Colonel .	365 0 0 „
Major . . .	292 0 0 „
Captain. . .	191 12 6 „
Lieutenant . .	118 12 6 „

Table IV.—Rates of Half-Pay of Medical Officers of British Army after a Full Pay Service of

	30 Years. Per annum. £ s. d.	25 Years. Per annum. £ s. d.	20 Years. Per annum. £ s. d.	15 Years. Per annum. £ s. d.
Inspector-General . .	736 7 6	611 7 6	547 10 0	0 0 0
Deputy-Inspect.-Genl.	465 6 6	410 12 6	383 5 0	0 0 0
Surgeon-Major . .	0 0 0	336 19 6	301 7 6	246 7 6
Surgeon . . .	0 0 0	0 0 0	0 0 0	0 0 0

Here I have first to remark that great complaints were repeatedly made to the East India Company of the utter inadequacy of the pensions which they granted to officers of their Medical service, and the answer given was to this effect that the Medical Department had Retiring Funds to which the Company gave considerable contributions, and its officers would obtain annuities from these upon their retirement, in addition to their pensions. After the Abolition of the East India Company, Sir Charles Wood, as Secretary for India, addressed a despatch to the Governor-General in reference to the Medical Department, No. 53, date London, February 14, 1860. In paragraph 8 of this despatch it is stated that the "subject of retiring pension will be taken up in connexion with the question of reorganisation of the army."

Four years and a-half after the above date the subject appears to have been taken up, and the result is the Scale of Medical Retiring Pensions published in the memorandum under discussion.

Individuals who are accustomed to deal with the business of life will naturally expect that after such a very long period of incubation the matter will have been dealt with according to some principle which people can understand; that a due regard will have been paid to the rates of pension established for Medical officers of the British army, who may pass a great portion of their service in their native land, and also to the period after which these pensions are available; and, above all, to the fact that Sir C. Wood had the responsibility of calculating a rate of pensions for officers who were to earn them in exile in a trying and unfavourable climate, while at the same moment he was abolishing the Medical Retiring Fund, which had been so often cast in the face of their predecessors.

Surely, under these circumstances, one would expect, first of all, that the pensions for Indian Medical officers would at least be made as favourable as those fixed for the Medical officers of the home service; that the period would not be made longer in the home than in the Indian service; and that in respect of the facts, that the officers trying to earn these pensions would be subjected to a greatly increased rate of sickness and mortality, and could never look to any augmentation from the Medical Fund. I say, under these circumstances, one is entitled to expect that the rates of pensions constructed by Sir C. Wood would be very greatly in excess of those granted to the home service, and not only very liberal, but bearing some sort of rational proportion to the circumstances in which officers must be placed.

Now, on this point, facts can speak for themselves; and I ask an attentive examination of the four tables which I have copied above.

Table I. shows the rates prevalent under a system which was being abolished. And let it be borne in mind that the Government expected Medical officers to receive, in addition to these rates, from the several Medical Funds, annuities of £200, £300, or £400 a-year. That the funds did not succeed ultimately in conferring this amount on all is beside the question. They were originally established to accomplish this object, and it pleased the Government to assume that they did so.

Table II. shows the amount of pension which Sir C. Wood has fixed for all officers now in the service, or hereafter entering it; and by contrasting it with the preceding table an estimate of the gain, such as it is, will be seen at once.

Table IV. shows the amount of pension obtainable by Medical officers of the home service, who may never have occasion to see India at all, and many of whom actually accomplish their period of service either within Great Britain or in temperate climates.

As regards this table, the most striking feature is the fact that the period of service fixed in it is actually shorter, and the rates of pensions are immensely higher, than those just fixed, as in Table II, for Indian Medical officers; while every man of common-sense would have expected an exactly opposite result.

It must, therefore, be perfectly evident to all that a great injustice has been inflicted upon the Indian Medical service in this matter of retiring pensions. In the lowest possible view of matters, Indian Medical officers were entitled to as good pensions, and after as short a period, as in the home service, or they were entitled to the pensions of military officers of relative rank, as shown in Table III.—*e.g.*, a Surgeon of seventeen years' service, ranking as a major, is surely at least entitled to Major's pension of £292, as shown in the table; whereas he is only to receive £220. A Surgeon-Major, ranking as Lieutenant-Colonel, is surely entitled to Lieutenant-Colonel's pension of £365; whereas, after twenty-one years' service, or one year after obtaining the relative rank of Lieutenant-Colonel, he is only to receive £292. And be it remembered that the Medical officer cannot enter the army until a more advanced age than the purely military officer; he is further required to serve a longer period. And all this injustice is done in the face of para. 17 of the old retiring regulations, which I quote :—"All other Surgeons and Assistant-Surgeons are permitted to retire from the service on the 'pay of their rank,' on the completion of seventeen years' service in India."

11. I have spoken at much length on the subject of retiring pensions, for in my time they were the principal inducements which attracted Medical men to India; but it has been impossible to separate the matter from the Medical Retiring Funds, which, like the "Military Funds," are abolished by Sir C. Wood's Despatch(a) as regards all Medical officers who shall hereafter enter the Indian service.

Formerly, Assistant-Surgeons proceeding to India were required, by an article of their covenant at the India House, to subscribe to the Medical Retiring Fund or to the Military Fund. In addition to the annuities of which I have already spoken, another great object accomplished by the Medical and Military Funds was a pension payable to widows and children of Medical officers. This also was one of the most important attractions to the Indian services, but it has now been swept away; while it lasted it has enabled India officers to marry, and should they happen to be sensible in those last hours which come to so many of them in India, they are not disquieted by harassing anxieties regarding those who are nearest and dearest to them, for they know that through these funds they have provided means which will carry home their families, and maintain them with very considerable comfort amongst their friends in Great Britain.

Many years ago it was not so. A friend informed me that before the institution of these funds there were very few married officers in India, and when one of them happened to die there was often a very sad scene;—no means were found to send the widow and children home; and then some kind friend went round with the hat, and the brother officers of the deceased raised sufficient funds to pay the passage of the family home to their friends, who, of course, had to support them. In those days also alliances with native women were ordinary events, and from this mainly has sprung the half-caste population of India; and many fear that the abolition of service funds will lead to a repetition of that deplorable practice. Neither the interests of morality nor those of the British nation generally seem to have been well considered in this matter.

Some have talked of "splendid pay," and of prudent men being able to provide for their families under the new scheme. Such speak very unadvisedly, and with much ignorance. Before pay can be pronounced as splendid, we must carefully consider the circumstances in which it is received, and the

(a) Para. 45.

obligations or wants of the individual who receives it;—for instance, the new rates of Indian pay might be very splendid for a single man with no claims upon him, living in lodgings or otherwise in an English city, and who, when required to move, has all those excellent and cheap facilities for accomplishing great distances, which are so common here. In India, however, it is now very different. House-rent and living have risen enormously within the last twenty years; many of the necessaries of life are threefold more expensive than they were. Servants' wages are much higher than they were. Frequent change of station involves the necessity of selling furniture for whatever the native chooses to give; transit over the ground is most expensive, and, on arriving at the new station, furniture and all the requisites for a domestic establishment must be bought at whatever rate the native chooses to ask. If the officer happens to be married, his expenses are immensely increased, and he must lay his account with having to send his wife and children home, the education of the latter, etc.; and it may thus be seen that pay which is very good for service in England may be much the reverse of splendid for service in India; and as I have shown that the new rates of pay are only at certain periods of service better than they were before, the men who find themselves able to save in India will be exceptions amongst their fellows; besides, much of the slight increase of pay where it occurs will be laid hold of as increased donations and subscriptions to military mess and band funds.

12. The seventh section of the memorandum refers to promotion. Assistant-Surgeons are henceforward to be promoted to the rank of Surgeon after twelve years' service. This is no more than it ought to be in the Indian service. Indeed, the late Mr. Alexander, of the Army Medical Department, was anxious to obtain promotion in it after from seven to ten years' service. In the Indian service the period passed before promotion has varied from thirteen to eighteen years within the last twenty years.

13. The eighth section refers to relative rank. I am strongly disposed to pass this subject over, for although I have been an army-Surgeon for many years, neither I myself nor any man I have ever met have been able to discover the least advantage conferred on the Medical service by the insertion of a few paragraphs in a Queen's warrant, declaring that such and such officers have such and such relative rank.

The only consequences which I have as yet seen to flow from relative rank have been demands on the purses of the Doctors declared to possess it; for instance, a Surgeon formerly ranked as a Captain, and paid all his subscriptions, etc., at Captain's rates; but after he was declared to rank as a Major the Paymaster required him to pay a Major's donation and subscription to mess and band funds; and in like manner a Surgeon-Major was required to pay as a Lieutenant-Colonel. It is well known that the senior officer present at mess has an important position with reference to the party present, and if the relative rank of Medical officers was worth anything, he might naturally expect it to go for something there; but not so, even at this social meeting. I shall relate a case in point: a friend of mine happens to be a Surgeon of a regiment of Dragoons, and is required to pay to the mess and band the same subscriptions as the Major of the regiment; still, when dinner has to be announced, or any question comes up about the band playing a little longer, the mess-sergeant looks out for the senior officer present, brushes past the Surgeon (relative major though he be) and often addresses himself to a lieutenant, a boy of two or three years' service. This young gentleman, accordingly, takes the chair at this social gathering, and the Surgeon, a Doctor of Medicine of the first University in the kingdom, is quite a subordinate.

14. The ninth section refers to pensions which are given to Surgeons on account of wounds and injuries received in action, and to the widows and children of Medical officers killed in action. What the precise amount of these pensions may be does not appear here, and we are referred to another warrant on the matter, and this closes the memorandum.

Before concluding I must mention that the *Spectator* of December 10th seems to have been strangely misled in reference to this new scheme, for its editor, in the issue of that date, states that under it "a Surgeon can return home at 50 with a pension of £650 a-year for ever"—how he makes this out I cannot comprehend. A Surgeon on entering the service must be between 22 and 28 years of age: if he have entered at the former age he will have served 28 years on attaining 50; or by the new scale of retiring pensions, quoted in Table II., his pension for 28 years' service is only £456 a-year. In like manner, if he have entered at 28, on reaching the age of 50 he will be entitled to pension for 22 years' service, or £292 per annum.

In conclusion, I have been led to examine in detail the various sections of the memorandum on the position and prospects of the new Medical service for India, as issued by the Secretary of State; and this because the matter is of great importance to the younger members of the Profession, and also because gross misconceptions prevail on the subject. I shall endeavour to summarise the results here.

The great distinguishing features of this new scheme, as compared with the two previous systems which have been in existence in the course of the current year, may be said to be:

1. The entire negation of any guarantee or covenant to all who may take service—their voluntary subjection to any alteration in these conditions of service, which the exercise of an arbitrary will may impose.
2. Passage money paid to India by Government.
3. Entire restriction of Professional duties to Medical charge of native troops, or to the native establishments at civil stations, with the two or three European officials attached.
4. Reduction of the number of the administrative officers, and diminution of the pay of some.
5. Reduction of the pay of all Surgeons-Major and Surgeons, as compared with the full batta rates of the same Warrant.
6. Increased pay of Assistant-Surgeons in charge of troops, as shown in Para 5.
7. The persistence of the withdrawal of their regular staff salary from Medical officers, which was initiated by the same Warrant, while staff salaries in addition to pay of rank are allowed to all officers of every other department of the army.
8. The denial of head money for extra charges, however numerous or responsible, or distant from each other they may be.
9. Retiring pensions at rates much below those allowed to the home Medical service, and only attainable after a much longer period of service in exile in an unhealthy climate.
10. Certainty of promotion after twelve years' service.
11. Entire abolition of the Military and Medical Funds; so that Medical officers have now no provision whatsoever for widows and children, and no allowance on retiring except those meagre and unworthy new pensions.

As regards officers now in the service, I am certain that the result will not be to diffuse at once a spirit of satisfaction and contentment; and if any young Medical men choose to enter it at the coming competitive examination I expect that the results will ultimately be similar to those which were obtained after the old service was thrown open to competition—that is, when these young men shall have been a short time in India, and shall have had opportunities of forming a clear estimate of their position and prospects, such information will be supplied by them to their colleagues and friends as will effectually deter others from following their example; and the spectacle will be again exhibited of more Indian appointments in the market than candidates offering for them—and that this new measure will signally fail to "secure for the future a certain supply of Medical officers of good social position, liberal education, and Professional ability for Her Majesty's service in India." I am, &c. An Indian Surgeon.

EXAMINATION OF YOUNG PHYSICIANS AT ST. MARY'S HOSPITAL.

Letter from Dr. Goddard Rogers.

[To the Editor of the Medical Times and Gazette.]

Sir,—The much-regretted resignation of Dr. T. K. Chambers at St. Mary's Hospital left a vacancy which was filled up by one of the "Physicians to out-patients," as I believe was lately their title. This necessitated preparations for the election of an "Assistant-Physician," the title by which henceforth the out-patient Physicians will be known. The rules of the Hospital relating to the election of fresh members on the staff deserve to be widely circulated.

When a vacancy is declared, it is advertised as at other Hospitals; a Medical Board is summoned, and the candidates are requested to attend. This is in accordance with the practice of similar institutions, but here the resemblance ends. A Medical Board is generally supposed to sit for the purpose of examining diplomas and testimonials, and making a few inquiries of such candidates as can attend as to their age,

previous engagements, etc. At St. Mary's Hospital, by an ill-judged regulation, the Medical Board is compelled to examine every candidate for the office of Assistant-Physician or Surgeon in Medicine or Surgery, in Physiology and Pathology, in Clinical Medicine or Surgery, and, in the case of an Assistant-Surgeon, in Operative Surgery. Two well-known men offered themselves as candidates on the present occasion; one a Lecturer in St. Mary's School, the other a Hospital Assistant-Physician of many years' standing, and a Fellow of the Royal Society. A third candidate was your humble servant. As the choice from the first lay between my two opponents, I merely appeared *pro formâ;* and I hereby desire to express my grateful sense of the extreme kindness with which I was received by the various officers of the Hospital during my brief candidature. I now heartily wish that I had withdrawn from the field before the day of nomination, and retained that self-respect which I feel I have in a measure forfeited by becoming a candidate during the continuance of the above-named regulation. My experience of Hospital elections and the mode in which they are carried is as large as that of most men of my age; and feeling as I do that the same influences prevail at St. Mary's as at other Hospitals, the wonder to me is that three grave and respectable Fellows or Members of the Royal College of Physicians could be found willing to undergo an examination at the hands of men whose status is no whit higher than their own(a), *quoad* the approval of the Censor's Board of their College.

Sir, it was a humiliating spectacle, and one which I hope may never again be witnessed. At the great baize-covered table in the Board-room of the Hospital sat such members of the Medical Examining Board as could be prevailed upon to attend; and the only enlivening feature of the exhibition was the extremely uncomfortable and confused appearance of these gentlemen, "dressed in a little brief authority," and invested with an air of priggishness against their will that would have done honour to Mr. Pecksniff. I have no doubt they devoutly cursed the framers of a rule which seems to be designed for no earthly purpose but to embarrass them. A dreary, solemn silence for the most part reigned; broken occasionally by the subdued and somewhat bashful questioning of the Examiner, or the curt and constrained answer of the examinee.

> "We sometimes thought we could a speech produce—
> Much to the purpose, if our tongues were loose;
> But being tried, it dried upon the lip,
> Faint as a chicken's note that has the pip."

And now, Sir, that this farce has been enacted, what is the gain to St. Mary's Hospital? Is she sure of obtaining the best man, supposing invidious distinctions to be drawn between the three original candidates? Every one possessing a grain of common sense, and the least acquaintance with the machinery put in motion on these occasions, knows that even an archangel with the highest qualifications would be thrust out unless he combined with these the highest interest.

I hope this letter may call attention to the subject, and that an important Hospital and rising School of Medicine may speedily dispense with this pseudo-*concours*, this sham "competitive examination." I am, &c.

G. Goddard Rogers.

Grosvenor-street, W., January 10.

THE CASE OF PRYCE *v.* BOWEN.

Letter from Mr. Edward Lund.

[To the Editor of the Medical Times and Gazette.]

Sir,—I have received a transcript of the shorthand writer's notes of the evidence given by me in the cause of Pryce *v.* Bowen, from which I will make a few extracts to show that some of the wording of the newspaper paragraphs gives an erroneous idea of the exact opinions which I expressed on that occasion.

But before doing so, being aware that exception has been taken—and as I think, on reflection, properly taken—to the answer given by me to question No. 2, viz.:—"I believe you are one of the Surgeons of the Manchester Infirmary—the Royal Infirmary."—Answer, "I am."—I will preface this letter by saying that, inasmuch as I am a Dispensary Surgeon, and not a full Surgeon to the Manchester Royal Infirmary, I am prepared to accept any blame that may attach itself to me for having omitted to mention this distinctive difference.

In the *Liverpool Mercury* it is stated Mr. Lund deposed that "he had heard Mrs. Pryce's description of the way in which her arm was placed, and that if that description was true he was of opinion that it was improperly placed." "The proper position was with the palm uppermost, and it was known amongst Medical men that the reverse position was wrong."

With regard to the latter part of this statement, what actually took place was this:—Having answered the fourth question put to me, in which I was asked if I had heard Mrs. Pryce's description of the treatment said to have been adopted, I was requested by the counsel for the plaintiff to place the bones of an articulated forearm in such a way as that they would be nearest to each other (prone), and then I was asked the next question, viz.:—"Now, assuming it to be true that her arm was placed in the splint as she described, with the back of the hand up, is that the proper way of setting the arm?"—Answer, "No." I was next asked, in the same way, to place the bones so that they should be furthest apart, (supine), and the question was put, "What would be the proper way of placing the arm?" I answered, "The best way of placing the arm would be thus: the fore-arm slightly bent with reference to the arm, and the palm uppermost;" and I made this answer as the direct conclusion or inference from the position in which I had just placed the bones, so as to show them as the furthest apart, for in the next question I was asked, "Is that the regular and well-known way of placing the arm in a simple fracture of the forearm?" and I immediately replied, holding my hand in the usual semi-prone position, "This is the best position in which to place it in a case of simple fracture;" and it is worthy of remark that, in the manuscript copy of the short-hand writer's notes now before me, the transcriber has emphasised the word *this* by placing a line beneath it, as if it were to be printed in italics, to indicate, doubtless, that when I used the word I threw great stress upon it to show that it was *the* position in the treatment of a fractured fore-arm—I being led to show the supine position only in illustration of that condition in which, for anatomical reasons, the bones would be the furthest apart. Then followed these two questions with the answers,—"Is the other way, with the back of the hand up, known among Medical men to be a wrong way?" "Yes, it is a wrong way of placing it." "Would it be wrong practice to leave the arm in this position with the back of the hand up during nine days?" "It would be wrong practice in my opinion."

The error, therefore, which has occurred in the newspaper description would lead those who have read the account to suppose that I said the supine position was the position, *par excellence;* whereas, as soon as I was asked to give "the regular and well-known way" of placing it I showed the semi-prone position.

Another mistake which has arisen from the newspaper description being so freely circulated, has been that it has appeared as if I had stated the bones were absolutely grown together, while this assertion was "denied by Mr. South," in his evidence.

In my written opinion made very shortly after I had examined the arm, I said—"She has no power whatever to turn the hand round so as to change the position of the palm or the back of the hand, although it is possible for another person to move it slightly in either of those directions, which gives her some pain." And when the following questions were put to me in the witness-box, the answers will show that I did not state that the bones were completely united together, but that passive motion could still be permitted:—"Is there something which is not bone which is between these two bones?" "Yes; a strong membrane called the inter-osseon membrane, between the bones." "If that becomes stiffened it prevents them turning one over the other?" "Yes." "Is that the reason why the wrist will not rotate?" "Yes, why she cannot perform this motion (the witness describes by turning his hand round)." "Can she perform this motion?" "She can let it be done for her."

It has been asked, How is it that I did not apply to Dr. Bowen and hear his version of the case before the trial? My answer is, that it did not occur to me to do so, and had I thought of it I should have considered it improper, after giving an opinion on the merits of the case to the solicitor for the plaintiff, to have had any communication with the defendant. I can only repeat how deeply I regret that I did not in the first instance decline to touch the case at all or to give any opinion whatever about it; but I beg to assure yourself

(a) "Every candidate approved by the Censor's Board shall be proposed as qualified to become a Member of the College." Bye-laws of the Royal College of Physicians, chap. xix., section xviii. London, 1862.

and the Profession generally that in my whole conduct in this matter I have erred from a want of judgment rather than from any desire to injure a member of my own Profession.

I am, &c., EDWARD LUND.

Manchester, January 10, 1865.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, JANUARY 3.

Mr. PRESCOTT HEWETT, President, in the Chair.

THE PRESIDENT declared the ballot open at eight o'clock, and appointed Mr. Hinton and Mr. Hulme to act as scrutineers.

The Treasurer's account and the Report of Council were then read.

REPORT OF THE SOCIETY.—SESSION 1863-64.

In summing up the proceedings of the past session the Council of the Pathological Society has much pleasure in being able to continue the tone of congratulation which has now become customary in these reports. It was stated in the Report for last year, that "the Society was at that moment constituted by a larger number of members than at any previous period of its existence;" and it is very gratifying to be able to state that at the present moment the number is even in advance of what it was last year, more new members having joined during the past session than in any other of which a record has been preserved. The receipts of the Society for the year do not show a proportionate advance—in fact, are somewhat less than in the previous year, but this is merely because last year several members availed themselves of the privilege offered to them by the Society of compounding for all future payments by a life subscription, while this year none have done so. This, however, is no permanent disadvantage to the Society, since if it diminishes the present receipts, it increases the future annual income. This annual income it must be allowed is now more wanted than ever. The large rent lately imposed by the Royal Medical and Chirurgical Society for the use of their rooms taxes the resources of this Society to the utmost. Still it has been thought undesirable to move from a situation which is so convenient and so well known to the members; and as a saving has been effected on the cost of the present volume, as compared with the last, the income of the Society has been still adequate to meet its expenditure, and even to leave a slightly increased balance in the treasurer's hands. This saving in the cost of the volume has not, it is hoped, been made at the expense of its value as a collection of pathological facts, but is the result partly of a reduction voluntarily made by the printer (in consequence of change of prices in that trade), but mainly of a diminished expenditure on engravings, in which the 14th volume was considerably in excess of the average. It is very gratifying to the Council to be able to state that the interest felt in the Society's meetings, as testified by the large attendance of its members, and the value of the specimens exhibited, appear to be steadily on the increase. It is also peculiarly pleasant to notice that while the new members of the Society are assuming their full share of the work, the old ones have not fallen off, but that the latest volumes of the *Transactions*, and the latest meetings of the Society, have been enriched by the matured experience of many of those whose contributions were the main source of interest to the earliest. The increasing number of the members of the Society renders some increase necessary in the number of copies of the *Transactions*, and the Council has accordingly sanctioned such an increase. The number now published leaves only a very small margin for purchase by future members and the public, so that several of the volumes are already out of print, and several more must be so in a very short time. A general index to the whole series of the fifteen volumes of *Transactions* has been prepared, and is in course of distribution to the members. A notice prefixed to this volume by the Council will explain the circumstances under which it came into the possession of the Society. The Council have now to call the attention of the Society to the general results of the Treasurer's account. The total receipts of the Society, including a balance from last year of £78 2s. 6½d., amounted to £430 3s. 4½d. Of this sum £27 14s. 1d. resulted from the sale of the *Transactions*—a very large increase on last year, and a testimony to the increased value in which the series is held; £8 5s. 9d. was interest on the Society's funded property, and the remainder, £316 1s., was received by the collector. The total expenses were £343 2s. 3½d., leaving therefore a balance of £87 1s. 1d. to carry forward. These expenses include a sum of £45 3s. for the purchase of stock, £49 7s. 11d. Three per Cent. Consols. The money represents the life subscriptions and composition fees, which it has always been customary to invest. This will make the funded property of the Society £308 11s. 4d. The Council cannot allow the retirement of their Medical Secretary, Dr. Bristowe, to occur without publicly recording their high sense of the valuable services which he has rendered to the Society in that capacity. It would be superfluous to point to the great value and extent of Dr. Bristowe's contributions to the *Transactions*, since they must be well known to all readers of these volumes. The Council indulge the hope that, although they have lost Dr. Bristowe's services as Secretary, the Society may long have the benefit of his co-operation in other offices.

Dr. WILKS moved that the Accounts and the Report be received and entered on the minutes. He adverted to the satisfactory condition of the attendance and of the finances of the Society. He advocated the continuance of the plan hitherto adopted by the Society, of rather devoting the time of the Society to the collection of facts than to the expression of pathological opinions.

Dr. MORRIS TONGUE seconded the motion.

The following specimens were then exhibited:—

Dr. BARLOW brought forward a case of

DISEASE OF THE TRICUSPID VALVE, WITH CURBOSIS OF THE LUNG.

He remarked that Dr. Wilks had pointed out the distinction between this condition of the lung and chronic inflammation. In this case the pathological condition of the lung had been predicated during life. The patient was a navvy, aged 38, who had led a dissolute life, and had a few months before been in St. Thomas's Hospital on account of hæmoptysis, after which he had never been restored to complete health. On his admission into Guy's he had cough and purulent expectoration, with systolic bruit not audible up the aorta. His face displayed much nervous congestion, with patches of skin exhibiting a sort of fibroid change. There was anasarca and slight albuminuria. The diagnosis was made from the long continuance of hæmoptysis in a man in tolerably good general health, with no symptoms of phthisis, and with probable disease of the right side of the heart, combined with the peculiar state of the skin of the face. On post-mortem examination the left side of the heart was found healthy. On the auricular surface of the tricuspid valve were some vegetations and thickening of the curtains of the valve. The state of the lung quite coincided with that usually described as cirrhosis. There was no curbosis of the liver.

Dr. WILKS raised the question as to the existence and as to the recognisability of bruit from disease of the tricuspid valve. Dr. Addison had taught that disease of this valve produced no bruit.

Dr. QUAIN stated that he entertained no doubt of the possibility of recognising disease of this valve. He referred to three cases in which this had been done in his experience.

Mr. J. HUTCHINSON exhibited a specimen of

DISEASE OF THE BRAIN, OF A TUBERCULAR NATURE, CONNECTED WITH LOSS OF SPEECH.

The patient, a male adult, had suffered amputation for caries of the tarsus, and was afterwards admitted for disease of the sacro-iliac symphysis. Suddenly one day he was observed to be unable or unwilling to speak, which was at first referred to to deception. There was no loss of intellect or power; but soon after he lost control over the sphincters, and other brain symptoms came on. The power of speech was never recovered (except that he sometimes enunciated the single syllable "Can't") for the three weeks he lived. After death a small mass of crude tubercle was found near the end of the posterior horn of the *right* lateral ventricle, and some thickening of the arachnoid. There were evident symptoms of inflammation extending up the *left* fissure of Sylvius, with softening around it. Mr. Hutchinson observed that it is this part of the brain which has lately been asserted by M. Broca and Dr. Hughlings Jackson to be connected with the function of language.

Dr. J. POLLOCK showed a case of

HYDATID CAVITY OF THE LIVER OPENING INTO THE LUNG.

The interest of the case lay in the fact that the disease

appeared to be in process of cure till this was interrupted by circumstances which might be called accidental. The patient, a lad aged 19, was admitted into King's College Hospital for cough and pain on the right side. He had had an attack of jaundice in St. Bartholomew's Hospital four months previously. On admission, the right side of the abdomen was found enlarged, and this enlargement was afterwards much increased. He frequently expectorated very large quantities of sputa, and these were often examined for the hooklets of echinococcus, but without success. After this copious expectoration, the bulging disappeared, and he was soon afterwards discharged convalescent, but was soon re-admitted with shivering, severe pain in the abdomen, and collapse. He died soon afterwards. On post-mortem examination, recent peritonitis was found. The liver and right lung were intimately adherent. There was tubercle in the bronchial glands, but on no other part of the lung. There was a large cavity filled with hydatids of irregular shape communicating between the liver and lung; the cavity in the liver was very small compared to that in the lung. Between the liver and gall-bladder was an abscess about the size of an orange which had burst into the peritoneum, and this had been the proximate cause of death, and had interrupted what had apparently been the commencement of the spontaneous cure of the disease. The gall-bladder was very small, and closely contracted on several gall-stones. A small part of the liver was in a state of incipient suppuration. No claws of echinocci were found on any part.

Mr. B. Squire introduced a case of

FAVUS.

The result of the ballot was then announced by the scrutineers.

Mr. Curling proposed that the thanks of the Society be offered to the President of the Society on his retirement from office, and to the Vice-Presidents and other members of the Council who are now retiring from office.

This was seconded by Dr. Greenhow, and unanimously agreed to.

The late President (Mr. Hewett) acknowledged the compliment, and presented to the Society the index to the fifteen volumes of the *Transactions* now published, which had been recently prepared, and is now in course of distribution to the members.

MEDICAL NEWS.

Apothecaries' Hall. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, January 5, 1865:—

William Porter Somerset, Claydon, Bucks; Albert Meeres, Haddenham, Bucks; Albert Octavius Haslewood, Darlington, Durham; Frederick Le Fevre Milburn, Aldringham, near Saxmundham; Henry Willson, 393, Strand.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Blandford, G. Fielding, M.B., M.R.C.P., has been appointed Lecturer on Lunacy at St. George's Hospital.

Bottle, Alexander, M.D. Edin., has been appointed House-Surgeon to the London Surgical Home for Diseases of Women.

Brunton, William R, M.R.C.S. Eng., has been appointed Medical Officer of Health for Redditch.

Davidson, J., M.B., has been appointed Resident Medical Officer to the Banffshire District Lunatic Asylum, Banff.

Finegan, James, M.D. St. And., has been elected one of the Medical Officers for the Parish of Liverpool.

Hughes, R., M R.C.S. Eng., has been elected House-Surgeon to the South Staffordshire General Hospital, Wolverhampton.

Jones, C. Handfield, M.B., F.R.C.P., has been elected Physician to St. Mary's Hospital.

Kough, J. O'Brien, M.R.C.S. Eng., has been elected Surgeon to the South Staffordshire General Hospital, Wolverhampton.

Miller, John N., M.B. Lond., has been appointed Physician's Assistant at the South Staffordshire General Hospital, Wolverhampton.

Pow r, William H., M.R.C.S. Eng., has been appointed House-Surgeon to the Royal Albert Hospital, Devonport.

Valpy, William H., L.F.P.S. Glasg, has been appointed Colonial Surgeon for her Majesty's Settlements in the Falkland Islands.

Watson, Patrick H., M D. Edin., has been appointed Acting Surgeon to Chalmers' Hospital, Edinburgh.

DEATHS.

Abbott, Charles Thompson, M.A., M.B., T.C.D., M.R.C.S. Eng., Surgeon 39th Regiment, at Aldershot, on January 2, aged 35.

Ayerst, Thomas, M.D. Aberd., at Rolvenden, Kent, on November 30.

Collingwood, James W., M.D., at Bishopwearmouth, Sunderland, on December 20, aged 65.

Dawson, H, M.R.C.S. Eng., at Islington, N., formerly of Maldon, Essex, on December 12, aged 69.

Dawson, John A., M.R C.S. Eng., at Newcastle-on-Tyne, on December 19, aged 32.

Evans, David P., M.R.C.S. Eng., formerly of Fronfelen, Machynlleth, on December 20, aged 76.

Fawcett, James E., M.R.C.S.E., R.N., Surgeon H.M.S. *Racehorse*, at the Bay of Lung Mun, Chefoo Cape, China, on November 4.

Flynn, T. P., L.K.Q C.P.I., Staff Assistant-Surgeon Army, at Jamaica, on November 19, aged 27.

Grant, George A., Assistant-Surgeon Royal Artillery, killed by a fall from his horse, on October 21, at Umritsur, Punjab, East Indies, aged 28.

Pickop, James, L.S.A., at King-street, Blackburn, Lancashire, on December 20, aged 72

Rowland, Henry M., L.R.C.P.L., at Derby-road, Bootle, Liverpool, on December 21, aged 31.

Presentation of a Testimonial. — On Tuesday, January 10, a handsome testimonial, value £150, was presented to Dr. Stainthorpe, of Hexham, by a number of his fellow townsmen and patients. The testimonial consisted of a silver tea and coffee service, a gold watch and appendages, a purse of gold, and a gold bracelet for Mrs. Stainthorpe. The plate bore the following inscription:—"Presented to Dr. Stainthorpe, M.D., M.R.C.S. Eng., etc., together with a gold watch and appendages and a purse of gold, by his numerous friends in Hexham, Hexhamshire, etc., to mark their appreciation of his ready and courteous attention in fulfilling the duties of his Profession, and as an expression of their appreciation of his worth." The presentation was made at a public dinner, at which the Rev. W. Sisson presided.

Memorial to the late Mr. Smyly.—Opening of the "Smyly" Ward.—On Thursday, the 5th inst., a very interesting ceremony took place in the Meath Hospital and County Dublin Infirmary, when his Excellency the Lord Lieutenant of Ireland, accompanied by Lady Wodehouse, the Right Honourable the Lord Mayor of Dublin, his Grace the Archbishop of Dublin, the Lord Chancellor of Ireland, and a large number of the friends and admirers of the late Mr. Smyly, met together for the purpose of formally opening a children's ward, lately erected by public subscription as a fitting memorial of that eminent Surgeon and benevolent Christian. Dr. Stokes, as senior Physician to the Hospital, having conducted the Lord Lieutenant and Lady Wodehouse to their seats, addressed his Excellency upon the object of the meeting, quoting the statements of various writers as to the rate of infantile mortality, and advocating the allocation of wards in general Hospitals to the diseases of children rather than the erection of special Hospitals for their treatment. The Lord Lieutenant, in an able speech, while he hesitated to differ from so high an authority as Dr. Stokes, was, on the principle of the division of labour, rather in favour of the establishment of special Hospitals, but accepted the allocation of children's wards in general Hospitals as a good beginning. The report of the Committee of Subscribers was read by Dr. Maurice Collis, to whose untiring exertions the marked success of the undertaking was mainly due. The Lord Mayor, the Archbishop of Dublin, the Archdeacon of Dublin (Dr. Lee), and others took part in the proceedings, which passed off most satisfactorily; nor can there be a second opinion as to the appropriateness of the form which the memorial to the late excellent senior Surgeon of the Meath Hospital has assumed.

The Late Mr. J. E. Fawcett, R.N.—James Edward Fawcett, R.N., Surgeon to Her Majesty's ship *Racehorse*, which was wrecked on the evening of November 4, of last year, was born at Woodhouse, in Leeds, in April, 1834, and received his early education at Mr. Hiley's, and the Grammar School, Leeds. In 1849 he joined the Leeds School of Medicine, being also an assistant at the Leeds Dispensary. He took out his diploma in the Royal College of Surgeons, London, in August, 1855, and in October of the same year he was commissioned as Assistant-Surgeon to the *Waterloo*, then lying at Sheerness. In the summer of 1856 he was appointed to the *Acorn*, in which he sailed for China, and served until 1859, when he was appointed to the *Chesapeake*, then the flag-ship on the China station. He was present at the taking of Canton, the battle of Fatshan, and at both attacks on the Peiho Forts, after the latter of which he was raised to the rank of full Surgeon by Admiral

Hope, in January, 1861, and was confirmed in that rank on his return home in December, 1861. In the many actions he was concerned in he was distinguished for his coolness and courage in the midst of danger and in the performance of arduous duties, especially after the Peiho engagement in 1859, when, after exposure in three different gunboats during the day, he remained throughout the night attending to the sick and wounded with a perseverance and fortitude under difficulties which could hardly be excelled. In May, 1862, he was commissioned to the *Racchorse*, and sailed in August for Japan, where he arrived in time to take part in the engagement against the forts at Kagosima. The *Racehorse* has not been engaged in action since, and was on her way from Shanghae to Chefoo Cape when the melancholy accident occurred which caused the death of so many brave men. Mr. Fawcett's death will be lamented by all who knew him, as he was not only a good officer and a skilful Surgeon, but a good Christian and a gentleman.—*Leeds Mercury.*

Fossil Remains.—In a letter addressed to the Academy of Sciences, M. Van Beneden gives an account of certain human remains discovered by him in a grotto situated in the valley of the Lesse. These remains, consisting of nearly complete skeletons, he considers as having been buried there by the waters during some great cataclysm. The grotto is situated at forty metres above the level of the Lesse. All the bones are dispersed in the mass of earth, the long bones always in a horizontal position. A skull in perfect preservation was found under a stone embedded in stalagmites. This skull was half filled with stones not much smaller than the occipital foramen, through which they had penetrated. In front of the cranium there was an omoplate, clavicles, ribs, long bones, vertebræ of children and adults. Bones were found firmly wedged between stones, so as to leave no intermediate space. Such effects, the author thinks, could only have been produced by water. In the midst of a solid bed composed of stones there was another cranium, the parietal bone of which was fractured. The bones situated where water could penetrate during the winter were either reduced to atoms or would fall to dust on being touched; the others were in a perfect state of preservaaion. These human bones were found together with those of bears (but not of the *Ursus Spelæus*, being rather nearer to the present species), of oxen, horses, reindeer, beavers, several beasts of prey, birds, fish (trout and pike), helices, and the *Unio Batava*, which still lives, together with helices, in the immediate vicinity. Mixed up with these bones there were flints of the most primitive form, bits of coal, calcined bones, looking as if they had just come out of the fire, and fragments of very old pottery. There were also some of the antlers of the reindeer, with marks upon them evidently made with human hands, but not forming any particular design. The ground where these remains were found presented no signs of having been disturbed, and there was no communication from without with the grotto except by the entrance only. The skulls above alluded to denoted a well-developed human race.—*Galignani's Messenger.*

Beef at Threepence a Pound.—Since the publication of our paragraph on the introduction to this country of the jerked beef of South America, we have received a great number of letters containing inquiries from persons desirous of turning the facts to practical account. The names of the merchants comprising the commission for the introduction of the beef will be found, with much other information, in a pamphlet on the subject published by Hedderwick and Son, of Glasgow. The wholesale agents are Messrs. James Gordon and Co., 11, Orange-court, Liverpool, and Messrs. Steel, of 5, Dixon-street, Glasgow. It is sent out in cases of one hundredweight. We may repeat that the "jerked" beef is prepared from the choicest parts of the animal, and, while it is not expected to supersede the use of fresh meat, it is believed that no greater boon has been lately offered to the under-fed classes of Great Britain. The following directions for cooking the beef have been published by authority of the commission: Steep the beef for three or four hours, or wash it well in hot water. 1st. Cut it in small pieces, about an inch square; simmer it by the fire for one and a half hours, add potatoes, pepper, and onions, and again cook slowly until ready. It will then be found a very good Irish stew. 2nd. Mince in the form of mince collops; cook it slowly, and when ready mix it up with mashed potatoes. It may then be put in a dish and browned in the oven. 3rd. Cut into pieces, and after simmering an hour and a half add turnips, carrots, or other vegetables, such as used in a haricot. 4th. It will also make very good pea-soup, and is also used in first-class hotels for giving a delightful flavour to all kinds of soup, particularly to kidney and other similar classes. In short, a good housewife will find a hundred ways of making it available and agreeable. 5th. It can be used as mince collops without potatoes; and a flitch is sometimes taken, rolled up and spiced in the form of a beef ham, which must be cooked slowly.—*Times.*

Anaphrodisia Resulting from the Prolonged Employment of Arsenic.—M. Charcot relates two cases in confirmation of a statement made long since by M. Rayer, that the prolonged use of arsenical preparations is sometimes followed by paralysis of the genetic functions. In M. Charcot's cases these had been taken in large and long-continued doses for the relief of obstinate cutaneous diseases, and the anaphrodisia which resulted was very well marked.—*Bull. de Thérap.*

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Mr. Maybury.—We cannot open our pages to the controversy between this gentleman and the *Lancet.*

Mr. M. S.—A Review of the London Hospital Reports shall appear very shortly.

An Anxious Parent.—The list shall be published as soon as received from the College of Preceptors, by which body the examination was conducted.

An Irish Student should write to the Secretary of the College respecting the extraordinary statement made by our contemporary. He will find that, although a graduate in Medicine, he will have to undergo precisely the same examination as without the degree.

Errata.—In announcing the appointment of three Demonstrators of Anatomy at St. Bartholomew's, we gave the name of a Mr. Turner We are informed, however, that there is no gentleman of that name connected with the Hospital or School. The names of the three Demonstrators are,—William Baker, F.R.C.S. (not M.R.C.S., as we previously stated), J. B. Vernon, F.R.C.S., and Alfred Willett, F.R.C.S. —In the remarks on the Blister Treatment of Acute Rheumatism, page 11, in the third paragraph, *for* "applied to prevent flow of serum," *read* "applied to promote flow of serum."

Consanguineous Marriages.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—"X" has invited discussion on a very interesting subject, and I regret that I had not collected sufficient facts to enable me to make more remarks in my last letter, but this I shall hope to do in a future one, as it is a subject I have had in my mind for some time, and have, therefore, left my eyes and ears open to see and hear all I could on it. The rough conclusions I arrive at are, that these marriages are not hurtful or injurious. But, in spite of all that science may say, or "warm debates" either, cousins will marry, if they have a mind to. Some justify themselves by quoting Numbers, chapter xxxvi., verses 10 and 11; and who is to blame them?

I am, &c., A. R.

Early Retirement in the Medical Branches of the Public Service.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The Committee of the College being now engaged in inquiring into the condition of the Army and Navy Medical Services, it is to be hoped that the Profession will not be disappointed when their report appears. The task will be of some difficulty, as there are many interests to be reconciled and anomalies to be removed. The welfare of the army and navy is to be made consistent with the dignity, honour, and welfare of the Medical Profession. The discipline and well-being of the services are to be consistent with the Professional and social position of the Medical officer. Every attempt to form a plan for the reconciling of these in some measure, opposed branches of the public service will only be attended by failure, unless established upon the basis of early retirement. The Medical officers of the army and navy are in the exact situation of the man between the two stools, who came to the ground It is to be feared the Medical Inspectors and Deputy-Inspectors do not represent the feelings, wishes, or interests of the body of Medical officers of both services. Any semblance of rank without the authority or privileges is the possession of the shadow without the substance. It is always considered as absurd to be querulous about a feather or stripe, but when persons have to pass a number of years—the most valuable of their lives—in the society of others, with whom the possession of such slight distinctions causes the difference of respect or contempt, these are more to be desired than can be imagined by persons having a choice of varied society. The Medical officer in the Royal Navy is confined to his ship, and (whatever his rank may be) cannot go on shore without asking leave of the commanding officer, who may be a midshipman or a carpenter. The exile, confinement, and servitude may all be borne, if there be a probability in a few years of its being terminated. The anomaly, however, is, the retirement is quicker in every branch of the naval service than it is with the Medical officers; and with the Army Medical officer the difficulty of obtaining even sick leave is very great, and not in proportion to the other officers.

The argument that on an early retirement the best men would leave is fallacious, as it has been proved in India that men do not retire because they have the option of doing so.

Medical officers, both of the army and navy, should be allowed to retire, after seven years, on a third of their full pay; after fourteen years, on the half of their full pay; and after twenty years, on the full pay of their rank. The Government would then be able to place incompetent persons on permanent retirement ("the shelf"), and the Medical officers themselves would have the satisfaction, under all disagreeable circumstances, to lay the unction to their souls—I can go if I like.

I am, &c. Medicus.

Chloroform Accidents.—How to Avoid Them.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—It is useful to say that of the two deaths from chloroform at Exeter, in last week's journal, one is a very old case, that has been commented on rather often; the other is a new case. There are, unfortunately, two other deaths to record this week, new cases: one at Leeds, with inquest, etc., which will probably be published shortly—a gentleman, who took chloroform himself (a most dangerous practice); the other, or fourth case, was not very dissimilar, and occurred in the "City."

It would be useful to say, too, that the 109 cases in the Medico-Chirurgical Society's Report are all old cases, and only about half of the real number that has been collected, and on which were founded some deductions that I see are now everywhere adopted in Germany and France.

All the four present cases, and 90 per cent. of the elaborate cases in the report of the Medico-Chirurgical Society's Committee, are remarkable all for a few things in common. First, that the doses of chloroform were very small; next, that the electricity is always used in exactly the wrong manner, due to the insufficient hypothesis that the death is from "cardiac syncope;" next, that there are twice, if not two and a-half times, as many males die as females, and few or no children; next, that the operations were trivial, or the death occurred before the operation was commenced at all, but never in the deep collapse or sinking of such an operation as ovariotomy, amputation of the thigh, resection of knee, etc., where one would *à priori*, on the cardiac syncope theory, expect death or fainting fits; next, complex apparatus, like Snow's or the modern balloons, increase rather than diminish the number of deaths.

I would like, in conclusion, to say a word or two as to the usefulness of collecting such cases, and the vital necessity of a sound hypothesis to explain them.

If you will excuse referring so much to figures and cases collected from all directions, I would wish to direct the reader's attention to a new Dictionary of Medicine and Surgery just published in Paris, this year (1865), where M. Giraldès gives a full and masterly analysis of the books and theories of Snow, Simpson, Black, Richardson, Nelaton, Lallemand, and Perin; Jackson, Erichsen, Arnott, Holmes, Longmore, and a dozen other well-known writers on anæsthetics. Nor does he omit the abstract of the report of the Committee in Berners-street, which he had read in your journal many months ago. M. Giraldès criticises Snow's views severely; he shows how singularly behind the time the other weekly journals are; but in the *Medical Times* he has followed our figures, and these singular deductions just enumerated. He objects much to Snow, ridicules the experiments on animals of Harley, Richardson, the views of "Holmes's Surgery," etc., and says, as his final verdict, "La theorie avancée par H—— qui regarde les accidents chloroformiques comme produits par une veritable apnée repond beaucoup mieux aux phenomenes observés chez l'homme, et explique d'une maniere plus satisfaisante le cas de mort subite;" that this theory agrees with all he sees in Paris; that idiosyncrasy and tetanic spasm of muscles cause death of Hospital patients by this apnea: that "cardiac syncope," Marshall Hall's "ready method," electricity to the heart, not to the phrenic nerves, and other superstitions, help to increase the deaths; that as Andral or the barber who bled Count Cavour have only 40 or 50 per cent. of deaths from pneumonia by the lancet, but Hughes Bennett only 5 without it, yet as Arabs we still go on in our stereotyped errors: book after book copying the old fallacy, electricity always tried in the wrong way, etc. He does full credit to the Silvester method rather than the Marshall Hall one. He believes over 200 deaths have occurred from chloroform, chiefly due to such errors and dishonest one-sided views of the facts under discussion.

Sackville-street, January 9. Charles Kidd, M.D.

Dr. Vogt's Lectures on Man.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Will any of your "Anthropological" readers inform us from what sources Dr. Vogt has obtained his information as to the external *physique* of the negro? With the truly unequivocal exception of Dr. Hunt's *brochure* on "the Negro's Place in Nature," it has not been my fortune to read a more glaring exhibition of either ignorance or misrepresentation (wilful or otherwise) than is given in the seventh lecture of Dr. Vogt's work. This is not the place, of course, to give a detailed criticism (with its accompanying extracts) of these lectures, but yet, with your permission, I may shortly adduce sufficient proof of what I have now said. He tells us that "most negroes can, without stooping, reach with the finger's end the region above the knee-cap." That "the shoulders are narrower and less strong than in the white. There is a certain resemblance in the form of the neck to that of the gorilla." He says the neck has "a curvature" like the "bull's neck," and that this is the reason why the negro carries his burden on his head; that the "belly is relaxed and pendulous;" that the arms are less rotund, etc., and that he "(the negro) rarely stands quite upright, the knees are usually bent, . . hands and feet are long, narrow, and flat." The author then summarises by adding that "most of these external characteristics remind us irresistibly of the ape," affording "a glimpse of the ape beneath the human envelope." Further on we are told "that we are struck by the fact that the S-shaped curve of the vertebral column is less distinct in the negro than in the white, the column approaching in its arrangement that of the ape;" and that "the dimensions of the small pelvis through which the head of the child must pass are considerably smaller in the negro." He states that the several measurements of the extremities show "a decided approach to the animal type,"—the ape, and that the arm is nearly of the same thickness throughout. I shall not extend these quotations, but will simply ask again, Where has Dr. Vogt got his information? He admits he has never seen a new-born negro child; one is forced to ask, after reading this caricature of the negro's outward form, whether he has seen half a dozen adult negroes in his life? Even some of those measurements he gives from Burmeister are opposed to his assertions in the text; and from a long residence among negroes in the West Indies and Africa, I unhesitatingly pronounce such a description as we have given us in this lecture as ludicrously false in its more significant parts. Let any one with the necessary personal knowledge or information derived from reliable sources just compare these statements with the men and women on a West Indian estate, with the Kroomen of Cape Palmas, or the Foolahs, Eboes, and other tribes as purely negroes as the Congoes, and a feeling of surprise will be excited that a man of Carl Vogt's position should allow himself to send forth such statements under the authority of his name. The truth seems to be that "the similousness in the negro" was a foregone conclusion, and the description to be given must needs be made to square with it; for a candid and well-founded exposition of the reality could never be made to support such a conclusion. I have only to add that our author's statements, original and quoted, as to the mental characteristics, moral and religious especially, of the negro are as true to the reality as are those I have thus shortly examined. I am, &c.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29·785 in.
Mean temperature	36·7
Highest point of thermometer	49·2
Lowest point of thermometer	19·0
Mean dew-point temperature	32·0
General direction of wind	S.W.
Whole amount of rain in the week	0·23 in.

APPOINTMENTS FOR THE WEEK.

January 14. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

16. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

17. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

Anthropological Society of London, 8 p.m. W. T. Pritchard, Esq., F.R.G.S., F.A.S.L., "Notes on Certain Anthropologic Matters connected with the South Sea Islanders." Edward Lund, Esq., F.R.C.S E. (communicated by Dr. F. Royston Fairbank, F.A.S.L.), "On the Discovery of Syphilis in a Monkey (*Macacus Sinicus*). E. Sellon, Esq., "On the Linga Puja, or Phallic Worship of India."

Pathological Society, 8 p.m. Meeting.

Royal Institution, 3 p.m. Prof. Tyndall, "On Electricity."

18. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

19. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Harveian Society of London, 8 p.m. Dr. H. C. Stewart, "On the Diagnosis of Embolia affecting the Great Vessels of the Heart, with Cases."

Royal Institution, 3 p.m. Prof. Tyndall, "On Electricity."

20. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m. Prof. Tyndall, "On Combustion by Invisibl Rays."

ORIGINAL LECTURES.

LECTURES ON CHEMICAL AND MECHANICAL DISEASES AND THEIR RELATIONSHIP.

By H. BENCE JONES, A.M., M.D., F.R.S.

Lecture I.

ON DISEASES OF SUBOXIDATION—DIABETES.

I have chosen diabetes for my first lecture, because, among all the diseases to which mankind is liable, it is the best example of a purely chemical derangement of health.

In slight or in severe cases, even from first to last, mechanical symptoms or complications rarely occur. Loss of nutrition and loss of power through the whole course of the disease bear a direct relation to the loss of saccharine fuel, and when the complaint proves fatal, no change of structure is found; no evidence of any disordered chemical action remains. Atrophy alone shows that the nutrition of the body has become more and more feeble.

Throughout its course the disease seems as though it might be cured at any moment, provided some change could be made in the chemical actions on which the production of the sugar depends.

There appears to be only one link wanting to make the healthy chain of action complete; if this could be supplied the disease would cease to exist; the sugar would disappear from the urine, and the symptoms of the complaint would be gone. What, then, is the nature of the disease? To understand it I must go back to physiological chemistry.

Very many substances are included in the term sugar. Though closely related, they have chemical and optical differences. The three great optical divisions of sugars are—Convertible, polarising to the right—these are cane sugars. 2. Inverted, polarising to the left—these are fruit sugars. And, 3. Unconvertible, polarising to the right—these are glucose and diabetic sugars. The chemical differences are best seen in the following table:—

Crystallised cane sugar	$C_{24}H_{22}O_{22}$
Combined cane sugar	$C_{24}H_{18}O_{18}$
Grape sugar, crystallised	$C_{24}H_{28}O_{28}$
Grape sugar, in combination	$C_{24}H_{21}O_{21}$
Melitose, from Eucalyptus mannifera	$C_{24}H_{24}O_{24}$
Eucalyne	$C_{24}H_{24}O_{24}$
Melezitose	$C_{24}H_{22}O_{22}$
Sorbin	$C_6H_6O_6$
Sugar from secale, cornutum mycose	$C_{24}H_{26}O_{26}$
Caramel	$C_{24}H_{18}O_{18}$
Mannite	$C_{12}H_{14}O_{12}$
Dulcose	$C_{12}H_{14}O_{12}$
Erythromannite	$C_8H_{10}O_8$
Pinite	$C_{24}H_{24}O_{20}$
Quercite	$C_{24}H_{24}O_{20}$

In addition to these there are saccharine substances of animal origin, of which the best known are—

Milk sugar, crystallised	$C_{24}H_{24}O_{24}$	
Milk sugar, in combination	$C_{24}H_{19}O_{19}$	
Glycogen	$C_{24}H_{20}O_{20}$	Bernard's saccharine substance from the liver.
Inosite	$C_{24}H_{24}O_{24}$	Scherer's sugar from the heart and other muscles.

All these different saccharine substances are not able to pass as glucose into the urine; but they are all capable of being oxidised in the blood and textures into carbonic acid and water, whilst giving heat or motion, or other energy, to the body.

Each grain of starch that is taken as food, when acted on by the saliva or pancreatic fluid, is converted into sugar, and becomes a source of fuel or power and ultimately passes out of the body as carbonic acid and water.

In diabetes the starch is still changed into sugar; but in the circulation and in the extravascular or parenchymatous structures the further change is partly or wholly stopped; more or less of the sugar remains as sugar, part reaches the kidneys and is thrown out in the urine, part exists in the structures unchanged; and thus the system is deprived of one part of that conversion of latent into active force on which the nutrition and power of the organs depends.

In the body or out of the body, when once a series of chemical action is set up, the series tends to become continuous; it propagates itself, unless a change of conditions occurs. For example, grape juice will remain as grape juice, if kept from the action of other substances. Under well-known conditions it will ferment, and continue fermenting, as long as sugar, and ferment, and the proper temperature are present. If the conditions are slightly varied, variations in the products will be observed. The series of actions will not pass rapidly from grape juice to alcohol, to vinegar, or to putrefaction; but according to the conditions one action or another action will be set up or will continue as long as that action is possible.

In health and in diabetes the sugar is subjected to different conditions. In health the chemical changes are propagated and continued to their full extent; whilst in diabetes the conditions necessary for perfect change are wholly or partly wanting. These conditions, on which the changes depend, are chiefly three. 1st. The proper temperature; 2nd. The presence of a not immoderate quantity of sugar; 3rd. The presence and activity of a ferment.

On each of these conditions a few words are necessary.

First, the internal temperature of the body, under all circumstances, is subject to so small a variation, that at present there is no proof that such a reduction can occur as can check the chemical actions in the human body, though under certain circumstances small animals can be exposed to cold so that sugar may be made to appear in the urine.—*Proceedings of the Royal Society, December* 15, 1864.

Secondly, by the most careful investigation, I have satisfied myself that Professor Brücke is right in saying that healthy urine contains sugar—that is, the amount of sugar derived from the food, or from the changes going on in the textures, is at all times more than can be entirely changed in the circulation and in the tissues. If, then, a considerable amount more is thrown into the circulation, some of it will pass out in the urine. Thus an injection of sugar into the rectum when absorbed causes temporary diabetes; so, also, large quantities of sugar, fruit, and farinaceous food tend to produce diabetes. Thus, also, if Bernard's amyloid or glycogenic substance were produced in excess in the liver, diabetes would result.

Thirdly, the ferment, the prime cause of change, has not been yet insulated. Whether it be the albuminous substance of the saliva or pancreatic fluid, or some other of the many albuminous substances in the blood, it requires for its action heat, the presence of alkali, and an undisturbed circulation of the changing fluid.

With regard to the effect of alkalies, something will be said when I speak of the treatment of diabetes; but concerning the influence of unobstructed chemical action some remarkable physiological experiments must be here mentioned, because they not only furnish the most striking illustrations of the relations of mechanical to chemical disease, but because they also help to account for the effect of sudden mental shocks and nervous disturbances, which do so much harm to the diabetic patient.

Bernard made the great discovery that the mechanical injury of the floor of the fourth ventricle alters the chemical actions going on in the body so as to cause sugar in excess to appear in the urine. This is a most remarkable demonstration of the relation which subsists between mechanical and chemical actions in the living body.

M. Schiff, in his "Untersuchung uber Zuckerbildung" (1859) states that this diabetes results from injury of the vaso-motor nerves of the abdominal organs which arise from the thalami optici and the crura cerebri—*partent des couches optique et des pedoncules cérébraux;* and he also shows that by injury of other parts of the nervous system temporary or permanent diabetes is produced.

Thus cutting the posterior roots of the nerves arising from the cervical portion of the cord, leaving the anterior roots untouched, causes temporary appearance of sugar (irritative

diabetes); whilst by division of the anterior roots on a level with or above the fourth cervical vertebra, permanent (or paralytic) diabetes results. These injuries, he says, cause an irritation or a paralysis of the vaso-motor nerves. The vessels of the liver become dilated and distended; and as a consequence there is an excessive secretion of sugar by the liver.

The permanent diabetes may be thus occasioned; but it is far more probable that the temporary diabetes is owing to the mechanical injury of the nervous system so affecting the vessels that the chemical changes are interrupted. The same phenomenon is seen in every fermentation. The chemical action is temporarily stopped when the fermenting fluid is disturbed by any sudden change.

These conditions of change may in diabetes be affected singly or all simultaneously. When the affection reaches to the extent of stopping the chemical change in the vegetable or animal sugar in the body, diabetes, intermittent or permanent, is the result.

That the disease is only a little way distant from health is shown by the existence of sugar in the urine in the healthy state; so that a small quantity of sugar in the urine is no proof of disease; and here, as elsewhere, there is no defined limit where health ends and disease begins.

Diabetes is the arrest of a healthy state; an increased quantity of sugar appearing in the urine, because the actions that constitute health are stopped.

In perhaps half the cases of diabetes the arrest of change in the food-sugar constitutes the complaint. This is proved by the fact that when a strict antifarinaceous diet is observed the abnormal amount of sugar ceases, and the patient is well as long as he keeps to the strict diet. When this fact was published in 1806 by Dupeytren and Thenard, they used these words:—"Que le traitment qui consiste surtout dans un régime purement animal a le même degré d'efficacité que le quinquina dans lês fièvres intermittants."—*Annales de Chemie*, vol. 59, p. 45.

But it was soon found that cases occurred in which a strictly antifarinaceous diet, consisting of animal food and water, did not stop the sugar in the urine. For days and weeks not a grain of vegetable starch or sugar may be taken as food, and yet sugar in excess will exist in the urine. Whence does this sugar come? It must either be taken in the animal food or it must be produced in the body.

Previous to Bernard's discoveries, this production of sugar when no vegetable food was taken admitted of no explanation. Now, the discovery of the amyloid substance in the liver, and of inosite in the muscles, lungs, brain, and other organs, gives a full solution of the difficulty. In the chemical changes going on in the body, animal starch is formed in the liver, and in other organs as in the prostate gland, and sugar in the muscles; not, as in vegetables, by the fixation of carbon and the decomposition of water by the action of light, but more probably by the gradual splitting up of the higher organic compounds of the different organs whilst performing their functions.

The good effect of an antifarinaceous diet in some cases, and its want of effect in others, marks the two great divisions of the disease—the two stages of diabetes. In the first stage vegetable sugar alone ceases to go through the healthy chemical changes, whilst the animal sugar is entirely changed; in the second stage, animal sugar as well as vegetable sugar are more or less unchanged. It may be concluded that animal sugar is more readily changed than vegetable sugar; and when in diabetes an antifarinaceous diet has no marked effect, then the conditions of change of the sugar in the body are furthest from the healthy state.

There is sufficient evidence that diabetes does not always progress from one stage to the other. The disease may halt anywhere in its progress, and remain stationary for years, or get better or worse. A gentleman has consulted me for the last four years occasionally; he is now 57. When I last saw him the specific gravity of the urine was 1020, about three pints in twenty-four hours, containing about four grains of sugar to the ounce. He had been diabetic for twenty-nine years, during which time he married, and has now healthy children grown up. When he takes care about his diet, the sugar and symptoms vanish, but when careless, the symptoms return, and the sugar can be found in the urine.

Diabetes, then, in its mildest or first form, is the loss of power to change the sugar of the food; in its more advanced or more intense form, it is the loss of power to change the sugar produced in the organs and textures of the body, as well as in the food. The changes in the animal as well as vegetable sugar are arrested.

On the Means of Detecting Diabetes.

The first and readiest means of detecting diabetes is to boil about a drachm of urine and a drachm of liq. potassæ for two or three minutes in a long test-tube. The colour of the urine after boiling should be compared with an equal quantity of urine mixed with as much water in another test-tube. In well-marked cases the boiled urine becomes darker than the darkest sherry. If the colour is only slightly changed, then the same quantity of urine should be mixed with two drops of a saturated solution of sulphate of copper and a drachm or more of liq. potassæ, and then boiled. Reduction of the copper rapidly takes place if much sugar is present; or half-an-ounce of urine should be boiled with ten grains of slaked lime. If none of these tests give a decided reaction, the amount of sugar in the urine may be considered scarcely beyond the quantity that exists in health. Before asserting that no tendency to the disease is present, it is well to repeat these tests with urine made about two or three hours after a farinaceous meal.

A gentleman was sent to me from the country for diabetes. His Medical man had found the sugar, and had put him on an anti-farinaceous diet. When he came to me the colouration and reduction, on testing the urine, were not perceptible. A portion of this urine was sent back with the patient, and the Medical man was surprised to find that the sugar was gone. When the patient returned to farinaceous diet the sugar reappeared in the urine.

On the Difficulties and Fallacies of the Tests for Sugar.

Regarding the presence or absence of very small quantities of sugar, positive and negative doubts may arise. Appearances may be observed resembling sugar when no sugar is present, and substances may hinder the reactions taking place when sugar exists.

When there is more than a grain of sugar in the ounce of urine, little difficulty occurs in finding it. When less is present, the organic matters in the urine hinder the reactions, and it becomes necessary to separate the sugar from other substances before the tests are used.

In a paper in the *Quarterly Journal of the Chemical Society*, vol. xiv., p. 27, "On the Detection of Sugar in Healthy Urine," you will find experiments on the value of the different processes for determining the presence and quantity of small quantities of sugar in the urine. In doubtful cases, by following Brucke's process, no case of diabetes can be overlooked.

There remains, then, the opposite error that may arise from the use of the sugar tests. Sugar may be thought to be present when the colouration or reduction may be caused by some other substance.

Long-continued boiling of the urine, even without alkali, causes the colour to become darker. The longer the boiling is continued the darker the colour becomes. Alkalies and heat together always have some darkening effect on the healthy colouring matter of the urine when exposed to the air.

When accidental colouring matters are present—as, for example, rhubarb or senna—alkali, without heat, gives a deep colour to the urine.

On this account, the test of colouration ought never to be trusted to alone. Reduction of the oxide of copper must occur if sugar is present; but substances may be present with the sugar, as muriate of ammonia, 1 grain to $\frac{1}{200}$th grain sugar; or urea in great excess, 1 gr. urea $\frac{4}{1000}$th gr. sugar; and these substances may hinder the reduction of the copper; or substances may be present when no abnormal sugar is in the urine, which may reduce the oxide of copper and lead to great errors.

In the Medico-Chirurgical *Transactions* for 1843, vol. 26, p. 211, in a paper on the detection of sugar in diabetic blood, I mention that uric acid will reduce the oxide of copper.

Tartaric acid also, under certain circumstances, will reduce the oxide of copper.

A Physician sent me some urine of a supposed diabetic patient, asking me to determine the amount of sugar. I told him I found no sugar present. He gave me an analysis in which the sugar was determined to the second decimal place. I took the urine I had examined to the analyst, and asked him to repeat his test. For convenience he had made a Winchester quart of Fehling's standard solution, and on testing the urine, reduction occurred to an immense extent; and the analyst thought I was wrong, until I heated his standard solution without adding any urine to it. Then the tartaric acid reduced the oxide of copper just as if sugar had been present.

These examples, and more might be given, of the reducing action of other substances than sugar are quite sufficient to show that no dependence can be placed on the reduction test alone. It would be just as wrong to assert that all reduction proves the presence of uric acid as to say that it alone indicates sugar.

On the Quantitative Tests for Sugar.

A practical eye can make an approximation to the amount of sugar by the colour produced by potass or lime, as a practised hand can tell nearly the weight contained in it; but thus no accurate results can be obtained.

The quickest and easiest method is to fix the amount of sugar by Soleil's saccharimeter. The decoloration by animal charcoal or acetate of lead causes a loss of sugar, because a portion is always retained with the colouring matter (see *Quarterly Journal of Chemical Society*, vol. 14, p. 28); but by using as little decoloriser as possible, this instrument gives accurate results; whilst for rapidity, and ease, and beauty, it far surpasses any other process.

Fehling's standard copper solution is easily, quickly, and accurately useful. I have already shown the necessity for testing the test.

The fermentation test requires considerable care, much time, and a good balance. At page 27, vol. 14, of the *Quarterly Journal of the Chemical Society*, you will find a comparison of these different processes.

Lastly, the specific gravity has by some persons been used as a means of determining the amount of sugar in diabetic urine.

Formulæ are given in books for calculating the sugar from the gravity of the urine. These tables might give an approximation to the truth if diabetic urine was a solution of sugar in distilled water; but there are very many other substances with the sugar, and these all vary as well as the sugar, and they all affect the gravity of the urine, and render all the formulæ worthless. To convince you of this I have made the following table from ten cases of diabetes. The amount of sugar present in an ounce of urine was determined by the saccharimeter. The specific gravity was determined by a first-rate balance.

Sugar to the ounce of urine. Grains.	Specific gravity.	Sugar to the ounce of urine. Grains.	Specific gravity.
1	1030.8 1029.5	18	1048.6
2	1009.2 1025.6 1031.2	19	1031 1037.8
4	1028.5 1029.6	20	1033.0 1037.8 1039.0 1042
5	1013.8 1014.4 1027.8 1029.6	21	1032.8
6	1034.4	23	1033.4
7	1029.4 1033 1035.4	24	1032.0 1035.0 1035.4 1036.8 1043.4 1044.4 1045.4
8	1027.3		
10	1029.2 1031.0	25	1030.0 1033.9 1044.8 1045.8
12	1024.5		
13	1033.4 1043.4 1045.0 1045.4 1045.4	26	1034.6 1037.8
		27	1037.6
		29	1041.2
14	1023.2	30	1035.4 1040 1042
15	1028.5 1030.1		
16	1032.4 1034.0 1034.8 1035.0	33	1033.4 1040.5
		34	1044.0
17	1025.6 1030.2 1035.4	37	1039.4 1043.4

The want of any correspondence between the amount of sugar and the specific gravity is very striking. Thus, 13 grs. to the ounce have a higher specific gravity than 37 grs. to the ounce. 24 grs. to the ounce in six different specimens give widely different specific gravities, proving that no dependence must be placed on any tables for calculating the sugar.

Or the following table from the urine of a single patient, aged 21. The analyses were made between February and November by Mr. Kemp, of Edinburgh:—

Specific gravity.	Quantity of sugar per ounce urine. Grains.	Specific gravity.	Quantity of sugar per ounce urine. Grains.
1023	2.2	1031	14 5
1025	2.1	1032	17.5
1026	4.0	1033	6.0
1027	0.7 4.5 4.5	1034	8.0
1028	14.5	1035	10.0
1029	3.3 2.5 3.	1036	5.5
1030	3.6 7.2	1038	7.5

Here is another case, with greater variations in the specific gravity. The sugar was determined by the saccharimeter:—

Specific gravity.	Quantity of sugar per ounce urine. Grains.	Specific gravity.	Quantity of sugar per ounce urine. Grains.
1013.8	5	1034.0	16
1014.4	5	1035.4	7 17
1023.2	14	1037.5	19 20
1025.6	2	1038.3	3
1028.5	4	1039.0	20
1029.6	4	1043.4	13
1030.0	15	1044.4	24
1031.0	10	1044.8	25
1031.2	2	1045.0	13
1032.2	24	1045.4	13
1032.4	16	1045.8	25
1033.4	13	1048.6	18

What are the Symptoms of the Disease?

In slight cases there are literally no symptoms at all. In the Medico-Chirurgical *Transactions*, vol. 36, p. 424, you will find this case: A gentleman, aged 63, in 1847 consulted Dr. Watson, who wrote me this note. "He calls himself well, and seems eminently so. Stout, fat, and ruddy; eats and drinks heartily and indiscriminately, and has no dyspepsia. Perspires copiously. Makes much urine, and often by day and by night, and has done so these forty years. Says his pulse occasionally intermits, and has long done so. I found it steady and at 80 in the minute. His father died of diseased heart at 77. My patient had some bronchial trouble last winter. Had lately some redness of the toe for a day or two. Comes to me that I may see what he is when well, as he means to put himself under my charge whenever he is ill." He had noticed some floating substance (not sand) in his urine, and was curious to know what it might be. I found the urine had specific gravity 1032·0, and it contained slight but decided evidence of sugar. In a year and a-half another examination found more sugar, and four years after that I found three grains, and on another occasion five grains of sugar to the ounce. There were no other symptoms of diabetes.

Usually the sugar acts as a diuretic and causes thirst, whilst the appetite is often voracious; but although much is eaten the strength and flesh rapidly fall off.

A girl, aged 18, was in St. George's Hospital April, 1852, who said she eat a two-pound loaf at each meal, and that she drank a pail and half of water daily. She passed twelve pints of urine in twenty-four hours, and rapidly grew thin and weak.

A labourer, aged 32, when admitted, told me his water ebbed and flowed. The greatest flow, he said, was seven gallons, the ebb five pints.

With regard to the loss of flesh take the following statements:—

A gentleman, aged 62, at the beginning of the disease lost two stone in three months.

Another, aged 37, in August, 1852, lost fourteen pounds in five days, passing two gallons of urine, sp. gr. 1050, daily.

A Physician, aged 72, told me that in four or five months he had lost forty pounds weight, but he regained most of his loss.

The following is the best example I can give you of the symptoms in an acute case:—

On the 15th of September, 1852, I was requested to see a gentleman, about 35 years of age, who six weeks previously was quite well, and shooting in Scotland, where he drank freely of whisky and took excessive exercise. He at that time passed a considerable quantity of urine, which he attributed to the whisky, and yet he was advised to consult me when he returned to London. So that he must have had some doubts about the cause of the excessive secretion.

When he came back he was depressed, and had great trouble with his bowels. He, however, after staying from his occupation for some days returned to it, and was getting better when he was attacked by great constipation of the bowels, much weakness, dry tongue, and soreness of the throat.

I saw him in bed: he could at first hardly speak, from apparently nervous anxiety and dryness of the mouth. There was no soreness of the throat to be seen. The tongue was quite clean. The pulse 110, and very feeble. The skin harsh and dry. He was not very much emaciated. The urine was clear, not above two pints. He had had a very confined motion, which he said burnt his inside in passing. He had a very unquiet night. The pupils were natural. The

head quite clear, and after some time he spoke in a good voice, and complained only of weakness. I examined the lungs and heart, and they were all quite healthy. I could find nothing wrong with the abdomen: it was rather hard and retracted. He did not complain of thirst, and could eat nothing. I had some trouble to persuade him he was far more anxious about himself than he ought to be, and that he was doing himself harm by it. I urged him to take jelly and brandy, and said that I would see him again after I had examined the urine.

On my way home I remarked to his Medical man that possibly it was a case of acute diabetes, and that if so he would die.

On examining the urine it had specific gravity 1030, and contained sugar.

The following morning I went to his Medical man to tell him he had diabetes: he said, "I was coming to you to tell you he is dying."

I saw him at half-past twelve on the 16th of September, perfectly comatose, and I tried in vain turpentine injections and blistering with ammonia. He died in about an hour.

The prognosis in diabetes depends chiefly on the nature of the attack, and on the constitution and age of the patient.

It is very difficult to decide upon the severity of an attack, because the disease does not usually proceed at a uniform rate. At one time the chemical change of the vegetable and animal sugar seems almost entirely stopped. Sugar, thirst, thinness, and weakness increase rapidly. After a time a reaction occurs. The sugar may almost or altogether disappear from the urine. The symptoms may pass away, and some part or all of the flesh and strength lost may be regained. Anywhere in the course of the complaint such a halt may occur, and the disease may stop for months or years. In some rare cases even the worst possible diet appears not to affect the progress of the complaint. Sufficient chemical change goes on to supply the heat and the force of the body, and sufficient nutrition takes place to keep the organs healthy. In this condition scarcely any exertion of physical or mental power is possible. It is sufficient work to live, but with care life may so last for years.

The increase of urine, of debility, and of emaciation in any fixed period may be taken as indices of the severity of the attack during that time, but not at any other, for the disease may become more or less severe; so that the future cannot be surely known from the past.

The goodness or badness of the constitution as regards diabetes usually may be estimated by the family disposition and by the weight of the patient. That a mode of chemical action should be propagated from parent to child, or that many children of the same family should lose the power of changing sugar into carbonic acid and water are examples of the law that like begets like. This law is so universal that in this instance as in other instances it is apt to be used as a solution when it is only a cloak for a difficulty. The transmission of peculiar features, habits, and dispositions is just as inexplicable as the inheritance of imperfect chemical change of sugar in the human body.

A shoemaker, aged 51, was in St. George's Hospital, having suffered from diabetes for four years. He had two daughters, one 12 the other 5. The eldest was healthy; the youngest was admitted with diabetes, having been ill about six months. She died before her father.

I was asked about a suspected diabetes in a boy whose sister had died when she was 7 years old, after being ill two years with diabetes. Another sister died of the disease when 4½ years old, after one year's illness; and a brother died when 15, after three years' illness. Post-mortem examination showed no tubercular disease in any of the three children.

If, then, there is a family history of diabetes, the constitutional worth of the patient may be estimated by inquiring into the intensity of the disease in other members of the family; for sometimes only a very slight disposition to diabetes is inherited.

I have attended three brothers, all clergymen, the eldest died aged 74; the second is now 68, and the youngest is a year or two younger. All of them have had intermittent attacks of diabetes. In the eldest I found sugar in the urine thirteen years before his death. In the second, sugar was found by Dr. Prout sixteen years ago, and he is now in good health, with sugar occasionally, not constantly, in the urine. In the youngest I found sugar eight or nine years ago, and he is now, I believe, in good health. This instance shows that occasionally the inherited disposition may induce only a very slight form of diabetes. Great accumulation of fat is also an inheritance in some respects allied to diabetes. Obesity may depend on an arrest of oxidation of fatty matter, and Dr. Prout long since remarked the tendency of fat people to diabetes. The increased liability is compensated by the mildness of the attack. The store of oleaginous fuel seems to counteract the waste, and sustain the force of the body, and the greater the accumulation of fat, the less the loss of the saccharine food appears to be felt. On the contrary, very thin people, having no supply of oleaginous food in reserve, are unable long to endure the continuous loss of the saccharine fuel, on which half the force of the mainspring of the body depends.

If, then, the patient is fat and the family history is good, the constitution may be considered most fitted to resist or to recover from an attack of diabetes.

Lastly, in the prognosis, the age of the patient must be taken into account. In the eighteenth volume of the *Med.-Chir. Trans.*, page 421, I have stated that in twenty-nine cases of diabetes eleven were above 60, and six above 70; and of these eleven all but one had the disease so slightly that it could hardly be known by the general symptoms. The diabetes of old age is rarely severe, but exceptions do occur, and at page 428 I have given a case in St. George's, aged 74: thirteen pints of water in twenty-four hours were passed, and in four months the disease was fatal.

The age of the youngest diabetic patient I have known was three years and a-half. The specific gravity of the urine was 1037. No sugar was in the urine on October 31, but it was found on December 14. The patient lived not quite one year. The sister was five years old when the sugar was first found. The highest specific gravity of the urine was 1043. She lived twenty months.

Hence, a very thin and very young child, in whose family severe diabetes is known, who is rapidly losing strength and weight, passing much water, is the worst possible case of diabetes; whilst an old, stout man, in whose family no diabetes, or very slight diabetes, is known, who loses no strength or weight, and passes but little more than two pints of water, may almost be considered as having no disease at all.

(To be continued.)

ORIGINAL COMMUNICATIONS.

CASE OF OVARIAN GESTATION.

By G. H. CASE, M.R.C.S.

On Friday last my father received a warrant from the coroner to make a post-mortem examination of the body of a woman who had died under the following circumstances:—Her husband took an order from the relieving officer to the parochial Surgeon to see his wife, and stated that she was ill, complaining of pain in the belly. The Surgeon told him he was just then going out, and that he would see her next morning, at the same time giving him some medicine for her. About half an hour afterwards she died.

On examination the body was well nourished, and there were no bruises or other marks visible. On opening the abdomen the whole cavity was full of blood. On removing the coagula, a fœtus, contained within its membranes, and floating in the liq. amnii, was seen lying on the intestines. We found that it had been contained in the right ovary, which had burst and allowed its escape. The placenta was still partially attached to the cyst, and on separating it completely a mass of decolorised fibrin, about the size of an egg and surrounded by coagula, lay between it and the cyst wall. The fœtus was a male, well formed, and about five months advanced. The left ovary was healthy; the uterus was enlarged to about the size of a closed fist, and lined by a thickened and congested decidua.

The following account of the symptoms was given in evidence to the jury:—Between eight and nine o'clock in the morning the woman complained of pain in the abdomen; this pain continued all day, and on her husband's return from work she asked him to "fetch a Doctor." He went to the Surgeon between seven and eight in the evening. Shortly after this she became much worse, vomited, and was then laid down on the bed, exclaimed "Oh, my back, my back!" fainted, and died. She was forty-two years of age, and had had one child three years ago. She supposed herself six months pregnant, and during the day some bloody discharge and coagula passed from the vagina.

It is clear that the rupture of the cyst could only have taken place just before death, but I think it probable that the pain she suffered during the day might have been caused by the partial separation of the placenta. That this detachment took place during life was evidenced by the mass of fibrin.

This case shows the desirability of a post-mortem examination in all cases of sudden death where an inquest is considered necessary. In this instance, the coroner did not intend to order an examination of the body till pressed to do so by the Practitioner to whom the Medical order had been taken. Then the cause of death would not have been known, and the jury, in all probability, would have reprimanded the Surgeon for not attending at once, under the impression that her life might have been saved by prompt attention.

Fareham, Hants.

SPONTANEOUS COAGULATION OF URINE.

By A. W. STOCKS,
Surgeon to the Salford Hospital.

J. W., AGED 27, warehouseman, married; sanguine temperament; has a fine soft transparent skin; has had gonorrhœa and iritis; never had syphilis; otherwise well. About nine years ago had a dry scaly eruption over the whole body, desquamating in large patches. The nails became corrugated and thickened by a deposit like plaster of Paris under them. Had sulphur-baths twice a-week, and recovered in about three months.

July 6, 1862.—Has a severely itching eruption like urticaria over the whole body, most intensely on the back of the hands and perineum, extending from the latter situation up the groins and down the inside of the thighs. The skin on the palms of the hands is hard and dry, cracking at each flexure, and there exudes from each crack a thin watery fluid. He had warm and Turkish baths, which greatly aggravated his distress.

August 12.—As the symptoms now seemed to divide themselves into two classes, viz., those connected with the skin and those connected with the urinary organs, I have arranged them accordingly.

The eruption on the skin is now vesicular, discharging a thin, straw-coloured fluid, which, drying up, covers the whole body with scales, most severely on the extremities, comparatively little on the trunk. When these are removed the skin is seen, red, thin, tender, and covered with small papules, and a thin fluid exudes rapidly, which, drying again, forms scales. The palms of the hands and soles of the feet are covered with the thick cuticle, with a pulpy feeling underneath, and when pressed upon there exudes a large quantity of milky fluid from the cracks at each flexure. The skin of the sole of the feet came off *en masse*. This process was repeated during the attack. All the nails came off, and were replaced by brittle masses, thickened as if by a layer of plaster of Paris underneath, and corrugated like an oyster-shell; they gradually became healthy. All the hair fell off. The mucous membrane of the mouth is red and tender. The conjunctivæ are reddened, and the eyelids constantly adhere. From each ear exudes a thick, yellowish discharge, which, gradually becoming thinner, at last ceased. There was numbness and pain in the fingers and toes, which were useless for three months; and though the fingers are much better, the numbness and pain in the toes continue even now, but more moderately. There was intense itching at first, but that gradually disappeared.

This state of matters continued from August until the middle of December, being most intense in October; and during this period the following symptoms were observed connected with the bladder, etc.:—

There is great pain over the kidneys, in the perineum, and about the anus, the passage of fæces aggravating the latter much. There is no tenderness in the prostate. There is continuous oozing of urine, with frequent and painful micturition, about half an ounce of urine passing at each attempt. Masses, about the thickness of an ordinary lead pencil, one inch to one and a-half inch long, very like pieces of tripe, were pulled from the urethra three or four times a day for a week. The urine itself is clear, highly albuminous, and when allowed to stand in a vessel coagulated spontaneously into yellow transparent masses, exactly like half melted calf's-foot jelly, floating in the fluid part of the urine—about half the urine being solid and half liquid. These masses again became fluid in about twenty-four hours, leaving floating in the urine thin cobwebby films. This continued about two weeks, the spontaneous coagulation ceasing, but the albuminuria continuing.

Under the microscope ($\frac{1}{4}$-inch), the white masses appeared to consist of wavy lines interlacing each other in all directions, and in great abundance, entangling numerous epithelial scales, and pus and blood corpuscles.

The yellow jelly-like masses had the same appearance, except that the wavy lines were far apart: in the former case the lines covered the whole of the field thickly; in the latter, only three or four lines appeared, the interstices being filled apparently with clear urine.

The cobwebby films appeared to be the fibres of the last fallen together, the fluid part having exuded. There were no fibrinous casts of the uriniferous tubes to be found.

These symptoms continued for a similar period to those of the skin, but the above peculiar appearances were seen only during October, when the skin disease was at its height; and at the present time the urine is slightly albuminous, containing a few pus corpuscles. The micturition is very frequent, and there is occasional severe heavy pain in the perineum increased by exposure to cold.

The treatment consisted of infusions of pareira brava, uva ursi, triticum repens, opiates, diaphoretics, and belladonna suppositories, but the greatest relief followed the exhibition of Tr. ferri sesquichloridi in drachm doses thrice a day, with generous diet, and the irritation of the skin was much allayed by the use of a lotion composed of a drachm of sesquicarbonate of soda dissolved in a quart of water.

Although the symptoms seemed to divide themselves into two classes, I am inclined to think that they arose from one disease—namely, an inflammatory eczema attacking both skin and mucous membranes, and that as fibrinous exudations were poured from the skin, in like manner fibrin was poured out of the mucous membrane of the bladder sufficient to produce the appearances related above.

I have failed to discover a case of a similar nature in any of the works which I have consulted, and should be glad to hear of any case that would throw some light on this, to me, most interesting one.

6, Crescent, Salford.

INSANE PAUPERS.—The annual return of insane paupers in England and Wales at the beginning of the year has been issued. The return is made up to January 1, 1864, and includes all but a few parishes rendering no account. The total number of paupers in receipt of relief on that day was little over a million—a considerable decrease (of above 130,000) as compared with January 1, 1863; but the number of insane paupers had increased, and amounted to 37,576, of whom 27,590 were lunatics and 9986 idiots. Thus, the pauperism ascribable to insanity, which was 3·17 per cent. of the whole pauperism on January 1, 1863, was as much as 3·7 per cent. on January 1, 1864. In every 100 insane paupers, 44 were males and 56 females. The distribution of pauper insanity appears to be very unequal. Thus, at the date of this return, London had among its 103,468 paupers as many as 5859 insane; the south-western counties had among their larger total of 108,628 paupers only 8705 insane. So, also, in the eastern counties among their 80,771 paupers there were but 2456 insane, and in Wales also only 2432 out of a total of 79,841; but stepping across the Welsh border into the west-midland counties (including Stafford, Warwick, Worcester, and Gloucester), we have 4887 insane, double the last two numbers, among the not so greatly increased total of 104,894 paupers. Of the 37,576 insane paupers, the number in county or borough lunatic asylums had risen to 20,257; the number in workhouses was still as large as 9608.

THE LIVERPOOL NORTHERN HOSPITAL AND ITS MEDICAL OFFICERS.—At the annual meeting of supporters of the Liverpool Northern Hospital the report was read by Mr. Charles Inman. It stated that "in reference to the action brought by a person in the employment of the corporation, named Hodge, against the hon. Medical officers, in which the plaintiff had been nonsuited and condemned in the payment of costs, it appeared that he had been quite unable to meet that liability; and as it would otherwise fall upon the hon. Medical officers, the committee had thought it only right that the charity should bear the cost, which made an extraordinary item in the expenditure of £120." We think the committee have set a worthy example to charities whose Medical officers are unhappily placed in similar circumstances.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ST. GEORGE'S HOSPITAL.

TABULATED REPORT OF THIRTEEN DEATHS FROM PYÆMIA OF THE YEAR 1864—JAN. 1 TO DEC. 31.

(For these notes we are indebted to Mr. PICK, Surgical Registrar.)

No.	Name and Age.	Disease or Injury.	Operation (if any) and Date.	Date of Commencement of Symptoms.	Remarks.
1	John W., 29; admitted Feb. 8	Fracture of right leg and left ankle	..	First rigor Feb. 25, 17 days after	He fell from a scaffold. Admitted with compound fracture of right leg, the wound being an inch long, and the end of the bone sticking out of the wound. Also, fracture of left tibia into ankle-joint. Rigors and sweating, followed by drowsy stupor and icteric tinging of skin; his pupils were contracted, and he was delirious at night. On the 26th he complained of pain in both shoulders and knees, and these joints became swollen; he had also slight hæmoptysis. He died March 3. Post-mortem.—Lungs congested in patches, and contained two small pyæmic deposits. Pus in pelvic cavity, and two sloughy abscesses in liver. Both knee-joints full of pus.
2	Elizabeth G., 43; admitted Feb. 28	Wound of finger	..	Day of admission first rigor	Was a midwife, and had attended a fatal Midwifery case on 22nd, having at the time a small wound on finger. Tongue red and dry; pulse quick and weak; countenance anxious. On March 1 her left ankle became painful and swollen, and she had another rigor. She became delirious, and died March 6. Post-mortem.—Near the apex of the left ventricle of heart was a small, round patch of discoloration on the surface, which covered a little circumscribed patch of a yellowish colour in the muscular substance. This was supposed to be a very early stage of pyæmic deposit. Lungs congested. The femoral and iliac veins on the left side were filled with coagulum. The arm was not examined.
3	Thomas D., 50; admitted Jan. 6	Pus in knee-joint; ulceration of cartilages	Amputation of thigh Feb. 26	March 15 .	Shivering and profuse sweating day and night. Stump sloughy; great amount of unhealthy discharge. On March 18, pain in belly, followed by delirium and death on March 25. Post-mortem.—Buff-coloured consolidation of lungs. The femoral vein contained a softened-down, buff-coloured coagulum. There was a large abscess in the abdomen in front of the psoas muscle, communicating with diseased bone upon the neck of the acetabulum by a funnel-shaped tube passing through the great sciatic notch.
4	Sarah T., 40; admitted March 23. (From Med. Reg. notes)	Delivery at full period (three weeks before admission)	..	March 18 .	On admission, right hand red and swollen; pulse low and weak; tongue raw; much wasted; anxious countenance. Died March 30. Post-mortem.—Right wrist contained pus; left knee a quantity of serous fluid. Iliac veins and vena cava natural.
5	William W., admitted June 8. (From Med. Reg. notes)	Spontaneous (?)	..	May 29 . .	Admitted in a state of great prostration, he stated that ten days before he had been attacked by rigors; since then he had had repeated attacks and profuse sweating. On admission, pulse was full and soft; skin hot and sweating; tongue dry and furred; intellect quite clear. He died from exhaustion on June 13. Post-mortem.—Lungs infiltrated with serum. On the surface of the heart were several extravasations of blood under the pericardium; these were found to cover deposits of soft, purulent lymph in the muscular substance. The right knee-joint was full of creamy pus, and there was a small quantity of semi-purulent fluid in right elbow and both shoulders. A small pyæmic deposit in kidney.
6	Thos. W., 30; admitted Oct. 22	Wound of hand on 18th	..	First rigor Oct 21	Was admitted with pyæmia; great pain in chest, and difficulty in breathing; bloody expectoration and constant cough; abscess at seat of wound; arm swollen, and covered with purplish streaks. Died on 23rd. Post-mortem.—None. Treated with sulphite of soda and stimulants.
7	Edw. S., 59; admitted Oct. 20	Compound fracture of leg	..	First rigor Oct. 28	He had also a large scalp wound, which was attacked with erysipelas; he had repeated rigors and profuse sweating; pulse very quick and weak; muttering delirium. Died Nov. 3. No post-mortem. Treated with sesquichloride of iron and stimulants.
8	Olivia Ann W., 13; admitted Aug. 31	Disease of hip; dislocation on the dorsum ilii	Excision, Oct. 27	First rigor Nov. 3	Suffered great pain after the operation, and had two attacks of secondary hæmorrhage; wound became very sloughy; had repeated rigors; the face became jaundiced; pulse extremely quick and weak; constant sickness and restlessness. Bark. ammonia, wine, and brandy. Died Nov. 9. No post-mortem,
9	Geo. P., 30; admitted Sept. 28	Fistula in ano	Division of sphincter, Oct. 10	First rigor Nov. 5	After the operation he went on well, though the wound refused to heal till Nov. 5, when he had a severe rigor, and there was a slight erysipelatous blush around wound. From this date he had daily rigors, constant sickness, followed by low, muttering delirium, and he died Nov. 12. Treated with brandy, bark, and ammonia. Post-mortem.—Pus in left pleural cavity; circumscribed abscesses in both lungs; large quantities of pus in peritoneum, smeared over the intestines; several abscesses in liver; the iliac veins and venæ cavæ healthy.

No.	Name and Age.	Disease or Injury.	Operation (if any) and Date.	Date of Commencement of Symptoms.	Remarks.
10	William H., 55; admitted Oct. 27	Strangulated hernia (?)	Exploratory operations, Oct. 29	First rigor Nov. 6	This patient had a tumour in the scrotum and most of the symptoms of strangulated hernia. An exploratory operation was performed, and an old hernia sac opened. His symptoms were relieved till November 6, when he had a severe rigor. The following day he had pain and swelling in left shoulder. He had constant rigors, cold sweats; tongue red and raw; pulse very quick; hiccough, and rapid emaciation. Treated by brandy, bark, and ammonia. Died November 12. No post-mortem.
11	George B., 64; admitted Nov. 15	Compound fracture	..	First rigor Dec. 1	The wound became very sloughy, and abscesses formed up the leg. Daily rigors. Constant sickness. Inability to take his nourishment. Death on December 7. Treated with brandy, bark, and ammonia. No post-mortem.
12	Sarah D., 29; admitted Nov. 16	Necrosis of tibia	..	First rigor Nov. 30	Admitted in a low, hectic state, with large abscesses in leg; the whole length of tibia became exposed and bathed in pus. She had frequent rigors and profuse sweating, followed by cough and purulent expectoration, mixed with blood. Treated with bark, wine, and ammonia. Died December 17. Post-mortem.—Abscesses in lungs.
13	Anna C., 22; admitted Nov. 25	Abscess of breasts from suckling	..	First rigor Dec. 12	She had intense pain in belly, anxious countenance, rigors, furred tongue, and quick pulse. Two days before death she had great dyspnœa. Treated with bark and chloric ether, wine, brandy, and opium. Died December 20. Post-mortem.—Pus in pleuro and peritoneal cavity.

GUY'S HOSPITAL.

CASE OF HYDROPHOBIA—DEATH—AUTOPSY.

(Under the care of Dr. OWEN REES.)

For the notes of the following extremely rare and interesting case we are indebted to Mr. Wootton Bushell.

Hydrophobia is a disease so very rare, that, Dr. Wilks says, this is only the second case admitted into Guy's since his connexion with the Hospital. One little circumstance mentioned to us by Dr. Wilks is not alluded to in the report. It is sometimes said of persons affected by hydrophobia that they "barked like a dog." It is generally believed that this statement is due entirely to the bystander's imagination. Now it seems that in this case the patient did occasionally make a strange explosive noise, which, although not like the bark of a dog, yet resembled it enough to account for the origin of the popular notion alluded to. The bite was several weeks before the symptoms set in. In the other case Dr. Wilks had seen the bite was several *years* before the actual outbreak. That case was a well-marked one, but the interval was so long that it is hard to believe the hydrophobia to have been connected with a wound inflicted at a time so very distant.

George R., aged 13, admitted into Guy's Hospital under Dr. Rees, January 16, 1865. Has always been a healthy boy; father and mother, and numerous brothers and sisters, alive and well.

On December 18, twenty-nine days ago, as he was returning home from school, he was bitten in the upper lip by a large dog. This dog was then under treatment for madness, but had got loose in some way. The dog subsequently bit a little girl slightly in the hand, and was immediately afterwards killed by a butcher with an axe. The boy went to a Surgeon's at Greenwich directly he had been bitten, and within a quarter of an hour the edges of the wound were pared and adapted by pins and strapping, as in the operation for hare-lip. The pins were removed in nine days, and very soon afterwards the wound was healed. The mother says that he had severe rigors just before the pins were removed; they came on twice a-day, and lasted about a quarter of an hour.

The boy was in his usual health after the wound healed, and, according to the mother, even sharper and quicker than previously.

On Thursday afternoon, January 12, however, he began to complain of headache and lassitude and stiffness of the face, which commenced in the right side (where the scar is), and afterwards extended to the left. He slept well that night.

On the following day he still had more or less headache, and the stiffness of the face continued.

On Friday night he was restlesss.

On Saturday he was about the same, but began to lose his appetite, which up to that day had been very good. In the afternoon, however, he went out shopping with his mother. He was very restless that night.

On Sunday morning at breakfast he first felt a difficulty in swallowing liquids, and had a spasm when trying to drink his tea, and stiffness of the neck came on. He swallowed a teaspoonful of gruel on Sunday with difficulty, but has taken nothing to eat or drink since.

On Sunday night he was very restless, and did not sleep at all. At 2 o'clock in the morning he asked for a draught of cold water, but could not swallow, as the attempt brought on a spasm. He was again offered drink, but could not take any, although thirsty.

State on Admission at 12 *o'clock on Monday Morning.*—He has an anxious, frightened expression of countenance. The intellect is quite clear, and he answers questions intelligibly, although unwillingly, because talking seems to bring on spasm of the cervical muscles. He had a convulsive attack when first placed in bed, owing to the draught caused by throwing a blanket over him. The scar on the right side of the upper lip is like that after the operation for hare-lip, with the marks of the pins on either side. He says that there has been no pain, itching, nor numbness in the part, and there is no evident inflammation nor swelling. He complains of pain in the neck and face, but there is no spasm when in bed. The breathing is very peculiar, accompanied by sighing; respirations 14 to 16, laboured. Pulse 92 to 98, irregular.

When a glass of wine was brought he declared that he could not take any, but when pressed he raised the cup to his lips with a determined air, and succeeded in swallowing a little with much difficulty; but immediately spasm of the cervical and thoracic muscles came on with a general convulsive fit. He then fell back into the bed exhausted and panting for breath. When asked some time after to take more he refused, and seemed almost to have a spasmodic attack at the thought of it.

2 p.m.—Continues in the same condition. Has had no more spasms. On trying again to drink some wine, he succeeded in swallowing about half a teaspoonful, but with much distress, and a spasm came on immediately afterwards. Respiration variable—14 to 18. Pulse very irregular, varying from 88 to 102 in a few moments. Dr. Rees ordered him to be kept as quiet as possible, and curtains to be placed round the bed to keep off draughts.

℞. Quinæ Disulph. gr. vj.; acid. sulph. dil. ♏ x.; vin. rubri, aquæ ää ʒj. fiat; enema 2 dis horis. As much port wine as possible; but only to be given at intervals of three hours.

4 p.m.—Pulse 98, irregular. Respiration 16, sighing and irregular. Complains of stiffness of the right arm. Injection at 4.30, retained. Refused to take wine.

5 p.m.—The pulse 104, irregular. Respiration as before. He complains of pain in both arms, coming on with the paroxysms, which are slight, the respiratory muscles being chiefly affected. They begin with a slight cough, followed by rigidity of the cervical muscles, and quick, sighing respirations.

6 p.m.—A spoonful of wine was administered, followed by the usual convulsions, and also by paroxysms of pain in the

legs as well as in the arms. The pain went off in a few seconds.

7 p.m.—Pulse 104; respiration 14. Has had two or three slight spasms during the hour. Complained of the light, and asked to have the gas turned down. He then for the first time wanted to spit, and with difficulty spat up a little thin mucus. Injection given and retained.

8 p.m.—Has been starting up in bed with a sensation of choking; complains of aching pain in the epigastrium. He asked for cold water. Some wine was brought in a mug; he held it for a moment, and then asked for a spoon; this he thrust into his mouth with a determined effort, but immediately spat out the wine, saying that he could not swallow. This was followed by spasm. Complained of the light of the fire, and curtains were put up. The spasms are frequent, more severe, and excited by any noise. The injection was repeated; but he passed it directly afterwards with some urine, the first since admission. Pulse 100, weaker; resp. 22.

10 p.m.—The spasms having become more frequent and severe, attempts were made to administer chloroform, but these caused violent spasms and a burning sensation, as of mustard, in the throat. He threw himself out of bed during one severe spasm. Another injection given, c. tr. opii. mxxx.

11 p.m.—Has had several spasms during the last hour, shrieking out apparently in great pain, and trembling all over. Is becoming strange in his manner.

Tuesday, 12·15 a.m.—Has been somewhat quieter. Asked for bread and butter, and swallowed a little without any spasm. He then asked for drink; but the sight of fluid caused a spasm, which was increased when he tried to drink. He said that his "throat was stuffed up." Asked the gentleman attending "to breathe away from him."

1 a.m.—After a good deal of trouble, we administered another injection (with opium). Before this he had continuous attacks of spasm, passing rapidly from one to another for eighteen minutes; after which he seemed quite exhausted, and panted for breath. He wanders in his mind.

2 a.m.—Quieter; has only had two or three spasms since the last injection.

3 a.m.—For the past forty-five minutes has been in a state of constantly recurring spasms. At the onset of a severe spasm he springs up in bed; then puts his hands furiously to his throat, as if to tear something away; the head is thrown violently back, the mouth open, and the eyeballs protruded; then he makes several expiratory efforts, sometimes with a shrill screaming cry, the head is thrown violently from side to side, and the hands tossed wildly about, beating his chest and striking anything that is near; the spasm generally ending by the expectoration of a viscid mucus, which recently has been tinged with blood. The passage of the enema tube caused a spasm, but the injection was retained. Pulse 114; respirations very irregular, and so interrupted by the spasms that they cannot be counted.

3·35 a.m.—Spasms continue, but, perhaps, somewhat less frequently. He has much trouble with viscid mucus, putting up his hands to tear it away from his mouth during the spasms. He asked for drink, and when wine was given him he took two or three spoonfuls hastily, just managing to swallow them before a spasm came on. He then asked for bread and butter, and ate some, though several times he was interrupted by spasms; before finishing it, however, a severe spasm came on, and he vomited the whole into his hands, and threw the vomit to the other side of the room. Respirations taken between the spasms 32 per minute.

4·15 a.m.—Is in a state of almost constant agitation, throwing himself about in the most frantic manner. Skin so irritable that the least touch throws him into a spasm. Says he is hungry, but that trying to eat brings on a violent spasm. He keeps jumping out of bed and crawling about the floor and under the bed. Mind wandering very much.

5 a.m.—Spasms continue very severe. He rolls about the bed, throwing his arms and legs about most violently. Vomits and spits a large quantity of a thin matter mixed plentifully with blood. Is wildly delirious.

6 a.m.—Has become so excessively violent that he is kept in bed with the utmost difficulty. Fights and struggles most violently, screaming, shouting, and spitting in all directions.

7 a.m.—The violence of the struggling is abating, and the delirium now assumes a playful character; he tosses his arms about in a choreic manner; keeps coughing and hawking up a viscid bloody mucus. An enema had been administered at 6·30, which before was quite impossible. Respirations laborious, and accompanied by a peculiar cry; pulse very irregular, and so weak as hardly to be felt, 150 to 180.

7·45 a.m.—Quieter, but still rolls about in the bed, and tosses his limbs. Intellect somewhat clearer, but still wandering. Answers questions intelligibly. When asked if he was thirsty, he said that he should like something to drink, and on wine being offered, he swallowed a mouthful pretty well with coughing and some spasm, and then asked for more, drinking altogether from two to three ounces, with very little general spasm only of the pharyngeal muscles. The mouth is filled with an adhesive frothy mucus, which he cannot spit up. Respiration less laboured; pulse somewhat stronger—114 to 120.

8·15.—Seems exhausted; going into a state of low muttering delirium, with twitching of the limbs. An enema was administered before 8 without any apparent effect.

8·25.—Is becoming insensible; pulse imperceptible; extremities cold. Died at 8·30 very quietly, apparently from syncope.

A post-mortem examination was made by Dr. Wilks, but nothing was seen, with the exception of redness of the back of the tongue and fauces, and some injection of the larynx and upper part of the trachea. Nothing was seen on a superficial view of the brain and cord, but the pons, medulla oblongata, and spinal cord are in the hands of Mr. Durham for careful microscopical examination. As these parts will require to be hardened by chromic acid before sections can be made, some time must elapse before we can give the results of Mr. Durham's researches.

KING'S COLLEGE HOSPITAL.

EXCISION OF PORTION OF THE SCAPULA FOR TUMOUR.

(Under the care of Mr. FERGUSSON.)

An interesting case of tumour of the scapula, for which excision of the greater part of the bone was necessary, was performed on Saturday last by Mr. Fergusson. The patient, a girl of 19 years of age, stated that the tumour had been growing to its present size for about four years, causing her pain of a continuous gnawing character. The tumour appeared to occupy the whole of the dorsum of the scapula, was hard, though elastic in parts, and the skin was freely moveable over it. The joint seemed unaffected.

The patient was placed under the influence of chloroform, and Mr. Fergusson commenced his operation by first making an incision into the tumour vertically in order to discover its nature. Finding it to be connected with the bone only, he next made an incision parallel to the spine of the scapula, joining the first incision near the acromion process, thus making a V shaped flap; next by dissecting up the integument he exposed the whole tumour. He then sawed through the bone just below the spine, and dissected the mass from the underlying muscles. Several fragments of bone were clipped away with the forceps, as they seemed affected.

The tumour was of the fibrous variety, about the size of a cocoa-nut, and was probably recurrent. It had caused absorption of the scapula from its pressure, and in the tumour were spiculæ of bone. It extended forwards to the ventral aspect.

There was very little hæmorrhage, three or four small vessels requiring ligature. The wound was brought together by sutures, and a pad placed over it and bandaged on.

Up to the present time (January 16) the patient has been doing well. We shall give further particulars of the progress of this interesting case.

At the next meeting of the Metropolitan Association of Medical Officers of Health, on January 21, Dr. Letheby will show the means of testing the illuminating power and chemical quality of coal-gas, and the circumstances which affect the result; with experimental illustrations. The engineers of the various metropolitan gas companies will be invited to be present.

Illness of M. Malgaigne.—This eminent French Surgeon, who has just been elected President of the Academy of Medicine, while endeavouring to fulfil the duties of his office, although in bad health, on the occasion of the discussion on M. Depaul's report on vaccinal syphilis, was observed to fall into a state of stupor. The meeting of the Academy was broken up, and its President conveyed home, and we are glad to hear that he afterwards rallied considerably.

Medical Times and Gazette.

SATURDAY, JANUARY 21.

THE CASE OF TIMOTHY DALY.

A free press, like most other good things, is not an unmixed blessing. It has its inconveniences and, even in England, its abuses. In America we all know that this freedom has long ago degenerated into licentiousness, and that the most profitable qualifications for the *litterateur* are plenty of imaginative faculty and a proportionate contempt for truth. We are far too patriotic to allow any similarity between ourselves and our Transatlantic neighbours in this particular; but we are forced to confess that the liberty of which we are so proud occasionally permits grievous wrongs to be done under its sanction. Take, for example, the case at the Holborn Workhouse, which has occupied the attention of all England during the past fortnight. How many of the non-professional readers of the *Times* were there, fourteen days ago, who were not convinced that Mr. Norton was either a monster of inhumanity or at least a most incapable and negligent person, regardless of the welfare of his patients, reckless of their sufferings, indifferent to their deaths, and careful about nothing except to save himself trouble and the guardians expense? These opinions were founded primarily on certain *ex parte* letters which were published in the *Times* newspaper; they were supported by the verdict of a coroner's jury, the members of which, before they entered on the inquiry, could hardly help being prejudiced by the statements they had read; and they culminated when a sensation leader from a weekly paper, imputing to Mr. Norton crimes of the deepest Professional dye, received the sanction of the leading journal by being reproduced in its columns. Now that a full and searching inquiry has taken place into the whole matter, that evidence from every available source has been obtained, and that everything which can possibly be urged against the treatment Daly received has been allowed its full weight, the thunder of Jupiter sinks to the lowest growl, the *Times* meekly acknowledges that no individual appears to have been to blame, and contents itself with attacking the system of workhouse Hospital management. But, we ask, does this retraction really remove the stain which has been thrown on the Professional character of the Medical officer? Will one half the public who have read the former assertions believe the latter; or will they not rather conclude that a fresh varnish has been given to the facts, and that, in the elegant phraseology of Mr. Lowne, the evidence has been "squared?" We leave it to every one of our readers who have had any experience of the charity, generosity, and fairness which generally actuate people in forming their opinions to answer these questions.

To the Medical Profession it is difficult to over-estimate the importance of this case. Two questions are involved in it which have been treated by the general press as if they were convertible, carrying the same signification, and incapable of any but one and the same answer. The first is—Did Mr. Norton, of the Union Workhouse, neglect his duty in the case of Daly? The second—Did Daly die from exhaustion produced by bed-sores? These inquiries have been regarded as so far synonymous that an answer to the second in the affirmative has been everywhere written and talked of as involving an affirmative reply to the first. The Profession know full well that under the most careful attendance and skilful nursing bad forms of bed-sores will occasionally occur; but this is not the doctrine which has been promulgated to the public; the result is, that an attempt has been made to throw upon a Medical officer a responsibility which, if generally admitted, would prevent any reasonable man from undertaking the conduct of any serious case of illness. Who would practise the Profession of Medicine, were public censure to be meted out, not in proportion to the care bestowed and the merit of the treatment pursued, but in proportion to the amount of attendant success?

It has, however, been asserted that Mr. Norton *did* neglect his duty in the case of Daly, and the assertion has been supported by a reference to the statements said to have been made by the patient whilst lying in, and after his dismissal from the Workhouse Infirmary. That there may be no mistake on this point, we shall recapitulate the facts in evidence which bear on Mr. Norton's treatment—facts sworn to by eye-witnesses, and not the hearsay evidence of Irish lodging-house keepers and *dilettanti* potato dealers. In the first place it was clearly established that Mr. Norton saw Daly every day, with two or three exceptions, during his six weeks' residence in the Infirmary. This does not rest merely on Mr. Norton's statement, but is proved by the evidence of the nurse and wardman. As soon as Mr. Norton learned that bed-sores were beginning to form on Daly, he examined him, and repeated his examination every two or three days whilst he was under his care. This, also, does not rest on Mr. Norton's unsupported statement, but is corroborated by the nurse and the wardman. With regard to the medicines ordered, Mr. Norton asserts that he placed Daly, when first admitted, on the alkaline plan of treatment, administering bicarbonate of potass, and, in addition, he gave Dover's powder and mild aperients. When a typhoid condition supervened, however, he changed the medicines for carbonate of ammonia and bitters. Throughout the treatment Daly was ordered a supporting diet,—meat, beef-tea, milk—two pints daily,—and from two to four ounces of wine, in addition to from half a pint to a pint and a-half of beer. This evidence given by Mr. Norton is entirely supported by that of the master and the attendants. It is, moreover, confirmed by the unpaid Roman Catholic priest who visited Daly on four or five occasions during his stay in the Workhouse Infirmary, and to whom Daly never once complained of neglect or ill-treatment, and who bore most important evidence as to the generally excellent hygienic condition of the ward in which Daly was placed, and which he asserted contrasted most favourably with the state of Hospital wards he had visited both in Ireland and on the Continent. With regard to the local treatment of the bed-sores, it appears that when they were first observed the nurse, without consulting Mr. Norton, applied Fuller's earth; that afterwards, when Mr. Norton became aware of their existence, he ordered poultices of linseed meal, which were afterwards changed for poultices of linseed meal and beer grounds; and Mr. Norton also asserts that he ordered the use of a disinfecting fluid. The use of Fuller's earth as a desiccant and absorbent is such a stereotyped practice with nurses, and it is so harmless, and in some cases so effective withal, that it may pass without challenge. Fuller's earth is, as our readers well know, a fine powder, free from grit, composed chiefly of silicate of alumina with a proportion of magnesium and iron. Altogether, before continuity had become broken, we cannot conceive that the soft absorbent powder could have been productive of anything but good, and even afterwards it is difficult to

suppose that it could have done harm. The propriety of poulticing Daly's sloughing wounds seems to have been acknowledged on all hands. He was poulticed by Mr. Norton; he was poulticed by Mr. Lowne; and finally by Dr. Andrew in St. Bartholomew's Hospital. The choice of a disinfectant need not detain us. Mr. Lowne preferred charcoal poultice; Mr. Norton, fermenting poultices of beer grounds, analogous to the *Cataplasma Fermenti* of the British Pharmacopœia. The beer-ground poultice is a very old disinfectant application. It is quoted from the Pharmacopœia of Guy's Hospital by Pereira, and it may be supposed to possess all the virtues of any other form of fermenting poultice evolving carbonic acid. With regard to it, as well as to the Fuller's earth, it must be remembered that neither remedy is less efficient because it is popular or because it is cheap.

It seems—on the authority of Dr. Goodfellow, of the Middlesex Hospital, we state it—to be an open question whether water beds or air cushions are useful in the treatment in these cases. For ourselves, we can only say that we believe them to be most valuable adjuncts. But be this as it may, we have ascertained by inquiry that there were none at Mr. Norton's disposal, and we know enough of the nature of Boards of Guardians to be well assured that any request by a Medical officer for these expensive appliances would have had scant chance of being listened to.

One point more. It was endeavoured to be shown by Mr. Lewis, the attorney who appeared for Mrs. Daly and the "committee of gentlemen," that it was Mr. Norton's duty to examine Daly's sores on each visit, and even to apply the poultices himself. With regard to this, we can only say that a daily examination, necessitating as it would the turning a heavy patient agonised with acute rheumatism on his side, in addition to the changes necessitated by nursing, would have been as inhuman as unnecessary. Such a proceeding could not have been productive of good that would not have been more than counterbalanced by the suffering inflicted, and we have no hesitation in saying that few Hospital Physicians or Surgeons in London would have felt bound to its performance.

We have thus summed up Mr. Norton's treatment in this case, and we leave it to our readers to judge whether it was not sufficient for the Surgical and Medical management of the patient, and was not such as might reasonably be expected to conduce to a favourable result. We believe that with the one exception of not having personally entered the notes of Daly's diet and treatment in the Infirmary books, he has come out of this inquiry with unblemished official character. That the case was an unfortunate one we do not deny, but it must be remembered that a patient in a Workhouse Infirmary is not, and cannot be, surrounded by all the appliances of the rich, all the luxuries of the sick room. It is not reasonable to expect that the poor should be better off in illness than the persons who are taxed to support them; and how many rate-payers are there in the Holborn district who would not be able to afford the luxury of a water bed at the cost of £14, and even the daily attendance of a Doctor, were they unfortunate enough to be in Daly's situation?

It is, however, high time that we turn to the second question, which we maintain is entirely apart from the first. Was Daly's death occasioned by exhaustion consequent on bed-sores? On this we have the direct affirmative testimony of Dr. Andrew, who made the post-mortem examination. Dr. Andrew's report of this examination we publish elsewhere. It will there be seen that besides the bed-sores there were other and grave sources of danger in Daly's case. The man had recent pericarditis and endocarditis, pleurisy, and œdema of both lungs. These conditions taken together with the signs of partial asphyxia he exhibited when taken into the Hospital,—the blue lips and difficult respiration, might point to a concurrent cause of death, but in the face of Dr. Andrew's direct testimony we do not advance such an opinion. The occurrence and progress of the bed-sores remains, therefore, to be accounted for. In the first place, Daly was a heavy, emaciated man. He told Mr. Lathbury, who first saw him, that he had been suffering from rheumatism for some time, but had gone to his work as long as he could. He was, therefore, suffering from a blood disease. He had had no proper nursing, and for three days before his admission to the workhouse no proper nourishment. When admitted he was in a filthy condition, and is said to have been very weak. He perspired so profusely that it was necessary to change his bedclothes every day. Three weeks after his admission he fell into a typhoid state; his tongue became dry, and sordes collected on his gums and teeth. It is not improbable that sudden loss of the high meat and beer diet to which, as a navvy, he had been accustomed, and the substitution of the more varied and less stimulating diet of the Workhouse Infirmary, might have been prejudicial to him, but the diet which he first received would probably not have differed much from what would have been prescribed for him in any Hospital in the kingdom. It must be remembered, also, that during the eight days which elapsed between his removal from the workhouse and his admission to St. Bartholomew's we have no certain information as to the amount of food and stimulants given him. Mr. Lowne trusted entirely to the occupants of the Irish lodging-house in this matter. Their evidence given at the Coroner's inquest and at the Holborn Workhouse is somewhat contradictory. The only meat which, at the inquest, he was stated to have had was two mutton chops on the two first days. He had neither wine nor beef-tea, nor broth every day, and he was, moreover, placed in an attic eleven feet square and seven feet high, with a shelving roof, in a low lodging-house, where the proprietor and his wife and son attended him, and, it seems, spent their chief time, night and day, in the room. Under these circumstances we think it more than probable that the bed sores, instead of getting better, became rapidly worse after Daly left the Infirmary, despite Mr. Lowne's Peruvian balsam, charcoal, and ten grain doses of bark.

There are two or three other points we had marked for notice in this case. We have already ventured to criticise Mr. Lowne's evidence before the coroner as evincing but little consideration for the Professional character of a brother Practitioner, and as not giving due weight to the probable difficulties of the case. That gentleman, in his evidence at the Holborn Workhouse, stated that it was not his custom to avail himself of the assistance of his colleagues, the Physicians and Surgeons of the Farringdon Dispensary, in cases requiring more than ordinary discrimination and attention; but remarkably enough he appears to have had a strong faith in the Medical knowledge and talents of the Honorary Secretary or the Institution, who is by profession, we believe, a potato dealer. Without disputing either the benevolent intentions or the scientific acquirements of the latter gentleman, even as exemplified in the examination of numerous patients and the diagnosis of female complaints to which he deposed, we cannot but think that some of the excellent staff of the Farringdon Dispensary would have afforded Mr. Lowne all the assistance, and even a better corroborative opinion, than his friend the Honorary Secretary. For the rest, we are quite ready to accept Mr. Lowne's statement that he was actuated by no feeling against Mr. Norton, and that his motives throughout were entirely and purely benevolent.

There is another point which, in justice to Mr. Norton, we are bound to notice. It is, that he had applied, on his first taking office, for the appointment of paid nurses to the Infirmary, and his application had been refused. Such a result would not encourage him to make fresh demands on the generosity of the Guardians. We cannot criticise at length the arrangements of the Poor-law Board for the care of the sick poor of this country. We need only observe that to expect that compulsory shall equal voluntary schemes of benevolence, either in excellence or completeness, is to look for too much from human nature in general, and from that of Boards in particular. Hundreds will be willingly subscribed to Hospitals by people who grumble at the parish

rates, and regard the collector in the light of a natural enemy.

There is one other inquiry which forces itself on our notice. How came it that Daly, a man earning from 3s. 9d. to 4s. a-day, or, in round figures, £60 a-year, and whose wife was receiving board, lodging, perquisites, and £14 a-year as housemaid at a City hotel, emolument which may be safely estimated at £40 per annum, or between them an annual sum of £100, who had no children, who paid no assessed or parochial taxes, who was in reality far better off than many a struggling rate-payer, should come on the parish for relief on the third day of his illness? The improvidence of the Irish labourer is proverbial, but is it not fostered by the indiscriminate manner in which parish relief is granted?

A CLINICAL LECTURE INVERTED.

We are familiar enough with clinical lectures in which Physicians and Surgeons tell us what they think of their patients; but it is rare to meet with a patient who tells the public what he thinks of his Doctors. This has now been done by Mr. Arnold J. Cooley,(a) who appears to be a *litterateur* by profession, and to possess a considerable amount of information on Medical topics. He has besides just that amount of *egoisme*, and of keenness of observation, which prompts a man to record his own sensations and observations minutely, and to consider few things as trifles which affect himself. His book is well worth reading as a narrative of Hospital practice and management, as seen from a patient's point of view, and it will furnish some useful hints to the managing bodies.

The author had long been living in seclusion, and injuring his health by literary labour and anxiety, when early one morning in January, "after a hasty breakfast"—with "injured health and shattered nerves"—he set off from Chiswick for London. There he seems to have been harrassed with tedious and disappointing calls; and, returning home, as it seems, fasting, he was knocked down by the pole of an omnibus, and—which most likely a stronger man with a cool head would have avoided—cruelly trampled on by the horses. He was soon taken to the Charing-cross Hospital, and put to bed in the accident ward, with severe laceration of the scalp, one ear almost torn off, fracture of the right collar bone, and some severe injury of one leg and ankle. From this moment to that of his leaving the Hospital, he gives a vivid and most minute history of his thoughts, sensations, and sufferings; of his despondency by day, and delirium by night; of his dietary, treatment, and visitors: of all that went on in his own mind, and in the wards around him, which may well make any one thank the Almighty for preservation from similar calamities.

The accident was painful enough, but the mere physical suffering seemed to have been mastered by the bewilderment and prostration of mind and body which accompanied it. Real agony seems to have begun with the waking next morning. The bandages seemed to compress the throat and chest as in an iron vice; the right arm was benumbed by pressure; the injured leg horribly painful,—not so much, be it observed, from the injury as from its being covered with cold-water dressing, and laid on a piece of oil-cloth; so that it felt as if frozen on a bed of cold iron or marble. In fact, he speaks most vividly of the sufferings occasioned by ice and other cold applications in himself and others, and of the shifting of position resorted to in order to escape them. Most practical men find out whether the temperature of local applications is such as to be grateful to the patient or not, as it seldom can be the case that what is very painful is beneficial. Whether the inquiry were omitted, or why the patient did not complain in the present instance, does not appear.

Then followed an attack of erysipelas, so early as the fourth day. Certainly the patient was predisposed, if any one ever was, to take such a complication; and he passes over with considerable delicacy the fact that a patient had died of erysipelas in the same bed eight or ten days before. Out of the 240 pages of which the work consists, fully 100 are devoted to the *ægri somnia* and delirious imaginings which the author-patient experienced during the acute stage of this terrible disease. Altogether, they seem to have been an agreeable diversion rather than otherwise, and we must say that whilst doing justice to the fulness with which they are recorded, we skip a great many pages uncut in order to reach the account of the still greater miseries of a slow and painful convalescence.

Considering the poor man's condition and disease, it will be palpable that stimulants and nourishment were the "sheet-anchors." Beef-tea, eggs, and brandy were, therefore, ordered to be fully administered, and were supplied by the Hospital; but it is clear that when Surgeons, and especially young House-Surgeons, talk of a "liberal allowance" of these things, they have little notion of the actual quantities required. For instance, the House-Surgeon assured our patient's wife, who wished to add to her husband's allowance, that he had ordered the largest quantity that was "safe or desirable;" and this was only four or five eggs per day. The instincts of the patient and his wife turned out, however, to be far better guides than the House-Surgeon's notions of what was safe or desirable; for the good woman brought six or seven more of the largest eggs she could procure, and administered one every hour, and without this it seems clear the patient would have sunk. But what becomes of poor creatures who have no such wife to visit them? A good hint is evidently to be got here.

On more than one occasion the patient brought his knowledge of Surgical appliances into collision with the recommendations of the Surgeons, and seems to intimate that the Hospital *armamentarium* was scantily supplied with various kinds of splints. His statements on this point, however, may be taken with some qualification, and are by no means proofs that he knew what was best.

Every Hospital patient cannot be so sensitive or so keenly alive to the nature of a joke as Mr. Cooley, but the fact that he suffered considerable annoyance from various attempts at jocularity is worth bearing in mind. Patients may be amused if possible, but any jokes founded on their own state or sufferings will probably give pain.

The patient seems to have been keenly alive to the clinical remarks made by the Surgeon on the nature of suppuration under the scalp, as well as to the touch of the "score or more of eager fingers tapping and manipulating the tumour." The Surgeon pointed out that "in such a well-defined case as the present one, all attempts to produce absorption or dispersion failed. The only remedy was bold incisions completely through the scalp with the knife; and that *on his next visit* this must be done, as further delay would be dangerous." The same day that the head was opened, eight ounces of gin were substituted for wine and brandy, a change which was not relished.

The observations on the duties and qualifications of nurses are sensible, and show the importance of making it worth the while of respectable and intelligent women to take the situation. The author nearly lost his life from secondary hæmorrhage one night, which the nurse on duty did not notice. It would have been just the same in a private house unless the accident had been foreseen, and the nurse specially enjoined to watch; but then a nurse who understands secondary hæmorrhage could hardly be set to scrub a floor. One night nurse to fifty patients is not enough.

The dispensing department comes under the author's criticism, and with justice, if, as he says, "putrid infusion of calumba, with lumps of green mould floating in it," was served up for quinine mixture. But the culinary department is spoken of with great praise; and one of the few cheerful passages in this very dismal book relates to the comfort derived from "full diet" during convalescence.

The writer gives the history of some few of his fellow-

(a) Two Months in a London Hospital: its Inner Life and Scenes. A Personal Narrative. By Arnold J. Cooley, author of "Cyclopædia of Receipts," "Dictionary of the English Language," "Latin Grammar," etc. London: Groombridge. 1865. Pp. 240.

patients, including that of a youth whom he affirms to have bled to death after the removal of a small tumour from the neck—(a case of which we should be glad to have an authentic version), and of another youth who broke his thigh because, as Mr. Cooley intimates with a sort of pious savagery, he broke the "Sabbath." If this youth belonged to the sect of Muscular Christians, he might fairly retort on Mr. Cooley as a man who got nearly trampled to death becaue he broke the laws of food, air, and exercise which the Creator has ordained as necessary for the preservation of health.

On the subject of large or small wards in an Hospital, Mr. Cooley speaks with a conscious air of superiority. After saying that it has been much disputed of late years, he adds :—

"I fear that many of the disputants were practically unacquainted with either of them; and that none of them spoke on the subject from knowledge acquired by actual residence as a patient in an Hospital. The utter desolation of a ward containing two, three, or even four beds, is horrible. There is no privacy. Every act is commented on; everything disagreeable is doubly perceptible. In a large open ward it is very different. There each patient sees one or more like himself, and all feeling of diffidence is lost. He can meet with some others to mix and talk with; something to engage his attention, and to pass away the time; and, more than all, fellow patients who will be very ready to assist him, and at least one nurse always within call. The reverse of all this is the case in a very small ward. I have known patients beg as a favour to be removed to a small ward, but who will in a few days have begged still harder to be allowed to return to their former one. It appears to me that a ward of from twelve to fifteen beds is the most comfortable and convenient; one with less than ten, or more than eighteen beds, is objectionable."

One thing is palpable from Mr. Cooley's book, and that is that the moral atmosphere of the Hospital, and the kindness and attention shown to the patients by all about them, from the Surgeons downwards, deserved all commendation. If he objects to cold lotions, and to rough pressure, he does not say that even he complained of them at the time; and the author of a "Cyclopædia" may perhaps be pardoned for exhibiting his knowledge of French and American apparatus for fractures—but, be this as it may, the picture which he gives of Hospital life is an encouraging one, and he certainly has added a new book on a new subject to our popular literature.

THE WEEK.

ROYAL MEDICAL BENEVOLENT COLLEGE.

In another part of our columns will be found a report of the proceedings at the Extraordinary General Meeting of the Governors of the Royal Medical Benevolent College, held on the 12th inst. The alterations in some of the bye-laws of the College proposed by the Council, and adopted at that meeting by the Governors, are of extreme importance, and we shall comment fully upon them next week; at present we must content ourselves with heartily congratulating the Council on having at last hit on a scheme which satisfies their scruples as to the reading of the Act of Incorporation of the College, and at the same time promises to restore to some extent the benefits which it was originally intended to extend to the "less fortunate members" of our Profession; and thus heals the dissension which has for so long prevailed among the Governors and supporters of that institution. The Profession at large is greatly indebted to those Governors who have so long and earnestly pressed upon the Council the claims of their less fortunate brethren, and to no one more than to Mr. Cattlin, without whose energy and perseverance, we believe, success never would have been attained; and it is only justice to these gentlemen—"the dissentient Governors"—to say that, while they have never ceased to dispute the policy and management of the Council, they have also never ceased to work for the support and welfare of the College. If the "Exhibition and Scholarship Fund" is but fairly supported, and the plan for providing for the admission of lay scholars to the College is carried out, the whole school will be immensely improved and benefited, and an admirable education will be provided for a considerable number of the sons of hardworking and struggling Medical men at the charge of only £30 a-year—a boon the value of which it would be impossible to over-estimate. Mr. Cattlin has, we believe, already provided the funds for the admission of the first real Exhibitioner of the College; let other gentlemen show only a tithe of his earnestness and energy in the matter, and the "Exhibition and Scholarship Fund" will soon be a great fact.

SALARIES OF POOR-LAW MEDICAL OFFICERS.

We are glad to observe that Mr. Symonds, the Medical officer of the Ormskirk Union, has been granted an addition of £20 to his annual salary. The payments to Union Medical officers are a disgrace to the modern Poor-law system. They offer the strongest inducements to negligence, or at least to a perfunctory discharge of duties. Look at the case of the Holborn Union Infirmary, where the Medical officer sees and prescribes, and dispenses at his own expense, for forty patients a-day. His salary is £100 a-year, which, when £20 is deducted for drugs, leaves the magnificent sum of £80, or, on an average, 1¼d. is paid for each patient seen. We are convinced that Mr. Norton does his duty to the sick under his charge; but what is to be expected as the natural and almost inevitable effect on a public body of men of such niggard treatment? In the speech of Dr. Ashton, made before the Ormskirk Board of Guardians, in proposing an increase of Mr. Symonds' salary, he proved to the Board that they had been paying Mr. Symonds less than artisans receive for their daily labour. Let the public act fairly by the Medical officers whom they employ to attend the poor. They are always ready to receive complaints against them, and they seize with greedy avidity on the details of an unfortunate case. But neither the press nor Parliament, although frequently appealed to, have attempted to redress one of the most crying grievances to which any class in this country is subjected.

FROM ABROAD.—TRANSMISSION OF SYPHILIS BY VACCINATION.

A discussion has arisen at the French Academy of Medicine having for its object to consider whether a report of a most mischievous character should be presented to the Government on the part of this learned body. To the Academy is intrusted the duty of performing gratuitous vaccination in Paris, and encouraging by rewards its practice throughout the country, and it makes an annual report to the Minister as to the manner in which the duty is performed. This report is prepared by the Director of Vaccination, and is usually agreed to as a matter of course. This year, M. Depaul, the present Director, appended to the usual administrative report what he termed a scientific portion, in which he represents to the Minister that the transmission of syphilis by vaccination is a well-ascertained fact, calling for special precautions. When the report was read to the Academy, the usual formal sanction was at once, and most properly, denied to this portion of it; and its future consideration and discussion, under the title of "Project of a Report," was determined upon. In his projected report, M. Depaul adduces no new cases in proof of his statement, but merely refers to those which have been before the public during the last few years; and he labours with all the ingenuity of a special pleader to reconcile the numerous discrepancies there present and to apologise for the shortcomings of the corroborative evidence. He also makes a somewhat severe attack on M. Ricord for the obstinacy with which he so long adhered to the Hunterian doctrines, this being, in the reporter's opinion, a chief cause why the reality of "vaccinal syphilis" has not long since been admitted. After all, M. Depaul admits, even in his own view of the case, and with all the extreme latitude he exhibits in his reception of ill-authenticated facts, that the occurrence of "vaccinal syphilis" is excessively rare, only some thirty or forty cases being recorded,

notwithstanding the millions of vaccinations which are constantly taking place; nor is he aware, amidst the two or three thousand annual vaccinations performed by the Academy, that such an occurrence has ever been suspected.

For the prevention of this propagation of syphilis by vaccination, M. Depaul has little novel to suggest. The chief point is, he says, to take our supply of lymph from none but pure sources; and he thinks that the danger of contamination is much lessened by taking lymph from infants only after they have passed the second or third month, symptoms of hereditary syphilis usually manifesting themselves long before this period. The vacciniferous infant should also be diligently inspected from hand to foot, and the antecedents of its parents inquired into. Although M. Depaul thinks that the statement which has been made, that it is not the lymph but the blood which is the agent of transmission are doubtful, he thinks that care should be taken to take lymph quite unmixed with blood. He thinks, also, the needle is a preferable instrument to the lancet, as a smaller quantity of fluid is introduced, and the chances of infection are diminished. Of direct vaccination from the cow as a means of protection he does not think highly; for not only is there no certitude that this animal is refractory to syphilitic affection, and may not become itself the subject of other diseases liable to be transmitted to man, but there would be great difficulty in carrying the procedure out in all but very populous places. After thus doing no little to shake confidence in vaccination, M. Depaul terminates his report to the Minister in these words:—"It must not be inferred from these words and unfortunate cases now brought under your notice that vaccination has ceased to be, in the eyes of the Academy, one of the greatest discoveries with which Medicine has enriched the world. It is more than ever convinced that the propagation of this precious method should be encouraged; and it will have attained its end if, while dissipating some illusions, it succeeds in impressing upon Practitioners that the practice of vaccination must be accompanied with the minutest precautions." Fine words these; but how little likely to have effect after the alarm has been sounded, that the poison of syphilis may be lurking in the innocent-looking vaccine pustule; and, as M. Ricord observed in his crushing reply, what a time to spread unfounded reports of the dangers of vaccination when variola has everywhere of late exhibited proofs of regenerated virulenee, and is indeed the true enemy to be contended with. M. Leudet, of Rouen, states that in the course of a few months, of 1,600 cases of variola occurring in that city, 130 have died. And at such a crisis the doctrine of "vaccinal syphilis" is to be transferred from the regions of scientific discussion to those of official life and general publicity! If the facts were all well and clearly demonstrated, the utility of their propagation in that mode is more than questionable; but how destitute many of them are of authenticity, or even probability, M. Ricord amply shows. One of the cases, upon which great reliance has been placed, has been since proved, through the industry of Dr. Pacchiotti, to have been the subject of syphilis prior to being vaccinated. M. Guerin observes, in face of the great mortality due still to variola:—

"So far from placing vaccination in suspicion of a complicity with syphilis, it would be far better to extend its application, and purify it in the eyes of the public of the accusations which have been made against it. We must not forget that M. Depaul formerly, in a moment of revolutionary vertigo, advocated the reintroduction of inoculation, which would indeed have been to introduce the wolf into the sheepfold. Now he seeks to sow fear and distrust, which is scarcely better, when vaccination needs all its credit, and when even all the truth may not be safely spoken. We agree with M. Ricord that we are not enough enlightened in this matter, and that it is dangerous, under the pretext of a love of progress and scientific severity, to exaggerate the bearing of this small number of cases of 'vaccinal syphilis.' No one can suppose that such prudent reserve could act as an impediment to progress; for, in truth, the attention of vaccinators cannot be too forcibly drawn to the possibility, however rare this may be, of vaccine lymph becoming contaminated by the poison of syphilis; not in order to prematurely alarm the public, but to teach Practitioners how to better recognise and appreciate facts, and especially inducing them to seek for the means of preventing or remedying this deplorable complication. In this direction lies true progress, and good service may be rendered in place of discrediting and bringing into question the benefits of Jenner's discovery."

DR. ANDREW'S REPORT OF POST-MORTEM EXAMINATION OF TIMOTHY DALY.

(From the Shorthand Writer's Notes.)

Ward John. Timothy Daly, aged 29, navigator, died December 25, 11·30 a.m. Examined December 27. Exhaustion from bed sores.

Body emaciated; right lower extremity extremely œdematous; several red blotches over left tibia, similar ones on the right forearm and hand; one on the trunk immediately over the right nipple. Large sores over the trochanters, that over the right $3\frac{3}{4} \times 2\frac{3}{4}$, but the integument is undermined for a distance varying from one to two inches, and a probe can be passed down the outer aspect of the thigh for seven inches, the trochanter and top of the thigh bone being denuded for a distance of full three inches. Over the left trochanter is a similar sore $3\frac{1}{2}$ by $2\frac{1}{2}$ inches, its edges also undermined, and the top of the femur exposed for four inches. A superficial sore on the lower part of the sacrum, not exposing the bone.

Thorax.—Pericardium, a few adhesions easily breaking down at the base and at the posterior surface of the right ventricle, the subjacent membrane vascular. The outer surface of the pericardium is also slightly adherent by recent lymph to the inner aspect of the right lung.

Heart.—13 oz. Proportions of cavities apparently natural. All the cavities contain moderately firm clots; on the right side the valves are natural, but on the aortic valves at their points of junction and along their lines of attachment are fibrous nodules, and their lunated margins are also thickened and opaque. The endocardium in the left ventricle appears also somewhat opaque, and there is slight thickening of the free edge of the mitral valve. Aorta healthy. Pleura—No adhesions in either, except on the lower lobe of the right lung, where there is a little reeent lymph with a few ecchymoses.

Lungs.—No tubercle detected in either. Left œdematous, especially in the lower lobe. Right very œdematous, their tissue greatly softened, but no part sinks in water.

Trachea and Bronchi.—A little viscid mucus; their membrane not congested.

Bronchial Glands slightly enlarged; soft, but not much congested.

Pulmonary Artery natural.

Liver.—4lb. 10 oz.; a little pale. Gall bladder contains a little thin bile.

Supra-renal Capsules appear natural.

Kidneys.—Left, $6\frac{1}{4}$ oz.; right, $5\frac{1}{2}$ oz. Capsules separate naturally; on section a little pale.

Ureters.—Both natural, but the left is rather smaller than the right.

Bladder contains some inspissated urine.

Stomach contains a considerable quantity of curdled milk.

Intestines appear natural throughout.

Large dark clots are pulled out from each femoral vein.

Head.—Pia mater somewhat congested, but the brain appears natural throughout.

Back.—Great œdema of cellular tissue in lumbar region.

Dorsal Muscles well developed.

Spinal Cord apparently a little softened throughout, but no change of colour.

THE COLLEGE LECTURES.—Professor Huxley, F.R.S., will commence his course of twenty-four lectures on the Mammalia on Monday, February 6, and will be followed by Professor Fergusson. The lecture days are now Mondays, Wednesdays, and Fridays.

THE LATE MR. GUTHRIE.—At the anniversary meeting of the Paris Surgical Society an oration upon our distinguished military Surgeon Guthrie, as Foreign Associate of the Society, was delivered by M. Legouest, himself holding the foremost position in the French army.

REVIEWS.

A System of Surgery, Theoretical and Practical, in Treatises by various Authors. Edited by T. Holmes, M.A. Cantab., etc. Vol. IV. London: Longman and Co. 1864. Pp. 1079.

The fourth and concluding volume of this work fully maintains the reputation of its predecessors. The authors of the several essays of which it is made up are judiciously selected, as will appear to any one acquainted with the favourite studies of the gentlemen whose names are appended to the monographs. For whatever may be said in disparagement of *specialities*, we all of us have some one or more branches of Surgery or Surgical art in which we somehow feel a higher interest than we do in others, and to the cultivation of which we devote our time and labour more zealously, and with greater pleasure to ourselves. The duty and interest of an editor of such a work as this would be, while taking care that all his contributors were men of broad and comprehensive minds, to avail himself to the fullest extent of the advantages that the bias of each towards his favourite topic would be likely to confer.

The essay with which the volume opens is written by Mr. S. J. A. Salter, of Guy's Hospital. It is upon the "Surgical Diseases connected with the Teeth," and includes the subjects of alveolar abscess, painful and difficult eruption of the wisdom teeth, tumours of the gum and tooth pulp, abscess of the antrum, dentigerous cysts, alveolar and maxillary necrosis from phosphorus, hæmorrhage after extraction of teeth, and the application of obturators and false palates in cleft palate, etc. All these are subjects of great importance. The author dwells very fully upon the subject of impaction of the lower wisdom teeth from misdirection, and upon the very serious results which sometimes follow, especially when the crown takes a forward, and especially a forward and outward direction. When the impaction is severe and not likely to be remedied by time, and when evil results are imminent, it is clear that either the offending tooth must be extracted or the second molar must be removed; and although, as a general rule, the former step is to be preferred, yet when the second molar is carious or necrosed, or the wisdom tooth cannot be reached on account of the rigidity of the spasm of the masseter, the second molar should be extracted, even if sound. Mr. Salter thinks that when this has been done, and the wisdom tooth has consequently attained an improved position, so as to be habitually used in mastication, as the second molar normally is, it is less liable to caries. Another excellent section is that on abscess of the antrum. The author alludes to that remarkable condition of the cavity to which Mr. Cattlin directed attention three or four years ago, in which, by a septum of bone projecting from its wall, a complete pocket may be produced, within which an adventitious body, such as the fang of a tooth, may be concealed; which, although undiscoverable by the ordinary methods of exploration, may, nevertheless, be producing an immensity of mischief in the antrum. In speaking of hæmorrhage after the extraction of teeth, while recommending the lint-plug saturated with turpentine or tannin as the best local application, Mr. Salter very properly dwells upon the necessity of viewing these serious hæmorrhages as indications of constitutional vice, and of the importance of adopting a corresponding general treatment. We regret that any considerations arising out of the necessity for preliminary discussion of physical questions, and especially out of limitation of space, deprived the possessors of this volume of the benefit which would have resulted from a brief discussion of the principal topics connected with Dentistry proper. It will necessarily be that these volumes will take the place of a host of separate treatises in the case of emigrating Surgeons and Practitioners in remote localities, and we submit to Mr. Holmes that the subject is one of sufficient importance to these classes of readers to warrant the devotion of some pages to it in a future edition. The bulk of the volume would not be very greatly increased, while its usefulness would, for Dentist-Surgeons are not to be met with everywhere, while the need for the practice of the art of dentistry is tolerably universal. A village or colonial Surgeon should be as capable of stopping a tooth as of extracting one successfully, and should be a judge of the condition under which the one operation or the other is to be preferred.

The section on "Diphtheria and Croup" is written by Dr. Barclay, of St. George's. In the former disease he condemns as "meddlesome" the activity with which some Practitioners apply caustics and astringents several times a day to the throat. We agree with him in his opinion that what is requisite is not an escharotic, but simply an astringent application, and that whatever benefit is to be hoped from this kind of topical medication is to be gained from weak and not from strong applications. The following extract embodies his views upon the benefits to be anticipated from tracheotomy:—"It may be assumed, then, first of all, with tolerable confidence that when the general symptoms indicate that the attack is comparatively mild, while the danger of suffocation is imminent, tracheotomy does give a chance of life in cases otherwise all but hopeless, and that it certainly does give prompt and certain relief to the suffering immediately caused by dyspnœa, than which nothing is harder to bear. But no Surgeon ought to undertake the operation, even in such circumstances, without fully explaining that relief, and relief only, from impending suffocation is its object. Secondly, when the dyspnœa is less intense, it becomes a question whether the relief to the breathing may not help forward the process of cure which Nature is working out; or it may rather be said whether the existing amount of dyspnœa does not materially hinder the recovery, and render it more uncertain. The French Surgeons are disposed to answer in the affirmative; and the opinion is shared by many among ourselves; but the practice is clearly not one that can be urged as necessary in the present state of our knowledge. Thirdly, in many severe forms of the disease, we may well pause before recommending the operation, because it is no longer a question of the possible saving of life, but one merely of giving temporary relief. The patient is in a condition most unfavourable for the operation; and, even setting aside the chances of an immediately fatal result, the fact of the operation having been performed is very apt to tell unfavourably on the issue."—p. 71.

Mr. Pollock, of St. George's, contributes the section relating to "Diseases of the Mouth and Alimentary Canal." Thirty pages nearly are most usefully occupied by discussing the very important subject of "Intestinal Obstruction," and it is illustrated by reference to cases. We are somewhat astonished, however, that no reference whatever is made to the labours of Dr. Brinton, the most philosophic contributor to the knowledge which we possess of this most difficult subject.

The subject of "Diseases of the Rectum" is taken by Mr. H. Smith. He dwells at some length upon the use of nitric acid in the treatment of internal hæmorrhoids, as originally recommended by Dr. Houston, of Dublin. He tells us that after a large experience of its use he has never witnessed anything like dangerous results, while its grand advantage in these busy days is that it is not necessary to confine our patient to his bed after applying the remedy.

An excellent treatise on "Hernia," extending over 100 pages, many of them closely printed, is contributed by Mr. Birkett, of Guy's, whose name will be sufficient to satisfy the reader that it is all that can possibly be desired.

The next hundred pages are occupied by Mr. Henry Thompson in an essay upon "The Surgery of the Male Urinary Organs,"—kidney, bladder, prostate, and urethra. There can be no necessity for us to tell what he has to say upon this subject, nor to dilate upon the rich store of experience on which he can draw for the benefit of his readers. His views upon all practical matters also are already well known. The subjects of "Urinary Calculi and Lithotomy" are treated by Mr. A. Poland, and "Lithotrity" by Mr. C. Hawkins. He is opposed to the employment of chloroform in this operation on several grounds—first, because the operation is not a painful one, and the operator who does not use chloroform is better able to ascertain to what extent the patient is able to bear the operation at each time; and, secondly, because the bladder does not retain the water so well when chloroform is employed. Still sometimes it is absolutely necessary, and Mr. Hawkins relates two cases in point.

Then follows a section upon the "Surgical Diseases of Women," written by Mr. J. Hutchinson, of the London Hospital. In discussing the treatment of "ovarian dropsies" he considers *seriatim* the several Surgical remedies that have been employed for their cure—repeated tappings, the several schemes for obliteration of the cyst cavity by compression after paracentesis, the establishment of fistulous channels, the exhibition of mercury, and the injection of the cysts with iodine, and lastly, the practice of complete extirpation of the tumour. Speaking of iodine injection, he says, "we must bear in mind that the dangers consequent on a mistake in the differential diagnosis between ascites and ovarian disease are much greater if iodine be injected than if ovariotomy be

attempted. Such mistakes have occurred: and it is precisely in the cases most suitable (were the diagnosis correct) for injection treatment—those, namely, of thin-walled single cysts—that the mistake is most likely to happen. Then, again, if the tumour be multilocular, it is exceedingly probable that the secondary cysts will be irritated by the inflammatory processes set up in the larger one. Even when the chief cyst has to all appearance been permanently obliterated, the Surgeon can never feel confident that there may not be others left behind it, which, sooner or later, will enlarge. To these drawbacks we must add, that even in the most suitable case it is quite possible that the patient may be poisoned by the iodine, or may sink under the attack of cyst inflammation which follows its use," p. 525. Mr. Hutchinson holds that the verdict of the Profession at large in favour of ovariotomy as a radical cure has been given, and that the operation does not now need any defence. He gives a succinct account of the customary method of performing it, discusses the still debated questions which relate to the mode of performing it, and gives excellent rules for after treatment. In replying to the question "Why has ovariotomy been appreciated more highly of late years than formerly?" he says, "The new method of keeping the end of the pedicle outside the abdomen is, I believe, the chief improvement of recent times. No doubt something has been done in the introduction of more cautious after treatment, especially in the comparative disuse of opium. But the chief amongst the reasons of the advance of ovariotomy in general favour is, *that it has been largely and openly tried*," p. 532. Mr. Hutchinson's account of the operation is the best we have yet seen in any systematic work on Surgery that has yet come under our notice.

"Diseases of the Male Organs of Generation" is written by Dr. Humphrey, of Addenbrooke's Hospital. Not by any means the least important topic he discusses is what he calls "functional disorders of the testicle," embracing a series of subjects respecting which the Practitioner should not only have the clearest views, but which demand from him in practice the exercise of a sound judgment and much discretion. This class of troubles, too, has Medico-legal as well as Surgical bearings, and is treated by the writer in a manner in every respect most commendable. We allude here more especially to his remarks upon "impotence" and the questions which are sometimes put to Medical men by their bachelor patients as to their fitness or unfitness for matrimony. He says, "The question of impotence, with its contingent—the unadvisability of matrimony—is one on which it is difficult to write, inasmuch as there is not much very definite to be written. In deciding it, it is usually necessary to allow a considerable margin for the nervousness of the patient. A quiescent state of the organs, consequent on long control over the passions, is not to be regarded as an obstacle, because they may be roused into activity when appropriate circumstances arise; and after a long continuance and frequent repetition of nocturnal emissions the organs usually retain sufficient vigour to admit of improvement under the influence of matrimony. It has happened to me often to be consulted on this subject; and I have very rarely felt it necessary to give a discouraging opinion. In the case of one gentleman, who from early life had been subject to very frequent emissions, who had long ceased to have erections or desire, and whom a variety of treatment, including cauterisations of the urethra, conducted by different persons, had failed to give relief, my advice was that he should remain a bachelor. Very soon afterwards he married, and had a family. It has been recommended that in doubtful cases the *experimentum* should be made *in corpore vili*. This appears to me to be useless, as well as wrong; for the experiment thus made as a test is no real test, and, as might be expected, has ended in disappointment. I know a gentleman, in every respect, I believe, well qualified to be a husband, and at one time anxious to be so, who has been prevented from marrying by the failure in this test, to which he most reluctantly and needlessly assented, in deference to the advice of an eminent Surgeon whom he consulted. The indications derivable from external appearances are of little value, and suspicions based upon them have repeatedly proved to be groundless. There are certain obvious disqualifications, such as imperfect formation or diseased condition of the necessary organs, and an entire absence of erections or desire. When such disqualifications exist, matrimony is rarely contemplated. When they are absent the Surgeon is seldom justified in giving an unfavourable verdict, the instances being few in which, by judicious treatment, the patient may not be fitted for matrimony. To the encouragement to matrimony it is well to add the hint, that though, for various reasons, the rite may not be at first consummated, yet that in all probability it will be so before long. This may prevent unnecessary disappointment or despair. I have known premature separation carried out—indeed, hurried on, by the Medical man, when there is reason to think that a little encouragement and patience might have resulted in a happy union."—P. 607.

The chapter on gonorrhœa is the joint production of Mr. Henry Lee and Dr. Marston. The author of that part which relates to the treatment of the affection objects to the use of strong solutions as injections, in what is known as the "abortive" treatment, preferring the weaker solutions repeated every three or four hours. The chapter is a summary of the most advanced knowledge of the pathology, etiology, and management of this disease.

Diseases of the breast, as might almost have been anticipated, fell to the lot of Mr. J. Birkett. After some preliminary remarks on the anatomy of the breast, general diagnosis, and general therapeia in its diseases, the author proceeds to discuss his subject under five divisions, viz.:—1. Morbid conditions of the tissues composing the breast; 2. New growths forming tumours, the elements of which, more or less, resemble those composing the gland; 3. New growths composed of elements foreign to the normal tissues of the body; 4, Diseases of the nipple, areola, sinuses, and sebaceous glands; and, 5, Diseases of the male mammilla.

"Diseases of the Thyroid Gland" is written by Mr. Holmes Coote, who says all that appears necessary upon the subject, and, so far as we can see, omits to notice no European contribution of importance to our knowledge of the chronic enlargements to which the thyroid gland is liable.

The next ninety pages are occupied by "Diseases of the Skin," the "general and constitutional affection" being partly written by Dr. Jenner and partly by Dr. Hillier; "the local and surgical affections of the skin and its appendages, as corns, warts," etc., being written by Mr. T. Smith. The arrangement of skin diseases adopted (and we are happy to see that the writers have had the good sense not to add a new one) is that of Willan, modified by the abstraction of certain members from his classes to constitute a class of "Parasitici." There is a great deal of matter in these ninety pages, inasmuch as they are closely printed in a small type.

Finally, there is an Appendix. First comes a treatise by Mr. Holmes, Mr. Brodhurst, and Mr. Shaw, on the "Surgical Diseases of Childhood." There are some admirable remarks, introductory to the subject, upon operations in childhood, and upon the special dangers to which children are exposed from shock and hæmorrhage. "The main principle to be borne in mind in operations on children seems to be this, that children bear the loss of blood, and all other causes of sudden shock, worse than adults, but bear protracted suppuration and long confinement to bed better, and are far less liable to the secondary complications of wounds. . . Our first care in operations on children must be to avoid shock. Hæmorrhage is the chief cause of shock where anæsthetics are used; but when this is not the case, pain, terror, and struggling are also most efficient causes of prostration. and more especially in protracted operations. . . Of the serious effects which may follow upon the shock, pain, and struggling of an operation, even when there is no hæmorrhage, the following example lately occurred to me:—A twin child, a few weeks old, was brought to me for advice as to a congenital tumour of the orbit, which had pushed out and ruptured the globe of the eye. In consequence of the rapid growth of the swelling, life could not long be maintained unless the disease was removed; yet the child was so exceedingly puny, emaciated, and feeble that it was obvious the least injury might prove fatal, much more so serious a proceeding as removing a tumour which filled the whole orbit, and projected a good deal on to the face. Having placed the risks of the operation fairly before the mother, I proceeded to remove the tumour without administering chloroform. The operation was finished without much blood having been lost, but then the child passed into an alarming state of syncope. Restoratives were at hand, and when by stimulation with ammonia, wet sponges dashed on to the face and throat, and artificial respiration, the process of swallowing had been regained, a little wine and brandy could be given, and the child seemed restored to life. But she soon relapsed, and appeared again to be dead,—in fact, was pronounced dead by some of those who were standing about. Artificial respiration roused her for the time; then the galvanic battery was brought into play, and applied to the chest

with marked benefit, stimulants being also constantly administered. But for three-quarters of an hour the child's life was in the most extreme danger, and as soon as the galvanism was suspended, syncope recurred. At the end of that period she recovered permanently from this alarming condition."—P. 800. With this are some excellent remarks upon the administration of anæsthetics to children. The writer says:—"It does not appear that there are any limitations to the use of anæsthetics in childhood. I have administered them at the earliest periods of life, and believe that, with proper care, operations are safer with them than without them, even in the most exhausted and puny infants."—P. 801.

The next section in the Appendix is on Surgical Fever, comprising the pathology and treatment of hectic and traumatic fever, and the treatment of cases after operation. It is by Mr. J. Croft. Dr. Harley contributes an essay upon Apnœa; Mr. Busk upon Parasites, and also on Venomous Insects and Reptiles. The final chapters are on "Surgical Diagnosis and Regional Surgery," by Mr. Holmes; "On Hospitals," by the veteran Sir Ranald Martin; and on "Surgical Instruments and Apparatus," by Mr. Holmes Coote and Mr. Wordsworth. All of these are admirable essays.

We congratulate Mr. Holmes on the successful issue of this grand and spirited undertaking.

FOREIGN CORRESPONDENCE.

GERMANY.

Berlin, December 28.

The question whether, after an injury to a nerve, its two extremities may unite again by first intention, with simultaneous rapid recovery of function, has recently attracted the attention of Continental physiologists and Physicians in a marked manner. Not only have hecatombs of dogs and rabbits been sacrificed on the altar of science for the purpose of settling the question, but there have been several Surgical cases of unusual interest under observation which have thrown considerable light upon the point at issue. One of these cases recently occurred at Paris, under the care of M. Nélaton, and was reported in the Société de Chirurgie by M. Honel. A patient was operated upon by Nélaton for a neuroma in the course of the median nerve, and a piece of the nerve, about an inch long, had to be excised. Both extremities of the nerve were then united by metallic sutures. As early as the following day, Nélaton observed some movements of the thumb and return of sensation in those parts of the skin animated by the median nerve. On the second day after operation these phenomena were quite distinct, and a week afterwards both motion and sensation were so far re-established that there could be no longer any doubt about the nerve having been quite restored to its natural condition. Most of the members of the Société de Chirurgie declared this to be impossible. Messrs. Broca and Verneuil asserted that either the observation of the case had been faulty, or the diagnosis must have been wrong from the first. There was no case on record at all similar to the one just mentioned, and physiology, as well as observations at the bedside, plainly proved that regeneration of nerves was exceedingly slow, and protracted over months and even years.

A few days after this discussion had taken place, M. Laugier related an analogous case which had just occurred in his wards in the Hôtel Dieu, at a meeting of the Academy of Sciences. The case was one of injury to the forearm, both the radial and ulnar arteries, the palmaris longus et brevis muscles, some bundles of the flexor sublimis and the median nerve being torn asunder in a transverse direction. When the patient was brought into the Hospital, hæmorrhage was so considerable that the House-Surgeon at once tied both arteries, and united the flaps of the skin by sutures. When M. Laugier saw the patient sensation was entirely gone in the whole extent of surface animated by the median nerve, viz., the palmar surface of the thumb, first and second fingers, and the radial side of the third finger; and partly gone in the skin animated by the radial nerve, viz., the index and the inferior part of the dorsal surface of the second finger; only two-thirds of the transverse diameter of the radial nerve having been torn asunder, opposition of the thumb was impossible. M. Laugier thereupon reopened the wound, and found the lower end of the median nerve free just above the annular ligament; the upper end was not visible, and for the purpose of finding it, he incised the flap to the length of about three inches, and after section of the flexor sublimis muscle, the upper end of the median nerve came to light. Laugier now united both ends of the nerve by a silk suture. The pain and fever after this operation were not more severe than they might have been after the original injury. On the evening of the same day sensibility appeared to a certain extent restored, but it was still very obtuse. The next day, however, it was much more distinct, although there was still some difference in the parts animated by the median and ulnar nerves respectively. Opposition of the thumb was easy. On the second and third days the patient was not yet able to feel pain or to distinguish heat from cold. On the fourth day the sensation of temperature had returned. M. Laugier was of opinion that the rapidity of recovery of nervous function in this case, when compared with the experiments made on animals, was partly due to a different operative proceeding, and partly to the perfect immobility of his patient; and he drew the following conclusions from the case:—

1. If after the section of a nerve, its two ends are united by suture, sensation and motion of the parts animated by the nerve may to a great extent be restored within a few hours.
2. The recovery of function is altogether rapid.
3. It is successive—that is, tactile sensation and motion return before the sensation of pain and temperature.
4. The nerve-suture causes neither particular pain nor other symptoms of a severe nature.
5. It therefore appears necessary to receive the suture of large nerves as a legitimate Surgical operation.

This first report was followed by a second, made thirty-six days after the operation, and which is to the following effect:—On the twelfth day the ligature came away, and symptoms of severe neuritis set in, viz., lancinating pains in the thumb, first, and second finger. At the same time, there was numbness in these fingers, and considerable decrease of the sensibility previously regained. The symptoms of neuritis disappeared after five or six days, and there was then gradual recovery of sensibility, although at the time of the report this was still in a somewhat unsatisfactory condition. The Academy has charged a committee, consisting of MM. Flourens, Andral, Velpeau, and Bernard, with the examination of the patient in question; and this is so much the more to be commended as the account M. Laugier has given is in several respects very loose, and his examination does not seem to have been made with that degree of caution which ought to be employed under such circumstances.

The most recent physiological experiments on this subject have been undertaken by Drs. Eulenburg and Landois, of Greifswald, who operated on all kinds of nerves—viz., motor, sentient, vaso-motor, and inhibitory—in dogs and rabbits. The general results at which these gentlemen have arrived are as follows:—If nerves are divided and afterwards united by suture, there is no tendency to healing by first intention, even if the coaptation of the ends has been most careful and aided by immobility of the limb, etc. On the contrary, there are invariably signs of interrupted conduction at the locality of the suture and lost function of the peripheral end of the nerve; that is, we observe loss of motion and of electric contractility of the muscles if motor nerves have been divided and re-united. In the case of sentient nerves there is loss of sensation; in that of vaso-motor nerves there is increase of temperature, profound disturbance of nutrition, and even gangrene; and in inhibitory nerves, loss of inhibitory influence. All these symptoms remain unchanged within the next days and weeks. The microscopical examination shows the same results, there being within the first few days after the operation fatty degeneration of the peripheral end of the nerve, just as after section without subsequent union. On the other hand, the fibres of the central end remain comparatively unchanged. The cylinder axis takes part in the degeneration. It is true that, on adding collodium, it becomes visible at the peripheral end, but its width is very unequal, and occasionally it is quite interrupted; while such changes have never been observed in the central end. The operation of nerve-suture causes, in many cases, a more or less extensive neuritis and peri-neuritis, which may even give rise to suppuration and metastatic abscesses in the lungs, and it is therefore by no means devoid of danger. It thus appears that M. Laugier's proposal of adopting nerve-suture as a legitimate operation ought to be rejected,—an opinion in which most Surgeons will probably coincide.

The treatment of disease by subcutaneous injections of medicines has now for several years been universally adopted

on the Continent for cases where there were objections to the ordinary administration of remedies, and, on the whole, with excellent results. I will to-day give you a few somewhat unusual instances in which this proceeding has been resorted to. Thus, M. Frémineau has cured a case of amaurosis of the left eye by the subcutaneous injection of a solution of the sulphate of strychnia. The case was that of a boy, aged 15, who was, on the third day of a severe typhoid fever, with predominant cerebral symptoms, affected by weakness of the left eye, which, after five days, passed into complete amaurosis. Within a fortnight he was convalescent, but the amaurosis persisted. He was not able to distinguish between light and shade, the pupil was very much dilated, and was not acted upon by light; but the ophthalmoscopic examination did not show anything abnormal. The right eye was quite healthy, and there were no symptoms of cerebral disturbance. After two months the general health was quite re-established, but the sight remained lost. M. Frémineau then made an injection of a solution of 20 centigrammes (3 grains) of sulphate of strychnia in 20 grammes (about 5 drachms) of water on the left half of the forehead, along the course of the frontal nerve. The first time he injected four drops, then twelve, then twenty, and twice thirty drops. After the second operation the patient began to see objects, but they appeared to him so small and distant as if seen through an inverted opera-glass. At the same time there was double vision. These anomalies disappeared after the third and fourth injection, and after the fifth vision was as perfect in the left eye as in the right, the iris having regained its contractility, and the left pupil being of quite the same size and condition as the right.

Another somewhat analogous case occurred under the care of Dr. Sæmann, of Königsberg. The patient, although being 80 years of age, was in good general health, with the only exception of profuse bleeding of the nose, of which he occasionally suffered, and for which a local application of the liquor ferri sesquichloridi was resorted to. One evening, having been quite well for some time before, he suddenly became totally blind; he could neither perceive objects nor distinguish between lights and shade. There were no other morbid symptoms, neither headache, nor febrile excitement, nor paralysis. A venesection of eight ounces was ordered, together with application of ice to the forehead and the eyes, and atropine was applied to the eyes in order to facilitate the ophthalmoscopic examination. A purgative of senna and sulphate of soda was also given, and perfect quiet enjoined. The pupils dilated very little, in spite of four successive applications of atropine. The examination by the ophthalmoscope did not show anything abnormal; the optic nerve appeared to be in good condition, and there was not a trace of extravasation or effusion within the eye. Six leeches were applied to the forehead the next day, but produced as little effect as all the other remedial measures which had previously been resorted to. A week after the commencement of the affection Dr. Saemann injected twelve drops of a solution of a grain of nitrate of strychnia in an ounce of water (equal to one-fortieth of a grain), in the region of the left supraorbital nerve. Scarcely two minutes had elapsed when the patient exclaimed,—"Good God! I suddenly see much clearer, I see the church steeple, the trees, I see the leaves moving." The patient was, in fact, able to distinguish large objects with the right eye as well as the left, but no small objects. Vision remained in this condition until the evening of the same day, but was again much worse on the following morning, so that the patient could only very faintly distinguish the outlines of large objects. Another injection of one-thirtieth of a grain of the nitrate of strychnia was then made, which had the same almost immediate effect as the former. The injections were now repeated six times successively, the whole quantity of strychnia injected amounting to two-thirds of a grain. At the end of the treatment, the patient could read his newspaper and play a game of cards.

The following case occurred in the practice of Dr. Friedreich, of Heidelberg:—A woman, aged 19, suffering from general *malaise* and a tumour which was of the size of a fowl's egg, scarcely moveable, of ovoid shape, and situated in a line with Poupart's ligament. It could be easily reached from the vagina, was exceedingly sensitive to pressure, had a smooth surface, and felt very firm. The external os was somewhat opened, the vaginal portion shortened and swollen; there was also a considerable muco-purulent discharge from the vagina. On pressing the left mamma a few drops of a greyish liquid came out, but there was no colouration in the areola and the linea alba. Two weeks afterwards a fresh examination was made, and it then appeared that the tumour had increased in size, the uterus being slightly displaced anteriorly. The uterus-sound could be made to penetrate with ease three lines beyond the knob, and was easily moveable in the cavity of the womb. On simultaneously pressing the tumour the motion was communicated to the sound. The patient continued feverish the whole time. Professor Friedreich, from these symptoms, diagnosed the existence of extra-uterine gravidity, and as the pain in the neighbourhood, and the increased growth of the tumour made him fear that rupture might take place, he determined on the injection of morphia into the tumour from the vagina, in order to kill the fœtus. Pravaz's syringe was for this purpose so modified as to resemble an uterus-sound in size and shape. After the first injection of one-tenth of a grain, the pain diminished very much. On the second day, one-seventh of a grain was injected, after which the fever became less. Two days afterwards the tumour had become smaller, and one-sixth of a grain was then injected. The tumour was after this no longer sensitive to pressure, and became smaller still. A fourth injection of one-sixth of a grain was made, after which the fever ceased entirely. The surface of the tumour had gradually become rugged, and it was then only as large as a walnut. Two months afterwards the catamenia returned and the patient was discharged, she being then in perfect health.

GENERAL CORRESPONDENCE.

THE INDIAN MEDICAL SERVICE.

LETTER FROM DR. F. BOWEN.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have read over the letter from "An Indian Surgeon" on the new Indian Medical Warrant and your remarks at pages 38 and 39 of this day's issue. The letter of this Medical officer is fairly and truthfully given, and I am sure you will allow me to say, in reference to your remarks on page 39,—"We are at a loss to understand the complaint with regard to the abolition of staff salaries, as by sec. 27 of the Warrant of November 7 the said staff allowances are distinctly and specifically admitted,"—that the truth of the matter lies here. This 27th section simply refers to staff allowances for Medical charge of divisional and brigade staff. The former gives 100 rupees per mensem, the latter 30 rupees only. The 300 rupees per mensem usually allowed for the charge of a European regiment is no longer given.

I am, &c.

62, Upper Berkeley-street, W. F. BOWEN.

PRYCE *v.* BOWEN.

LETTER FROM MR. BRANSTON NASH.

[To the Editor of the Medical Times and Gazette.]

SIR,—I am instructed by the Medical officers of this Infirmary to forward the enclosed correspondence, and to request the favour of your publishing the same.

I am, &c.,

BRANSTON NASH, House-Surgeon.

The Royal Infirmary, Liverpool, January 7, 1865.

Dear Sir,—Complying with the instructions of my colleagues, I beg to transmit to you the accompanying document.

I am, dear Sir, your faithful servant,

J. VOSE.

To the Chairman of the Medical Board of the Manchester Royal Infirmary.

"Liverpool Royal Infirmary, December 14, 1864.

"At a meeting of the honorary Physicians and Surgeons of the Liverpool Royal Infirmary, held on Saturday, the 24th of December, 1864, it was resolved:—

"'That the attention of the honorary Medical officers of the Manchester Royal Infirmary be called to the cause "Pryce *v.* Bowen," tried at the Liverpool Assizes, before Mr. Justice Blackburn, on Thursday last, the 22nd instant. From a perusal of the evidence given upon that occasion, it will be observed that a gentleman of education and of experience, who holds the office of Surgeon to one of the Hospitals in this district, had an action brought against him for alleged unskilful treatment of a broken arm.

"'The plaintiff's solicitors, after vainly endeavouring to procure Medical evidence against the defendant from the Profession in Liverpool, turned their attention elsewhere, and succeeded in obtaining the services of Mr. Lund, who declared himself at the trial to be "a Surgeon of the Manchester Royal Infirmary," and who gave evidence for the plaintiff, which evidence, the Medical officers of the Liverpool Royal Infirmary submit, was not to be expected from a member of the Profession who holds the appointment of Surgeon to the Manchester Royal Infirmary.

"'Signed on behalf of the meeting,
"James Vose, M.D.,
Fellow of the Royal College of Physicians, Chairman.

"'P.S.—A copy of the *Liverpool Mercury* containing an account of the trial is herewith enclosed.

"'To the Chairman of the Medical Board of the Manchester Royal Infirmary.'"

"Manchester Royal Infirmary and Dispensary,
January 5th, 1865.

"Sir,—In reply to your communication of the 24th ult., to the Medical Committee of this Hospital, I am directed to inform you that Mr. Lund is not a Surgeon to the Manchester Royal Infirmary; but Mr. Lund is one of the Dispensary Surgeons; and, inasmuch as Mr. Lund is not a member of the Medical Committee, this Board must decline entering into the consideration of Mr. Lund's conduct in his capacity as a private Surgeon.

"I have the honour to be, Sir, yours obediently,
"George Reed, M.D., Resident Medical Officer.

"To the Chairman of the Medical Committee,
Liverpool Royal Infirmary."

THE TREATMENT OF MALARIOUS FEVERS.

Letter from Dr. Macpherson.

[To the Editor of the Medical Times and Gazette.]

Sir,—My attention has been directed to a series of papers "On Malarious Fevers," by Deputy Inspector-General E. Hare, which have been appearing in your columns. They seem to be mainly a reproduction of his former papers, and of the report of the Royal Medical Board in 1851, or what was called the experiment at the General Hospital.

More than a dozen years ago, while combating many of his views, I acknowledged that Mr. Hare's enthusiastic, though indiscriminating advocacy of the use of quinine had given a great impulse in Bengal to the use of an invaluable remedy. I have no intention of entering on any fresh examination of his latest views on the theory or practice, but I observe that he incorporates in his paper many of the numerical returns of the report by the Medical Board, already alluded to, and on them I must say a few words.

To those which refer to the General Hospital, and to H.M. 70th Regiment, I took exception in a pamphlet published in 1852, now become one of the curiosities of Medical statistics, but of which I have a few spare copies, which are much at your service, or at that of any one who is interested in the subject.

Being practically the head of the General Hospital, I took it on myself—not without risk to my prosperity in the service in venturing to throw discredit on the report of my superiors—to show, by a detailed analysis of the returns referring to that institution, that owing to the loose and careless way in which the experiment had been conducted and the inaccuracy of the figures, they were valueless for statistical purposes.

With regard to the returns for H.M. 70th Regiment, I had only the means of showing that they bore on their face the evidence of some great mistake, but the Surgeon of the regiment, Dr. Harvey, who died soon after, wrote officially to the Medical Board denying the correctness of the returns; and Assistant-Surgeon Bassam, since also dead, when leaving India placed in my hands the detailed proof of their mistakes, in case it should be required.

But it never was wanted. Neither the Medical Board nor Mr. Hare, so far as I have ever heard, made any reply to our public impugnment of the accuracy of their numerical statements.

The subject had grown old and stale, and I had hoped never to have had to refer to it again; but it is only fair that your readers should be made acquainted with the fact that the value and the accuracy of the returns now resuscitated was openly denied from the date of their publication.

I am, &c.
John Macpherson, M.D., Surgeon-Major H.M.I. Army, formerly 1st Assistant, General Hospital, Calcutta.

35, Curzon-street, Mayfair, January 18.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, January 10.

Mr. Partridge, F.R.S., President, in the Chair.

A paper by Mr. Furneaux Jordan was read,

ON ECZEMA OF THE EYELIDS, CONJUNCTIVA, AND CORNEA.

Many observers, and especially writers on the diseases of the skin, have considered ophthalmia tarsi to be simply eczema of the lids. Dr. Mackenzie has pointed out that scrofulous, or, as he terms it, phlyctenular ophthalmia, is frequently associated with eruptions on the skin. It is the object of this paper to show that not only ophthalmia tarsi is eczema of the lids, but that granular lids, a peculiar swelling of the sub-integumental connective tissue of the lids, lippitudo, strumous ophthalmia, certain forms of simple or catarrhal ophthalmia, keratitis and strumous keratitis, and certain ulcers on the cornea, are merely varieties of eczematous disease. Cases of extreme, firm, indolent, pale or pinkish swelling of the lids occur occasionally, the only cause of which is eczema of the margins of the lids. The eczema may be very slight, or it may pass away quickly, and leave only the swelling behind. Unchecked eczema of the eyelids terminates in lippitudo, just as persistent and progressive eczema of the cornea produces pannus. Both these conditions are analogous to the eczematously red, swollen, and moist condition of the skin which may persist for an indefinite period. Eczema of the conjunctiva presents many important features. The so-called strumous ophthalmia may be regarded as chronic eczema. The several stages of pimple, vesicle, ulcer, or thickened patch, admit of indisputable demonstration. In acute eczema of the conjunctiva, there is for a few days a uniform scarlet colour; then a crowd of vesicles, which soon pass away, and leave an irregular or patchy redness—each patch, however ill-defined, having a redder, thicker, and possibly ulcerated centre. These cases have a slight muco-purulent discharge, and are always tedious. If treated as eczema, they speedily recover. The so-called keratitis, or strumous keratitis, is eczema of the cornea. When vesicles, white patches (necessarily white because of the anatomical structure of the cornea), or ulcers occur on the cornea in conjunction with vesicles on the conjunctiva, the term "scrofulous ophthalmia" is commonly used. If the same pimples (necessarily flat), vesicles, patches, or ulcers occur on the cornea alone, especially near its centre, the term keratitis is applied, notwithstanding the symptoms are similar, and notwithstanding that there is usually, if it be carefully sought for, evidence of eczema of the lids or face, or ears or scalp. The characters of eczema of the cornea are quite as typical as they are of eczema elsewhere. The several varieties of eczema of the cornea, conjunctiva, and lids are combined in a great variety of modes. They are much more frequently combined than not, and very frequently indeed associated with cutaneous eczema in its favourite localities. Eczema is often limited to sites as small as the cornea. The treatment should be directed to eczema. Its chief features are non-stimulating diet and alkaline medicines, with a little iron added in most cases. If the lids are affected, as also in pannus, lippitudo, and granular lids, a little of any of the "eczema ointments" may be used, with the customary attention to details; if much photophobia, a little morphia may be given in the morning.

The President said he supposed the author's communication was intended to show that many cases of strumous ophthalmia were really eczema, and that this was proved by the fact that there was in such cases eczema elsewhere.

The Author said the President had correctly apprehended the purport of his paper. It might seem strange to say that such diseases as pannus, keratitis, etc., were in reality eczema; but, from the arguments he had stated in the paper, he believed that conclusion was warranted.

Mr. Barwell had no doubt but that any new view of so common a disease would be considered important; but he thought the Author had taken too many cases into the grasp of one hand. He (Mr. Barwell) could not think that granular lids and strumous ophthalmia belonged to the same category. He thought the Author had not sufficiently distinguished herpetic eruptions from eczema. He was surprised to find the Author describing a long treatment by alkalies and iron for a disease like phlyctenular ophthalmia. He considered the disease to be herpetic, and that the photophobia attendant on it might be relieved by treatment in twelve hours. As for the connexion of certain ocular affections with eczema, they might arise from similar general conditions of the system, and alkalies might be of use. Yet he should not be inclined to treat phlyctenular ophthalmia on the slow method recommended by the Author.

The President hoped that before long the time would come when Ophthalmic Surgery would be free from the frightful nomenclature which did not afflict other branches of Surgery.

[We have received the following in reference to the discussion on this paper:—]

"Birmingham, January 13.

"Sir,—Had time permitted, I intended to say in reply to Mr. Barwell that the tendency of the best authorities on skin diseases is to reduce their number, and that many skin diseases which formerly had separate and distinct names are now recognised as varieties merely of eczema. The eruptions on the cheek which accompany certain forms of ophthalmic disease are certainly eczematous, and frequently precede the ocular lesions. "I am, &c. "Furneaux Jordan."

A paper (communicated by Mr. John Birkett, Hon. Sec.), by M. P. H. Desvignes,

ON THE SUBCUTANEOUS INJECTION OF QUININE FOR THE CURE OF AGUE AND OTHER MARSH FEVERS,

was then read. The author had had large opportunities of testing the value of this remedy in the intermittent fevers which were so common in the district of Tuscany called the "Maremma." The use of quinine and arsenic, in the usual manner, having repeatedly failed, he resolved to try the subcutaneous injection of solutions of quinine. The solution he employed was a grain and a-half in fifteen drops of water, acidulated with a drop of dilute nitric acid. With this he successfully cured several hundred cases.

Dr. Webster was glad to hear of a new method of giving quinine, but he doubted whether it would be so efficacious as giving it by the mouth. He was interested in observing that the author got his experience whilst a railway was making. Dr. Webster observed that at Birchweller, near Strasburg, while a railway was constructing in its vicinity, fever proved very frequent. In this commune, having about 1500 inhabitants, two-thirds at least became attacked chiefly by intermittents, although such diseases had rarely occurred previously. Further, he would mention that when the Southern Railway of Portugal, leading towards Spain, was being made, during the autumn of his visit to that country, an authority stated that among upwards of 5000 labourers there employed nearly 1500 were suffering from fever, and often of a severe type; the cases were mostly agues, which malady, however, frequently prevailed in these districts during hot weather and in autumn. Analogous results are likewise apt to occur when digging canals, in consequence of the newly-turned up earth then exposed to atmospheric action. Hence the making of railways and canals, especially in countries where fevers otherwise prevail, are dangerous employments. He (Dr. Webster) would also allude to the Maremma, which extended along the coast from south of Leghorn towards the Papal States. This was a most dangerous district, where the very worst forms of fevers often devastated its residents, and even more severely than in the Pontine marshes. Therefore, should the treatment mentioned by the Author always prove so efficacious as had been stated, great, indeed, would be the boon thereby conferred on suffering humanity. Fevers from malaria, every person well knew, were very common throughout many parts of Italy, as he (Dr. Webster) could assert from personal experience, having been attacked after simply passing through an unhealthy district—namely, that adjoining the Lake of Bracciano, on the road from Rome to Florence. This was a most pestiferous place during hot summer and autumnal weather. Although travelling by the mail courier without stopping at any place, yet having unfortunately slept for some hours in the night time, when malaria always acts more powerfully than if the person were awake, he (Dr. Webster) was attacked by fever. He, however, suffered less severely than another Medical gentleman, who, with his family, had left Rome the same day, and was also going towards Tuscany. Having much money in his carriage, and fearing attacks from robbers, who were then infesting that road, he would not risk travelling during a dark night, but preferred sleeping in some miserable Italian "Albergaccio," whereby he and several of his party took the fever, and died.

In reply to the President, Dr. Webster said that cases of ague had occurred in making railways near London.

Mr. C. H. Moore said that twelve years ago he had under his care a patient who had periodical attacks of inflammation of the knee-joint. The joint inflamed for two and a-half days, and then gradually subsided. Punctually on the ninth day it re-inflamed. It had begun eighteen years before he saw the patient, and eight years after an attack of ague. At first it occurred every thirty days. After a time she married, and then during pregnancy she had no attacks. Quinine did no good. The only case at all like this that he could find on record were three cases of periodical sickness, published in the *Transactions* of the old Medical Society of London. In two of these there was a connection with ague, and two were cured by arsenic. On Tuesday last Mr. Moore said he admitted into the Middlesex Hospital a girl, aged 21, who told him that she had attacks of inflammation of the right knee every twelve days, and that she had thus suffered three months. He was now waiting to see if an attack would come on at the time mentioned by the patient. In a case like this he should feel inclined to adopt the injection plan, and to inject the solution near the joint at the time of the attack. He inclined to think that this would be better than giving remedies internally in the interval.

Mr. Charles Hunter said that he had no doubt the subcutaneous injection of quinine would answer the expectations of the last speaker, if properly and carefully tried. In an economical point of view, he considered this mode of administration highly valuable, and alluded to the experience of Dr. Moore, of Bombay, who had found four or five grains by injection equal to five or six times that quantity by the mouth. Mr. Hunter could fully corroborate this advantage of the cellular administration, from a large experience with other alkaloids, especially atrogeni and morphia. Another advantage was, the quicker effect than by stomachic administration, the symptoms being often manifested in five minutes. A third advantage was, that quinine could be given this way for a certainty; whereas frequently the stomach is not in a state to absorb the medicine. Mr. Hunter protested against the way in which M. Desvignes injected the fluid. He considered a lancet quite unnecessary, and stated that if the perforated needle were used, and the fluid more concentrated, none of the local evils mentioned in M. Desvignes' paper need or ought to result.

Dr. Sanderson said the practical importance of the subject of the paper was undoubted, especially at a time when the country poor were suffering from the dearness of quinine. From the parsimony of the poor-law authorities, Medical men were obliged to provide expensive medicines, so that although most could agree that quinine was the better remedy for ague, arsenic was often used instead. Again, if smaller quantities were required when injected, the plan would be a great boon. It seemed clear that if it cured the "pernicious" agues of Italy it would be of at least equal value in the milder cases in this country. He imagined that the cheapness of this plan was its great advantage, as he supposed the author did not conceive it to be of greater therapeutical value than the giving of larger doses by the mouth.

Dr. A. P. Stewart said that in the wards of M. Chomel he saw quinine used endermically in cases in which it was rejected by the stomach. The great objection to it was the great pain it caused. He (Dr. Stewart) asked if there was no pain after the injection of concentrated solution—no accidents? He had seen considerable depression of the system in nervous patients after the injection of morphia. He wished to know the truth on both sides. In regard to the general subject of the cheapness of these alkalies, people seemed to forget (Dr. Stewart said) that there was a cheap drug, which was quite as effectual as quinine, viz., cinchonine. It was slightly weaker—four grains of quinine being equal to five of cinchonine. In 1850 he had under his care at the Middlesex Hospital many cases of periodical affections. He therefore prescribed so much quinine that he was asked by the Hospital authorities to give it up, on account of the great expense. At this time he began to use the liquid

extract of bark prepared by Mr. Bullock. Although this preparation was made from the liquor remaining after the extraction of all the usual alkaloids, it was very efficacious. Ten minims was a sufficient dose in ague. It was then generally used in the Hospital, and is still used. It was (Dr. Stewart said) an exceedingly cheap preparation.

Dr. Althaus had listened with pleasure to M. Desvignes' paper, as it well illustrated the value of a mode of treating disease which was in many instances far superior to the ordinary administration of remedies. He was quite disposed to believe in the great success which had attended the Author's operations, as he had himself successfully treated by the same means a very obstinate case of intermittent fever, which had resisted the internal use of quinine and arsenic. He had altogether much faith in hypodermic injections, and had found that, amongst others, the effects of strychnia thus used were far greater and more rapidly brought about than if given in the ordinary way. He had injected the nitrate of strychnia in a variety of paralytic affections, and had never seen any unpleasant effects follow its use. Morphia was very beneficial, especially in certain forms of neuralgia, but was liable to produce general symptoms of narcotism, which might appear alarming, although no real harm was done. This was even more the case with atropine. He had never seen inflammatory action or sloughing following the injections, and believed the use of lint and other applications to the place where the puncture was made to be unnecessary.

Mr. Birkett (Hon. Sec.) said that the Author (who was not present) had great difficulty in getting a proper instrument for injecting. It was very likely, then, he (Mr Birkett) would suggest that the lancet was necessary from the clumsiness of the syringe. As to the cheapness of quinine in practice amongst the poor, Mr. Birkett said that he had noticed in one of the poor-law books at the investigation of the case of Timothy Daly an order to the effect that expensive medicines, such as quinine, must be supplied by the guardians.

A Fellow said that this order had not been confirmed by the Poor-law Board.

THE ROYAL MEDICAL BENEVOLENT COLLEGE.

An extraordinary general meeting of the governors of this College was held on Thursday, January 12, at the premises in Soho-square, Dr. Babington, V.P., in the chair, to discuss certain resolutions proposed by the Council as to the election of a President, and the cancelling Bye-laws 2, 12, and 23, and substituting new ones in their stead. The advertisement convening the meeting having been read by the Secretary,

Mr. Propert said the first business they had to transact was the election of a President. They had to regret the retirement from that office of one of the best of men, whose exertions had given so much satisfaction, and who upon all occasions had proved himself a friend of the institution; he need scarcely say he referred to the Right Hon. Lord Chelmsford. The fact was that his Lordship's time was so much occupied in the House of Lords that he himself expressed an earnest desire to be released from the office, because he felt he could not conscientiously discharge the duties of President. He (Mr. Propert) then determined to look about him, and the first man he called upon was a nobleman of great distinction and a member of her Majesty's Government—he applied to Earl Granville, who was President of the London University. The noble Earl told him he recollected this College, and would let him (Mr. Propert) know his determination by letter. The noble Earl wrote him to this effect:—"If you really think I can be of any use to your institution, I shall be happy to accept the office of President." The hon. gentleman then proposed Earl Granville, K.G., as President.

Francis Hird, Esq., seconded the motion, which was carried with acclamation.

Francis Hird, Esq., then proposed that Bye-laws 2, 12, and 23 should be rescinded, and that the following Bye-laws be substituted, and stated his willingness to adopt the verbal alterations which appear in italics:—

"Proposed New Bye-laws.

"*II. The School.*

"The school is intended for the education of boys between the ages of eight and nineteen, none being above fifteen years old on admission. Two hundred or more of such boys shall reside in the College; forty of them shall be foundation scholars, and the remainder may either be exhibitioners *or other pupils* (the sons of members of the Medical Profession), or the sons of gentlemen not in the Medical Profession; but boys of the latter class shall be admitted only when there are vacancies not required for the sons of Medical men.

"The foundation scholars shall be educated, boarded, clothed, and maintained by the College, except during the school vacations. The exhibitioners shall be the sons of some of the less fortunate members of the Medical Profession, and shall be admitted by the Council in such numbers and under such regulations as the Council may from time to time determine. They shall pay *not more than* £30 a-year each for education, board, lodging, and washing, without any extra charge for the use of books or school materials. *Other pupils, the sons of Medical men*, shall pay £40 a-year each for the like advantages. *Pupils* not the sons of Medical men shall be admitted on such terms as shall be from time to time fixed by the Council, and any profit which may arise from their admission shall be added to the Exhibition and Scholarship Fund.

"Every boy entering the College after Easter Term, 1865, except the foundation scholars, the Surrey Society's scholars, and the exhibitioners, shall pay to the Exhibition and Scholarship Fund an entrance fee of two guineas, and (after his first year) a fee of seven shillings a term.

"All payments shall be made in advance at the commencement of each term.

"*XXII. Exhibition and Scholarship Fund.*

"The Exhibition and Scholarship Fund shall be formed from the fees and profits assigned to it by the 2nd and 23rd bye-laws, and from subscriptions, donations, and bequests, specially made to it.

"Governors of the College only, who shall contribute one guinea annually, or ten guineas as a life donation to *this* fund, *or shall collect twenty guineas for it*, shall be entitled to an additional vote at the elections of pensioners and foundation scholars for every such subscription, donation, *or collection.*

"The exhibitions shall be of the value of *not less than* £10 a-year each.

"Donors or collectors of £50, if paid at one time, and executors paying a legacy of £100, to *this* fund, *or such other sums as the Council may from time to time determine*, shall be entitled to present *one boy* duly qualified to become *an* exhibitioner to an exhibition of *not less than* £10 a-year, tenable for five years or any shorter period during which such boy shall remain in the school, provided that in every case the nominee be approved by the Council, and be not more than fourteen years old on admission. Such donation, collection or bequest shall not give any additional right of voting in respect thereof.

"The scholarships shall also be of the value of *not less than* £10 a year each, and shall be open to the competition of the whole school, under such regulations as the Council may from time to time determine.

"Two-thirds of *this* fund shall be appropriated to exhibitions and one-third to scholarships.

"*XXIII. Day Scholars.*

"The day *pupils*, who shall not necessarily be the sons of Medical men, shall be admitted by the head master. They shall pay £12 a year each, if the sons of Medical men, and £15 a year each, if not the sons of Medical men, for education, inclusive of the use of books and school materials. They shall also pay two guineas entrance fee, and (after their first year) a fee of seven shillings a term, to the Exhibition and Scholarship Fund; to which fund any profit arising from their admission shall likewise be applied.

"In addition to the above, the sons of pensioners may be admitted by the Council as day *pupils*, on such terms as the Council may from time to time determine."

He (Mr. Hird) said every one in the room was probably aware that many governors had desired that £30 a year should be the maximum charge made for the education of the sons of the less fortunate members of the Profession, but the Act of Incorporation prohibited any portion of the funds of the College being used for that purpose, and it had been estimated that the prime cost of each boy was £40 a year. The Council had for the past two years been endeavouring to carry out the desired object, and from time to time had appointed sub-committees to consider and report upon the subject. After much discussion, the Council had determined to recommend the plan embodied in the proposed new Bye-Laws for adoption by the governors, and he believed, if adopted, it would increase the usefulness of the school and give general satisfaction. Mr. Hird fully

explained *seriatim* the object of the various changes proposed, and stated that the entrance fee and annual payments of the pupils to the "Exhibition and Scholarship Fund" was upon the principle that the rich should contribute to the poor. He could find nothing in the Act of Parliament to prohibit the proposed alteration of the laws, but he was bound to tell the meeting that there were two prizes, one of which was given specially to the exhibitioners of the College by Mr. Watts, a gentleman now deceased, and the other by Mr. Brand, who was living, and who, no doubt, would generously adopt the views of the Council. As a substitute for the Watts' prize, the new Bye-Laws created several scholarships, which would be open for competition to the whole school, and he hoped they would receive the unanimous approval of the meeting.

Mr. Cattlin said he had peculiar pleasure in seconding the proposition which had been so ably and fully explained by Mr. Hird, because he believed it to be a gracious concession to the opinions of a large body of governors, who had for a long time advocated the change which the Council had proposed; and he believed a majority of the present Council were now anxious to provide for all the requirements of our needy Profession. He (Mr. Cattlin) had attentively listened to the arguments and explanations which Mr. Hird had brought forward in support of the new bye-laws, and he was glad to say there was only one point upon which he differed, and only one matter which seemed to require additional explanation. The point upon which he differed was upon the construction of the 38th clause of the Act of Incorporation. Mr. Hird had stated "that the Act of Parliament prohibited any portion of the funds of the College being used for the purpose of reducing the charge for exhibitioners to £30;" whereas, the present Attorney-General (Sir Roundell Palmer) had given a very decided opinion to the contrary. The most that could fairly be said upon this vexed question was that great lawyers and good friends of the College had differed widely upon the subject. However, he (Mr. Cattlin) would be greatly wanting in discretion if, at a peace meeting, as this was intended to be, he did more than allude to the subject. The matter which seemed to require additional explanation was the application of the Scholarship Fund. It was true, as Mr. Hird had stated, that the richer scholars contributed an entrance fee of two guineas, and an annual subscription of one guinea, while the poorer were exempted from those contributions; but it ought to have been stated that in return for this the richer received one-third of the subscriptions, donations, and bequests, and also one-third of the profits of lay and day scholars, which would more than equalise the respective advantages of the two classes. He (Mr. Cattlin) considered the proposition to admit lay scholars was the main feature of the whole scheme. Class education was a sort of epidemic poison, and it was a moral impossibility that boys of the same class should associate together from year to year without contracting a certain amount of mental contamination. If a special Building Fund could be established to provide for the admission of 100 lay scholars at a charge of £55 a-year each, a moral benefit would be conferred upon the Medical scholars, and no less a sum than £1500 annually, in the shape of profit, would be contributed to the "Exhibitioners and Scholarship Fund." Having taken great interest in this matter, he (Mr. Cattlin) was sorry to know that some governors now present had not strict confidence in the intentions of the Council; but, without wishing to flatter that body, he not only believed the new bye-laws, if adopted, would be fully and fairly carried out, but he further believed the members of Council would be the largest contributors to the Exhibition and Scholarship Fund. The time of day at which the meetings were held was so valuable in his branch of the Profession, and his health not being sufficiently strong for public work, on these grounds he should be obliged to resign his seat upon the Council; but he felt confident that good faith would not be broken. Every governor in the room was freely at liberty to raise objections to the plan now proposed by the Council; but he hoped no one would do so without substituting some improvement which would rather enlarge than diminish the benefits intended to be conferred upon the less fortunate members of the Profession.

Mr. Tayler, of Kennington, inquired what arrangements would be made for the admission of the proposed "exhibitioners?" He had heard it was intended to admit them by competition, and he wished to know whether the examination would be regulated by the ages of the candidates?

Mr. Hird replied that a sub-committee of the Council would be appointed, to whom a confidential communication as to the circumstances of the candidates would be made, and that the examinations would be regulated by age, as Mr. Tayler had suggested.

Dr. Webster, of Dulwich, expressed his entire approbation of the measure now proposed by the Council, which he described as a "healing" one; and concluded some very appropriate and congratulatory observations upon it by saying that it should have his cordial support.

Mr. Harrison said, that as a Governor of the College from its first foundation, he had watched its progress with great interest, although he had never yet interfered with the management of its affairs; and that, fully approving of the principle of the scheme proposed by the Council, as one likely to allay those internal dissensions which had unhappily existed among its supporters for some time past, he had attended the meeting for the purpose of giving it all the support he could; but prepared, nevertheless, to move the verbal amendments upon it which had been brought under their notice by Mr. Hird, had this been necessary—as he believed them to be improvements upon, and yet in keeping with the principles of the proposed new bye-laws as originally advertised by the Council. He was glad, however, that Mr. Hird, acting as the representative of the Council, had expressed his willingness to adopt these verbal alterations, as it would be much more agreeable to him (Mr. Harrison), and he thought could not be otherwise than more agreeable to the Council, that they should be proposed and carried (if carried at all) as coming from the Council, than as amendments upon their proposition. He believed that, to accomplish this in order, it was necessary that some one should move that the verbal alterations be incorporated with the proposed new bye-laws as originally advertised, and he now rose for that purpose. He added that, at that late hour of the evening, and in the temper in which the meeting seemed to be, he would not detain it by entering at any length into the grounds on which he was prepared to support the propositions before it, but would content himself with saying (as Dr. Webster and others had done) that he fully and cordially approved of them, as proposed to be altered; and that he believed, if carried, that they would not only prove "a healing measure," as had been said, but that, if taken up and acted upon cordially and zealously, they would be calculated also to give a new impetus to the further success of the College.

This proposition being seconded by Mr. Bradley, was put, and carried unanimously.

The original propositions from the Council, as thus amended, were then put, and also carried unanimously.

Mr. Propert proposed, and Mr. Jonson seconded a vote of thanks to the Chairman, who gracefully acknowledged the compliment, and congratulated the meeting upon the good feeling which had characterised its proceedings.

GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

SCOTTISH BRANCH.

Physicians' Hall, Edinburgh, January 13, 1865.

Sederunt.

Mr. Syme, *Chairman.*	Dr. Allen Thomson.
Dr. Fleming.	Dr. Christison.
Dr. Alexander Wood.	Dr. Andrew Wood.

Dr. William Robertson, *Registrar.*

1. The Minutes of last meeting were read and confirmed.

2. The subject of the proposed Amendments of the Medical Act was resumed, and the following resolutions were agreed to:—

"The Branch Council for Scotland having, in terms of the remit made to them by the General Medical Council, considered carefully the subject of the amendment of 'The Medical Acts,' particularly with reference to Clauses xx., xxxi, and xl., of 'The Medical Act 1858,' 21 and 22 Vict. cap. 90,—Resolve, that any Act for amending the Medical Act should be restricted to specific clauses, whereby the following objects may be carried out:—

(1.) "To confer on the Medical Council definite powers to issue to the various licensing bodies regulations on the subjects of preliminary and professional education and examination.

(2.) "To amend Clause xl., so as to render it more efficient than it has hitherto been, for enabling the public to distinguish between qualified and unqualified Practitioners, and for preventing unqualified Practitioners from assuming Medical titles to which they have no right."

In order to carry out the first of these objects, the Branch Council recommend clauses to the following effect —

"That it shall be lawful for the General Medical Council from time to time to issue to the various licensing bodies such regulations respecting the preliminary and professional education and examination of persons desirous of obtaining any of the qualifications mentioned in Schedule (A to 'the Medical Act,' as may appear to the Council fitted to secure, on the part of such persons, the requisite knowledge and skill for the efficient practice of their Profession.

"That all such regulations as shall have been passed by a majority of two-thirds of the General Council shall be obligatory on all Universities, Colleges, and other bodies enumerated in Schedule (A) to the Medical Act of 1858.

"That, in the event of any of the said bodies not conforming to such regulations, it shall be lawful for the General Council, if they see fit, to intimate to the said body that it has not conformed to such regulations; and to direct that, in the event of the said body not conforming within six months after such intimation, the qualification granted by such body, after the lapse of the said period of six months, shall not be registered.

"That it shall be lawful for any body in regard to which such direction shall have been given, to appeal to the Privy Council, who shall have power, if they see cause, to disallow the direction of the Medical Council.

"That it shall be lawful for the General Council to restore any right to registration which may have been suspended by them, when they shall be satisfied that their regulations have been conformed to."

In order to carry out the second of these objects, the Branch Council recommend a clause to the following effect:—

"It shall not be lawful for any person, unless registered under this Act, to practise any branch of the Profession, taking or using the name or title of a Physician, Doctor of Medicine, Licentiate in Medicine or Surgery, Master in Surgery, Bachelor of Medicine, Doctor, Surgeon, Medical Practitioner, or General Practitioner, or Surgeon-Apothecary, or Licentiate or Practitioner in Midwifery, or Professor of Medicine, or Professor of Surgery, or any other Medical or Surgical title; and every unregistered person so offending shall, upon summary conviction for such offence, forfeit or pay a sum not exceeding twenty pounds."

It was resolved—

3. "That the Scottish Branch Council having considered the propriety of amending Clause xxxi. of the Medical Act, are of opinion that what is objectionable in it would be obviated were the combination and co-operation of the licensing bodies, as provided for by Clause xix, encouraged or even made obligatory, so that facilities may be given to Medical students for acquiring the complete or double qualification without having to pass repeated examinations on the same subjects, which is at once irksome and unnecessary; and, in order that the public may be best provided with General Practitioners who have been educated and tested in every branch of the Profession, as well Physic as Surgery."

It was resolved—

4. "That the Branch Council consider that it is highly expedient that a Bill for amending the Medical Acts should be prepared and submitted to the Home Secretary within two months from the present time, so that it may be possible to have it introduced into Parliament, and passed into a law during the ensuing session of Parliament."

5. The Registrar laid on the table the Registers of Medical Students which had been transmitted to him by the various licensing bodies in Scotland.

In laying these returns before the Branch Council, the Registrar intimated that, from the number of blanks occurring in them, it was impossible for him to comply with the 4th regulation of the General Medical Council, and to frame an accurate register of Medical students.

The Branch Council resolve to report this to the General Medical Council as an illustration of the necessity which exists for enabling the Council to issue regulations of a compulsory character.

6. The Treasurer's annual accounts, with Auditors' report thereon, likewise the Treasurer's statement of gross receipts during the past year, were read, approved, and ordered to be printed with the Minutes.

Account, Charge and Discharge, of Treasurer's Intromissions with the Funds of the Scottish Branch of General Medical Council, from January 5, 1864, to January 5, 1865.

Charge.				Discharge.			
In Consols, as formerly stated.	£1907	10	0	Balance, cash due to Registrar, as per Account of Jan. 5, 1864	£6	2	0
In Bank, on January 5, 1864, at credit of Scottish Branch Council.	1032	8	4	Postages and receipt-stamps	3	3	0
7 Registration Fees at £2	14	0	0	Messengers and petty expenses	0	11	2
162 do. do. at £5	810	0	0	Fees paid in error by, and returned to, Dr. M'Innes	4	15	0
14 additional do. at 5s.	3	10	0	Additional fee paid by Dr. M'Innes and transferred to English Branch Council	0	5	0
Dividend, January, 1864, on £2000 Consols	22	2	6	Stationery (Waterston).	0	17	6
Dividend, July, 1864, on do.	29	5	0	Printing (Constable)	7	0	0
Interest, allowed by Bank of Scotland, on Account of 1863	19	11	2	Fees and travelling expenses of Branch Councillors to Jan. 5, 1865	59	17	0
				Registrar's salary and office rent to Nov. 11, 1864	210	0	0
				Remitted, on Account of General Council, with Bank Commission	570	14	8
				In Consols, as formerly stated.	1907	10	0
				In Bank on January 5, 1865 at credit of Scottish Branch Council.	1040	13	10
				Balance, being cash in Registrar's hands, on January 5, 1865	33	17	10
Sum of Charge	£3845	7	0	Sum of Discharge	£3845	7	0

Edinburgh, January 11, 1865.—The undersigned have this day examined the above account, and find it accurately stated and duly vouched. There is a balance of Thirty-three Pounds Seventeen Shillings and Tenpence in the Registrar's hands.

Andrew Wood, Alex. Wood, } Auditors.

Statement by Treasurers of Scottish Branch of General Medical Council of Gross Receipts from January 5, 1864, to January 5, 1865.

7 Registration Fees at £2	£14	0	0
162 do. at £5	810	0	0

Interest allowed by Bank of Scotland on Account of 1863	19	11	2
Gross receipts of Scottish Branch Council	£905	8	8

James Syme, R. Christison, } Treasurers.

MEDICAL NEWS.

Royal College of Surgeons.—The following members of the College having been elected "Fellows" at previous meetings of the Council, were admitted as such on the 12th inst., viz.:—

Messrs. Henry Sterry, J.P., Paragon, Southwark, diploma of membership dated January 2, 1824; William Blathwayte, Louth, Lincolnshire, September 27, 1832; Abraham Wolff, Gower-street, December 16, 1839; James Nance, Eccleshall, October 16, 1840; and John Kilner, Bury St. Edmunds, April 12, 1843.

The following gentlemen have just passed the Preliminary Examination in Arts, etc., viz.:—

Messrs. T. B. Archer, A. J. Bell, C. H. Bird, S. B Brooks, F. W. R. Burgess, G. E. E. Borroughs, J. J. Conybeare, C. A. Carter, H. P. Deacon, B. Daymon, H. E. Dixon, G. A. Eldred, R. Favell, A. A. Gillitlie, T. Gurney, A. S. Groves, R. Humphreys, W. Hardman, E. J. Hart, F. W. Hamlin, T. W. Hubbard, A. Jukes, H. H. Jeffreys, J. W. Ley, F. O. Lovell, G. J. Llewellin, T. L. Lack, F. W. Laslett, T. H. Lovegrove, F. H. Laking, W. H. Mann, J. H. More, C. Mead, A. C. Newman, T. W. Norbury, S. E. Owen, E. Perkins, F. Pestivee, R. F. Phibbs, C. H. W. Parkinson, R. H. Pritchard, C. W. Pratt, W. Rosser, R. Riches, A. Risden, H. J. Rope, W. J. Rae, S. J. Rowlands, R. Steele, E. Snell, F. A. A. Smith, T. Strafford, W. H. Staveley, C. H. S. Stevens, F. E. Taylor, B. Thorp, A. R. Ticehurst, H. C. Turner, E. Walford, F. White, G. Willis, and W. B. Wood.

The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 17th inst., and when eligible will be admitted to the Pass Examination:—

Edward Scott Jones, Charles Arthur Bush, Edward England Phillips, John Lawrence, and William Powell Keall, Students of the Bristol School; Henry Bowden Lyle, Edwin James Fairland, William Evatt Wright, Frederick Everard Hunt, and James Thorne, of Guy's Hospital; Herbert Ridley, Alfred Wilson, and William Anderson, of the Newcastle School; Thomas Nathaniel Twigge, John Parks, and Richard Strange Hall, of the Manchester School: Edwin Charles Garnsey and Joseph Channing Pearce, of University College; Charles Thomas Ennals and Henry Sissmore Shaw, of the Middlesex Hospital; Ferdinand Albert Purcell and Arundel Hill Cotter, of Cork; David Roberts Pughe and Charles Iliffe, of the Birmingham School; Walter James Leckie, Westminster Hospital; Thomas Soars Johnson, Charing-cross Hospital; Frederic Richard Fisher, of St. George's Hospital; Edward William Adrien, of Dublin.

The following passed on the 18th inst.:—

Josiah Paull, Ernest Thomas Raimbach Evans, John Yeomanson, and John Arnold, Students of St. Bartholomew's Hospital; William Cook Hewby, Edward Butler Ruttledge, William Wiles, and Robert Walter Ceeley, of the London Hospital; George William Mansley, Christopher Haynes Jenner Hogg, and William Edward Green, of Birmingham; Mark Antony Kilroy, William Gosselin, and Evan Elias Williams, of Dublin; Nelson Albert Hilder, and Henry Goldsworthy Shorter, of Guy's; Thomas Edward Stafford and Charles George Edmonds, of St. Thomas's Hospital; Frederick Mainzer Charles Beechey, of St. Mary's Hospital; Henry Tonnon Staples, of King's College; Charles Henry Hines, of University College; John Thomas Morgan, of St. George's Hospital; John Jefferson, of Belfast; Frederick William Binns, of Leeds: James Algernon Temple, of Quebec.

Apothecaries' Hall.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, January 12, 1865:—

George Clements, Middlesex Hospital; George Henry Eccles, 7, Felix-terrace, Islington; Reuben Zacchæus Miller, Louth Lodge, Richmond; John Hughes Williams, Holyhead.

As an Assistant:—

Job Haddock, 27, Bridge-street, Rancorn.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Barclay, John, M.D., has been appointed one of the Medical Officers of the Banff Dispensary.

Eagles, W., M.R.C.S. Eng., has been elected House-Surgeon to the Bolton Infirmary and Dispensary.

Ferguson, George, M.B. Lond., has been appointed Resident Surgical Officer to the General Hospital, Birmingham.

May, A. S., M.R.C.S. Eng., has been elected Apothecary and Secretary to the Chelsea, Brompton, and Belgrave Dispensary, Sloane-square.

Nolan, James J., L.R.C.S.I., has been elected Medical Officer to the Workhouse of the Ballina Union, Co. Mayo.

Oliphant, J., M.D., has been elected Assistant House-Surgeon to the Chester General Infirmary.

Reid, K., M.D., has been elected Resident Surgeon to the Birmingham Lying-in Hospital and Dispensary for Diseases of Women and Children.

Stewart, James, M.D. Glasg., has been appointed Physician to the Glasgow Royal Infirmary.

DEATHS.

Baikie, Dr., at the residence of Charles Heddle, Esq., Sierra Leone, aged about 40, on December 12, 1864, Dr. Baikie, Surgeon, Royal Navy, the well-known African traveller, a native of Kirkwall, Orkney, and son of Commander Baikie, R.N., Kirkwall. Dr. Baikie, after travelling for six years in the interior of Africa, and after having established a native colony some distance from the confluence of the Niger, returned to Lagos on October 21 in her Majesty's ship *Investigator*, which had been up the Niger 400 miles on a cruise. Dr. Baikie's remains were interred with military honours.

Black, John, L.F.P.S. Glasg., at Macfarlane-street, Glasgow, on January 8.

Brown, William Henry, F.R.C.S. Eng., at 2, Cornwall-terrace, Belmont, Lee, Kent, on January 13, aged 56.

Fogarty, Frederick W., M.D., at Elm Bank, Mary Church, Devon, on January 15, formerly of Percy-circus, London.

Grant, Peter, L.R.C.S. Edin., of Seamont-place, Aberdeen, on December 7, aged 44.

Holden, Robert, L.R.C.S. Edin., R.N., at Arbroath, Forfarshire, on January 3.

Johnson, George, M.R.C.S. Eng., at St. Andrew's-street, Cambridge, on January 7.

Loughnan, Jeremiah, M.D. Glasg., at Listowel, Ireland, on January 2, aged 52.

Paton, James F., M.D. Glasg., at Greenock, N.B., on December 25.

Sprague, John H., M.R.C.S. Eng., at Bedminster Down, Bristol, on January 5.

Sweetnam, Michael, L.S.A., at St. John-street, Clerkenwell, on December 11.

Tyman, John, M.D., at Florence-street, Glasgow, on December 25.

Williams, W. R., M.R.C.S. Eng., at Bangor-street, Carnarvon, on January 3, aged 31.

Williamson, Henry George, M.D. Edin., of Holmes Chapel, Cheshire, at Nantwich, on January 10, aged 25.

Birth of a French Princess.—On Friday Her Royal Highness the Duchess de Chartres gave birth to a daughter, the first great grandchild of the last French King born in this country. The event took place at Ham-common, near Richmond, in the presence of Dr. W. O. Priestly and Dr. de Mussey. The news was immediately telegraphed to Queen Victoria, at Osborne, and to Queen Amelie, at Claremont.

Collegiate Elections.—The claims of the provincial Fellows of the Royal College of Surgeons to vote by proxy papers for vacant seats in the Council Chamber, have again been brought before the Council of the College by the President and members of the British Association, who complain of "the general dissatisfaction of the Fellows and Members of the College at the mode of electing the Council, and requesting that the Council will be pleased to obtain a new or supplemental charter, in order to render it lawful for the election of councillors to be conducted by means of voting papers, which may be filled up by non-resident electors after some such plan as that prescribed for the Universities of Oxford and Cambridge in their elections of Members of Parliament." The Council of the College of Surgeons having re-considered the application at its last meeting, saw no reason to alter its opinion upon the subject, as communicated to the British Medical Association in November, 1863.

Presentation from the Queen to Dr. Cass.—On New Year's Day, Dr. Cass, of Cowes, received, through the hands of Sir Charles B. Phipps, a massive and magnificent silver inkstand, "As a memorial from the Queen of her Majesty's appreciation of his skill and attention during the many years he has attended in his Professional capacity at Osborne." Dr. Cass, who has long been held in very high esteem at Cowes, has been the Medical attendant upon the Royal Family and household at Osborne, for nearly twenty years, but finding of late that his sight had become so seriously impaired as to threaten absolute blindness, he felt constrained (though still in the prime and vigour of his life) to resign his appointment at Osborne, and to withdraw altogether from the Profession in which he had established a high and well-earned reputation. This circumstance has been a matter of universal regret throughout the whole of the wide district over which Dr. Cass's practice extended; but among the many expressions of sympathy which have reached him from all quarters none have been so warm, and none, of course, so deeply gratifying, as those which have been conveyed to him from the Queen. "Her Majesty," says Sir Charles Phipps, in the letter which accompanied the costly memorial, "hears with great regret that she shall no longer be able to avail herself of your valuable Medical services, and the Queen still more laments the sad cause which has thus forced you to abandon your Profession at an age when your usefulness should be greatest." Again, Sir Charles says, "I am directed to express Her Majesty's sincere sympathy for the affliction which has obliged you to discontinue your valuable services." These are queenly words, and well calculated to convey to Dr. Cass the highest solace he can possibly receive under the calamity which has fallen as a fatal blight upon his Professional career, and marred the fairest hopes and promise of an honourable and laborious life.

The Queen's College.—Quarterly Meeting of Professors.—The quarterly meeting of the Professors to the Queen's College was held in the library of the College, at five o'clock yesterday afternoon, Mr. Sands Cox in the chair. The other Professors present were—Messrs. Postgate, Clay, and Suckling, and Dr. Hinds. The minutes having been read, Professor Postgate said that he and Dr. Hinds had had an interview with the Earl of Lichfield, in accordance with the wishes of the last quarterly meeting, to ascertain what was being done with reference to the affairs of the College. His Lordship stated that he had communicated with the Charity Commissioners, and he had received from them a letter stating that the affairs of the College were in the hands of the Attorney General, and would soon be in the Court of Chancery, and that that Court would take the charters and the trust deeds and other documents, and come to some practical settlement of the College difficulties. His lordship spoke very hopefully of the prospects of the College.—The Chairman asked whether any reference was made by Lord Lichfield to the connection between the College and the Hospital.—Professor Postgate said that had not been the subject of special remark.—Professor Suckling said the Hospital had materially suffered by its separation from the College. It had now only about three students, instead of sixteen, and twenty, and thirty, which were the number formerly.—Dr. Hinds said Lord Lichfield said, in reference to the Hospital, that nothing could or would be done by the Lord Chancellor without direct communication with him. His Lordship appeared to be of the same opinion as the Professors with reference to the Hospital.—Professor Suckling: It appears to me that the Hospital is under a very much greater monopoly than when it was in connection with the College. Its patronage—the men who regulate and guide it—is not so noble as that under which it flourished whilst connected with the College.—A vote of thanks was then passed to the Chairman, and the meeting separated.—*Birmingham Daily Gazette*, January 11.

The annual meeting of the Odontological Society was held on Monday evening, the 9th inst, Edwin Saunders, Esq., President, in the chair. Contributions to the Museum were announced from Messrs. Hepburn, Lord, and Statham. Mr. Hulme mentioned a case in which a lady had her three front teeth attacked by tartar, and could be readily removed and replaced. The curious point was that, although remaining in that state about seven years, the presence of the teeth had preserved the gum from being absorbed. The President then read the balance-sheet and the report of the Audit Committee. It showed an excess of expenditure over receipts of £7 4s. 1d. for the past year. The total balance in the hands of the Treasurer was £539 4s. 6d. The report of the Library Committee showed an addition of 102 volumes during the past year. Fourteen non-resident, four resident, and one corresponding member had been elected, making a total of 302 members. The following officers were then elected to serve during the present year:—*President*—Thos. A. Rogers, Esq. *Vice-Presidents*—(Resident:) W. A. N. Cattlin, W. Imrie, W. Perkins, G. A. Ibbetson, and James Parkinson, Esqrs. (Non-Resident:) W. K. Bridgman, Esq., Norwich; S. Tibbs, Esq., Cheltenham; Dr. Roberts, Edinburgh; J. R. H. Moore, Esq., Dublin. *Treasurer*—Arnold Rogers, Esq. *Librarian* J. B. Fletcher, Esq. *Honorary Secretaries*—A. Coleman, C. Vasey, and J. Underwood, Esqrs. *Councillors*—(Resident:) T. Sheffield, C. J. Fox, H. T. Kempson, R. T. Hulme, G. Owen, A. Hill, S. Cartwright, E. J. Winterbottom, J. Saunders, F. Weiss, and N. Stevenson, Esqrs. (Non-Resident:) C. D. Rogers, Esq., Newbury; S. L. Rymer, Esq., Croydon; E. P. Parkinson, Brighton; W. Hunt. Esq., Yeovil; T. A. Baker, Esq., Dublin; and T. R. M. English, Esq., Birmingham. The retiring President gave his address, glancing at the events of the past year, and paying a warm tribute of respect to the late Samuel Cartwright, their first President. A vote of thanks to the President was proposed

by Mr. S. L. Rymer, and carried by acclamation. Votes of thanks were also proposed to the Treasurer, Secretaries, Librarian, and Curator of the Museum. The Society then adjourned.

THE ELECTION OF CORONER FOR LEOMINSTER.—Dr. Kemp has addressed the following letter to the electors of the Leominster district:—"Gentlemen,—In the local journals of the last fortnight I have submitted to your notice a few lines, preparatory to a further explanation of the reason why a comparative stranger should venture to address you on the subject of the vacant coronership. I was, during that time, unprepared to enter more specifically into the essential points of the case, the details of which had yet to be sought for. Still, the principle on which I proceeded was sufficiently clear:—That, *cæteris paribus*, a person who had been engaged for years in the higher departments of organic chemistry, whose researches are as well known in Germany and France as in his own country; those researches, at the same time, involving the application of the laws of Medical jurisprudence, had fully as high a claim to your support as a candidate who takes his stand upon mere local circumstances; and you will immediately see that, allowing this latter claim, the parish beadle of Leominster would be as fitting a candidate as any other, and probably cost the county a much smaller sum than that which you now offer. The tribunal to which the final appeal in this case must, constitutionally, be made is peculiar in many respects: it is a fixed one, has no elasticity, and is utterly unsuited to a progressive state of society. Time was when poisons of the subtlest nature were passed about to *savans* in morsels, as cabinet specimens; these are now manufactured by the ton, handled in the daily occupation of thousands, and toyed with by children. Time was, when dangerous gases, which are now employed in nightly exhibitions, were produced in test tubes, and, even thus, astonished large audiences. Time was, when explosive compounds were treated with respectful caution; whilst now the momentary loss of a batch of lives through careless handling may, perhaps, elicit a sigh, but excites no extraordinary emotion. What is our deduction from these facts? Wherever vast progress is made in scientific discovery, and profitably employed for the public good, evil is also at work, and human life becomes endangered proportionately; for its protection, therefore, a higher order of intelligence, education, and practical science is demanded to meet the exigencies of the case. The Prussian and French codes provide for this altered state of things to a great extent; and a time must come when the Legislature will see the necessity of requiring specific and practical knowledge of Medical Jurisprudence, with its cognate sciences, in those to whom fortune, life, and fame are in a great measure confided, as Coroners of our country. I have offered you acknowledged qualifications without the smallest amount of local interest; but here, local interests must necessarily override the merits of the case. To follow up the matter, then, under such circumstances, would involve the employment of a complicated and costly machinery, generally reserved for elections of another kind; indeed, I could not undertake a personal canvass of a numerous and scattered constituency without other objects in view than the occupancy of the office in question. Trusting that your future Coroner may be gifted with all those qualifications, and supported by all that influence necessary for the conscientious performance of his responsible duties, I am, Gentlemen, your obedient servant, GEORGE KEMP, M.D. Cantab., Fellow of the Cambridge Philosophical Society, Hereford, December 27, 1864."

ANTHROPOLOGICAL SOCIETY OF LONDON.—At a meeting of this Society, on January 17, J. F. Collingwood, Esq., Vice-President, in the chair, ten new members were elected. The following papers were read:—1. E. Sellon, Esq., "On the Linga Puja, or Phallic Worship of India." 2. W. T. Pritchard, Esq., F.R.G.S., F.A.S.L., "Notes on Certain Anthropological Matters connected with the South Sea Islanders." 3. Edward Lund, Esq., F.R.C.S.E., "On the Occurrence of Syphilis in a Monkey," communicated by Dr. F. Royston Fairbank, Loc. Sec. A.S.L. "To Frederick Royston Fairbank, Esq., Local Secretary to the Anthropological Society of London, etc., etc. Manchester, June 13, 1864. Dear Sir,—The only remarks I have to make in sending you these specimens of diseased bone from a monkey, for exhibition at the next meeting of the Anthropological Society of London, will refer to the manner in which I became possessed of them, and the inferences which I think may be drawn from the appearances which they present. Some months since, a person, who is in the habit of preparing skeletons of animals, stuffing birds, etc., for museums, called upon me to say that he had the skeleton of a monkey which had died of syphilis, and that the state of the bones indicated the constitutional effects of that disease, and that I might have the skeleton, or the greater part of it, if I liked. He further stated that the penis of the animal had been almost entirely destroyed by ulceration, that the hair had fallen off in patches from several parts of the body, and that the frontal bone, as well as some of the long bones, were completely carious. On inquiry at the Zoological Gardens at Belle Vue, near Manchester, where the animal had died, I learned from the man who for many years had had charge of the monkeys, that it was quite a generally believed opinion that these animals are occasionally the subject of syphilis, or of some disease attended by ulceration of the genital organs, and propagated by sexual intercourse. He pointed out to me, in the same collection as the one in which the male animal had died, a female monkey which he said was so affected; and as far as I could observe, the vulva was surrounded by several rather large condylomatous growths, attended by an abundant sero-purulent discharge. The cage in which these animals were placed was rather small in proportion to the number of inmates, and other cages and dens being in close proximity to it, the ventilation was imperfect, and the general arrangements not such as to conduce to the health and constitutional vigour of the animals. Now it is well known that animals, such as monkeys, when kept in menageries, are very liable to die from strumous disease, especially from tubercular pulmonary consumption, and we have here in this particular instance an illustration of how far cohabitation under circumstances unfavourable to health may engender a cachectic state in which the genital organs are diseased, and that this condition may be regarded as the first step in a degeneration which, by frequent repetition, would at last culminate in true syphilis. I am aware that a theory has been promulgated, that struma in infancy and early youth is but syphilis diluted through many generations, manifesting itself in a distant offspring; but this assertion has not, to my knowledge, been sufficiently supported by observation as to be in any way accepted. Syphilis and struma are both cachexiæ, both are due in some way to defective nutrition or to imperfect vital power, and always aggravated by the persistence of those external conditions which are at variance with the laws of health. It would seem, therefore, as if animals pent up in small cages, and cohabiting promiscuously together, as monkeys are so prone to do, might form in the vitiated secretions of their genital organs a *materies morbi* communicable among themselves, capable of absorption, and, by poisoning the general system, of impairing the nutrition of the skin, the bones, and other structures. I do not say that a poison similar to that of syphilis can always be so produced, but I think the circumstances here briefly narrated will suggest the idea that the essence of such a disease as syphilis was originally developed through these agents, and that it would be more likely to have occurred among the closely-packed members of large communities, whether of animal or of human beings, than among the denizens of the forest or the plain, or the untutored specimens of savage life. I send you with this five of the long bones of the creature, the lower jaw and the skull, but the latter, as you will perceive, has been very clumsily mended with putty or some other cement; and if these specimens should be considered worthy of a place in the Museum of the Society, I shall have great pleasure in presenting them for that purpose.—Believe me to be, dear Sir, very truly yours, EDWARD LUND, F.R.C.S.E., Lecturer on Anatomy, etc., etc." The subject of the above report was a "Chinese bonnet monkey," *Macacus Sinicus*.—F. R. F.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Dr. Lionel Beale's "Remarks upon Dr. Benee Jones's Preface to Lectures on Chemical and Mechanical Diseases" shall appear next week.

A Subscriber.—Being registered as a Surgeon, he could recover according to his registered qualification.

Mr. H. P. Chandler.—The Children's Hospital, the Infirmary for Scrofulous Children at Margate, and the Home for Cripples.

M. P.—Dr. Freind was elected Member of Parliament for Launceston, Cornwall, and, on suspicion of working for the restoration of the Stuart family, was committed to the Tower

Ovariotomist.—Dame Mary Page, wife of Sir Gregory Page, Bart., was tapped sixty-six times in sixty-seven months, and had 240 gallons of water taken away. Dr. Mead was the first who introduced the bandage after the operation.

Dr. Mapother.—It is perfectly possible for a work to show great ability in its construction, and yet to have great faults in plan or purpose. The physiological work in question is doubtless very convenient to gentlemen preparing for examination; it may serve to refresh the memories of those who have learned already from broader and deeper sources, but it is not a good book for the educated public, nor yet for students beginning their career.

The Daly Case.—The office of sitting in judgment on one's brethren (though, it will be said, one daily exercised by the press) is exceedingly difficult, and it behoves those who, like ourselves, constitute themselves guardians of the privileges of Medical men, to see that no precedent is set which is liable to abuse. Trial by a jury of equals, every one of whom may be challenged, or by a judge of known position and responsibility, who can be removed for abuse of power, are the models. We have every respect for the Medical assessor to Mr. Farnall, but possibly every Poor-law Commissioner might not choose so good an adviser.

The Bedroom Spray Fountain.—It is well worth our readers' while to examine an ingenious little instrument, costing a shilling, which we have seen at Messrs. Piesse's, in New Bond-street, and at Rew's, Regent-street, and other chemists'. It consists of two glass tubes, meeting at a right angle. By blowing through one, a vacuum is created over the mouth of the other, which causes an upward current through it. If the latter be immersed in any perfumed solution, it is capable of raising it so that it may be dispersed in a fine vapour throughout the apartment. We recommend the instrument or toy, call it which you please, not only in order to perfume the apartments, but to illustrate the phenomena of the barometer, watersponts, etc. Could not some clever fellow apply the principle to smoky chimneys, and to ventilation generally?

Erratum.—In the article in our last number, entitled "The Medical Trial at the Holborn Workhouse," *for* "Mr. Ferrall," *read* "Mr. Farnall."

Pryce *v.* Bowen.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—By inserting the following names of additional subscribers to the "Bowen" Fund, you will oblige Yours, &c.,

H. D. Scholefield, M.D., &c., Treasurer.

14, Hamilton-square, January 17.

Dr. Vale, £1 1s.; Dr. Purdon, £1 1s.; Dr. Selwood, £1 1s.; Dr. Skinner, £2 2s.; Dr. Dobie, £1 1s.; Dr. Fenton, £1 1s; Dr. Higgins, £5; J. Pennington, Esq., 10s. 6d.; James Rowlands, £1 1s.; E. Parker, £1 1s.; J. W. Foulkes (chemist), £5; John Green (chemist), 10s. 6d.

Report on Cheap Wine.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I am sorry not to be able to continue this Report this week. Meanwhile, in acknowledgment of several correspondents, let me say—*A Dry Man's* capital story as to the use of Tokay in hysteria shall not be forgotten.

Acidity of Wine.—Correspondents who write on this are referred to Bence Jones's translation of Mulder on "Chemistry of Wine." Also to Sutton's "Manual of Volumetric Analysis," and to Griffin's chemical works, published in Bunhill-row, London. Messrs. Griffin supply standard solutions of soda, etc., with burettes and finely graduated glasses for estimating the quantity of standard solution of soda of known strength required to saturate the acid in a measured quantity of wine.

The table of Lowitz, for finding the quantity of alcohol in spirits of various density at different temperatures, is to be found in "Turner's Chemistry," Organic part. Fownes's table is in Brande and Taylor's "Manual of Chemistry."

Beta writes thus:—"Since the writing of these valuable articles I have tried Bordeaux in erysipelas, when otherwise I would have given port and brandy, and I was delighted with the result, and so was my patient. The attack could not well have been more severe; it was in a delicate lad, and extended over the whole body, and was attended with vesications"

The address of the Beaujolais Wine Company is 10, Pall-mall East, and 23, Rood-lane, E.C. I am, &c.

Your Commissioner.

The Treatment of Varicose Veins.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—As a subscriber to your journal from its commencement, will you allow me to make an observation relative to the treatment of varicose veins? In your number of Saturday last, under the head of "King's College Hospital," page 38, I see there is a method practised of subcutaneous ligature on a new plan. It may have advantages over the ordinary ligature of a pin thrust under the vein, and then a thread twisted from right to left so as to secure the vein; but I have a great dread of applying ligatures in these cases, having seen so many fatal cases in the Paris Hospitals thirty years ago from the practice. One Surgeon, now Professor de Clinique, I saw in one week apply the ligature in the way I have described to three patients, all of which cases proved fatal. In the first case, death ensued on the third day; the second, about the same time; and the third, in forty-eight hours On a fourth case presenting itself, I remonstrated on what I believed would have been equally unfortunate, when nothing more for that time was done. I have seen the practice on other occasions terminate quite as unhappily; therefore, let Surgeons be very careful they do not fall in with the same misfortune.

I believe varicose veins can be frequently cured by a much more simple process. I know I have succeeded in former days by a treatment an old cobbler (in a Norman village where I resided years ago, and which I accidentally stumbled upon) gave me. It consists of a saturated solution of alum and sulphate of copper, equal parts; compresses kept constantly applied to the veins. In twenty-four hours the veins become inflamed and hard; and the result was a cure. I have given you this in a rough and slovenly manner for you to make what use of you please—not from any wish to throw discredit upon Mr. John Wood's treatment, but merely to put him and other Surgeons on their guard. I remember that fine old Surgeon, my friend Marjolin, used to say forty years ago, "Be careful how you make a wound, even with a pin. Remember there is no such thing as a small Surgical operation: all are alike attended with risk."

APPOINTMENTS FOR THE WEEK.

January 21. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

Metropolitan Association of Medical Officers of Health, 7½ p.m., Meeting.

Royal Institution, 3 p.m. Prof. Marshall, "On the Nervous System in Man and Animals."

23. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

Medical Society of London, 8 p.m. Dr. James Jones, "Inflammation as an Exciting Cause of Tuberculosis."

24. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

Ethnological Society of London, 8 p.m. Mr. Wallace, "On Civilisation in North Celebes." Professor Busk, F.R.S., "On Human Remains from Gibraltar."

Royal Medical and Chirurgical Society, 8½ p.m. Dr. Dobell, "On the Natural History of 'Winter Cough.'" Mr. T. Longmore, "On Osteomyelitis consequent on Gun-shot Wounds."

Royal Institution, 3 p.m. Prof. Tyndall, "On Electricity."

25. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

Hunterian Society (Council Meeting, 7 p.m.), 8 p.m. Mr. Bryant, "On Some Cases of Herpes-Zoster Passing the Median Line."

26. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Royal Institution, 3 p.m. Prof. Tyndall, "On Electricity."

27. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m. General Sir Henry Rawlinson, "On the Results of Cuneiform Discovery to the Present Time."

MESSRS. CURTIS & Co.

Were the largest Exhibitors of Pharmaceutic Preparations at the International Exhibition of 1862, in conjunction with the Pharmaceutical Society, which obtained the Prize Medal.

In returning their grateful acknowledgments for the many encouragements bestowed upon them during a period of twenty years, Messrs. CURTIS & CO. beg to assure their numerous customers that every endeavour to maintain their reputation will be made on their part which industry and a due regard to the progress of Pharmacy alone can sustain. Among the numerous specialties recently introduced, the following are the most prominent, and bear Medical testimony as to their curative properties :—

GRANULAR EFFERVESCING CARBONATE of IRON.
GRANULAR ,, ,, of LITHIA.
GRANULAR ,, CITRATE of CINCHONINE.

LIQUOR SECALIS CORNUTI.—(Recognised Preparation.)

THE PRICE OF THE LIQUOR IS REDUCED TO 10s. PER POUND.

Exhibited at the "Obstetrical Society of London," by the President, June 1st, 1859.—Vide "The Lancet," July 11th, 1859.

University College Hospital, Oct. 28th, 1858.
I have much pleasure in stating that, after numerous trials under Dr. Murphy's direction, I have found the Liquor Secalis, as prepared by Mr. Curtis, to *far exceed* all other preparations of the kind.—HENRY HEMSTED, M.R.C.S.

Reigate, Feb. 2nd, 1862.
Gentlemen,—I have used your Liquor Secalis Cornuti for a considerable time, in a rather extended practice, and I am quite satisfied of its efficiency, and can recommend it with confidence to any of my Professional friends.
Messrs. Curtis and Co. Yours truly, JOHN SISSON STEELE.

January 21st, 1862.
Gentlemen,—I have great pleasure in testifying to the value of your Liquor Secalis Cornuti. I have used it extensively in obstetrical practice, and have found it to be exactly similar in effects to ergot itself, and to be of the relative strength announced by you. Since I first used it I never think of recurring to the tinctures formerly in use, or to the ergot itself.
Yours, &c., EDWARD NICHOLSON, M.R.C.S., F.C.S.,
Late Resident-Accoucheur to St. Mary's Hospital,
Messrs. Curtis. Paddington.

Clarendon-square, Feb. 4th, 1862.
I am constantly in the habit of using Messrs. Curtis and Co.'s Liquor Secalis Cornuti, and invariably find it give satisfaction.
JOHN WRENTMORE, M.R.C.S.

3, Jeffrey's-terrace, Kentish-town-road, Dec. 28th, 1861.
Having for some time prescribed the Liquor Secalis prepared by Messrs. Curtis, of Baker-street, and having on all occasions found its action to be most speedy and certain, I have much pleasure in bearing testimony to ts efficacy in all those cases in which the drug itself has a beneficial effect.
H. G. KNAGGS, M.D.

15, Wimpole-street, Cavendish-square, May 8th, 1862.
Gentlemen,—The Liquor Secalis I had of you some time since has succeeded so admirably that I am induced to give my opinion in writing, and you are at liberty to make any use of my name you may think proper.
I remain, Gentlemen, yours faithfully,
Messrs. Curtis and Co. J. WHITMORE.

49, Welbeck-street, May 12th, 1862.
Messrs. Curtis and Co.'s Liquor Secalis Cornuti, in my opinion, possesses all the virtues of the ergot itself. G. BIRD, M.D.

CURTIS & CO.'S INHALER.

Recommended by Dr. QUAIN *and others.*

This INHALER, invented by CURTIS & Co., CHEMISTS, 48, BAKER-STREET, LONDON, W., is in extensive favour with the Profession. To be had at the Manufactory, and of all Chemists and Surgical Instrument Makers in the United Kingdom.

Vide "Med. Times and Gaz.," Dec. 14th, 1861; "Dublin Med. Press," Jan. 29th, 1862; "British Association Journal," Feb. 22nd, 1862.

COMPOSITION OF **PASMA.**

Aluminiæ Oxyd. ..	6
Ferri Prot-Oxyd. ..	3
Amylum Oryzæ	50

PASMA, or HEALING POWDER,

The REMEDY for EXCORIATIONS, BURNS, ULCERS, and ERUPTIONS; also a PROPHYLACTIC of ABRASIONS in DELICATE, TENDER, and IRRITABLE SKINS. For the NURSERY this POWDER will be found INVALUABLE.

This preparation, during many years, has been submitted to the test of Professional experience, and is now confidently introduced to the Medical public as possessing Healing Properties *of a most marked and rapid character*, and on that account as meriting publicity and a place in every Hospital and Surgery.

PLASMA, or PASMA cum GLYCERINÂ,

ORIGINATED BY CURTIS & CO.

48, BAKER-STREET, LONDON, W.

ORIGINAL LECTURES.

LECTURES ON
CHEMICAL AND MECHANICAL DISEASES AND THEIR RELATIONSHIP.

By H. BENCE JONES, A.M., M.D., F.R.S.

Lecture I.
ON DISEASES OF SUBOXIDATION—DIABETES.

(Continued from page 58.)

On the Complications that occur in Diabetes.

There is no special complication belonging to diabetes, unless it be cataract. Generally it may be said that all the accidents of the disease are not owing to the diabetes, but to the debility which that diabetes produces. Thus, imperfect nutrition of the skin occurs, as in lepra, boils, carbuncles, mortification; or imperfect nutrition of the mucus membrane, as in irritations of all the mucous surfaces; or imperfect nutrition in the basement membranes or parenchyma of organs, as in phthisis.

Usually diabetic patients are exempt, in consequence of debility, from acute inflammations, and from stone and dropsy on account of the diuretic action of the sugar.

The experiments of Drs. Kunde, Mitchell, and Richardson on the production of cataract artificially by loading the blood with sugar furnish the most perfect demonstration of a chemical condition of the blood producing a mechanical alteration of the structure of the lens. In the early part of this lecture I dwelt on the reverse relation of chemical to mechanical disease—that is, on the injuries of the nervous system causing diabetes, and in this formation of cataract we have diabetes producing a mechanical complaint; and this complication occurs in nature so frequently that the connection has been observed by many Physicians.

Although only one direct complication of diabetes exists, yet the debility induced by the saccharine diathesis gives rise to many other diseases. It must, however, be remembered that debility arising from any other cause will give rise to exactly the same complaints.

The following remarkable cases will bring before you one of the frequent terminations of diabetes. A young lady, aged 19, passing four quarts of urine, specific gravity 1048, had probably been diabetic for twelve months. She gradually was growing weaker, when a sudden prostration of strength took place. After stertorous breathing for three hours, she became conscious, remained so for ten or twelve hours, again became comatose, and in twelve more hours she died.

A man, aged 36, came to me from Reading. He passed eight or ten pints of urine, specific gravity 1030, containing twenty-five grains of sugar to the ounce. He spoke of being able to walk two miles. On his return the same day from London, he passed a very restless night, and in the morning his breath was hurried; his pulse very quick and very weak. There was great inclination to stupor, though when aroused he was quite clear. He gradually became comatose, and died in thirty-six hours from his return home.

A gentleman came from Vichy in a very debilitated state. He had been three years under my care. His appetite was very small, and his emaciation and weakness very great. By great quiet he was regaining strength, when he was suddenly seized with nausea, and vomited once in the evening. He passed a very restless night, with retching and extreme debility. I went early in the morning to him, and found him comatose; and within twenty-four hours of the first sickness he died insensible.

A young lady, aged 15, with urine specific gravity 1055, came eighty miles for advice, and returned the day after. "The journey prostrated her to the most frightful degree." "She was unable to help herself in the least." During this extreme illness the diabetic symptoms disappeared. By no test could sugar be found. After a few days of the greatest danger, she gradually improved; the urine became five pints in twenty-four hours, sp. gr. 1041. Six months afterwards the specific gravity was 1022. Sugar was present, but the general symptoms were better.

In other weakening diseases the same attacks of prostration occur, and are often fatal. I went into the country to see a gentleman, about 45, who for some years had been my patient with dyspepsia and wasting; and perhaps latterly he may have had miliary tubercles in the lungs, I found him drinking port wine after dinner; hardly able with help to put on his coat when I had taken it off to examine his lungs. He was fearfully emaciated, but able to walk a few minutes in the air daily. Seeing his weakness, I examined him with the least possible fatigue. A few hours after I left him he complained of excessive feeling of debility. He gradually became comatose, and died in twelve hours after my visit.

Almost every month, at St. George's Hospital, during my admission week, I was able to trace the fatal effect of even very short journeys in very low states of different diseases.

The next consequence of extreme debility produced by diabetes that must be noticed is the deposit of tubercles. Phthisis has been considered as one of the necessary results of diabetes, but this is very far from the truth. When the nutrition of the body is feeble, tubercles are always ready to form, and every cause of feeble nutrition, not diabetes alone, produces a tendency to tubercular disease. Thus phthisis is not a secondary, but a tertiary result of diabetes. The imperfect nutrition produced by the sugar in the blood and extra-vascular tissues is the root of the evil. Among the rich, who can afford every strengthening food, phthisis is comparatively a rare ending of diabetes. Still, it occurs sufficiently often to prove how helpless medicine is to promote the nutrition of the body when the nutriment itself becomes a poison.

Another consequence of the feeble nutrition of the body is degeneration of the kidneys. Bright's disease may doubtless precede diabetes, although I have never seen this sequence. The reverse very frequently occurs; in the progress of the diabetes at varying times traces of albumen may be found, and gradually with great fluctuations the albumen increases, and ultimately the two complaints modify one another, so that I am accustomed to think sometimes that it is better to have these two diseases together than either of them separately. The increased flow of urine produced by the diuretic action of the sugar compensates for the imperfect filtration effected by the diseased cortical structure of the kidneys; and for years I have watched the diabetes stationary or lessening, or occasionally disappearing, whilst the Bright's disease slowly increases and causes its secondary or tertiary symptoms which gradually destroy the patient.

On the Treatment of Diabetes.

Almost every substance in every Pharmacopœia has been tried as a specific for diabetes; but hitherto no remedy has been found to have a constant effect in stopping the sugar from appearing in the urine.

This by no means renders it impossible or improbable that some substance may be discovered which may be able to effect a perfect cure of this functional disorder.

Meanwhile the effect of diet is far beyond that of any known remedy.

An antifarinaceous, or, in other words, an antisaccharine diet will remove the sugar from the urine, and stop all the symptoms of the complaint in all those cases in which the power of consuming the animal sugar remains unaffected.

Even when the consumption of the animal sugar is imperfect or impossible, an antisaccharine diet will lessen the thirst, the flow of water, the dryness of the mouth, and even the constipation, and check, though it may not stop, the waste.

The simplest formula for the diet may be thus stated. All animal produce, including fish, flesh, fowl, game, eggs, cream, and meat soup should be taken; and all vegetable food that contains starch, dextrin, and sugar should be avoided.

As generally it is of the utmost importance to shun the forbidden food, I shall dwell upon it first.

The vegetable substances that contain most starch, dextrin, and sugar are rice, maize, arrowroot, sago, potatoes, oatmeal, peas, beans, bread, biscuit, toast, maccaroni, vermicelli, and all confectionery.

Fruits are even worse than vegetables. Apricots, plums, peaches, cherries, pears, gooseberries, are nearly as bad, and some worse, than rice and maize. Stout, porter, and ale, cider, port, Madeira, champagne, and sherry are more or less highly saccharine; cocoa and chocolate contain near 20 per cent. of starch and dextrin naturally, and more is often added.

The harm of each of these substances may be determined by the amount of starch, dextrin, and sugar they contain.

The following table, in which the fruits and farinaceous vegetables are taken as perfectly dry, will answer many questions regarding the diet of a diabetic patient :—

	Amount of Starch, Dextrin, or Sugar.
Ripe dry Apricots . .	about 93 per cent.
,, Plums. . .	,, 92 ,,
,, Peaches . .	,, 86 ,,
,, Cherries . .	,, 85 ,,
,, Pears . . .	,, 84 ,,
,, Figs . . .	,, 79 ,,
,, Gooseberries .	,, 37 ,,
Dry Rice	,, 90 ,,
,, Maize	,, 88 ,,
,, Arrowroot . . .	,, 77 ,,
,, Potatoes . . .	,, 76 ,,
,, Oatmeal . . .	,, 70 ,,
,, Peas	,, 67 ,,
,, Beans	,, 67 ,,
,, Bread	,, 61 ,,
,, Milk	,, 21 ,,

Stout . .	about 45 to 64 grs. of sugar per ounce
Porter. .	,, 23 ,, 40 ,, ,,
Ale . .	,, 12 ,, 45 ,, ,,
Sweet cider.	,, 18 ,, 44 ,, ,,
Port . .	,, 16 ,, 34 ,, ,,
Madeira .	,, 6 ,, 66 ,, ,,
Champagne.	,, 6 ,, 28 ,, ,,
Sherry .	,, 0 ,, 12 ,, ,,

If dry rice contains 90 per cent. of starch, dextrin, and sugar, and potatoes contain 76 per cent. of starch and dextrin, and if all the starch and dextrin pass off in the urine as ugar, it is evident that to forbid potatoes and to allow instead an equal quantity of rice is simply ordering the quantity of sugar from this source in the urine to be increased 14 per cent., thus adding to the thirst and waste. Or if half-a-pint of port wine is forbidden eontaining from 128 to 272 grs. of sugar, and if a pint of porter or stout is ordered which contains from 368 to 960 grs. of sugar, it is clear that the quantity of sugar in the urine will thus be increased from half-an-ounce to an ounce and a-half daily.

Before passing to the best diabetic diet, there are two substances—bread and milk—which require to be further mentioned here.

Ordinary bread contains water, salts, starch, dextrin, sugar, and gluten.

If the salts, starch, dextrin, and sugar are washed away, the gluten remains, which, in a chemical point of view, is as unobjectionable as meat.

In making the different kinds of gluten bread this washing is more or less perfectly performed.

In the following analysis the water, starch, dextrin, and sugar were determined, the residue or difference was taken as gluten :—

	Water.	Starch and Dextrin.	Sugar.	Gluten.	
Ordinary bread .	36	40	1	23	per cent.
Aerated bread .	37	42	2	19	,,
Gluten bread from Toulouse . .	2	16 to 44	0	82 to 54	,,
Dried bread . .	2	60	1	37	,,

The best washed gluten bread contains less starch than bran cakes or any brown bread ; Dr. Pavey's almond bread is free from all starch, but the almond flour must be well washed to remove the sugar and dextrin, of which ten per cent. are present.

Badly-washed gluten may be made into dry bread containing bulk for bulk more starch than ordinary undried bread ; thus an excess of gluten bread may keep up the amount of sugar in the urine, and prevent an improvement in the symptoms.

With regard to milk, one hundred parts may be taken to contain three parts of lactine, or about half-an-ounce of lactine exists in a pint of milk. If all of this animal sugar was incapable of being consumed in the system, milk would be nearly as injurious as an equal quantity of many wines, and the best sweet ale ; but experiment shows that this sugar is often partly or entirely consumed.

A diabetic patient lived upon butchers' meat alone for two days. The quantity of urine passed was forty ounces the first, and forty-two ounces the second day ; specific gravity, 1029·0. No trace of sugar could be found. He then took milk for two days ; the first day eighty-eight ounces, the second day ninety-nine ounces. The urine was forty-five and a-half ounces the first day ; specific gravity, 1024·1 : and the second day sixty-nine ounces ; specific gravity, 1011·9. Sixty-seven grains only of sugar were passed the first day, and twenty-three the second day.

At a more advanced period of the disease, when strictly animal diet did not cause the sugar to disappear from the urine, milk alone was again taken.

The first day 138 ounces of milk were drank ; the urine was 61 ounces ; specific gravity, 1030·5. The second day 88 ounces of milk were taken ; the urine was 34½ ounces ; specific gravity, 1027·8. The quantity of sugar in the urine was 854 grains the first day, and 414 grains the second day. At this time, on animal diet alone, one day 280 grains of sugar were passed, and the next day 600 grains.

Thus milk is more or less injurious according to the stage of the complaint. When animal sugar can be consumed milk is comparatively harmless.

In the advanced stages of the complaint curds or sour milk, with the acid nearly neutralised by potass, soda, or ammonia, would be as unobjectionable as gluten bread.

The following *carté* of the dishes suitable for diabetic patients is given by Professor Bouchardat to those who consult him ; and with a few alterations I consider it as much superior to any table I could draw up as French is to English cookery.

ENUMERATION OF THE DISHES SUITABLE FOR DIABETICS, ACCORDING TO THE OPINIONS PUBLISHED BY M. LE PROFESSOR BOUCHARDAT IN HIS "MEMOIR ON DIABETES." PARIS, 1859.

Important Remarks.

The farina of wheat and every kind of flour made from cereals or leguminous vegetables—in short, all farina must form no part of any sauce ; also raspings of bread. The farina of Martin, or the powder of gluten bread of Durand, or more simply the yolks of eggs, butter, or cream, must be used instead.

Sugar, caramel, carrots, onions, turnips are also forbidden.

All leguminous vegetables must be washed repeatedly, and, if possible, they should first be well dried and chopped up small.

Rochelle salt may be substituted with advantage for common salt in the seasoning of food.

The dishes marked with a query are only fit for some patients. The urine should be analysed after their use. (They should not be taken without express permission.)

Bread.

Sliees of gluten bread of Durand of Toulouse.
The same heated in an oven.
The same made of bran.
Various kinds of bread prepared with Martin's gluten farina when gluten bread is not to be had.

Soups.

Consomme without bread.
Broth without bread.
Cabbage soup.
Leek soup.
Poached egg soup.
Bisque soup without bread or flour.
Game soup.
Broth with cheese and olive oil.
Semolina soup. The semolina made from the gluten of Durand.
Vermieelli soup. The vermicelli made from the gluten of Martin.
New paste soup from the gluten of Durand.
Soup made from granulated gluten of Martin.
Soup with butter and semolina of the gluten of Durand.
Soup with butter and the pure gluten of Martin.
Soup with olive oil, garlic, sage, with semolina of gluten, or with pure granulated gluten.
Yolks of eggs and cream may be added to these four last soups.

Hors d'Œuvre, Warm.

Fresh eggs, sausages, cabbage sausages, sour kraut sausages, truffled sausages.
Pickled pork with cabbage, also with sour kraut. These should be washed in much water and well dried.
Pigs' feet à la Sainte Menehould, (?) or stuffed with truffles (?).
Black pudding. Ham. Ham and spinach.
Roast pork. Pork cutlets, fresh, simply dressed, or with mustard sauce, or with sauce piquante.

Forced meat balls of Troyes (?).

Fresh herrings with butter, or with sauce piquante. Dried herrings.

Fresh sardines. Fried oysters. Oysters dressed in the shell.

Black beetles with butter, garlic, and other herbs.

Hors d'Œuvre, Cold.

Oysters, white, English, Ostend, Marennes, and pickled.

Butter.

Pickled mackerel. Anchovy salad. Sardines pickled in oil. Salt herring with olive oil.

Olives. Stuffed olives. Artichokes with pepper.

Half slice of melon (???).

Ham salted or dried. Bayonne ham with jelly.

Lyons or Arles sausages. Bologna sausages. Troyes sausages.

Tongue. Wild boar's head. Prawns, Caviar. Lobster. Craw fish. Crabs.

All butchers' meat or pork smoked or salted with nitre and salt agree very well. They should have the salt removed by water, and be served in dry slices with olive oil or fines herbes.

Beef.

Boiled beef; with marrow; with cabbages; with well-washed sour kraut; with sauce piquante; with vinegar.

Beef-steak; with water-cresses; with beans; with anchovy butter; with Parmesan cheese; with cauliflower; with spinach; with chicory.

Roast beef; with the same things.

Fillet saute dans sa glace; with olives; with anchovy butter; with dry Madeira; with truffles; with pickle sauce, à la Bearnaise.

Minced beef with piquante sauce, or ribs of beef with the same.

Slices of palates of beef. Tongue with sauce piquante. Strasburg beef.

Lambs.

Larded lamb. Lamb sweetbread with truffles. Lamb chops.

Lamb with asparagus points; with spinach; with chicory.

Fricasee of lamb with mushrooms, without flour. The same with truffles.

Leg of lamb. Breast of lamb with aromatic herbs.

Mutton.

Leg of mutton. Mutton chops. Cutlets with mushrooms or truffles; with crumbs of semolina of Durand; with chicory; with spinach; with beans; with asparagus tops, à la Provençale.

Fillet of mutton pickled like a kid.

Small fillets grilled.

Kidneys on the skewer, or dressed with Malaga.

Breast of mutton with chicory.

Lambs' feet "à la poulette," without common flour.(?)

Veal.

Sweetbread larded with gravy; with chicory; à la financiere with truffles; à la poulette (butter, yolks of eggs without farina).

Mesentery of the calf in oil (very good).

Fricandau in gravy, or with chicory, or spinach, or lettuce, or French beans, or asparagus tops.

Calves' ears, plain.

Calves' head, plain or as mock-turtle.(?)

Calves' brains, with butter, or à la poulette, or fried with gluten flour.

Tongue in paper.

Cutlets in paper or grilled plainly; with truffles or mushrooms; with ham; with asparagus tops, chicory, or lettuce.

Veal kidneys. Omelette of veal kidneys.

Cold veal with jelly.

Entrees of Poultry.

Fowl or capon with coarse salt; with jelly; with oysters; with Tarragon; with broth or fricaseed with gluten flour; "à la tartare;" with truffles or mushrooms; with lettuce.

Chicken salad.(?) Mayonaise of chicken.(?)

Capon or duck with olives. Slices of goose with olives.

Pigeon à la crepaudine, with Durand's semola.

Gelantine of poultry.

Entrées of Pastry.

All these dishes should be prepared with gluten flour instead of ordinary flour, the best butter, and very fresh eggs.

Vol au vent of poultry; of sweetbread with truffles or mushrooms(?); of salmon turbot or codfish.

Petit pâtes with gravy; with ham, lobster, prawns, and oysters.

Entrées of Game.

Partridges in cabbage, or en salmis.

Fillet of partridges with truffles.

Woodcocks en salmis, or with truffles.

Snipes en salmis. Wild duck and larks en salmis. Larks with bread crumbs.

Larks "en caisse," also quails. Quails with lettuce. Teal en salmis.

Fillet of venison with peppered sauce, or with mushrooms.

Venison cutlet with truffles. Haunch of venison with sauce piquante.

Partridge salad. Purée of game with poached eggs.

Hashed hare.

Eggs.

Eggs stirred up. Eggs with Parmesan cheese, broiled with asparagus tips, or with truffles.

Poached eggs, with butter, with gravy or chicory, with spinach.

Omelette aux fines herbes, with truffles, with ham or sausage, with kidneys, with different kinds of cheese.

Omelette with hashed game.

Fried Fish.

In frying, ordinary flour should be replaced by gluten flour.

Fillets of sole. Plain sole. Whiting. Gudgeon. Smelts. Carp.

Fried oysters. Carp's roe. All fried fish. Fried legs of frogs. Fried crabs' tails.

Entrées of Fish.

Pike with caper sauce or oil.

Barbel "au bleu" with caper sauce or oil.

Trout. Barbel. Chub. Perch. Tench. Chub roasted with butter and herbs.

Dabs with caper sauce or oil. Turbot with capers or oil, with crumbs of semolina of Durand.

Turbot with lobster or oyster sauce. Salmon with capers or oil, with lobster or oyster sauce.

Salmon trout with capers or oil. Mayonnaise of salmon.

Sole aux fines herbes and au gratin with Durand's semolina. Sole matelotte Normande.(?)

Fillets of sole en mayonaise. Whiting with white wine and fines herbes. Fillets of whiting au gratin.

Mackerel à la maitre d'hotel. Smelts au gratin with Durand's semolina, and aux fines herbes.

Matelotte of carps or eel. Carp "au bleu," or with oil.

Eel à la tartare, or à la poulette. Mackerel roe en matelottes.

Herring with butter, or oil, or mustard sauce.

Cod fish à la maitre d'hotel, or à la Provençale, or with oil.

Ray with butter or caper sauce. Sea eel with oil or butter. Brill. Cod with oil or butter.

Mussels à la poulette or pickled. Frogs. Lobster salad. Crabs. Prawns; or beetles' or crab sausages.

All the sauces should be prepared with butter and the yolks of eggs, without flour or with gluten flour.

Salads.

Plenty of oil should be used and little vinegar, or it may be replaced by wine.

Lettuce with or without eggs. Romaine. Escarole. Chicory. Monks' beard.

Corn salad. "Scorsonere."

Watercresses. Celery (?). Green haricots. Cauliflower alone or with eggs.

Roasts.

Fillet of beef larded or roasted. Fillet of horse. Loin of pork.

Leg of mutton or lamb. Roast veal. Venison. Fowl or capon roasted.

Roast pigeon, duck, goose, turkey. Truffled turkey or capon.

Pheasant. Red or grey partridge truffled. Ortolan. Quail. Ruddock.

Snipe. Woodcocks. Thrush. Quails. Golden plover. Teal. Bec figues.

Several of these dishes may be garnished with watercresses, or chicory, or lettuce, or mushrooms, or bread of Durand's gluten in place of bread crumbs. Slices of gluten bread may be soaked in olive oil.

Entrémets of Pastry and other things to take the Place of Confectionery.

Gluten cake made as follows:—Something more than three-quarters of a pint of water; three and a quarter ounces of very fresh butter; a sufficient quantity of salt or bicarbonate of soda are mixed and made to boil; remove it from the fire,

and add rather more than eight ounces of flour of gluten; mix it well; beat it well on the fire to obtain a stiff paste; withdraw it from the fire, and let it cool for five minutes; then add, stirring violently, three very fresh eggs; divide into little cakes the thickness of the finger and the size of a plate; bake them in a slow oven for about half an hour.

Pancakes au gluten with Martin's flour and goose grease, or with semolina of Durand.

Wafers with flour of gluten or semolina.

Rum or Kerch jelly, or coffee jelly without sugar. Rum omelette without sugar with a little gluten flour.

Vanille omelette without sugar.

Light pastry answers very well with gluten flour, but sugar must be replaced by salt. In some cases the liquid part of the best honey, from which the solid injurious part has been removed, may be taken.

Gluten bread made with gluten flour. Take two pounds and a quarter of gluten flour; fresh yeast the size of a filbert, mixed with a little cold water; two pinches of kitchen salt; hot water at 96° F. (35° C.) to 104° F. (40° C.), in quantity sufficient to make a thin paste, which is to be put in a pan powdered with gluten flour or bran, and then kept in a warm place until it has raised. This may take from an hour to two hours, according to the heat. Then divide this paste, using gluten flour, into little rolls, which are to be baked like ordinary bread. When there is constipation one quarter the amount of bran may be added to the gluten flour.

Entremets of Vegetables.

Artichokes with butter; same without flour, or with oil; or à la Barigoule; or fried, or à l'Italienne; or à la Lyonnaise, without flour.

Cauliflower with sauce, either oil or gravy; au gratin, with Durand's semolina; with Parmesan.

Cabbages with butter or oil. Brussels sprouts with butter and oil. Lettuce with gravy or cream.

Asparagus with same or oil. Mushrooms with gluten semolina. "Salsifis" with sauce or gravy.

"Cardons" with gravy or marrow. "Morilles à la poulette." Truffles with Madeira or à l'Italienne.

Cucumbers well washed, or à la Béchamel with gravy or marrow. Celery with gravy, well washed.

Carrots cut very small, washed with much water, with gravy of meat.

All these vegetables should be washed by making them boil with the greatest possible quantity of salt water and drying them well.

Sweet vegetables, such as radishes, onions, turnips, may be used if they are cut very small and boiled with much water, and then well dried.

Coffee—Tea.

Mocha, slightly roasted, made with cold water without sugar. The same with cream, rum, brandy, and Kirsch.

Bourbon and Martinique coffee without sugar.

Pekoe tea à pointes blanches without sugar. Souchong.

Cream, rum, brandy, Kirsch may be added to the tea instead of sugar.

Petals of orange flowers, make like tea, without sugar.

Dessert.

Cream cheese without sugar. Neufchatel cheese, "bondon raffiné."

Cheese de Brie, d'Epounessés, or Auvergne, or Mont d'Or, or Gruyere, or Dutch, or Rochfort, or Pont Lévêque, or Chester, or Parmesan, or Stilton, or Silton, or Strakeno.

All should be dried, and without sugar.

In very rare cases, strawberries (?), peaches (?), raspberries (??), gooseberries (??), cherries (??), may be taken without sugar, either preserved by Appert's process or in brandy.

Fresh almonds, nuts, walnuts, young green walnuts in salt water without vinegar; the same dried.

Raw apples (??) and pears (??) may rarely, if ever, be taken.

Liqueurs.

Eau de vie de Cognac, de Marc. Kirschwasser. Jamaica rum.

Alcohol of Garus, diluted with orange-flower water, without sugar. Gin without sugar. Absinthe without sugar.

Wines.

Red.	*White.*
Avallon-Tonnerre.	Madeira.
Mâcon.	Marsala.
Beaune.	Chablis.
Côte Saint Jacques.	Pouilli.
Pomard—Nuit, old.	Girolles.
Chambertin—Clos Vougeot.	Nauchévre.
Châinette.	Mont Rachet.
Romanée.	Grave.
Hermitage.	Sauterne.
Bordeaux.	Côte Rôtie.
Médoc.	Hermitage.
Château Larose.	Sherry.
Saint Julien.	Rhine (?).
Château Lafitte.	
Cahors—old.	

The following general statement regarding the amount of sugar in wine and beer may be useful:—

	Amount of sugar in an ounce of fluid. Grains.		Grains.
In Sherry the sugar varied from	4	to	18
Port ,, ,,	16	to	34
Madeira ,, ,,	6	to	20
Malmsey Madeira ,, ,,	56	to	66
Tokay ,, ,,	74		
Samos ,, ,,	88		
Paxarete ,, ,,	94		
Cyprus ,, ,,	102		
Champagne ,, ,,	6	to	28
Sweet Cider ,, ,,	18	to	44
Bitter Ale ,, ,,	12	to	130
Porter ,, ,,	23	to	40
Stout ,, ,,	45	to	64

The fluids examined may be arranged in the following order, commencing with those which contain no sugar, and ending with the most saccharine:—

Geneva, Rum, Whiskey, Claret, Burgundy, Rhine, Moselle. These have no sugar. Brandy, Sherry, Madeira, Champagne, Port, Cider, Porter, Stout, Malmsey, Ale, Tokay, Samos, Paxarete, Cyprus.

(To be continued.

ORIGINAL COMMUNICATIONS.

REMARKS UPON

CERTAIN VIEWS RECENTLY ADVOCATED BY DR. BENCE JONES

IN A "PREFACE" TO LECTURES ON CHEMICAL AND MECHANICAL DISEASES.

By LIONEL S. BEALE, M.B., F.R.S.

There are few branches of inquiry more likely to advance Medicine than the study and investigation of first principles. We all desire to learn what actually occurs in the process we call nutrition, what really goes on in diseased nutrition, inflammation, etc.; how matters become oxidised, —in short, in what particulars the changes occurring in healthy and diseased living things resemble those going on in the external world, and in what they differ from them. We want to be taught what, in the present state of science, should be understood by the word "life." Is "life" but a modified form of heat and motion, or some power quite distinct from physical or chemical force? or is "life" made up of physical and chemical actions, and actions distinct from these (vital actions)? Again, does the "life" of one of the higher animals comprise phenomena distinct in their essential nature from those which make up the "life" of a monad? Do the vital actions going on in the latter approach more nearly to the phenomena occurring in the inorganic world than the actions which constitute the "life" of the former? Never were such questions more intensely interesting than at this present time,—never could they have been investigated with greater hope of success.

In considering a problem so vast and so difficult of solution, it would seem most natural to begin with the lowest, simplest living things, and advance from these to the consideration of the higher and more complex,— to inquire what goes on during the life of a monad or a microscopic fungus, or a single cell of one of the tissues—and then attempt the discussion of more complex changes. Instead of proceeding thus, however, many who express most positive opinions upon these difficult questions discourse upon the nature of the phenomena going on in the entire organism of man himself in his fully developed state. The inquiry is prefaced by some reference to force, and the constancy of its amount in the universe. Systems, and suns,

and worlds, and steam-engines, and mills, and wheels, and springs, and telegraphs, and furnaces are then referred to. The student has been told over and over again that in plants and animals the same forces are at work as in the inorganic world, and that the investigation of the laws of the indestructibility and correlation of force will explain much concerning the nature of "life;" while his attention is not drawn to the phenomena peculiar to living things which receive no explanation whatever from what is yet known of physical and chemical laws; and hence in the present day many are led to believe that the identity of *vital* and physical actions has been fully and completely established, although such an inference is not justified by any scientific observations or discoveries yet made.

In an interesting "preface" to some lectures on "chemical and mechanical diseases," published in the *Medical Times and Gazette* for January 7, 1865, Dr. Bence Jones makes some statements with reference to the changes going on in living beings to which I would draw the attention of Physicians and Physiologists. The following chemical and mechanical doctrines, expressed or implied in this paper, seem to me open to objection:—*By oxidation "used organs" are made soluble or volatile, to facilitate their removal from the body. Heat acts by dilating the capillaries, and thus permitting freer circulation. Cold acts by constricting the capillaries. The solid parts of the food increase chemical action in the stomach. Nutrition is a great chemical process. Nutrition and oxidation are always taking place in each particle of the human body during life.*

Dr. Bence Jones also remarks that,—*We are just ceasing to regard the nervous force as the origin of all the power in the body. We have ceased to look on the human machine as a creator of vital force.* I would ask, When was the nervous *force* regarded as the origin of all the power in the body, and the human machine as a *creator* of vital force?

I shall venture to offer a few observations upon some of the views entertained by Dr. Bence Jones, feeling sure that he, and indeed every one who enters upon an examination of the first principles of medicine, desires that every theory propounded should be subjected to the most careful investigation. Moreover, there are no questions better adapted for free discussion than some of those upon which Dr. Bence Jones offers opinions; and in certain instances he speaks so very confidently that I feel sure he would be pleased with criticism at the hands of those who have studied the same questions from a somewhat different point of view.

With regard to "the two great *chemical processes* of oxidation and nutrition," which are "*always* taking place in *each particle* of the human body during life," and which constitute the mainspring of those forces which are summed up in the word "life," I venture to remark:—

1. That nutrition cannot properly be termed a chemical process since the term "nutrition" implies much more than either physical or chemical change, or both, while there is no known chemical process or action which resembles the process of nutrition, as it occurs in things which "live."

2. Are oxidation and nutrition always taking place in each particle of the human body during life? There are tissues in the body which are never nourished and never oxidised after their formation is complete. Were it not stated in two distinct places, I should have doubted if Dr. Bence Jones really intended to say "each particle." I cannot conceive a statement less justified by what is known of the changes going on in living beings than the assertion that "oxidation and nutrition are always taking place in each particle of the human body during life." Every single texture of every living thing consists of matter in two distinct states, in which changes of a totally different kind are going on. I doubt if we can obtain from any organism a single piece of structure of any kind measuring $\frac{1}{500}$th of an inch in every direction which exhibits uniformity of structure and composition, or consists of particles all undergoing the same sort of changes. Take even a single epithelial cell; its outer part is dry, and hard, and passive, and dead; its innermost portion is soft, and diffluent, and active, and living. The latter alone is the seat of *vital* actions.

What is to be understood by a "particle" of the human body? If the tissues were composed of matter exhibiting the same character throughout, a "particle" might mean a small piece, of no very great size or definite form; if of a number of bodies like stones or pebbles, or bricks as in a wall, "particle" might mean one of these, and each might be said to consist of smaller "particles;" but the tissues are not so constituted. If "particle" stands for what is usually called "cell," such particle is not of the same character throughout, and is certainly not always undergoing the processes of oxidation or nutrition. If by "particle" is meant a smaller portion of one of these "cells," there will be in many tissues a number of particles differing in almost every character which can be assigned to them. Some capable of being the seat of nutritive operations and of most wonderful and perhaps rapid changes (vital), having nothing in common with mere physical and chemical actions; others so passive that they may retain their general character and composition for centuries, and, although capable of being altered by external conditions, have no power of assimilation or increase of their own. Every tissue and every cell is composed of two different kinds of matter, and the particles constituting each possess very different properties. Does "particle of the human body" refer to a particle of tissue or fluid, or a particle of "nucleus," ("proto-plasmic," or living matter)?" I would ask Dr. Bence Jones to state what he wishes the reader to understand by the term "particle of the human body."

3. "Nutrition and oxidation," two great chemical actions, "which constitute the *mainspring* of those forces which are summed up in the word 'life.'" By this I conclude Dr. Bence Jones intends to express the opinion that the forces which constitute "life" depend upon, or spring from or are the result of, the two chemical processes of oxidation and nutrition. Now, a thing must "live" *before* it can be nourished. The process of nutrition presupposes the existence of something *alive* to be nourished. Many lower beings, and many living cells from man himself, may "live" without nutrition or oxidation *always* going on; nay, it would, I think, be far nearer the truth to say that oxidation was opposed to vital forces rather than in part their mainspring. At any rate, there are beings to which, according to Pasteur, oxygen seems to act as a poison. "Life" may undoubtedly exist without either nutrition or oxidation always going on. Matter must surely not only live, but die before it can be oxidised in the body. Unless oxidation invariably precedes the manifestation of vital actions, it is difficult to understand how these can depend upon oxidation. Now, the developmental period is not remarkable for the activity of oxidation, although it is very remarkable for the activity of vital action. The doctrine that "chemical actions" constitute the "mainspring" "of those forces which are summed up in the word 'life,'" is a doctrine which is not supported by evidence, and in other communications I shall endeavour to show that chemical actions cannot form the mainspring of the "*vital* forces."

To say "that the resemblance of inflammation to ordinary combustion has long been recognised" is to assert a proposition with which, I venture to think, very few physiologists and pathologists in the present day would agree. Had I been asked, I should certainly have answered that the notion of the resemblance of inflammation to ordinary combustion had long been abandoned. In what points, I would ask, does inflammation resemble ordinary combustion? It seems to me that there are few processes more unlike, except in name, than inflammation and combustion, and if any one form of inflammation be selected for discussion, I am quite ready to support this view.

"We are beginning now to see that fevers bear the same relation to inflammations that fermentations do to combustions." Fermentation takes place through the agency of living beings alone, or, in other words, living things are necessary to what we call "fermentation;" but what is the relation of living things to "combustions"? Fever and inflammation, and fermentation are peculiar to living organisms, and cannot occur except in connexion with living organisms. Combustion, however, is opposed to, and destroys that which lives. It remains, therefore, for Dr. Bence Jones to show the relation to which he refers. I am not certain that I interpret properly the following sentence, so that it is but fair that I should forbear to criticise the statements it contains until the author has had an opportunity of defining his meaning more precisely:—"Thus oxidation depends on the nutrition of the blood-globules, the heart, and the blood-vessels which admit of the diffusion of the oxygen and the fuel into each portion of the extravascular structures; whilst nutrition depends on oxidation directly by transformation of force, and indirectly by the heat causing a relaxation of the vessels, and thus permitting an increased flow of nutritive substances to the parts."

ON THE NATURE AND TREATMENT OF CHOLERA IN THE COLLAPSED STATE.

By HENRY GREENWOOD, M.D. St. And., M.R.C.P. Lond.

In the laws of cholera it is stated:—"At the first appearance of the epidemic in 1832, and for many subsequent years, it was a subject completely shrouded in mystery; its nature was not understood, its movements were a riddle, and its proper treatment, even amongst the most scientific and experienced, was unknown." This statement is literally true, and the explanation is to be found in the fact that the attention of Medical men was diverted from a calm consideration of the phenomena of the disease to a wild search for an immediate remedy.

A review of the symptoms ought soon to have convinced any dispassionate inquirer that no remedy was applicable to the condition of collapse—that is to say, that no medicine administered to a person in that state was capable of removing it.

But the inquiry which would have led to this unsatisfactory result was also capable of affording important suggestions, and on them might have been founded a rational mode of treating cholera in the collapsed state.

I will just give the symptoms of cholera in the collapsed state, as described by Mr. Moss, of Windsor, "in words of terrible precision," to be found in a popular and highly valuable article on cholera, contained in the "British Almanack" of 1849:—

"It is characterised by vertigo, great prostration of strength, severe cramps in the legs or abdominal muscles, with loud and violent vomiting of large quantities of a thin gruel-like fluid, devoid of smell; at the same time forcible and most profuse ejections from the bowels of a precisely similar fluid, in such astonishing quantities as to show that all the watery portions of the blood are being drained off; the body becomes colder than an ordinary corpse, and often as pulseless; and the countenance far more cadaverous and ghastly than that of death under any other form of disease. The eyes are deeply sunk in their sockets, which are perfectly hollow from the abstraction of their natural fluids; the voice is a tremulous croak, or sunk to a deep sepulchral whisper; the breath strikes your cheek like the air from an icehouse; and the tongue feels like the touch of a frog. Different parts of the body assume a leaden hue, owing to the thick and stagnant blood of the cutaneous vessels shining through the attenuated skin, which is as cold and clammy as in the approach of death from low fever. When a vein is opened in the arm, the blood will rarely flow, and, on being squeezed out, has the appearance and consistence of treacle; add to this that the thirst is insatiable and restlessness extreme, and you will have a faithful portrait of a disease which none can fail to recognise or mistake for any other." A sense of heat and intolerance of heavy clothing must not be omitted.

Such are the phenomena which characterise the state of collapse, and a moderate consideration of them will very distinctly point out the cause of that state, and, at the same time, the hopelessness of finding a remedy.

The facts prove satisfactorily that the state of collapse is occasioned by the blood being so drained of its fluid portion as to be greatly diminished in quantity, and at the same time rendered incapable of free circulation by the thickened state to which it is reduced by that drain; so that there is not only an effect equivalent to that produced by large sanguineous depletion, but also another, arising from the difficulty of circulation in consequence of the inspissated condition of the blood remaining.

The state of a person in the collapsed stage of cholera is analogous to one who has lost a very large quantity of blood, with the additional evil that the blood remaining is unfit for circulation from want of sufficient fluidity. So that whilst in the case of sanguineous depletion reaction may be safely restored as quickly as possible by means of stimulants, in the condition of collapse it cannot be so without considerable danger, until sufficient time has been allowed for the absorption of fluid into the system to fit the blood for circulation.

The state in some degree resembles that of the frost-bitten limb, for though the causes differ the effect is nearly the same.

The condition in both cases is one of low vitality with suspended circulation, occasioned in one by the application of cold, in the other by the thickened state of the blood, and in both cases reaction may be encouraged by suitable means, but cannot safely be forced. Experience tends to confirm these views. The necessity of restoring the fluidity of the blood was recognised in 1849, and various means were adopted to effect this first condition of reaction. Transfusion was employed, and various forms of fluid were injected into the veins, but although early reaction was thus obtained, the cases ended fatally. On the other hand, it now and then happened that a person in an extreme state of collapse, who had been left to die quietly, after every means to induce reaction had been tried in vain, spontaneously revived, and eventually recovered, thus proving that the natural powers are capable of producing reaction, even under the most hopeless circumstances, and suggesting that the state of collapse, however dangerous in itself, is yet favourable to absorption, and therefore to eventual restoration of the circulation.

Having endeavoured to establish some principles of treatment, I will now attempt their application.

The necessity of restoring to a certain degree the fluidity of the blood before a beneficial reaction can be established, as suggested by the cause of collapse, would lead us to encourage absorption by every means in our power. There are indications, moreover, in the state of collapse to assist us in applying the most appropriate means. The excessive thirst, for which cold fluid, and especially cold water, is earnestly coveted, suggests a free supply of fluid, and as cold water is most agreeable to the sufferer, so it will also be found a very important agent in relieving the existing condition. Another indication is afforded by the great heat complained of, even during the coldest state of collapse, accompanied by intolerance of heavy clothing. This seems to indicate that fresh air and light covering are very likely to assist the absorption of fluid, and concur with the cold water in bringing about the gradual change required in the condition of the blood.

The general treatment that I would recommend in cases of cholera in the collapsed state consists in preserving the patient carefully in a recumbent position, allowing no exertion that can be avoided, and providing for the removal of all discharges without disturbance; in admitting the air freely, covering the bed lightly, and satisfying the thirst by giving cold water in small quantities at a time, frequently repeated; in avoiding all stimulants, whether external or internal, heat and friction especially included, and applying cloths wrung out of cold water to the parts affected by cramps instead of rubbing them.

It will be found that whilst by these means a great deal of annoyance is saved to the patient, and a great deal of trouble to the attendants, the probability of a favourable reaction is considerably increased. The only medicine I would recommend is a grain of calomel every hour until reaction is established. When reaction does take place and the patient rallies, the case must be treated as one of low fever, stimulants, however, being avoided until the period of dangerous congestion is passed, nourishment being supplied in the meantime principally by the use of animal broths in small quantities, at intervals of from two to three hours.

Besides the complete state of collapse of which I have been speaking, there occurred frequently in the attacks of 1832, 1833, and 1848, 1849, a state of incomplete collapse of a much less dangerous nature. It was characterised by great prostration and some of the symptoms of complete collapse, but the circulation was never suspended, though very depressed. This state was readily amenable to treatment, and after the early part of the attack in 1848, 1849, I saw no patient sink under it. The general treatment was as before directed; the Medical modified to suit the less dangerous condition of the sufferer. Thus the grain of calomel was administered only every four hours, followed by a tablespoonful of simple saline mixture until a proper reaction was established.

It is necessary to distinguish these two states, or rather degrees, of collapse, as by confounding them a much larger number of recoveries from cholera in the collapsed state appear to have occurred than really took place, and the varying degrees of success recorded by Medical men can be reconciled only in this way.

It is a melancholy fact, but in accordance with general experience, that of any given number of persons in the state of complete collapse a large proportion will die in that state, and of those who rally a considerable portion will sink during the period of reaction.

Thus, according to my own experience, of twelve persons in that condition six will die, and of the six who rally two will sink during the period of reaction, leaving only four, or one-third, who eventually recover.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

CENTRAL LONDON OPHTHALMIC HOSPITAL.

CASE OF MALIGNANT DISEASE OF THE ORBIT—CLINICAL REMARKS.

(Under the care of Mr. HAYNES WALTON.)

Malignant disease in the orbit is sufficiently rare to the mass of men in practice, to render the report of a case of the kind interesting, and even instructive, especially when we are able to report with it remarks by one so long engaged in ophthalmology as Mr. Walton. A single case is reported because there is, Mr. Walton says, so little variety in the symptoms objectively, or subjectively, as not to require several to illustrate the nature of the affection. The commencement, the course, and the termination are, he thinks, much alike in all; if there be any obscurity in the diagnosis in the first instance, it is shown alike by every example.

A female 40 years old was sent to Mr. Walton at the Hospital several months ago, with the eyeball a little prominent; there was no other symptom whatever. The orbital muscles acted in their full integrity, sight was perfect, and there was no pain. The duration of the disease, whatever it might be, was short. From this, the first interview, Mr. Walton expressed a suspicion of the existence of soft cancer, because of the apparent suddenness of the symptoms to the patient, which indicated quick growth, and the healthy state of the front of the orbital walls, as far as they could be felt, which showed that the protruding cause was behind, the position at which soft cancer is usually first detected, and because that form of malignant affection is more common there than any solid or cystic growth. The displacement of the eyes increased rapidly, still there was nothing more to substantiate the diagnosis, and yet Mr. Walton believed in the correctness of his opinion. In five months, when the eyeball was almost out of the orbit, and pushed below the natural level, a swelling, conveying the idea of a fluctuating tumour, was to be felt in the upper part of the orbit.

In consultation it was determined to make an exploratory incision into the supposed fluctuating mass, and this was done; no fluid escaped, but some of the orbital fat which had been thrust forward protruded and was cut off. The incision healed rapidly, but this trivial operation produced a still more rapid increase of the ocular protrusion, and now the orbit appeared filled with an elastic mass, which might be felt from any part of its circumference. Later than this, a large tumour covered by very attenuated and vascular integuments at the apex was jutting out of the upper portion of the orbit, and even now there was no pain, and there yet remained enough sight for the discernment of large objects. The general health was, however, much impaired, and the face presented the pale and peculiar look that so often accompanies the later stages of cancer. The patient left the Hospital because she was asked if she would submit to an operation, should it be thought advisable. She said that she would not be touched any more so long as she could see.

The two points which Mr. Walton selected for comment were the diagnosis and the treatment.

Respecting the first, he pointed out that when malignant tumours have a deep-seated orbital origin there is no peculiarity in the physical changes that they produce in the orbit, orbital appendages, or eyes, by which they can be at first distinguished from simple tumours in the same situation. That in some instances the rate of progress, or other peculiarities in any given case, may, however, produce the suspicion of malignancy at an early period; and when the tumour has approached the surface, or when the constitutional effects of the disease have become developed, the diagnosis is easy. On the other hand, we may have a tumour which, neither in its progress, early or late, nor in its appearance after extirpation, resembles any of the ordinary forms of cancer, but which recurs repeatedly, assuming at each recurrence a more decidedly malignant character till it destroys life,—this is the recurrent fibroid.

He mentioned that, except in one other instance, all the cases of soft cancer that he had seen made their external appearance at the inner side of the orbit. The eyeball has been more or less thrust aside, and sometimes forwards. Also that the characteristic of malignancy has, at a later stage, been manifested in the immobility of the tumour, and that the fixedness is more to be relied on for the nature of the disease, when the growth admits of examination, than any other symptom; and if disregarded, the absence of pain and the apparent health of a patient are apt to lead to a wrong diagnosis. This holds good when the cancer is dense to the touch, or of less firmness; only when there is a degree of softness that causes a feeling of fluctuation, may the ultimate attachment be more or less marked, or not easily made out, and the nature rendered very obscure. The sense of fluctuation was marked here.

As regards the treatment in an undoubted example of orbital encephaloid, he thought that Surgical interference was, as a rule, injudicious. In every case in which he had operated, or had been present when others have operated, it had either been impossible to clear the orbit without scooping the bones, or a portion of the cancer has passed out of reach through some of the orbital apertures. In no case, therefore, could the disease be said to have been removed. He proceeded to say that scarcely any one now-a-days would undertake to remove soft cancer with the idea of effecting a cure, for hardly is any fact better known than that the patient would soon die of the disease, in spite of all operative measures, and that when every particle of the diseased structure was not eradicated, as was impossible here, but, on the contrary, cut into, and when every stroke of the knife passing through the diseased parts opened up channels by which the cancerous germs are conveyed directly into the circulation, the patient's condition is rendered infinitely worse. He thought, however, that in such cases, after having made the patient fully aware of the danger of his position, and having explained that our interference is not with the hope of effecting a permanent cure, but merely with the view of averting impending death, it will be proper to deviate from the general principle, and to excise the tumour, removing at the same time the whole of the contents of the orbit, should it be judged expedient to do so.

KING'S COLLEGE HOSPITAL.

CONGENITAL CLEFT PALATE—CLOSURE OF THE FISSURE BY OPERATION.

(Under the care of Mr. FRANCIS MASON.)

In reference to this case Mr. Mason said that in introducing the stitches he had acted upon the advice, so often given by Mr. Fergusson, of not approximating the margin too closely, for should there be any subsequent swelling of the parts there would be sure to be a drag on the stitches, and sloughing would be apt to occur. In this case there was a space of a quarter of an inch between the edges of the wound in the situation of the front stitch; nevertheless, as the result showed, there was perfect adhesion at that part.

M. H., aged 17, was admitted into the Hospital, under the care of Mr. Mason, on August 29, 1864, with a congenital cleft palate, the fissure extending through the soft, and through nearly an inch of the hard palate. The patient was a strumous-looking girl, but enjoyed good health. She had had no hare-lip.

August 30.—Mr. Mason proceeded to close the fissure in the soft palate, adopting the method recommended and practised by Mr. Fergusson; three silk threads were introduced. The patient was ordered a generous liquid diet, and strictly enjoined not to speak.

September 2 (third day after the operation).—The stitches were removed, and union of soft palate found perfect. There remained, however, a small opening, about one-sixth of an inch in size, in the hard palate.

14th.—The parts having become quite firm, she was discharged to go into the country, and requested to return at a future time to have the hard palate closed.

BIRMINGHAM GENERAL HOSPITAL.

CASES OF CHOREA—CLINICAL REMARKS.

(Under the care of Dr. RUSSELL.)

Chorea shows well the danger there is in thinking of a disease as one of a nosological division. Although in one sense a disease of the nervous system, its frequent association with rheumatism shows that it would be a great error to work at it as a nervous affection only. What its precise association with

rheumatism may be is a question very much disputed. Some think that the rheumatic "poison," be it what it may, produces chorea by its direct effect on the nervous centres; others, as the late Dr. Kirkes, that the association is indirect—with organic disease of the valves of the heart. There is certainly very frequently a mitral murmur in chorea, but as to the interpretation of this murmur there are various and contradictory opinions. Dr. Walshe thinks it is frequently due to irregular action of the muscular apparatus of the valves. Other Physicians think that it is frequently due to organic disease of the valves themselves. According to the late Dr. Kirkes, vegetations are invariably found on the valves at post-mortem examinations of patients who have died of chorea. We have frequently heard Dr. Wilks and Dr. Andrew make the same remark. But admitting that the connexion is, as Dr. Kirkes believed, between valvular disease and chorea, and not directly between rheumatism and chorea, we have difficulties in explaining the manner of the connexion. The association of some other diseases of the nervous system—hemiplegia, for instance—with valvular diseases is, as Dr. Kirkes first pointed out, by embolism. It is possible that a similar explanation may hold good as regards chorea. Yet chorea, even when strictly unilateral, cannot be due to plugging of any main trunk, like the middle cerebral, or there would be actual paralysis. Dr. Kirkes believed that the direct causes of the motor phenomena of chorea were partly the circulation of morbid blood in the brain, and partly the temporary obstruction of the minute capillaries by fibrinous particles. Dr. Hughlings Jackson has suggested that the cause may be obliteration of the small branches supplying convolutions near the corpus striatum. It seems certain that there are convolutions in this region which have to do with guiding the muscles of articulation; and it may be reasonably supposed that there are others for corresponding actions of the muscles of the limbs.

The following cases of chorea, with remarks, by Dr. Russell, are valuable additions to the clinical history of chorea. It is most important to complete the clinical history of this disease, as it has wide bearings on the pathology of the nervous system:—

The first case is of interest by showing in a typical manner the presence of two factors, both of which are frequently in combined operation in producing the disease, viz., a depressed (paretic) condition of the nervous centres and remote irritation in the shape of valvular or other disease of the heart. This union of causes was especially insisted upon by Dr. Kirkes (*Medical Times and Gazette*, June 20, 1863) as very influential in producing chorea.

In this patient the cardiac affection, which was undoubtedly in part, if not wholly, connected with the preceding rheumatic fever, was closely connected with the outbreak of the chorea. On the other hand, the occupation of the patient, the protracted exposure to muscular effort day by day in a young and growing boy, and the obvious evidence of fatigue which his history affords, conjoined with his attenuated frame, afforded ample testimony to the existence of great exhaustion of cerebral and spinal power. To such exhaustion the highly emotional character of the boy fitly answered, and probably his sudden death must be in great part attributed to the same cause. In the post-mortem examination, although the pale softening of the nervous centres—noticed by Dr. Kirkes as observed in all the fatal cases of chorea examined by himself, and in a large number of those recorded by others—was not present; yet the emaciated condition of the brain, as shown by its separated convolutions and by the increase in the sub-arachnoid fluid, and also the empty state of the minute arteries of the brain and cord, fully answer to the same description of disease.

Chorea—Recent Peri- and Endo-carditis—Death by Fainting.

J. B., aged 14, a messenger of the Electric Telegraph Company. He was sometimes occupied for twelve hours, as a day's work, and suffered much from fatigue. He would come home quite fagged. He had, besides, a poor appetite for meat. He has been very much exposed to wet and cold, not only in his occupation, but also in consequence of very defective accommodation provided for the boys at head-quarters. His father is very rheumatic, and when a boy had chorea.

The patient had his first attack of rheumatic fever, after exposure, in September last. During the fever his side was blistered, and his doctor said that his heart was inflamed. He was confined to bed for a fortnight, and three days after he got up the chorea commenced. The movement at first affected the left side of the body; but whilst in the Hospital each side of the body seemed affected to an equal degree. He was much emaciated, exceedingly emotional, but very quick and intelligent.

The choreic movements at his admission, four days after the commencement of the attack, were very severe and general, implicating the muscles of the face and eyeballs, and at times rendering articulation unintelligible. In the chest the physical signs indicated the disease in the heart discovered after death, though Dr. Russell was not then aware of its full extent.

His amendment after his admission was very rapid, and for the first week was effected without the aid of medicine, the treatment being confined to rest in bed and nutritious diet; subsequently he took zinc, and then steel and cod-liver oil.

Unfortunately, he was sent too early to the Convalescent Institution, whence he returned with effusion into his chest and increase of the movements. He was confined to bed; but one evening he got up to go to the water-closet, and in returning fell forwards on his face, and was taken up dead.

Autopsy Sixty Hours after Death.—Considerable emaciation; general fluidity of the blood. The large veins of the pia mater were full of blood; a spot of ecchymosis, about the size of a sixpenny piece, existed on the left hemisphere. A considerable quantity of sub-arachnoid fluid lay over the surface of the brain, and the sulci between the cerebral convolutions were much increased in width. The vessels at the base of the brain were perfectly healthy, their branches quite pervious. The grey matter of the convolutions, Dr. Russell thought, was rather pale. Every part of the brain was beautifully healthy in structure; the edges of the sections were sharp, and not a particle of cerebral tissue adhered to the scalpel.

The tissue of the cord was equally firm and healthy. Dr. Russell examined by the microscope the spinal cord and one corpus striatum, and says:—"So far as my means of investigation extended, these organs were perfectly healthy, with one exception; that in each there was marked deficiency of blood in the minute vessels; the contrast in this particular between them and the corpus striatum of an old hemiplegic patient which I had examined the night before was most striking."

The heart presented the remains of recent pericarditis, in an universally adherent pericardium. The left ventricle was, besides, greatly dilated, and hypertrophied to a corresponding degree. A thin layer of lymph lay upon the lining of the left auricle, and the mitral valve was thickened and puckered at the edge. The pulmonary artery was perfectly free. The other organs were healthy.

A portion of the history of another case of chorea is added by way of contrast to the preceding, as it illustrates the operation of a cause which acted directly and solely upon the brain. Severe mental emotion, in the shape of fright, induced in a child constitutionally feeble, sufficed to bring on the disease almost immediately; the rheumatic and cardiac element being entirely wanting.

Chorea from Fright—Heart Healthy.

A. W., aged 7, a feeble child of a family apparently consumptive, but quite free from rheumatic tendency, has never suffered from rheumatism, unless some pain in his joints, which is relieved by rubbing, is to be referred to that disease. Ten months ago the child was taken to see his dead mother; he was impressed by the sight, but not mischievously. Two days after he was locked up in a dark room by a servant girl from noon till eight in the evening. His screams at last aroused the neighbours, and he was taken out through the window. Next morning, at breakfast, the boy looked ill; he shook in every limb, and was not able to hold his cup. This was the commencement of the chorea, from which he had never fairly recovered. His sleep was disturbed after the fright; he was afraid to go to bed in the dark, and screamed in his sleep. At the same time he lost his appetite, and his spirits were depressed. His memory also became impaired: "he seemed to lose his recollection of his learning," and "he gets very forgetful," and learns with difficulty. In all these particulars he has undergone a complete change.

The choreic movements have been confined to the right side. His articulation has never been affected. He is a very small-made child, with dark hair and eyes, thin, and delicate. Repeated examination fails in discovering any abnormity connected with the heart, save feebleness of impulse according with the general weakness of his body.

It may, however, happen that mental influence and cardiac disease may co-exist in the same subject. Of this the following case is an example. There can, however, be no hesitation

in assigning the alarm as the immediate cause of the chorea. The disease of the heart may not improbably date from the attack of scarlet fever in childhood, and doubtless co-operated with the other unfavourable influences noticed in the history to depress the power of the nervous centres.

Chorea after Fright—Mitral Disease of the Heart.

A. P., aged 17. Her family history and her own are quite free from rheumatic tendency, but her father was insane. She had scarlet fever when very young, but has never suffered from short breath until quite lately. She has been much confined at a very sedentary occupation, and has lived very badly: she looks dirty and ill cared for. Six months before Dr. Russell saw her she was on the water with a pleasure party, when the boat filled, and she was in danger of drowning.

The alarm effected an entire change in her mental condition; she became extremely nervous and timid; at times she has been hysterical, and "awfully passionate." Her nights have been unquiet, she dreamt vividly, and was deeply impressed by her dreams; one night she became persuaded that her sister's child was dead, and was with difficulty persuaded of the groundlessness of her fears. She has even been quite "wild." In all these respects her character has become quite unlike what it was before the accident. Her intellectual faculties, however, have remained entire.

Her aunt cannot fix the exact date of the commencement of the chorea; she never worked after one week from the date of the fright, but it was a month before she had Medical attendance: she was then declared to be suffering from St. Vitus's dance. On closer questioning, however, it was ascertained that a week after the fright she was obliged to leave off work because she could neither thread nor use her needle; she drew out the thread as fast as she put it in, or twisted it about.

The left side of the body was chiefly affected, the lips and tongue inclusive, so that articulation was impaired.

On examining her chest, a soft systolic bellows sound was heard at the apex of the heart; no bruit was present in the course of the aorta.

She perfectly recovered in seven weeks under morphia, tonics, and cod liver oil: her sleep also became sound. It is to be particularly observed that the bellows sound underwent no change after the cessation of the chorea.

THE LONDON HOSPITAL.

INVOLUNTARY EJACULATIONS FOLLOWING FRIGHT—SUBSEQUENTLY CHOREA.

(Under the care of Dr. HUGHLINGS JACKSON.)

THERE seems to be nothing more certain than that fright is often followed by chorea. The history is frequently too definite to leave it doubtful that there is some relation. For instance, a child at the London Hospital had chorea soon after seeing a man in an exhibition eat a live rat; another soon after her mother fell downstairs. In a third, the following case, there were circumstances which rendered it quite certain that fright had much to do with developing certain quasi-mental symptoms in a patient who a year later had chorea. Yet it is scarcely likely that fright can be considered as a sole cause. It could not, one would think, produce chorea nearly limited to one side of the body, as it is now and then. The probability is, that there is some previous enfeebled condition of the nervous system which renders it liable to suffer from undue excitement. At all events, fright produces chorea most frequently in those who have had rheumatism or who have valvular disease. What the condition of the nervous tissue in chorea is we have little evidence. Dr. Russell's examination was nearly negative in its results. Perhaps a minute examination of nervous tissue on Lockhart Clarke's plan might show some change in this motor tract or convolutions near it. So far as we know this has not yet been done. The recent researches of Dr. Beale lead us to hope that many obscure points in cerebral pathology will be at length cleared up. Now that he has succeeded in *working with* a fiftieth (*sic*) of an inch, we may hope to discover what the disease of apparently healthy tissue in such diseases as chorea is.

A boy, 13 years of age, was admitted on August 16 for twitching of the face. Five or six years before he had been frightened by a man shouting the word "bloody" after him. For three days and nights he kept saying this word continually, and for three weeks he said it very frequently. Ever since he has had the habit of ejaculating it occasionally. A year afterwards he had an attack of chorea, which chiefly affected the right side.

When Dr. Jackson saw him, there was merely a little twitching of the face on each side, and as this had continued for several years treatment was not likely to do much for it. There was no bruit, and he had not had rheumatic fever; he had, however, had scarlet fever some time before the fright. He seemed in good health and looked intelligent, but his mother said that his temper was very bad, and that he would frequently swear. It was then suggested that perhaps he used the word "bloody" in that way, but she replied that he said it when quite calm, and that not unfrequently he ejaculated it in church, to the manifest surprise of those sitting near him. He had another trick, more curious still. He would frequently blow out the candle. He was very fond of reading, and yet sometimes he would suddenly blow out his own candle, much to his annoyance.

In this instance quasi-mental acts were performed without the intervention of the patient's will, even when he was apparently quite conscious. They look like reflex actions, though what the exciting cause is it would be difficult to say. Some patients who cannot talk (who cannot *say* anything)—in cases of loss of speech with hemiplegia on the right side—sometimes swear; but it must be observed that, as a rule, their ejaculations are involuntary, like the boy's just mentioned. In these cases, however, there is nearly always an exciting cause, as anger or surprise. But although the patients swear when vexed, they cannot repeat the oaths when calm. Perhaps some Physicians would class the boy's ejaculations in the same general category with the uncontrollable impulses we sometimes meet with in cases of epilepsy. In the latter, however, there is, Dr. Jackson says, so far as he has observed, more or less unconsciousness. Yet it is possible that this may be but a question of degree. Besides, the important thing is to determine the relation of these morbid quasi-mental actions to healthy mental processes, and not to label them, or the diseases with which they occur, with nosological names. Moreover, to determine their nature, it is a matter of great moment, as a first step, to study exactly the more purely physical symptoms with which they occur, and in each case on its own merits, without particular reference to established groups of disease. Now, it is in some classes of cases of disease of the nervous system hard to say where obviously motor symptoms end and where the purely mental ones begin. Thus there is (in cases of hemiplegia on the right side) every gradation betwixt, on the one hand, a total loss of the power to express ideas, or a loss of knowledge of the relations of words to things, and, on the other, apparently scarcely more than a peculiar motor defect in talking—an ataxy of articulation. And sometimes in the same case we find that the patient makes mistakes in words, and also articulates badly. In the case the subject of these remarks there are (1) involuntary ejaculations, (2) involuntary and yet complete actions, and (3) local spasm or twitching of muscles. We may, perhaps, find all shades, degrees, and analogies betwixt obvious and coarse motor reflex actions, and disorder of what Dr. Laycock has described as the reflex function of the brain. We may thus analyse with some success, from the study of phenomena which are superficial and simple, more hidden and intricate mental conditions.

AUSTRIAN BATHS.—The Bohemian baths occupy the first rank, and chief among these is *Carlsbad*. During the season of 1863, it was frequented by 10,589 persons, 2777 of these being natives and 7812 foreigners. Among these last there were 3650 Prussians, 1200 Russians, more than 500 Poles, and 250 Swedes and Norwegians. At *Toplitz-Schonau* there were 8700 visitors, 2598 natives and 6122 foreigners, Prussians constituting the great bulk of these last; while there were also 450 Poles, 400 Russians, and many French. At *Marienbad* there were 4492 guests, 1413 natives, and 3073 foreigners, 1300 of these being Prussians; while the Poles and Russians were numerous. The numbers at *Franzensbad* were 3860, 2587 foreigners and 1273 natives. There were 900 Prussians, 600 Russians, and 130 Moldavians. At *Baden*, near Vienna, there were 6653 visitors, but only 173 were foreigners. At *Isohl* there were 2931 visitors, 2556 natives and 375 foreigners. At these two last places the numbers have considerably fallen off since 1861 and 1862, as they have also at *Hall*, resorted to for its iodine waters. At all the Bohemian baths the numbers have considerably increased.

SATURDAY, JANUARY 28.

THE SCHOOL OF THE ROYAL MEDICAL BENEVOLENT COLLEGE.

Magna est veritas et prævalebit. This was the motto adopted by a large body of the governors of the Royal Medical Benevolent College when in behalf of their struggling brethren in the Profession they claimed the rights accorded to them by the original constitution of the College, and demanded admission for their sons to the school of the College upon a privileged footing. This demand was refused by the then existing Council, and the result was that a siege was regularly established in 1857. After eight years' determined opposition the Council have at length capitulated, and an honourable peace being concluded, the war is now happily at an end. We have no desire to rake up its embers, but a brief summary of the struggle may be pardoned. Our principal object is to entreat the friends of the College to make the best of the advantages which their perseverance has gained for them, and to follow up their success by appropriate action.

The original prospectus of the College was put forth in 1851, and a main feature was the establishment of a school, at which not only a certain number of boys, sons of Medical men, should be educated gratuitously, but also that others should be admitted to the privileges of the school on a payment of £25 per annum. Between 1851 and 1856, on the strength of this prospectus, £45,000 were collected from the public. In 1854 the first general meeting of the governors was held, and the bye-laws were agreed to upon which the College was to be governed. Under these bye-laws the charge for paying scholars, then first styled "Exhibitioners," was settled at £30—a rise of five pounds. In August, 1856, the Council proposed, and managed to carry at an extraordinary general meeting, attended by only thirty-eight (including the Council) out of 6000 governors, a retrospective law raising the charge to £40; entrenching themselves behind an Act of Incorporation obtained actually before any scholar had been admitted—an Act, too, the interpretation of which, so far as this question is concerned, is disputed, two very eminent counsel having given diametrically opposite opinions. Against this proceeding a large section of the governors, led by Mr. Cattlin, instantly protested as unjust; and, constituting themselves into an "Exhibitioners' Committee," determined to fight the matter out. Numerous and stormy meetings of the general body of governors were held from time to time, and hard knocks, after the manner of Englishmen, were exchanged. Very little was gained in this way; but still the dispute was kept alive. One by one, however, as new blood was infused, several members of the Council became convinced, and at length, in the course of last year, Mr. Cattlin was invited to join the Council, in order that he might have an opportunity of advocating therein the views of his party. The result of this most judicious step was the proposal, on the part of the present Council, of precisely those changes in the school which had been so long called for by the dissentient governors, and so long met by the dreary *non possumus* of the Treasurer and Council. Justice and truth have had all they wanted—an earnest advocate at head-quarters and a fair hearing. And now for the upshot.

This consists in nothing less than a revolution. Our less wealthy brethren have no longer any ground for complaint, for the resolutions carried at the late extraordinary general meeting not only give them all they asked, but more than they asked. The sincerity of the present Council is evidenced beyond question by the heartiness and completeness with which the alterations have been made.

The school is to consist of at least 200 boys. Forty of these will be maintained and educated as "Foundation Scholars," as heretofore. The "Exhibitioners," however, are in future to be what their title infers—boys admitted to the privileges of the school at a low charge. The charge is to be, for the present, that determined upon at the first annual meeting of the Governors—namely, £30 per annum; but it may be reduced to any less sum. This privilege, also, is to be confined to those who really need it, for the boys who are to be admitted upon this footing will be *selected* boys. The selection will lie with the Council, who on any application will require a confidential communication of the circumstances of the applicant to be made to a sub-committee. No one can quarrel with such an arrangement; for in what other way can it be ascertained which of the applicants has the strongest claim on the ground of misfortune? The number of "Exhibitioners," as well as the regulations for their admission, is also to be determined by the Council from time to time. This is the only point which we cannot quite approve of. The number of "Foundation Scholars" is settled at forty; we think that a minimum number of Exhibitioners should also be stated. We do not question ourselves the *bona fides* of the Council, in their present temper; but we think we can perceive looming in the not very distant future fresh dissatisfaction as arising from the omission. Let us, however, hope that the new law will be carried into effect in the same liberal spirit in which it has been conceived.

Thus far the new arrangements affect the "benevolent" element of the school, and are conducive to the satisfaction of the *quondam* "dissentients." But the school has other, beside benevolent, objects. It is to be a school for the sons of Medical men of all grades and classes; and so long as Medical men can be found to send their sons at a charge of £40 up to the full complement of 200, or as many more as can be accommodated, it is to consist of Medical men's sons only. But when the supply of these shall fail, then pupils are to be admitted who are not the sons of Medical men; but while the former are charged for at somewhat over cost price, the latter are to be received at a charge which will leave a profit after all expenses are paid. The charge for lay scholars is not yet fixed; but considering the high character of the education provided, we quite agree with Dr. Sieveking (a letter from whom we print elsewhere) that sixty guineas per annum would not be an exorbitant charge. In addition, scholarships of £10 per annum and upwards are to be established, open to the whole school, so that clever boys both among the Foundation Scholars and Exhibitioners may obtain for themselves additional advantages.

But for the realisation of this scheme money is requisite, and three sources are looked to for this. The first and main source of improved income will consist in the profits derivable from the lay scholars and day pupils. If a hundred lay scholars could be introduced (and a single school of 300 boys is as large as can well be managed by one head) an annual profit of £2000 per annum would be obtainable. Secondly, all boys entering the school (with the exception, of course, of the "Foundation Scholars," "Exhibitioners," and Surrey

Scholars) are in future to pay an entrance fee of two guineas, and a fee of seven shillings a term. Thirdly, an Exhibition and Scholarship Fund is established, for which special subscriptions, donations, and bequests are solicited. Now, of all these changes, that which commends itself to us most forcibly is the admixture of lay scholars with the sons of Medical men. Class education is an evil which, with Dr. Sieveking and Mr. Cattlin, we must all join in condemning. We are all aware how much of the breadth of mind derived from an education at our grand public schools is dependent upon the association of boys whose connections, antecedents, and modes of thought are greatly diversified. But this leads us to another topic. It is all very well to say that the profits from lay boys are to be devoted to the Exhibitioners, but first we must find accommodation for lay boys, and for this new buildings will be required. A special building fund for this purpose must be raised, and, if necessary, an amendment of the present Act of Parliament obtained to enable the Council to admit lay boys to this part of the School. We see no need for a "new and independent foundation," as suggested by Dr. Sieveking. A sum of money amounting to about £700 has already been subscribed for a testimonial in honour of the chief founder and present treasurer of the College. Could the money be better applied than, as Dr. Sieveking suggests, towards the erection of a new wing to the school, "which might not inappropriately be called the Propert wing?" Is it possible that this money—which we do not doubt for one moment might, by subscription and other methods, be rapidly raised to the requisite sum—could be better expended than in providing the means of carrying out the sanguine hope of Mr. Propert, when the first prospectus was issued, that an education for the sons of our less fortunate brethren might be provided at a charge of £25 per annum? Once let the lay school be filled, and it might and ought to be reduced much below even this sum. Of course, Mr. Propert would have to be consulted in the matter, but we cannot for a moment anticipate any obstacle in that quarter. Should there be any deficit after the building of the wing is completed, it might be fairly met by devoting a share of the annual profits of the school to its liquidation.

Now that the school is to be re-modelled, we see no objection to the change which has been proposed in the name. The term "benevolent" may well be dropped. We shall have the substance, and may dispense with the shadow. A new Charter or Act of Incorporation would then be desirable, granted to the "*Epsom College*," for which we will breathe a prayer, "*Esto perpetuum*."

MODERN SYPHILOGRAPHY.—No. VI.

TWO-FOLD INOCULATION; OR, THE TRUE CHANCRE COMPLICATED WITH THE SOFT VENEREAL ULCER.

As a very considerable amount of scepticism and misconception appears to prevail on this subject, and as it is in accordance with our own observation, we must dwell a little upon this knotty point, which is, in reality, a very simple one. Let us assume, as an hypothesis, that there are two distinct poisons, producing, the one a local, the other a constitutional affection, and that these are not interchangeable. Now, as the latter alone possesses a true incubation, it follows that if a man be exposed to the two poisons at once, the soft local sore will first appear, and will run its course during the incubation of the other, and that we may thus have a soft sore, which becomes hard before it heals, from the action and development of the true syphilitic element. Instances of this are not very uncommon; and the converse may equally happen, whenever a patient labouring under an indurated chancre exposes himself to the virus of the local soft sore. If the poisons produce their results in close proximity one with another, we can then watch these separately and mark the contrasts in their characters; but if one and the same abrasion be inoculated with both poisons, from exposure to one or many sources of contagion within a limited period of time, then, we have the two diseases existing together, or one succeeding the other, on the same spot. So that if we see the common, soft form of sore, we can positively pronounce it to be, so far, a local disease; frankly telling our patient at the time, however, what is the interval before any syphilitic poison would declare itself and the characters by which it may be known. If there be no such appearances afterwards we can most surely guarantee the local nature of the disease.

So long, however, as we had to depend upon our observation of cases contracting the diseases in the ordinary way, we might never, perhaps, have demonstrated the fact of this double inoculation; but this has now been effected by artificial inoculation. Under ordinary circumstances, these occurrences were, of course, strongly suggestive of a variety only in the processes and the unity of their cause, and so long was Nature apparently giving the contradiction to all our distinctions between the infecting and non-infecting forms of sores. Now, however, a specific induration has been inoculated with the pus of the soft ulcer, a pustule has formed, and the characteristic soft sore has resulted. We will give a few examples of the two modes by which the occurrence has been traced. Take that related by M. Fournier (which was seen by M. Ricord) of a double inoculation in the natural way. A man was labouring under a chancre affected with cartilaginous induration. This suddenly began to ulcerate, and, coincidently therewith, a large soft sore appeared on the skin of the penis. One of the indurated chain of inguinal glands inflamed and suppurated, and the pus from it was successfully inoculated. "Secondaries" subsequently appeared. Now, it was *proved* that this patient had contracted these soft ulcers from sexual intercourse with a woman suffering from the same affection, at the time he was under treatment for his indurated chancre. M. Rollet and his *interne*, M. Laroyenne, have succeeded many times in producing the pustule and soft ulcer by the artificial inoculation of an indurated sore with the pus of soft sores. Instances of similar experiments may be met with in most of the recent works of Continental Syphilographers. Although the poisons and their manifestations are mixed, in so far as they both appear in the same locality, one does not destroy nor essentially modify the other; both follow their ordinary courses and preserve their characters. Nor is the subsequent manifestation of secondaries arrested or modified apparently by the induced ulceration of the chancre or the presence of suppuration in the groin. It is asserted even further, that it is possible to take pus from the artificially-produced pustule on the induration, or that of the bubo in the groin, and to produce a soft sore by inoculation on the same, or on another and healthy individual; that is, provided the secretion used be pure and unmixed with any blood.

Our readers can repeat these experiments, and test their accuracy for themselves—at least, as far as regards inoculating a true chancre with the secretions from a soft sore; for we presume no English Surgeon would have the hardihood to *be guilty of performing any* experiment, of the nature we have indicated, upon a *healthy person*. If these observations be correct, what follows? Are we to believe that from varieties in the kind or condition of two secretions—both acting as vehicles of one and the same poison only—these are capable of affecting the same individual, exactly on the same spot, each in its own way? This seems to us as improbable as the view of their being the two perfectly distinct results of two dissimilar causes appears to be strongly corroborated. We never see anything allied to this from any varieties in the condition of vaccine lymph, although we know that the introduction of a bloody lymph from the pock of a syphilitic infant may give rise to the two diseases—vaccinia and syphilis; showing that two distinct animal poisons are not, on that account, at all antagonistic.

We think that the two affections are occasionally superimposed, as MM. Diday, Rollet, and others contend. If we are to

believe—and this must be conceded, we imagine—that the virus of *true* Syphilis does not manifest itself until after a relatively long interval—let this period be called one of incubation or not—and the late appearance of induration in a sore of soft character is easily accounted for.

Let us admit the distinctions in the causes, and so far from its making "confusion worse confounded," it seems to us to be a key to all the difficulties. Peruse a treatise on Syphilis, wherein these distinctions are taken as cardinal doctrines (such as that by Dr. Bumstead), and then turn to another treatise, by even the best author who holds the reverse doctrine, and you at once feel the absence of that system which commends itself to the understanding. We know, as Archbishop Whateley remarked, that minds are more prone to be captivated by a love of system often than by a desire for truth; but here the theory appears to us to be capable of combining and explaining all those facts which would otherwise be so irregular and discordant.

It was M. Ricord, unquestionably, who first applied the key which unlocked the door and displayed the road along which all subsequent syphilographers had to pass. But for his introduction of inoculation, as the test by which we could distinguish the specific from simple ulcers, we should never have been led to the further conclusion—so little anticipated by M. Ricord himself—viz., the differentiation of the common *soft specific* ulcer from the specific *syphilitic* chancre. The English Practitioner owes a debt of gratitude to Mr. Acton as one of the most sagacious and energetic exponents of M. Ricord's views. Mr. Acton has always boldly advocated them, at a time too when they were both novel and unpopular, and he was foremost in advancing our knowledge of these diseases. The Continental schools have furnished the leaders in this modern revolution of our ideas. While the French have laboured hard at the history, etiology, causes, and various forms of the disease, the Germans have worked equally hard at these, and the pathology of syphilis. Among the works recently published we may call attention to Dr. Hermann Zeissl's "Treatise upon Constitutional Syphilis."(a) We think our author's pathology calculated to make some men of the good old school "raise the eyebrows of astonishment." In the first place, it contains 432 pages upon syphilis, and syphilis only, with which the soft ulcer is held to have nothing whatever to do. Acquired syphilis is held to be a constitutional malady, having for its cause the reception of a poison derived from a syphilitic source. This real "syphilization" is characterised by exactly the same type of phenomena as mark other diseases of the enthetic group. The implantation of the virus is followed by a definite and true incubation before the appearance of any lesion at the point where the virus was inserted, and, for the rest, we have the evolution of a very definite chain of phenomena—differing chiefly in their degrees of severity, according as the manifestations are very mild or very severe.

A German professor never starts on a journey by his own path without securing a pack of learning upon his shoulders first of all; and whenever he undertakes the investigation of any subject he generally does it thoroughly. We have only to glance at the Index to see that this has been the case here. The history of syphilis, the evolution and the forms of its manifestation, the vehicles of contagion, the modern doctrines concerning the non-identity and duality of the poisons, the symptoms and pathology of the disease, are not only laid down in a very minute and lucid way, but the conclusions are supported by the results of a most extensive experience, and illustrated by some new experimental evidence.

We commend Dr. Zeissl's treatise to our New Sydenham Society, and to all who desire to be *au courant* with the latest and fullest information upon constitutional syphilis.

(a) "Lehrbuch der Constitutionellen Syphilis für Aerzte und Hörer der Medicin." Von Hermann Zeissl, M. et Ch.D., Prof. an der Universität zu Wien, 1864. ("Treatise on Constitutional Syphilis for Practitioners and Medical Students.")

We may venture to add a few remarks that have occurred to us from the perusal of Mr. Gascoyen's interesting papers, which have appeared in the pages of our contemporary since the foregoing was written. He strongly advocates the unity of the poisons, although he recognises the characteristic differences between the local soft and the true chancre. We think, however, that he has not thoroughly appreciated the nature, or the strength of the position occupied by the so-called "dualists;" nor has he succeeded, to our minds, in penetrating that position.

The blood disease which Mr. Gascoyen excepts from comparison—hydrophobia—seems to us the very one which is most analogous to the syphilitic.

In fine, the dualists point to the history of the two diseases; the results of traced descent; the differences as regards the intervals before their manifestation after exposure; the marked differences in the symptoms, and the pathological processes; the very easy inoculability of one, compared with the difficult auto-inoculability of the other; and the remarkable contrast in the effects, as establishing their theory of a difference of causation.

No one would deny that varieties in the condition of the inoculating fluid, or the source from which it is taken, may give rise to some differences; but it is maintained that these cannot account for such as are observed between the true syphilitic lesion and the local venereal ulcer.

Whether they be right or not remains to be established; but the grounds they take are very similar to those on which Physicians rely for the separation of typhus from typhoid fevers, for example.

THE WEEK.

THE ELECTION OF PRESIDENT AT THE MEDICO-CHIRURGICAL SOCIETY.

So much interest has been excited by the last two meetings of the Committee of the "Medico-Chirurgical," and the discussion as to the election of the new President, that, however unwilling we may be to discuss semi-private or confidential gossip in a public journal, we cannot with any sort of justice to our readers refrain from some comment on what is talked about at every Medical dinner-table. So close has been the division at each of the two meetings just mentioned that Dr. Alderson has been selected for recommendation by the Council to the Fellows by the casting vote of the Chairman. At each meeting exactly one-half of the members of Council present voted for Dr. Burrows, and half for Dr. Alderson. At each meeting the casting vote of the Chairman was for Dr. Alderson. Between this and March 1 the Fellows must make up their minds which section of the Council they will support.

MR. LUND AND THE CASE OF PRYCE *v.* BOWEN.

THERE is great virtue in confessing oneself in the wrong, and in doing one's best to repair an injury done. We know that such a course is talked of as being the barest morality, but practically how very few there are who pursue it. One of the few is Mr. Lund, of Manchester. Our readers are already aware from his letters published in recent numbers of this journal that he heedlessly allowed himself to be entrapped into giving evidence, on faith of the plaintiff's statement, in an unjust and unfounded action against Dr. Bowen for malpraxis. Mr. Lund has confessed his error, but he has not stopped here. He has sent the very handsome sum of fifty guineas to the fund which is being raised to meet Dr. Bowen's legal expenses. "'Sorry for it' is all a gentleman can say;" but, beyond mere words, Mr. Lund's regret has prompted him to taking this very decided method of reparation. We believe that the Medical Profession will accept Mr. Lund's act as the best proof that his error was one arising from want of caution and wrong information, and was not dictated by any wish to damage a brother Surgeon, or to gain *eclât* at his expense.

CHARQUI.

It is a self-evident fact that there is a close connection between the art of cookery and that of Medicine. It was formerly the doctrine that they stood in the relation of cause and effect, the patient and doctor being the intervening links. Medical men of these latter days have grown wiser, and look on a good cook as their most valuable ally. But, whichever belief is uppermost, we are clearly pursuing our legitimate functions as chroniclers of all that bears on the noble science we profess, when we put on record anything new or untried in an art and mystery which, from whatever point it is regarded, is of such vital importance to physic. Just now the public papers are full of letters from enterprising travellers and *maitres de cuisine*, on the subject of the South American beef which is to be bought in Cheapside at 3d. a pound. According to some authorities, it is likely to be a perfect boon to the lower orders; according to others, its chief value is that it affords an excellent "stock" for the gravies and soups of the upper. Mr. G. Warriner, Instructor of Cookery to the army, takes the latter view. He says that "to make chaqui into a palatable dish requires good cooking; and as our labouring population are bad cooks this is against it. None of the receipts hitherto given to the public are right."

"Chaqui beef, at 3d. per pound, is equal to 3lb. with bone of the usual stock meat, in addition to which the gravy is of a finer quality, for the same reason that a French cook can make better soup in France than in England. When he comes to this country he is surprised to find that he is obliged to use 2lb. of meat instead of 1lb. to give the same flavour. This is owing to the age of the animal."

But the most amusing and instructive writer on the history, virtues, flavour, and preparation of charqui that we have seen is Mr. W. Bridges Adams. Our readers will find that the following quotation from his letter to the *Times* will well repay perusal:—

"The earliest notices on the subject are given in the voyages and travels of the circumnavigators and bucaniers, and the article is therein commonly called 'jerked beef.' The bucaniers were originally driers of meat, not especially beef, but of swine's flesh, prepared by smoking, so called from the French word *boucaner*, to dry by smoke, as the Caribs did by the prisoners they ate. The 'jerked' beef is a sailors' corruption from the colonial Spanish *charqui*, evidently a corruption in turn from the *chair cuit* of dried flesh of the French bucaniers, and to this day a French pork-butcher is called a *charcutier*, because originally pork was sold in the dried form of ham and bacon.

"*Charqui* proper, as prepared in Chili, is the muscular fibre of beeves pared from the bones in thin flakes or strings with all the fat extracted, and then exposed to the sun to dry, which process takes place in the course of a few hours, all the moisture disappearing in the dry air, and the meat remaining in the condition of glue, not subject to putrefy, but only to engender mites like cheese. No flavour is lost in the process, as when the carcasses of animals are frozen, other than a change similar to that of preparing 'raisins of the sun' from grapes. The meat thus dried is usually packed in bags formed of dried hides. Chili is the especial country of *charqui*, because while it is a great cattle-producing country for its area, a large portion of it has an especially dry atmosphere. My first acquaintance with this meat was on a journey, when for my sins I undertook to prepare supper, and so boiled the dried meat in an earthen pipkin. My guide grinned askance, at what I knew not, but it soon came out, for after boiling the meat for an hour I thought it was done enough, and tried to eat it, but found that I was of that especial race of cooks said to be sent from below, for the meat was very like india-rubber in the chewing, so I turned it bodily over to my man Friday, and watched his process. First he toasted the meat on the red embers of the wood fire till it began to hiss; then he selected a large flat stone, on which he pounded the meat to shreds with another stone, and then restored it to the pipkin, with a lump of dripping fat dyed to a deep Indian red with ground capsicum. Then he sliced in some onions and hard-boiled eggs, added a portion of salt, with two or three small red pepper-pods and boiled potatoes, and finally turned out a stew for which Esau might have sold his birthright twice over. This dish is in Chili called a *charquiean*—a national dish, of which there is a tradition that once a Pope of Rome, having ordered to be prepared for him the national dishes of all nations, and tasted them in succession, gave orders that thenceforth he would have *charquiean* three days in the week.

"For travelling purposes this meat is prepared ready pounded, and packed in lamb or sheep skins with butter or dripping, and is analogous to the preparation of flesh called pemmican, only that is prepared by smoking in North America.

"*Charqui* proper can only be prepared in a dry atmosphere, and the climate of the Pampas and River Plate is a moist atmosphere, and therefore the natives do not prepare *charqui*, but only *tasajo—i.e.*, meat salted and hung in the air to partly dry—in short, hung beef, which is exported to the West Indies to feed the blacks, and this, probably, is the 'moist beef in rolls' alluded to by your correspondents. But it will not compare with the *charqui* of Chili, one pound of which is equal in nutriment to three or four pounds of fresh meat from which the water has not been abstracted. It is well known that the application of salt to muscular fibre destroys to a great extent its nutritive qualities."

LONDON FOG.

The "genuine London fog" which wrapped the metropolis in "thick darkness" on Saturday may be considered from very different stand-points. Some look upon it as a curiosity,—as one of the sights of London; some as a useful topic of conversation,—a kind of God-send to journalists and talkers in this dull season; some as an annoyance and a nuisance, but nothing worse; but the Medical man knows it to be a terrible scourge, and to many a patient it makes all the difference between life and death. Very many of us could, we doubt not, give instances of phthisis and bronchitis hurried to a fatal close by those hours of fog. We, therefore, gladly hail any suggestion that seems to promise to make a "London fog" a matter of history, and we reprint a letter on the subject from the *Times* of January 24. The writer is perfectly correct in his description of the clay lands round Harrow, and we have often noticed mist and fog hang over that region when the atmosphere has been clear elsewhere; but we fear he is too sanguine in believing that drainage, however perfect, of that district will destroy London fog. We should be inclined to place far more reliance on extension and perfect carrying out of a Smoke-consuming Act:—

"*To the Editor of 'The Times.'*

"Sir,—Is there good reason why London should continue to be remarkable for its fogs? Fog is, doubtless, a serious element of winter discomfort in London, and is very probably a cause of much sickness and of suffering to those whose respiratory organs are weak or otherwise affected.

"The Thames is popularly supposed to be the source of London fog, but, I believe, in this particular Father Thames is grossly maligned. The atmosphere in the immediate neghbourhood of the Thames is often comparatively clear, while the districts northward of it are wrapped in impenetrable vapour.

"The land surrounding the northern segment of the metropolis is for miles practically undrained. The land lying north and north-west is, for the most part, a stiff clay, and clay almost in a primitive state.

"By reference to the Ordnance map it may be seen that the tract of land bounded on the east by the road to Edgware, on the south by the Uxbridge-road, and on the north-west by a line drawn from Stanmore to Uxbridge, is almost uninhabited.

"The lines just named include a triangular space, in the centre of which stands Harrow-on-the-Hill. This triangle, excluding Harrow, is a notch cut out of civilisation, the cold wet soil hitherto hindering settlement upon it.

"Drainage is almost neglected, except in some rare instance where property has recently come into the hands of spirited and enterprising landlords. And until lately it is said that at Edgware ague was a common disorder, so that within nine miles of the Marble Arch, within an hour's drive of the centre of civilisation, we come upon one of the characteristics of the swamp and the jungle. Foot-rot quickly attacks flocks placed upon the pastures of the Harrow weald from the wetness of

the land. A journey of fifteen or twenty miles down the Great Northern line will show the same undrained condition to be the rule.

"Thus, from the backwardness of the proprietors or of the tenants of the agricultural districts indicated, the Londoner is literally compelled to swallow his own smoke and to inhale the poisonous products of the combustion of tens of thousands of tons of coal and feet of gas.

"I am, Sir, your obedient servant,

"January 20." "T. W. N.

SUICIDE AND QUACKERY.

If anything could rouse the public and the Legislature into action on the subject of the "Dirty Quacks" it is the tragedy brought to light by an inquest lately held at Higham, in Kent. The story is a short one: it is simply that of a man of somewhat weak mental power, but of irreproachable character, equal to the ordinary duties of life, and performing them conscientiously, who was goaded into suicide by the representations and extortions of some of the harpies who are allowed by our excellent postal arrangements and free press to scatter their obscene advertisements and lying statements broadcast in every town, village, and hamlet in the kingdom. We are not weak enough to suppose that quackery in all its forms can be put down by legislation; but if it be the duty of Government to protect the lives—we will say nothing of the morals and health—of the people, it is imperative that another Session of Parliament should not be allowed to pass without a stringent measure being carried against an infamous imposture which drives men to insanity and suicide. The following report of the inquest we extract from the *Daily Telegraph* of Saturday, January 21:—

"Yesterday evening an inquest was held at the Chequers Inn, Higham, Kent, before Thomas Hills, Esq., Coroner, on the body of James Miles, a foreman in the employ of Thomas French Nettleingham, Esq., merchant, at Gravesend. The deceased was found drowned in the canal on Thursday evening last.

"Sarah Reed, a widow, residing at Gravesend, identified the body as that of her nephew by marriage, and said he was married on Christmas-eve last, at Kingston. I have lived with the deceased and his wife for the last month. The deceased was 24 years of age, and, I believe, lived with his wife very comfortably. A few months ago the deceased was rather queer in his manner, and appeared very low-spirited, but he got better afterwards. About a fortnight ago he received something which made him worse. On Wednesday morning he was very desponding, and at dinner he complained of his head and stomach. The deceased told his wife that he did not know what he was about, and could not eat. At about five minutes to two in the afternoon he kissed his wife and shook hands with her, wishing her good-bye. He then lit his pipe and went out. I never saw him alive afterwards. He was always on good terms with his wife since their marriage.

"Police-constable Burr deposed to finding deceased's body in the canal, about half a mile from Higham.

"Police-constable Mitchell, who was present at the finding of the body, said: I found several papers and printed bills in deceased's jacket pocket. They are those now produced. Two are from Dr. De Roos, of Tavistock-square, and one from a Dr. Smith, of Burton-crescent, London. They are what are called quack handbills. At the residence of deceased I found this pamphlet. It is a work on secret diseases. I did not find any medicine at deceased's house.

"Thomas French Nettleingham deposed: I am a merchant, and carry on business at Gravesend. The deceased has been in my employ for the last six months as foreman at the wharf. He appeared to be rather weak-minded, and seemed languid and dull when we were very busy, and frequently forgot orders that were given to him. On Wednesday morning last deceased was much flushed. He has been very abstemious and steady ever since he has been in my employ. The deceased never made his appearance after dinner. His accounts are perfectly correct.

"J. J. Ely deposed: I am a Surgeon, practising at Chatham. I have examined the deceased, and have not found any marks of violence. From an inspection of the papers found upon the deceased, I have no doubt whatever they would cause a great depression of spirits, and tend to a person committing suicide. Persons suffering from disease are susceptible to depression of mind. The papers or bills are issued by quacks. It is not unusual for cases of suicide to arise from reading pamphlets similar to those produced.

"At this stage of the inquiry Mr. Nettleingham asked the Coroner to take the evidence of John Willsher Packham, a fellow-workman of the deceased, who had found a large packet of letters from Dr. De Roos, of Tavistock-square, London. The witness deposed that he found the articles now produced in an upstairs room in deceased's house. They consisted of two large-size tins, which evidently had contained medicine supplied to the deceased.

"The Coroner then read to the jury several letters from Dr. De Roos, which stated that the deceased must still continue with the medicine, and impressing upon him the necessity for remitting money, as he did not make it a practice to give credit to his patients, and stating that, in consequence of having numerous correspondents in all parts of England, he hoped he would not neglect writing to him, as he (Dr. De Roos) might forget the case. About thirty letters had been sent to deceased in the course of ten months.

"The Coroner summed up. He said: Gentlemen, you have heard the evidence which has been adduced. From this it would appear that the deceased had in all probability been reading the pamphlets which have been produced, and you will have remarked that on opening one of these pamphlets the word 'suicide' appeared written prominently round the margin. The number of letters from Dr. De Roos, of Tavistock-square—letters which it is impossible to stigmatise too strongly, and which, when read by the weak-minded, would lead them to the commission of suicide—must be noted as a weighty fact, and they tend to prove that the mind of the deceased had been deeply harassed by them.

"The jury returned a verdict to the effect that the deceased had committed suicide whilst in an unsound mind.

"After the delivery of the verdict a consultation between the coroner and the jury took place, which resulted in the foreman intimating that they considered deceased's insanity to have been brought on by the perusal of certain pamphlets issued by, and letters received from Dr. De Roos, of Tavistock-square, London. The jury expressed a wish that the press would take notice of this addendum to the verdict.

"The Coroner ordered that the pamphlets and letters should be kept in safe custody."

FROM ABROAD.—ALARMING MEDICAL LEGISLATION IN BELGIUM —INNOCUITY OF CONSANGUINEOUS MARRIAGES.

The Medical Profession in Belgium is at present in a state of some consternation. For a long time past, dissatisfied with its present position, it has been calling for some additional legislation, especially as regards the suppression of irregular Practitioners. A Bill has at length been brought into the Chambers, the provisions of which seem so thoroughly objectionable that all efforts are being made to throw it out, as were it to become a law fears are entertained that one evil will have been only exchanged for another—unbridled license for undue interference with the rights and liberties of legitimate Practitioners. The objectionable part of the Bill is that which relates to what is termed in it "Medical discipline," for the carrying out of which it establishes Disciplinary Councils, endowed with most extensive powers, in every juridical district. In districts where the Practitioners do not number seventy-five the Council is to consist of six members, and in others of nine—a third of the number being *pharmaciens* and two-thirds Medical Practitioners. All Practitioners who have been registered during five years are eligible, and the elections are made annually by ballot at a general meeting of the Practitioners of the district, under the supervision of the civil authorities. When there are fewer than fifty Practitioners resident in a district, two or more districts may be combined.

"The Disciplinary Councils will have to watch the dignity of the Medical Profession, maintaining the principles of humanity and delicacy which should prevail in its practice; and they will punish by disciplinary penalties faults which do not fall within the competence of the Medical police. They will reconcile any differences which may arise between Practitioners during the exercise of their Profession, and such that may arise between them and their patients in regard to fees."

The disciplinary penalities are—1. *Avertissement;* 2. Censure, with an injunction to be more circumspect for the future; 3. Reprimand, with threat of future interdiction of practice; 4. Interdiction of all Medical practice for a period not shorter than a month nor longer than a year. The accused must be heard in defence before any decision is pronounced, and may appeal to the civil tribunals. The expenses of the Councils are to be provided for by an annual tax levied on the Practitioners of the district, the contribution not to exceed 10 francs in communes where there are more than 5000 inhabitants, and 5 francs where the population is less. On reading such provisions as these, to be put into compulsory operation, one cannot feel surprised at the indignation which they have excited throughout Belgium.

"As Belgian citizens," exclaims the *Presse Médicale*, "we are revolted at the idea of losing our liberties, and being placed in so exceptional a position; and as Practitioners we ask ourselves whether the Medical Profession, in place of being an agglomeration of well-educated and instructed persons devoted to the cause of suffering humanity, is an assemblage of unprincipled men, destitute of moral sense, strangers to delicacy and to the most elementary principles of good breeding. There can be no doubt Practitioners are about to be transformed into privileged culprits; new crimes have on their account to be created, entirely referable to the conscience, which until now has been respected. To inculpate them, informations will have to be put into practice, and the Profession, tormented even at the bedside of their patients, will have to undergo, in 1865, all the agreeable amenities of the censorship and the inquisition."

M. Crooq, President of the *Fédération Médieale Belge*, has formally brought the Bill under the notice of the Academy of Medicine with the view of enlisting the influential action of this body against the measure.

M. Auguste Voisin read a paper at the Academy of Medicine tending to show the innocuity of consanguineous marriages. It is founded upon the results of his observations made during a month's residence at the village of Batz, near Croisic, in the Loire Inférieuse. It seems that consanguineous marriages have been frequent there for ages past, the inhabitants living quite isolated from neighbouring places. M. Voisin investigated the condition of the present families, inquired into their antecedents, and examined the physical and intellectual condition of the various members, besides listening to details from the older inhabitants. He has tabulated the information thus acquired, and comes to the conclusion that mere consanguinity has given rise to no disease, degeneration, or physical malformation, this race of people still being a very fine and pure one. At the present time, he says, there exist at Batz 46 consanguineous unions, 5 between cousins-german, 31 between cousins the issue of cousins-german, and 10 between cousins in the fourth degree. The 5 marriages between cousins-german have produced 23 children, none of whom have exhibited any deformity, and two having died from natural causes. The 31 marriages between the issue of cousins-german have resulted in 120 children, none exhibiting congenital affections, and 24 dying of disease. The 10 marriages of cousins in the fourth degree have been followed by 29 children, all in good health except 3, who died of acute diseases. No diathesis prevails in the community. "These facts," says M. Voisin, "seem to me to prove that, under the condition of a good selection being made, consanguinity does no mischief whatever to the product of marriage or the race. On the contrary, it augments the qualities, just as it would, under other circumstances, increase defects and causes of degeneration."

Professor Chelius.—This venerable Surgeon has resigned his Professorship at Heidelberg, after holding it fifty-two years, as also the Directorship of the Surgical Clinik, which he founded forty-seven years ago! (It seems that our own country is not the only one in which men continue to hold posts long after the period at which they can satisfactorily fulfil their duties.)

REVIEWS.

Diseases of the Ovaries; their Diagnosis and Treatment. By T. Spencer Wells, F.R.C.S., etc. In two volumes. Vol. I. London: Churchill and Sons. 1865. Pp. 376.

At the time when it was still a moot question whether ovariotomy be a justifiable operation, those who were opposed to it asserted that no satisfactory conclusions could be based upon the published record of cases, as operators were prone to print their successes, while they forgot entirely to speak of their failures. This assertion was not at first satisfactorily answered, but towards the close of the year 1857 Mr. Wells pledged himself to publish the details of every ovariotomy which he performed, whether the result were successful or not. From time to time reports of Mr. Wells' ovarian operations have appeared in this and other Medical journals, but he now redeems his pledge in the fullest manner. In the volume before us he gives an account of every case, both Hospital and private, in which he has either completed or commenced the operation. The volume consists entirely of a record of cases. Mr. Wells has reserved for his second volume the systematic teaching of the diagnosis and treatment of ovarian disease. At present we have the facts before us, and we may draw our own conclusions.

The reasons for such an arrangement are obvious, and are well put in the Introduction to the book.

"The cases, if not the most important, are certainly the most original part of the work, and it seems to be desirable to use them as the foundation, not as a mere appendix." Again, —"Ovariotomy is comparatively a new operation. Unlike lithotomy, herniotomy, or amputation, it wants the guidance, and it is free from the trammels, of tradition or long history. It is hardly fifty years since it was first performed; not forty years since Lizars first attempted it in Great Britain; not twenty-five years since its first performance in a London Hospital; there are still many Hospitals in this kingdom in which it has never even yet been performed; and there are some few men of eminence and authority in this country, and very many more abroad, who still regard it as an operation which is never justifiable under any circumstances."

The great mass of Mr. Wells' book is taken up by a record of one hundred and fourteen cases in which ovariotomy was completed. Among these there were seventy-six recoveries and thirty-eight deaths, or exactly one death to two recoveries. It is impossible to object that only favourable cases have been selected. A careful perusal of the book will show, on the contrary, that the operation was performed in many cases where little hope of a successful issue could be entertained, but where the Surgeon felt bound not to refuse to give the patient the only chance of life which remained to her.

As a specimen of the careful manner in which Mr. Wells enters into the question of prognosis, we quote from page 289 a letter sent to the Medical attendant of a patient who had consulted him as to the expediency of ovariotomy in her case. Mr. Wells writes:—

"(1) Believing that she has a compound cyst of the right ovary, with rather extensive adhesions to the abdominal wall, I should say that the case is a fair average one for the operation, not one of the most nor one of the least favourable cases which are met with, and that the chances would be about two to one, not more, in her favour.

"(2) If left alone, or with such palliation as tapping can afford, she is not likely to live (at the utmost) more than two years; and it is much more probable that she would not live one year.

"(3) At forty-two her expectation of life, according to insurance tables, is twenty-six years. By electing ovariotomy she risks two years, with two chances to one in favour of gaining twenty-six years; while the two years would be certainly years of suffering, and the twenty-six probably years of comfort.

"(4) But this question need not to be decided immediately; one or two tappings would probably not add to the risk. Temporary relief might be gained, diagnosis verified, and time allowed for full consideration. On the other hand, there is some risk even in tapping, and unexpected changes might follow it. I tell the patient it is one of those cases in which a Surgeon cannot give very positive advice. She herself, with the elements of the calculation before her, must assist her advisers by her own feelings."

The report of each case occupies on an average about two

and a-half pages. In each there is an attempt, often a futile one, to fix the precise date at which symptoms of ovarian disease showed themselves; any probable exciting cause, such as *suppressio mensium*, etc., is noted down. The age, conjugal condition, temperament, and general mode of life of each patient are all stated, and will doubtless form the groundwork of interesting generalisations in the forthcoming volume; then the actual condition of the patient before the operation is described, and in some cases the description is aided by woodcuts taken from photographs. The diagnosis and prognosis written down at the time of consultation are then given—at least, in the later cases. The operation is described; the after-treatment is, when necessary, fully entered into; and a line at the end gives us the latest news of the successful cases. One has gone to America, a second is married, a third has been delivered of a baby thirteen months after the operation; a few, only four, have died since the operation—one of hemiplegia two years later, and three of abdominal cancer, one ten months, one four months, and one six weeks after ovariotomy. Among the cases interesting in their after-treatment are several of tetanus. In two of these the Woorara treatment was tried, once successfully. Very interesting and instructive, too, are those cases in which fluid collected in the Douglas' space. Whenever such a collection was diagnosed, it was at once evacuated by puncture through the vagina. Mere puncture was found insufficient, and in one case a drainage-tube was introduced; while in another, where Chassaignac's plan was impossible, a flexible canula was allowed to remain in the opening made by the trocar. In all the latter cases the ovarian tumours removed have been carefully examined and fully reported on. Many of the pathological reports are valuable additions to our knowledge of the morbid anatomy of the ovaries. In a large number of the fatal cases the post-mortem appearances are detailed, and Mr. Wells frequently sums up by stating in a few lines the points of the case which chiefly impressed him, and from which he thinks lessons for the future may be deduced.

After the 114 cases of ovariotomy follows a unique one in which the operation was performed twice on the same patient. The result was unsuccessful, although the operation itself presented no unusual difficulty.

Then follow the cases of incomplete ovariotomy. In four cases a simple incision was made. One patient died four months afterwards from the spontaneous rupture of an ovarian cyst into the peritoneal cavity; the other three are still alive. In two of them the disease is undoubtedly ovarian; in the third it is probably tubercular peritonitis. The operation gave relief to both of the ovarian patients (one of them has since married); but, stranger than all, in the third case the incision appears to have cured the peritonitis, at least, temporarily.

In four cases tapping followed the incision; in two of them the fatal result was accelerated by the operation; in the third, the patient, already far reduced, did not suffer more than from an ordinary tapping, but sank on the fifteenth day from the natural progress of the disease. In the fourth case the patient made a good recovery, and lived on for a year, during which she was tapped seven times.

In one case in which iodine had previously been injected, the cyst was tapped, and an attempt made to separate it. Hæmorrhage was so free that the attempt was desisted from, and the patient sank on the sixth day with symptoms of blood poisoning.

In a single case, Mr. Wells was forced to leave a large portion of ovarian cyst adherent; the patient died in twenty-three hours. In the last section of reports are five cases of fibroid and fibro-cystic tumours of the uterus, in which gastrotomy was performed. Only one of the patients recovered from the effects of the operation.

Mr. Wells concludes with a few suggestions for facilitating the taking of notes of cases. For some years he has been in the habit of keeping a separate pass-book for each patient, and he now publishes that form which he has found most useful in ovarian cases. The points requiring notice are printed down one side of the page, and space is left opposite them for the written answers; while, at intervals, diagrams of the female figure are given very similar to those recommended by Dr. Bright in his monograph on abdominal tumours.

It requires some little trouble to accustom oneself to such an arrangement, but it possesses the great advantage that no point of interest is likely to be overlooked in rapidly noting down the chief features of a case.

We have no hesitation in saying that of Mr. Wells's cases the unsuccessful are the most instructive. The operation of ovariotomy has now, as Mr. Wells himself remarks, gained such a footing that the danger is that it will be performed too often, and not too seldom. The results, when successful, are so brilliant, the patient is so evidently snatched from the jaws of death and restored to health, that the temptation to operate is almost irresistible. The operation itself is sometimes so easy, that an onlooker is tempted to say, "I, too, will perform ovariotomy;" and this, although he possess no Surgical skill, and would shrink from the performance of an amputation, or from the extirpation of a simple lipoma. To such we would say, "Wait till you see a really difficult case." There is probably no operation in which Surgical *sang froid* and careful manipulation are more needed than in the extraction of some ovarian tumours. As an instance, we might refer to page 8, where a rent was apparently made in the iliac vein, or to page 221, where part of the cyst was so firmly adherent to the pelvic viscera and vessels that it was impossible to separate it.

It is true that nothing can be more alarming or require greater presence of mind and fertility of resource than serious post-partum hæmorrhage, but we submit that the means for arresting such a hæmorrhage are essentially different from those which are necessary in the cases under consideration, and that a pure accoucheur would be as much at a loss in the Surgical case as a pure Surgeon would be in the obstetrical one.

We cannot conclude our notice of the volume before us without referring to the elegant manner in which it is got up. It is printed upon cream tinted paper—a tint which, we believe, has been shown to be less trying to the eyes than any other. The edges, too, are cut. The additional cost of these little luxuries is very trifling—not more than three-halfpence a volume; and we sincerely trust that they will in future be indulged in by Medical authors more frequently than they have been hitherto.

Clinical Lectures and Reports by the Medical and Surgical Staff of the London Hospital. Vol. I. 1864. London: Churchill and Sons. Pp. 521.

The Medical staff of the London Hospital have commenced the publication of a series of reports upon the plan so successfully pursued by the staff of Guy's Hospital. It is only a matter of surprise to us that the attempt has not been made before. We say a "series of reports," for we do not doubt for one instant that the volume before us is destined to be but the forerunner of many equally good, if not better. Over and over again we have regretted the burial in Hospital case-books of much that is valuable in Professional experience; for notwithstanding the scope afforded to writers by the periodical Medical press and the certainty that any Medical work that is based upon accurate and extended observation will now-a-days obtain a sale commensurate with its deserts, it would not be difficult to show that the present opportunities of publication do not exhaust by any means the stock of information for which they are the outlets. Besides, a vast deal of good is, we think, effected when we succeed in fostering an *esprit de corps* in any large Hospital, and nothing promotes this like engaging its staff and *alumni* in some common work. Another good thing is rivalry, when its object is good and it is carried on in good humour. The Guy's Hospital reports have already obtained a world-wide reputation; we hope and wish the same for the younger publication. It will be the fault of the staff of the London Hospital if the London Hospital reports do not take their place at its side, and on an equal footing. May the Profession never see the last of them!

The reports have commenced well. Contributions are furnished by Dr. Herbert Davies, Dr. Down, Dr. Hughlings Jackson, Dr. Woodman, Dr. Andrew Clark, Dr. Barnes, Dr. Ramskill, Dr. Powell, and Messrs. Hutchinson, Maunder, Curling, Couper, Heckford, and Little. Amongst other things there is printed a series of cases reported by the Hospital gold medallists, a Statistical Report of the Maternity Department of the Hospital, and the Statistics of the Hospital for 1863. With respect to the latter, we should be glad in future years to see a more extended tabulation, and would like to suggest the adoption of a plan somewhat similar to that adopted by the registrar of St. Thomas's Hospital.

To repeat an inquiry which we have before made, we ask why the registrars of the great metropolitan Hospitals do not meet and agree to a scheme of registration which shall be uniform and complete, and such as shall supply to the

Profession year by year a summary of the whole Hospital experience of London?

In our review of this volume we do not propose to notice every paper, but merely a few which may be taken as samples of the entire series. Nor would we have it supposed that those we select for special notice are necessarily the best; our object is merely to give our readers an idea of how the volume is made up.

There is a very good and suggestive paper by Mr. Hutchinson upon "True Leprosy," which is of special interest just now in consequence of the inquiries upon the subject instituted by the Royal College of Physicians. Five cases are narrated, one having been under the care of Mr. Adams, two under the care of the author, and two communicated by Mr. Curling.

Mr. Hutchinson also furnishes a long paper upon "Cerebral Amaurosis, more especially with reference to that form supposed to be connected with the use of Tobacco." So far as that narcotic is concerned, the data which he has collected seem insufficient for any definite conclusion. The following is his summary. We may state that altogether notes of fifty-four cases are furnished:—

"1. That there is a special form of cerebral amaurosis usually unattended by other permanent disorder of the nervous system, in which white atrophy of the optic nerve supervenes. 2. That there is little doubt that this form of amaurosis commences centrally, the alterations in the supply of blood to the optic nerve and retina being secondary. 3. That in the early stage of this disease symptoms of functional brain disturbance are usually present: somnolence, headache, giddiness, slight stupor, and sometimes vomiting. 4. That the symptoms last mentioned almost always pass off when the amaurosis is more advanced. 5. That the rapidity of the extinction of sight is usually in ratio with the severity of the other cerebral symptoms. 6. That this form of amaurosis may occur in any age and in either sex. 7. That it now and then follows exanthems, congenital syphilis, disturbed menstrual functions, great anxiety, injuries to the head, etc. 8. That it occurs in large excess in adult males, typical and uncomplicated examples of it being, indeed, very infrequent in women. 9. That in men it is sometimes attended by disturbance or suspension of the generative function, but that in the great majority of cases no such connexion is proved. 10. That there is no reason to think that it is frequently consequent on masturbation, or that it occurs in any especial connexion with acquired syphilis or intemperance. 11. That no adequate explanation can be afforded of the clinical fact that men suffer from it much more often than women. 12. That it does not occur in connexion with any special occupation. 13. That a large proportion of those who suffer from it have been smokers."—P. 81.

Dr. Down narrates a case of "Polysarcia" which was observed in an idiot child, aged 13 years, who, when admitted to the Asylum at Earlswood, weighed 113 lb., although only 4 feet 4 inches high. This was in 1850. In 1862, although of the same height, she weighed 210 lb., and measured 55 inches round the waist. Although now aged 25 years, she had never menstruated. The chief object of the author, however, is to show the influence of several kinds of treatment to which she was subjected. The results are represented in the following table:—

	Weekly increase in weight.	Weekly decrease in weight.
	oz.	oz.
Mixed diet, unrestricted in amount	$7\frac{3}{4}$	—
,, restricted ,,	$1\frac{2}{5}$	—
,, ,, & iod. potassium	*nil.*	*nil.*
,, ,, & liq. potassæ	—	$2\frac{1}{7}$
,, ,, & fucus vesic.	—	$4\frac{1}{3}$
Purely meat diet, without medicine	—	28
,, ,, with fucus vesic.	—	29

She has now been reduced to a weight of 155 lb.

The sixth in the series of "Cases illustrating some very rare forms of Fracture and Dislocation of the Vertebræ," by Mr. Curling, seems to be unique. The following is an abstract of the case:—A robust man, aged 38, walked into the Hospital on May 17, 1838, having just slipped from a ladder and struck the back of his head and neck. He was stupid and pulse was slow, but the pupils acted freely. There was slight pain in the head and some deafness. The next night he was restless, and the pulse became rapid. On the 19th he was unconscious, but became sensible again on the 20th. In the course of the day, however, he again became insensible suddenly; the vessels of the head and face became congested, and breathing stertorous. He was relieved by bleeding, and became able to answer questions, but in the evening suddenly expired. On examination after death, the brain and its membranes were found congested, and there was more fluid than usual found in the lateral ventricles and cavity of the arachnoid. But the most remarkable point was a narrowing of the aperture of the foramen magnum and the odontoid process was found unusually moveable. On further dissection the processus dentatus was found to constitute a separate bone, articulated with the second vertebra. There were no appearances in the medulla of injury or disease, no rupture of ligament or extravasation of blood. Mr. Curling remarks upon this:—"The absence of all mark of recent injury, the perfect condition of the false joint, as evinced by the opposed surfaces being tipped with cartilage, the development of a bursa, and the large surface presented by the anterior part of the ring of the second vertebra for the play of the odontoid process, all tend to show that the parts had existed in this state for a lengthened period. . . . . The interesting question here presents itself, Whether the abnormal state of the odontoid process had any connexion with the symptoms of the disease which caused the patient's death?" —P. 144. Rokitansky tells us that in a few cases of fracture of the odontoid process "they have not only not proved fatal, but have even existed a considerable time without union of the fragments. A specimen of this kind is contained in the Vienna Museum (vol. iii. Syd. Soc. Edit., p. 246)." He says nothing about a false joint being formed in such a case.

There is some of the best advice to students on the subject of estimating the relative value of various kinds of symptoms in disease which we have ever read, in a paper by Dr. Hughlings Jackson, entitled "On the Study of Diseases of the Nervous System." He warns them against "ever taking a complete view of one aspect of a case for a knowledge of the patient's disease." "Learn the health tissues of a patient, as shown by the colour of his hair, the elasticity of his skin, the tint of his complexion, the feel of his arteries, and the condition of his urine. Examine the chief organs, and with especial care the one in fault, or supposed to be in fault; and, lastly, be most careful to ascertain if organs near or distant to the one or more most damaged act in harmony, if function be disordered." Again,—"Never treat a patient on stethoscopic evidence only. The heart may be a bad musical instrument, and yet a good force-pump." Again, speaking of paralysis, he says:—"How exceedingly various are the sets of symptoms produced by the same tissue changes. But we have to think, as regards treatment, of effusion of blood into nervous tissues rather than of disease of the corpus striatum, crura cerebri, pons Varolii, etc. To attend to the seat of damage only, is to study merely the physiology of disease, and is not practical Medicine. I should be misunderstood if I were supposed to underrate the physiological study of diseases of the nervous system. Indeed, I think that to neglect it shows want of education, but to neglect the clinical shows want of experience and sagacity. Never forget that we may run the risk of being over-educated and under-cultivated. We may be gorged with facts in anatomy, physiology, and pathology, and yet our facilities may be little trained for investigating disease."—P. 158.

Dr. Down gives the results of his experience of the use of sesquicarbonate of ammonia in a recent epidemic of scarlet fever at Earlswood. Out of a population of 440 persons 192 had the disease. Of these "147 were idiotic or imbecile in various degrees, and of these 9, or about 6 per cent., succumbed to the disease; while of the remaining 45 officers and servants, whose attacks were of an equally severe character, only one (or rather more than 2 per cent.) died; and even this isolated case (a male attendant) could scarcely be placed to the credit of the scarlet fever alone—it was one only of the factors which accomplished his overthrow. He had not long since recovered from an attack of acute rheumatism, which terminated with an adherent pericardium and a seriously damaged mitral valve. . . . Among the nine idiotic cases that died, no less than seven were the subjects of tuberculosis, and who, although they struggled through the febrile attack, failed to rally during that period when in others convalescence might have been fairly expected. The remaining two died from convulsions—a termination not infrequent amongst the idiotic."—P. 160. All the cases were treated with this salt, 5 grs. being given every four hours, and no trouble was experienced in administering it.

Mr. Couper relates an interesting "case of strangulated

femoral hernia, in which no sac was present. The protruded part seems to have been a portion of the cæcum uncovered by peritoneum.

The "Gleanings from the Field of Observation," by Dr. A. Clark, will be read with interest. The matters he treats of are "warty growths on the soft palate, nasopalatine gland disease, the production of free nuclei by the tonsils, three illustrations of the use of the microscope in the diagnosis of diseases of the lung, the products of pneumonia, the migrations of spermatozoa, spermatozoa in the urine of women, other products associated with spermatozoa in urine, pus in non-albuminous urine, the best method of detecting small quantities of albumen in the urine, notes on albuminous urine, renal calculi without hæmaturia, an hitherto unnoticed condition of the urine, etc., notes respecting false casts, relations of casts to kidney disease, kidney disease without albumen or casts, and the use of magenta in the detection of certain matters in the urine."

Mr. Couper gives "an account of an attempt to reduce dislocation of the lower jaw, which had lasted nearly four months." The attempt was unsuccessful; but the case is of importance as showing what nature can effect, even in so short a time, to remedy the effect of such an accident.

There is a long paper, with a record of thirty-six cases, by Dr. Hughlings Jackson, in which he confirms, by an independent series of observations, M. Broca's views of the association of loss of speech with hemiplegia of the *right* side. "M. Broca believes that diseases of the left side of the brain only, produces loss of language; and, moreover, he locates the faculty of articulate language in a very limited part of that hemisphere. My observations tend to support the first hypothesis, and, in a general way, the second."—P. 388.

Dr. Davies' paper on the Blister Treatment of Acute Rheumatism must not, however, be passed over. He blisters near every inflamed joint, and believes that when free secretion is obtained he thus eliminates the *materies morbi* locally, wherever it gives external manifestation of its presence. In the cases recorded the treatment seems to have been unusually successful. He adds: "I may say, with some amount of confidence, derived from the observation of twenty-five cases, that we may fairly hope and expect, by bold and efficient treatment, to deprive this fearful affection of its most dreaded result—organic disease of the heart." Patients do not seem to complain of the severity of the treatment.

Our readers will now, we think, be in a position to judge tolerably well of the character of these reports. They are illustrated by three lithographic plates (one coloured), and several woodcuts, all well executed. The editors are Drs. Down and A. Clark, and Messrs. Hutchinson and Maunder.

FOREIGN CORRESPONDENCE.

GERMANY.

Berlin, January 9.

As the question of the utilisation of sewage promises to become one of much practical importance at no distant time, I think that the views on this subject recently brought forward by Dr. Stamm, of this city, deserve to be placed before your readers. This gentleman, who is a philanthropist, has given many years of his life to the study of epidemic disease in the different parts of the world, and believes in the possibility of annihilating all such diseases merely by proper attention to cleanliness and other simple hygienic measures. In his pamphlet on the removal of sewage just published, he inveighs against our continuing to erect statues, build museums and buy expensive pictures, when whole towns are infested with stinks; and believes good privies to be a far higher sign of general civilisation than grand palaces and museums of art. According to him, all systems of canalisation for the removal of sewage have been utterly faulty, in ancient as well as in modern times. Liebig went so far as to ascribe the fall of the Roman empire to the system of sewers adopted there; and although this may excite a smile, yet there can be no doubt that sewers waste the productive force of the agricultural soil, and give nothing in return but stinks. Wherever there is an extensive system of sewers, epidemics are inevitable; where there are cesspools and latrines the evil is increased. History furnishes ample proofs of this. When the capital of Egypt was removed from Thebes to Memphis—that is, from the healthy upper country to the marshy lowlands—the empire gradually declined. Not only was all the sewage wasted, but the infection of air was carried on in an almost systematic manner. Cultivation decreased, the population diminished, the sanitary condition of the people was deteriorated. The origin of plague had the same cause. The locality where Cairo is now situated was originally quite surrounded by hills. A canal was led from the Nile to this low valley, where there was no access either to winds or to the pure air of the desert. This canal received the sewage of the whole population. The dead bodies were not properly interred, but covered with a thin layer of earth in the dwelling-houses themselves. The consequence was plague; and as soon as the conditions just named were removed, the plague ceased. The causes of yellow fever and typhus are of a similar kind, and Dr. Murchison has even proposed to call typhus "pythogenic fever," as he thinks that it takes its origin from exhalations from sewers, containing feecal matters in a state of fermentation. In the obstetric wards of the Vienna General Hospital there was an epidemic of puerperal fever in winter 1862-63; and Professor Braun, on the recommendation of Dr. Stamm, ordered the windows to be kept open by day and night, with the most beneficial result, as the epidemic ceased soon afterwards. A curious circumstance in this epidemic was, that in the wards on the second floor far more cases of the fever occurred than in those of the first floor. On examination, it was found that the pipes for the escape of gases from the cesspools opened just above the second floor, in a garret which was quite closed. On opening the windows there, no fresh cases of fever occurred in the second floor. From numerous other instances Dr. Stamm draws the conclusion that wherever there is stink there is *materies morbi;* and that even where there are waterclosets instead of cesspools the poison will penetrate into the dwelling-houses.

He then proceeds to prove that in every system of canalisation, the value of sewage as manure is either entirely or partially destroyed. In Asia Minor, in Syria, in Egypt and North Africa, in Italy and Naples, near Rome, and in Spain are vast tracts of country which have been much cultivated in former times, but where the soil has to so great an extent been deprived of nutritive material that it can no longer furnish produce. It appears extremely difficult, according to general experience, to freshly cultivate such tracts of country, probably because the manure employed does not contain all the elements required for the purpose. Moreover, such tracts easily become fever districts, because after the autumnal rains grasses grow, and are afterwards putrified. Similar conditions may be observed in some of the Confederate States of North America. Tracts of country, which were from the first exceedingly fertile, were cultivated without manure, and relinquished after they had become impoverished. Thus, large portions of Georgia, North Carolina, and Virginia are entirely impoverished, and territories which were formerly populous are now desolated and devastated by fever. Even England begins to suffer in consequence of the system of canalisation pursued throughout the country, and the English are, therefore, compelled to spend annually enormous sums for manure for territories which were once exceedingly fertile. If native sewage were utilised, there would be no necessity for guano. Native manure, however, is not to be had in sufficient quantities, and is comparatively dearer than guano. The consequence is an increased price of provisions; while at the same time the Thames, the Leith, the Clyde, and other rivers are horribly infected. The system of canalisation seems, therefore, equally bad according to the principles of hygiene, national economy, and chemistry; but canals for the removal of rain and slops will always be indispensable.

A general water-closet system cannot exist without canalisation, whereby the fæces are removed. The former is therefore equally bad as the other. In the same way, cesspools and latrines should be entirely done away with. Pettenkofer's researches on the propagation of cholera are alone sufficient to prove the utter worthlessness of this system. The water of wells may be infected by neighbouring cesspools; river-water may become poisoned by the opening of sewers in the river, and both may thus give rise to a spread of cholera. The same system also entails a loss of the largest portion of valuable manure, as ammonia and sulphuretted hydrogen go off in vapours, and only serve to poison the atmosphere. Of all fæcal manures, guano resists best to atmospheric influences; nevertheless, the upper strata of the guano on the Chincha Islands is found to be rotten. The valuable qualities of guano have, however, only been preserved for centuries for this reason, that it never rains on the Chincha Islands. There are

deposits of guano further south on the Pacific coast of South America; but the more we approach the South Pole, and rain becomes more frequent, the more guano loses its efficacy. Where there is much rain, the guano is useless, as the best parts of it are washed away by the rain. There is scarcity of manure in Europe as well as in North America; and we must not forget that it is manure which satisfies hunger, that in the natural course of things it is changed into bread and meat. At no distant time the guano beds on the Chincha Islands will be exhausted, and then no more manure of that kind will be forthcoming. It is therefore necessary that all cesspools and latrines should be done away with as soon as possible. The only good system of dealing with this matter is one which entails direct removal of fæcal matters, and by which neither the air, nor the soil, nor the water can become impure, and which finally allows of the full value of manure being turned to practical account. How should, then, the water-closet system be replaced, so that the comfort attending the water-closet may not only not be lost, but even increased? Dr. Stamm says that the comfort of water-closets consists chiefly in their being devoid of odour. Entire absence of odour, however, can never be had by that system, while it may be easily had by disinfection. A porcelain vase, with a wide funnel-shaped opening, may be made to communicate with a porcelain bucket which receives the fæces. These vases may have an opening from which, by pressure of a piston or some similar arrangement, a small amount of disinfecting fluid may flow into the funnel. This fluid may be kept in a special reservoir behind the stool. Such arrangements could be had in every bed-room or cabinet. The buckets should be emptied in butts placed in the court-yard. Such disinfecting stools do not waste the manure, they do not annoy the neighbours, they do not poison air and water; and as regards the complete absence of smell, they are even more comfortable than water-closets.

The costs for the necessary apparatus ought, in Dr. Stamm's opinion, to be borne by the landlords, as there would be no further costs for cesspools, water-closets, etc. The whole operation for the removal of sewage and rubbish should be conducted either by the municipal authorities or by a Great Removal and Utilisation of Sewage Company (Limited).

The advantages that would, in the inventor's opinion, be connected with the adoption of his system would be the following:—

1st. The cultivation of the soil would gain, provisions, and more especially vegetables, would become cheaper, or at least they would no longer increase in price. The manure might be sent by water or rail to a certain distance, where it could be applied to the soil, which would at once increase in fertility and value. Vegetables, especially for the poorer classes, might be grown where they would not thrive at present.

2nd. The drinking water would be considerably improved, and would no longer give rise to disease. In large towns it is, as a rule, exceedingly difficult to procure good drinking water, especially in summer, when people feel the want of it most. Pure water for cooking is also of great importance, and could easily be had if this system were adopted.

3rd. The average duration of life would be prolonged. In the same measure as air and water become purer, and good vegetables would be accessible to the whole population, the health of the people and the mean duration of life would increase. The more considerable the mean duration of life, the greater would be the work done by a nation. Before man is in a state to become of use to society, a certain time of more or less costly training and education is required, both for body and mind. The longer the life given to an individual for doing work, the richer the population will become. Thus we invariably find that increase of wealth in a nation goes *pari passu* with increase of mean duration of life. Where much time and money is spent on training, and afterwards little work is done, there is great loss to the country. Baron Rothschild, sen., therefore very properly used to say, that every man might become a millionaire provided he lived long enough.

4th. Morality and civilisation would increase. Men who starve in dirty alleys and stinking courts are more likely to become criminals than those who enjoy pure air and water and good food.

5th. Millions of money which are now thrown away would be saved for the country. The amount gained by Dr. Stamm's proposed utilisation of sewage would, in his opinion, more than cover the wants of the poor population, for which now poor-rates (a by no means popular impost) are necessary. Thus the adoption of his system would be, he thinks, a blessing for the nation at large.

GENERAL CORRESPONDENCE.

THE COLLEGE AT EPSOM.

LETTER FROM DR. SIEVEKING.

[To the Editor of the Medical Times and Gazette.]

SIR,—I trust that the changes which were effected in the laws of the Epsom College at the meeting of the governors on January 12, may not remain a dead letter.

The main feature of the new enactments consists in the establishment of exhibitions, the holders of which shall be educated, not as now at £40 per annum, but at £30 a-year. Scholarships are also to be created; but while these are to be rewards of merit, open to the competition of the whole school, the former are intended solely to meet the *res angusta domi* of the poorer members of the Profession. Let us hope that in the former case undeserving or illiterate boys may not convert what is intended as a boon to themselves as well as to their parents into an excuse for idleness. While I willingly admit the policy of the recent act of the Council, which was calculated to throw oil upon the troubled waters, I would venture to suggest that there is a great interval between the theoretical conclusions arrived at, and the practical realisation of the scheme, and it is because I would desire the Profession at large to see how much yet remains to be done that I take the liberty of addressing to you a few remarks on the subject.

It is determined to create a fund for the purpose of establishing the scholarships and exhibitions. Manifestly a long period must elapse before a fund will be collected which can be at all adequate to the purpose. But it will be observed that the new regulations advert to the admission of lay boys, which is made conditional on the failure of the application of Medical men's sons for admission to the College. This is practically a contradiction, for as yet there has been no lack of such applications, and with the increasing prosperity of the school, this failure is still less likely to occur, and can scarcely be said to be desirable. At the same time, there is but one opinion on the subject of restricted class education; it is pronounced to be objectionable by all who have seriously thought on the subject, and it is desired by all earnest supporters of the College that there may be an admixture of lay boys, not only for the purpose of obtaining an accession of income, but also on account of the moral and intellectual advantages which will accrue to the present denizens of the College.

The question then naturally arises whether it may not be possible to reconcile this apparent anomaly. Everybody, I believe, is agreed that the proposal to create exhibitions is good in the abstract; everybody also, I think, is of opinion that an infusion of the lay element among the pupils is most desirable, and that the school will not occupy that position which it ought to fill in the eyes of the public, as well as in that of the Profession, so long as the whole of the boys are derived only from one class of the community. The laws say that no sons of gentlemen not in the Medical Profession shall be admitted unless there are vacancies not required for the sons of Medical men.

I see no way out of the difficulty except by a new and independent foundation, to which no boys shall be admissible at a rate of less than sixty guineas a year. If the school is good for anything, the applications are certain to be numerous enough. It already offers many advantages not found in the majority of public schools, and the continued care and watchfulness of the Council will, I trust, still further enhance its attractive features. I would propose the erection of a new wing, which might not inappropriately be called the "Propert Wing;" and as a Propert fund already exists which has not yet been appropriated to any precise object, the few hundreds collected, to do honour to our treasurer, might form a nucleus to a distinct fund for that purpose. In this way we may reasonably hope to kill two birds with one stone. We should secure a permanent increase of income by the higher charges of the boys admitted to the Propert foundation, which would be at once applicable to the exhibitionerships; and the school would gain intellectually by the contact of a greater variety of ingenuous youths—a point that has been over and over again urged by the head-master no less than by many members of the Council.

Much more might be said upon this subject than you would probably care to admit into your paper; but I cannot conclude without urging one point which I deem vital, and without

attending to which I hold that the whole proposition would fail altogether. I advert to the present name of the College.

The present unfortunate name implies that all boys educated at the Epsom College are recipients of charity. There is not a public school in England in which the element of charity is excluded. In many of our foundations this element has been too much ignored. But it exists everywhere. There are few cases, however, where, as at Epsom, it is customary to affix a stigma to the sons of gentlemen by the very name of the school destined to lead to the highest honours which a preliminary education can prepare boys for. Many Medical men who think well of the school have been deterred from sending their boys there by the soubriquet of "benevolent," and it is utterly out of the question that, while it is retained, any excellencies of the College would ever tempt gentlemen out of our Profession to send their sons at an advanced rate of payment, though still much below that which they would have to pay at schools that in no way but their name merit a higher rank.

Before we can ask the general public to avail themselves of the advantages of Epsom College, it is absolutely necessary to change its present name.

Many of our public schools are not known by the names by which they are called in the charters, and there is no reason why, as there is no other College at Epsom, it should not ordinarily be called the Epsom College. But should the legal authorities object to this, I think that before we take the steps that may be deemed requisite to admit lay boys, we ought to go to the expense of a new charter or new Act, so as to do away with the present obnoxious name.

I am, &c. E. H. Sieveking.

THE CAUSE OF TIMOTHY DALY'S DEATH.

Letter from Dr. Septimus Gibbon.

[To the Editor of the Medical Times and Gazette.]

Sir,—In these days of legal proceedings against Medical men for malpraxis you have done a service to the Profession by printing the notes of Timothy Daly's post-mortem examination. It has gone forth to the public as an "indisputable fact" in this case that the immediate cause of death was "exhaustion from bed-sores." Inasmuch as this opinion would assuredly, with a less firm and less experienced coroner than Mr. Payne, have consigned Mr. Norton to Newgate on a charge of manslaughter, and may yet subject him to the anxiety and expense of having to defend a civil action for malpraxis, and as it may be quoted as a sort of precedent against any future Practitioner who may have a patient die with bed-sores, it behoves the Profession to come to some conclusion as to how far it is correct. Unfortunately, Dr. Andrew, who alone was present at the autopsy, and came to this conclusion, was not questioned on the point at the recent Poor-law investigation by the Medical assessor or any other Medical man.

Having heard Dr. Andrew's evidence, and having had some experience in bad cases of bed-sore, I feel bound to say that I do not agree in the conclusion he has drawn as to the cause of death. The examination Dr. Andrew made of the patient during life was admittedly a very cursory one. Although the case was brought into the Hospital as one of rheumatic fever, and the patient had "hurried respiration," "blueness of lips and countenance, with cold extremities," no stethoscopic examination was made; and the reason for not making one was quite inconsistent with the exhaustion theory—viz., because it was intended to remove him to a Surgical ward as soon as there was a bed to receive him; and yet this man was "in such an exhausted condition that he ought not to have been moved from one bed to another in the same room."

But Mr. Lowne, who had charge of the patient a whole week previously, does not agree in this description of Daly's condition at the time of his removal to the Hospital, for he describes him as being "quite comfortable," and free from the usual symptoms of fatal exhaustion, as hectic fever, pallor, faintness, etc.

During the Crimean war, many of the typhus and dysentery cases when they were admitted into the Smyrna Hospital, to which I was attached, were suffering from extensive bed-sores. These patients were of about Daly's age, and although they laboured under more debilitating diseases they all recovered. Others who had not this complication died. I have not recorded the exact dimensions of the sores, but the following description is given of several cases:—"Extremely emaciated, with a very large undermined bed-sore on sacrum, and two smaller ones over both trochanters." One poor fellow had sloughs on the calves of his legs, another on the heel of his foot. I think, therefore, that, *quoad* the sloughs, my cases were as bad as Daly's.

No doubt this is a true cause of death to many old and worn-out patients in St. Bartholomew's Hospital, and I have known a bed-sore in an earlier stage before the slough has separated, by inducing sleeplessness and irritative fever, determine a fatal result in continued fever. In Daly's case the sloughs had come away, and the sores looked healthy, and were granulating. The exhaustion caused by such sores compared with that resulting from pericarditis and recent pleurisy and pneumonia (Dr. Andrew stating that rheumatic pleuro-pneumonia—a complication, if untreated, of a very fatal character—existed at the time of death) must have been extremely small. This is evidenced by the firm clots that were found in all the cavities of the heart. The œdema of the lungs and cellular tissue no doubt was of post-mortem occurrence, as four days elapsed before the examination was made.

Although I doubt the accuracy of Dr. Andrew's opinion, I must bear testimony to the conscientious and impartial manner in which that gentleman gave his evidence.

I am, &c.

Septimus Gibbon, M.B., Cantab.

3, Finsbury-square, E.C., January 25.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

Tuesday, January 17.

Dr. Peacock, President.

In taking the chair for the first time, Dr. Peacock expressed himself as feeling highly gratified at being appointed to preside over the Pathological Society of London. At no period in its history, he remarked, had it been more flourishing than at present. He recollected some years ago hearing it stated that the Society was on its last legs, that it had exhausted the subjects for exhibition, and that the members were beginning to repeat themselves. After an experience of sixteen years, during which the Society had steadily increased in usefulness and reputation, they might well smile at such a remark. During that time the number of members enrolled had steadily increased, the interest of the meetings had been maintained, and there had been issued to the Society fifteen volumes of *Transactions*, which he believed would bear a favourable comparison with those of any other society, and the general reputation of which was attested by the frequency with which they were referred to, not only in this country, but abroad. The success of the Society was due, he believed, chiefly to two causes. First, that it devoted itself to the study of a branch of Medical science of the greatest interest and importance. It had never degenerated into meetings for the exhibition of specimens of morbid anatomy, but had aimed at cultivating pathology in all its bearings. Fresh subjects of pathological interest were continually arising, and many such had received a large amount of the Society's attention, and important information for their elucidation would be found in the pages of its *Transactions*. The other element in the success of the Society was, that it embraced a large number of young and energetic men; and if such continued to join the Society, and if the members continued to display the same energy, it would continue to increase in importance. He would say to the present younger members of the Society that their communications would also receive the greatest attention, and he would tell them that a reputation made in that room would be a sure prelude to higher distinction in a wider sphere. Many members who had been little known, and were amongst the most active at its commencement, now enjoyed a high reputation in their Profession, and he could confidently predict the same for those who had recently joined. The Society had from the first made it a point that the younger as well as the older members should be represented in the Council, and it would be seen from the list for the year that the principle had not been departed from. As regards the secretaries who had conducted the work of the Society during the last session, it was impossible for him to speak too highly, and they had to regret the loss of one of

them—Dr. Bristowe. He would, however, be replaced by a gentleman, Dr. Murchison, whose labours in the Society and elsewhere afforded a sure guarantee that he would prove himself not less efficient than his predecessor. The President concluded by saying that, having attended all the preliminary meetings of the Society, and nearly all those for business, he had seen its steady progress, and that had afforded him the greatest gratification. He had been anxious to promote its interests in his former position, he could be no less so as its President. He felt, however, that his position was a difficult one. He could not forget that the post he was called upon to occupy had been previously held by the most eminent members of the Profession, and he especially alluded to the able presidency of his predecessor. It would, however, be his earnest desire to fill it worthily, and he hoped he should in doing so promote the interests of the Society. It would indeed be a source of great gratification if, at the end of his term of office, he preserved the same kindly feelings on the part of the members which were manifested towards him in his election as President.

A report, by Dr. Harley and Mr. Francis Mason, was read, on Mr. Fergusson's specimen of

GALACTOCELE.

The report was in great detail, a thorough chemical and microscopical examination having been made of the fluid. The chief results, however, were that the fluid differed from ordinary hydrocele fluid, with which it was carefully compared, simply in containing fatty matter. The reaction of the two was identical, so also was the odour, and both contained sulphuretted hydrogen. The specific gravity was also nearly the same, the ordinary fluid being only two degrees higher than the other. In fact, in all respects they appeared alike, except one, viz., in the absence of oleaginous matter in the ordinary fluid. As previously stated, by removing the fatty matter from the milky fluid it assumed the appearance of the other. The counter experiment was also made, and by adding animal oil to the ordinary fluid it assumed precisely the same appearances as the other. The natural conclusion, therefore, was that the milk-like fluid was ordinary hydrocele fluid *plus* some of the fatty matter of the blood probably exuded by the capillaries of the tunica vaginalis.

Dr. Wilks showed a specimen of

LOSS OF THE PULMONARY VALVES.

A man, aged 31, came amongst Dr. Wilks' out-patients, suffering from phthisis. He had at the same time a double bruît, heard over the valves of the heart, and traceable with equal intensity upwards on the left side. There was no indication in the pulse of aortic valvular disease, and yet from the improbability of the affection being in the pulmonary artery, it was thought to be due to an aneurismal or other morbid condition of the aorta. He had had an attack of rheumatism ten years before, and had since been obliged to leave a laborious occupation for that of a cabman. After death, which took place from disorganisation of the lungs, the cause of the systolic and diastolic bruit was found to be in the pulmonary artery. One only of the sigmoid valves remained, another had completely disappeared, and of a third there was a mere vestige at the point of attachment. There was no thickening of the healthy valve, nor other signs of an inflammatory process in the neighbourhood; the morbid process appeared to be simply an ulcerative one. Two of the aortic valves were slightly adherent as the result of a former endocarditis; the right ventricle was not enlarged. As regards the origin of the disease, Dr. Wilks said some difficulty existed. The fact of the patient's health failing after an attack of rheumatism ten years before might point to that time as the occasion of the mischief, whilst, on the other hand, the absence of all the ordinary signs of endocarditis, with the simple loss of the valves, might suggest a congenital malformation. The latter theory would be merely throwing back the time of the occurrence of the endocarditis to intra-uterine life, but would be favoured by the fact that affection of the pulmonary valves appears to be more prone to occur at that time than after birth.

Mr. Hinton presented a specimen of

SUBACEOUS TUMOUR IN THE TYMPANUM.

The case was peculiar inasmuch as instead of a single laminated mass enclosed by a membrane, which is the usual form in which these tumours are met with in the tympanum, two were present in the form of small rounded bodies of a glistening white aspect, and attached not to the walls of the cavity, but to a semi-membranous pultaceous mass, which filled it. This mass itself appeared to be of the same character as the smaller tumours, but to have undergone a process of decay. The membrana tympani was thick, white, and fallen in, and at its posterior part was a perforation, round and with smooth edges—apparently the point at which the growth of the tumour had commenced. The bone was not diseased, but the upper wall of the tympanum was thicker and denser than is usual, and also than on the opposite side. The Eustachian tube was pervious. The external meatus contained thickened flakes of epidermis. The vestibule contained a large quantity of otoconic much in excess of the usual amount. The nerve fibres were small, and of fibroid appearance, and some of the epithelium cells exhibited marks of fatty degeneration; in the semi-circular canals were numerous large circular or oval forms, lined with epithelium; these were not seen in the opposite ear. In the cochlea the teeth appeared small and their outline indistinct. The patient was a man aged 56, who died in Guy's Hospital of cancer of the liver. He could hear a distinct voice within a foot of the ear, and a loud click of the nail at the distance of six inches; he had been deaf in that ear (as he said "from colds") for upwards of twenty years; neither pain nor tinnitus. The left ear also had at one time been deaf, but was cured by syringing; in the left ear, the hearing of which, three weeks before his death, was good, though not acute, the tympanic cavity contained a large number of fine but firm adhesive bands which surrounded the assicula in all directions. The opecula were fairly moveable. Labyrinth healthy.

At the desire of the exhibitor, the specimen was referred to Mr. Toynbee and Mr. Thomas Smith for further examination.

Dr. Crisp exhibited the

STOMACH, DUODENUM, AND PART OF THE JEJUNUM OF A VERY FAT MAN, SIXTY YEARS OF AGE,

who weighed about eighteen stone. The case occurred in the practice of Dr. H. Davis, of Putney. The patient for many years had been a great eater and drinker. He suffered much from flatulence, and was in the habit of taking large quantities of aperient pills. He had coliky pains in the abdomen, followed by a low form of peritonitis, and sank six days after he was first seen. There was obstinate constipation, but no stercoraceous vomiting. The intestines were glued together by recent lymph, but no other mechanical obstruction was found, The stomach and small intestines were much distended and of large capacity, the coats of the former being very thin. The length of the stomach was fifteen inches; its breadth, when opened, eleven inches. The lower part of the duodenum and the jejunum, when opened, measured five and five and one-half inches from side to side; the kidneys were deeply embedded in fat, and this material was deposited in many other parts to an enormous extent; thus, large flakes were connected with the small intestines that measured three inches in diameter. The liver was large, light coloured, and very fatty, but notwithstanding this the fæces presented a normal appearance, and the gall-bladder was filled with what appeared to be healthy bile. It was thought that the great capacity of the stomach and small intestines was due to the long-continued over-feeding, gaseous distension, and the injudicious use of aperients.

Dr. Crisp likewise exhibited the

LUNGS, SPLEEN, AND OTHER PARTS OF A YOUNG ORANG [*S. satyrus*] (WITH WAX CASTS).

The right lung was in a state of grey hepatisation, and the spleen, which had a supplementary one attached to it, had several small tubercles attached on its surface. This was the only organ affected with tubercle, and Dr. Crisp had met with the same localisation of tubercular deposit in other of the quadrumana, but he believed that in man tubercle was never confined to the spleen alone.

With these preparations was sent round the os penis of the chimpanzee and orang, a discovery Dr. Crisp thought that would tend much to lower these brutes in the animal scale.

Mr. J. Z. Laurence then showed a patient who had a

CANCROID AFFECTION OF THE CORNEA.

The patient was a man, 27 years of age. The eye presented the following appearances when Mr. Laurence first saw him in April, 1863:—Occupying nearly the whole outer half of the cornea was a soft, vascular, conical growth measuring about 4‴ transversely, about 3‴ from above downwards, and rising $1\frac{1}{2}$‴ above the surface of the cornea. The greater part of the tumour appeared to spring from the deeper layers of the cornea, the smaller portion on the outer side passing insensibly into the adjacent scleral surface. Numerous vessels passed

from the highly congested conjunctiva to the surface of the growth, especially one large vein from the inner side. The patient stated that he had experienced but little pain in the eye, and that the growth was but slightly sensitive to the contact of a foreign body, such as a fine probe. The portion of the cornea unobscured by the tumour was nebulous and highly vascular, and at its upper and outer part adherent to the upper lid, which was very much thickened and congested, and its palpebral surface roughened by minute fungoid elevations having the character of surgical granulations. The visual power of the eye was reduced to mere quantitative perception of light. When last seen on January 17, 1865, the eye appeared to have undergone little general change, excepting that the conjunctiva was more vascular, the growth larger in all its dimensions, and its apex flatter, softish, uneven, and of a dirty white colour (ulcerated); numerous large tortuous vessels running to it, and ramifying over its surface. The protrusion of the growth between their edges prevented the complete closure of the lids. The upper lid was considerably thickened at its margin, and projecting from its under surface, moving freely upon the cornea, were two lobular fleshy growths, each measuring about 1½‴ in length. Three cases of cancroid of the cornea (an affection which Mr. Laurence said is by no means frequently observed) have been reported in the *Ophthalmic Review* (i. 79).

CIRRHOSIS OF THE LUNG.

At the last meeting of the Society Dr. Bristow having exhibited a specimen of this disease, Dr. Quain suggested that a microscopic examination of the lung should be made. The President requested Dr. Wilks to do so, but Dr. Wilks having been very much engaged, asked Dr. Sutton to make the examination, and the following is an abstract of Dr. Sutton's report:—The greatly thickened pleura was found to be made up of bundles of fine fibrous tissue, and between the bundles were a number of fusiform and large spherical corpuscles with granular contents, the nuclei not being very distinct. By the naked eye it could not be decided where the thickened pleura ended and the lung tissue began, but a section made in the immediate vicinity of the pleura showed (as seen in the drawing) spherical and spindle-shaped cells, and with a high power it could be distinguished that there were fine bundles of newly-formed fibrinous tissue, which were continuous with those of the thickened pleura, and these had in some partly, and in others completely, obliterated the air sacs. The connective tissue around the bronchial tubes and pulmonary vessels was unusually distinctly seen and was apparently increased in amount, and from a similar extension into the lung tissue. Therefore, Dr. Sutton concluded, that there had been a formation of new tissue elements, and of such as usually represent connective tissue, and that these were in the highest state of development in those parts of the lung in the vicinity of the diseased pleura and of the increased fibrous tissue around the bronchial tubes; and in those parts of the lung most removed from these situations spherical granular corpuscles only were seen.

Dr. W. Squire exhibited, on behalf of Mr. W. Dunnett Spanton, of the North Staffordshire Infirmary, a specimen of

RUPTURE OF ONE OF THE MUSCULI PAPILLARES OF THE TRICUSPID VALVE.

The heart was taken from a young woman, admitted into the Infirmary seven weeks after a second confinement. She was suffering from pelvic inflammation, peritonitis, and from want. A very loud, rough, systolic murmur was heard at the base of the heart. She lived five days, the rough and intense character of the cardiac bruit being remarkable throughout. At the autopsy thick pus was seen surrounding the intestines and uterus, and filling the ovaries. There was pneumonia in the right lung, but no trace of tubercle. The pericardium contained half an ounce clear yellow serum; its inner surface was smooth. There was a soft fibrinous clot in the pulmonary artery and aorta, and in both the right and left cavities of the heart. On the tricuspid valve, at its free margin, were numerous large, firm, nodulated vegetations, and recent soft ones were seen to be attached to the columnæ carneæ. One of the musculi papillares was ruptured near to the origin of the cordæ tendineæ; the broken extremity was covered over and rounded by fibrinous deposit. The endocardium was of a bright red colour; mitral, aortic, and pulmonary valves were healthy. Tissue of heart soft and flabby, with fatty degeneration. Mr. Spanton remarks that "among eleven cases of rupture of the valves, Dr. Peacock found but one case affecting the tricuspid, and I cannot find an account of any other."

Dr. Squire also exhibited, for Mr. Spanton, a specimen of

CHRONIC ULCERATION OF THE LARYNX,

from a man who had suffered more than two years from the affection. The laryngoscope had shown extensive and deep ulceration below the epiglottis, and round its left base; there had been swelling about the uvula and tonsils for some time. There was no history of syphilis, and no evidence of any disease of the lungs either before or after death.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, DECEMBER 7.

Dr. Oldham, President, in the Chair.

Professor Pajot, of Paris; Professor Hecker, of Munich; and Dr. Marion Sims, of Paris, were elected Foreign Honorary Fellows. Dr. J. B. Potter and Mr. G. H. C. Cooper were elected ordinary Fellows.

Mr. Gayton presented to the Society a pair of forceps with a spring-racket attached to the handles, as made at his suggestion, and employed by himself on many occasions without a still-birth.

Dr. Barnes exhibited a piliferous cyst of the ovary.

Mr. Baker Brown showed a

LARGE FIBROID TUMOUR AND UTERUS, THE LATTER CONTAINING A LARGE MASS OF FIBROID GROWTH, TO WHICH THE OVARIES WERE ADHERENT, AND ENLARGED BY CYSTIC DISEASE.

It was proposed to remove only the large mass, which from its weight had become so troublesome as to render the patient's life a burden. Upon opening the abdomen the tumour was found to be pendulous, attached to the uterus by a very small pedicle. This was divided by the écraseur, but as it contained a very large artery, profuse bleeding ensued; and it was then considered advisable to remove the whole uterus and ovaries in one. This was done, the cervix uteri being transfixed by two ligatures an inch and a half from the os, and each broad ligament being pierced with a needle and tied with strong twine. After the removal of the mass it was found that the ligature of one of the broad ligaments had slipped, and that bleeding was going on. It was taken up with the vulsellum, and a second ligature applied. The external wound being closed, the patient went on very well for ten hours, when, suddenly vomiting, she became faint, and shortly afterwards died. It was found at the post-mortem examination that bleeding had taken place from a portion of the broad ligament which had not been included in the second ligature. Mr. Brown remarked that in any future case he should tie the broad ligament with a double instead of a single ligature, to prevent the possibility of slipping.

Dr. Graily Hewitt exhibited Dr. Marion Sims's modification of Chassaignac's écraseur, which did not arrive in time for the last meeting.

Dr. W. Wade, of Birmingham, read a paper

ON PUERPERAL EMBOLISM.

The author reviewed the history of the disease, which he took as a real evidence of the progress of Medicine. He entered into a description of its nature and varieties, and gave a sketch of Virchow's doctrine and of his experiments upon the production of embola. He then described a case which had occurred in his practice, in a woman suffering from phlegmasia dolens, who was suddenly, during exertion, seized with severe dyspnœa three weeks after her delivery. The pulse was feeble; skin cold and clammy. This state continued, but became each day more severe, for a fortnight, when she died. As was prognosticated, a large clot was found in the pulmonary artery, extending from the third or fourth ramification.

Dr. Greenhalgh stated that cases of fatal embolism after parturition were rare. He had met with but one case in his own practice. It occurred in a very healthy young lady, who had been confined of her first child. She had had a perfectly normal labour, not followed by hæmorrhage or any untoward circumstance beyond some acceleration of the pulse on the third day after delivery. She was suddenly seized during the evening of the sixth day after her confinement with severe dyspnœa, acute agony in the cardiac region, and intense mental excitement, speedily followed by alarming prostration and death in less than three hours. No post-mortem was made.

Dr. Ballard asked if there had been any febrile disturbance in Dr. Greenhalgh's case.

Dr. Barnes observed that the history of this case and of others in which embolism followed upon phlegmasia dolens had an important bearing upon treatment. Thus it was usual, after the subsidence of the acute symptoms of phlegmasia dolens, to rub the affected limb with the view of promoting absorption and supplying passive exercise to the muscles and other tissues. It might be that this friction would favour the detachment of a clot from the femoral vein, which being thrown into the circulation would constitute "embolism." This danger should be borne in mind. He thought the connexion between a febrile state and clotting or thrombosis, suggested by the question of Dr. Ballard, was very frequent. He believed in most cases of phlegmasia dolens there was a pre-existent abnormal state of the blood which predisposed to coagulation. He (Dr. Barnes) had gathered up in his memoir on Thrombosis and Embolia, published in the Society's *Transactions*, vol. iv., most of the information at that time extant upon the subject. Since then, however, our information had been considerably enlarged by the publication of new cases.

Dr. J. Braxton Hicks read a paper on

AN INQUIRY INTO THE BEST MODE OF DELIVERING THE FŒTAL HEAD AFTER PERFORATION.

In introducing the subject of this paper, the author said that, notwithstanding the employment of premature labour and version, cases would occur in which it was either necessary or desirable to perforate. He pointed out that the subject had of late years not received the attention it deserved. He alluded to the disputes which arose upon Dr. Osborn's case of E. Sherwood, when that Physician asserted he could draw a child's head through a brim having an inch and a-half antero-posterior diameter, by tilting the base of the skull sideways, and concluded that Cæsarean section might be done away with. The disputes which followed were so acrimonious that the valuable points elicited by Drs. Hull, Hamilton, and Burns were, to a certain extent, lost sight of, at least as far as they were calculated to give any rule in practice. Dr. Burns in particular deduced from his experiments that the calvarium of the fœtal head being removed, the base of the skull could be drawn down easier face foremost than in any other direction. With this the author's experiments entirely agreed. And he pointed out further the advantage of the chin pointing anteriorly during the descent. He further instituted a comparison between the opposing diameters when the face is made to present and the other modes of drawing down the base of the skull. He then proceeded to answer the inquiry: if in cases of extreme lessening of the antero-posterior diameter, it is best to cause the face to present; and if, after simple perforation, it is best to continue vertex presentation, at what degree of reduction of the size of the head do the two presentations cause equal obstruction? This he answered by the results of experiments, which might be thus concisely stated. That, as is acknowledged by all, vertex presentation in natural labour is the best; and that after perforation and evacuation of the brain up to the extent of one-fourth, this rule holds good; yet if the evacuation of the brain and collapse of the calvaria by this means, or by more or less fracturing the bones, be carried to a greater degree, we find that the facial presentation affords the easiest mode of delivery, provided that the mentobregmatic falls beneath the bizygomatic diameter. And, further, that if we remove the whole calvarium, leaving merely the base, and then induce face presentation, taking care that the chin, as it descends, points anteriorly, we diminish to the smallest possible amount, short of wholly breaking it up, the opposition of the head, leaving only from one to one and a-half inch in depth to oppose the conjugate diameter of the brim, and from three to four inches at the outside to oppose the transverse. The author, as practical deductions from these facts, recommended that in cases where simple perforation failed, to allow the descent of the head in cases of obstruction —say above three inches antero-posterior diameter—to break up purposely and carefully the bones of the calvarium, and remove at least a portion, preserving the scalp as protection to the edges, and then to induce face presentation. That when the diameter was under three inches, then to remove all the calvarium, and then to induce face presentation, taking care to bring the chin forwards, if not already in that direction. Dr. Hicks then pointed out the facility of doing this with a small blunt hook, which could be readily, and without chance of injury, passed up to the orbit. The chin, he had found, had a tendency to point anteriorly upon being drawn down. He then entered upon some useful details, and compared this mode of craniotomy with the cephalotribe. He remarked that by this means, in deciding upon whether craniotomy or Cæsarean section should be performed, the head was not so much to be considered as the size of the body in cases of brim obstruction. The paper was illustrated by eight cases of craniotomy, six of which were required for contraction of the conjugate, and two for obstructions in cavity. In all the induction of face presentation was attended by instant and complete passage through the obstacle. In some of the cases the shoulder and pelvis of fœtus gave more difficulty than the head. The paper was accompanied by details of the experiments.

Dr. Greenhalgh considered that the author had done much service to the Profession by bringing the subject forward in such a scientific and practical manner. He drew attention to the dangers attending cases of extreme deformity of the brim, remarking that there was a wide difference between extraction and safe extraction, especially (as is often the case) where the passages are swollen and inflamed. He called to mind the occasional difficulty of entering the skull with the perforator, and quoted a case where this was almost impossible. He thought, from a case which he had seen at Vienna, that he should use Braun's cephalotribe in a future difficulty. He had, in a case where the whole vault of the calvarium had been entirely removed before he arrived, delivered by fixing three crotchets outside of the presenting part.

HARVEIAN SOCIETY OF LONDON.

Thursday, November 3.

W. Adams, Esq., President.

An abstract of a paper, by Mr. B. Squire, M.B., was read

ON THE DIAGNOSIS BETWEEN SYPHILITIC AND NON-SYPHILITIC DISEASES OF THE SKIN.

The author, after remarking on the importance of the subject, observed that an eruption, even when the question of antecedent primary syphilis was well made out, was by no means necessarily of syphilitic origin; and that where an eruption was clearly syphilitic, it was often extremely difficult to obtain a history of primary syphilis. He, therefore, placed very little reliance on inquiries of this kind as a means of diagnosis. The best evidence that we could obtain of the nature of an eruption was the evidence that was within our personal knowledge. The most reliable direct evidence of previous chancre was the cicatrix left by that chancre. One of the most important means of distinction between syphilitic and non-syphilitic eruptions was the situation of the eruption. The most frequent situations for syphilitic eruptions in the order of their frequency were the neighbourhood of the alæ of the nose, the angles of the mouth, the forehead near the roots of the hairs, the back of the neck near the roots of the hairs, the inner canthus of the eyelids, the middle of the chest, the inner surfaces of the limbs, the neighbourhood of the axillæ and groins. It might be stated generally that the face was the most favourite locality for syphilitic eruptions. The age at which syphilides most commonly appear for the first time was another means of diagnosis. The most common age for this was between 25 and 35. Infantile syphilis appeared generally at the age of one month. The earliest time at which the author had met with a syphilitic eruption dependant on syphilis communicated by intercourse was in the case of a female aged 8 years. The colour of the eruption was a favourite, but, unless under certain restrictions, a fallacious means of diagnosis. He meant that the notion that a coppery tint would enable one to distinguish syphilitic from non-syphilitic eruptions was an erroneous one: this tint was found more or less marked in every case of non-syphilitic psoriasis. Again, syphilitic eruptions did not present it at all at their outset; it was only as they became developed that the coppery tint gradually appeared. The form of the eruption was a more reliable means of diagnosis. Most commonly this was annular or oval. If not in actual rings, the eruption formed segments of circles—incomplete rings; or by the juxtaposition of two rings, it might form figures of eight. This, of course, however, would not enable us to distinguish, as by a touchstone, syphilitic from non-syphilitic eruptions. Psoriasis, *e.g.*, sometimes occurred in rings; so did lichen; so again did herpes circinatus. Lupus was another example of a non-syphilitic eruption of annular form. The absence of itching and smarting was a peculiarity which would often aid in the recognition of a syphilide. The mixed character of syphilitic eruptions was another means of distinguishing them.

Thus, in an eruption that was not syphilitic, it was rare to find rashes mixed with vesicles, or pustules with scales. Not so in a syphilide. What might be termed the "products of the eruption"—such as the scales or the crusts—were a means of diagnosis. The scales of a syphilitic eruption were finer, smaller, and more adherent to the surface beneath than those of a simple squamous disease. The scaly patch, too, was circumscribed by a whitish border, to which great importance had been attached by Biett as a diagnostic symptom. This whitish border was the result of the separation of the epidermis from the cutis around the diseased patch. The crusts, which might either follow the scales or succeed to pustules, were much harder, thicker, and greener, than the crusts of a simple cutaneous disease; they were sometimes, at all events at their centre, as thick as they were broad. The ulcers that were left by either pustular or tubercular syphilides were generally circular, with abrupt and perpendicular edges, and a grey pultaceous floor, the skin around them having a copper tint. The scars left by a syphilide, though at first of a violet hue, soon acquired even a more tawny-brown tint than the eruption that had preceded them; this tint in its turn at length faded, but even when the scar had at length been left perfectly white, its annular or reticulated form, as the case might be, would distinguish its origin. Another means of recognising a syphilitic eruption was attention to other changes produced by syphilis besides those wrought in the skin itself. With regard to the sore-throat, we should be on our guard against relying too much on it as a diagnostic symptom. There were many diseases of the skin (and some that resembled pretty closely one or other of the syphilides) that were dependent on scrofula, or, at all events, occurred more frequently in the scrofulous than in any other constitution. No people were more liable to sore-throats than the scrofulous, and perhaps no two diseases were more frequently confounded together than syphilitic lupus and the lupus that occurs in the scrofulous. In doubtful cases the question, "Have you suffered from sore-throat?" is often allowed to settle the difficulty. The most characteristic condition of a syphilitic sore-throat was either the presence of mucous tubercles or of cicatrices. The presence of mucous tubercles, either in the throat or elsewhere, was one of the most conclusive signs of syphilis that one could have. The erythema of the buttocks and scrotum, that was so common in sickly children whose cleanliness was hardly attended to, was often mistaken for infantile syphilis, and if they happened to have a cold at the same time, it was still more likely to be set down to a specific cause. This mistake happened the more commonly that simple erythema in infants, as it faded, often assumed more or less of a tawny tint. The effect of the common remedy for infantile syphilis—grey powder—on the other class of cases, was greatly to aggravate them. Again, the author had frequently seen severe cases of eczema in infants taken for infantile syphilis, and treated for it with the same unfavourable result. There was no better or surer means for establishing the disease to be syphilitic than the existence of mucous tubercles when these were present, and in the majority of cases of infantile syphilis they were. Their most common situations were, the angles of the mouth, the alæ of the nose, the vulva, the anus, the scrotum, or within the mouth. The author then referred to rheumatic pains in the limbs, along the bones, or in the larger joints,—to bitemporal neuralgia, to falling off of the hair, to indolent swellings of the glands of the neck, and, in the female, frequent abortion, or still-births, or suspension of the catamenia (not arising from any other ascertainable cause), as evidences of the syphilitic nature of an eruption, and to the chronic course and the progressive changes in the character of the syphilides, observing, however, that it was not upon any one symptom alone, but on the general issue of the evidence afforded by many symptoms that we should rely for our diagnosis of syphilides from the other diseases of the skin. He concluded by expressing his regret that the limits of a paper precluded his entering on the much larger subject of the diagnosis of the different syphilides from the several diseases of the skin for which they might be taken.

London Hospitals.—Two ladies, Miss Foster, of Hyde-park-square, and Miss Ellis, of Balham-hill, lately deceased, have left the following sums to Medical charities:—The first-named lady of £1000, to the Charing-cross Hospital, and the latter of £100, to the Royal Free Hospital, and similar amounts to the Asylum for Idiots, and other institutions not strictly Medical.

THE CASE OF PRYCE *v.* BOWEN. MEETING OF THE MEDICAL PROFESSION IN LIVERPOOL.

A numerous meeting of the members of the Medical Profession of Liverpool and the neighbourhood was held on Monday evening, at the Medical Institution, with reference to the case of Dr. Bowen.

Dr. Vose presided, and in opening the business said it was not long since the Medical Profession of Liverpool and the neighbourhood had thought it necessary to hold a meeting for the purpose of condemning the conduct of the witnesses for the plaintiff at a notorious trial in an adjacent city, and it was mortifying that they had so soon found it necessary to hold another meeting to express their opinion upon a like subject. All probably had heard more or less of the case of Pryce *v.* Bowen, tried at the last Liverpool assizes. The case belonged to a class which appeared to be rapidly establishing itself as one of the institutions of the country. Actions of this kind were set on foot by a certain description of the community, in concert with a certain description of attorneys, for the purpose of plunder; but they could never be brought at all were not these people aware that there was also a certain description of Medical men always ready, perhaps eager, to hire themselves out for a paltry pecuniary consideration to give evidence against their Professional brethren, and thereby involve them in disaster and in loss. They all remembered the formidable expense entailed upon the defendant in the Chester case, although the verdict was triumphantly in his favour; and in the present case, although Mr. South, of St. Thomas's Hospital, as well as other Surgeons of eminence, together with the judge and the jury, concurred in the opinion that Dr. Bowen's Professional skill had been unquestionable, they found that that gentleman had been mulcted in £200 costs to defend himself; to say nothing of the annoyance, the waste of time, and the suspense in which he had been involved. It was to be hoped that the machinery of the British Medical Association would without delay be brought to bear upon this and similar transactions, and that its opinion would be expressed unflinchingly on the conduct of its members when they came forward to give evidence against Professional men in cases like Pryce *v.* Bowen. ("Hear, hear," and cheers.) So strongly had his (the Chairman's) colleagues of the Royal Infirmary felt on this matter that they lost no time, after the trial, in addressing the Physicians and Surgeons of the Manchester Royal Infirmary with reference to it. In rather less than a fortnight afterwards they had the honour to receive an answer to their remonstrance, but only from a functionary of the Hospital who subscribed himself its "Resident Medical Officer."

Mr. Ellis Jones, who moved the first resolution, said that no doubt many members of the Profession had been extremely annoyed at the imaginary opinions formed by patients of the maltreatment of their cases. Both he and his colleagues had suffered in some degree in this way, and he mentioned a case at the Northern Hospital (with which Mr. Hakes had been more particularly concerned) where the patient expressed himself perfectly satisfied with the treatment he had received, and thanked Mr. Hakes and others for their attention to his case. But when he had left the Hospital, he got hold of a Medical man or two in the town, who told him that the treatment was not correct, that Mr. Hakes and the other Medical men had no right to interfere with his limb, and even went so far as to say that no dislocation had taken place. The president had told them that actions like these were frequently brought in consequence of the assertions of persons who knew nothing of the treatment adopted, and who sought only to injure the fair fame of an honourable man. ("Hear, hear," and applause.) Mr. Jones mentioned another case in point within his own experience in Liverpool where, though no action was actually taken, a Medical man had been served with a writ, and sustained great anxiety and annoyance. With regard to Dr. Bowen's case, he (Mr. Jones) had been requested by the attorney for the prosecution to appear against Dr. Bowen, but he declared that he would rather sacrifice his property and even his life than do so, and he recommended the attorney to give up the case. (Cheers.) What, then, was his surprise to see a man whom he had thought highly respectable come forward from Manchester and give evidence for the prosecution? The gentleman in question described himself as an honorary Surgeon of the Manchester Infirmary, but though attached to the Dispensary

he was not honorary Surgeon to the Infirmary. So much, therefore, for his veracity. ("Hear, hear," and laughter.) Mr. Jones then criticised the evidence adduced by Mr. Lund, and ridiculed the statement of Mr. Evan Thomas, jun., as to his having seen "thousands" of cases of arm dislocation. In conclusion, he warmly vindicated the talents and standing of Dr. Bowen, and pointed out how immense and unknown an injury might be done to a Medical man by such unjustifiable attacks. The resolution was :—

"That this meeting desires to express their deep sympathy with Dr. Bowen for the annoyance to which he has been subjected in the trial of Pryce *v.* Bowen, and to congratulate him on the very satisfactory manner in which he has vindicated his Professional reputation."

Dr. A. T. H. Waters seconded the resolution. Painful as it was, he said, it was their duty on an occasion like this to come forward and express their sympathy and congratulations, and also, in firm and unmistakeable language, to declare their opinion of those who unjustly and unfairly gave evidence against their Professional brethren. Meetings like the present would ultimately tend to put a stop to these most unjustifiable prosecutions ; they had an important influence, both on the Profession and the public, tending to show in both cases that a man who acted honourably and conscientiously, and to the best of his ability, when unjustly accused, would have the support of his Profession. (Applause.) If they respected and appreciated their own Profession, so would the public respect and appreciate them. (Hear, hear.) With regard to Mr. Lund, he (Dr. Waters) could not help remarking that had Mr. Lund acted upon the golden rule, not to give an opinion upon the case before he had consulted with his Professional brother, he would never have placed himself in the painful position which he now occupies, and the case of Pryce *v.* Bowen would never have been tried. ("Hear, hear," and applause.) No honourable member of the Profession would hesitate to give evidence against a Professional brother who had been guilty of culpable negligence, but in this case everything had been done which skill could dictate, and it was inexcusable for a member of their Profession to give evidence such as that which had been adduced. Dr. Waters hoped that meetings of this description would tend rather to diminish trials of the kind under review, and he believed this had actually been the result, as was shown by the difficulty of procuring Medical witnesses in the case which had been alluded to by Mr. Ellis Jones, in which both Liverpool and London were canvassed in vain. In conclusion, Dr. Waters warmly echoed the congratulatory terms of the resolution, which was then put and carried unanimously.

Mr. Bickersteth moved—"That this meeting feels bound to record their strong disapprobation of the course pursued by Mr. Lund in the matter of Pryce *v.* Bowen." It was extremely painful to pass a vote of censure upon any man, and nothing but a stern sense of duty would have impelled him (Mr. Bickersteth) to move the resolution. Had it not been for the conduct of Mr. Lund, he believed the trial would never have taken place. He had it on the authority of the solicitors for the plaintiff, that they had canvassed Liverpool, and had found no one who would support the evidence. (Hear, hear.) By Mr. Lund's own acknowledgment, he had been called upon by the solicitors for the plaintiff with the object of involving a Professional brother in disgrace, and he did not hesitate to give his services. Having alluded to the misstatement as to Mr. Lund's connexion with the Royal Infirmary of Manchester, Mr. Bickersteth asked if they could expect Professional morality where there was such an evident deficiency in ordinary morals. He (Mr. Bickersteth) had read Mr. Lund's defence or explanation, but explanation it was not. Mr. Lund "regretted that he had ever appeared in the case," and no doubt he would regret it as long as he lived ; for they were a strong Professional body, they had expressed their opinion of Mr. Lund, and Mr. Lund and Evan Thomas would for the future be connected in the minds of the Profession with this case. In conclusion, Mr. Bickersteth pointed to the fact that in Mr. Lund's statement a simple regret was expressed that he had erred from a want of judgment, no regret that he had injured a member of his own Profession and a brother Practitioner. (Hear, hear.)

Mr. Steele wished to place the nature of the meeting in its true light. It must be clearly understood that they had not met for the purpose of attacking any individual ; it was not an aggressive, but a defensive, movement on the part of the Medical Profession. (Applause.) All present would acknowledge that, as public servants, they were responsible to the public for the efficient discharge of their duties, and any Physician or Surgeon who undertook the care of a case of disease or injury was bound to bring to its treatment a reasonable amount of skill, judgment, and attention. If a person suffered damage in life or limb through the gross negligence or ignorance of his Medical or Surgical attendant, he was undoubtedly entitled to compensation at the hands of that attendant ; and if such a case as this were brought before a legal tribunal, any member of the Profession summoned to give evidence was not only justified, but bound to obey that summons, and to give his honest opinion upon the case. Mr. Steele further argued that the case of Dr. Bowen was not at all an analogous case to this, inasmuch as all necessary skill had been shown, and that the gravamen of the offence against Professional propriety, the injury which Mr. Lund had done to himself, and the scandal that he had brought upon his Profession, did not consist so much in what he said and did at the trial as before the trial. (Hear, hear.) Mr. Steele then quoted from the *British Medical Journal* of January 14, which contained a letter from Mr. Lund to the editor. It was clear, he said, that the prosecution in Price *v.* Bowen had submitted a case to Mr. Lund, with the view of getting his opinion as to how far an action would lie, and what chance they had of getting a verdict. In this case Mr. Lund had placed himself in the position of a grand jury, with the very important distinction that grand juries never ventured to cut or to find a bill without hearing the evidence on both sides. (Hear, hear.) Mr. Lund said in his letter :—"It has been asked, How is it that I did not apply to Dr. Bowen and hear his version of the case before the trial? My answer is, that it did not occur to me to do so ; and had I thought of it I should have considered it highly improper after giving an opinion on the merits of the case to the solicitor for the plaintiff, to have communicated with the defendant." Thus he admitted giving his opinion on the merits of the case—an opinion which must have been founded upon an extremely ambiguous statement of an uneducated woman as to whether the arm was in a prone, semi-prone, or supine position during a certain period of the treatment. But that was not all. Mr. Lund actually went further, and anticipated the defence Dr. Bowen was likely to set up, and suggested to the prosecution how they should be prepared to meet that defence. Mr. Steele gave quotations from the letter to support his argument, and then went on to say that the whole letter went to show Mr. Lund seemed at times to be desirous of conveying the impression that he was not prejudiced against Dr. Bowen, while at the same time he afforded all the materials requisite for an attorney to go on with an action. ("Hear, hear," and laughter.) Mr. Steele could not but again refer to the extraordinary statement of Mr. Lund "that it did not occur to him to apply to Dr. Bowen before he ventured to give an opinion." Dr. Waters had alluded to this matter, and at the last meeting held in that room this very point was brought forward by a speaker in reference to Drs. Ramsbottom and Lee, that a great portion of the offence that they committed consisted in the fact of venturing to give an opinion upon the treatment of a case without consulting the Professional man who had the case in the first instance. Mr. Lund could hardly be ignorant of that case, and he (Mr. Steele) could really not understand how he could have forgotten to have communicated with Dr. Bowen. ("Hear, hear," and cheers.)

The resolution was then put, and carried unanimously.

Dr. Stookes moved :—"That a subscription be opened to assist Dr. Bowen in defraying the needful expenses incurred for his defence." Dr. Stookes remarked that there could be little doubt that, in addition to the annoyance and harass which he had experienced, Dr. Bowen had been put to very large expense in the case, and it was most desirable that his Professional brethren should assist in defraying this expense.

Mr. Hakes had much pleasure in seconding the resolution, having had the misfortune himself to have been harassed in the same way as Dr. Bowen. In referring more particularly to his own case, Mr. Hakes said that, in order to procure witnesses against him, not only Liverpool, but London, and other parts of England, were canvassed for the purpose, and he mentioned the fact that Mr. Erichsen (of London), who had given an opinion on the case which precisely accorded with the treatment which he (Mr. Hakes) had adopted, after doing so declined to have anything more to do with the case until he had communicated with the defendant. Mr. Erichsen wrote him (Mr. Hakes) a letter, telling him all he had discovered, and which made it easy for him to ask Mr. Erichsen to offer

his services. Fortunately he was not required, for the case broke down, the plaintiff being nonsuited; but this conduct of Mr. Erichsen formed so marked a contrast to that which had occurred in connection with Dr. Bowen's case, that he (Mr. Hakes) felt bound thus publicly to call attention to it. (Applause.)

At this point of the proceedings Mr. Ellis Jones read a letter from Dr. Bowen, which stated that the expenses of the case would be under £175. The resolution was then put and carried unanimously.

Dr. Scholfield (Birkenhead), said he had received a letter from Dr. Hammond, of Preston, stating that a meeting had been held in that town in reference to Mr. Bowen's case, and that upwards of £17 had been subscribed. Resolutions had also been passed condemning the practice of Medical men giving evidence against their Professional brethren without first communicating with them, and in favour of establishing a General Medical Defence Fund for the protection of the Profession, the nucleus of such fund to be formed by the balance remaining after defraying Dr. Bowen's expenses.

In reply to Mr. Ellis Jones, Dr. Scholfield stated that Dr. Dobie and Mr. Harrison, of Chester, had each contributed to the fund, Mr. Harrison having also engaged to canvass the Profession in Chester.

Dr. Desmond moved and Dr. Fenton seconded, "That Dr. Stookes be requested to act as treasurer to the fund." This was adopted unanimously.

Mr. Manifold proposed, and Mr. Parker (Kirkdale) seconded, a resolution that the proceedings of the meeting be forwarded to the Medical journals. This was adopted. Mr. Parker remarked that accusations of this kind were now so frequent that it would really in a short time be a question with many how far they would be justified in the treatment of cases which were likely to end in a manner not quite so satisfactory as they could wish. He suggested that a committee should be appointed from the present meeting to take into consideration some further means of preventing similar proceedings in future. The resolution was then adopted.

Mr. Lowndes remarked that as Mr. Martin's name had been brought in question in connection with the case, and as Mr. Martin was present, it was desirable to hear any explanation he might wish to make.

Mr. Martin said that when he saw the case they asked him what he should propose. He said he would not do anything without meeting Dr. Bowen in consultation, and that he should like to meet him (Dr. Bowen). He (Mr. Martin), in consequence of this application to him, and hearing that the case was going to trial, thought it his duty to go over to Oxton, and he had two interviews with Dr. Bowen. ("Hear, hear," and cheers.)

Thanks to the Chairman were then moved by Mr. Stubbs, seconded by Dr. Imlach, and carried unanimously; after which subscriptions were received, Mr. M'Cheane and Mr. Harrison acting as secretaries to the fund.

MEDICAL NEWS.

Royal College of Surgeons of England.—The following gentlemen, having undergone the necessary Examinations for the Diploma, were admitted members of the College at a meeting of the Court of Examiners on the 24th inst.:—

George Fortescue Webb, Exeter (St. Bartholomew's); George Clements, Brixham, Devon (Middlesex); Richard Douglas Powell, St. John's-wood (University College); Griffith Griffith, Edeyrn, Pwllheli, North Wales (Liverpool); Richard John Lupton, Bradford, Yorkshire (Liverpool); James Fernie, Kimbolton, Hants (Middlesex); George Stokes, Hanley, Staffordshire (Dublin); James Taylor, L.S.A. and L.F.P. and S., Glasgow, Chapel-en-le-Frith (Glasgow); George Dixon, M.D. Edin., Penrith, Cumberland (Guy's); Robert Duncan Logg, Calcutta (University College); Charles Webb Iliffe, Coventry (Birmingham); George Arthur Rogers, Commercial-road (London); Thomas James Webster, Conway, North Wales (Manchester); Frederick Sutton, L.S.A., County Asylum, Norfolk (Guy's); John Brady, Belfast; Samuel James Hulme, Bowdon, Cheshire (Manchester); Henry Pearson, Manchester; Thomas Edgelow, Teignmouth, Devon (St. George's); David Wilson, Carmoney, County Antrim (Belfast); Robert Whipp, Bowdon, Cheshire (Manchester); William Bell, Uppingham (King's College); Thomas Wilson, Darlington (Newcastle); Anthony Charles Farrington, Ottery St. Mary, Devon (St. Bartholomew's).

Admitted on the 25th inst.:—

Henry George Walker, Great Russell-street (University College); James Campbell Macaulay, Leicester; Edwin Wykes, Birmingham; Septimus Henry Liddle Murray, Newcastle; Miles Astman Wood, Ledbury, Hereford (King's College); Pierre Georges Cox, Mauritius (University College); John Smith Wallbridge, Demerara (University College); William Boughton Stirling, Whitechapel (London); Frederick William Armitage, Louth, Lincolnshire (Guy's); Francis Grealy, Galway; Charles Broom, Llanelly, South Wales (Guy's); Herbert Ray Archer, Montague-street, Portman-square (St. George's); Henry Greenway Hawse, Liverpool (Guy's); Owen Thomas Williams, Bangor, North Wales (Dublin); Henry George Samuels, Liverpool (Dublin); Evan Parry Davies, Denbigh (Dublin); Charles Glen Bott, Brentford (Guy's); William Lewis Hughes, Llandudno, North Wales (Dublin).

Naval Surgeons.—At a meeting of the Court of Examiners of the Royal College of Surgeons, on the 24th inst., the following gentlemen passed their Examinations for Naval Surgeons:—

Charles Henry Slaughter, of H.M.S. *Royal Adelaide*, M.R.C.S. Eng., June 20, 1856; George Bellamy, of Haslar Hospital, Gosport, M.R.C.S. Eng., August 31, 1859; Henry Normand MacLaurin, M.D. and L.R.C.S. Edin., 1857, of Greenwich Hospital.

Pharmaceutical Society of Great Britain.—Names of Candidates who passed the Examination, January 25, as Pharmaceutical Chemists:—

Samuel Booth, London; Edward P. Guest, Brentwood; William H. Holt, Altrincham; John C. Hyslop, London; Thomas Solman, London; Thomas C. Sloggett, Plymouth; Edward Smith, Worcester.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Banks, John T., M.D. Dub., has been elected a Physician to the Masonic Female Orphan School, Dublin.

Beatty, Thomas E., M.D. Edin., has been elected a Physician to the Masonic Female Orphan School, Dublin.

Casey, Edward, M.B. Lond., has been appointed Resident Medical Officer and Tutor to the Birmingham General Hospital.

Collis, Maurice H., M.B. Dub., has been elected a Surgeon to the Masonic Female Orphan School, Dublin.

Gornall, John H., M.R.C.S. Eng., has been appointed Resident House-Surgeon to the Warrington Dispensary.

Hyde, George E., L.R.C.P. Lond., has been appointed Surgeon to the Worcester Ophthalmic Institution.

Maunder, Charles F., F.R.C.S. Eng., has been elected Consulting Surgeon to Queen Adelaide's Dispensary.

Shaw, T. C., B.A., M.R.C.S. Eng., has been appointed Resident Medical Officer to the St. Pancras and Northern Dispensary.

Smyly, Philip C., M.D. Dub., has been appointed a Surgeon to the Masonic Female Orphan School, Dublin.

Waghorn, Frederick, M.D., M.R.C.S. Eng., has been appointed Medical Officer and Public Vaccinator to No. 1 District, Axbridge Union, Somerset.

Wells, J. Soelberg., M.D. Edin., has been appointed Ophthalmic Surgeon, to King's College Hospital.

Wood, Nathaniel C., M.R.C.S. Eng., has been appointed Medical Officer to the Macclesfield Workhouse.

Yeo, J. Burney, M.R.C.S. Eng., has been appointed Medical Tutor to King's College, London.

DEATHS.

Browne, James B., L.R.C.S.I., at Brownlow-hill, Liverpool, on January 12, aged 21.

Clarke, Charles Hall, M.D. Edin., at Stonyhurst, Blackburn, Lancashire, on January 14, aged 49.

Cooksey, Walter C., M.R.C.S. Eng., of Worcester, at Southampton, on January 5.

Gross, Edward, M.R.C.S. Eng., at Earl Soham, Suffolk, on January 7, aged 59.

Harrington, Dr. D., at New York, on January 5, aged 60, formerly of Kerry, Ireland.

King, Henry, Surgeon, at Calne, Wilts, on January 15, aged 90.

Maitland, John, M.D. Glasg., Deputy-Inspector-General of Hospitals, at Anglesea, Gosport, on January 23, aged 57.

Schuyler, Allen P., L.R.C.P. Edin., at East Badleigh, South Devon, on January 16.

Silver, William, M.D., at Sion House, Clifton, Gloucestershire, on January 19, aged 85.

Smallhorn, John K., M.R.C.S. Eng., R.N., at Monte Video, in H.M.S. *Bombay*, on December 14.

Smythe, W. Dumville, Assistant-Surgeon R.A., at Calcutta, East Indies, on December 13, aged 27.

Wills, Douglas C., M.D. Glasg., at George-street, Paisley, on January 11, aged 25, formerly of Cumnock.

Wrentmore, John, M.R.C.S. Eng., on January 18, aged 47.

Yeoman, Thomas H., M.D. Glasg., at 25, Lloyd-square, Pentonville, W.C., on January 21, aged 51.

Molluscum Simplex.—Professor Hebra exhibited two patients, the subjects of *molluscum simplex*, to the Vienna Medical Society. The entire surfaces of their bodies were covered with an enormous number of globular tumours, varying from a pea to a man's fist in size. He remarked that during his practice, extending over twenty-two years, and embracing 80,000 cases, he had never met with a similar case, and now, by an extraordinary coincidence, two such came into his wards at the same time. There are, he observed, two forms

of molluscum, *simplex* and *contagiosum*, the contents of the first being connective tissue, of the latter only *sebum*.

Zoological Society.—At the last meeting of this Society, held on January 10, Mr. Francis Day, F.L.S. and F.Z.S., of the Madras Medical Service, read a valuable paper on the "Hard-rayed Fishes of Cochin, on the Malabar Coast of India," where he had been stationed for some years as civil Surgeon. He entered upon the scientific and native names, the seasons of the year at which they arrive and depart, and the uses to which they are and may be put. The paper, he remarked, was only the description of the first part of his collection, and contained 125 species, of which 9 were entirely new, 3 had been previously described, but their existence had been doubted, whilst he showed that several fishes now in our catalogues were in reality the same in different stages of growth, or modifications of the same influenced by the localities in which they reside. He illustrated his paper by upwards of forty elaborately coloured drawings and engravings executed by himself. Mr. Day is, we understand, engaged in preparing for publication a monograph on the fishes of India.

The Late Prosecution against Dr. E. Bowen.—Meeting in Preston.—A meeting of the Medical Profession of Preston was held at the Literary and Philosophical Institution, Cross-street, on Wednesday evening, 18th inst., for the purpose of expressing sympathy with Dr. Essex Bowen, of Birkenhead, on the occasion of the unjust prosecution to which he has recently been subjected. At the meeting there were present Drs. Altham, Broughton, Brown, Gilbertson, Hammond, Heslop, Moore, Ridley, Smith, Stavert, and Walling, and Messrs. Pilkington and Richardson. Dr. Stavert occupied the chair. Letters, approving of the objects of the meeting, and expressing strong sympathy with Dr. Bowen, were read from Messrs. Allen, Haldan, and Howitt, of Preston; Ashton, of Walton-le-Dale; Gradwell and Fisher, of Lytham; and Eccles, of Longridge. The first resolution was proposed by Dr. Broughton, seconded by Dr. Hammond, and carried unanimously, viz.:—"That this meeting sympathises most deeply with Dr. Bowen on the annoying and vexatious trial to which he has recently been subjected, and begs most cordially to congratulate him on its satisfactory termination." The second resolution, which was proposed by Dr. Gilbertson, seconded by Mr. Pilkington, and carried unanimously, was as follows:—"That this meeting most strongly condemns the practice of Medical men giving evidence against their Professional brethren without first communicating with them." The third resolution was proposed by Dr. Smith, seconded by Dr. Altham, and carried unanimously:—"That a subscription be commenced to assist in defraying Dr. Bowen's legal expenses, and that Dr. Hammond be appointed treasurer, and Dr. Moore honorary secretary." It was next moved by Dr. Altham, seconded by Dr. Ridley, and carried unanimously:—"That this meeting is of opinion that it is desirable to establish a General Medical Defence Fund for the protection of the Profession, and suggests that any funds left after defraying the cost of Dr. Bowen's suit should be devoted to that object." The last resolution was proposed by Dr. Walling, seconded by Mr. Richardson, and carried unanimously:—"That copies of the foregoing resolutions be forwarded to the different Medical journals, and to Dr. Scholfield, the chairman of the Birkenhead meeting." A vote of thanks to the chairman terminated the proceedings.

The Health of Woolwich and the Main Drainage Sewer.—A serious epidemic having existed in Woolwich, stated to have been occasioned through the main outfall sewer of the Metropolitan Board of Works, at Crossness-point, Erith, Dr. Bristowe was requested to make a report on it by the local authorities, and this report has just been presented. Dr. Bristowe says:—"Admitting the fever to have been essentially typhoid or enteric fever, the important question arises, What has been the cause of the fever? The drainage has been accused. It would seem that about ten years ago the whole town of Woolwich was drained (under the present surveyor) chiefly by pipe drains of sufficient diameter and with sufficient fall. The total length of the main drains constructed was over fifteen miles. The outfalls of these drains are four in number, and are below low-water mark, so that they are rarely, if ever, exposed. Each of the principal drains is provided (according to its length) with one or two ventilating shafts, which consist of pipes carried up along the sides of houses, and above any openings in the houses. The majority of the houses in Woolwich are connected with the drains, and all can be connected with them, but it appears that out of about 5000 houses 800 are as yet undrained. These are not aggregated in any particular spot, but are scattered irregularly throughout the town. Early in the year the southern outfall sewer came into use. This sewer passes through Woolwich parallel to the course of the river, presents in its passage through the town four or five ventilating holes, and receives the drainage of the valley between Woolwich and Charlton, the original drains of this valley having been connected with it. There is no doubt that great complaints are made with respect to the smells which escape from the ventilating holes of the outfall sewer, and that there is an impression that the fever has prevailed in its course, and especially in the valley, which would suffer, if it suffered at all, from the effluvia arising from this particular sewer. It certainly is an odd circumstance that diarrhœa should have commenced in April, somewhere about the time, as I am informed, at which the outfall sewer came into operation; and it cannot be overlooked that the sewage is discharged at the pumping-station during a very limited period of the day only, and that during the greater part of the day the sewage is allowed to collect in it, and to become stagnant, and, therefore, to generate gases. There is no reason to suppose that any smell direct from the pumping-station can affect Woolwich, and as regards the river it is generally admitted that this has been less offensive of late than it was in former years; besides which, the absence of undue prevalence of fever on the river bank demonstrates that the river is not the cause of fever. Before, however, expressing any opinion of my own in reference to the causation of the fever, it is important to consider the sanitary circumstances of Woolwich. That the drainage on the whole is good seems pretty certain; but it is equally certain that a good many houses are still unconnected with the sewers, and that (at least in the lower localities) there is a great deficiency of water for flushing of drains and closets. It is certain, too, as I ascertained by personal visitation of many localities, that excessive overcrowding, filth, and dilapidation of premises, accumulation of offensive refuse, and neglect of privies and private drains, prevail to a large extent. The Board, though evidently anxious to do their duty to the inhabitants of the town, have evidently not considered it their duty to institute habitual house-to-house inspection and hunting up of nuisances, measures which have had such beneficial effects in the metropolis generally. Taking all the above circumstances into consideration, I think it can scarcely be assumed that any one of them is of itself the cause of the typhoid epidemic. Certainly there is not sufficient reason to attribute it to the main outfall sewer, although there is sufficient ground to suspect that that may have concurred with other causes in producing it. At all events, the main drainage cannot reasonably be condemned until other matters liable to produce fever which prevail in Woolwich have been remedied."

Flint Implements.—The Academy of Sciences has received a communication on this subject from M. Ch. des Moulins, of Bordeaux, which derives peculiar interest from the author's remarks on the "patina," or kind of rusty crust with which flint implements that have lain long underground are often covered, and which, in the eyes of archæologists, are a sure sign of their being antediluvian, and not merely Celtic. In the first place he contends that the word "patina" is not correct, because it is used by archæologists to denote the crust which covers metallic surfaces, and that it cannot, therefore, be applied to stone. M. Boucher de Perthes, he remarks, is aware of this, since he uses the word varnish instead. But other observers who have come after him have observed on other instruments a different kind of modification of the fractures of certain flints, modifications of colour and sometimes of texture, penetrating below the surface; and this has by them been equally considered a test of antiquity, and by degrees these two very different things have been blended together by a supposed assimilation under a common name which properly belongs to neither. Moreover, this "patina," which is believed to distinguish the antediluvian from the Celtic specimens, is only found as a varnish on certain sorts of flint, and not on others, so that it does not offer a general characteristic; and, again, it is liable to disappear, and hence it does not constitute an absolute feature. It has been affirmed that every polished hatchet is Celtic, and not antediluvian; and yet the other kind of "patina," which also exists on certain kinds of silex only, appears not only on the knives and hatchets made by chipping off large splinters, such as M. de Perthes considers antediluvian, but also on polished

hatchets of the same species of flint. Hence of itself alone this "patina" signifies nothing, since it cannot, by its presence prove a flint implement to be antediluvian when it may be post-diluvian, so that archæology has not sufficient resources of its own to rely upon, and must refer to the geologists in order to ascertain the nature and age of the deposits in which the flints are found.—*Galignani*, Friday, Jan. 6.

CONJURING *v.* ANIMAL MAGNETISM.—An anecdote is told in the *Union Méd.* which illustrates the correct reply when we are called upon to explain some of the feats of alleged animal magnetisers—viz., that these are equalled and even surpassed by those of avowed conjurors. At a recent *soirée* in Paris a celebrated *prestidigitateur* was amusing the company with his wonderful skill when M. Tardieu, the Dean of the Faculty of Medicine, was announced. The conjuror was introduced to M. Tardieu just as he was excusing himself for being so late. "That is nowise surprising," was the reply, "for Monsieur has either been robbed of or lost his watch." M. Tardieu put his hand to his waistcoat, and sure enough there was his chain without the watch. This was in the conjuror's hand! How he could have detached it from the chain without M. Tardieu or the bystanders perceiving it quite passes explanation.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

A delay in the post has this week deprived our readers of an article on Cheap Wines, by our Special Correspondent. It will appear in our next number.

G. H.—R. B. Carter, "On the Ophthalmoscope," from the German of Zander; Hardwicke. Jabez Hogg, "On the Ophthalmoscope;" Churchill and Sons.

A Fellow.—The election of Councillors generally takes place in July. At present there is no death vacancy.

Methylated Spirit.—A naturalist asks where he can buy methylated spirit wholesale? That which is got in common shops spoils his preparations from the resinous matter it contains. He should apply to Messrs. Bowerbank, Sun-street, Bishopsgate.

A Student.—You have, in common with many others, misinterpreted the regulations. There is no occasion to spend *four* years at the Hospital—only three winter and two summer sessions are necessary; the four years are made up as pupil to your father. You are exempted from the Preliminary Examination.

M.D, Guernsey.—You will find the lines in Pope's translation of Homer, who, speaking on Machaon's being wounded, says,—

"A wise physician, skill'd our wounds to heal,
Is more than armies to the public weal."

Butler, in his "Hudibras," part i., canto ii., says:—

"A skilful leech is better far
Than half a hundred men of war."

Farriers were called "*horse-leeches*," and persons skilled in the distempers of cows and other horned cattle are, in several counties, to this day called "*cow-leeches*." They are, of course, giving way to the Members of the Royal College of Veterinary Surgeons.

Erratum.—In Dr. Kidd's letter on "Chloroform Accidents," p. 53, *for* "H." *read* "K."

THE GRIFFIN TESTIMONIAL FUND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The following subscriptions have been further received on behalf of the above fund:—Chas. Arnison, Esq., Abston, 10s. 6d.: J. Byerley, Esq., Birkenhead, 10s. 6d.; Dr. Lambert, Birkenhead, per J. Byerley, Esq., 10s. 6d.; R. S. Daniel, Esq., Birkenhead, do., 10s. 6d.; Dr. Downing, Birkenhead, do., 10s. 6d. Amount previously announced, £111 16s.; received at the *Lancet* Office, £6 16s. 6d.

I am, &c.
ROBERT FOWLER, M.D., Treasurer and Hon. Sec.

145, Bishopsgate-street Without, January 25.

PRYCE *v.* BOWEN.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The following subscriptions have been received for the "Bowen" fund since your last issue, which I acknowledge for Dr. Scholfield.

I am, &c.
Sudley House, Birkenhead, Jan. 24. JOSH. GODDEN, Hon. Sec.

John Harrison, Esq., Chester, £5; Dr. W. Roberts, Manchester, £2 2s.; Dr. Eason Wilkinson, Manchester, £2 2s.; Dr. Parr, New Brighton, £1 1s.; Dr. Trull, New Brighton, £1 1s.; Dr. Bird, Egremont, £1 1s; J. Byerley, Esq., Egremont, £1 1s.; Dr. Nottingham, Liverpool, £10 10s.; Dr. Gee, Liverpool, £3 3s.; Dr. Holcombe, Liverpool, £1 1s.; Dr. Fenton, Liverpool, £1 1s.; Dr. Hill, Liverpool, £1 1s.; Dr. Vose, Liverpool, £5 5s.; Dr. Desmond, Liverpool, £1 1s.; Dr. Nevins, Liverpool, £1 1s.; Dr. Turnbull, Liverpool, £2 2s.; Dr. Fitzhenry, Liverpool, £1 1s.; Dr. Walker, Liverpool, 10s. 6d.; Dr. Stookes, Liverpool, £2 2s.; W. H. Manifold, Esq., Liverpool, £1 1s.; E. R. Bickersteth, Esq., Liverpool, £5 5s.; S. Kisch, Esq., Liverpool, £1 1s.; C. B. Wilson, Esq., Liverpool, £1 1s.; A. M. Bligh, Esq., Liverpool, 7s. 6d.; R. H. Taylor, Esq., Liverpool, £1 1s.; H. Stubbs, Esq., Liverpool, £2 2s.; J. Hakes, Esq., Liverpool, £1 1s.; Ellis Jones, Esq., Liverpool, £3 3s.; W. McCheane, Esq., Liverpool, £1 1s.; H. Lowndes, Esq., Liverpool, £1 1s.; *E. Lund, Esq., Manchester, £52 10s.; John Stewart, Chemist, Birkenhead, £2 2s.

* With Mr. Lund's cheque for £52 10s. came the following note, which was received the morning after the Liverpool meeting by the Treasurer, Dr. Scholfield, Birkenhead:—

"22, St. John's-street, Manchester, Jan. 23, 1865.

"Sir,—As the correspondence relating to the case of Pryce *v.* Bowen seems at length exhausted, I feel more at liberty to follow out my original impulse to subscribe towards the fund for defraying Dr. Bowen's expenses, and I now place 50 guineas at the disposal of the Committee, to be applied to that purpose, merely remarking that, had I followed the suggestions of others instead of acting on my first intention, I should perhaps have been content with forwarding the fee of 15 guineas which I received from the plaintiff's solicitor. "I am, &c., "EDWARD LUND.

"To Dr. Henry D. Scholfield, Birkenhead."

APPOINTMENTS FOR THE WEEK.

January 28. *Saturday (this day).*

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Marshall, "On the Nervous System."

30. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

31. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ANTHROPOLOGICAL SOCIETY OF LONDON, 8 p.m. G. D. Gibb, Esq., M.D., LL.D., F.G.S., "On the Larynx of the Negro." T. B. Peacock, Esq., M.D, F R.C.P., "On the Weight of the Brain and Capacity of the Cranial Cavity of a Negro." T. B. Peacock, Esq., M.D., F R.C.P., "On a Skull Exhumed in Bedfordshire." T. Bendyshe, Esq., M.A., F.A.S.L., "On the History of Anthropology."

ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, "On Electricity."

February 1. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

OBSTETRICAL SOCIETY OF LONDON. Dr. Snow Beck, "On Puerperal Fever." J. Baker Brown, Esq., "New Mode of Securing the Pedicle in Ovariotomy." And other Papers.

2. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

HARVEIAN SOCIETY OF LONDON, 8 p.m. Dr. Chas. Drysdale, "On the Antecedents and Treatment of Phthisis."

ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, "On Electricity."

3. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 8 p.m. Prof. Odling, "On Aluminium, Ethide, and Methide."

WESTERN MEDICAL AND SURGICAL SOCIETY, 8 p.m. Mr. George Nayler, "On Syphilitic Diseases of the Skin following Vaccination."

ORIGINAL LECTURES.

LECTURES ON

CHEMICAL AND MECHANICAL DISEASES AND THEIR RELATIONSHIP.

By H. BENCE JONES, A.M., M.D., F.R.S.

Lecture

ON DISEASES OF SUBOXIDATION—DIABETES.

(Continued from page 84.)

There are two great ends to be gained by the use of medicines in diabetes.

Of these the first and most important is to promote the oxidation of the sugar; or, failing this, to compensate the system for the loss of saccharine fuel and the consequent loss of power and nutrition by promoting the supply and oxidation of the oleaginous fuel.

Of all the medicines that can be given for the promotion of the oxidation, whether of sugar or fat, in the body, iron and alkalies are the most energetic; and hence, beyond all other remedies, iron or the ammonio-citrate of iron with excess of ammonia, or with other alkalies, are the best medicines for diabetes. The iron may be given in potass or Vichy or in Fachingen water, and that preparation which confines the bowels least is most to be preferred. Hence the potassio-tartrate and Griffiths' mixture are often useful.

Alkalies without iron promote oxidation. This is very evident in the copper test for sugar. M. Miahle even has stated that alkalies are the specific for diabetes; without doubt they are of importance in promoting oxidation. Soda or potass may be given in the caustic state or as carbonates. Carbonate of ammonia in ten, fifteen, or even twenty-grain doses thrice daily in any gaseous mineral lessens the thirst.

Long since Professor Graham tried the phosphate of soda, with three equivalents of soda, on the ground that the blood required this substance and could not get it in the animal food. I have not found any great advantage from its use.

Vichy water, more particularly the Celestin, is recommended by M. Bouchardat. It contains between eighty and ninety grains of carbonated alkali and alkaline earths in a quart of water. The Hospital spring contains about ninety-six grains, the Grand Grille ninety-two, the Hautrive eighty-nine, and the Celestin eighty-five grains to a quart of water.

Carlsbad Sprudel water and the more aperient Muhl spring is highly praised by Dr. J. Seegen. It contains about one-fourth or less of the alkali of Vichy water, but half a drachm or more of sulphate of soda in each quart gives an aperient action which the common salt of Vichy water rarely possesses. Marienbad Kreutzbrun water is twice as aperient, but rather less alkaline than Carlsbad Sprudel. Fachingen water has one-third or more of the alkaline power of Vichy. Seltzer water one-sixth.

Besides alkalies some animal substances are thought to promote change in the sugar in diabetes. Of these rennet and pepsine may be mentioned. In 1852 Dr. James Gray published some remarkable results in the *Edinburgh Monthly Medical Journal*, p. 396, but I am not satisfied that rennet is very useful in diabetes. It is an albuminous substance in a state of change, and, therefore, it exactly fulfils the conditions required in the undiscovered specific for diabetes. It should be well washed with water to remove the adhering sugar and dextrin, and it should be given on an empty stomach, so as to enable it, if possible, to act on the sugar in the blood rather than on the sugar in the food.

Pepsine is another albuminous substance in a state of change. Its action in the stomach is to help the solution of the albuminous food, but when it passes into the blood it might be the animal diastase that carries on the change in the sugar. With this idea it has been given in diabetes, but with no satisfactory result; although many patients have said they were better whilst taking this remedy, yet I have never found the sugar diminish under its use. It usually helps the action of the bowels.

Lately oxygen gas has been tried by Dr. Richardson in diabetes. It would be splendidly simple if this were the specific for diabetes. This view implies that a deficiency of oxygen is the cause of diabetes, but the chemistry of the disease does not admit of this explanation. There must be a much more complex chemical error than a want of oxygen, and it is far more probable that no deficiency of oxygen exists, but that it does not act because the proper animal diastase is not present.

Vegetable and animal oils and fats constitute important remedies in diabetes. Of all these, cod-liver oil and cream are most frequently used. The following case may be taken as an instance of the amount of cod-liver oil that can be given:—

A man, aged 24 years, was admitted into St. George's Hospital, having lost two stone in weight during eight months. He passed seven quarts of urine daily. He remained under treatment for a month, during which time he was on animal diet and cod-liver oil. He began with half an ounce daily, and this was gradually increased up to eight ounces. The quantity of urine fell to two pints and a-half, specific gravity 1030, and he increased in weight from 8 st. 8 lb. to 9 st. 1 lb.

Cream may be given in any quantity until the tongue begins to be coated, then it soon disagrees, and the stomach refuses to take it, or rejects it when taken.

Fats, combined with alkalies, as soaps, are more ready to undergo oxidation than when the glycerine is unseparated. Pure glycerine is, however, often very useful as a substitute for sugar in tea and in other liquids.

To lessen the thirst and the craving for food opium is very useful. The alkaloids of opium diffusing out of the blood in contact with the nerves of the blood-vessels cause contraction of the capillaries; this affects secretion, so that the quantity of urine, saliva, bile, and intestinal secretion is greatly diminished. The drain of urine and the desire for food are thus checked, but the increased constipation and dryness of the mouth almost, and in some instances quite, counterbalance the gain obtained by checking the flow of water. By the use of very small quantities of opium, as five or ten grains of Dover's powder, or five or ten drops of laudanum once or twice daily, the thirst and excessive flow of urine may be stopped, and the constipation may not be excessively increased.

The second great object in the treatment of diabetes is to remove the constipation.

The excessive determination of water to the kidneys causes increased dryness elsewhere, hence the mucous membrane and the skin are harsh and dry; probably also the production of acid being greatly diminished by arrest of change in the sugar, the healthy secretion by the intestines and skin cannot take place.

Notwithstanding the amount of food eaten, the action of the bowels usually is very difficult. All saline aperients increase the thirst and pass off by the urine. Magnesia from the absence of acidity is usually inactive. Castor oil is by far the best aperient, when it does not nauseate, then capsules containing castor oil with minute quantities of croton oil are most efficacious. Compound extract of colocynth with jalapine, scammony, or gamboge, or podophilline will act when oil cannot be taken. Mercury when soluble combines with the albuminous matters with which it comes in contact and sets up increased chemical action. The nutrition of the parts to which it is directly applied, or carried by absorption and diffusion, is so altered that increased action, inflammation, and ulceration are produced. This altered nutrition has no influence on the oxidation of the sugar or fat, and hence diabetes is not benefited by mercury. Calomel may be used as an aperient, but it has not any advantage over other chemical or mechanical irritants to the mucous membrane of the bowels, and promoting a more rapid change in the albuminous structures of the textures causes a feebler nutrition to take place.

In extreme cases the constipation of the bowels becomes the most serious symptom. The chemical disease leads to a mechanical difficulty amounting almost to an obstruction of the bowels. Strong chemical irritants are required to excite the muscular action, sometimes even "croton oil" is necessary. When the bowels do act the prostration of the strength is sometimes alarming; so little power seems to be set free in the body that any extra expenditure seems to deprive the heart of the force necessary to carry on the circulation, in the same way as a fatiguing journey to London for advice or extreme mental anxiety will bring a prostration of strength from which with difficulty recovery takes place.

On the Loss of Mechanical Power Caused by Diabetes.

Loss of chemical action necessitates loss of heat, mechanical power, and healthy nutrition; neglecting the loss of power consequent on deteriorated structures, some estimate of the

loss of power in those who suffer from diabetes may be obtained by calculating the amount of carbon which escapes in twenty-four hours in the sugar unoxidised.

In extreme cases from twenty to forty ounces of sugar may be lost in twenty-four hours. This is equal to 8·4 to 16·8 ounces of carbon, and this if fully oxidised would generate a force capable of raising from ten to twenty millions of pounds one foot high.

In diabetes if no other fuel but sugar was supplied to the human machine, it would rapidly cool and come to rest; the motion of the heart and lungs would stop; but fatty and even albuminous food may partially or wholly supply the force which ought to be got out of the sugar. When the coals fail in the steamer, the wood of the ship itself may furnish the fuel necessary to keep up the motion. The body may waste to move the heart and the lungs, until the supply of power failing, or the use of it being too great, feebleness and exhaustion constitute a general mechanical wrong which terminates in the stoppage of all muscular motion.

In addition to this general mechanical disease, the feebleness of the chemical action in and around the capillaries tends to produce local congestions and imperfect nutritions; hence, low inflammations, effusions, tubercles, and wasted muscles may arise from the deficient chemical action in the body, consequent upon the want of oxidation of the sugar.

ORIGINAL COMMUNICATIONS.

REPORT OF SOME CASES TREATED IN THE REGIMENTAL HOSPITAL, COLDSTREAM GUARDS.

Under the care of Surgeon-Major WYATT.

Case 1.—*Acute Bronchitis, complicated with extensive Diptheritic Deposit on Throat and Mouth—Recovery.*

November 13.—M. H., aged 32, a man in tolerably good condition, but looking anæmic, was admitted with the usual symptoms of acute bronchitis, accompanied by more than ordinary amount of dyspnœa and depression. Bowels rather constipated and skin moist. Tongue glazed and morbidly clean. His account of himself was that he had been exposed to the weather a few days previously and taken cold. On examination posteriorly no bronchitic râles could be heard, but in front, and below the left nipple especially, cooing respiration and moist râles were universal. The expectoration was scanty and rather tinged with blood. Pulse 120, full and soft. He was ordered a mustard sinapism, and to take the following mixture three times a day:—Carb. ammonia, gr. v.; tinct. scillæ, ʒss.; camphor mixture, ʒj.

14th.—Expectoration still discoloured; pulse as before; respiratory murmur is blended with fine crepitating sounds, above the position where the moist râles are audible. Tongue inclined to dryness. Bowels relaxed. To add chloric ether and decoction senega to the mixture and employ a suppository of extract of opium. Beef-tea and wine, ʒiv.

15th.—Depression much greater, and expectoration less in quantity, very tenacious, and brown. Complains of great thirst; pulse 104, soft and compressible. Diarrhœa almost involuntary, with great tenesmus. Wine, ʒvj.; turpentine stupes to the abdomen.

16th.—The fine crepitation increases in front, but posteriorly the respiration is natural; depression greater; pulse 96; tongue dry; secretion and expectoration very difficult; the sputa being so very adhesive and scanty; the diarrhœa is quite controlled. Hydrag. c. creta, gr. ij.; c. pulv. Doveri., gr. ijss. four times a day, with ʒjss. of the following mixture:—Ammon. carb., acid, citric, āā ʒj.; potass chlorat., ʒj.; sp. æther nit., ʒjss.; vin. ipecac. ɱxl.; mist. camph. ʒiiij. Complains of much pain in the left side anteriorly during inspiration; pulse fuller, and with much force; expectoration more easy. Emplastr. vesicat. to the side, and to be dressed with ung. hyd. Continue turpentine stupes to belly.

17th.—Crepitation now audible in the left axillary space. Inspiration not so difficult or painful, but expectoration very tenacious and scanty; pulse 100; bowels regular; still no abnormal sounds audible behind; mouth parched. Continue powders night and morning. Wine and nourishment.

18th.—Depression now very great indeed, and during the night considerable delirium; pulse 120, soft and full; skin moist; urine scanty, and passed occasionally involuntarily. Diarrhœa quite checked, but the tongue this morning was white and pasty, and the aspect of the man when attempting to expectorate was peculiarly distressing. On examining the throat, which was quite dry, the right tonsil and pillars of the fauces, as well as the uvula, were covered with a dense whitish opaque substance of a glassy appearance, as if smeared with a dirty white paint. The man complained of intense thirst, and constant ineffectual attempts to swallow. The back part of the throat was brushed with a strong solution of nitrate of silver (ʒij. to ʒj.), and to take every four hours a mixture composed of chlorate of potash, hydrochloric acid, and bark. Wine ʒxij., and strong beef-tea *ad libitum*.

19th.—The left tonsil is now becoming coated with the white deposit, and the dryness of the throat is extreme; there is now no form of expectoration; pulse 120, small and weak. The fine crepitation audible over the front of the chest is now blended with moist râles. The throat to be painted with equal parts of glycerine and tinct. ferri sesquichloridi. To take champagne and mock-turtle soup.

20th.—Some of the false membrane was removed from the back of the throat (nearly the whole of which is now covered with it) and placed under the field of the microscope, when it assumed the character of sporules arranged in clusters; when treated with dilute acetic acid, one long adhesive piece was easily detached from above the uvula, and from the hard palate a thick portion was removed, which had quite a cast of its surface; its removal afforded the man great relief. Pulse 130, small and soft; and delirium frequent.

21st.—More vigour of aspect, and pulse stronger—80; less delirium, and slept well; another large portion of adhesive matter was removed from the right side of the throat; it was very tenacious, like bird lime; but the surface of the mucous membrane beneath appeared healthy. Continue the wine and nourishment.

22nd.—Aspect improved; bowels relaxed five times, with much tympanitis; pulse 100, fuller; throat less implicated, particularly on the left side; thirst not so great. To take powdered charcoal, ʒss.; and compound chalk and opium, ʒss. three times a-day; and to use a gargle composed of liq. sodæ chlorinat ʒijss., to water ʒviij. Port wine, ʒviij., instead of champagne. Brandy and eggs.

23rd.—Aspect much improved, and no fresh amount of deposit. A large portion of that which existed yesterday has become renewed; pulse 120; less tympanitis; and diarrhœa checked.

24th.—Throat much more free from deposit; pulse 88 only; and less diarrhœa. To continue the charcoal and mixture; also wine, etc.

25th.—Scarcely any deposit can be seen, and in every respect he is better. To take the charcoal once daily, and mixture as before.

26th.—Improving most satisfactorily, and the throat is now quite free from all diseased aspect. Complains of excessive weakness; the bronchial secretion is excessive; and there is wheezing over the whole of the left side of the chest; pulse 120. To have a mutton chop, also pint of porter and two eggs daily.

December 3.—Progressing favourably, but still looks pale and weak. Upon subsequent examination there was found to be a considerable portion of the left lung in a state of consolidation, with mucus and subcrepitant râles above. Pulse 120. Pulv. Doveri, gr. iij.; hyd. c. cretâ, gr. ij., nocte manque. Potass. iodid., gr. v.; decoct. sarzæ, ʒij. bis die.

January 10.—The man's condition has gradually improved. Syrup ferri. iodid., ɱxx.; c. Ol. morrhæ, ʒj.; acid hydrocyanic, dilute, gtts. ij., with a bitter infusion, twice a-day.

15th.—The expectoration continues most profuse, and the whole of the right lung is in a state of condensation. He was selected to proceed to the convalescent station at Walmer for the benefit of the sea air, and after remaining there nearly three months he returned with an increase of 36 lbs. in weight, and with the respiration clear at both apices; but at the seat of the original disease, on the left and posterior aspect, there was still some slight evidence of previous implication, the expansion being less, and respiratory sounds not so clear, but the bronchophony is decidedly much less, and he is able to undertake modified duties with his battalion.

Case 2.—*Case of Supposed Catalepsy.*

W. P., aged 21, had been several times admitted into Hospital on account of sudden attacks of unconsciousness to which during the past twelve months he has been subject. The first attack occurred when he was a recruit, after drill,

and he is quite sure that prior to his enlistment he was not subject to anything of the kind. His aspect is healthy, and his functions appear well performed. There is no reason to suspect any deception, and he does not dislike the service. He states that he seldom has any premonitory symptoms beyond a kind of heavy, dull feeling about the head, with an irresistible inclination to drowsiness, after which he becomes unconscious, and sleeps profoundly for twenty-four or thirty-six hours. During this trance he is in a perfectly cataleptic state. The pupils are dilated widely, and his arms and legs remain for a long time in any position in which they are placed. He is insensible to the most powerful galvanic shocks, and except by reflex muscular action there is no evidence of his vitality, except by respiration and circulation.

A very careful examination has often been made of this young man's physical condition, and nothing of an abnormal character can be detected in any part of his body; there is no evidence of any previously exhausting nervous complication, and his general condition and aspect are compatible with perfect health: he sleeps like any ordinary individual when not troubled with these cataleptiform seizures, which are very variable as regards periodicity; they have frequently occurred early in the morning in the barrack-room, where his comrades, not being able to awake him, have left him in what they considered a profound sleep; they have also occurred while a patient in Hospital, so that every opportunity has been afforded to guard against deception of any kind; and during this condition powerful galvanic shocks have been most ineffectually tried; reflex action has, of course, been powerfully excited, but no return to consciousness; the breathing is generally quite natural, and pulse about 86, the pupils being dilated, and his arms and legs will remain for a long time quite tense when raised in abnormal positions. Every practicable opportunity was taken of testing the genuineness of these attacks while the man was in Hospital; on one occasion being found in this insensible condition at the morning visit, the hot water cautery was employed down the spine, with no other appreciable effect than increasing the pulse some forty beats per minute; he was, upon another occasion, placed upon his legs, without knowing that any preconcerted arrangement had been made to prevent his falling backwards, when he would have fallen upon his head if he had not been securely caught. From this state of unconsciousness he awoke some hours afterwards, quite ignorant of what had been done.

Every kind of remedy, both external and internal, was resorted to, and for a time the daily use of the cold shower-bath appeared to control the frequency of the attacks; but they recurred at such irregular intervals that, after many months' close observation, it was quite evident he was unfit for the duties of a soldier, and he was consequently discharged from the service. It may be remarked that when in these states of insensibility he always appeared quite calm and easy, as if in a sound sleep, with no distortion of features, or irregular contraction of any muscles; so that I was led to believe the cause of the seizures to be allied to the subtle and unknown influence of epileptiform attacks. Being a case of such peculiar interest in a physiological point of view, I had the gratification of showing him to several eminent Professional friends, who could not detect any evidence of diseased action.

Case 3.—*Acute Rheumatism with Pericarditis—complete Recovery.*

J. K., aged 40, a stout muscular man, accustomed to drink daily considerable quantities of porter, came under my care on January 31, 1864. He had felt unwell for some days with wandering pains, and about twelve months since had been under treatment for nearly two months; the affection now appears to be chiefly confined to the right elbow and wrist joints, which are much swollen and very painful, depriving him entirely of sleep; urine very high coloured, and loaded with pink lithates; bowels constipated; aspect very anxious and pallid; pulse 56; heart's sounds appear indistinct, but there is no abnormal bruit; tongue much coated. To have a warm bath, and take a dose of senna purgative.

February 1.—No perceptible change in the symptoms. To take potass. bicarb., gr. xx.; tinct. colchici, ♏. xx.; solut. morph. muriat, ♏. v.; aquæ, ℥j., three times a-day. Milk diet.

2nd.—Pulse very soft, 52. Omit colchicum on account of the action of the heart being so subdued. To have a garter blister applied above the knee and wrist, where the pain and effusion are most acute.

3rd.—States that he feels much better, and that the pain in the joints has quite subsided, the only remnant being a feeling of stiffness; his countenance is clearer, and less expressive of anxiety. Hot fomentation. To add aromatic spirit of ammonia with each dose of the mixture, and to take four ounces of gin daily. Also the following pill at bedtime: Pil hydrarg., gr. j.; ext. colchici, gr. j.; ext. opii, gr. j. M.

4th.—The heat and pain in the knee and wrists have quite disappeared, but the heart's sounds are very indistinct, and the pulse weak.

5th.—Not so well. Complains of a feeling of stiffness in the pericardial region. Urine very high coloured, and loaded with lithates still. Tongue furred. Countenance very anxious. Pulse 37. Complains of a "heaving" at the heart upon any exertion, and the pains have appeared in the left wrist. To apply a garter blister above the joint.

6th.—Pain has quite disappeared from left wrist joint, and the pulse intermits, 58. Countenance less anxious. Tongue cleaner; and says that although weak he feels much better, except a slight soreness about the pericardium. Apply a blister to the pericardial region, and to be dressed with ung. hydrarg.

7th.—Both hands are red and hot, but he says that excepting a feeling of stiffness he has no kind of pain. Apply two garter blisters, one to each arm. Pulse 88, full. A distinct to-and-fro friction sound can now be heard to the right of the left nipple. Bowels inclined to be loose. Pil hydrarg., gr. i.; ext. opii, gr. ½, every three hours, with potass bicarb., ʒij.; sp. ammon. aromat., ♏. xxx.; mist. camph., ℥ij.; c. acid tart, gr. x.

8th.—The countenance now very anxious. Pulse 70, and intermittent. Friction sound very distinct, and experiences difficulty in lying down; lithates less abundant. To continue the gin, also mutton broth and milk diet. To take calomel, gr. j., ext. opii, gr. j., with each dose, instead of pil. hydrarg.

9th.—Slept well. Pulse 80, and very intermittent; heart's action heaving, and friction sound very distinct; bowels rather relaxed; tongue dry in centre.

10th.—Friction sound modified in intensity, and the heart's sounds are very indistinct. Rapid effusion has supervened. Pulse 80, soft and fuller; aspect not so distressed; bowels less disturbed; gums becoming affected; tongue brown and dry; sleeps well. Says that he feels much better.

11th.—Complains of pain over the region of the heart, the sounds of which are muffled and indistinct. Omit calomel and opium.

12th.—Not much change. Gums sore. Potass chlorat., ʒj., aquæ, ℥viij. for a gargle.

13th.—Much improved in every respect.

14th.—Pulse 80, quiet and soft. Urine more natural. Potass nit., gr. xv.; potass acet., gr. xx.; mist. camph., ℥ij.; liq. opii sedativ., ♏ v., four times a-day.

15th.—Much improved in every respect. Has no pain in the chest, and sleeps well. Pulse soft and regular. Sounds of heart much more distinct, and quite free from friction murmur.

17th.—Decoct. cinchonæ, ʒiss., *vice* mist. camph.

20th.—Is now able to sit up after dinner.

From this date his daily condition was much improved, the heart's sounds became natural in every respect, and on 5th March he was dismissed Hospital quite well.

This man suffered more acutely than any it has ever been my duty to treat for acute rheumatism, and considering the nature of his constitutional powers, there was sufficient reason to prognosticate grave and permanent cardiac complication, which, I believe, was much controlled by the repeated blistering of the cutaneous surface from the very commencement of the attack. Since his dismissal he has continued to perform his duties in every way with more energy than for a long time previously, so that this case may be considered complete.

Case 4.—*Acute Peritonitis, probably Tubercular—Recovery.*

R. C., aged 23, a delicate lad, of fair complexion, who had been twice in Hospital for a similar affection, was admitted on March 17 in a state of acute suffering, and almost bent double with violent pain in the abdomen, which is tense and intolerant of the slightest pressure. Bowels much constipated; skin pungently hot; pulse small and hard. To have a warm bath, mustard poultice, and dose of castor oil.

18th.—No better; pain intense; pulse 110; tongue coated, and expression anxious. Twelve leeches to abdomen, hot fomentation with calomel and opium every four hours.

19th.—Pain still intense, particularly in the hypogastric region; face flushed; skin hot and dry; bowels opened. Repeat leeches and fomentation.

20th.—Pain slightly relieved. Pulse 84.

21st.—Pain decidedly less acute, and expression of anxiety diminished. Can bear pressure of abdomen. Pulse quiet, and not so characteristie of serous inflammation. Faee less flushed. Slept badly last night. To take the pill twice a-day, and 20 minims of Battley's sedative at night.

24th.—Much better in every respect, and only eomplains of pain in the right iliac fossa. To omit the pills, and take a teaspoonful of cod-liver oil three times a-day.

27th.—Almost well; can bear firm pressure; expression of anxiety quite disappeared.

April 1.—Quite well, and dismissed to-day. This man throughout bore in a remarkable manner the physiognomy of serous inflammation more than is usually witnessed, and although relieved entirely from the present attack, the irregular feeling of induration experienced on pressing deeply below the abdominal parietes leads to the belief that these seizures will be recurrent, and that they are eonnected with tubercular implication of the mesenteric glands. No evidence of disease eould be traced in the lungs.

Case 5.—Acute Pneumonia of Apex of Lung—Simulating Phthisis—Complete Recovery.

R. M., aged 19, a healthy-looking lad, was admitted on April 4, complaining of pain in the ehest, with cough and dyspnœa. Physical examination detects nothing abnormal. The skin is hot and dry, with furred tongue and much thirst. Pulse quick, 96. To have a warm bath and senna draught; also, pulv. Doveri, gr. x.; potass. nitrat., gr. xv., h. s. Spoon diet, with pint of milk daily.

5th.—Has vomited, and been much purged. Mist. salin, ℥j., ter. die.

6th.—Complains of acute catching pain in the left breast, with great dyspnœa and inability to lie on the affected side. Skin hot and dry; face flushed; expression anxious; pulse 120; respirations 40. Diminished expansion of the left side of the chest, and very slight respiration audible from apex to base of the lung; but no crepitation or other dulness appreciable, neither are the voice-sounds increased. To have a mustard poultice and take calomel and opium pill every four hours, with antimonial mixture, etc.

7th.—Is very weak and low this morning; respirations rapid; pulse small and compressible; tongue rather dry in the centre. Crepitation is now audible in the middle lobe of the right lung, and slight dulness can be detected at the base. Expectoration rusty, and mingled with muco-purulent masses. Was delirious last night. Omit antimonial wine, and substitute chloric ether. To take at bedtime tinct. opii and vin. ant. tart. āā ℥ss.; brandy, ℥ij., and beef-tea, daily.

8th.—Slept well; skin still hot and pungent; respirations frequent and catching; pulse 112; expectoration tenacious and rusty; dulness is now pretty general over the right lung, but is most marked at the base and beneath the clavicle; bronchophony and bronchial breathing are also audible. Hyd. c. creta gr. ij., c. pulv. Doveri gr. ijss. ter die. Continue sinapisms.

9th.—Is rather better to-day, and does not look so anxious. Breathes with greater freedom; distinct crepitation now audible at right apex, with moist râles occasionally.

11th.—Decidedly improved; has little pain in the chest and the cough is less troublesome. Pulse, 86; respirations 20. Crepitation not now audible at apex, but dulness below continues with large mucus râles anteriorly. Cough less troublesome.

12th.—Is very weak and perspires profusely; expectoration quite free of the tenacious character, and now consists of a thin, reddish fluid in which are suspended circular flakes of purulent matter, having central streaks of blood; dulness and tubular breathing still well marked at the apex, but at the base, both before and behind, respiratory murmur is audible; pulse 80. Omit the powders and mixture; to take cod-liver oil ℥j. three times a day; mutton chop daily.

13th.—Feels better and coughs less; tongue clean, large crepitation now audible at apex. Emp. lyttæ below the clavicle. To omit the beef-tea for a light pudding.

16th.—No very marked change, except that the breathing from below upwards is becoming more natural.

18th.—No crepitation audible at apex, and dulness diminished in intensity. Sputa still purulent; tongue morbidly red, and complains of occasional sickness after food. Potass iodid., gr. iij.; potass bicarb, gr. x.; ammon. sesquicarb., gr. v.; infus. gentian ℥j.; bis die.

May 1.—Has gradually but effectually improved since last report, the morbid sounds at right apex being reduced to a mere shade of dulness, with some comparative harshness of respiration; still looks pallid; pulse ranges from 80 to 90.

19th.—He was sent this day to the Convalescent Hospital at Walton-on-Thames, where he remained for six weeks, and then returned to his duty with no trace of disease.

Upon a review of the treatment adopted in this case, which was certainly a very serious one as regards prognosis, it may fairly be inferred that had the firmer vigorous "anti-pneumonie" treatment by antimony, bleeding, etc., been employed, the chances of arousing any latent predisposition to tubercular degeneration would have been very much increased; and I think that although the term "conservative" is more frequently applied to our Surgical practice, yet that the above case may be fairly adduced as an instance of the propriety of the conservation or retention within the body of the vital fluid.

Case 6.—Acute Pneumonia, with Rapid Consolidation of Lung and Albuminuria—Recovery.

J. B., aged 18, having recently been enlisted, was sent to Hospital this afternoon, being scarcely able to stand upright. He complains of hacking cough and pain in the chest, skin perspiring, and pulse rapid; faee flushed; respirations frequent, oppressed, and catching, 40 in number; tongue coated with red edges; pulse full, 120; expeetoration viscid and rusty; states that the pain came on with a violent shivering fit. He is a man of powerful frame.

On stethoscopic examination, no crepitation is audible, but dulness and tubular breathing can be detected over the middle and lower lobe of the right lung, especially well marked from the spine to the angle of the scapula, where it is very intense.

Sinapisms to the front of the chest were at first employed, and subsequently a blister; also antim. tart., gr. $\frac{1}{6}$; potass. chlorate, gr. x., every two hours. Hyd. c. creta, gr. ij.; pulv. Doveri, gr. ij. ss., night and morning.

April 12.—Better to-day; the pulse quieter and softer, 100; respirations more easy, 28; tongue moist, and skin warm and perspiring; face still much flushed; sputa viscid and rusty. The physical signs are much as before, except that crepitation can now be distinctly heard at the base of the lung. To have beef-tea.

13th.—Is much weaker, and the face assumes a dusky hue; pulse 112, small and eompressible; respiration 32; urine free from chlorides, but loaded with albumen. Wine ℥iv. daily.

14th.—Improving both in aspect and physical condition; pulse 80, and cough less.

15th.—Much better. Dulness and bronchial breathing in the right lung are rapidly clearing up. Expectoration almost free of rusty discoloration. Pulse 85; respirations quiet. To omit the antimonial mixture, and take quinine and sulphuric acid three times a-day.

18th.—Continues to improve. Pulse 80. Still eoughs and eomplains of dyspnœa; physical signs of eonsolidation still audible, but less intensely.

20th.—Improving in every respect.

22nd.—Much better. To sit up daily.

28th.—Almost convalescent, with very little evidence of diseased action remaining.

May 12.—Dismissed Hospital quite well.

Case 7.—Acute Gangrene of the Lung—Death.

G. H., aged 32, was admitted on July 15 with very severe eough and copious expectoration of a peculiarly fœtid odour. The stethoscopic signs of disease were very slight, and much out of proportion to the embarrassment of respiration and frequent cough. After a short time he beeame gradually weaker, the cough being almost constant, with the same fœtid expectoration, which at times was sanious. Pulse small and rapid; integuments yellow and dusky; tongue furred; appetite very trifling; he complained of pain about the right apex of the lung.

July 25.—Auscultation now revealed slight dulness and large moist crepitation over the anterior part of the right lung. The treatment has consisted of alkaline and sedative medicines, with wine and strong beef tea daily.

August 1.—Some slight improvement; the pulse is gaining strength, and the crepitation has almost disappeared from the right lung; countenance very sunken and yellow; sputa of a dark brown hue, and mixed with blood; very fœtid still. ℞. Sp. amm. aromat. ♏ xx.; tinct. camph. co. ℥ss.; vin.

ipecac. ♏ xx.; æther chlorin. ♏ xv.; decoct. senegæ ʒj. ter. die.; chlorodyne ♏ xx.; aqua ʒj. ter. die.

4th.—Expectoration less profuse.

5th.—Aspect much sunken, and is very depressed in spirits; cough very frequent, after which he is tormented with efforts to vomit, for which hydrocyanic acid was prescribed.

10th.—There is now considerable enlargement of the abdomen evident.

31st.—Since last report the change has been daily more unfavourable, the debility increasing, and emaciation also; the countenance dusky, and at times almost livid; breathing very laboured; expectoration profuse, and the odour insupportable; large, moist, crepitating râles audible over the right lung; appetite capricious; sickness and diarrhœa present; abdominal distension increasing, evidently from flatus, and the pulse is at times imperceptible.

September 1.—Sinking rapidly from exhaustion.

2nd.—Died at 10.30 p.m.

The post-mortem examination corroborated the prognosis which had been formed during life: the whole of the upper lobe of the right lung was in a state of gangrene; no actual cavities could be detected, but most of the lung tissue was soft, and easily broken down by the finger; a great part of the lower lobe was in the condition of grey hepatisation. There was but little evidence of tubercle throughout.

Case 8.—*Morbus Addisonii—Rapid Exhaustion—Death.*

T. F., aged 25, a well-made and muscular man, who had hitherto enjoyed good health, was admitted on August 12 in a state of extreme depression and prostration, complaining of great languor and debility; his expression was very anxious, and countenance dusky with a brownish discoloration below the lower eyelids; lips livid, but says that he suffers no kind of pain. His account of himself is that, during the last fortnight, he has had occasional attacks of retching, which have resulted sometimes in his vomiting a thick fluid streaked with blood, having an offensive odour; he suffers from dyspnœa after the slightest exertion. The whole integument of his body is dusky, but around the nipples and umbilicus it is almost black; the circulation and respiration are both very feeble; complains of coldness of extremities, and no appetite. No abnormal condition whatever could be detected either of the breast or lungs, and the abdominal rigors afforded no indication of disease; the urine is also natural; bowels regular; the temperature of the whole body is evidently reduced, but particularly of the tongue. ℞. Æther sulphuric, ♏. xx.; acid sulph. dilut., ♏. xx.; aquæ, ʒiss., ter die; pil. hydrarg., gr. j.; pulv. Doveri, gr. ij., night and morning. To have spoon diet, with two pints of strong beef-tea, and champagne with ice.

13th.—Feels better; less depression and anxiety of countenance; nausea and sickness abated; temperature of body raised; pulse 84, small and feeble; complains of great thirst. To have a tepid bath, and lemonade.

14th.—The bath afforded him ease, but he was unable to walk from it; has had one attack of coughing and retching; pulse weaker than yesterday. To have four ounces of sherry, and a boiled egg; but his inclination for any kind of nourishment is very variable.

16th.—Continues very low, and sinks down in the bed. To have an effervescing mixture with quiuine, etc.

21st.—Much the same; pulse almost imperceptible.

24th.—Appears better; pulse has more power. To have a mutton chop.

27th.—Improvement continues.

29th.—Not so well; very restless and depressed; pulse scarcely perceptible. Has vomited a greenish, bitter fluid. To add hydrocyanic acid to each dose of the medicine.

30th.—Very depressed and collapsed, his aspect being almost like that of cholera; has vomited several times; dark halo round the eyes, which are sunken; no pulse to be detected; and the heart's sounds are almost inaudible; hands and feet dry and cold, also the tongue, which is clean; whispers that he has no pain. He took thirty drops of chlorodyne last night, which produced but little sleep, and is now unable to swallow anything unless it is very cold; every kind of nourishment now causes intense retching as soon as it is swallowed, and he appears to be sinking from exhaustion (asthenia). To have beef-tea enemas, with port wine.

31st.—A slight amendment. Brandy, ʒiij.

February 1.—Pulse can be felt, small and weak. Takes beef-tea in very small quantities at a time; was sick last night. ℞ Spirit. am. aromat., ♏xxv.; tinct. opii, ♏v.; infus. rosæ co., ʒj. ter die.

3rd.—Again much better; the extreme prostration having subsided, and takes wine with nourishment.

5th.—Complains of feeling giddy on sitting up in bed; bowels have acted twice from a simple enema; sickness after food continues.

7th.—Continues to improve, but has the same disinclination for food; to have bread-and-milk with lime-water, also rice.

12th.—Acid hydrocyanii dilut. ♏ ij., brandy ʒj., aquæ ʒjss., with ice every four hours, in order to restrain the vomiting if possible.

14th.—The pulse is more distinct, but vomiting almost as constant after swallowing anything; he begs to be allowed some stout, which was given him in small quantities.

16th.—Creosote was now administered in pills, but could not be retained; the strength of the man is daily diminishing, and he lies in bed in a semi-torpid state, answering questions in a very faint voice.

17th.—To omit all medicines, and take small beef-tea injections with ʒij. brandy frequently.

18th.—Very restless, and almost pulseless; countenance much collapsed.

19th.—Passed a very restless night; takes no food by mouth; to have an opium draught.

20th.—After lying in this collapsed state all day, he gradually expired at 6.30 p.m. without a struggle.

The autopsy revealed but little general emaciation, the whole of the integuments had a dusky brown aspect, which around the umbilicus, nipples, and orbits was of a much darker hue; rigor mortis very slight. The lungs were much collapsed, but healthy in structure; heart pale and flabby; the adipose structures all over the body had an intensely yellow colour, and emitted a very peculiar faint odour; the mesenteric glands were pale and enlarged; intestines also free from any vascularity, and quite empty; liver healthy; the pancreas larger than natural, but the duct was quite pervious throughout; the cortical structure of the kidneys was vascular and enlarged, but the supra-renal capsules were very dark, irregular in form, and quite hard on section; the thoracic duct was traced, and appeared healthy in structure. Every organ of the body was most carefully examined to discover some organic cause for the rapid exhaustion and failure of nutrition; but with the exception of the change noticed in the supra-renal capsules, nothing to account for death could be discovered.

Case 9.—*Paralysis of Portio Dura—Recovery.*

J. F., aged 28, married, a healthy looking man, was admitted on November 23, 1864, complaining of deep-seated pain in the head, particularly behind the left ear, and of a sense of tingling around the angle of the mouth on that side. He stated that he first experienced these sensations about a week since, without any apparent cause, and that it had increased in severity since. He has always led a steady life.

Whether the result of congestive action or not, there is now distinct evidence of paralysis of the facial branches of the portio dura on the left side of the face, evidenced by almost complete loss of power of the muscles on that side. The motor division of the fifth does not appear to be affected, and sensation is perfect on the paralysed side. The power of hearing is very slightly affected, and deglutition also perfect. The eyelid cannot be closed, and the tongue is protruded to the opposite side of the median line to a great extent. Pupils rather dilated, but irides act efficiently. Bowels regular; pulse quiet.

Although the pain complained of has often been intense, it is singular that, until his attention was drawn to the peculiarity of his expression to-day, he had not noticed it. To have spoon dict and a purgative.

November 24.—Slept well, but pain and tingling as before. To apply a blister behind the left ear, and the surface afterwards to be dressed with ung. hydrarg.; also, to take internally the solution of bichloride of mercury in camphor mixture twice a-day.

25th.—No change in the symptoms. Low diet.

26th.—Pain in head much increased since last evening. To apply a blister to the vertex.

27th.—Pain less. Urine examined to-day; it was clear, and sp. gr. 1020, depositing phosphates.

28th.—Much sensation of singing in left ear. Repeat blister, and take the bichloride in decoction of bark.

29th.—Blister has acted well, and the pain and singing are quite removed.

December 1.—Repeat the blister to the vertex, which is to be followed by the application of ung. hydrarg. The eyelid can now be almost closed.

5th.—The paralysed muscles are now beginning to act. He feels quite well, and free from pain in the head. Gums slightly affected.

10th.—The evidence of paralysis is now almost gone. He was subsequently dismissed the Hospital, and became quite restored.

Case 10.—*Acute Phymosis from Syphilitic Sores—Sloughing Phagadæna, with Great Destruction of the Penis—Recovery.*

W. N., a delicate-looking young man, 21 years of age, was admitted on April 9, 1864, on account of an acute state of phymosis. After a previous illicit intercourse a large amount of sanious discharge issued from beneath the swollen prepuce, which was livid, and it was evident that a venereal sore existed behind the glans. To have an aperient dose, and apply hot fomentation.

April 11.—No beneficial result has ensued, and as there is now much redness, tension, and pain complained of in the body of the penis, the exuding pus being very sanious and fœtid, an incision was made in the middle line above, from which free hæmorrhage ensued. Injections of dilute Condy's fluid to be constantly employed.

12th.—Some relief to the tension and pain has followed from the incision, but there is now a gangrenous spot about the size of sixpence on the lateral aspect of the prepuce, the surrounding integuments being red and puffy; discharge extremely fœtid; numerous ulcerations were observed on and behind the glans; the man looks weak, pale, and is much depressed; complains also of excruciating pain. Lotio opii. to be constantly applied, and to take thrice a-day, Acid nit. dilut., ♏xx.; tinct. opii., ♏x.; decoct. cinchonæ, ℥j. To have a mutton chop, and wine ℥vi., daily.

13th.—The sloughing process is spreading, and reaches to within two inches of the pubis; the denuded corpus cavernosum immediately behind the glans is soft and ash coloured, evidently in a state of gangrene; the sloughing edges were freely touched with nitric acid, and the frequent application of a charcoal poultice ordered. To continue the mixture, and take extract opii, gr.j. night and morning. Beef tea, Oij. daily.

14th.—The opium has produced a satisfactory sleep; general aspect improved, and the pulse is stronger; hæmorrhage to a great extent ensued this morning, and could only be controlled by pressure with the lint saturated with perchloride of iron. The diseased action does not appear to have spread, but a portion of the cut edges of the prepuce still have an unhealthy aspect, and were again treated with nitric acid. The injection of Condy's fluid to be continued, and the penis to be kept in an elevated position. Nourishment as before, with six ounces of brandy.

15th.—No increase of the sloughing; hæmorrhage quite checked; there has been a considerable detachment of a sloughy portion of the prepuce, and the glans is partially removed from its attachment to the corpus cavernosum.

16th.—General condition has deteriorated; tongue very dry and brown; pulse rapid; skin hot. To omit the opium.

17th.—The whole of the glans in a state of sphacelus, but it was necessary to apply the nitric acid again to the lower part of the prepuce.

19th.—Sloughing action quite arrested, and the edges of the ulcerated parts both clean and healthy. There being no further dread of the violent hæmorrhage, the blackened glans was removed.

20th.—Much improved in every way; granulation proceeding satisfactorily. To omit the brandy, and take instead four ounces of wine daily.

23th.—The denuded parts have a very healthy aspect, and the corpus cavernosum projects about half an inch beyond the surface; the orifice of the urethra distinctly visible below.

27th.—Considerable contraction has now taken place, and the corpus cavernosum is on a level with the surrounding integuments; its surface is very vascular and florid, the slightest touch causing excruciating pain.

May 1.—Healing process continues favourably, but an abscess has formed over the coccyx. To be placed on an air-bed.

3rd.—Abscess opened and fœtid pus discharged.

6th.—Discharge from abscess has a very unhealthy aspect, thin and sanious; granulating surface of the penis satisfactory.

9th.—Appears now to lose ground, but says that he feels better. Eyes are sunken and pupils dilated. Complains of great pain over the lower part of the sacrum. The discharge still continuing unhealthy, and it being now evident that his condition would be likely to benefit by change of air, on May 28 he was sent to Walmer Convalescent Hospital, and returned quite strong and well on August 17; the mutilated penis entirely cicatrised over.

Case 11.—*Laryngitis, with Rapid, Sub-mucous Effusion—Tracheotomy—Recovery.*

W. C., aged 24, a healthy-looking man, was admitted on the evening of July 23, complaining of sore throat, with dyspnœa and cough. He had complained in the morning, and was excused duty for the day, but there was only a superficial congestion of the right side of the throat to be then observed. During the afternoon he felt at times as if he should be suffocated. He stated, on admission, that he had felt unwell, and unable to take food for several days. He cannot now swallow, and on making the attempt the fluid retrogrades through the nostrils. Is in perpetual fear of suffocation; respiration hurried; skin parched; cough constant, and expectoration glairy and muco-purulent; pulse small and rapid. Can speak with difficulty, and only in whispers. Bowels acted during the day. He was examined by Assistant-Surgeon Trotter, who could discover only a slight amount of redness and swelling of the right side of the fauces. There was, however, some swelling over the larynx, upon which, when pressure was made externally, pain was experienced. Six leeches were applied, and a pill of calomel, antimony, and opium ordered every two hours. To have fever diet, with ice and milk. About midnight the distress became so urgent, with cough incessant, and increased dyspnœa, that tracheotomy was deemed necessary; but as some relief to the breathing ensued, this operation was not performed until 6 a.m., to relieve the symptoms of impending suffocation. The relief was great after the introduction of the tube, and he became calmer, and lost the anxious expression of countenance. The respirations were 25, and pulse 128 per minute.

24th.—After the operation the tube by some means became displaced, and the previous urgent symptoms again returned, which subsided after the re-introduction of the tube. I saw the man for the first time about 10 o'clock a.m., when he whispered that he felt much easier; the breathing was quiet, and he had slept for short periods since the operation. Skin was hot and dry; pulse 118; respiration 30. To continue the pills, with an increase of the antimony and opium, and apply hot fomentation.

25th.—Passed a quiet night, with considerable amount of sleep. Disturbed by coughing, which is now less constant, and the expectoration diminished. Swelling less, but there is an erysipelatous-looking redness extending downwards to the chest from the wound. Can now swallow fluids gradually. Countenance calm; pulse 100. The tube was removed to be cleansed of the tenacious secretion. To have a pint of beef-tea.

26th.—He was troubled last evening with the accumulated secretion about the tube, but it was not considered necessary to remove it; passed a good night, but cannot swallow the beef-tea, as it appears to cause irritation and cough, which he does not experience from the iced milk; pulse 84, intermittent; respirations 26; feels very week. There is considerable amount of œdema about the opening, and extending round the neck (probably from inflammatory effusion in the cellular tissue). When the tube was removed for cleansing, he breathed quietly; but on attempting to close the wound, the dyspnœa recurred. On examining the epiglottis with the finger, it appeared rigid, hard, and as if curved lengthways on itself. A strong solution of nitrate of silver was applied to the adjacent parts internally, and externally the erysipelatous blush was painted over with collodion. To continue the pills night and morning. Towards the evening the artificial opening was found to maintain its patency without the tube, which was removed, and he could breathe comfortably through the nares. Some light gauze was placed lightly over the wound.

27th.—Passed a good night, and was able to swallow a pint of beef-tea, and two pints of iced milk. Pulse 84, firmer; respiration 22; the erysipelatous redness nearly disappeared, and swelling diminished; expectoration still tenacious, but not so troublesome; breathes though the wound and mouth; cough less. To continue the application of the solution of nitrate of silver three times a-day, and the pills twice as before.

28th.—Can swallow better, and slept well. Temporary closure of the wound does not produce the same amount of

irritation; tongue coated, and bowels constipated. To have a common saline enema.

29th.—Can now breathe comfortably when the wound is closed. It was ordered to be covered with wet lint and oiled silk, and to take an ounce of the cold infusion of bark twice a-day.

30th.—Wound now granulating and filling up. The same sensation of rigidity is experienced on feeling the epiglottis. To continue the beef-tea and milk, with three ounces of sherry daily.

31st.—The edges of the wound were now approximated by suture, which produced no inconvenience.

August 1.—Improvement continues.

3rd.—An abscess is forming on the side of the neck; tracheal wound closing fast; the voice is rough and thick. Ordered a Plummer's pill every night, and decoction of bark with nitric acid twice a-day.

5th.—The abscess in the neck was opened. Half diet and porter daily.

6th.—Abscess refilled; voice thick and husky; could not swallow the solid food.

7th.—The difficulty in swallowing varies; the external wound surrounded by large pale granulations.

12th.—All traces of abscess disappeared, and the wound into the trachea quite closed; feels stronger, and can swallow much better; cough almost gone, and no difficulty in breathing.

14th.—Improving, but voice still husky, and rigidity of epiglottis as before. Half diet with porter and one egg daily.

17th.—Walked out for a short time. Examination with the laryngoscope revealed a vascular condition of the mucous membrane about the epiglottis, and the condition of rigidity as described previously.

The daily improvement continued, which it is unnecessary to describe, and on August 25 he was dismissed as a convalescent to attend as an out-patient, which he did for several weeks.

Case 12.—*Popliteal Aneurism—Complete Cure in Fifteen Hours by the Combination of Forcible Flexion with Digital Compression.*

S. M., aged 23, a healthy-looking young man with florid complexion, was admitted into the Hospital, complaining of pain and swelling round the left knee, which extended to the calf of the leg and thigh; it was of a spasmodic character, and often very intense; there was a generally diffused redness also present. After a few days' rest he recovered from these symptoms, which were supposed to be rheumatic; but then, on February 25, a circumscribed swelling was detected in the popliteal space, a little to the outside, which communicated a distinct pulsation to the fingers; the surface of the swelling was red, and it measured longitudinally three inches by two and a-half in breadth. A *bruit de soufflet* was heard with great intensity over it, and all pulsation ceased on pressure being exerted over the femoral artery above, the swelling also much subsided; he had been under treatment on seven different occasions for venereal disease, but his constitutional powers were in no way impaired. The heart's action was somewhat weak, and the circulation in the left is not so vigorous as in the right lower extremity. He complains of dyspnœa on exertion.

26th.—A bandage was applied to the thigh at 11.30 a.m., and modified pressure made by the double tourniquet, but this could not be borne except for a short time, on account of the pain produced. At 7 a.m. forcible flexion of the thigh was made, immediately after which a simple roller was applied tightly, to act as a compressor of the femoral artery against the bone below the profunda, while digital compression was kept up on the downward course of the artery towards the knee for several hours, which materially controlled the circulation in the sac, the impulse of which was afterwards much diminished. The whole extremity was then bandaged from the foot upwards as high as the groin, and also placed on an inclined plane.

27th.—At 10 a.m. the tumour was examined very carefully, and all pulsation in it had quite ceased; its volume also diminished. The roller was again applied to the groin, and the extremity carefully re-bandaged. To have milk diet, and one grain of opium every night.

28th.—Slept well; no pulsation; pulse 100. Continue as before.

29th.—The outline of the sac can be clearly defined; it appears to be connected with the outer side of the artery, and has a soft, semi-fluid feeling. To continue the roller and bandage.

March 1.—The pressure is still kept on the extremity; but there has never been the slightest return of the pulsation; pulse 80; he complains of no pain.

3rd.—The contents of the sac now appear harder.

5th.—Progressing most favourably; all bandages were removed.

7th.—Is now walking about; the circumference of the limb is still half an inch more than the opposite; no pulsation can be detected below the seat of compression in the thigh.

11th.—Sac hard and contracting in size, and pulsation in the artery above returning. Dismissed.

September 12.—Has done his regular duty since, and, on examination, the sac is very hard and about one-third its former size.

The above case may be considered to have had a very favourable and speedy termination; and the sudden detachment of some portion of the contents of the sac by the forcible flexion of the leg upon the thigh, combined as it was, immediately afterwards by the uniform and equable compression and elevation of the whole extremity, fulfilled, according to my mind, that which modern experience has indicated as the most rational treatment for external aneurisms.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

KING'S COLLEGE HOSPITAL.

FOUR CASES OF EPISPADIAS, WITH EXTROVERSIO VESICÆ, SUCCESSFULLY TREATED BY PLASTIC OPERATION.

(Under the care of Mr. JOHN WOOD.)

The peculiarity of Mr. Wood's mode of operating in these cases consists of, firstly, following the method of Pancoast, of New York, in turning the surface of the skin to the bladder, he takes flaps chiefly from the sides over the groins, carefully avoiding wounding the peritoneum, and the admission of urine into its cavity. These flaps are made with the base downwards, so that they may be sustained by the recurrent branches from the common femoral artery, traction being made on the extensible structures of the scrotum, and the new urethra rendered more compact. His object is to cover the raw, abraded, and protruding mucous membrane, to protect it from the friction of the clothing, to render the application of a urinal more easy and effective, to confine the exit of the urine to an aperture above the penis, and to enable the patient to wear trousers.

Case 1.—*Operation Successful so far as the Closure of the Epispadias was concerned—The Patient Died afterwards from Erysipelas of the Head and Neck Six Weeks after the Parts had healed.*

A boy, aged 6½. Anterior wall of bladder and abdominal parietes deficient; posterior wall of bladder thrust forward, showing the openings of the ureters; penis small and ill-developed; upper wall of urethra and corpora cavernosa wanting; pubis deficient at the symphysis; the two branches separate to the extent of two and a-half inches; a testicle to be felt in each inguinal canal. The first operation was performed on October 17, 1863 (from Case-book, vol. i.). Mr. Wood dissected a triangular piece of skin off on each side, with the base downwards; these were then brought into the middle line, and fastened with silver wire; the upper extremity was then fastened; the edges of the raw surfaces then brought together by hare-lip pins, and the rest of the surface left to granulate. A second operation was performed on November 21. As the surfaces separated in several places on this occasion, they were brought together by a quilled suture on their deep aspect, and by fine wire on their superficial. A third operation was performed on December 5. On this occasion a flap of integument was dissected off from the abdomen above the bladder, and united to the deep surface of the flaps below, which covered in the bladder in front. The fourth and last operation was performed on January 17, 1864. A square flap was dissected from the scrotum on one side of the penis, and a smaller one from the other; these were turned up and united to the old flaps; a small bent catheter was in-

troduced through the artificial urethra (formed by the lower surfaces of the flaps and the lower surfaces of the undeveloped urethra) to draw off, as a syphon, the urine and mucus formed in the bladder. These flaps united speedily and completely, and a useful covering was made for the bladder. He appeared to be in perfect health, but on February 23 there appeared a swelling of a livid hue of one side of the face below the eye. There was foul tongue, quick pulse, disinclination for food and vomiting, but no delirium, and he complained of no pain. The day before his death he did not pass his water. He died on February 27. No morbid appearance about the parts operated upon, the operation having been a successful one. The parts operated on were exhibited at the meeting of the Pathological Society, May 14, 1864. The ureters were dilated and free, with slight dilatation of the pelvis of the kidneys. A bad case of erysipelas had been placed in the next bed, and there was much of this disease at that time in the Surgical wards of the Hospital.

Case 2.—Case Complicated with Pneumonia and Debility—Cure after Three Operations, a small Fistula only Remaining.

A boy, aged 12, from one of the London workhouses, of a feeble constitution, and pale and cachectic appearance. The deformity in this case was very similar to the last. An operation had been performed some years before at the Middlesex Hospital, but was not successful. On January 17, 1864, Mr. Wood performed the first of a series of operations by dissecting two broad flaps from the upper part of the groin, one on either side, with the base downwards and outwards, large enough to overlap one another; he next dissected off a semicircular flap from above the bladder; then the lateral flap on the left side was turned with its cutaneous surface towards the mucous membrane of the bladder; the lateral flap from the other side was next turned over on this, their raw surfaces being opposed; and, lastly, the superior flap from the abdomen turned down and tucked behind the other two, its cutaneous surface being applied to the wall of the bladder. These were then fastened together by hare-lip pins, and a small catheter introduced as in Case 1. The edges of the flaps sloughed, and union was obtained only by the surfaces at the lower half of the opening. After two months a second operation (cicatrisation having been accomplished) was performed of the same kind, at the upper part where non-union had occurred. After this he was considerably weakened by a bad cough, with purulent and rusty expectoration, indicating pneumonia. Notwithstanding this, the edges united very well, leaving only a small chink above the position of the pubes. To close this a third operation was performed on May 21, the edges being pared and brought together by wire sutures. This gap gave considerable trouble, as it showed a disposition to slough, but it ultimately granulated over almost entirely, leaving a very small opening through which a few drops of urine dribbled. He was then discharged to have the benefit of a change of air at one of the country branches of the Workhouse Infirmary (Edmonton), where he is now enjoying good health.

Case 3.—Case Complicated with a Right Inguinal Rupture—Arrest of Development almost entirely the same as in the last Case—Union by Adhesion.

A boy, aged 13. First operation October 15, 1864. An incision was made commencing at the scrotum across the hernial sac, and then upwards and inwards towards the upper margin of the imperfect bladder; the flap contained by this incision was then dissected off to within about half an inch of the bladder and turned over to the opposite side, lying upon its skin surface. A second flap was then made from the left or opposite groin (with its base downwards as before) towards the scrotum and thigh, terminating on the left side of the urethra, opposite the point where the first incision commenced; this was then turned over the other, and united to it by wire sutures. The flaps united by first intention; but on the upper part of the left, for the space of an inch and a-half, union did not take place.

A second operation was performed on November 19, when the upper border of the united flaps was split up for about a quarter of an inch, and a small, semi-oval flap dissected from the abdominal wall above the bladder and inserted into the bifurcation in the upper border of the lower flaps. These were then united by wire sutures.

Owing to ulceration caused by the stitches, a small portion still remained uncovered, through which the water came away above. A third operation was performed December 10, the edges being pared and brought together by a quilled suture. This operation was successful, so far as to close the opening with the exception of about half an inch, and he left the Hospital very much relieved, there being scarcely any escape of urine except by the artificial urethra. He was sent out for the benefit of fresh country air, having become somewhat pallid by long residence in the Hospital wards. He is to be re-admitted at some future time to have the small remaining fistula closed.

Case 4.—Very Rapid Union by Adhesion of Extensive Raw Surfaces.—Case now in the Hospital.

A boy aged 7. The first operation in this case was performed in a similar manner to the last, on November 19, 1864. The union was very rapid and complete, almost entirely by adhesion, only a small portion of the bladder protruding above the flap on the right side. A second operation was performed December 17, in which the upper margin of the flaps was split (as in the former operation), and a small flap turned down from the abdomen and inserted into it, and kept in its place with a wire suture transfixing it and the under portion of the first flap; the corners of the lower flap were then brought into apposition with the skin of the abdomen, and fixed with a quilled suture. This case is now in the House (January 23, 1865), about to be operated on for the closure of the small fistula (of about half an inch) remaining. He is getting stout, and in excellent health, having lost entirely a cutaneous pustular eruption which he had when admitted.

HOSPITAL FOR SICK CHILDREN.

TWO CASES OF OPERATION FOR EXTROVERSION OF THE BLADDER.

(Under the care of Mr. HOLMES.)

Two operations for extroversion of the bladder have been performed at this Hospital by Mr. Holmes. The first took place on March 21, 1863, and was described by Mr. Holmes in the *Lancet* for June 27, 1863. Mr. Holmes had the advantage at the operation of the presence and assistance of Mr. Partridge, of King's College Hospital. It is believed to have been the first case of this kind in which the operation has been performed successfully in this country; in fact, the first in which complete success has been obtained, since in Dr. Ayres' case, operated on in New York in 1859, the success does not seem to have been quite perfect, and in Dr. Pancoast's case, operated on in Philadelphia, though ultimate success appeared probable, the patient died of another disease before the treatment was complete.

In Mr. Holmes's first case the patient was a boy, aged 9, otherwise well formed and healthy. There was no hernia. The operation consisted in taking a square flap out of the groin, with its base towards the exposed mucous surface of the bladder, and turning it back over the latter, with its raw surface upwards. This first flap was then covered by a second, taken from the opposite side of the scrotum, and twisted slightly so as to be over the former flap, with its raw surface in contact with that of the first flap. The two flaps being united by silver sutures at their upper and lower edges, kept each other in place, and formed a broad bridge of healthy soft parts over the exposed bladder. The upper edge of this bridge was then implanted into the skin of the abdomen, which was pared to receive it. The wound was not dressed in any way whatever, nor was any attempt made to hinder the contact of the urine with the raw edges, previous experiments having shown that such attempts were more likely to do harm than good. All went well, except that the part where the bridge had been implanted into the abdomen failed to unite. Two subsequent operations, however, obtained complete union of this part, by a firm and healthy cicatrix, in which only an opening remained through which an Anel's probe could be passed, but through which no water seemed to exude, and which, therefore, was not thought worth treatment. The boy was perfectly relieved of all the distressing complications of his infirmity, except the constant dribbling of water, so that a common railway urinal kept his clothes clean and free from odour.

He died about a year after the operation, of the growth of a tumour, apparently of the fibroplastic variety, in the brain. The parts concerned in the operation were shown at the Pathological Society (Pathological Society's *Transactions*, xv. 254), and are preserved at the Hospital, together with accurate drawings of the case before and after operation, by Dr. Westmacott.

The general idea of this plan of operation was suggested by a case reported by M. Follin in *L'Union Médicale*, Sept. 10, 1862.

Mr. Holmes repeated a similar proceeding on a male infant, aged a year and a-half, on May 20, 1863. In this case there was hernia on one side. The operation differed from that in the previous case, in the fact that no attempt was made to implant the bridge into the skin of the abdomen at the first operation. This first operation was perfectly successful, and a bridge of healthy skin was obtained to cover the exposed bladder. A first attempt to implant this into the skin of the abdomen did not succeed, and the child was being kept in the Hospital, in order that a second might be made, when he was attacked with typhoid fever. The case seemed to be going on well, and he might have recovered, but that his friends insisted on taking him home, a considerable distance into the country. He died a few days after reaching home. This case may be said, like Professor Pancoast's, to have been successful as far as it went.

ST. GEORGE'S HOSPITAL.

TWO CASES OF PLASTIC OPERATION FOR EXTROVERSION OF THE BLADDER.

(Under the care of Mr. HOLMES.)

Mr. Holmes has also operated on two cases of this malformation at St. George's Hospital, the plan pursued being the same as in the last mentioned operation. Neither cases had any success, though in neither did any injury result. In one the patient was a man about 21 years of age, an agricultural labourer, of ruddy complexion and fair proportions. He was most anxious to submit to anything which would lessen his sufferings. He was the subject of a very large hernia on both sides, the skin covering which was so thin that much care was requisite in dissecting flaps off it, and when formed they were very deficient in fat and cellular tissue. Nevertheless, the first operation seemed to likely to succeed, when unfortunately a short time after the sutures had come away, phagedæna attacked the raw edges, and the union melted down. Some weeks afterwards the proceeding was repeated, reversing the sides, but with no better result. Another attempt was afterwards made by uniting the remains of the flaps over the median line; but it also failed, and the man was sent home, having been provided with the usual cumbrous and inefficient apparatus.

In the fourth case, the patient was a little boy about 7 years of age, in very weak health. In him also the deformity was complicated with large herniæ on both sides. The operation failed, and it was thought better not to repeat it until the general health was more satisfactory. In both these unsuccessful cases, the cicatrisation induced by the operation in the groin and scrotum appeared to be of some service in diminishing the size of the hernial tumours.

WESTMINSTER HOSPITAL.

COMPOUND COMMINUTED FRACTURE OF TIBIA AND FIBULA—PRIMARY AMPUTATION—DEATH.

(Under the care of Mr. CHRISTOPHER HEATH.)

On August 24, 1864, William W., aged 38, was admitted into Northumberland ward at 3 p.m. with a bad compound comminuted fracture of both bones of the leg. He was driving a brougham, when the horse ran away, and dashed the driving-seat against a lamp-post with such violence as to wrench the post out of the ground. The driver's right leg came in contact with the post, and received all the violence of the shock, but was uninjured otherwise.

On admission he was bleeding freely from the right leg, the lower part of which was completely smashed, the bones being broken in several places and into the ankle-joint. The skin was divided vertically all down the shin, and was torn at the side at the lower part; there was also a deep wound at the lower part of the calf punctuating the muscles. Mr. Heath was in the Hospital when the patient was admitted, and proceeded to amputate at once.

Operation.—Chloroform being administered, Mr. Heath made a skin flap over the upper part of the front of the tibia, and as long a flap as was possible from the muscles of the calf, and sawed through the tibia and fibula necessarily very high up. The popliteal artery was the only vessel which required a ligature, and this was applied just above the point of bifurcation. The flaps were brought together, without any tension, with wire sutures, and wet lint was applied. ℞. Brandy, ʒss., 2ndis hôris.

24th.—There was some oozing of blood in the evening, which, however, stopped on the application of a bandage over the face of the stump at nine o'clock. ℞. Brandy, ʒss., 4tis hôris; liq. opii. sed., ♏. xx.

25th.—Patient had a good night, and is very comfortable to-day. All symptoms of shock have passed off. Beef-tea, O. ij. Chop.

27th.—Stump dressed to-day; looks healthy. Porter, O. j.; brandy, ʒiv.

29th.—Patient's progress uninterruptedly good. Put on full diet. Porter, O. j.; wine, ʒiv.

The remainder of the case was supplied by Mr. Power, who took charge of the case during Mr. Heath's absence from town:—

This patient came under my care on the 1st of September. The wound was looking healthy, except that the upper border of the cut edge of the tibia projected one-eighth of an inch, white, and dead. During the next day or two cicatrisation rapidly progressed, and though more of the circumference of the bone appeared, the granulations around it were perfectly healthy, and the discharge was small in quantity. There was no bagging of matter in the upper part of the thigh. About a fortnight after I first saw him he had a violent rigor, and on the following morning his pulse was frequent and small; his complexion remarkably sallow, and he lost his appetite; he had no pain in the limb or elsewhere, except in the chest; some dyspnœa; no pneumonia or bronchitis. At this time he began to have violent sickness and delirium at night, Discharge from stump became rather fœtid, and all dressings were removed except lint and water. I directed him to be taken upstairs to another ward, and gave him an additional quantity of stimulants (brandy and wine). Very soon, the limb remaining unchanged in appearance, excepting that it had nearly healed up, the jaundiced appearance increased, and he became violently delirious. His bowels were carefully attended to; one or two enemata were administered. The delirium continued, but the sickness was relieved. ℞. Ammoniæ acetas. He gradually sank, and died on September 26, 1864. No post-mortem allowed.

VARICOSE VEINS OF BOTH LEGS TREATED BY LEE'S AND WOOD'S METHODS RESPECTIVELY—CURE EFFECTED.

(Under the care of Mr. CHRISTOPHER HEATH.)

The treatment of varicose veins has been modified from time to time by various Surgeons. Mr. Henry Lee advocated the plan of passing two needles beneath the vein at a little distance from each other, and a figure-of-eight ligature being applied to each sufficiently tight to compress the vein, the subcutaneous division of the vein was effected with a narrow knife. For the ligatures he has latterly substituted small slips of thin india-rubber, which answer every purpose, and are more easily removed. Mr. Wood's plan we detailed in the *Medical Times and Gazette* of January 14, and we need not, therefore, allude to it any further at present.

Charles T., aged 47, admitted into Mark Ward, August 17, 1864. Has suffered from large varicose veins of left leg for eighteen months, and has large clusters of engorged veins at various parts of the leg, and specially about the inner ankle, at which there is a small ulcer. The internal saphena vein is also much enlarged. The external saphena vein of the right leg is considerably enlarged.

August 17.—Mr. Heath introduced two hare-lip pins beneath the lower part of the saphena vein at a distance of an inch apart. Having passed an india-rubber band over each so as to compress the vein, he then divided it subcutaneously midway between the two. The divided vein bled freely, and it was necessary to tighten the lower india-rubber band. A pad of lint was applied, and a bandage over all.

19th.—Lower pin withdrawn. Patient has suffered no inconvenience whatever from the operation.

21st.—Upper pin removed. The vein is apparently blocked with clot at the seat of the operation, but the veins of the leg do not appear to have undergone much change at present.

24th.—Veins of left leg much diminished in size, and ulcer healed. The external saphenous vein of the right leg was operated upon in a similar manner.

26th.—Lower pin withdrawn.

27th.—Upper pin withdrawn.

29th.—The vein has much diminished in prominence, and is only visible when the patient stands up. Discharged.

November 3.—Readmitted with a varicose ulcer of the left leg, the veins of the leg being apparantly as large as before the operation. It appears that he has been working and walking about without his elastic stockings. The external saphena vein of the right leg appears to be perfectly obliterated, and that leg has given him no inconvenience.

December 6.—Mr. Heath introduced a Wood's hernia pin beneath the internal saphena vein of left leg three inches below the knee. A wire suture was then passed subcutaneously and over the vein, and the wire was attached to the pin, after which the pin was rotated, so as to twist the wire and compress the vein.

13th.—The pin has been turned from time to time, and to-day, being quite loose, was drawn out with the wire and a portion of the vein included between them. The vein is apparently quite obliterated, and the ulcer healing rapidly.

27th.—Discharged. Ulcer nearly healed, wound of needle not quite closed. The vein appears to be perfectly obliterated, as when he stands up it does not project at all beneath the skin.

TERMS OF SUBSCRIPTION.

Medical Times and Gazette.

SATURDAY, FEBRUARY 4.

THE MEDICAL COUNCILS ON MEDICAL TITLES.

The preamble of the Medical Act is very brief. It says, "Whereas it is expedient that persons requiring Medical aid should be enabled to distinguish qualified from unqualified Practitioners," be it enacted, etc. The Legislature proposed to accomplish this object in a fashion which promised, according to the views of the period, to be successful. Experience has falsified the anticipation. The Act has now been some six or seven years in operation, and it is most difficult, if not impossible, for the public to distinguish the qualified from the unqualified Practitioners. To the Council constituted under this Act was assigned, as the first and especial duty, the preparation of a list of Practitioners who were duly qualified. It was supposed that this list—the "Medical Register"—would be in the hands of the public, and that a reference would be made to it by persons inquiring into the qualification of Medical Practitioners. Few copies of the register are to be found except in the official hands in which they are placed, and few or no references to it are ever made by the public. In popular estimation, a Doctor is a Doctor and a Surgeon is a Surgeon, and no further inquiry into Professional qualifications is thought of. The public do not know that any one, qualified or unqualified, may call himself a Doctor, and practise on their credulity and their pockets, as well as on their bodies, though he were as unacquainted with physic as with honesty. The Medical Act has failed to remedy this evil. The case of "Dr. Henery," who was lately sent to the very suitable occupation of hard labour at Holloway, has in some measure awakened the public to a knowledge of the fact. Still, the fact will soon be forgotten, and it is the duty, as well as the interest, of the Medical Council to seek to apply their experience to correct this wrong.

Under the Medical Act qualified Practitioners are encouraged to register by the grant of certain privileges withheld from the non-registered—viz., the recovery of debts, the holding public appointments, etc. (clauses 35 and 36); whilst by another clause (40) a penalty is inflicted on "any person who shall wilfully or falsely pretend to be, or take or use the name . . implying that he is registered under this Act." To the first two clauses no valid objection has been raised; the last clause—and it is the most important clause of the Act, for on its operation depends the value of the Register—has proved inoperative. It has been found impossible to convict in cases in which it was necessary first to prove what a man pretended, or what he implied by assuming a name. A person may take the name of Doctor, and may practise Physic; and, if sued under this clause, he may say—"I am a Doctor of Philosophy; I never implied that I was registered under the Medical Act."

We are given to understand that the several branch Councils have met and discussed at length the means of remedying this great evil. We published at page 76 the resolution arrived at by the Scottish Branch Council, which is very similar to that previously adopted by the Irish Council, and which is as follows:—

"Section XL.—On and after the day of , 186 , it shall not be lawful for any person, unless registered under this Act, to pretend to be, or to take or use the name or title of, Physician, Doctor of Medicine, Licentiate in Medicine or Surgery, Master in Surgery, Bachelor of Medicine, Doctor, Surgeon, Medical or General Practitioner, or Surgeon, or Apothecary, or Accoucheur, or Licentiate or Practitioner in Midwifery, or any other Medical or Surgical name or title; and any unregistered person so offending shall forfeit and pay a sum of not exceeding £20, to be recovered in a summary way before the justices of the peace."

The English Branch Council, at a meeting held on Friday last, adopted the following as a substitute for this 40th clause:—

"Any person practising Medicine or Surgery, or being engaged in the treatment of diseases or injuries, for gain, not being registered under this Act, nor being able to give evidence of being qualified to be registered under this Act, who shall take or make use of any of the titles or designations enumerated in Schedule (A) to this Act, or that of Physician, Surgeon, Doctor, Professor of Medicine, Professor of Surgery, or any Professional title, name, or distinction commonly used by, or used to distinguish, duly educated or qualified Practitioners in Medicine or Surgery, shall, upon a summary conviction, be liable to a penalty not exceeding £ for each offence."

Of these several proposals, we prefer the last: it is more comprehensive and more practical. It differs very materially from both the others in this respect—that whilst they render registration compulsory before assuming any title, the English proposal is satisfied with qualification for registration as well as with registration; and this is right. If Oxford, or Cambridge, or London, have conferred on a man the degree of Doctor of Medicine, he cannot be prevented from calling himself, nor can others be prevented from calling him, Doctor. A College of Physicians can make a man a Fellow or a Member: it would be strange if he could not practise, calling himself a Physician. Universal registration is certainly the simplest plan; but we doubt whether the Legislature would grant, the corporations agree, or the Profession submit to a compulsory tax of five pounds or five guineas to be added to the funds of the Medical Council. With the exception of the words "for the sake of gain," which would inevitably lead to evasions, we approve of the clause suggested by the English Branch Council. It is conceived in a liberal spirit. It aims at, and it appears to succeed, as far as language is intelligible, in preventing unqualified persons from assuming the designation and names by which the qualified are generally recognised. More than this the public do not want, and more than this we should not ask. In asking more we may get none.

INDIAN MEDICAL SERVICE.

Every student of English history cannot fail to have observed that no great measure of reform, however urgently required, has been proposed, nor any vital change in the constitution of any long-established system, however intrinsically faulty, has been attempted, without drawing forth expressions of dissatisfaction and dissent from many quarters, perhaps from quarters where it was least expected. These expressions of feelings and opinions assume in some instances a bitterness of invective wholly inconsistent with a pure desire after truth; but even where this is not the case, parties who are incidentally interested in the subject under discussion, from viewing it at different points and through varying media, are apt to form very discordant views regarding it, and these they express in a mild, philosophical spirit, which is essential to elucidate the real merits and bearings of the case. Both these classes, for the most part, employ the periodical press for the purpose of giving circulation to their opinions, and it is a matter of congratulation that this is so, as the subject thus becomes thoroughly opened up and ventilated and the cause of truth and right promoted. In this way the periodical press is a great public benefactor.

We have been led into these remarks by some strictures which we have received—one published in to-day's issue—on our previous articles on Sir Charles Wood's new scheme or Warrant for the organisation of the Indian Medical service. For ourselves, we need hardly say that in our editorials on this subject we have been actuated solely by an honest desire to place the whole subject in what we had, and still have, reason to believe to be its true light. We had no foregone conclusions to substantiate, no "preconceived notions" to maintain. We are not, however, in the least surprised to find that our views on some points have not met with the unhesitating approbation of all. In the very nature of things, as we have before said, it was only to be expected that dissentient voices would be raised, and we look upon it rather as confirming our own view of the matter that, though our remarks on the subject have been so widely circulated, the voices raised in dissent have been so few.

We have given careful attention to all that has been urged by our correspondents on the subject of the New Indian Warrant, and we see no reason for changing our previously expressed opinion that it is a great and substantial boon to the Indian Medical Service. Under it those painful days of 225 Rs. per mensem, rendered beautifully less by large subscriptions to the Medical Fund, have passed away for ever; a gradually increasing rate of pay, according to length of service, has been established; the long delayed and anxiously looked for promotion to the rank of Surgeon (which of late has rarely been under fifteen years, and in many instances extended to seventeen and eighteen years) is now reduced to a certainty after twelve years' service; the injustice of half-batta pay has been abolished; a liberal scale of "unemployed pay," a new feature in the service, instituted; the right of all service from date of commission to count for promotion to the rank of Surgeon-Major conceded; the rate of furloughs and sick pay have been increased; the retiring pensions (for the lower grades, at any rate,) augmented; and all claims, present and contingent, on the Medical Funds guaranteed. These are broad facts which are patent to all, and can we be wrong in looking with a favourable eye on any scheme by which such substantial advantages are secured? That so comprehensive scheme as the present should have its faults was only to be expected in the very nature of things; some interests may have been prejudicially affected; others, perhaps, altogether over-looked. Much, perhaps, yet remains to be done; indeed, we believe that some further changes—such, for example, as the grant of extra pay, in the form of head money or otherwise, for extra incidental charges—are indispensable to the fair and proper working of the scheme; still, looking at it as a whole, we see no reason for changing the opinions we have already expressed on its merits.

Our correspondent, "An Indian Surgeon," whose letter we published in our issue of the 14th ult., has favoured us with a second communication in elucidation of his views; its great length (nineteen pages), however, precludes the possibility of our publishing it *in extenso;* but this is less to be regretted as it contains little beyond what he has already so ably and temperately advanced in his former letter. We shall content ourselves, therefore, with taking a few prominent passages from his present paper, and answering them to the best of our ability.

1. *As to Staff Pay.*—Our correspondent says (paragraph 13):—"You express yourself at a loss to understand the complaint made with regard to the abolition of staff salaries; and you say that in paragraph 27 of the Warrant staff allowances are distinctly and specifically admitted. I reply that either as proof of the existence of staff salaries, meaning thereby a fixed allowance, extra and in addition to the regulated pay of rank and given for the performance of military duty, such as 300 Rs. a-month for Surgeons, or 165 Rs. for Assistant-Surgeons, which existed up to June 15 last, or as a Warrant to establish such, the said section is not virtually worth to the service the value of the paper on which it is written." He then furnishes the dates of the various orders for the staff pay, of staff, ordnance, and regimental officers, and he adds—"When I see another such order referring to Medical officers, I shall give it due credit; till then I must maintain my present opinion."

Now, what says paragraph 27 of the new Warrant?—"I have now to inform you that it has been determined that in future all employment on the part of the Medical officers of the Indian Service involving the receipt of special staff salary shall be considered as staff employment, the salaries being in all cases consolidated." If these words mean anything, they admit the existence and establishment of staff salaries, although, for some reason which we do not comprehend, they are for the future to be consolidated. A case by way of illustration. Under the old system, previous to June 15 last, the pay of a Surgeon-Major in charge of a corps at a full batta station was 563 Rs., in addition to which he drew 300 Rs. staff allowances, = 863 Rs.; by the new Warrant the staff allowances are consolidated with the pay proper, and the income fixed at 1000 Rs. per mensem. So in the Civil Department. An Assistant-Surgeon, for example, holding the appointment of Surgeon to a political agency: instead of drawing as heretofore 256 Rs. from the Military Department as pay proper, and 400 Rs. from the Civil Department as staff salary, these sums will be consolidated, the staff salary abolished in name, but remaining intact, in fact, and the gross income of the appointment will be 656 Rs. per annum. Whilst, therefore, we agree with our correspondent in thinking that no extra staff pay will be granted to specific appointments, we yet maintain that the *principle* of staff allowances is distinctly and specifically admitted. There are many special appointments—such, for example, as that of Chemical Examiner to the Presidency, the Professorships at the Medical Colleges, etc.—appointments requiring peculiar qualifications, and entailing not only much extra work, but heavy responsibilities,—which it would be an act of the greatest injustice, as well as impolicy, to deprive of staff allowances, placing them on an equality, as to pay, with the comparatively easy appointments of a civil Surgeon at an up-country station or of one in charge of a native corps. Almost all these appointments have special staff salaries attached to them, and we look upon paragraph 27 of the new Warrant as guaranteeing these in their integrity, although instead of their being drawn as heretofore as a separate charge (perhaps in two divisions, one from the Civil and the other from the Military Department), they will for the future be drawn from one source in the form of consolidated pay.

2. *As to the Medical Funds.*—Prior to the appearance of our correspondent's letter we had expressed ourselves against the clause by which the Medical funds were abolished, though

not, perhaps, in the same forcible language. On that point, therefore, our opinions are happily in unison. He, however, takes strong exception to the passage in our article in which we expressed our opinion "that the funds had long ceased to become little better than insurance offices; and that on the increased rate of pay under the new Warrant, without deductions for these funds, the prudent Medical officer may obtain very nearly as great, if not greater advantages, by effecting an insurance in some of the many good insurance companies now existing." Our correspondent has quoted the passage correctly with the exception of the last sentence, which in our article ran as follows:—"By effecting an insurance in some of the many good mutual insurance companies now existing in all the large presidency towns of India." This distinction is all-important. When we penned these lines we had in view one office in particular, of which we happen in times past to have known something, the Madras Mutual Insurance Company, of which Messrs. Arbuthnot and Company, of Madras, are secretaries. We have not the figures before us to speak with the precision desirable on such a subject, but we may say generally that in the course of years the sums paid in the way of bonuses (the whole profit being divisible amongst the insured) were so large that the premiums required in some years were reduced to a very small amount, enabling a man to effect an insurance at rates very little in excess of the life rates which obtain for Englishmen in England. Similar mutual insurance offices we believe to exist in the other presidency towns; and, as we observed before, it was to these, and these only, we had reference, in penning the above passage. And we have no hesitation in counselling the new members of the Indian Medical Service who have now no Medical funds to fall back upon to lose no time after their arrival in India in effecting an insurance in one of these local offices—that is, if they should have belongings for whom they wish to provide in case of their death. As far as our experience goes, they are quite as trustworthy as the home offices, and very considerably cheaper. They require to be inquired for, as for the most part they advertise little, if at all.

3. *As to appointments awarded by selection versus seniority*, the "Indian Surgeon" remarks that he "is convinced, if the service were to be polled on the subject, we should find nine-tenths would give their votes for *seniority with competency* versus *simple selection*." True, if that were the question to be settled. But it is not; it is simple seniority (with or without competency; for who is to decide as to the competency?) *versus* simple selection. The "Indian Surgeon," in his long experience, must remember the time when the seniority system was in full force; and could he not put his finger upon men who, for the accidental circumstance of having a few extra years of service, have attained the appointment of Superintendent-Surgeon, and subsequently a seat at the Medical Board, without any one other single recommendation in their favour? Under the old seniority system, who could hope ever to attain to the top of the tree? Who could hope to attain even the rank of Superintendent-Surgeon (now Deputy-Inspector-General)? To the young Medical officer entering the service there was a long vista of years, stretching into the far future, unenlightened by a single ray of hope of attaining to the higher grades. All stimulus to ambition was damped. Be his talents, acquirements, or good qualities what they might, he could never hope to raise himself over his seniors in the service. Under the new *régime* all this is altered, and we think beneficially. Our correspondent says:—"It opens the door to interest or intrigue, and gives an undue advantage over his equally well-qualified seniors to the man whom circumstances happened to bring more in contact with the Powers that be, and who had opportunities of blowing his own trumpet or of impressing the man in authority with a conviction that he was more qualified than others, or in creating a desire in them to advance his interest." We admit the objection here advanced. At the same time, we think it is one which comparatively seldom is likely to arise and to operate prejudicially on the service at large. In our opinion, it is better, far better, that such exceptional cases should arise than that the young, ambitious, and talented member of the service should succumb to the operation of a pure seniority system, such as was formerly in vogue. This, however, is a matter of opinion.

We had hoped here to have been able to conclude; but we cannot, in justice to ourselves, do so without noticing briefly two passages in the letter of "Another Indian Surgeon," who, it will be seen, takes us somewhat roughly to task for the opinions which we have advanced in our former articles.

He objects to our saying all the civil and other charges at the presidencies remain intact, and he adds "Will you read section 20 of the Despatch, and say if you still adhere to your statement? You cannot, for Sir C. Wood distinctly orders uncovenanted members to be employed." Now, Section 20 referred to runs as follows:—"In making the calculation (*i.e.* for the reduction of the establishment consequent on the transfer of the European regiments to the royal service) you will of course take into account the several situations which may be properly filled up by uncovenanted members of the Medical Profession." That is the whole of the section, and we confidently appeal to our readers whether this conveys the "distinct orders" of Sir C. Wood to fill up all the civil and other charges at the Presidencies with uncovenanted men? Decidedly no. We beg respectfully to adhere to our former finding—as they say at court martials.

Once more and finally he says, "the highest pension under the old rules was £700 a-year. With the Medical Retiring Fund (at Madras) £100. Under the new rules the highest pension is £500. Now let the reader judge for himself.

	Old rate of pension. £	New rate of pension. £
After 17 years	191	220
,, 21 ,,	250	292
,, 25 ,,	300	365
,, 29 ,,	365	550
,, 32 ,,	500	
,, 35 ,,	700	—

If these figures were all, our correspondent's statement might have the appearance of correctness; but by Section 36 of the new Warrant it is distinctly laid down that an Inspector-General after five years' employment in that grade in India is entitled to an extra £350 a-year; and by Section 37 a Deputy-Inspector-General under the same circumstances to £250 extra; so that after 30 years' service in India the highest pension, that of an Inspector-General, is £900, and the next highest, that of a Deputy-Inspector-General, £800 a-year! exclusive of the annuities to which they may respectively be entitled from the Medical fund.

We now leave the subject for the present, awaiting confidently the verdict of the Medical officers in India, who are the parties most interested in the question.

PERSONAL RESTRAINT FOR THE INSANE.

A CASE has lately been decided in the Durham County police-court which is of considerable importance to the Medical Profession. A great question is involved in it—a question, however, which appears to have been entirely ignored by the magistrates who decided it—viz., whether a Medical Practitioner is justified by the law in interfering in his own person to place an insane patient under mechanical restraint. The magistrates seem to have entirely ignored the insanity of the patient and the position and responsibilities of the defendant as Medical adviser; in fact, they treated the case as one of common assault. We have not sufficient data before us to offer an opinion as to the propriety or non-propriety of Mr. Carpenter's interference at the particular moment at which he acted, but there seems to be abundant proof that the patient Mary Lamb was a dangerous lunatic, and there appears no doubt that Mr. Carpenter acted *bonâ fide*, and, as he believed,

for her benefit. The result, however, is that he has been fined £5 and mulcted in the costs of the proceedings. We think when our readers have perused the following narrative they will come to the conclusion that he has been treated with but scant justice, whatever be the law of the case.

In November last, Mr. R. H. S. Carpenter, a Licentiate of the Royal College of Physicians and of the Apothecaries' Society of London, residing at Carrvilla, Durham, was called to attend a woman named Mary Lamb, aged 68. It does not appear at whose request he first saw the patient, but it is evident that Mr. Carpenter's attendance had the approval and sanction of the patient's husband. He found Mary Lamb to be a person of unsound mind and requiring care and control, and after several fruitless applications to the relieving officer of the parish, he wrote to the Commissioners of Lunacy, calling their attention to the case, and enclosing the following certificate:—

"I certify that, having examined Mary Lamb, and received the following statements from her husband and neighbours, I believe her to be a lunatic, and not under proper care and control. "R. H. S. CARPENTER, Physician.

"November 25, 1864.

"'*Statement from Neighbours and Husband.*

"'That Mary Lamb is about 68 years of age; that for some months past she has been insane; that she has frequently threatened to drown herself, and, on many occasions, had rushed from her house to execute her threat; that on several of these occasions a policeman has hurried after her; that on one occasion a man caught hold of her just as she was about to throw herself into the river; that she was taken by him to the Durham police-station, and detained there until taken away by her husband; that her husband then made an application to the Durham magistrates, but was referred by them to the relieving-officer, who refused to interfere; that about four months since she took a knife and threatened to cut the throat of a young woman; that she will sit up in bed, and for some time continue vociferously to shout "Murder," under the influence of imagined danger; that two certificates have been given by Surgeons in Durham testifying to the unsound state of her mind; and that she is a fit person for a lunatic asylum, but that no attention was given to these certificates by the relieving officer.'"

A good deal of correspondence followed between Mr. Carpenter and the Commissioners of Lunacy; certificates were forwarded to them, signed by the churchwarden of the parish, Dr. Watkin (Consulting-Physician to the Durham Infirmary), and Messrs. Pratt and Sutherland (Surgeons), which remove all doubt as to the degree of insanity under which the patient was labouring, and the danger in which it involved those around her. In proof of our assertion we quote Mr. Pratt's certificate:—

[Copy.]

"Having had frequent opportunities of seeing and conversing with Mrs. Lamb, I am able to certify that she is a lunatic requiring to be placed under proper treatment in an asylum. During my last visit she was smoking lighted paper: said she liked 'flame,' and that the smoke was beautiful. A short time since she broke eight panes of glass. She also said she would cut Mrs. Cockburn's head off, and roast her like a herring; that she would get some arsenic to poison Dr. Carpenter, her husband, and myself; and that when she had the chance she would split Mrs. Jones's head. The reason she assigned was that the devil had told her through the wall that she had to do these things. "JOHN PRATT,

"Member of the Royal College of Surgeons.

"Durham, December 29, 1864."

On January 14 Mr. Carpenter wrote the following letter to the Commissioners:—

"Carrvilla, Jan. 14, 1865.

"Gentlemen,—On Thursday last Mary Lamb succeeded in breaking another pane of glass, and yesterday (Friday) she broke two more before the poker she was using could be taken out of her hand. To-day she was shouting "Murder," stating in the presence of a dozen people that the devil had told her through the wall to do so. Her husband has not had his clothes off since Tuesday last, and last night he had two men to sit up with him to watch her. *To-day he attempted to tie her hands with a towel*, and if *something be not done* with her, I am afraid *I shall have to sanction mechanical restraint*. Yesterday the county police reported the case to the chiefs in the county police office, but I am informed that they considered they could do nothing, as the magistrates had pronounced her sane. "I am, gentlemen, your obedient servant,

"R. H. S. CARPENTER.

"To the Commissioners in Lunacy.

"P.S.—Since this has been written the lunatic has broken two more panes of glass; states that she likes to break glass; that she will have all the panes in the house out before she has done; and that then she will smash in the wood-work."

Three days afterwards, after hearing that she had threatened to split the skulls of some children in the neighbourhood, Mr. Carpenter paid her an evening visit. According to his account, contained in a subsequent letter to the Poor-law Commissioners, he found her excited and threatening to leave the house to put her threat of splitting the heads of the children in execution. Her husband urged Mr. Carpenter to put on her a strait-waistcoat, at the same time declaring that unless Mr. Carpenter did so he would not remain in the house with her. Not having a strait-waistcoat, Mr. Carpenter secured the lunatic to the bed-post by placing her arms round it and tying her wrists with a handkerchief. Accounts vary as to the time which passed whilst she was in this position, but, at the highest computation, it was less than an hour. Mr. Carpenter then removed his patient to bed. About this time her son, who denied his mother's insanity, entered the house. According to Mr. Carpenter's statement,

"He rushed into the room, accompanied by several people, and created a complete riot. The lunatic's husband was dragged several times to the floor, and his shouts of 'Murder' and for help were heard for a considerable distance off. I myself was violently dragged backwards and forwards, and at one time detained in the house as a prisoner, and charged by the son with being inebriated. The fury of this son, who has for some years been a patient of mine, was directed against me for using the handkerchief and interfering in his father's behalf, as he asserted, to assist in the obtaining the removal of the lunatic to an Asylum."

Mr. Carpenter threatened this very enthusiastic maintainer of his mother's sanity with a summons, but before he could procure one the son obtained one against Mr. Carpenter for an assault on his mother by tying her to the bedpost. The magistrates, declaring that they "were not sitting *de lunatico*," found the defendant guilty, and inflicted, as we have already said, a fine, with costs.

In a letter to the *Durham Chroniele* Mr. Carpenter states that he paid the fine "under a protest, with a view, if possible, of obtaining a re-hearing of the case elsewhere." He asserts that he was employed by the husband of the lunatic, and that he placed her under restraint by his express desire. He therefore argues that he is not liable to be convicted of an assault, and he quotes a case (Hill *v.* Philp, Court of Exchequer, 1852) in support of his position. Whether he be right in law, we do not now offer an opinion, although we think he has the strongest *primâ faeie* case in his favour. There cannot, however, be a doubt, if the statements made be true, that the patient required restraint; and even if Mr. Carpenter were not himself legally justified in applying it, to impose a heavy fine for such an offence is an outrage on every principle of equity. We wonder what would have been the verdict of "the great unpaid" who adorn the Durham Bench had this mad woman been allowed by Mr. Carpenter to murder her neighbour's children, as she threatened.

CO-OPERATION OF THE LADIES.—M. Amedée Latour, while noticing the frequency with which the names of French ladies appear in the lists of benefactors in the Medical Associations, generally in commemoration of a husband or a son, asks what reason can be adduced why the wives, sisters, and daughters of Medical Practitioners should not be admitted as members of the Medical Benevolent Societies. Of the value of their co-operation there can be no doubt. Much of the success of the French Humane Society is attributable to the number of lady subscribers.

THE WEEK.

THE PRESIDENCY OF THE ROYAL MEDICO-CHIRURGICAL SOCIETY.

Our readers will learn from a letter which we publish elsewhere that Dr. Burrows declines to allow himself to be put in competition with Dr. Alderson for the President's Chair of the Medico-Chirurgical Society. The course he has taken in the matter has been dictated by that high sense of honour which has ever distinguished him. The result must be that the Fellows of the Society will ultimately have the benefit of the services of both these distinguished Physicians. If Dr. Alderson be the President-elect, Dr. Burrows must succeed him as the next Physician who shall fill the Chair of Baillie and Halford, Bright and Addison.

ARMY MEDICAL DEPARTMENT.

A report has appeared in some of the papers that the Indian Government intend to withdraw the last Warrant, which, despite some dissentient voices, has given, on the whole, satisfaction to Indian Medical officers in this country. We learn from a reliable source that the rumour is not founded on truth. Such an act of childish vacillation would be too great an outrage on good sense and public opinion even for Sir Charles Wood to perpetrate. The affairs of the Royal Army Medical Department, however, have assumed no healthier appearance since we last noticed them. It will soon be seen whether our young Medical men possess the "moral courage" so much extolled by H.R.H. the Duke of Cambridge in his address to the seventy candidates at Netley, or whether the redundant display of it there has not exhausted the supply. A man entering the Army Medical Department just now binds himself and his future brother officers with very different fetters to those of the Brothers Davenport kind, and if he hopes—as the late candidates did, no doubt—for a speedy and radical change, it is one more illustration of the triumph of hope over experience. So long as candidates can be had the Horse Guards will not be such fools as to make any changes; silently, but surely, will an additional rivet be added here and there, and as surreptitiously as certainly will a few more indignities be imposed upon the Medical Department. For some two or three years the journals—Medical and lay—have been teeming with complaints from the Medical men serving Her Majesty. Are all these complaints pure fictions, and has a spirit of disaffection and distrust spread over the widest geographical limits, like the advance of some mysterious epidemic, for no causes whatever?

When the whole question is mooted in the House of Commons, what will be the ready reply? "There is a small section only of Medical officers in H.M.'s service who have been dissatisfied. The evils do not exist, or have been most grossly exaggerated. Our army and navy are becoming daily more and more popular with the outside Profession, and we have no lack whatever of Medical candidates." Thereupon the question is shelved for another year. The Horse Guards register another victory over the Doctors, and congratulate His Royal Highness upon the decision he has shown. So that the forage allowance for the Commander-in-Chief passes muster at the annual voting of the Estimates, the whole Medical Department may be sunk in the Thames, running at the back of Whitehall-yard, for anything the military officials care.

All the Royal Colleges in the United Kingdom may unite in memorialising Government on this subject, but their labours will be as completely wasted as the paper on which their opinions and prayers are impressed so long as the Government have a goodly supply of Medical candidates.

TIMOTHY DALY'S CASE.

Mr. Farnall's report has not yet been made public, but it is generally surmised that its probable tenour as regards Mr. Norton will be that no blame attaches to him on the score of neglect of his duty as to his attendance on Timothy Daly or as to his Professional skill, and that there was no case for complaint against him; but that, generally, as Medical officer of the workhouse, he is open to censure for not keeping his forms personally and for entrusting their filling up to other persons.

POOR-LAW MEDICAL OFFICERS.

Such Poor-law Medical officers as have been devoting their whole time to the service of the unions for which they act should not overlook the fact that, at length, their claims to a retiring allowance have been acknowledged, and that, under certain conditions, they can, on their ceasing to hold office, be voted by the board of guardians a pension equal to two-thirds of the salary which they are receiving at the time of their retirement. This boon to union Medical officers, circumstanced as above stated, is secured by the statute 27th and 28th Vict., cap. 42. The statute will be found set out, and its provisions explained, in the work on the subject by Mr. Cecil Austin, of the Home Circuit (published by Butterworth and Co. and Knight and Co). We understand that, although the Act has only been a short time in operation, it has been already made useful in the case of a Medical officer.

ASSISTANT-SURGEONS TO THE FORCES.

We commend the following to the attention of Regimental Surgeons, and shall be glad to hear what they think of it. Does it mean the formation of a General Medical Staff system?

"*Circular No.* 889.—*Commissions of Medical Officers.*

"War Office, January 9, 1865.

"The Secretary of State for War having decided that, from and after July 1, 1864, all candidates appointed to Assistant-Surgeoncies in the army should be gazetted and commissioned as 'Assistant-Surgeons to the Forces,' and that subsequent transfers should be notified in the *Gazette* only; and further, that the same course should be followed on promotion to the rank of Surgeon and subsequent transfers; a deduction on account of stamp duty will, therefore, be made in cases of first appointment, or promotion of the classes of Medical officers alluded to from the above-mentioned date.

"Edward Lugard."

NURSING SISTERHOODS.

Our attention has been called to a fierce controversy which has been excited at Gloucester, by a proposal to nurse, or supplement the nursing of, the County Infirmary by the aid and supervision of the "Sisterhood of St. Lucy's Home, in the parish of St. Mark, Gloucester." The term "sisterhood" has on many a good Protestant John Bull the same effect that a red rag has on his four-footed namesake, and as every one knows the intensity and virulence of the "*odium theologicum*," it may be easily imagined how high feeling may run on this matter. We know nothing whatever of the constitution and rules of the "St. Lucy's Home," but that the nursing in our Hospitals, Infirmaries, and Workhouses may be universally improved by the help of educated lady-nurses no one with any knowledge of the subject will deny; and the patients of the Gloucester Infirmary will be very fortunate if they can obtain the services of ladies as devoted to the earnest and effective performance of their duties as nurses as are those of the St. John's House, the All Saints' Home, and the Deaconnesses' Institution, who, respectively, nurse the King's College, University, and Great Northern Hospitals, in London.

MR. ERASMUS WILSON ON FOOD AND DISEASE.

The lecture on "Food as a Means of Prevention of Disease," by Mr. Erasmus Wilson, delivered before the Association of Medical Officers of Health, and published in this journal, is now published in a separate form, and may be had for twopence. It is a capital tract for distribution amongst schoolmasters and heads of families inclined to keep children on too low a diet.

FROM ABROAD.—DISCUSSION ON "VACCINAL SYPHILIS" CONTINUED — PROSECUTION OF ILLEGAL PRACTITIONERS IN FRANCE—FUNCTIONS OF THE SPLEEN.

The discussion at the Paris Academy of Medicine, on "vaccinal syphilis," was resumed by M. Blot, who, as a member of the Vaccine Committee, wished to protest against the assertions of M. Depaul, the Reporter of that Committee, as exaggerated and dangerous. Not one of the cases adduced by him in proof of communication by vaccine lymph will bear examination, the accompanying blood having been doubtless the agent in the few cases in which syphilis really seems to have been conveyed. M. Blot refers to various observers who have vaccinated from avowedly syphilitic children without transmitting syphilis, where care has been taken to introduce lymph alone. In several of the cases cited by M. Depaul the appearances described may be explained either by the presence of vaccinal phagadænism, or the presence of eruptions which would have appeared had not vaccination been performed; and M. Blot repeats the assertion that up to the present time there has not been recorded a single case in which the insertion of unmixed vaccine lymph has given rise to syphilis. But still who could be always certain that in vaccinating he did not also convey a particle of bloody serosity? and, in fact, if the cases adduced of the propagation of syphilis by vaccination are authentic and exact, M. Blot says the only logical course is to abandon vaccinating from arm to arm and to repair to the cow, for the precautions advised by M. Depaul are perfectly illusory. At all events, the matter is at present in the condition of hypothesis and obscurity, the present discussion is premature, and any report relating to it sent in to the Minister would be most inopportune.

M. Jules Guérin, also a member of the Vaccine Committee, pointed out the consequences which would have attended the adoption of M. Depaul's report, declaring on the part of the Academy the transmission of syphilis by vaccination to be an established fact. Such a manifestation addressed to the Minister, and dispatched to the préfets, and from the préfets to the various Medical Practitioners, would have obtained a most unrestricted publicity. But what do we see? The discussion has hardly commenced when it is found that the facts upon which the statement is made are deficient in number, in character, and in precision, and already M. Depaul beats a retreat by declaring that he does not care that this portion of the report should be sent in. "The Academy will surely agree with him here, and then all results which could be desired from such a discussion will be attained. It will have aroused the attention of Practitioners to a new and very important order of facts, will call forth new observations, and suggest the means of better observing, better characterising, and, perhaps, of preventing vaccinal syphilis. But such an end may be attained without the concurrence of ministers, administrations, and *préfets*. It is by the Academic debate that Practitioners will be made acquainted with what ought to be known to them, and the future will one day furnish the solution of a question which for the present should not be canvassed beyond scientific precincts."

On this occasion M. Trousseau delivered one of his brilliant extempore discourses, delighting a crowded auditory, but contributing literally nothing to the further elucidation of the points at issue. He ridiculed the excessive prudence, or, as he termed it, prudery, of the Academy in approaching this subject—not perceiving, apparently, that the objection raised was not to an Academical discussion, but to the bringing the Minister and the public in contact with a question yet unsettled. However, M. Trousseau could see no objection to M. Depaul's report being sent in to the Minister, especially as he added that there was little chance of his reading it. He narrated a case of vaccinal syphilis which occurred in his own wards at Hôtel Dieu, and which formed some two years since the material for a remarkable clinical lecture by M. Ricord. The subsequent history of this case adds additional doubts to those then expressed as to the source of the syphilis in this instance. However, M. Trousseau declares that, although vaccinal syphilis is now and then met with, it is a "prodigiously" rare occurrence, and forms no argument against the practice of vaccination. Vaccinal erysipelas is a far more common and a very fatal occurrence in young infants vaccinated in Hospitals; so that M. Trousseau has lost about twenty such cases in a children's ward containing twelve cradles, and yet he considers that no reason for abstaining from vaccination, seeing that almost every young infant taking variola dies. The fact of even a rare occurrence of vaccinal syphilis imposes upon us the necessity of a careful selection of subjects to vaccinate from; and, perhaps, the greatest security would be derived from employing healthy-looking children two or three years old.

The French Practitioners seem well satisfied with the penal laws they possess against quackery and illegal practice, and they contrive, by the aid of the Medical Association, to put them into pretty vigorous operation. The last account we have seen narrates the conviction at Niort of a man and his wife and another woman for illegal practice and swindling as magnetisers. The woman Morel was condemned to pay ten francs fine for each of 173 contraventions of the law, and her husband the same sum for 89 contraventions, the woman Revan paying ten francs for each of 69 contraventions. Morel and his wife were also each condemned to a year's imprisonment and a fine of 1090 francs as swindlers. They also had to pay $\frac{8}{10}$ths of the expenses of the trial, the woman Revan paying the other $\frac{2}{10}$ths. This accumulation of penalties is a highly important feature, upon which the Association lays great stress, and if the legality of such accumulation is confirmed by the Court of Cassation (of which there is some doubt), the law will prove a formidable repressive agent. It is strange that none of the numerous persons so convicted have as yet appealed in Cassation. Certain it is that if they possessed the funds and the impudence of the quacks who infest our country they would have done so long since, and thus have got the question settled. Much of the success of the prosecutions now so frequently instituted in the different provincial districts of France arises from the energetic support given to their institution by the Medical Association, notwithstanding the assertions to the contrary by the editor of the *British Medical Journal*. It is true that the Association cannot itself institute prosecutions as a corporate body, but it supplies advice and funds, and numerous instances of its successful intervention are recorded in its *Annuaire*. One remarkable feature of the French law is that the Medical Practitioners of any district may prosecute illegal Practitioners in that district, and recover damages as persons whose interests have been wantonly injured.

One more new theory on the functions of the spleen. MM. Estor and Saint Pierre, in a communication to the Academy of Sciences, observe that since M. Claude Bernard's researches physiologists are aware that the activity of the functions of glands coincides with the acceleration of the course of the blood; and that during their own researches on the gases of the blood the idea occurred to them that the reddening and oxygenation of venous blood may afford a guide for determining the instant of the performance of their functions by certain glands, the physiology of which is at present obscure. With this view they have undertaken certain experiments on the spleen by M. Bernard's method of displacing the gases of the blood by oxide of carbon. These experiments have been made successively on the arterial and venous blood of dogs, both during digestion and while fasting; and the conclusion arrived at is, that while the quantity of oxygen contained in the arterial splenic blood is sensibly constant, that of the venous splenic blood varies up to double the amount. The experiment has been varied on the same animal. Thus, after having found 11·69 of oxygen in the blood of the splenic vein of a dog which had fasted during twenty hours, milk was injected into the stomach. Immediately, besides modifications in colour, size,

and consistence in the spleen, the blood of the splenic vein was found to contain only 7·26 of oxygen. "From the researches related in this memoir we conclude—1. That the principles laid down by M. Claude Bernard concerning the different qualities of the venous blood of glands, in the state of active function and repose, may enable us to determine the instant when glands, the physiology of which is yet unknown, manifest activity of function. 2. We have found in our experiments the quantity of oxygen contained in the venous blood of the spleen increasing from once to twice its amount during abstinence. 3. We infer that the functions of the spleen are performed in alternation with those of the stomach."

REPORT ON CHEAP WINE.—NO. X.

(By our Special Empirical Commissioner.)

(Continued from page 44.)

Hungarian and Austrian Wines continued—Imperial Tokay: its Uses—Dry White Wines: Ruszte, Szamarodnya, Dioszeger Bakator, Œdenburg, Steinbrueh, Villany Muscat, Neszmély, Somlau, Badaesony, and Hungarian Hock and Chablis. Attempt at Classification; Grape Flavour to be distinguished from Wine Flavour; Red Wines: Ofner, Szegszarder, Menes, Erlaure, and Carlowitz; Austrian Wines from Vöslau.

WHOEVER would know whether Hungarian wines may suit his own tastes or those of his patients, may very likely be perplexed with the number of specimens whose strange names appear on the lists of the wine merchants, and will possibly find it to his advantage to follow the course I venture to point out for studying these wines in logical order. Truly, whether we owe it to Mr. Gladstone, or to the vine disease, or to whatever seeondary causes, the educated and refined middle classes of England have reason to be grateful for the vast addition to their means of innocent festivity, of health and appetite and restoration from sickness which the numerous most excellent and fragrant wines of Hungary confer on them.

Let us suppose that the conscientious student has ordered a sufficient case of speeimens from some of the gentlemen who deal in these wines, and whose names, taken alphabetically, are, I believe, Andres, Azémar, Denman, Dioze, and Max Greger. Probably a laudable curiosity, combined with the wish to do homage to the female members of his family, will tempt him to begin with a bottle of Imperial Tokay. This is by no means a cheap wine, for it costs 60s. per dozen and upwards for pint bottles; but besides its reputation, it is worth studying as a kind of landmark or standard. We need not repeat the information to be found in every book, that it is made of the first pressings of the finest over-ripe grapes. The result, as it reaches us, is a sweet wine, of delicate pale tint, in which the sweetness and fragrance of the grape, though perceptible, are partly hidden by, or converted by age into, an exceedingly rich, aromatic, mouth-filling wine-flavour, so that, rich as it may be, it is not cloying nor sickly. I have many times had a sip of Tokay at the end of a state dinner, but never studied it deliberately till of late, when I have had specimens from Denman, Max Greger, and from Monsieur A. Günzberg, from Pest, now of 13, Auckland-road, Old Ford, near Victoria-park, who was good enough to send me a bottle through Messrs. Churchill, and says he has a considerable quantity to sell. One specimen of Denman's that I examined had sp. gr. 1050, and about 25 of proof spirit per eent.

Of course, Imperial Tokay can hardly figure in a list of cheap wines; yet it is really cheaper than it seems, for a very small quantity suffices, and, measure for measure, it is therefore only half so costly as its nominal price. There are, as I am informed, large quantities in the English and French markets, which meet with a slow sale (at least here), because there seems no place for it. English customs are more and more adverse to sweet cakes and wines, for morning callers, etc.; and English meat-eating people prefer naturally a dry kind of wine. Yet, I conceive not only that this wine may be useful as a cordial in cold weather for the aged, before going into the open air, but my solitary bit of experience shows in what respects it is preferable to some other cordials. A short time since I was attending a gentleman, nearly 80, dying with senile decay and atrophy of the heart, with probably some obstruction to the circulation through the lungs, for though the air entered forcibly, the dyspnœa was most intense—so intense that the act of swallowing could only be performed by snatches, and every movement and everything that "caught his breath" threatened instant suffocation. Having worn out every form of nourishment and stimulant I could think of, at last I suggested some Tokay, which the patient eagerly eaught at, and a servant was despatched to get a bottle. The wine merchant had none; but, as it was late in the day, very properly sent on trial what came nearest in his opinion—viz., a bottle of very fine old malmsey. Next day I had the opportunity of judging of both wines, and of their adaptation to the case in question. The malmsey was uncommonly fine, rich, and old, but, though mild and soft, was very strong; the alcoholic potency was unmistakeable, and it caused distress to the patient, who could not drink it undiluted. The Tokay from Max Greger's, on the eontrary, was marvellously fuller flavoured, and had no prominent alcoholic character at all. It was curious to notice how superior its true wine-body and flavour were to the lesser-wine and more spirituous character of the malmsey; and the patient swallowed it easily. This may give a useful hint to some of us who are at our wit's end with a patient ill of diphtheria, hopeless phthisis with aphthous tongue and throat, etc., etc. In this case I also ordered a mixture of Tokay and cream. Such things may sometimes soothe a dying bed, and enable an old man to forget the peevishness of suffering, and to bless his family tranquilly before he falls into his last sleep.

There are other sweet wines of high class, both red and white, on the lists of the merchants, of which I know only a "Ruszte," said to be "rich" in Denman's catalogue, price 40s., which may be described as a lesser Tokay; deeidedly sweet, and full of flower fragranee, as of fresh grapes; very different from those excellent wines the Vinsanto and Cyprus. which taste rather of dried raisins, yet having similar generic characters and uses.

Tokay is a classical wine, and its name tempts one; not so the red and white Magyar Husszar Bor, and others, whose names would have puzzled Milton's "Stall-readers," and recall his sarcasm on the names of some of those northern preachers who attacked the Greek title of "the book called Tetrachordon," which he wrote in favour of divorce.

> "Cries the stall-reader, 'Bless us! what a word on
> A title-page is this!' and some in file
> Stand spelling false, whilst one might walk to Mile-
> End-green. Why is it harder, sirs, than Gordon,
> Colkitto, or Macdonnell, or Galasp?"
> "Those rugged names to our like mouths grow sleek,
> That would have made Quintilian stare and gasp."

I may plead that I have got them up pretty aceurately, and find, besides, that such words as Szamarodnya and Dioszeger Bakator Auslese are, thanks to the wine that they designate, by no means too rugged for ladies' lips.

Turning, then, from the sweet to the dry white wines, if we take them in a descending series, I will mention first Max Greger's *Ruszte Ausbrueh, finest, dry*, at 54s.

This *dry Ruszte* is a remarkably fine wine, and, with peculiarities of its own, resembles some samples I have tasted of first-class white Burgundy or of a dry St. Peray. There seem to be, as I have said already, two kinds of wine flavour—1st, that derived absolutely from the grape; 2ndly, that which is *wine proper*, and engendered by fermentation and improved by age. Each has its charms. Writing with some of these Hungarian white wines on the table before me, it is impossible not to be struck with their admirable fragrance, and how they bring before one the vision of flowers, and likewise of *honey*; not the sweetness which is common to all honey, but the fragrance which is peculiar to the best, and which seems to be of the same nature as this grape perfume. This is especially noticeable in Tokay; and it was noticed by a veteran wine taster to whom I gave some old choice white Mount Hymettus of Denman, whieh he said had a decided Tokay

flavour. Any one who has ever tasted old dry *mead* knows it; but I shall, with your permission, descant on that old English wine presently. Now, if I taste, side by side, a bottle of the Szamarodnya, described as "a dry Tokay wine," No. 13 of Max Greger's list, at 36s., I find in said Szamarodyna a most agreeable sound wine, with prodigious fragrance, great dryness, and fine wine flavour; a mouthful is a nosegay. But a sip of the *dry Ruszte* puts out the Szamarodnya; there is in it more body-fulness and a *souvenir* of Burgundiacal bitterness, which shows much greater potency and value. I affirm judicially that the *dry Ruszte* is a great acquisition, and that no dinner will fail to be gratefully remembered at which a man of sense first becomes acquainted with it.

The "*Szamarodnya*, or *Dry Tokay*" of Denman, at 42s., is a very fine specimen; and "*Szamarodnya Muscat*, first quality," of Max Greger, at 48s., has a prominent flavour of the muscat grape in addition. I need hardly say how the flavour of all muscat grapes is preserved in the wine that is made from them. I have not taken the alcoholic strength of these wines; nor is it necessary. Colour, flavour, and the whole purity and fineness of the wines forbid the suspicion of such a suicidal sophistication. Besides, I would rather drink the wine than distil it.

Taking the Dry Ruszte and the Szamarodny as examples of wine possessing as it were a duplex aroma (*i.e.*, the fragrant grapy and the true vinous), we may take the *Dioszeger Bakator* as an example of a wine with single aroma of the fresh, fragrant, grapy order. I have already mentioned one specimen of this wine which I got from Denman's, price 32s., and which particularly pleased me. My note was "very agreeable, clean, grapy, fruity." Another specimen from Max Greger's, "Count Stubenberg's own growth," price 36s., is on the table before me, and deserves at least equal praise.

I have been obliged to describe a few of the higher priced Hungarian wines, because it was necessary in studying these wines, most of which were quite new to me till last year, to ascertain what were the qualities which we ought to expect in the lower priced. Of course my readers will not think that I am presumptuous enough to set myself up as a judge of all Hungarian wine by the few bottles I have drunk. My title shows that I only treat of such as are sold here in 1864, and of their effects on my own palate and stomach. Yet, so far as I see, it seems that the low priced dry white wines may be ranged under two orders, according to the nature of their flavour, whether of the fresh, fragrant, flowery, unaltered grapy, or of the true dry wine flavour derived from fermentation and improved by age.

In the former class I venture to place the *Œdenburg*, No. 16 on Max Greger's list, of which I have drank two kinds, one being "selected muscat." *Delicacy* is the charm of wines of this class; and if they have a fault it is that of being a trifle too thin, so that the acidity is not veiled. Both of these are delicate, one with slight muscatel flavour, and body enough. Alcoholic strength of the muscat sort about 20. They compete well with high class Rhine wines.

I doubt whether the *Somlau*, No. 10 on Max Greger's list, price 26s., ought to come into this class or the other. It seems a sound, dry, firm wine, with plenty of flavour, and cheap for the money. Alcoholic strength about 21.

There is a *Hungarian Chablis* of Denman's at 16s., which I note as "a light wine, of light straw colour, not too acid, rather much bouquet;" alcoholic strength about 20. As I have said before, if rational people must economise in the wine they drink at dinner, why martyrise themselves on bad Sherry when such cheap and fragrant wines as these are to be had so easily?

The *Neszmély* (No. 8 on Max Greger's list, price 18s.,) is a very cheap wine of slightly darker colour, not deficient in flavour, but of the second or vinous order, seeming as if it were a diminished example of the Szamorodny.

Of the *Badacsony*, I have drank one specimen from Denman at 24s.; alcoholic strength about 21; aroma full and peculiar, and of the vinous order; and one from Azémar (alcoholic strength 22) at the same price, and of the same character.

Of the *Hungarian Hock*, I got one specimen in 1863 from Messrs. ——·——, at 30s., which I noted as poorish and too thin, not body nor flavour enough; and one in 1864 from Azémar at the same price, which has alcoholic strength about 22, and satisfactory stoutness and flavour; more than the Badacsony, which it otherwise seems to resemble.

Here let us pause one moment, because that knowledge of wine which every Medical Practitioner ought to possess, and which seems difficult at first owing to the infinity of names and qualities, may be rendered easier of attainment by any glimpse, however partial, of a reasonable classification.

White wines, then, in which we decidedly taste the grape, form, as it were, a sub-kingdom of themselves, and it is interesting to observe how the actual state of the grape may be tasted in many of them. Thus, there are many which speak out for themselves, so to say, and bear testimony to the fact that they are made of grapes which have not attained the fullest maturity of sweetness,—whether from a northern climate, as many of the Rhine and Moselle wines, or from a cold northern aspect, or from the gathering of the grapes at an early stage. Hence a kind of greenness as it were; a very light straw, passing into a greenish colour, and general characters of grace, juvenility, delicacy, insubstantiality,—just the characters of a young girl with a young head on her shoulders. Such wines, if of bad quality, are thin, poor, and sour, as aforesaid; if of good quality, their very acidity tends to the generation, in time, of the most exquisite superadded bouquet. Such a wine of low quality is the first met with by the tourist who proceeds along the western coast of Brittany to the south. At a village named Sarzeau, famous as being the birthplace of Le Sage, they make a wine of the small white grapes, which is put on the table at the inn for the guests to drink of gratis, as they do cider elsewhere in Brittany, and water in England. It is sold at five sous per bottle. Similar wine, of rather more stoutness, is made near Nantes, and sold at ten sous per bottle. Such is the wine to be expected at the northern limit of vine culture, but the Hungarian Dioszeger Bakator and Œdenburg are good specimens of the more generous wines of this sort, so are two wines that I have not mentioned yet, the *Pesther Steinbruch*, of Denman, at 26s., and the *Villany Muscat*, at 24s. Each of these is about alcoholic strength 21, and there seems little difference between them. I drank Denman's *Steinbruch* in 1863, and noted it as a very clean, well-flavoured dry wine, deserving further study.

Can we, then, venture to guess at the conditions under which these delicate wines would be appreciated and useful? I think so, if we remember what a help the fresh acid fragrant juice of the lemon is, to a man who is eating something too sweet or too rich; and how the Orientals squeeze the half-ripe grapes to make delicious sherbet, and sauce for their *kibobs* and *pilafs*. These are wines for delicate refined people; it would be of no more use to give them to a day labourer than it would be to use a lancet to chop sticks. They are wines better adapted for hot weather than for cold. If a man dines on a single joint, he would prefer a bottle of Erlaure or Ofner; if he has a complex repast, he would drink these light wines with his fish or *entrées*. Give one of these wines to a man whose tongue is too red, and who has diarrhœa, and he would reject it; on the other hand, a man with a clammy coated thirsty tongue would probably drink them greedily. I may add that I am satisfied of the entire wholesomeness of these white wines. I have drunk of them freely, both singly and in combination, and one night when very tired took half a bottle of the dry Ruszte with unmixed pleasure at the time, slept soundly and awoke as if I had had "food for the nervous system." It is worth knowing too, so far as my limited experience goes, that they are slightly aperient, or at least the reverse of constipating.

So much for the grapy wines, whose grapiness is of the immature (or certainly not *dead ripe*) sort. Then we have a class which is redolent of the ripe sweet grape, as the Muscats, Rivasaltes, Tokay, sweet Ruszte, and the like. Other wines there are which bring before us a reminiscence of grapes in various stages of drying; as the Como, Vinsanto, Cyprus, Constantia, Malaga, etc., etc., and, of course, in the higher specimens with true vinous flavour superadded.

If I have been tedious over the classification of the white Hungarian wines, I shall be short enough about that of the red; for, in truth, they have certain *general* characters, but I have not been able to attach a specific character to each. For example, I drink an Erlauer, and endeavour to impress its character on my mind side by side with a Szegszarder; but then if I get another Eclauer and another Szegszarder from another dealer, the characters which I hoped to find are either not there or are interchanged. So that I can do no more than take each sort I have drank, and describe it as a unit, leaving the classification to some more deeply bibulous hand.

One of the commonest and best kinds of red Hungarian wine is that which is called *Ofner*, from the town of Ofen, near which it is made, and of which some varieties have distinctive names,

such as *Adlerberg, Blocksberg, Burgerberg*, etc., from various hills in the neighbourhood. My first essay of these was of a specimen of *Ofner*, price 24s., from Denman, in 1863; of which my note is "apparently pure and full-bodied; not acid, nor astringent, *quere* sweetish (?), agreeable, and satisfactory." Specimens from the same dealer, at the same price, in 1864, sp. gr. ·995, alcoholic strength about 21, deserve the same note, except that I should substitute the words "fruity" or "grapy" and "smooth" for "sweetish." A specimen of *Ofner Adlerberger Auslese*, retail price 28s., from Messrs. Azémar, 40, Mark-lane, deserves at least equal praise. Alcoholic strength about 23. There is also a fine *Ofner Auslese*, at 36s., No. 31 of Max Greger's list, which is very good indeed, pure, smooth, and delicate. I should be inclined to recommend a good Ofner, as I would a good Bordeaux, to any patient whose veins wanted filling with good blood.

Next I may take the *Erlauer*. A specimen of Max Greger's (No. 27), at 17s., was some time ago brought to me as a rarity, and I was led to believe it was an Assmanshauser. I found it a pure wine, with something of an old dry quality, subaustere, subacid; no volatile bouquet, but a pleasant vinous taste, greatly enhanced by nursing it up to 60°, at which temperature its slight austerity and acidity greatly decrease. I could find in it no high vinous character, and was greatly relieved when told it was a seventeen shilling wine, at which price it is uncommonly cheap and satisfactory. An *Erlauer*, from Azémar, at 24s. did not seem to belong to the same family; much fuller and fruitier; specific gravity, 995; alcoholic strength, about 22. A good useful wine; but I could not have distinguished it from a Szegszarder. An *Erlauer*, at 30s., of Denman's has received great commendation at my table from friends, who have pronouneed it "an excellent claret"—a verdict I concur in.

A *Visontaere*, at 20s., of Denman's, I marked as a wine of good colour, body, and flavour; quite satisfactory. A *Visontá seleeted*, No. 4 of Max Greger, price 24s., alcoholic strength about 19; and a *Visontá*, 1858, of Messrs. Azémar, at 24s., may be described in the same terms.

I once fancied that I could tell a *Szegszarder*, of which I have had some from Denman at 16s., from Azémar at 18s., do., No. 3, from Max Greger at 20s., which I noted as powerful-tasting and strong-bodied, though its alcoholic strength was only 19. Also the *Menes* wine seems a full-bodied wine, insomuch that I have suspected some specimens to have been a *little* fortified; but perhaps I am wrong. I have drank a *Menes* stout and full-bodied, of Denman, at 28s., alcoholic strength about 25. Also a powerful-tasting full-bodied Menes of Azémar, alcoholic strength 24.

There is a *Menes Maslas Ausbrueh*, 1841, at 42s., of Max Greger's, which is an interesting study of a red wine which has thrown down its crust and become tawney. It is said to be a rare wine, highly valued in Hungary, but I doubt if it ever will become popular here.

The last kind of red Hungarian wine is the *Carlowitz*, of which I have drank an ordinary sort of Max Greger's No. 6, at 24s.; another from Azémar at 27s.; and several, procured some time ago, through different friends, of a "selected" of Max Greger's No. 25, at 32s. The "selected" was noted as specific gravity 996, alcoholic strength 21, as a full-bodied, subastringent wine of *drier* character. These wines were tasted with some curiosity, because they have acquired a sort of vogue in certain circles on the alleged ground that they contain phosphate of iron; a sort of contamination which, if true, would make every sensible man drive them from his dinner table, and consign them to the Apothecary's shop. The Carlowitz of Azémar, alcoholic strength about 22½, was noted as "full-bodied and roughish;" otherwise, a good wine which I could not distinguish from a Mencs, except that this astringency seems to distinguish the Carlowitz from other Hungarian wines; but whereas Azémar's was somewhat "fruity," I fancied that the other two were of a slightly different character, with less of the purple colour of the grape, and less taste of the grape, and more of the ruby colour and astringent smack of *port wine*. Altogether I do not think it so good as the Ofner, which of these wines seems the best.

I must keep till next week my observations on the kindred and excellent wines of Vöslau, near Vienna, from the vineyards of Mr. Robert Schlumberger, who is, I learn, determined to distance all competitors in the task of growing wine that shall be pure and wholesome, and yet full, sound, and dry enough for the English taste. Meanwhile, to sum up what I have to say on the Hungarian red wines, there seem as yet no products of such very superior excellency as to acquire a cosmopolitan reputation. With the exception of the Carlowitz (so far as I can tell from the few bottles I have drunk) their character is a full, grapy, subfragrant fruity body. If they have not that charming bouquet and quality which distinguish very good Bordeaux, and even some of the lower qualities when aged, yet they have not the acidity, austerity, and fancied coldness of the latter, which so repel the sweet-ale-loving Englishman. They have the round, full, soft body of the better Bordeaux. I never met with any positively bad Hungarian wine. If what is already imported never rises above a certain level, it never (so far as I know) sinks below it. Hence a man who calls for a pint of Hungarian at a railway refreshment room ought to be able to get exactly what he looks for. Of course, the higher varieties, as the Ofner and Erlauer, that I have spoken of, have greater delicacy, smoothness, and flavour. I would advise any one disposed to try them to order from the wine merchant an experimental lot, comprising a series of increasing excellence and price, and leave it to him to make the selection.

In conclusion, they seem a thorough English middle-class wine, and I hope that both red and white may be abundantly used to give variety to our dinners, and to displace the beastly compounds which do duty at some entertainments for "sherry."

(To be continued.)

REVIEWS.

Lectures on the Diseases of the Stomach, with an Introduction on its Anatomy and Physiology. By Wm. Brinton, M.D., F.R.S., Physician to St. Thomas's Hospital. Second Edition. London: Churchill and Sons. 1864. Pp. 368.

Dr. Brinton's new edition would call for few remarks—so well is the book now known, and so acceptable has it been to us all—were it not for the addition of two new chapters to which we wish to direct attention. One of these is upon what Dr. Brinton calls "gastric phthisis." We think that the author has done well in recalling this condition to our minds, since, somehow or other, it has not received the recognition which it deserves since the time when Louis' researches on phthisis became popular in this country. The attention has for many years past been concentrated on the chief seat of pathological changes, and very much diverted from the associated phenomena presented by the digestive system, notwithstanding that symptomatically these latter are sometimes the first in point of chronological order. We may refer in illustration to one of the most recent works upon the subject, namely, the valuable work of Dr. Edward Smith on "Consumption in its Early and Remediable Stages," where he merely lays down the following proposition, viz., that "the whole of the processes concerned in alimentation are commonly lessened in vigour," and then proceeds to say that he believes it "to have the widest application, and yet at the same time to have only a limited force." Respecting vomiting, which Dr. Brinton, as we shall see, especially dwells upon, Dr. Smith says merely "a tendency to vomiting not unfrequently occurs," and adds, "we do not know that in the instance in which vomiting occurs there are evidences of any especial disorder of the stomach, and hence we do not think that the primary cause of it is associated with indigestion." "The symptom," he says, "is almost restricted to such as evince much sensibility of the pharynx and the general system," etc. . . "It is a symptom which, in the stage now under discussion, is never permanent, but passes away in a few days." Our own experience is certainly more on the side of Dr. Brinton.

We say our author has done well in "recalling" this condition of early phthisis to our minds; and we use this word advisedly, inasmuch as in our student days, when Sir James Clark was our head master in all that related to phthisis, we recollect reading something of this kind. We quote from the "Cyclopædia of Practical Medicine" (vol. iv., p. 326) because it is handy on our shelves:—"It is during the middle period of life, from thirty-five to fifty, that it is accompanied with more marked symptoms, such as dyspepsia with its various concomitants, which exist often for a considerable time, and not unfrequently obscure the pulmonary affection till tuberculous disease has made considerable progress. This is the form of the affection which has been denominated *dyspeptic phthisis*. . . . We do not know such a disease as dyspeptic phthisis as constituting a particular species, but we are well acquainted with *that form of tuberculous phthisis which is long*

preceded and accompanied in its progress by dyspepsia." [The italics are ours.]

The impression left on our mind is that Sir James Clark regarded the dyspeptic phenomena as "links of the chain which connects special functional disorder with the formation of tuberculous cachexia." Dr. Brinton does not seem to take quite this view—at any rate, not exclusively. "In some instances it is fair to infer," he says, "that the dyspepsia causes the phthisis, which in point of time it certainly precedes and ushers in. In other cases, perhaps more numerous, the thoracic lesion and the gastric disturbance seem to be twin effects of a common cause—a bad and cachectic state of the constitution. Far oftener, I believe, the dyspepsia, as well as the various appearances which we sum up by the word cachexia (so far as the word has any exact meaning), is itself the result of the injurious reaction of tuberculous deposits—dying, dead, or decomposing.—P. 340. More exactly he says in another place :—"These cases of gastric phthisis may thus be regarded as a kind of neuralgia of the pneumogastric and sympathetic nerves : certain thoracic segments of these compound nerves forming the starting-point of an irritative and morbid action, which is transferred to their abdominal connexions, and is manifested in the visceral branches of the solar plexus."—P. 350. Dr. Wilson Philip, with whom the terms "dyspeptic phthisis" we believe originated, clearly distinguished between the class of cases in which the gastric were consecutive to the pulmonary symptoms from those where they preceded them. He says :—"What is the nature of the relation observed between the affection of the lungs and that of the digestive organs in this species of phthisis ? Is the one a consequence of the other, or are they simultaneous affections arising from a common cause ? They are not simultaneous affections, for the one always precedes the other. In by far the majority of cases, in which both the lungs and digestive organs are affected, the affection of the digestive organs precedes that of the lungs. In some instances we find the affection of the lungs the primary disease ; but in these the case does not assume the form above described, but that of simple phthisis."—(*Med.-Chir. Trans.*, vol. vii.)

Having thus very briefly indicated the historical position of Dr. Brinton, as respects the literature of phthisis, we proceed to quote his description of a typical case of "*gastric phthisis.*"

"The patient, usually under 35 years of age, feels the first approach of the malady as an 'indigestion,' an epithet which, on inquiry, resolves itself into a pain beginning between the first and second hours after food, and going off gradually. At first such a pain often follows but one of the daily meals, perhaps oftenest a full morning repast. It rarely brings with it any flatulence, and is still more rarely relieved by eructation. As the malady advances the pain becomes more frequent and follows all the meals, only distinguishing by attacks of unusual severity those in which the food is more copious in quantity or more solid and indigestible in quality. By-and-by, the sickening depression which has gradually been recognised as an element of the increasing pain diverges into distinct nausea, and this soon provokes retching, which, in its turn, sometimes gradually deepens into vomiting. Often, however, the latter symptom remains long or permanently absent. If present, it is only rarely or after long persistence that it brings back from the stomach any of its alimentary contents ; and even then scarcely ever unloads the organ, much less relieves the pain by which it is preceded. By longer continuance the pain and retching become more severe, and more easily provoked, and therefore continually approach the period of taking food, so as not only to follow it by shorter interval, but at length to limit the meal to little more than painful and unavailing attempts to take food, the suffering which immediately follows its deglutition becoming almost unbearable. The climax of gastric disturbance thus attained is, in rare instances, itself the chief cause and immediate forerunner of death. But it much more commonly either inaugurates a rapid infiltration of the lungs with tuberculous deposit, or is displaced by the thoracic symptoms of tubercle already deposited, to alternate (it may be) with such symptoms during the brief remainder of life. In other cases, the dyspepsia amends spontaneously, or is vanquished by appropriate treatment ; and the patient, slowly recovering flesh and strength, advances towards that imperfect health which in so many instances is associated with the retardation or arrest of the progress of tuberculosis ; perhaps until the infirmities of declining years, mingled with the insidious symptoms of the malady, leave it in doubt to which of these two causes—natural decay or tubercular disease—we must chiefly refer the eventual death."—P. 342.

The grounds which the author indicates as those on which the diagnosis is to be chiefly based are the absence of signs indicative of even moderate aggregations of tubercles in the lungs, much less of their disintegration and removal, the febrile reaction being in excess of what is observed in gastric ulcer or ordinary functional gastric derangement ; the variable character and situation of the pain, which rarely or never reaches to the severity of "spasm," as it is called ; its capriciousness as respects diet compared with the pain of cancer or ulcer ; the rapidity with which in advanced cases the vomiting succeeds the digestion of food, thus anticipating the pain of which otherwise it would have proved the climax ; the absence of hæmorrhage ; and concurrence of constipation. This new chapter deserves careful study.

The other subject newly introduced is one upon "Gout in the Stomach." It consists in an attempt to define this affection in answer to the following questions :—"(1.) What do we see in actual practice suggestive of such an affection ; and what is the exact nature of the cases thus grouped ? and (2.) How far do these cases correspond with those descriptions of authors which represent what may be called our traditional knowledge of the affection ?" Dr. Brinton refers to four conditions—viz., 1st, what Dr. Watson jocosely terms "*pork* in the stomach—that is, the effects of offending ingesta ; 2nd, biliary colic ; 3rd, gastric symptoms which are associated with renal degeneration ; and 4th, those connected with valvular heart disease and ushering in its close. And then he asks, "Is there any 'gout in the stomach' left after the abstraction of these affections ? I can only say that I know of no such case ; have never seen one ; have never been able to get trustworthy evidence of one from some of the most accomplished Physicians living, or from the best records."—P. 361.

FOREIGN CORRESPONDENCE.

AMERICA.

Near Petersburg, Va., December 28.

Since the dispatch of my last communication to you, the army has continued its operations in front of Petersburg. No grand assault or general engagement has taken place, yet so constantly have the men been kept upon the *qui vive*, and so laborious have been their duties, that an assumption of hostilities in the open field would by many be looked upon almost as a relief. Until lately the troops have had no opportunity given them of making themselves comfortable. Those on duty in the fortifications, spending as they do one-half their time in the picket pit and the other in their gopher-holes or bomb-proofs, are permitted to think of comfort only as a thing of the past. The reserve divisions have been kept almost constantly in motion ; one day in rear of one part of the lines, the next supporting another point, while the third is spent, perchance, in pushing outwards as a reconnoitring column into the *terra incognita* beyond our lines. In no one place have they been permitted to remain for more than three or four days at a time. Repeatedly during the course of the autumn have they policed new grounds ; felled trees, split them, and constructed winter huts, when the inexorable order to march would arrive, and render their labour profitless. So frequently has this occurred, that they ultimately become rather shy of building, fearing a repetition of the marching order.

The weather during September was decidedly disagreeable. Heavy rains rendered the grounds so muddy that a walk of a few yards out of camp, and in some instances a few steps within its precincts, would secure damp feet to the adventurer for the rest of the day. The low-cut army shoe affords but little protection in such depths. On the left of the army, however, where a sandy soil prevails, this was not the case. The nights were very chilly, and many of the men unprovided with blankets. August was sultry ; blankets and overcoats were of no immediate use, and were thus doubly a burden upon the march. Many of the men, more especially of the recruits, threw them away ; September came, and not a few of the admissions into Hospital during that month owed origin to the lack of these articles. Every man drew a full supply at next issue.

Yet this army has been healthy. A fortunate army it has been, and is, in this respect. No epidemics have ever

paralysed it. Its march has never been impeded by its sick. Four per cent. has been the daily ratio of sick during the past three months treated in the field, both in Hospitals and in quarters, and at the same time the number sent to northern Hospitals for treatment has not been many.

As usual, camp diarrhœa forms the largest figure in the sick report. Dysentery has not been common. Cases of unmodified typhoid fever have been rare, and of pure intermittent scarcely less so. Typho-malarial fever has occurred frequently. Four-fifths of the mortality from sickness has been owing to it.

The division field Hospitals are in excellent condition. They have been comparatively stationary since my last writing—the changes in the position of the troops, though frequent, being seldom to such an extent as to render necessary any alteration in the site of the Hospitals—hence they have arrived at a degree of comfort seldom attained in the field during active operations.

Of late the grand drama being enacted by Sherman and Thomas in Georgia and Tennessee has drawn the eyes of the country from the army of the Potomac, which, as the *Richmond Examiner* would say, lies exhausted and impotent after its many futile attempts upon our noble city. This army, however, has been playing a very important *rôle*. By its continued feints—feints in such force that were the opportunity favourable they could be readily transformed into most deadly assaults—Lee and his troops have been kept upon the alert and chained to Petersburg, how effectually is seen in the war bulletins detailing the rout of Hood and the capture of Savannah. One of these feints I will refer to at greater length, as it shows the difficulties the Medical officer has sometimes to contend with in army practice. On such expeditions, as fighting is not intended, more especially if the enemy be met with in force, very few ambulance waggons are permitted to accompany the troops, to the end that in case of a rapid rearward march the progress of the movement may be unimpeded. The same holds good in the case of the march of a reconnoitring column.

Part of the 2nd and 5th Corps with Gregg's cavalry were the Union troops engaged in the fight extemporised on the Boydton Plank Road on October 27. At 2 p.m. on the 26th the different commands broke camp, and marched to the extreme left of the army, bivouacking for the night outside the fortifications near the Halifax Road. All the waggons belonging to these troops were ordered to go into park near a house in this vicinity, called the Gurley House, there to remain until further orders. To this arrangement no exception was made, even of the medicine waggons, so that on the following morning when the march was resumed only a few ambulance waggons followed in rear of the troops.

Reveillé was sounded at 3 a.m. It was intensely dark, and a drizzling rain falling contributed to our discomfort. After a hurried cup of coffee, the troops fell in and marched, the 5th Corps westward, the 2nd Corps southward along the Halifax Road for over two miles and then westward, the cavalry still farther along the Halifax Road and then westward also. Why westward? Evidently that the party as a whole might turn up in the course of the morning in front of the Danville railroad, forming a line of battle parallel to it, with the cavalry on the left, the 2nd in the centre, and Warren with the 5th on the right.

Let us follow the second column, for in its neighbourhood all of interest transpires. Three miles through dense woods are travelled over, and the grey light of early morning is showing objects with increasing clearness as a few dropping shots from the skirmishers ahead tell that the enemy has been encountered. Still the march is continued; his pickets are falling back before our advance. We pass the first of the day's wounded. He is lying by the roadside, shot through the abdomen. A Hospital steward waits beside him to see him transferred to one of the ambulances that are coming up in rear of the leading division. Now the skirmishers report the enemy entrenched on the west bank of Hatcher's Run, a small stream, but with precipitous banks, running south and eastward towards the Nottoway River. Their position commands the ford. Our advance is arrested for a short time. A couple of regiments are deployed into line. Forward! With an exultant hurrah, they dash from cover across the run and up the rising ground towards the works, receiving as they proceed a well-directed volley that causes many a gap in their line. There is a hesitation or wavering manifested as the storm sweeps past them, but it is instantly recovered from, and the work is gained. A few of the enemy are captured in it. Crossing this little stream with the head of the column, as soon as the march is continued, we find that its possession has cost us about fifty men. The ambulance officers are picking them up, as the Doctors look at the nature of the wounds, and give an encouraging word to each of their patients. One case is worthy of more particular attention. The patient, an officer, whose blanched appearance speaks of active hæmorrhage, is lying on a stretcher within the captured work. Three or four Medical officers are bending over him, utterly unobservant of all that is passing around, of the march of the troops or the singing of the random bullets. He has been shot through the thigh; the bone is uninjured, but the femoral vessels have been severed. The Surgeons have enlarged the wound, cut the sartorius across, and are searching for the proximal orifice of the injured artery. There! Now the tenaculum has found it. The section is smooth as if a knife had formed it. A ligature is passed around, and the knot is run fairly and firmly home, relieving the stiffening fingers of the officer who has been hitherto controlling the bleeding at the groin. An energetic oozing of darkish blood continues from the lower end of the wound. After some difficulty its source is found in the distal orifice. The patient is lifted into an ambulance, and the officers as they mount their horses feel proud as the man who led the storming-party to success. They feel that to-day they have not lived in vain. In the end, however, this case was a failure. Three days after the operation, while the patient was being conveyed on a stretcher to a Hospital some distance in the rear, hæmorrhage recurred; the ligature occluding the mouth of the artery had separated, perhaps owing to some rough or careless handling during the transportation. Little blood was lost; an officer accompanying the patient controlled the flow until assistance arrived, when the sheath was opened about an inch above the injured point, and the vessel re-ligatured. Two or three days after this, amputation had to be performed on a level with the original wound, on account of gangrene of the limb. He rallied well after the operation, but succumbed subsequently to pyæmia. The whole of the ambulances belonging to the division engaged—fifteen in number—were loaded up with the proceeds of this assault. It is to be regretted that they were not sent back to the Gurley House where the main train was parked; but as the country behind us was now in the hands of the rebel cavalry, travelling was unsafe unless accompanied by a formidable escort, and this the military authorities would not grant. The wounded therefore had to be carried onwards.

Cautiously through the woods the advance continued, skirmishing occasionally as a few of the enemy showed themselves; on the right all was silent, but from the left every now and again the sounds of Gregg's guns was wafted to us. As we approached the Boydton Road, near the point where it is intersected by Hatcher's Run, we were opposed more sternly; the enemy seemed inclined to strive for its possession, but the weight of our lines drove him across it with little fighting. At this point connexion was made with Gregg on the left; but as no news of the Fifth Corps' advance had been received, it was decided to halt, form line of battle, and await Warren's arrival.

The line formed ran from east to west across the road, and then curved southwards, parallel to, but a few hundred yards distant from its western margin. By the roadside, about half a mile south of the point crossed by the line of battle, and quite close to the position held by the dismounted cavalry, was a frame building known as the Rainey House. This was settled upon as our depôt for wounded. It was as safe a place as could be fixed upon, while yet ignorant of the direction from which the storm was to come. Military men decided that the enemy, if they attacked at all, would make the attack on our right, in which case the Rainey House would be out of the line of danger, save from such round shot as might be bowled at random along the plank road. The ambulance officers were instructed to carry their wounded there, and the Medical men, except those previously named to accompany their regiments into action, rendezvoused at it with their stewards and attendants, their operating-cases and field companions.

We do not wait long in vain for developments. The enemy speedily discover a part of the right of our line, as it stretches across an exposed field. They open with shell upon it from a couple of batteries, while a third rolls round shot along the road, in the hope of injuring the traffic they expect is going on upon it. They fire well, and the men exposed get uneasy; infantry do not love artillery fire, and *vice versâ*, an artillery-man who is heedless of the scream of a shell, dodges at the

softer note of a Minié bullet. Four guns are planted upon an eminence to distract the attention of the rebel batteries from our infantry. The *ruse* succeeds. They point their guns at our battery, and overwhelm it from their numerical superiority. Their fire, too, is killingly accurate—so much so, that unless reinforced our guns cannot remain in position. Four more are sent to their assistance, and the early part of the afternoon is spent in a noisy light artillery brawl. Still Warren does not come; his left has beeome entangled in the woods, and cannot find our right so as to eomplete the line. The ammunition in our caissons is about expended, hence the firing from our artillery flags. Since there is no supply nearer than the Gurley House, it would not pay to waste it all in such profitless duelling. Our guns are limbered up and removed from the knoll, and the enemy, satisfied with having silenced their opponents, become silent also.

What is to happen next? Hark! That long rolling volley on the right, preluded by those scattered shots, gives speedy answer. Can it be the 5th corps that has found the enemy and is giving him battle? Ah, no. It is the enemy that has found the gap between us and the 5th corps, that has inserted a mass of men into the unguarded interspace, and that is now pouring in a galling flank fire and advancing with resistless impetuosity to roll our right into disorder. To an inexperienced eye the right seems already in disorder; in fact, the whole line beeomes agitated as aides gallop hither and thither with orders from the fiery Hancock to his subordinate generals. It breaks up and its component parts are coursing at the double-quick in all directions; they are forming anew to meet the unexpeeted blow.

Meanwhile on the right the troops are, as they laughingly express it, "doing some tall running" to avoid being cut off by the advancing foe, while every few seconds some of their numbers are struck down by the ruthless fire poured in upon them. Wounded men are, more slowly, limping, crawling rearwards to avoid that undesirable fate expressed as "wounded and a prisoner;" while others less fortunate, inasmuch as their fractures prevent retreat, resignedly hitch themselves towards the cool and shady side of a neighbouring tree, or lie looking at their flying comrades with a longing eye and sinking heart. There are Doctors there, too; you may know them by the green silk sashes they wear. There is one with a wounded officer bearing on his shoulder; there another leaning upon the shoulder of his steward, he is shot through the thigh. No matter; it is but a flesh wound, and if he but limp actively he may yet escape the Hotel de Libbie or Castle Thunder.

The enemy are foiled; our men fled too eleverly for the success of their attempt. They advanee, there is nothing to oppose them, until their flank becomes exposed to a line that has been rapidly formed. Their own game is played upon them, and played successfully too; they fall back in confusion, leaving their wounded among ours, and quite a number of unwounded prisoners in our hands. The lines are re-established, and quiet prevails, if we except the snarling fire kept up between the opposed pickets and the occasional groan of a wounded man as the stretcher-bearers, carrying him to Rainey's, stumble over a stone or a stump.

(To be continued.)

GENERAL CORRESPONDENCE.

THE PRESIDENCY OF THE ROYAL MEDICO-CHIRURGICAL SOCIETY.

Letter from Dr. George Burrows.

[To the Editor of the Medical Times and Gazette.]

Sir,—I have only this day learnt, and with some surprise, from a paragraph in the *Medical Times and Gazette* of Jan. 28, that there has existed considerable difference of opinion in the Council of the Royal Medico-Chirurgical Society, in reference to the nomination of a Physician to fill the office of President of the Society during the ensuing two years. It appears that my name has been brought forward in opposition to that of Dr. Alderson, and that upon two occasions the Council were equally divided in their votes in favour of Dr. Alderson or myself. The paragraph to which I refer in the *Medical Times and Gazette* also intimates that the fellows of the Society may possibly be called upon at the annual meeting in March to decide with which section of the Council they will coincide.

I should greatly deprecate any such contest, and however much I should prize the honour of presiding over such a distinguished body of men as the Fellows of the Royal Medico-Chirurgical Society, and grateful as I feel to those members of Council who have thought me worthy of such a post, I must request you will make known that I could not possibly accept such an honour when it was obtained by the disparagement of Dr. Alderson, who is much senior to myself on the list of Fellows of the Society, and who is also my personal friend. I am, &c. George Burrows, M.D.

18, Cavendish-square, Jan. 31.

PROFESSOR CHELIUS.

Letter from Dr. Jones.

[To the Editor of the Medical Times and Gazette.]

Sir,—Although quite aware that "men continue to hold posts long after the period at which they can satisfactorily fulfil their duties," I cannot help feeling how little this observation applies to that venerable Surgeon, the Geheimrath Chelius, whose clinical lectures I enjoyed the privilege of attending more or less frequently for the space of eight years. It is not yet two years since I left Heidelberg, at which period the Geheimrath was in the full possession of all his faculties, and as competent to perform his Medical and Surgical duties as our own Prime Minister, Lord Palmerston—several years the older—is to rule over this empire. Chelius graduated when only 18 years of age. His lectures on Surgery were delivered at the early hour of 7 a.m. winter and summer, and, to the best of my recollection, he seldom or never missed lecturing during the whole time of my residence in Heidelberg. When I last saw him his voice was as clear, his eye as bright, and his step as elastic as if he had been 40 instead of 70 years of age.

I hope you will kindly find room for these few lines, as I fear the Geheimrath, who is well acquainted with and highly esteems our English Medical literature, may feel justly pained and grieved at perusing your observations.

I am, &c. J. Jones, M.R.C.P.

Springfield, Upper Clapton, Jan. 28.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, January 10.

Dr. Basham, V.P., President, in the Chair.

A paper, by Dr. Horace Dobell, was read, entitled

A CONTRIBUTION TO THE NATURAL HISTORY OF "WINTER COUGH."

The paper was an analysis of fifty-eight cases of "winter eough," the details of which were given in an appendix. The cases were arranged in four groups, according to the physical signs:—1. Cases in which there were physical signs both of bronchitis and of emphysema. 2. Cases in which there were physical signs of bronchitis, but not of emphysema. 3. Cases in which there were physical signs of emphysema, but not of bronchitis, and in which there was no history of previous bronchitis. 4. Cases in which there were physical signs of emphysema and not of bronchitis, but in which there was a history of previous bronchitis. Each case was reported in the form of answers to a set of forty-one questions relating to the short breath, the cough, the taking of colds, the past illnesses, the occupation, the dwelling, the food, the habits, and the family history of the patient, in addition to a concise statement of the personal condition at the time of examination. The number of facts thus collected was too numerous to admit of their being discussed within the limits of a paper; the author therefore restricted himself to an analysis of the cases under the several groups, and a comparison of some of the principal facts in a series of twenty tables, thus putting the materials into a convenient form for future use.

Dr. Salter questioned the appropriateness of the words "natural history" in the title of the paper. He thought nothing was gained by removing the ordinarily received landmarks of a vocabulary by taking up a word and transplanting

it into a position not its own, and that nothing tended so much to weaken and impoverish the resources of a language as attempting to expand the use of words too far. By "natural history" was generally understood the history of organised beings, animal and vegetable. No doubt the study of disease was the study of a department of nature; but if the use of the expression "natural history" was defended on this ground, it would be as appropriate to speak of the natural history of astronomical or any other natural phenomena. The point on which the paper seemed to promise to throw some light was the causation of emphysema; but in this it had disappointed him. The only case that really bore on the subject was the single one in which emphysema was said to have existed without bronchitis; but he could not conceive that bronchitis really was absent in this case. Emphysema with cough and without bronchitis he could understand; but emphysema with winter cough and without bronchitis he could not understand: the bronchitis might be very feebly pronounced, but he did not believe in any non-bronchitic winter cough. While containing much that was interesting, and suggestive of many hints for future useful work, he thought the paper suffered a great disadvantage from being so entirely a paper of figures. And he thought, too, that it very well illustrated what had been often said of figures—that they could be made to prove anything. Take, for example, the fact stated by the author—that patients with emphysema had bad spirits, while those with bronchitis had good; and his explanation—that this difference depended on the presence of expectoration in the one case, and its absence in the other. He (Dr. Salter) thought that this statistical evidence of the exhilarating tendency of expectoration was a strong proof of the omnipotence of figures. He differed from the author in the little importance he assigned to occupation in the causation of winter cough; he (Dr. Salter) found it the most potent of all circumstances in the production of the affection. By far the larger proportion of sufferers from it who came under his observation were those whose occupation exposed them to all weathers, and at the same time prevented their lying by—such as vendors of things in the streets, cabmen, porters in Covent-garden Market, etc. Indeed, the fact that the disease was due to climatic influences was itself a proof that those whose occupations the most exposed them to those influences must be the greatest sufferers. He quite agreed with the author as to the undefined use of the word "asthma;" that a great many cases of so-called asthma were simply chronic bronchitis; and that any chronic difficult breathing is commonly called asthma. At the same time, he thought that a carefully directed inquiry would generally detect whether such cases were truly asthmatic or not.

Dr. Dobell said he begged to thank the Society for listening so patiently to his very dry paper. He had hesitated to bring it before them because of the number of tables and calculations which it contained. He was much obliged to Dr. Salter for his suggestions about the term "natural history" used in the title; but he entirely disagreed with him. When treating of animals or plants, the term "natural history" was used to comprise a description of the "conditions of their existence;" the circumstances influencing their development, maintenance, growth, and reproduction; their habitats, habits, and the like. It was precisely this kind of information which he had collected with regard to "winter cough;" and he must, therefore, maintain that it was correct to call it "natural history." With regard to occupation, he entirely agreed with Dr. Salter, that the influence of occupation on winter cough was of the greatest importance. Dr. Salter had simply misunderstood the words of the paper. It was there stated that, as there were only fifty-eight patients, and as they followed twenty-eight different sorts of occupation, no more than seven following any one of these, it would not be fair to draw any conclusion as to the influence of occupation on the disease from the tables, but that, as a correct record of facts, it would become valuable when added to others of a similar kind. With regard to the whole paper, he (Dr. Dobell) wished particularly to impress that, as it only treated of fifty-eight cases, broken up into four groups, and as each case necessarily differed to some extent from the rest, he did not consider that it ought to be taken as a safe basis for general conclusions respecting such an important and widely-spread class of diseases. He had scrupulously abstained from making such conclusions, and he hoped that others would do the same. The title described the paper as no more than a "contribution" towards a natural history, and he did not wish it to be considered as more than it assumed to be.

A paper, by Julius Althaus, M.D., M.R.C.P., was read

ON SEA-SICKNESS AS A FORM OF HYPERÆSTHESIA.

Most writers on sea-sickness consider this affection to be due to hyperæmia of the brain and spinal cord, or to a morbid condition of the gastric nerves. The object of this paper is to show that sea-sickness is, in reality, caused by anæmia of the brain and the cervical portion of the spinal cord, arising from insufficient power of the heart, and whereby a general increase of reflex excitability throughout the system is brought about. The first and most constant symptom of the disorder is not retching or vomiting, but vertigo, which is most severe in the standing posture, and at once relieved by a strictly horizontal position, and which is thus proved to arise from a deficient amount of blood in the nervous centres. The increase of reflex excitability is also shown by greater sensitiveness of the patient to light, sound, touch, etc.; and in some cases there are even reflected spasms in the lower extremities. It is, however, greatest in the stomach, as evidenced by retching and vomiting, the degree of which is dependent upon the posture of the patient, but not upon the full or empty condition of the stomach, or its greater or less vital power. This increase of excitability is, after a time, generally followed by a considerable diminution of it, there being great torpor and profound indifference. The organ primarily disturbed, therefore, appears to be the heart, which, in consequence of the ship's motions, becomes unable to propel the blood with sufficient power into the nervous centres. The blood is accumulated in the chest and the abdomen, where it produces a feeling of pressure and heat. Persons with a strong heart and a slow pulse generally suffer little from sea-sickness; while irritable people, with a quick pulse and a tendency to palpitations, are more liable to be affected. This explains to a certain extent the different liability to sea-sickness of the different nations; for, as a rule, the French and Italians, being of a more irritable temper, suffer most, the Germans less, and the English least, of the disorder. The treatment of sea-sickness flows directly from the pathology just enunciated. Our task should be to facilitate the afflux of blood to the nervous centres, and to strengthen the heart's action. For this purpose a horizontal position should be enjoined, and a few tablespoonfuls of well-seasoned beef-tea, and small doses of brandy, should occasionally be given.

Dr. Basham said that most persons had some experience of sea-sickness, and inquired if any explanation of its cause had suggested itself to any of the fellows present.

Dr. Althaus said that since he had written the paper just read to the Society he had seen an essay on sea-sickness from the pen of Dr. Chapman. That gentleman considered that sea-sickness depended on the presence of an undue quantity of blood in the middle and lower portions of the spinal cord, and suggested the use of ice to the part as a remedy. He (Dr. Althaus) did not believe that the local congestion was the cause of the sickness, though it might possibly exist. If it were the cause, then change of position would relieve the sickness; but change of posture from the back to the stomach did no good, whilst, as was known, it often relieved spasm immediately. He had not tried the use of ice, and therefore could offer no opinion respecting its use. Cold was a powerful agent, and he should be glad if it were found generally successful. He knew of no remedy so effectual as the recumbent position. The administration of very small doses of morphia endermically had been recommended, but he had not tried it.

Dr. Barclay's experience differed from that of the author. He had found liquids, and particularly alcohol, aggravate the sickness.

Dr. Basham remarked that we must not shut our eyes to the fact that, with very few exceptions, most persons at sea soon became tolerant of the cause of sickness, whatever it might be. He had never met with any one who, after being at sea a day or two, could not join the dinner-table. The exceptions were from idiosyncrasy. He thought there had been too much speculation as to the cause of sea-sickness. Many other conditions, such for instance as being in a "roundabout," produced the same effect. The true pathology of sea-sickness, whatever it might be, had not yet been ascertained.

A Housebreaker was captured at Oxford through the instinct of a small terrier. The man had effected his entrance to the house by giving a dose of chloroform to a large mastiff. He then hid himself under a bed, but was discovered by the uneasiness of the smaller dog.

WESTERN MEDICAL AND SURGICAL SOCIETY.

FRIDAY, DECEMBER 2.

Mr. GEORGE POLLOCK, President, in the Chair.

A PAPER was read by Mr. B. E. BRODHURST upon

BONY ANCHYLOSIS.

The author gave the details of a case of bony anchylosis of the hip-joint, in which the neck of the thigh bone was cut through to form a false joint. Cases of bony anchylosis are rare. When of the hip-joint the patient is very helpless, and can only move by the aid of crutches. He is less helpless when any other joint is affected. The propriety of interfering with bony anchylosis of the knee or ankle joint may be questioned, but in the case of the hip and the elbow joint it is of great importance to give the patient a chance of renewal of motion, even where motion would seem to have been hopelessly lost. In operating it is important to divide the bone as near as possible to the articulation. In the elbow a wedge-shaped piece may be taken from the centre of the articulation; and in the hip the neck of the femur may be divided just below the head of the bone. The divided ends of the bone may then be scooped out, so that both surfaces shall be concave. There is difficulty in retaining motion in these cases, so strong is the tendency for bony union to occur. A swinging limb need never be feared. If the action of the muscles cannot be gained, reunion by bone is certain to take place. It is important, therefore, to divide the bone in the most favourable position for the action of the muscles, and that point must be the nearest possible point to the articulation itself. In these cases we have to deal with tolerably healthy structures, and hence it is that the tendency to repair is strong in them. The muscles, too, which formerly moved the limb are somewhat altered in structure, and through disuse they will have lost power. It will require, therefore, for a lengthened period both patience and fortitude to gain fair muscular power after bony anchylosis has once become fully established. *Case.*—A. M., aged 23 years, suffered from bony anchylosis of the left hip. When she was 10 years old she met with an accident, through which inflammation was excited. She continued to walk, however; no attention being paid to the limb for many months. She limped as she walked. The limb swelled; an abscess formed, and continued more or less to discharge pus, with portions of necrosed bone, for ten years. Pain and abscesses at length ceased, and the limb became motionless. The author first saw the patient in 1862: she was in fair health. The question simply was, Could motion be given? Anchylosis had taken place without dislocation of the head of the femur occurring. The neck of the bone was in part absorbed. The limb was shortened one inch and a-half. The pelvis was rendered oblique—apparently increasing the shortness of the limb by two inches. She had during the previous year walked with crutches, and worn a boot which was raised three inches in the sole. The case appeared favourable for operation, and it was thus performed:—An incision three inches long was made commencing over the head of the femur and passing to the outer side of the great trochanter; from the upper angle of which another incision extended inwards for two inches. The neck of the bone was divided, and the ends gouged out as before described. The flesh wound healed almost by the first intention. Movement of the limb was attempted when the cicatrix had formed, but it was difficult, and so painful that without chloroform it could not have been borne. This passive motion was, however, continued, and at length the limb moved readily, and even some voluntary motion was gained, so that the patient could flex the limb to a right angle. After six months she could rotate the limb outwards, and sit down at ease. The pelvic obliquity was easily removed; the horizontal position being in itself almost sufficient for this purpose; and the foot was consequently brought by so much nearer to the ground. A steel support, with joints opposite to the hip, knee, and ankle, was fitted to the limb; and the buttock was supported by a leather shield. With this instrument, and a couple of sticks, the patient moved about easily. The operation has now been done two years. There is no lack of firmness about the hip joint; but, on the contrary, it requires constant exercise to keep it free. The patient now walks without the instrument, and with one stick for support.

OBITUARY.

DEATH OF DR. JONES QUAIN.

WE regret to announce the death of Dr. Jones Quain, which occurred on the 31st ult. Many of Dr. Quain's former pupils, men who have now long left behind the period of middle life, will hear this announcement with sincere sorrow, for few teachers were more beloved by their pupils than was the subject of this brief notice during the period that he filled the chair of anatomy and physiology at University College, ending with the session 1836. Accomplished as a scholar, eloquent and impressive as a lecturer, endowed with remarkable tenderness of feeling and kindness of heart, his retirement from his duties was regarded at the period as a great calamity. Annoyances coming from sources where they were least to be expected, told on his refined, perhaps too sensitive temperament, and he withdrew from public and Professional life to enjoy in retirement those scientific and literary studies which afforded him constant pleasure and satisfaction. Dr. Quain was also a member of the Senate of the University of London, an office which he continued to hold for a few years after his retirement from the chair in University College. We need not perhaps say that he was the author of "Quain's Anatomy,"—a work the value of which has been appreciated by every member of the living generation of Medical Practitioners, and of which successive editions continue to be published. He was also, in association with Mr. E. Wilson, the author of the series of anatomical plates which bears his name; and he translated a valuable little manual called "Martinet's Pathology." Dr. Quain had reached, we believe, very nearly the age of seventy, and his health had latterly been failing. Always sensitive to cold, he seemed to suffer much during the recent severe weather. He gradually sank, and died on Monday last. His remains will be interred in Highgate Cemetery.

METROPOLITAN WATERS IN DECEMBER, 1864.

THE SEWING-MACHINE.—Dr. Küchenmeister observes that it is much to be regretted that the girls and young women of the present day, who suffer so much from chlorosis and dysmenorrhœa, have not the healthy exercise of the spinning-wheel so much pursued by their more robust grandmothers. In the sewing-machine, however, we have the same motion of the foot as in the spinning-wheel, and he strongly recommends the employment of this as a good gymnastic procedure for females suffering from chlorosis and dysmenorrhœa.—*Zeitschrift fer Medicin*, 1864, No. 3.

(a) The amount of oxidisable organic matter is estimated by the colou of the water when seen through a column of it, two feet in length, and by means of a solution of permanganate of potash, every 1000 septems o which contain 0·5 grains of available oxygen, the mean value of which has been estimated by its action on humurcrenic and apocrenic acids, and other vegetable organic matter in water.

(b) The loss by incineration, which is generally estimated as organic matter, consists of various volatile substances, as hygrometric moisture, combined water in sulphates, oxygen from nitrates and nitrites, carbonic acid from earthy carbonates, ammoniacal salts, and organic matter.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary Examinations for the Diploma, were admitted members of the College at a meeting of the Court of Examiners on the 26th ult. :—

Ferdinand Albert Purcell, M.D., Queen's University, Ireland (Cork); William John Morgan, Burwood-place, Edgeware-road (Charing-cross); Arundel Hill Cotter, Cork; Edwin Child, L.S.A., Vernham, Andover (Charing-cross); Richard Jeffreys, Chesterfield (Sheffield); Frank Charles Plumptre Howes, L.S.A., Great Yarmouth (King's College); John Grimes, Castle Thorpe, Bucks (King's College); Edward William Adrien, Old Town, County Dublin; Alfred Charlton, Tunbridge (Guy's); Charles Edwin Curtis, Yately, Hants (St. Bartholomew's); Arthur Taylor, Kennington (Guy's); John Murray, Aberdeen (Edinburgh); Richard Colville Parkinson, Guildford (Dublin); James Shaw, Handsworth (Birmingham); Bushell Armingson, Hampstead (King's College); John Thomas Jacques, Birstall, Leicestershire (St. Bartholomew's); Edward Drummond, M.D. Edin., Blyth, Northumberland (Belfast); Edward Cheatle, Tamworth (Birmingham); Joseph Rymer Dowman, New Zealand (Birmingham); Robert Ormc, Instou, North Devon (Guy's).

The following were admitted members on the 27th ult. :—

Ebenezer Shedd, L.S.A., Montreal (London); John Morgan Bryan, Northampton (St. Mary's); Charles Creasy Clayworth, Spilsby (London); Thomas Hall Redwood, Rhymney, Monmouth; Mark Autony Kilroy, Virginia, County Cavan (Dubliu); William Gosselin, Cavan, Ireland (Dublin); Charles Pitt Wetherell Neate, Fowey, Coruwall (St. Thomas's); John William Armistead, Leeds.

APOTHECARIES' HALL. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, January 26, 1865:—

William Matthew Renton, Newcastle-on-Tyne; John Hedley, Newcastle-on-Tyne; John Geo. Fredk. Wilford, Brompton, Yorkshire; Geo. Henry Watson, Jersey; Charles Broom, City-road, E.C.

The following gentleman, also on the same day, passed his First Examination :—

Ebenezer Shedd, Manchester.

PRELIMINARY EXAMINATION IN ARTS. — The following Gentlemen passed this Examination on January 27 and 28, 1865, and received Certificates of Proficiency in General Education :—

Augustus Hewitt Aldridge, Poole, Dorset; Edward Francis Atkinson, Alma-square, St. John's-wood; William Arthur Attwater, Lawn-place, Shepherd's-bush; Sydney O. Bishop, Sandhurst, Berks; William A. S. Blue, St. Bartholomew's Hospital; Edward J. H. Booth, Queen-street, Huddersfield; John Charles Chester, Redruth, Cornwall; George Charles Coles, Blenheim-crescent, Notting-hill; Frank Cufaude, Aele, Norfolk; Arthur F. L. Dorin, Drayton-grove, Brompton; David Henry Goodsall, Windmill-street, Gravesend; Joseph Hargrove, Wolverhampton; Charles Irving, Duncan-terrace; Henry E. Jackson, Highbury-grove-villas; Nathl. Howard Jarvis, Kingsbridge; Wm. Henry Kesteven, Manor-road, Holloway; William Moore King, Sussex County Hospital, Brighton; Alexander Longhurst, Farnham, Surrey; Burford Norman, Guy's Hospital; Perring Pickering, Henley-on-Thames; Thomas Pink, Croom's-hill, Greenwich; Frederick Prigg, Bury St. Edmunds; Chas. Frederick Rigg, Wigan, Lancashire; H. H. C. A. Rodberd, Preston, near Yeovil; Thomas Somerville Smith, Sittingbourne, Kent; John R. A. Taylor, Dorchester; Lewis Thorpe, Bradford-street, Walsall.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BUCANNON, Dr. R. F., has been appointed Surgeon and Agent for the Admiralty Coastguard Stations in Achill.

CAMERON, LEWIS, M.D., has been appointed Junior House-Surgeon to the Dispensary, Preston, Lancashire.

EAMES, JAMES A., M.D. St. And., has been appointed Resident Physician to the Letterkenny Lunatic Asylum.

JACKSON, GEORGE, M.R.C.S. Eng., has been elected Assistant House-Surgeon to the West London Hospital, Hammersmith.

MAUGHAM, WILLIAM, M.D., has been elected Medical Officer of Carnarvon Workhouse.

ROUSE, THOMAS M., M.R.C.S. Eng., has been appointed House-Surgeon to the West London Hospital, Hammersmith.

SMITH, ALFRED R., M.D. Edin., has been elected one of the Visiting Surgeons of the Hereford Dispensary.

SNEWIN, ALFRED G., M.R.C.S. Eng., has been appointed House-Surgeon to the Royal Pimlico Dispensary.

STOCKWELL, THOMAS G., F.R.C.S. Eng., has been elected Surgeon to the Bath United Hospital.

TAYLOR, JOHN W., M.D., St. And., has been appointed one of the Surgeons to the Malton Dispensary.

WADE, WILLOUGHBY F., M.B., has been elected Physician to the Birmingham General Hospital.

DEATHS.

BELFOUR, EDMUND, at 37, Lincoln's-inn-fields, W.C., on January 30, aged 76. Upwards of fifty years Secretary to the Royal College of Surgeons, England.

BULL, CHARLES, M.R.C.S. Eng., at Catton-grove, Norwich, on December 5, formerly of Diss, Norfolk.

CALLAGHAN, Dr. ARTHUR, of Limerick, at the Clifton Hotel, Liverpool, on January 23.

CURTIS, WILLIAM, M.R.C.S. Eng., at Harting, Petersfield, on January 27, aged 61.

DEBOUT, M., with whose name our readers must be familiar, has just died. He was editor of one of the most celebrated French Medical periodicals, the *Bulletin de Thérapeutique*, and an active member of the Paris Surgical Society.

DUCE, JAMES, M.R.C.S. Eng., at Wednesbury, Staffordshire, on January 27, aged 28.

FALCONER, HUGH, A.M., M.D. Edin., V.P. of the Royal Society, at 21, Park-crescent, Portland-place, N.W., on January 31, aged 56.

PAYNE, WILLIAM, Surgeon, at St. Austell, Cornwall, on January 13.

ROBERTSON, DAVID, L.R.C.P. Edin., at Dunkeld, Perthshire, on January 19, aged 26.

WATSON, JAMES, M.D. Edin., at Edinburgh, on January 23.

ST. MARY'S HOSPITAL.—At the election for Assistant-Physician to St. Mary's, which took place on Tuesday last, Dr. Broadbent was elected by a large majority. The other candidate was Dr. Edward Smith, F.R.S.

MR. HENRY SMITH will give the Lettsomian Lectures on the "Surgery of the Rectum," at the Medical Society of London, on Wednesdays, February 8, 15, and 22.

COMPARATIVE ANATOMY. — The Course of Lectures on this subject annually delivered at the Royal College of Surgeons, will be commenced on Monday next, by Professor Huxley, F.R.S., who will deliver twenty-four lectures "On the Structure and Classification of the Mammalia," in continuation of the course published last year in the *Medical Times and Gazette*. The following is a syllabus of the proposed lectures—viz., "The Anatomy of a Hedgehog," "The Principal Modifications of the Insectivorous Type," "The Anatomy of a Bat," "The Principal Modifications of the Cheiropterous Type," "The Structure and Systematic Position of the *Galeopithecus*," "The Anatomy of a Rabbit," "The Principal Modifications of the Rodent Type," "Remarks upon the Subdivision of the Mammalia constituted by those Mammals which have Discoidal Placentæ," "The Anatomy of an Armadillo," "The Principal Modifications of the Edentate Type," "The Anatomy of a Horse," "The Anatomy of a Pig," "The Principal Modifications of the Ungulate Type," "The Anatomy of a Porpoise," "The Principal Modifications of the Cetacean Type," "The *Sirenia*," "Remarks upon the Subdivision of the Mammalia constituted by those Mammals which have Diffuse or Cotyledonary Placentæ," "The Structure and Systematic Position of *Hyrax*," "The Anatomy of an Elephant," "The Principal Modifications of the Proboscidean Type," "The Anatomy of a Dog," "The Principal Modifications of the Carnivorous Type," "Remarks on the Affinities of those Mammalia which have Zonary Placentæ," "The Anatomy of an Opossum," "The Principal Modifications of the Marsupial Type," "The Anatomy of an *Echidna*," "The Modifications of the Monotreme Type," "Remarks upon the Classification of the Mammalia Generally."

THE LATE DR. BAIKIE.—At a time when his friends and the many who are interested in African exploration and discovery were anticipating with eager interest the arrival in this country of Dr. Baikie, the sad news has come giving information of his death at Sierra Leone on December 12, of fever and dysentery. During the past six years our lamented countryman has devoted himself with extraordinary enthusiasm and energy to African exploration, chiefly along the course of the Niger, and for a part of the time in the interior of the country, undergoing surprising privations, overcoming the greatest difficulties, escaping imminent dangers, and collecting, during these six years, an immense mass of the most important facts in natural history and physical science, as well as a large accumulation of specimens, which we trust may be preserved as a fitting memorial of the perseverance and heroism of this gifted Orcadian. Dr. Baikie had made every preparation for returning to his native country by the American mail steamer, and had arrived on October 21 at Lagos, from which place his friends had received letters from him by the previous mails. Indeed, had it been possible, he was to have come home by the previous mail; but the labour of arranging his African collections occupied longer time than he had anticipated. Arriving at Sierra Leone, "the European's Grave," he was suddenly seized with illness, and died in a couple of days. The loss of such a man to science and to civilisation is very serious indeed, and while we cannot but offer our condolence with Dr. Baikie's relatives in Kirkwall, we cannot but feel that the public loss is in one sense even a greater cause of

sorrow. Dr. Baikie has for years been in a great measure lost to his friends, and by his extraordinary devotion to the mission with which he was intrusted has rendered himself peculiarly an object of public attention and affection, and we venture to say that there are few public men who have recently been called away whose death will be more generally deplored. Dr. Baikie was born in Kirkwall, and was son of Captain John Baikie, R.N., long agent for the National Bank of Scotland. He received his early education in Kirkwall Grammar School, and thereafter studied, with a view to prosecute the Medical Profession, at Edinburgh University, whose diploma he earried. At an early age he manifested unusual interest in travel and adventure, and it was not difficult to foresee that, if spared, his future life would be distinguished in that respect. As a Medical student, Mr. Baikie gave evidence of singular ability, and it was in that capacity that he was first fixed upon to undertake duties that ultimately urged him into the theatre of African exploration. In that department Dr. Baikie's history has been full of marvel. He has, especially during the last six years, gone through scenes of adventure and escaped dangers which entitled him to one of the highest positions in the list of travellers, and render his history since the day he left Kirkwall Grammar School one of the most wonderful of any age; and there is no doubt that, whether Dr. Baikie's papers have been left in such a state as to justify his friends in giving to the public a detail of his last six years' adventures or not, enough is known of him to justify us in placing his name by the side of the galaxy of modern African travellers who have done so much to enlighten the world regarding its swarthy tribes and its physical characteristics, and to advance the interests of scientific discovery and advancing civilisation. And certainly, among the long list of honoured sons of which Orkney can boast, there is none of whom it has more reason to be proud than "Dr. Baikie, the African explorer."—*Northern Ensign.*

Asylum for Idiots for the Northern Counties.—On Thursday last, a meeting was held at Liverpool for the purpose of hearing the statements of the High Sheriff (Sir J. P. Kay Shuttleworth) and Dr. de Vitre, relative to the proposed asylum for idiots in the six northern counties, which it is proposed to erect at Lancaster. There was a very numerous and influential attendance. The Chairman said that in the six northern counties which had been indicated as the area of the proposed institution, the number of pauper idiots alone was nearly 2000, while the number of idiots not indigent was great in proportion to their superior position. The Central Committee in Lancaster had in their eye a most eligible site for an asylum, embracing about forty acres of beautiful land near the town of Lancaster. The Committee had already received subscriptions to the amount of £9000, including £2000, a grant, the residue of the Ripley fund. The Mayor then read out a list of subscriptions from Liverpool gentlemen—non-subscribers to the original fund—amounting to upwards of £4000. The proceedings terminated with the appointment of a local committee.

Death of Mr. Edmund Belfour.—There are many Members of the Royal College of Surgeons who will regret to hear of the death of the venerable Secretary of that Institution, with which he had been connected for upwards of half a century. Mr. Belfour had never recovered from the blow occasioned by the terrible death of his only son little more than a year ago, and owing to this, and increasing attacks of bronchitis, had quite secluded himself from nearly all Collegiate intercourse; occasionally his opinion would be sought by members of the Council, well aware of the importance of his sound judgment on all affairs conneeted with the Profession. So highly was he esteemed by the governing body, that in 1860 a sum of 200 guineas was unanimously voted to present him with a service of plate, bearing on one of the pieces the following inscription:—"Presented by the Council of the Royal College of Surgeons of England, with other plate to the value of 200 guineas, to Edmund Belfour, Esq., in acknowledgment of his zeal, fidelity, and honourable conduct, and of the invaluable services he has rendered the College, in all its departments, during the fifty years of his tenure of the office of Secretary.—John Flint South, President. November 9, 1860." And well did the deceased merit this encomium passed on him by one so well qualified to judge as the late Joseph Henry Green, with whom he was always an especial favourite. The very inclement weather which set in with an intense fog on Saturday, the 21st ult., told seriously upon him, and notwithstanding the kind and unremitting attention of his attached friend and Medical adviser, Mr. J. S. Streeter, F.R.C.S., who sat up with him the whole of the night preceding his decease, he quietly and almost imperceptibly sank, and died of senile exhaustion and decay in the 76th year of his age, leaving a widow and two daughters, one of whom is married to Captain E. Ward Fox, of Haddon House, Bakewell, Derbyshire. The remains of Mr. Belfour will be interred this day (Saturday), in the family vault in Hackney Old Church, and notwithstanding the wish of the deceased that the funeral should be strictly private, it is believed that it will partakemore of a public character from the high estimation in which he was deservedly held, not only by the members of the Council, but by the Profession generally. Mr. Belfour will be suceeeded by Mr. Edward Trimmer, M.A. Cantab., a grandson of the celebrated authoress of the same name, who, having filled the office of Assistant-Secretary for several years, has proved himself eminently qualified for the important duties of Secretary to the Royal College of Surgeons of England.

Non-Ventilation of Cornish Mines.—The Cornish agricultural labourers are second to no class in the kingdom in point of longevity and health. The Cornish miners die young, chiefly of pulmonary disease. It has long been known that the most prominent cause of this early mortality was a preventible one—the non-ventilation of the mines. Lately, however, the point has been again brought before the public by a Royal Commission. Dr. Angus Smith, who, at the request of the Commission, has investigated the subject, writes:—"A healthy atmosphere may be taken to be one with 20·9 per cent. of oxygen, and ·04 per cent. of carbonic acid gas. Late in the evening in the pit of London minor theatres as much as 0·252 and 0·320 per cent. of carbonic acid has been found; but the average of above 300 samples of air taken from these mines had 0·785. Two-thirds of the samples presented an atmosphere exceedingly bad, and the worst parts of the mines had only about 18·69 per cent. of oxygen, and as much as 1·8 or more of carbonic acid, in one instance 2·26 per cent." In order to test the effects of such bad air, Dr. Angus Smith caused to be constructed a small close chamber of lead, with windows sufficiently large that they might in any emergency be broken through for a way of escape. The first trial was made by sitting down in the chamber for an hour and forty minutes. This produced about one per cent. of carbonic acid, and the air became cheerless. A young lady was anxious to be in the chamber when the air was such that the candles would not burn. She was not much struck by the impurity of the air on entering, although the candles were threatening to go ont; there were not quite 19 per cent. of oxygen, and there was rather more than 2 per cent. of carbonic acid. No one had been breathing in the chamber, so that organic matter from the person was absent, and that makes a great difference. She stood five minutes perfectly well, making light of the difficulty, but suddenly became white, and could not eome out without help. On another occasion a still greater amount of carbonic acid was present in the chamber, but it was not accompanied with a eorresponding loss of oxygen, for the gas was driven in upon pure air; there was 20·19 per cent. of oxygen, with 3·84 of earbonic acid. Two persons got headaches instantly, and were unable to stay above seven or eight minutes. Dr. Smith staid about twenty minutes, but felt very anxious to get out, as his movements were made with great haste, and both mind and body betrayed symptoms of feverish activity. The face was flushed, and the lungs acted more rapidly than usual. In fact, there was a burning haste to live, as if life were afraid of being put out. It seems to him impossible to endure 4 per cent. of carbonic acid for any length of time. There was a very remarkable lowering of the pulse, and as this happened regularly he puts it down as the result of poisoning with carbonic acid gas, and asks whether it may not suggest a mode of lowering the pulse in a fever. These experiments show the great mischief that must arise from the impure, unwholesome air in metalliferous mines. The men call it "thin," "poor," "dead;" the effect is slow poisoning. The explosions of gunpowder produce sulphide of potassium, the effect of which is probably like that of sulphide of hydrogen, but from its acting more slowly there is distributed over a long period that death which might ensue instantly, and so, in chemical phrase, the effect is dissolved in health, and becomes disease. Gun-cotton seems to promise to perform the work of blasting with less injurious influence upon the air. In the coal districts, where, on account of the dangerous gases, great

attention has been given to the proper ventilation of the mines, the mortality (accidents excepted) is considerably less than in the metalliferous districts, and this shows that the excessive mortality in the latter is not caused by the mere working underground in dark galleries. Dr. Smith touches incidentally to his report upon various points of practical importance. He notices the purifying effects of rain upon the air, of which there was such a scarcity last year. Moisture with a high temperature is oppressive, but moisture with a lower temperature improves the air, and he holds that cold and moisture in such amounts as those in which they are found in Great Britain are capable of producing powerful constitutions, and that the more watery districts of the kingdom present in many instances the most healthy spots. Still, in relation to ventilation he notes that "chemical action, and with it the feelings demand a certain amount of warmth first and above all things. No function can go on without it. You may live hours, days, or years, in badly ventilated places with more or less discomfort and danger, but a draught of cold air may kill like a sword. In railway carriages, and in houses also, the great instinct of man is first to be warm enough, and he is quite right. Such a universal instinct must not be sneered at."

Medical Provident Society.—The second meeting of the Directors of the Medical Provident Society was held at the Freemasons' Tavern, London, on Friday, January 27. There were present—Dr. Richardson, in the chair; Dr. Armstrong (Gravesend); E. Bartleet, Esq. (Campden); R. B. Carter, Esq. (Stroud); Dr. Chevallier (Ipswich); J. Clay, Esq. (Birmingham); Dr. Desmond (Liverpool); Dr. Fayrer (Henley-in-Arden); Dr. Latham (Cambridge); C. F. J. Lord, Esq. (Hampstead); Dr. Morris (Spalding); T. Heckstall Smith, Esq. (St. Mary Cray); Dr. A. P. Stewart (London); H. Veasey, Esq. (Woburn); S. Wood, Esq. (Shrewsbury); and Dr. Henry, Secretary. *Rules of the Society.*—The minutes of a meeting of the Executive Committee, held on November 18, at which a draft code of rules was prepared for the consideration of the present meeting, were read. The rules having been printed, and a copy forwarded to each Director a month previously to this meeting, it was agreed that they should be taken as read, and discussed *seriatim*. Mr. Clay said that, before the rules were discussed he wished to have the opinion of the meeting as to whether they should be registered under the Friendly Societies' Act. There were several reasons in favour of their being so registered; for example, legal power was thereby given to the Society to sue and be sued in courts of law; and the safety of its funds was insured. He moved—"That the Medical Provident Society be registered under the Friendly Societies' Act." Mr. Heckstall Smith seconded the resolution, which was carried unanimously. Mr. Clay also moved, Mr. Heckstall Smith seconded, and it was unanimously resolved—"That the Chairman and Secretary be requested to communicate with the Registrar in reference to the registration of the Society, and to make the necessary alterations in the rules in accordance with the requirements of the Registrar and of the Friendly Societies' Act, provided that these do not interfere with the scheme propounded by the Directors." The rules were then discussed *seriatim* by the members present, various additions and amendments being made. As they are to be submitted to Mr. Tidd Pratt in accordance with the foregoing resolution, and further consultation with Mr. Finlaison is required in regard to the tables of payments, an outline only of their principal provisions is here given. The Society is to be denominated "The Medical Provident Society in connection with the British Medical Association;" and may be ordinarily designated "The Medical Provident Society." Its object is to enable certain duly registered Medical Practitioners to provide, by mutual assurance, for those exigencies of sickness or casualty which render them unable to discharge their Professional duties. The Society is to consist of honorary and contributing members. Donors of ten guineas and upwards, being duly registered Practitioners, and approved by the Board of Directors or Executive Committee, may become honorary members for life; and shall be eligible to office, but shall not have any claim on the sick fund unless they be also contributing members. The Board of Directors may also confer the title of honorary members on benefactors of the Society, but these shall have no part in the management of the Society nor claim on its funds. Contributing members are to be duly registered Medical Practitioners residing in the United Kingdom, and approved by the Board of Directors or Executive Committee, enrolled in the books of the Society as contributors to the sick fund for benefit. They must not be in active service or on full pay in the army or navy. They must be healthy; and must not have any organic disease, or predisposition to periodical or recurring attacks of illness, likely to incapacitate them from discharging their Professional duties. A candidate for admission as a contributing member is to be required to fill up an examination paper (resembling those of insurance companies) and to obtain a certificate of health from two registered Medical Practitioners; and also to sign a declaration of the truth of the statements made on the examination paper. These being found satisfactory, he is to be admitted by the Executive Committee, and duly enrolled. Any contributing member obtaining admission by means of false statements is to be expelled if the fraud be proved by investigation within twelve months from his admission, and will thereon forfeit all interest in the society. The annual contributions are to be paid within a fixed time; and any member not doing so will be suspended from receiving benefit; but the suspension may be removed if the arrears are paid within a certain period, and a certificate of health is produced. Members who have been struck off in consequence of not paying their subscriptions may be again admitted on complying with the rules for original admission. The funds of the Society are to consist of an Auxiliary Fund, a Sick Fund, and a Management Expense Fund, of each of which a distinct account is kept. The Sick Fund, or a competent part thereof, is to be from time to time applied, as occasion shall require, for the benefit of such of the contributing members respectively as shall have conformed to the rules of the Society, and who, suffering from sickness or casualty, may be unable to follow their usual Professional occupation; but no member is to be entitled to claim benefit in consequence of infirmity. Every contributing member who has been enrolled a member of this Society upwards of twelve months, and who has paid his annual contributions, shall be entitled to receive, during the first twenty-six weeks of his illness, £2 per week; and if his illness continue longer than twenty-six weeks, he shall then be entitled to receive £1 per week. The affairs of the Society are to be managed by a board of directors, elected in part by the committee of council and the branches of the British Medical Association, and in part by those members who do not belong to the Association. The chairman and vice-chairman are to be elected by the British Medical Association at its annual meeting. The directors are to hold an annual meeting either in July in each year or at the time and place of the annual meeting of the British Medical Association, and are to meet at such other times as the business of the Society may render necessary. Provision is also made for calling special meetings of the board. A report is to be presented to the annual meeting of the British Medical Association. The directors are to elect a treasurer, secretary, trustees, and auditor; as well as an executive committee for carrying on the business of the Society. The special duties of the various officers are defined. Power is given to the Society to appoint agents in such localities as they may think fit; and they are instructed to appoint duly registered Practitioners to act as referees in cases demanding inquiry. After the appointment of Dr. Henry as Secretary, with a salary of £100 per annum, and some votes of thanks to Mr. Finlaison, the Actuary, Mr. Clay, and the Chairman, the meeting adjourned.

Conviction under the Health of Towns Act.—At the Thames police-court, on Saturday, January 28, Messrs. Alexander Scott Duncan and Joseph Stott Campbell, proprietors of the Albion Chemical Manufactory, Old Ford, Bow, appeared before Mr. Partridge to answer an information and summons exhibited by Mr. Edward Fulcher, sanitary inspector of the Board of Works for the Poplar district, for permitting a nuisance injurious to the health of the inhabitants of the neighbourhood to exist on their premises, and not using the best practical means for abating the nuisance. Dr. Thomas Ansell, Medical officer of the north district, Poplar, Board of Works, said he had visited the defendants' works with Dr. Letheby, and they had made a joint report. The defendants were manufacturers of sulphate of ammonia and carbonate of ammonia from ammoniacal liquor of gas-works, brought in covered tank barges alongside the works on the banks of the Lea river. The liquor was pumped from the barges into a large tank on the upper floor of the building. This tank was about sixty-two feet long, seven feet wide, and two feet six inches in depth. It was capable of holding 6500 gallons of liquor. The tank was covered, and everywhere air-tight as far as could be perceived, except at the opening, where the liquor was pumped into it, and here the offensive effluvium from the liquor could, and no doubt did, escape at the time of filling the tank. The liquor was pumped from the store

tank into two tanks on the same floor, or run into a tank on the ground floor, where it was saturated with sulphuric acid. Each of those tanks would hold about 3000 gallons of liquor, and at the time of its being saturated with sulphuric acid it evolved abundance of sulphuretted hydrogen, which was conveyed by an iron pipe to a furnace, where it was burnt. While the process of saturation with acid was going on, the vapour of ammonia and sulphuretted hydrogen and steam was conveyed into the saturating tank from a charge of ammoniacal liquor contained in a boiler heated by steam or by a fire, and as soon as the liquor was saturated it was run off by a syphon into evaporating troughs, situated on the ground-floor of the building. This was being done at the time of his visit, and he and Dr. Letheby ascertained that the hot saturated liquor was evolving abundance of sulphuretted hydrogen, which escaped freely into the open air. The quantity of sulphuretted hydrogen so evolved was sufficient to blacken lead paper he prepared as a test in a minute. The vapours were poisonous and injurious to health when evolved, depressed the nervous system, and produced nausea, headache, loss of appetite, and general debility. The best means had not been used to abate the nuisance. He had visited the works that day. The manufactory was not in operation; alterations were being made, and the saturating tanks were being cleaned out, with a view of carrying out the suggestions of himself and Dr. Letheby. After the several witnesses had been called to prove that their health and that of their families was injured by the works in question, Mr. Partridge said it was proved by clear and most indisputable evidence that the defendants' factory was a nuisance and injurious to health, and that the best practicable means had not been used to abate the nuisance. He fined the defendants £5, with two guineas costs.

Number of Doctors in Medicine in France.—M. Bonjean, in the *Journal de la Soc. de Statistique*, gives the following as the number of the persons to whom Doctors' degrees were granted in France between the years 1795—1863:—By the faculty of Paris, 16,043; of Montpellier, 6820; of Strasburgh, 1800; total, 24,663. According to an official statistical inquiry made by the French Government, in 1861, there were then practising in France 11,546 Doctors of Medicine, and 5687 *officiers de santé;* giving a total of 17,233 Practitioners. It is thought that 18,000 Practitioners, in round numbers, may amply suffice for the wants of the population; and the question is, how many need to be annually admitted to keep up this number. Very discrepant accounts have been published as to the annual mortality among French Medical men, varying from 1 in 56 to 1 in 30, and requiring recruitals to the amount of 321 or 600. The mean of these numbers—460—would seem to be pretty near the truth, and is, in effect, the figure arrived at by M. Salvandy by a separate calculation. As to the question whether, in the present tendencies of the middle classes, these numbers will be supplied, it is to be observed that during the ten years 1853-62 there had been 408 Doctors' diplomas annually recorded—furnishing the required number all but by 5; and that without counting the *officiers de santé*, a grade which Medical reformers are seeking to abolish.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

H. O.—The paper is intended for publication, and will appear shortly.

Douglas, Isle of Man.—You had better apply to the author of the paper.

Hope (Micheldever) will find relief from a tonic *régime* prescribed by any Practitioner of experience.

An Invalid can consult either of the Surgeons he names with entire confidence.

G. (Stoke Newington) should apply to Dr. Robert Barnes, President of the Obstetrical Society.

Our notice of the *Drainage Difficulties at Bournemouth* is unavoidably delayed by want of space.

We shall, as soon as possible, give an article, or short series of articles, on *Modern Dermatology* (or *Dermopathy*, or *Dermotherapia*), in which the recent works of Erasmus Wilson, Mr. Williams Williams, Dr. Squire, Dr. Hillier, Dr. Frazer, and Dr. Tilbury Fox shall be dualised.

M.D., Dublin.—Dr. Theodore Goulston was the founder of the lectures bearing his name, for which he left £200 to the College of Physicians. He died in 1632.

West London Association for the Suppression of Public Immorality.—We believe that Sir Richard Mayne is right in his law, and we regret it. The whole subject of prostitution must come under review shortly, and some effective law be framed for freeing our streets from congregations of prostitutes, as they have been freed from assemblies of betting men.

Vaccine Virus.—Yes; Baron Dimsdale represented Hertford in Parliament in 1780, and again in 1784. He was created a Baron of the Russian Empire, with a pension of £500 per annum and a present of £12,000, for his successful inoculation of the Empress and her son.

Mr. B. T. Lowne writes very angrily, but all that he says strengthens what we have before said. We said that he did not consult the Physicians and Surgeons of the Farringdon Dispensary, and that he did consult the Honorary Secretary of the institution, who is a potato dealer. Mr. Lowne says the same. Mr. Lowne says "I simply called Mr. Shuter to see Daly, that he might hear the poor man's statement of the treatment he had received in the workhouse, and so relieve my mind from the terrible responsibility of knowing of such a case and keeping it a secret." We say this is just what we accuse Mr. Lowne of doing—of not calling in the Medical officers, his superiors, who ought to have been consulted, and of bringing in the potato dealer, who had no right whatever in a sick room.

Medical versus Legal Coroners.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—We need a stroke from your powerful pen on the old subject, "Medical *versus* Legal Coroners." Our coroner (Mr. Cooper, Surgeon) has just died, and we expect a great fight for the vacant office. Amongst the candidates are two lawyers and, I am happy to say, a Surgeon (Mr. Garrington), who has the entire confidence of his brother Practitioners. Having been mayor of the borough, at present wearing the aldermanic gown, and being, moreover, J.P. (made so by petition of the inhabitants to the Lord Chancellor ten years ago), universally respected and esteemed as a man of integrity and sound judgment, we feel a more eligible man could not be found to fill so important an office. I am, &c.

One of the Medical Practitioners of Portsmouth.

Portsmouth, January 31.

Pryce *v.* Bowen.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I wish to inform the members of the Profession that sufficient contributions have been raised to enable Dr. Bowen to defray the legal expenses incurred by the late trial, Pryce *v.* Bowen.

I am, &c. H. D. Scholfield, M.D., Treasurer.

14, Hamilton-square, January 31.

Further contributions to the Bowen Fund:—Preston, per Dr. Hammond, £17 16s. 6d.; Dr. Waters, Chester, £5 5s.; Dr. Stevenson, Birkenhead, £5; Mr. Mallock, chemist, Birkenhead, 10s. 6d.; J. Bontflower, Esq., Manchester, £1 1s.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I shall feel greatly obliged if you will publish the following additional list of subscribers to the Bowen Fund in the next issue of the *Medical Times and Gazette*:—James Hall, Esq., Preston, £1 1s.; W. H. Spencer, Esq., Preston, £1 1s.; E. L. Dixon, Esq., Preston, £1 1s.; Dr. Arminson, Preston, 10s. 6d.; Dr. Marshall, Preston, 10s. 6d.; J. Rigby, Esq., Preston, 10s.; Dr. Gradwell, Lytham, 10s. 6d.

I am, &c. J. H. Hammond.

Winckley-square, Preston, January 31.

Diabetic Dietary—Potato Gluten.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—In the interesting and singularly full diabetic dietary by Professor Bouchardat, cited in Dr. B. Jones's Lecture in your last, I see no mention in the list of permitted articles of the gluten of potatoes. Potatoes in their ordinary state are very properly placed in the list of prohibited articles. I am in the habit myself, however, of ordering potato gluten in diabetic cases. I did so in the case of a diabetic patient whom I saw for the second time yesterday. The case was that of a poor farmer. There is nothing peculiar about it. There is a very copious emission of highly saccharine urine. The habits of the poorer classes in the country here render the employment of potato gluten comparatively easy. I directed my patient then to discontinue baker's bread and to substitute "boxty." I also recommended eggs and boiled fish, along with butcher's meat, as often as he could procure it. I made him clothe in flannel, and directed the occasional use of a hot air bath, bricks being heated in a common fire for the purpose.

The country people prepare for laundry purposes potato starch. Raw potatoes are peeled, grated, and washed. The gratings from which the boxty cake is made remain in the colander, while the starch passes through. This boxty cake, which I beg to commend to the notice of the Profession, has a peculiar but not unpleasant flavour. I remember to have partaken of it in the country while a child, in one of the houses of the peasantry. Grated potato might be readily dried and converted into gluten flour. If ground after being cooked it would answer nicely to thicken soup or custard, and might even help as part ingredient in a pancake. Flour gluten, however, can be prepared at any time by kneading dough in water. But when good potatoes can be obtained I would strongly commend the boxty bread, if only as a change. I am, &c.

Belfast, January 29. Henry MacCormac, M.D.

The Indian Medical Service.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I read with great pleasure the admirable letter in your last number signed "An Indian Surgeon," which I beg to endorse; and the only regret is that others do not come forward and give their opinion before it is too late.

You say the Court of Directors dispensed with the services of their

Medical officers "without scruple when occasion required," whereas the very opposite was the case, the Court of Directors invariably directing that their officers should be tried by Court Martial, and in the case of Captain B. (connected with the mutiny in the 6th Madras Cavalry), who was tried by Court Martial, but whose sentence was not satisfactory to the Commander-in-Chief, who wrote to the Court of Directors not to confirm it, but to dispense with his services, to their honour be it said, they declined to interfere with the sentence of the Court Martial, and ordered it to be carried out. And now the strange part remains to be told. Lord Tweedale was so annoyed at his advice being declined, that he virtually forgave the officer.

As I was at Madras at the time the services of the Medical officer you allude to were dispensed with, I must inform you that you are wrong in your statement as to his case not being cognisable by Court Martial: the Commander-in-Chief stated that he could be brought to trial by Court Martial, but as it would entail great expense, the witnesses being in England, he advised his services being dispensed with. I should say, the Court of Directors sent him out from England with orders to have him tried, and it was only after months of correspondence they acted on the advice of the Commander-in-Chief, and it was very seldom they exercised this prerogative, as there was a mutual covenant between the Company and their officers, under which they could not be put on half-pay, as in the British service, on the reduction of the army. Had this not been the case, the Indian Secretary would long since have put hundreds of officers on half-pay, so anxious was he to get rid of them; but he had to give large bonuses, in the shape of increased pensions, to induce some to retire. The Medical officers alone got nothing, as they have no one to fight their battles; even their own journals, instead of taking their part, raise their voice against them, as witness your last editorial, where you write of our "discontent being chronic." But journalists who profess to instruct the public should be more cautious in their assertions. Have you compared the so-called advantages of this despatch (for it is not a Warrant, which makes a great difference) with the privileges and pensions under the Company? If you do, you will find that, though we under the Company grumbled, yet we were far better off than those will be who enter under Sir C. Wood's despatch, which, as your correspondent states, gives "no guarantee for anything."

You say, "all the civil and other European charges at the Presidencies remain intact." Will you read Section 20 of the despatch, and then say if you still adhere to your statement? You cannot, for Sir C. Wood distinctly orders "uncovenanted members" to be employed; and when this is done at the Presidencies and civil stations, it will be in his power to place the Medical officers he may not want on half-pay. And is a good opening for young men to get private practice in India?

That there have been complaints of the seniority system in India I will not deny, but upon what grounds I never could ascertain. You write as if you supposed the duties of a Deputy-Inspector of Hospitals required great Medical talent; on the contrary, their duty is to audit and check the expenditure in Hospitals—in fact, they are commissariat officers, their whole time occupied in useless correspondence regarding the extra expenditure of perhaps a quarter of an ounce of lamp-wick, washing, or a few limes. They visit Hospitals at head-quarter stations once a week; and it is true their advice may be asked in important cases, and we are ordered to do so; but from the date of their appointment they may put their talents to grass.

Your remarks on the Medical Funds are wholly inexcusable; any Medical officer could tell you they were the great boons of the Company's service, and not to be compared with insurance offices for a moment. That the Bengal and Bombay Medical Funds are not what they were or should be is no fault of the Company. I give you particulars of the Madras Medical Fund, which was established in 1807, and consists of three branches—viz., annuity, charity, and sick allowances. "The annuity" gives £400 a-year, according to seniority, to members who have served for a pension. (To those who leave the service from ill health before completing their service their subscriptions are returned.) For this annuity we pay £1200 by monthly deductions from our pay. "The charity" branch gives pensions to widows of £228 11s. 5d. a-year, and to children, according to age, from £20 to £70 17s. 1d. (the latter beginning at 11) a-year, to boys till 21, and to girls till death or marriage, with reversionary benefit in the event of widowhood. And for these we pay according to age, thus:—I married at the age of 28, and paid £370, which secures a pension as above to my wife. At the birth of my last child (a girl) I was 46, and paid £88 16s. to secure a pension as above to my daughter. "The sick allowance" branch gave, when on sick leave to Europe, £108 7s. 6d. a-year to Surgeons, and £81 7s. 6d. a-year to Assistant-Surgeons for three years. For this we paid £200 by monthly deductions from our pay. Now, Sir, will you tell me the insurance office that will give the same advantages for the same money? If you do, I promise to pay to any charity you name the sum of £50. I am often surprised at the public ignorance on subjects connected with India, but I was not prepared for the amount of ignorance shown by Medical journalists during the discussion of this subject. And yet the editors do not fail to lash the writer who asserts anything contrary to their preconceived notions. How could you have read Section 27 of the despatch as still giving staff salaries? It says distinctly "in future, the salaries being in all cases consolidated;" and the next section gives the amount of the consolidated salary for each rank. Heretofore we drew pay and allowances, with staff salary, according to the appointment we held. Thus, as regimental Surgeon, with a staff salary of 300 rupees a month, I have had charge of a garrison Surgeoncy, for which I got 500 rupees a month. All these extras are now abolished, and, no matter what the work is, pay is according to standing or rank.

In conclusion, I must say your last paragraph is in very bad taste; you have attempted to criticise your correspondent's letter without being well up in your subject. Nor have you shown the good points in the new service. The highest pension under the old rules was £700 a-year, with Medical Retiring Fund (at Madras £400); under the new rules the highest pension is £550. I leave your readers to draw the conclusion which is best.

I am, &c.

January, 1865. ANOTHER INDIAN SURGEON.

P.S. Since writing the above I have read in your last number Dr. F. Bowen's interpretation of the 27th Section of Sir C. Wood's despatch, which was as much a surprise as the interpretation you gave; and as to an allowance of 100 rupees per mensem for Divisional Staff, it is the first time, after twenty-two years' service, that I heard of it. I have had charge of divisional and brigade staffs on more occasions than one, and never received more than 30 rupees a month; nor have I seen the pay code that authorises more. The words of the Section are plain—"the salaries being in all cases consolidated."

APPOINTMENTS FOR THE WEEK.

February 4. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Marshall, "On the Nervous System."

6. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

EPIDEMIOLOGICAL SOCIETY, 8 p.m. Dr. Babington, "Suggestions for the Diminution of Venereal Disease among the Civil Population."

MEDICAL SOCIETY OF LONDON, 8 p.m. E. Symes Thompson, M.D., "Notes on Cases of Tumour in the Mediastrium." Mr. Teevan, "On Certain Fractures of the Skull."

ROYAL INSTITUTION, 2 p.m. General Monthly Meeting of Members.

7. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ETHNOLOGICAL SOCIETY OF LONDON, 8 p.m. Professor Busk, F.R.S., "On Human Remains from Gibraltar."

PATHOLOGICAL SOCIETY, 8 p.m. Meeting.

ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, F.R.S., "On Electricity."

8. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

HUNTERIAN SOCIETY, 7 p.m. Annual General Meeting. 8 p.m.—Annual Oration, by Mr. Hutchinson.

MEDICAL SOCIETY OF LONDON, 8½ p.m. Lettsomian Lectures—Lecture I. "On Some Points connected with Fistula in Ano," by Henry Smith, Esq., F.R.C.S.

9. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, F.R.S., "On Electricity."

10. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

HUNTERIAN SOCIETY, 6 p.m. Annual Dinner.

ROYAL INSTITUTION, 8 p.m. W. G. Palgrave, Esq., "On Arabia."

ORIGINAL LECTURES.

LECTURE ON THE RESULTS OF THE SURGICAL TREATMENT OF CANCER.

By T. SPENCER WELLS, F.R.C.S.,
Surgeon in Ordinary to Her Majesty's Household.

GENTLEMEN,—Perhaps there is no question which more frequently arises in practice, or which is answered with so much doubt and hesitation, as the question, "Should a cancer be removed?" At one time removal was the general rule of practice. Then the frequency of return after removal, and the revival of the humoral or chemical pathology, led to the rule only to operate in exceptional cases. It was asserted that by removal of a cancer in the early stage we only removed one seat of deposit, left the blood unaltered, encouraged deposit in some other part, and so did more harm than good, often shortening life. Therefore it came to be a sort of rule of this school not to attempt to remove or destroy a cancerous tumour, unless it was either actually ulcerated, or growing so fast that the skin was about to give way, or the destruction of some vital part was threatened. It was urged that growths, having all the characters of cancer, occasionally disappeared under the influence of hygienic or Medical treatment—that other such growths have sometimes remained completely dormant for many years without injuring the health or shortening the life of the individual—and that it was absurd to say the disease was not cancerous in such cases because the patient recovered, or lived to old age unaffected by the local disease. But the most determined leaders of this school admitted that in cases where an open cancer gives great pain, and is wearing away the patient by bleeding or profuse discharge, this cancer should be removed, in the hope first of relieving suffering, and secondly, of prolonging, though not of saving life. In some other cases where a cancer caused great mental anxiety to a patient, it was to be removed at her earnest entreaty, after fairly explaining the probability of a return of the disease. For many years these rules were followed in practice, and are so still by many excellent Surgeons. But during the last four years a marked change has been taking place, and the Professional mind is still in a state of transition. The transudation hypothesis is falling before the cellular theory. The belief that cancer is always a disease of the blood is severely shaken by the vigorous attacks of Virchow, and the positive and visible demonstration which he affords of the local origin of morbid growths, and the secondary contamination of neighbouring parts and of the blood by extension and by absorption of the products of local disease. He has gone very far towards proving that the cells of the connective tissue (commonly known as cellular or areolar tissue) are the ovules of cancerous growths, as they are of all the new cellular productions. We are still ignorant of the nature of the peculiar change or irritation which, in the first instance, alters a connective tissue cell into a cancer cell; but when once this change has taken place, and the altered cells begin to grow and multiply by division, we have clearly a focus both of local and general contamination—local, by imbibition of the fluid formed by the diseased cells into the healthy cells of adjacent tissues; and general, by absorption or transudation of the morbid products through the lymphatics and veins. Thus the harder the tumour, the less likely to spread; the softer, the more likely both to spread locally and to contaminate the blood. The direct and necessary practical deduction for the Surgeon from these views is, that all malignant growths should be removed in their earliest possible stage—as soon, in fact, as their nature is ascertained; and to this rule Surgeons seem to be partially, though perhaps unconsciously, returning.

It requires the observation, and careful observation, of many years, and of many independent observers, to settle such a point as this; but a great deal has been done to show, by comparing a large number of cases of cancer where removal has been practised with others where the patient has been left without operation, that the average duration of life in the patient operated on is decidedly lengthened. No trustworthy data exist for making such a comparison with cases in which the tumour was removed at a very early stage; but my own experience is leading me to adopt the rule deduced from the pathology of Virchow. I have had several cases since the publication of my pamphlet on "*Cancer Curers*," in which I have excised growths which microscopic examination has proved to be truly cancerous, and in which no return has yet been observed. The time is obviously too short to speak of them as permanent cures—indeed, it is almost certain that in nearly all there will, sooner or later, be a return; but the result has satisfied me that the rule of practice most commonly followed may be advantageously modified in cases where the disease is in a very early stage. The operation at that stage is a very trifling one, is perfectly painless under chloroform; and so little necessity does there appear to be to keep patients to their rooms, that I have both in private practice and among Hospital out-patients allowed them to come backwards and forwards from their homes. Supposing the general health to improve, and the cause which led to the first change in the connective tissue cells should not operate again, then *removal* really becomes *cure*.

If the teaching of Virchow, the greatest of living pathologists, be true—if the belief in the universal constitutional origin of cancerous tumours be unfounded—if the constitutional disease is, even in some few cases, secondary, the morbid condition of the blood originating in, and being kept up by, a supply of hurtful ingredients from some diseased locality—how hopefully may both Surgeon and patient look upon the treatment of cancer in its early stages, before the germs have spread into neighbouring tissues, before they or any irritating fluid have been conveyed to a distance, before the healthy cells of neighbouring parts have imbibed by endosmosis the specific or parenchymatous fluid, or this fluid has been carried by lymphatics or veins to distant parts. And, on the other hand, how fearful is the responsibility of the cancer curer who tampers with the life of the poor sufferer who has confided in his knowledge and skill! If he attempt to procure absorption of the tumour and succeed, he may produce the general contamination of the blood of which the growth itself was erroneously regarded simply as an "outward and visible sign." If he fail, he still gives time for the growth of germs, and for extension first locally and then by absorption. If he employ caustics, he may be adopting the very practice of all others most likely to lead to a rapid and general development of cancer throughout the body, by hastening softening of the growth, setting up irritation in neighbouring parts, and assisting the transmigration of cancer cells through the blood to distant parts of the body.

The fact that *removal* may really result in *cure*—that the disease may not return—should certainly encourage both patient and Surgeon to think of removal in any case where the whole of the diseased part can be removed without unusual risk or difficulty; but it would be very wrong to conceal from any patient the fact that this happy result is extremely rare, and that, except under very unusual circumstances, no more can be expected from removal than prolongation of life and diminution of suffering.

That *life is prolonged* by removal is now satisfactorily established by statistics. The results of different statistical tables vary. But those most to be relied on tend to prove that the average duration of life in those operated on is certainly greater than in those in whom the disease is allowed to run its course without operation. In a valuable lecture, published in the *Medical Times and Gazette* in 1862, Mr. Paget says, "In a recent tabulation of Hospital and private cases, 85 cases operated on lived an average of 55-6 months, and 62 cases not operated on lived an average of 43 months. And some such proportion as this will probably always be found."

Not only is life prolonged, but *suffering is lessened*. The amount of suffering, mental and bodily, of a patient during the ordinary course of cancer is very great. "Consider," says Mr. Paget, "the pain and anxiety—the pain likely to increase daily—the misery of waking every day to the consciousness of an incurable disease; the sometimes loathsomeness; the restlessness for cure—cure, such as there are *never wanting dishonest men to promise.*" By an operation painless under chloroform, and not followed by painful dressings, this constant, daily, weary pain is relieved for a time, and the patient is also restored to a state of mental comfort which is as great a gain as the relief from pain. In some cases, where there is no hope of prolonging life, the pain and suffering from an open cancer are so great that it is right to operate simply to obtain for the patient a comparatively painless death.

If, then, the oft-repeated objection to operation—that life is not lengthened but shortened—is satisfactorily answered; if we also dismiss as unproved, and certainly erroneous, the suggestion that when the disease returns it will be in a more aggravated form than if the disease had run its own course,

the question arises, "Why not operate in every case?" And the answer is ready, "Because the operation is one attended with risk to life." In some cases this risk is very great, in others very small; but taking the average of some hundreds of cases, Mr. Paget estimates that "a patient runs a risk of 1 in 10 of dying" from the operation. Others estimate the risk as low as 5 per cent., or 1 in 20.

In a consultation, however, upon any individual case, neither patient nor Surgeon will be content with a mere statement of averages. It is seen at once, as from 1 in 20 to 1 in 10 die of the immediate effects of the operation, and the average life of those operated on is over 55 months, that some patients must live many years. And the questions which are asked are not: What are the *general* results of operation? How long do people *in general* live after it? How soon does the disease *generally* return after operation? but the individual case is pressed home: What risk would there be to *my* life? How long should *I* be likely to live? How soon might *I* expect a return of the disease?

It is said, and said truly, that general conclusions can only be drawn from general averages. Mr. Paget says—"To deal with single cases is a sort of Surgical gambling." The gamblers, however, are they who operate in nearly every case which comes before them and they who operate in none, both classes satisfying themselves by statistical tables and general averages, rather than by forming a careful estimate of the probable results of treatment in each case. Each case must be considered by the light of general experience, but it is no less in itself a subject for separate calculation. And in every case which comes before us we must be guided by certain general rules, the most important of which may be shortly summed up as follows:—

Risk of Removal.—The average mortality being from 5 to 10 per cent., in what cases is the risk above and in what below the average? Supposing the patient to be placed under the most favourable circumstances possible to prevent the occurrence of erysipelas, pyæmia, any form of septicæmia, or secondary hæmorrhage (the chief causes of death *soon* after operation) the probable liability of any patient to these dangers may be estimated by observing certain general and local conditions. The *general* conditions favourable to operation, or those which may fairly justify the hope that a patient will not die from its effects, are that she is not more than 60 years of age, not emaciated, is well-nourished, clear-complexioned, temperate, courageous and even-minded, and free from other organic disease. The reverse conditions are seen in patients over 60 years of age—in over or under fed people—the emaciated, or the fat and plethoric—those of cachectic, leukæmic, or chloro-anæmic aspect—the dejected or hysterical—and they who, in addition to the cancer, have some organic disease of heart, lungs, liver, or spleen. The favourable *local* conditions are that the skin over and near the tumour is soft and healthy, free from œdema, freely moveable, and free from scattered nodules of cancer—that there are no diseased cervical glands—none, or few, diseased axillary glands—that the breast is small—that only one breast is diseased—and, if only part of one be affected, that this is the lower part. The unfavourable local conditions are that the skin is brawny, the hair-follicles large and open, the skin over the tumour adherent, that there are scattered cancerous tubercles in the skin, that the supra-clavicular glands are swollen, that there are many diseased axillary glands, that the breasts are large, that both are diseased, or, if only part of one, that it is the upper part.

By bearing these things in mind it is not difficult so to select cases as to reduce the risk of removal to a very low average, and there can be no difficulty in deciding in any case whether the risk is greater or less than the average.

When part of one breast only is affected, the rule generally followed is to remove the whole breast; and this rule is a good one if the breast is small. But when only a small portion of a large breast is affected, it is much less dangerous and equally effectual to remove the diseased part and some of the surrounding healthy tissue, than to remove the whole breast. There is good reason to believe that the disease is as long in returning when only the diseased part has been removed, as when the whole breast is removed.

When it has been decided to remove cancer, the question will arise, "Should it be removed by the knife, or by caustic?" And the answer must be framed again upon full consideration of all the circumstances of each case, but guided by the following general rules:—

1. There is no proof whatever that the return of cancer after removal by caustic is less rapid than after removal by the knife. On the contrary, it is probable that the return will be more rapid, (*a*) from the greater probability that some portion of the cancer will escape the action of the caustic than the dissection of a careful Surgeon; (*b*) from the inflammation set up in the surrounding tissues and the irritation of neighbouring glands.

2. Admitting that the immediate risk to life from the removal by caustics may be less than after removal by the knife—in other words, that pyæmia and hæmorrhage are less likely to occur—we have abundant proof that the risk is very considerable, and that the intense and long-continued suffering does in itself lead to exhaustion and death.

3. It is possible that the attempt to remove a cancer by caustics may fail altogether, that the irritation set up in the diseased growth and in the parts surrounding it, or the extension of the sloughing to vital parts in the neighbourhood, may destroy the patient before the cancer is destroyed.

These objections will generally lead the Surgeon to advise the patient rather to submit to excision than to caustics. But in some cases, where the situation of the growth is such that the knife cannot be used safely, caustics are decidedly preferable, as they are also in cases where the growth is small, or of moderate size, and slow in its progress, while the unhealthy general condition of the patient would render the knife more than usually hazardous; for, as Mr. Paget has said, "the constitutional maladies that greatly increase the risk of cutting, do not, except very rarely, increase the risk of caustics." There are also some cases of open cancer in a very late stage of the disease, so adherent that the knife could not be safely used, where the diseased part may be completely destroyed by caustic, and a sound cicatrix may result. Sometimes it may be well to leave the choice to a patient, after representing to her fairly the advantages of the two methods. Some may be guided by the dread of the knife, others more by the dread of pain, and it is right to allow these fears their full weight.

The cases decidedly unfit for caustics are those of acute or rapidly-growing cancer, or those of large size, and those where there is an œdematous, brawny, or tuberculated or ulcerated condition of the surrounding skin, and those where the supra-clavicular or axillary glands are enlarged and indurated. And most of the conditions which on general grounds forbid the use of the knife also forbid the use of caustic.

Supposing it to be decided to destroy a cancerous tumour by caustic, all the evidence before us goes to prove the chloride of zinc to be the most effectual and safest yet employed; that it is a matter of great indifference whether it is employed as a paste or in solution; but that its action is considerably hastened by scoring through the slough, as Justamond did, down to the living tissues beneath, so that they are not protected by the slough from the action of the caustic. This scoring is not so necessary when the chloride is used in solution as when it is used as paste, after destroying the skin by nitric acid; and it is not at all necessary if one or more pairs of galvanic plates are used as the caustic. If a piece of zinc be placed on any raw surface, and a piece of silver near it, a silver wire connecting the two, the part covered by the zinc is destroyed very rapidly, and the slough formed is a very soft one, which is easily sponged away. I saw a lady in 1854, with Dr. Lawrence, of Connaught-square, suffering from cancer of the breast, and we decided, on consultation, to adopt this method, which Dr. Lawrence carried out most effectually. I should not be at all surprised to hear that the next great empiric who appears in London will profess to cure cancer by galvanism.

Occasionally it is advisable to apply the actual cautery instead of using caustic, and I have recently found the use of a small jet of lighted gas, by means of the instrument made by Mathieu for M. Nélaton, very efficacious. It is much more easily arranged than the galvanic cautery, is equally manageable, and has the great advantage of destroying parts without touching them; so that there is no fear of the eschar adhering to the metal, being removed as the metal is withdrawn, and bleeding thus being set up. In cancer of the upper jaw, or base of the skull, which project into the mouth, very great temporary relief is gained, even if only a partial destruction of the growth can be effected.

When removal cannot be recommended either by the knife or by caustics, it must be remembered that we can do a great deal more towards arresting, even curing cancer, than is generally believed—that our art is not nearly so powerless as charlatans assert. Growths with all the characters of cancer have occasionally, although very rarely, disappeared under the influence of remedies. Other such growths have remained com-

pletely dormant for many years, without affecting the health or shortening the life of the individual; and it is absurd to say that the disease was not cancerous in such cases because the patient recovered, or lived to old age unaffected by the local condition.

ORIGINAL COMMUNICATIONS.

RATIONALISM AND EMPIRICISM IN MEDICINE.

By J. STEVENSON BUSHNAN, M.D.,
Fellow of the Royal College of Physicians of Edinburgh, Resident-Physician Laverstock House Asylum, Salisbury, etc., etc.

It is a singular proof of the slow progress of Medicine as a science, that the controversy which arose among the Greek Physicians between two and three thousand years ago, known as that between the empirics and dogmatics, still exists. As it seems to me, this requires to be fully understood by all who desire to penetrate into the real character of Medical science and Medical practice. The modern Medical world is indebted to Celsus for a succinct summary of the arguments employed in ancient times by the contending parties. There are also due to Celsus certain views which constitute the foundation of a middle course between the two original extremes of the controversy such as in recent times has been known under the name of the "empirico-rational, or the rational empirical."

There would not, however, be much profit afforded to a modern audience by a detail of the several particulars made use of by Celsus to illustrate the differences between the empirical and the rational, or to bring out his ideas regarding an intermediate empirico-rationalism or rational empiricism, since that which in ancient times was regarded as physiology and pathology represents only in a very remote degree the physiology and pathology of the present day. The rationalist of modern times would not regard his cause as in any degree promoted by a recital of the grounds on which, in the age of Celsus, it was argued that the treatment of diseases should essentially rest on theory or principle. Here the empirical Physician has the advantage, for he may still adopt the arguments recited by Celsus in behalf of the empirical as bearing on that view of Medicine which he has embraced. Moreover, he may insist on putting this posing question to an opponent upholding the rational—namely, Would not a rationalist two thousand years hence regard your physiology and pathology as no more fit to found the treatment of diseases upon than you consider what was called physiology and pathology in the days of Celsus adequate to that object? No thinking man could venture to give an absolute negative to this question. He might no doubt point out that many of the natural actions which the empiricist in the age of Celsus held to be inscrutable have been since sufficiently laid open so as to afford explanations of certain parts of the treatment in diseases; and he might thence infer that at the distant future referred to other natural actions, now imperfectly understood, would then be so known as still further to render theory available for the foundation of practice. But in this argument the rationalist has taken a lower stand, and has identified himself with the supporter of the middle course referred to above as empirico-rationalism or rational empiricism; not to mention that in this argument the assumption is made of the impossibility of physiology and pathology retrograding from the height on which these sciences unquestionably stand at present.

Nevertheless, in presenting such a view of the empirical, the rational, and the empirico-rational, as belongs to the actual state of Medicine, it is of consequence, for many reasons, to preserve as far as possible the original limits pertaining to these three several aspects of the whole body of Medicine.

For this purpose a slight notice of some of the leading points in the survey taken by Celsus of this celebrated controversy will not be out of place by way of introduction to the subject to be treated of.

In the first place, then, it is to be remarked that in the account which Celsus gives of rationalism he takes care to make it appear that the rationalist does not neglect experience. On the contrary, he represents him as regarding experience as ineffectual without the previous knowledge of what constitutes theory or principle. He says "Practice is not sufficient unless the constitution of bodies and things be known." In another passage he points to the still more explicit limitation of the doctrine of the rationalists. He says, "Nor do they deny that experiments also are necessary, but they contend that not even access can be had to these unless from some theory." Again, he shows the rationalist view as teaching that experience is essential to establish the truth of what principle had suggested. "The more ancient Practitioners did not prescribe at hazard anything for their patients, but considered what would suit them best, and examined that by experience, to which some conjecture had previously led them."

It may be said, then, that according to the light in which Celsus exhibits rationalism, it includes all that the empirical view requires, while it seeks theory or principle to be superadded. If it were true that this is rationalism in its reality, and that it had preserved this character through all past ages, no excuse could be made to raise a finger against its pretensions. But it will be found that the history of rationalism is far from confirming this favourable idea of its character. It may be the case, however, that the mischiefs of which it has been the source are solely the result of an abuse of its principles.

The empirical does not by any means make so favourable a figure in the hands of Celsus. He represents the idea of the empiricists as to Medical inquiry as similar to that of the barbarian Mussulman as to other books besides the Koran. "They ask," says he, "whether theory teaches the same thing as experience or another; if the same, that it is needless; if different, that it is even mischievous." In short, it does not appear that in the time of Celsus the empiricists had any idea of an ulterior improvement and progress in human knowledge, whether relating to Medicine, or to any department of the knowledge of nature. They gave attention to the evident causes of diseases, because it was necessary to teach men to avoid these; but they held it to be superfluous to inquire into the concealed causes of diseases and the natural actions of the body, because a knowledge of these is unattainable. "They contend, he says, "that an investigation of the obscure causes and natural actions is fruitless, because nature is incomprehensible. But that it cannot be comprehended is evident, from the discord of those who have disputed concerning these things; since it is not agreed upon concerning that matter, either among the professors of philosophy or among Physicians themselves."

The frequent coincidence between theory and practice they held to be of very easy explanation—namely, that remedies were first of all discovered by experience, and that after this discovery men set about finding a reason why these remedies should succeed. "Not that medicines were discovered after theory, but that theory was sought for after medicines were discovered."

In the view which Celsus takes of the middle course which he recommends between the extreme opinions respectively held by the empiricists and rationalists there is great good sense. With respect to the causes which secure health and give origin to diseases, to the mode in which breathing and digestion are carried on, the professors of philosophy, he tells us, have not a clear understanding, but only a conjectural idea. But, he adds, when there is not a certain knowledge of an action, a theory of that action cannot suggest a certain remedy. On the other hand, he says there are many things not specially belonging to an art which are of much service, because they arouse the ingenuity of him who practises that art. It will be well to remember the maxim, "Itaquè ista quoque naturæ rerum contemplatio, quamvis non faciat medicum, aptiorem tamen medicinæ reddit;" the contemplation of the nature of bodies, although it may not make a Physician, yet it renders him more fitted for the practice of Medicine.

But not to dwell longer on the ancient views of this controversy, it is time to consider the place to be assigned in our own age to each of these doctrines—namely, the rational, the empirical, and the empirico-rational.

It is manifest that those who in modern times profess themselves rationalists give too great latitude to the term rational, and thereby thrust the empirical within too narrow limits. It is true, indeed, that, looking merely to the persuasion of the ancient empiricists, they obtain no small ground for that mode of proceeding; and were it incumbent on modern empiricists to adhere strictly to the opinions of their brethren in ancient times, the rationalists of modern date would possess an overwhelming advantage over their opponents. But th

controversy between the rationalists and empiricists is almost coeval with the origin of Medicine, and if it be not destined to continue as long as Medicine shall exist, it is at least certain that it will be prolonged far beyond the improvements so conspicuous in recent times; and it is therefore essential that the points in dispute should be from time to time modernised and made to accord with the advancing progress of Medicine. That the empiricist should reject the study of physiology and pathology does not any longer carry with it the necessity apparent in ancient times. Such studies he may insist on being conceded to him, not to teach him how to practise, but merely as a source of mental exercise and improvement in reference to the more nice appreciation of the phenomena of life. That this much must be conceded to the empiricist in the present day is evident from the undeniable fact that a preliminary education in anatomy, chemistry, and physiology is essential to every Medical man, whether he is thereafter to be governed in his views of practice by the tenets of rationalism or those of empiricism. The ancient persuasion of the empirico-rationalists, as represented by Celsus, is now undisputed and common alike to rationalism, empiricism, and empirico-rationalism. "And it is probable that Hippocrates and Erasistratus and others who, not satisfied with simply treating fevers or ulcers, inquired also to some extent into the nature of things, though not made Physicians by that means, yet became thereby better Physicians."

In the investigation of diseases it is not to be disputed that the empiricist is bound to bestow as much pains as the rationalist. The governing idea in the mind of the empiricist is that, having observed a remedy to produce a certain effect in one case, he is to lay up that fact in his memory till he meet with a case as nearly as possible identical with the first case, in which, and in which only, the remedy is to be again prescribed. The empiricist is not to be content with that identity of cases of disease which results from their bearing a common name. With the improved lights of modern times it is incumbent upon him to employ every means within his reach to distinguish from each other all the varieties of morbid action which fall under one name. Nay, he is not exempted any more than the rationalist from considering the same variety of disease as still farther varied by the peculiar temperament, habits, and constitution of the patient. Thus, it is imperative on the empiricist to apply himself equally with the rationalist to the study of the modifications produced on diseases by sex, age, temperament, mode of life, place of abode, and the like. No more has he license to dispense with the examination of the urine, blood, and other animal products by the microscope, or by reagents and other chemical means, or to neglect the search into the condition of inward parts by the aid of auscultation and percussion; for it is manifest that if the empiricist neglect any means of the kind just enumerated, he runs the risk of violating his fundamental principle, and employing a remedy in a case in which the whole circumstances were only apparently, but not really, the same as that in which its curative power was originally observed.

It is quite true that many who proclaim themselves rationalists at the present day claim to themselves the exclusive patronage of all the means of instruction just recounted, and seem to believe that their title to be called rationalists rests on the patronage so extended. Here they forget that the terms "empirical and rational" are not terms wholly peculiar to Medicine, that these terms are general terms applicable to numerous arts and pursuits, and that the signification of these terms cannot be limited by any views held of them in ancient times, when art and science in almost every department were in their first infancy. There are but few instances in which art did not precede science—that is to say, the empirical naturally first arises, and is succeeded by the rational. In other words, art is the foundation of science, while science, after its first advances, repays to art the debt which it had contracted. As knowledge advances, the aid which science affords to art is very variable in different cases; in proportion as any science attains exactness and perfection, in like measure the arts dependent on that science derive benefit, so that the empirical in them is apt to be lost sight of. In the sciences founded on the exact relations of number and quantity everything is rational, so that in the arts connected with these there is hardly room for the empirical—unless, perhaps, at their very first foundation. In the arts associated with chemistry there was at first a striking predominance of the empirical, which predominance has declined step by step in accordance with the approach of chemical science to a higher and higher degree of perfection. In Medicine, the sciences of physiology, pathology, and therapeutics have made very slow progress as compared with the advancement of many other departments of knowledge; hence the proportion of the empirical to the rational in the heart of Medicine is still very great, and must continue to be excessive so long as the sciences on which the art of Medicine rests remain in a backward state.

Thus, then, it is clear that, though the distinction of empirical and rational arose in ancient times, there is not a shadow of reason for retaining the exact same relation between these terms in the present day as prevailed in the distant ages referred to.

But in order to obtain a firmer hold of the general distinction between the empirical and the rational in subjects of human knowledge, it is necessary to contrast some acknowledged examples of the one with some equally acknowledged examples of the other.

When primitive man, after satisfying his hunger with the seeds of such common légumes as the pea, the bean, the lentil, observed that new plants sprung up where he had by chance dropped some of those seeds, he made an observation more important to him at that time than all the after philosophy of the schools. He now knew a fact by the empirical use of which he could raise a crop of such légumes, even where these did not spontaneously shoot up. If, on any after occasion, he put some of these seeds into dry sand instead of putting them into moist earth, he learned a negative fact, which taught him, with a kind of foretaste of science, yet still empirically, that he must attend to all the conditions present in the ground in which he had originally succeeded in getting a crop. If, again, he put the seeds in what appeared to be the same kind of soil in which he had raised a former crop, and yet no plants came up, or, coming up, soon perished without producing fruit, he ascribed his failure of success, not to the true cause, namely, the occult deficiency of the requisite materials in the soil, but to the evil agency of some angry demon. It is manifest that agriculture prosecuted in this fashion was carried on in a purely empirical manner; and yet, every now and then, its usages will be found to border on the rational. When men found that after successive crops had been taken from one field the following crops were deficient in that field, and observed also that a field recovered its original productiveness by lying fallow, they could not but attempt a theory to account for what was an undeniable truth. Accordingly, it is found to be a prevailing belief, even at present, among the peasantry, that there are occult qualities in the soil by which it is fitted for the successful production of different crops, and that these qualities being exhausted by a repetition of the same crop, time is required for the exhausted quality to be reproduced. Thus theory, though untrue, served the purpose of an explanation, and runs parallel in a very remarkable manner to the true theory. Again, when the ancient philosophers taught that fire, water, earth, and air, were the elements of the organic world, it is evident they made a very shrewd conjecture, or rather, it might be said, they reached the truth in distant general terms. But while such general explanations of the phenomena of living nature undeniably fell under the rational, they were not sufficiently close to the truth to afford any direct aid to the agriculturist. Thus all the improvements in agriculture in the early ages of its progress were derived from the empirical method. When the exact chemical composition of plants and animals came to be known, and that composition was found to correspond to the composition of air, water, and soil, then the foundation of a rational agriculture was laid. The distinction between the empirical and the rational might, in like manner, be traced through the useful arts in general, particularly through those dependent on chemical principles.

But to return to Medicine. The theory or science of Medicine is commonly reduced to the three heads Physiology, Pathology, and Therapeutics. Under physiology, of course, anatomy ranks. The object of physiology is to determine the laws of organic nature in the normal state. It is a very wide subject, but does not directly lead to the cure of disease, which is the sole object of Medicine. It is one of those departments of knowledge which do not make one a Physician, but which render one more fit to be a Physician. The same thing may be said of pathology, which has for its object to determine the character of deviations from the normal state of health, and the conditions under which such deviations occur. But while it is true that a man may be a pathologist without being a Physician, it is also beyond doubt that a man cannot be a Physician without being a pathologist; because a knowledge of pathology is essential to the discrimination of

the nicer shades of diseases. Still, neither physiology nor pathology constitute the true science of Medicine. The object of Medicine is to cure a disease when that disease has become known; which object can be accomplished only by therapeutics. When a man, then, boasts that he practises Medicine rationally, what ought to be understood is, that he learns to cure diseases from the science of therapeutics, or from that part of Medical science which determines the principles applicable to the restoration of health, when such deviations from the healthy state have arisen.

Such, then, is rational Medicine in the present day. There is nothing else that can be called rational Medicine, according to the current use of that term in all arts which rest on a scientific foundation.

To what extent, then, can Medicine be rational? Certainly only within narrow limits. It can be calculated how far a certain amount of gunpowder can project a shot of a given weight, and that calculation will remain the same for all like circumstances. It can be reckoned what quantity of a certain kind of coal used to convert water into steam will raise a given weight so many feet from the ground, and that reckoning will remain the same for all cases in which these circumstances are the same. But when the would-be rational Physician has ascertained how much fox-glove is required to bring down the pulse from 120 to 60 per minute in one individual under a particular disease, he has obtained no certainty that in the same individual at another time, under apparently the same circumstances, that effect will be produced by the use of exactly the same quantity of the drug as nearly as possible in the same manner; and the same thing is true of drugs in general. It is not, indeed, to be believed for a moment that effects are not uniformly proportioned to their causes in the organic world as certainly as in inorganic nature; but where the thing acted on varies, the cause, however much conforming to the same measure on each successive occasion, is no longer a measure of the effect. Every single human body, from the moment of birth to that of death, is in a continual state of change, so that agents can never produce twice exactly the same effect,—still less can exactly the same effect be expected from one agent on one human body which that agent has produced on another human body; so that the wonder is not that rational medicine is imperfect, but that there is anything at all resembling a rational medicine.

Are there, then, any cases in which the treatment of diseases can be duly said to be rational? The only instances in which Medicine can be correctly represented as rational fall within the following predicament: when the physiological effect of a remedial agent (established independently of Medical practice) and the essence of a disease have been successfully pursued up to the extent that the coexistence of the two in the living system is found to be impossible, whence of necessity one of two things must happen: the use of the remedy must cure the disease, or the disease must destroy the remedy. In either case, however, it should be admitted that the treatment is rational.

When, for example, it seems certain that cardialgia depends on an excess of acid in the stomach, it is rational treatment to employ such ant-acids as preparations of pure potass and its carbonates, preparations of the carbonates of soda, preparations of pure ammonia and its carbonates, preparations of lime or magnesia and their carbonates. Again, when a violent and painful spasmodic affection of the fibres of the stomach and the adjacent abdominal muscles seem to be dependent on acid in the stomach, it is merely empirical treatment to employ tincture of opium mixed with peppermint water as a combination of an anodyne with an antispasmodic; but if an ant-acid, such as calcined magnesia, is conjoined, then a rational treatment is added to the empirical—unless, indeed, it could be shown that magnesia was employed in such cases before it came to be known that excess of acidity on the stomach is a cause of the spasmodic affection referred to.

But how few are the cases of this description in the whole range of Medicine? The therapeutic value of most drugs—that is, their value in actual disease—came to be known long before their physiological action was investigated, hence their use was established by empirical Medicine.

But it were needless to dwell longer on points so obvious.

Our conclusions then are—that rational Medicine must in modern times rest exclusively on its success in establishing the previously unknown physiological action of remedial agents and the incompatibility of that action with definite forms of morbid agency, that empirical Medicine can no longer reject the study of physiology and pathology, organic chemistry, microscopic investigation, and all the other departments of knowledge which tend to discriminate from each other the long train of morbid affections to which the human body is subject, and to render the diagnosis of these in actual practice more easy and unerring; and, therefore, that the only contest which remains between rationalism and empiricism is the extent to which, independently of actual practice, the physiological action of remedial agents can be discovered; and the degree in which their therapeutic value can be deduced, without actual trial in diseases, from their physiological action.

According to the view which seems most tenable the rational mode of cultivating therapeutics must for long ages, if not to the end of time, lie within very narrow limits, while the empirical method of proceeding promises the most abundant harvest to the ardent cultivator.

Thus the true doctrine, which is elicited from the contest of thousands of years between the dogmatics and empirics, is the empirico-rational, or that which, while it admits the soundness of rationalism within due bounds, contends that the empirical method is that by which Medicine at the present time can most successfully extend its sway over diseases.

APPARENT ATTACK OF TUBERCULOSIS IN THE LUNG, WITH SPEEDY RECOVERY.

By JOHN C. THOROWGOOD, M.D., M.R.C.P., Lond.
Assistant-Physician City of London Hospital for Diseases of the Chest, Victoria Park.

The following case seems to illustrate an attack of tubercle in the lung, passing quickly away and leaving the patient apparently well:—

Edward C., an omnibus man, came to the Hospital for Diseases of the Chest at Victoria-park, December 19, 1864, and gave the following history of his present attack:—He said that rather more than three months ago he began to be troubled, chiefly on rising in the morning, with a dry hacking cough, coming from no cold caught or other ascertainable cause. He often felt severe pain under the left clavicle; his strength declined; and he lost flesh rather rapidly.

Within the last month the cough from being dry has become moist, and he has coughed up a good deal of thick, yellowish-white and grey phlegm, never mixed or streaked with blood. Since the cough has become thus moist, he makes a spontaneous statement that he is conscious of much general relief; his spirits have been better; and his appetite has improved greatly. Now, he says, the spitting is diminishing, and he feels that he is getting better, but at night he has profuse sweating; and this alarms him somewhat.

On examination the pulse was 114; skin not hot; tongue clean; face thin and pale, but not anxious. The left infra-clavicular region is a shade duller than the right, and bronchial breathing, with some few moist sounds, are to be heard at this spot; the rest of the chest seemed healthy. He was ordered ol. morrhuæ., ʒij., ter. die.; hst. quinæ c. ferro., ter. die.; pil. conii. co., gr. v., om. noct.

January 2, 1865.—Feels very much better; cough and spit much diminished; pulse 84; only complains of the night sweats. Ordered decoct. cinchonæ, ʒj., c. ac. sulph. dil. ♏ x., ter. die.; pt. ol. Omit pil.

12.—Cough entirely gone; already has gained flesh; lost all pain, and feels so well that he says he ought not to trespass on the charity any longer. Sit dosis ol. morrh., ʒss., ter. die. Pt. med. for fourteen days, and let go at own request.

I have given this case from the rough notes made at the time; for it was an afterthought to send the case to this journal.

The cough coming from no known cause, the wasting and depression, and then the general relief felt when free expectoration took place, are matters which, in my mind, seemed to point to the tubercular nature of the attack; and nature was already perfecting the cure when the man applied to me for advice. To have substantiated the fact of a small cavity at the left apex would have been interesting, but I could detect nothing further by auscultation than the signs I have noted down; and the tubular breathing was still present in a less degree up to the time of the man's discharge.

In another case lately under my observation, a patient, in his youth decidedly tuberculous, remained free from all cough and expectoration for near thirty years. He then had, in the

course of three weeks, two or three severe attacks of hæmoptysis, and as he recovered and the lungs got clear of blood, the signs of a small cavity at the right apex were recognised.

In this case, before the hæmoptysis there were no symptoms pointing in any way to the organs of the chest; during convalescence there was for a few days some expectoration, but this did not continue, and the patient, after an illness of but a few weeks, gained flesh fast, and seemed to his attendants perfectly well, with the exception of the physical signs of the small cavity at the right pulmonary apex.

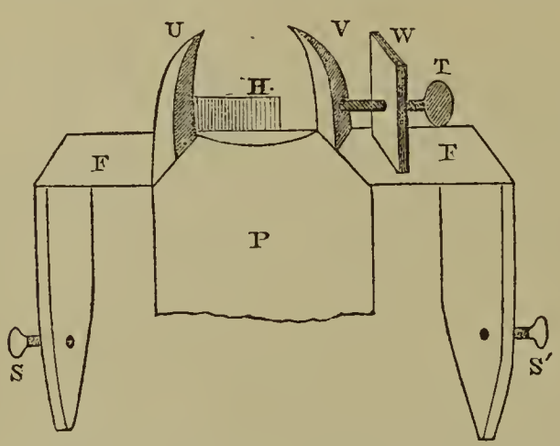
The presence of disease in the right lung had been recognised in the former attack many years previously, and it seemed as if the fresh outburst of disease had seized upon the weak lung, and there expended itself in the form of free hæmoptysis, ceasing at last, and leaving the patient to all outward appearance well.

Finsbury-circus.

AN APPARATUS FOR FIXING THE HEAD IN OPERATIONS ON THE EYE.

By J. ZACHARIAH LAURENCE,
Surgeon to the Surrey Ophthalmic Hospital.

The following is an account of a very practical appliance I have had made for steadying the head in operations on the eye. Its construction will be best understood by reference to the annexed figure:—



U, V are two uprights, concave internally, where they are lined with slightly-padded canvass; V is moveable at pleasure, horizontally, towards the fixed one (U) by a thumb-screw (T), which works through a nut let into the third fixed upright (W). P is an inclined, hard, padded pillow, sloping from between U and V downwards on to the operating-couch, to which the frame (F) of the apparatus is fastened, or unfastened, by two screws (S and S′). The patient to be operated on lies on the couch, with his head resting between the uprights (U and V), on the upper part of the pillow (P). The moveable upright (V) is then screwed up, till it meets the corresponding side of the head, and between the two uprights (U and V) the head is thus firmly fixed. I need hardly say every part of this apparatus must be made most firmly. The uprights (U and V) must thin off gradually upwards, as in the figure, so that their upper edges may not be in the way of the operator. By the space between their summits being less, than between their centres, the head is prevented moving forwards; the lateral compression prevents the head moving sideways; a ridge of the pillow prevents the head moving downwards; whilst a second hollowed wooden one prevents it moving upwards. In fact, if the apparatus is properly made, the patient's head is thoroughly and efficiently fixed.

I have now used this apparatus repeatedly, both in adults and children, with the best results, and am satisfied any other operators who may try it will find it most convenient. With it, when chloroform is not given, we need no longer the hands of an assistant, so often in the way of the operator, to "steady" the head; or if chloroform is given, we need not fear any of those convulsive starts of the head, not uncommon, especially when the patient is getting out of the influence of the chloroform. My apparatus was made for me by Mr. Gorvin, carpenter, 9, Nottingham-street, Marylebone, London, W.

30, Devonshire-street, W.

A CASE OF

PUERPERAL PERITONITIS, FOLLOWING CRANIOTOMY AND HÆMORRHAGE, SUCCESSFULLY TREATED BY LARGE DOSES OF OPIUM AFTER MERCURY HAD FAILED.

By KEITH N. MACDONALD, L.R.C.S., Edin.

The facts subjoined appear to me to be of especial interest, inasmuch as recovery, under such complicated and unfavourable circumstances, must be of rare occurrence, and also as demonstrating the relative value of certain lines of treatment which have hitherto been employed more upon empirical principles than with the view of discriminating the different effects of the remedies under consideration.

Catherine V., aged 32, unmarried, a stout, healthy-looking woman, was taken in labour of her first child on September 4, 1862, at 9 p.m. During the period of her pregnancy she had been leading rather an irregular life, consequent on being a victim to seduction and desertion, by dosing herself pretty freely with brandy, and entirely neglecting the state of her bowels for several weeks before her confinement. The result was, that the first stage was prolonged for forty-eight hours from extreme rigidity of the os uteri, which for some time resisted the action of tartar emetic and other appropriate remedies. But this was not all; delay was also occasioned in the second stage by the fœtal head becoming arrested at the pelvic brim from slight narrowing, where it remained stationary for sixteen hours longer, though the expulsive efforts were of the most violent character. By this time it appeared evident that the natural powers were inadequate to effect the delivery, and that constitutional symptoms were about to develope themselves by the pulse rising to 120, and the presence of a brownish discharge issuing from the vagina. Without further delay I applied the long forceps; and on using tractive efforts without making any impression on the head, the bed suddenly broke down, to the imminent danger of producing a laceration. Fearing the result of this unexpected interruption, I immediately unlocked the instruments, placed the patient on a mattress on the floor, and completed the delivery by craniotomy. On extracting the placenta, an alarming hæmorrhage took place, which was with difficulty arrested by ergot, the application of cold, and pressure by the hands' grasp over the uterus. Notwithstanding this, she recovered the shock tolerably well; but her attendants considered, contrary to my orders, that premature stimulation was necessary, and accordingly allowed her a liberal supply of wine and nourishing diet. The sequence may be readily imagined. An attack of peritonitis set in on the third day, with suppression of the milk and lochia, and exquisite tenderness on pressure, especially over the epigastric region, which soon occupied the whole peritoneal surface. Calomel and opium were immediately administered every three hours, and vaginal injections, hot fomentations, and poultices were applied locally, the bowels being at the same time kept open by emollient enemata. This constituted the mercurial part of the treatment, which was persevered in unremittingly for the next thirty hours, but without producing the slightest benefit. The only relief afforded was from the constant application of hot poultices to the abdomen. Without further detailing minutiæ, suffice it to say that under the above treatment all the symptoms continued to advance. The pulse became rapid and feeble; the tongue foul; the abdomen swollen and tympanitic, and there was great depression of spirits with slight delirium. Anticipating a fatal issue from these circumstances, as a *dernier ressort* I tried the effects of opium alone in large doses. Two grains were given the first hour, and one grain every succeeding hour during the day, which was to be doubled at bed-time, and repeated twice during the night. Its effects were narrowly watched, but the soporific action of the drug was not manifested in proportion to the doses administered. After pursuing this treatment for twenty-four hours a marked improvement took place. It was now diminished to half grain doses every three hours. This dose was continued until the pain, swelling, and tenderness had almost disappeared, which was effected on the 19th, or ninth day—dating from the period of the first rigor. Convalescence was now rapidly established, she left her bed on the 24th, and has since completely recovered.

In conclusion, I may remark among other points worthy of note, that during a period extending over nine days she had taken upwards of forty grains of opium, and this, moreover,

as we have seen, with the best results. At first I feared an injury might have been inflicted, but subsequent observation led me to conclude that such was not the case. That in this case the mercury had signally failed in staying the progress of the disease will be apparent to the greatest sceptic, but of the fact that the favourable issue was mainly due to the large and repeated doses of opium no doubt can be entertained. It may with good reason be questioned if mercury would exert any beneficial influence over inflammations of the sero-fibrous tissues without the aid of opium, but that the latter does so independently of the former must be admitted by all. If mercury is a specific in these cases, it ought to prove itself such unassisted. The only natural conclusion, therefore, to be drawn from the preceding is, that as mercury failed here it may fail in other cases also; and, in like manner, why not expect of opium in future results similar to those it has so beneficially manifested in the case before us?

Wrexham.

A CASE OF

ANEURISM OF THE PROFUNDA FEMORIS.

By Mr. SPENCER WATSON, F.R.C.S. Eng.

The profunda artery of the thigh has been rarely known to be affected with aneurism. Several cases, however, have been put on record. One occurred to Mr. Cock at Guy's Hospital. This and another case are related by Mr. Erichsen; and at a recent meeting of the Medical Society of London a third was mentioned by Mr. Peter Marshall as having occurred in his practice.

The history of the patient whose case I am about to relate did not throw any light on the origin of the disease. She was an unmarried lady, 39 years of age, of very spare habit, pallid, and prematurely aged. She had suffered from menorrhagia at various times, but very much more severely during the six weeks previously to my seeing her, on June 30, 1864. She had then a pulsating, painful, obscurely-fluctuating tumour occupying the greater part of Scarpa's triangle of the left side and extending a little beyond the outer and upper boundaries of that space. It was tender when pressure was made on it, and the pain extended down the inside of the knee and calf of the leg. The latter was slightly œdematous. A loud bruit was heard over the tumour.

My first impression of the case was that it was an aneurism of the femoral artery. On subsequent occasions, however, there appeared to be distinct pulsation in the superficial femoral, independently of that in the tumour itself, and the diagnosis was thus rendered very doubtful. A very eminent Surgeon, who was called in, after two very careful examinations, was unable to arrive at any certain conclusions, but was inclined to look upon the disease as of a malignant character, and the pulsation to be due to the large size of the vessels by which the growth was supplied. The patient died on Sept. 10, apparently of acute tuberculosis, after an attack of sudden and urgent dyspnœa, which lasted only a few days. For the last ten or fourteen days it was observed by my friend, Dr. Ablett, who was in constant attendance, that the bruit could not be heard in the tumour, and that the pulsation gradually ceased.

On a post-mortem examination, the lungs were found infiltrated with purulent matter, and one of them more solidified than natural. The tumour was with difficulty dissected out from the surrounding tissue, to which it was at many points closely adherent, and it was found to extend some distance upwards beneath or in the sheath of the psoas and outwards beneath the sartorius. The superficial femoral artery was lying in front and to the inner side of the tumour, and was pervious in its entire length. The profunda, however, from the commencement of which the aneurism sprung, was obliterated on the distal side. The opening by which the communication with the artery was kept up was of one-eighth of an inch diameter. The aneurism was firm, and unfluctuating, of the size of two fists, and of an irregular pyriform shape. On section it presented concentric layers of fibrine occupying the whole of its cavity, with the exception of a space of the size of a walnut in the centre, which was occupied by recent clot. The profunda vein on the distal side of the tumour was completely obstructed by laminated fibrine. In the walls of the uterus were found several fibrous tumours, one of the size of a walnut and the others varying in size from that of a pea to that of a pin's head. Dr. Symes Thompson having kindly examined these tumours microscopically, ooks upon them as ordinary fibrous tumous.

Preparations of the aneurism and of the uterus are now in King's College Museum.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ST. GEORGE'S HOSPITAL.

ACUTE RHEUMATISM, QUICKLY SUBSIDING ON THE OCCURRENCE OF INFLAMMATION OF THE TONSILS AND THROAT.

(Under the care of Dr. JOHN W. OGLE.)

Margaret M., a young woman, was brought to this Hospital with unusual redness of the fauces and structures at the back of the mouth, and difficulty in swallowing, and slight feverishness. She had been told that it was diphtheria. Under the use of ordinary salines and a senna aperient these symptoms abated, but three days after admission a decidedly acute rheumatic attack came on—swelling and redness and very painful condition of the knuckles and joints about the wrists, and excessively acid-smelling perspiration. For all this Dr. Ogle prescribed half-drachm doses of bicarbonate of potash with small doses of chloric æther and water, Dover's powder of a night, and occasional senna purges; afterwards bark was added. At the end of seven days, quite suddenly, all the rheumatic symptoms disappeared, and as suddenly acute inflammation of the tonsils and back of the throat came on. Bark and chlorate of potash were substituted for the other medicines, and bark and hydrochloric acid gargle used, and ordinary diet substituted for fish and meat. Subsequently the tincture of sesquichloride of iron with quinine and port wine. She gradually recovered in all ways. No return of rheumatic symptoms recurring, she left the Hospital on the fifteenth or sixteenth day after the sharp attack in the throat came on. Dr. Andrew Clarke holds that enlarged tonsils are frequently associated with rheumatism. About the same time as the above the following case occurred:—

ACUTE RHEUMATIC FEVER — SUBSIDENCE OF SYMPTOMS ON THE OCCURRENCE OF EXTENSIVE HÆMORRHAGE FROM ULCERATED TONSILS.

(Under the care of Dr. JOHN W. OGLE.)

Henry C., aged about 30, was admitted under Dr. Fuller's charge with acute rheumatic fever, for which large doses of acetate and bicarbonate of potash were prescribed, with occasional doses of Dover's powder and brisk purges. Of the details of the case Dr. Ogle was ignorant, but in Dr. Fuller's absence Dr. Ogle had to attend the patient after he had been in the Hospital three weeks. He went on with alkalies and bark for three weeks, when his rheumatic symptoms somewhat abated, and a sharp attack of tonsilitis came on. He was very low and prostrate, very pale, with a soft, perspiring skin. Dr. Ogle gave him six-grain doses of the sesquicarbonate of ammonia with chloric ether, and a gargle with chlorate of potash, myrrh, and dilute hydrochloric acid, and strong beef-tea and much milk. The inflammation of the tumour, however, went on to ulceration, and on the third day he was affected by sudden hæmorrhage from the tonsils, and was said by the nurse and those around him to have lost at least a pint and a-half of blood. This left him very exhausted and pale, with a small, quick pulse, but all the rheumatic affections of the joints quite suddenly vanished, and never showed themselves again; neither was there any return of the hæmorrhage in any quantity, and the throat gradually recovered under the use of quinine and steel and good food.

Whatever may be the *rationale* of the changes in this and the preceding case, there was no doubt that the acute rheumatic symptoms were resolved quite coincidently with the establishment in one case of the inflammatory throat symptoms; in the other, partly then, but especially when the loss of blood was experienced.

MIDDLESEX HOSPITAL.

THE BLISTER-TREATMENT OF RHEUMATIC FEVER.

(Cases under the care of Dr. GREENHOW.)

With reference to the following cases, Dr. Greenhow remarked

that the use of blisters in cases of acute rheumatism was not altogether new, but that it had been comparatively rare, and had never been relied on as the chief remedial measure. Dr. H. Davies had, however, in the recent volume of London Hospital Reports, strongly advocated the application of blisters in the immediate neighbourhood of the affected joints, in the belief that the discharge caused by them would eliminate the *materies morbi*, and cure the patient without the aid of any of the medicines usually employed, and had supported his belief by the publication of an interesting series of cases treated in this manner. The success of the plan in Dr. Davies' hands had appeared to be so great that he (Dr. Greenhow) had been induced to try it in these two cases, combined, however, with a moderate use of the alkaline salts. It was certain that these two patients had begun to mend in a much shorter time than was usual in such severe cases of rheumatic fever, and had escaped relapses in that respect contrasting favourably with other cases which had come under his care shortly before the admission of these two, and some of which had remained in the Hospital a considerable time after their discharge. In both cases there was cardiac complication, and in the first case irreparable endocardial mischief, before the patients came under treatment, and therefore it was not possible to judge from them whether Dr. Davies' plan could, as he supposed, avert the cardiac symptoms; but in neither case did those symptoms increase after the application of the blisters.

George M., aged 18, admitted October 13, 1864. Had been healthy until three days before admission, when he was seized with pain in both knees, which soon extended to his ankles and feet, and then attacked his wrists, hands, elbows, and shoulders, and he lost all power of movement in his limbs.

On admission, his face was flushed, his skin hot and moist, and he had pain and tenderness in ankles and knees. A soft systolic murmur was heard below left nipple. Pulse 116; tongue very much coated with white fur at sides, and brown in centre. He had no appetite. Bowels had not been open for several days; urine, specific gravity 1028; no albumen. Pil. coloc. c. hyoscyamo, gr. x., statim sum. et capiat in 4 hor. Haust. sennæ co. Curtains to bed.

14th.—A louder blowing murmur heard at apex of heart. Complains of pain in every limb, and of much thirst. Lips very much parched. Pulse 120. Has been well purged by the pills and draught. Ung. potass. iod. ext. belladonnæ, partes æquales, reg. cord. app. Mist. rubr. 6tis hôris.

15th.—Complains of very great pain in wrists. Haust. potass. nit. c. potass. acetat., gr. x., 4tis hôris. Pil. ipecac. co., gr. x., h. s. s. Blisters, two inches in width, to be applied round both arms above the wrists.

16th.—Blisters have risen, and are discharging freely. Pains gone from elbows and wrists; but much pain in right shoulder. A blister two inches in width to be applied round right arm below shoulder.

17th.—Had a restless night; but there is no pain in shoulders nor in any other part. Systolic murmur still heard below nipple; still has considerable heat of skin, and perspires freely; tongue cleaner and moister; urine neutral, paler coloured, and not turbid. Omit haust. Blisters to be dressed with unguent. zinci.

18th.—Quite free from pain. Skin much cooler, but still perspiring; tongue cleaner; no appetite; urine in good quantity, alkaline, normal. Pil. coloc. c. hyoscyamo. gr. x. hac nocte.

19th.—Has no pain or stiffness in limbs; systolic murmur still heard below left nipple and also at base of heart; pulse 86; tongue coated at sides; still much thirst; appetite improving; bowels open once this morning; urine abundant and slightly acid. Fish diet.

22nd.—Has no pains either in joints or limbs; heart sounds as before; tongue coated at sides; bowels open yesterday. Blisters healed.

24th.—Continues to improve. ℞. Syr. ferri. iod., ʒss.; aq. menth., ʒj.; M ter. die. sum. Mutton chop daily.

29th.—Ol. morrhuæ, ʒj.; t. d. sum. ℞. Syr. ferri. iod., ʒj.; aq. menth., ʒi.; M. t. d. sum.

November 5.—No pain; pulse 76, very feeble; still sweats a little at night; urine clear, of normal appearance, slightly acid. Pt.

10th.—Free from pain, and gaining strength; systolic murmur still heard below left nipple, and at base of heart. Pt.

14th.—Discharged convalescent.

Thomas E., aged 18, potman. Admitted October 26, 1864, having been taken ill three days before. On admission he had pain and swelling in both feet, ankles, and knees, also in right hand, wrist, and elbow. There was loud friction sound at apex of heart; respiration rather hurried; breath-sounds normal; great heat of skin; profuse acid perspiration; pulse 120, full and hard; tongue slightly coated; much thirst; bowels open; urine high-coloured, specific gravity 1025, slightly clouded by heat; no albumen. Pil. coloc. c. hyoscyamo., gr. x., h. s. s.; mist. rubr. 6tis hôris. Curtains to bed. Blisters two inches in width to be applied round both legs immediately above ankles and knees, and also round right arm above wrist, and to be dressed with warm poultices when they shall have risen.

28th.—Blisters have risen well, and pains are much relieved, especially in ankles and wrists. Friction-sound still heard at apex of heart; still profuse acid perspiration; pulse 120; tongue furred; much thirst; bowels have been moved freely; urine high-coloured, transparent, and acid. Blisters to be dressed with unguent. zinci.

29th.—Complains of pain both in knees and shoulders, and of stiffness in knees, ankles, shoulders, and right wrist. Pulse 108; tongue coated in centre, red at tip. Did not sleep well. Capiat haust. potass. nit. c. ʒj. potass. acetat., 4tis hôris.

30th.—Complains still of pain in ankles and knees, which prevented his sleeping. Friction sound as before. Pulse 120. Skin less hot; still sweating profusely. Urine neutral. Pt.

31st.—Pains in legs much relieved. Pains in both shoulders and arms, but almost exclusively felt on movement. Friction sound continues. Pulse 96. Bowels confined. Pt. haust. Pil. coloc. c. hyosc., gr. x., h.s.s.

November 2.—Still complains of pain, or rather of stiffness in ankles, knees, and wrist, but can move all these joints freely. Pulse 94. Skin warm and moist. Tongue cleaner and moist. Urine slightly alkaline. Omit haust.

3rd.—Pains much relieved. Friction sound at apex of heart fainter. Skin warm; perspiration slighter; slept well. Urine clear, faintly acid. Fish diet.

5th.—Still occasional pains, but only in ankles and knees. Has slept throughout the last two nights. Friction sound still fainter. Pulse 72. Skin cool; perspiration much diminished. Tongue clean. Urine abundant, very faintly acid.

9th.—Quite free from pain, but still has stiffness in knees Pulse 84. Skin cool; perspiration has ceased. Tongue moist. Bowels regular. Urine copious, pale-coloured, faintly acid. Is very pallid, and complains of feeling weak. ℞. syr. ferri iod. ʒss.; aq. meuth, ʒi. M. ter die sum. Mutton chop daily.

12th.—Going on well; complains only of weakness. Pt.

16th.—A number of boils have appeared on the blistered surfaces. In other respects patient still improving.

19th.—Boils to be dressed with ung. bals. Peruv.

21st.—Going on well. Pt. syr. ferri. iod. Capt. ol. balenæ, ʒj. ter die.

23rd.—Has been quite free from pain for some time. Boils are nearly healed. Has gained flesh; is less pale, and feels stronger. Pt.

26th.—Discharged well.

ENCEPHALOID TUMOUR OF THIGH RECURRING TWICE IN SIX MONTHS AFTER REMOVAL.

(Under the care of Mr. DE MORGAN.)

[Communicated by Mr. G. E. PYLE, late House-Surgeon.]

E. C., aged 56, schoolmistress, a short, stout, and exceedingly healthy looking woman, applied for admission on September 15, 1863, on account of a rapidly-growing tumour of the right thigh.

Her history was a peculiarly good one. Her parents were healthy and long-lived, and she had never heard of a tumour existing in any member of her family. She had always resided in Yorkshire, chiefly in a small sea-port town, where she was schoolmistress. Had been married, and had had two children, both of whom were dead. She had herself enjoyed remarkably good health up to the autumn of 1863.

Between four and five weeks previous to her application at the Hospital, she first noticed a small swelling just below the right groin; it was then about two-thirds its present size. She had felt pain of a trifling character in various parts of the thigh before she discovered the tumour, but it gave her no particular inconvenience either then or after the discovery, and she was induced to consult her Medical attendant only when the tumour was found to increase. Iodine was prescribed, but the growth continued, the general health remaining unimpaired.

When admitted, there was a tumour about the size of a

hen's egg at the outer part of the right thigh, just below Poupart's ligament. It felt elastic, and was tolerably moveable. The following day (16th) the tumour was removed by Mr. Lawson. It was found to be entirely confined to the fat and cellular tissue, and proved, as was conjectured, to consist of soft medullary cancer tissue. She recovered from the operation without a bad symptom; the wound cicatrised perfectly in less than a month. She was discharged on October 13, and resumed her duties in the country.

After this she remained in perfect health up to November 23, when she noticed the return of the disease.

On Christmas-day she was readmitted under Mr. De Morgan, when the following note was taken:—

"There is now a nodulated tumour, the size of a walnut, below the skin, just at the inner end of the cicatrix left by the operation; one or two of the nodules feeling as if they contained fluid. It is freely moveable, and has little connexion with the skin. To the outer side of this and below it are some scattered small nodules deep beneath the skin, and barely moveable. The cicatrix is generally soft, but towards its outer end is a fulness as though the disease were forming beneath it. Running up from the larger mass, towards the spinous process of the ilium, is a harder deposit beneath the skin, more doughey than elastic, and not moveable; it seems to lie on, and to be connected with, the fascia, but cannot be traced dipping into or below the muscles; its breadth in the widest part is about two inches and a-half. The patient has no pain; has gained flesh since she went out; has a quiet pulse, and no appearance of constitutional disturbance."

26th.—Under chloroform, an incision was made ten inches in length below, and following the line of Poupart's ligament. The old cicatrix was first dissected away; then another incision was made from the centre of first obliquely upwards for two or three inches towards the outer side. The tumour felt towards the inner side was first removed; then the nodular masses towards outer side. Numerous small nodules were found during the dissection, especially to the outer side, imbedded in the fat, which was very abundant; in some places they were adherent to the fascia, but none of the growth dipped between the muscles; it was deemed advisable, however, to remove some of the fascia covering the adductors. The operation of necessity lasted some time, and several small arteries had to be tied. The incision was closed by metal sutures, and a large compress and spica bandage applied.

For several days after the operation there was considerable oozing of a thin sanious fluid from the wound; and on the 29th a good deal of swelling above and parallel to it. Her general condition evinced the effects of the operation; she was drowsy and thirsty, with a dry tongue, and a quick, small pulse.

On the 30th the countenance became very sallow; the face pinched; and the pulse sharp and up to 120. Some sloughing of the edges of the wound took place, and she remained in this condition until January 8 or 9, when suppuration was freely established, and she gradually rallied. The swelling, too, above the wound, which had remained, and which at one time threatened to suppurate, disappeared. During this time she took a mixture containing tincture of the sesquichloride of iron, chlorate of potass, and hyposulphite of soda; had generous diet, and a good quantity of wine daily.

On the 21st the wound looked perfectly healthy; the discharge was becoming gradually less, and her general health was much improved; but on the 28th the discharge became thin and sanious again, and continued so for some days.

After this the wound gradually closed, and cicatrised in almost all its extent, the general condition of the patient resembling what it had been before the operation. She had grown stout again, and, indeed, seemed to be gaining flesh every day.

This state of things did not last very long. The following note dated February 27 indicates the second recurrence of the disease:—

"For some days past there has been swelling and hardness above the outer part of the wound, which has healed in the whole of its extent, except the extreme outside. This swelling is increasing, but there is no tenderness."

Still, in spite of this, the swelling decreased again after a few days, suppuration having taken place, and the pus finding an exit at the outer end of the wound. New disease began to appear, however, about the cicatrix; and at the end of March there were numerous masses of soft fungoid growth cropping up, and hæmorrhage frequently took place from them.

As nothing more could be done for the patient, and she was anxious to go home, she was discharged on April 11. The last note taken is as follows:—

"For some weeks past masses of the old kind of tumour have been developing themselves in the course of the cicatrix. They assume a rounded form, are purplish, soft, grow rapidly, and bleed easily. Besides the separate masses, there is general hardness about the cicatrix. The patient's general health has changed; she is thinner, and rather sallow, has some shooting pain now in the tumour, and does not sleep so well as she did."

After her return home she lost a great deal of blood from time to time, and the tumour increased, but she lingered on till May 17, gradually growing weaker and weaker. The fungoid growths attained the size of a large peach; then withered away, sloughed off, and were succeeded by others.

Remarks by Mr. Pyle.—This case receives its interest chiefly from the rapidity and virulence in the growth of the tumour, and its occurrence in a woman whose previous health had been so remarkably good, and who, as far as could be known, was so peculiarly free from hereditary taint of any kind. It is seldom, probably, that cancer occurs with so few outward signs, except of the actual tumour itself, which was palpable enough, its destructive progress, and so little clue to the reason of its appearance. It was remarkable, too, that the disease seemed to have its seat entirely in the adipose tissue. When the tumours were removed by the second operation, numerous as they were, they were all found in this situation; and for a considerable distance around the principal masses were small points of disease, looking as if they were enclosed in capsules of fat tissue. Numbers of these were so small that they were unnoticeable without the aid of a lens. But the glands were little affected, and with the exception of the adhesion to the fascia and to the tensor vaginæ femoris, no other parts above or below the fat were involved. Rapid, moreover, as was the return of the disease after the first operation, there was no indication that the cicatrix was involved in it.

The microscopic characters were throughout those of rapidly-growing medullary cancer.

The plan of treatment adopted—*i. e.*, its removal, prolonged the patient's life probably some little time, and inflicted less suffering upon her than if the tumour had been allowed to remain either at first or at its reappearance. The absence of pain and cachexia were doubtless in part connected with the rapidity of development, although pain seems by no means an essential symptom of malignant growth.

LIVERPOOL SOUTHERN HOSPITAL.

LITHOTOMY—PERFORATING ABSCESS IN THE CHEST WALL—RECOVERY.

(Under the care of Dr. NOTTINGHAM.)

For the notes of the following cases we are indebted to Dr. Gulston Wollaston:—

J. K. was admitted on August 13, of last year, under the care of Dr. Nottingham, in order to be operated on for stone in the bladder. He was a thin, pale boy, of 8 years old, and had been all his life exposed to the effects of insufficient food, dirt, and bad ventilation. Lateral lithotomy was performed on the 18th; there was nothing peculiar about the operation; the stone was of moderate size, and composed of lithic acid. All went on well for three days; but on the night of the 21st, without any previous warning, he was suddenly seized with intense pain in the region of the bladder, became deathly pale, pulse very frequent and almost imperceptible, breathing rapid and intermitting, and he, in fact, presented all the appearance of speedy dissolution. During the day there had been some slight hæmorrhage from the wound, but nothing of importance. The bladder appeared to be somewhat distended, but he could not bear the least pressure on that region. A catheter was passed per urethram, and a small quantity of urine, slightly tinged with blood, evacuated. Stimulants were administered, etc., and by morning he had rallied. The following night, the 22nd, the same symptoms showed themselves, but in a milder degree, and at this time accompanied by distinct rigors and severe pain in the left side of the chest. The lungs were examined, and nothing abnormal detected. He was put on generous diet—wine, eggs, etc.—which he took freely. The pain in the chest continued, but became more confined to one spot—the left nipple. About three days afterwards (26th) there was pointing at this spot, and about three drachms of healthy pus were let out. A few

days afterwards it again became evident that there was more matter: the wound, which had healed, was reopened, and about two ounces of curdy pus evacuated. At this time there was a free entrance and exit of air during inspiration and expiration; the lungs continued acting well. The wound was closed, so that no more air could enter. In three days the wound was again opened, and three or four ounces of fairly healthy pus let out; air entering the chest during expiration and being expelled during inspiration with a whistling sound. There were no bad symptoms: in fact, during this time the little fellow was gaining flesh rapidly. In three or four days the wound, which had been kept closed, was reopened, and a few drachms of pus oozed out; air ceased to enter. The opening continued to discharge for two or three weeks, and then healed; during which time the wound in the perineum cicatrised, and the boy was discharged cured in the end of October.

LITHOTOMY FOR THE REMOVAL OF CALCULI FORMED ROUND A FOREIGN BODY.

(Under the care of Mr. HAMILTON.)

Another case of stone, operated on in this Hospital during the past year is worthy of notice.

T. M., aged 47, a labourer, presented himself in the out-patients' room about the middle of June. He stated that a few hours previously, feeling some irritation in the urethra, he was induced to pass a feather some distance down the canal, when it slipped from his fingers. He described the feather as an ordinary one out of a fowl's wing, but with much of the quill part removed. Several attempts were made to remove it, but without success, and he departed, refusing any further treatment. He remained well till the end of October, when all the usual symptoms of calculus in the bladder came on. He refused all operative interference until he could bear the pain no longer, the 27th of January following, when he was admitted an in-patient under the care of Mr. Hamilton, who operated in the usual manner the next day, and removed five calculi of small size, and composed of phosphates, in the centre of each of which was found a piece of the identical feather passed into the urethra more than seven months previously. He made a good recovery, and was discharged cured three weeks after the operation. He has since enjoyed good health.

STOCKPORT INFIRMARY.

KICK ON A SCROTAL HERNIA—ENTERITIS—DEATH.

(Under the care of Mr. MASSEY.)

For the notes of the following case we are indebted to Mr. J. Peeke-Richards, House-Surgeon:—

Charles W., aged 25, a hawker, was admitted into the Infirmary on January 12, 1865, suffering from the effects of a kick upon a scrotal hernia.

On admission he stated that about noon on the preceding day, as he was about to enter a beerhouse, a man who was standing in the doorway, and with whom he had had some slight difference, kicked him on the "privates." He staggered across the road and fell down, but, with the assistance of a passer-by, was enabled to walk home—about five minutes' walk. He complained, when he reached home, of great pain in the hernia and lower part of belly, and this continued until the following day, when he was seen by the visiting Surgeon of the Infirmary, who ordered him into the house. He likewise stated that he had been ruptured for the last fifteen years, that the hernia was scrotal, and was down at the time of the receipt of the injury, and that he never wore a truss.

On examination a large, hard, and tense swelling was found on the left side of the scrotum, in the situation of a scrotal hernia, the surface of which, as well as the perineum below, was considerably bruised and discoloured; and on applying pressure, a portion of intestine was found to return into the abdomen with a gurgling sound, but without much diminishing the size of the swelling, which was extremely painful, and in a high state of inflammatory action. His pulse was quick and thready, and his countenance betrayed the utmost anxiety. Vomiting came on soon after the receipt of the injury, and continued incessantly up to the time of his death, becoming stercoraceous about the second day.

Leeches, calomel and opium, hot fomentations, poultices, enemata, etc., were tried, but without avail, his bowels remaining unopened until his death, which took place on January 18, seven days after he received the kick.

Autopsy, Twenty-four Hours after Death.—Nearly the whole of the scrotum, the perineum, and the inner and upper part of the left thigh were much discoloured, the scrotum having a sphacelated appearance, which, on being laid open, showed that the whole of the tissues of which it was composed, as well as the hernial sac it contained, were in a complete state of inflammatory disorganisation. The tunica vaginalis contained about two ounces of a bloody serum. On opening the sac, a coil of gangrenous intestine was brought into view, but was found to be readily returned into the abdomen, there not being the slightest indication of stricture in any part of the inguinal canal. The gangrene was not limited to the portion of intestine contained in the sac, but had extended to the contiguous bowel to the extent of twelve or fourteen inches. It was completely gangrenous, and its calibre was considerably diminished. The intestines above were much dilated, and showed evidences of extensive enteritis. There was no peritonitis, and not any source of constriction could be found in the abdomen.

SATURDAY, FEBRUARY 11.

CONTAGIOUS DISEASES BILL.

We have been given to understand that some difficulties attend the practical working of the above Bill, which will, we trust, be overcome. These are of a kind that may be readily imagined. In the first place, our soldiers and sailors manifest a strong disinclination to indicate the sources of contagion, or the exact localities in which they have contracted their diseases. The other obstacle relates to the treatment and cure of the unfortunate women. No real good whatever can accrue from treating a case of syphilis in Hospital for a few days, or even a week or two. The fact is that the sooner we enlarge our views and dismiss the idea from our minds that the contagious powers of syphilis are exclusively limited to the primary stage the better. No doubt the secretions are most active then, but so long as any manifestations of syphilis are conjoined with uterine lesions and discharges, these women cannot be at large with impunity or entire safety to the health of the community.

It appears to us, therefore, that the observation and treatment of diseased women require to be very carefully and efficiently done, and our efforts must be directed to the detection and the *cure* of their affections; and for this it is clear that a short stay in Hospital is inadequate.

We hope that all members of our Profession who may have it in their power will put their shoulders to the wheel, with an eye to the great advantages which must arise from an honest and systematic effort to control the evils of prostitution. As Professor Parkes has remarked, the State is bound to step in and deter individuals from endangering the lives of their fellow-subjects; and a prostitute affected with syphilis, and at large in our streets, is effecting an incalculable amount of disease and injury.

The detention of these unfortunate women in Hospital is a

work of great mercy to themselves. Morally, it offers some of them a chance of retracing their steps, and of effecting a change of life; while, physically, it may be the means of saving them an immense amount of present and future suffering, to say nothing of the control it has over the dissemination of one of the most lethal agents among our civil and military populations. It is, to our minds, a truly Christian work, if looked at from a proper point of view. It certainly is our duty to guard our soldiers and sailors from evils to which they are, of all men, the most exposed by reason of their occupation. Let it be remembered that these men are compelled to lives of celibacy on our behalf. We cannot shut our eyes to the fact that temptation must assail the young sailor or soldier—shut out as he is from a married and domestic life—with a very different force to that with which it attacks the civilian, returning to his wife and children, or, at any rate, with the prospect before him of possessing these.

THE GOOD SAMARITAN AT WINCHESTER.

What a magnificent institution is an English County Hospital! How superior in its well-ordered benevolence, in its broad and Christian charity, in its scientific resources, in the cleanliness, skill, and quiet that govern it to anything those dark, dirty, superstitious middle ages could show! With what internal gratulation and self-satisfaction must every Briton look at it! How proud he must feel at belonging to the same nation as the President, Vice-Presidents, the Chairman, the Deputy Chairman, the Committee, the Honorary Secretary, the Treasurer, and my Lords, Ladies, and Gentlemen, the Governors! What ornaments to the neighbourhood must these good people be! How unselfish the interest they take in the welfare of the sick poor! How careful are they never to turn the charity to their own purposes by filling up its wards with their own dependants! Are not my lady's maid and my lord's coachman, and the parson's butler, and the squire's groom, when ill, tenderly nursed in the castle, the rectory, or the hall, and doctored by the family Apothecary, with, if needs be, the help of the well-fee'd county Physician? Is not the Hospital solely for the hard-handed children of the soil? Is not the pleasure of doing good the only reward the supporters of such a noble charity propose to themselves—with perhaps the occasional harmless, natural, and in itself highly philanthropic, gratification of playing the patron to some obsequious Doctor who humbly solicits their vote and interest?

Such were some of our thoughts a few days ago when, being detained for some hours in the classic town of Winchester, we found ourselves "doing its lions," and amongst them the old Hospital of St. Cross and the County Hospital. After spending some time thus, and feeling mightily comforted and refreshed with our reflections on ancient and modern schemes of national philanthropy, we returned to our inn. Our little dinner over, which we enjoyed the more appetisingly from our satisfied patriotic frame of mind, we called for a modicum of the true British port, which is the proper beverage on such occasions; and, turning to the fire and reposing our feet on the fender, we began to think over an article in which we intended to give our readers the benefit of some new and striking reflections on the subject of mediæval and modern Medical charity. Our reverie was broken by the entrance of a semi-inebriated waiter, who stumbled into the room with the county newspaper. There was no help for it; we could not reconstruct the broken circle of our thoughts; and we soon allowed ourselves to gravitate into an account of an agricultural dinner and the witty and original speeches which were delivered on the occasion by a number of orators whose names are unhappily unknown beyond their own too limited circle—when, on turning the page, an article caught our attention, headed "Important Inquiry at Alresford." In the first line we saw the word "workhouse." "Ah!" we thought, "something of the Timothy Daly kind, though with such a fine institution as that County Hospital it is hardly possible that many bad cases can find their way into the union workhouse. The Poor-law system is doubtless not perfect, but better far than those monasteries with the lazy almoner and the buttery hatch, the lazar house and the ignorant leech friars; in fact, in country districts like this, where the poor have the benefit of a good Hospital, we suspect they are best off when they are ill." However, as we feared that some Professional reputation might be implicated in the matter, we commenced reading.

The article was an account of a coroner's inquest which had been held on the body of one Sarah Pearce, aged 22, the wife of a railway excavator. The following were the particulars:—Her husband had been employed on the new line of railway from Alton to Winchester. They had been married about a year, and up to two months ago she had been in good health. She then caught a violent cold, and was attended by Mr. Lipscomb, Surgeon, of Alresford, who was sent to her by Mr. Harrisson, the contractor. Mr. Lipscomb saw her several times, and sent her medicines. At that time the man and his wife lived at an inn at Alresford, but three weeks before her death they removed to a temporary hut, built of loose bricks and sand, near a bridge which was being erected at Itchen Stoke. This hut had a door and a chimney, but no window. As might be expected, the woman, unprovided with proper clothes, bedding, and necessaries, became worse, and lost the use of her limbs. In this state she was again visited by Mr. Lipscomb, who found her partially paralysed, and considering that it would be folly to endeavour to treat her in such a hut as that, he recommended that she should be removed to the County Hospital and took his leave. For a week or ten days afterwards it appears that she had no Medical attendance and no nursing. She was occasionally visited by the wife of another railway labourer, and by a scripture reader named Brown. The latter at last got an in-patient's recommendation for Winchester Hospital for her. The husband borrowed a horse and open cart from the time-keeper of the line, and at 8 o'clock on a Wednesday morning in January, with the ground hard with frost, the poor paralysed wretch, wrapped in the few tattered clothes and blankets she possessed, was hoisted into the cart by her husband and some of his fellow-workmen, and, lying on straw, was driven off to the County Hospital. The journey took two hours, for it is six or seven miles from Itchen Stoke to Winchester; yet she survived it. The husband drove straight to the Hospital. The letter of recommendation was duly inspected, and the sick woman was taken into the waiting-room. After a delay of a quarter of an hour, two porters carried her upstairs into a ward, where she was stripped, and had a clean chemise put on her. She was then placed in bed. A clergyman and a lady came into the ward and looked at her. The clergyman, it appears, was the Rev. E. Stuart, the Chairman of the Hospital. He said he did not think she was fit to stop there. He then went to Mr. Yeo, the House-Surgeon, and said, "You must go up into No. 1 and see about getting that woman out of the Hospital that I have just seen there; for she is in a most filthy and disgusting state, and never ought to have been sent here." He also asked the House-Surgeon to write to the lady who gave the admission to say that the woman was not in a fit state to be admitted, but that if she were sent clean she should be taken in. In a county Hospital who would dispute the benevolent commands of a Rev. Chairman? They were carried out to the letter. The woman was taken out of bed, her wretched filthy rags were put on her again, a few spoonfuls of broth, at the suggestion of the House-Surgeon, who noticed that she was "extremely pale, but not very cold," were poured down her throat, and, after waiting half-an-hour in the waiting-room until one of the porters could help her, again she was hoisted on the straw in the open cart. They returned, the husband and the wife and a woman who had accompanied them. The sick woman complained of her head—she seemed much worse than in the

morning. On arriving at their village they met a clergyman, the Rev. E. A. Young. When Mr. Young saw them the husband was crying. The poor fellow told the tale of his wife's admission and dismissal; he seemed anxious to do what he could for her. Mr. Young advised that she should be taken to the Union, and himself went with them to secure her admission. When they arrived, she was lifted from the cart into a room downstairs. She could hardly sit up, and upon a blanket being removed from her she seemed almost naked. The Governor of the Union ordered a fire and gave her some broth. She only spoke once, saying, "I can't," when they gave her some of the broth. "She died in the chair about twenty minutes after she was brought to the Workhouse. She went off quietly, as if fainting, and made no noise at all."

The further particulars elicited at the inquest were that the woman was undoubtedly dirty. The House-Surgeon of the County Hospital said that her hands were black, that she smelt, and that she had vermin about her. This, and the laws of the Hospital, which enact "that no person shall be admitted as an in-patient without a change of linen," and "that no person apprehended to be in a dying state or incurable shall be suffered to remain," were apparently, in the eyes of the Coroner and jury, ample justification for consigning this poor, dying girl, in her nakedness and weakness, to the open cart in the cold, biting January wind. Mr. Lipscomb gave it as his opinion that her death was caused partly by the paralysis from which she was suffering, and partly by the exhaustion caused by the journey to Winchester and back, which was more than she was able to bear, and terminated in fatal syncope after her arrival at the Union. The Coroner blandly recounted the evidence, and summed up in general terms "that every one appeared to have acted according to the best of their judgment," and "that he did not see that any one was responsible for the result." The jury concurred, and returned a verdict "that deceased died from syncope occasioned by the causes and circumstances detailed in the evidence, but not by reason of any neglect or ill-treatment of any person whomsoever."

When we finished reading this account, we must confess that our mental condition was one of intense bewilderment. We looked at the heading of the paper, to see in what century and in what country it had been published. But there were the date and the place staring us full in the face. We were completely puzzled. Altogether a change had come over us —the room seemed dark and cold, our dinner had evidently disagreed, and we had some most uncomfortable sensations in the region of the waistcoat. We rang the bell, called for our bill, rated the waiter soundly for the execrable cookery, and declared the Port to be the vilest Hambro'. We started immediately after by the night train, but did not recover our equanimity until we had been carried far past the borders of Hants, and were quietly dreaming that we were in Winchester Cathedral listening to an eloquent sermon, on Christ cleansing the lepers, from the Reverend the Chairman, in aid of the funds of the County Hospital.

THE WEEK.

THE CASE OF TIMOTHY DALY.

We do not reproduce Mr. Farnall's report on this case, which has already, doubtless, been read by most of the Medical readers of the *Times*. As it embodies the principal of the conclusions on the case which have been already advanced in this journal, we shall dismiss it with the remark that it appears to us completely borne out by the evidence adduced. Dr. Carr's report, which is appended to that of the Medical Inspector, was not published in *The Times*, and we therefore republish that portion of it which relates what he himself observed at the Holborn Workhouse Infirmary, only adding that we trust his recommendation to increase Mr. Norton's salary to £150 per annum, to provide drugs at the expense of the Board, and to appoint two salaried nurses in the Infirmary, will be carried into effect by the parochial authorities:—

"On my visit to the workhouse, I was perfectly satisfied with the general aspect of the entire building, making allowance for the original defect of the limited space it occupies. No house for Medical or Surgical treatment, or for the occupancy of the poor, should be built on all the sides of a square. A current of air and the admittance of the direct rays of the sun are essential to a well-constructed Infirmary.

"The wards of the house are generally spacious and well ventilated, making allowance for the comparatively low ceilings. Sufficient space was allowed to each bed. The bedsteads were all of proper length, and that which Daly occupied was in all respects well adapted to the treatment of his case. The bedding and bed-clothes were also good and proper. The floors of the wards were clean; and proper arrangements existed for regular washing of the floors. The walls were painted for three feet from the floor, and above coloured. The ceiling was also clean. The ventilation was good, and the temperature well regulated. In an adjoining room was a properly appointed bath, with an abundant supply of hot and cold water.

"I visited the kitchen and stores; examined the various provisions, and found everything good and wholesome. The bread was excellent. During an ordinary dinner, and when I was not expected, I went into the dining-hall, and tasted all the various dishes provided for the paupers, young and old, and approved of everything on the tables; as well also of the plan of serving the numerous and various grades. Altogether, I cannot withhold my general approval of the whole establishment in its domestic relations."

The following is a copy of the letter which has been addressed to the Guardians of the United Parishes of the Holborn District by Mr. Gilpin, the Secretary to the Poor-law Board:—

"I am directed by the Poor-law Board to inform you that they have received and considered the report of their inspector, Mr. Farnell, on the official inquiry which he recently held, by direction of the Poor-law Board, as regards the treatment which Timothy Daly, deceased, received while an inmate of the Workhouse of the Holborn Union, and that they have also received a Medical report from Dr. Carr upon the same subject, to which they have given equal consideration. The Board have also examined the whole of the evidence in this case; but they do not think it necessary to dwell upon the details of that evidence, because the report adverted to sets forth very fully all the material facts of the case. After the most careful consideration of the evidence the Board feel justified in stating that, in their opinion, Mr. Norton, the Medical officer of the Holborn Workhouse, was not guilty of either neglecting or ill-treating Timothy Daly while under his care as a patient in the Infirmary of that workhouse. The Board, however, observe that Mr. Norton has systematically neglected to keep that portion of the workhouse Medical book which he is directed to keep by the regulations of the Poor-law Board, and they also observe that no reliance can be placed on the entries of that book, so far as they afford evidence of Mr. Norton's visits to the sick poor under his charge in the workhouse; and, though evidence of these visits in the case of Timothy Daly has been furnished by the officers of the workhouse, the Board cannot refrain from expressing their great displeasure at the neglect of the Medical officer in this particular, and they must request that the Guardians will convey their opinion of this misconduct to Mr. Norton. The Board have further to state that they expect that this part of Mr. Norton's duty, to which they attach considerable importance, be strictly adhered to."

SANITARY PROCEEDINGS IN EAST NORFOLK.—"CLARKE *v.* BURROUGHES."

The following letter shows how easily parochial authorities can, by indifference and a "masterly inaction," render useless and inoperative existing sanitary enactments. It is true that "A Barrister" has written to *The Times* to point out that there is a legal remedy for such cases as Mr. Clarke describes, for he remarks,

"By refusing to obey such order (the order of the justices), the party against whom it is made commits a misdemeanour at common law, for which he may be indicted at either the Quarter Sessions or assizes, and, on conviction, be punished with

fine or imprisonment, or both, in the discretion of the Court." But it can hardly be expected, or intended, that the Sanitary Inspector should incur the risks and expense of indicting an offender, when the guardians refuse to move in the matter:—

"*To the Editor of the Times.*

"Sir,—Permit me through your columns to draw attention to the termination of the above case, alluded to in *The Times* of the 7th of September last.

"It will be remembered that the defendant, Mr. H. N. Burroughes, a county magistrate and an ex-M.P., was summoned before the magistrates at Blofield Petty Sessions for neglecting to provide proper privy accommodation for his cottages, and an order was made by the justices to abate the nuisance. Notice of appeal was given. Your readers may not be aware that he did appeal at the Quarter Sessions, but the appeal was dismissed.

"Having again inspected the premises, and found them in the same neglected state, I then applied to the Board of Guardians for authority to proceed for a penalty, but the guardians did not consent.

"I subsequently appeared before the magistrates, and stated that their order had not been complied with, and asked them to grant me another summons; but on being asked by the Bench if I had authority from the guardians to proceed for a penalty, I stated that I had no authority beyond the original one, authorising me to summon the defendant and proceed thereon to judgment and execution. The magistrates consequently refused the application, and the nuisance remains unabated, consisting of dilapidated old buildings and twenty-one human beings without any privy accommodation. Fever prevails, and one death has occurred.

"Under these circumstances there was no alternative but to place my resignation in the hands of the Board of Guardians, which I accordingly have done.

"I can see no remedy to this state of things, unless it be by an exposure through the columns of *The Times*.

"I am, Sir, your very obedient servant,

"Samuel Clarke, Sanitary Inspector.

"Inspector's-office, Dereham-road, Norwich, Feb. 3."

THE ARMY MEDICAL SERVICES.

The Competitive Examinations for Her Majesty's Army Medical and the Indian Services are at hand. Our readers will, naturally, look to us for our advice. Presuming, then, that the Indian Medical Warrant be a *bonâ fide* one and uncancelled, we can recommend this as an excellent opening for those of our young Medical friends who desire to pursue their Profession in one of the public services. With regard to the other—Her Majesty's army—we wish we could urge it in the same way. Until something be done we shall certainly abstain from doing so; because we are well assured of this—that so long as candidates are forthcoming, no changes will be effected. If any well-educated young Medical man will take up an "Army-List," look at what will be his position in it, and his chances of promotion within a reasonable limit of time, we think he will discover that there are hundreds of openings in civil life wherein he can pursue his Profession with more pleasure and self-respect, and with much more hopeful prospects of success.

PARLIAMENTARY.

Parliament has again met, but, judging from the tone of Tuesday night's debate, it has determined, like a servant after giving warning, to get through the smallest possible amount of work with the least possible trouble. As in previous years, we shall furnish our readers weekly with a short report of any debates which may have reference to Medical interests, or to the great social and scientific questions of the day. The debate on the Address does not require particular notice: its most salient feature was Lord Derby's opening, in which the noble lord, comparing the Session to the last hours of a dying man, described with great humour the consultation of the Physicians over the moribund patient,—showing clearly that his versatile talents have neither been exhausted by Homeric translation nor dimmed by his long occupancy of the Opposition benches.

FROM ABROAD: THE RIBERI PRIZE—ACTION FOR THE RECOVERY OF MEDICAL CHARGES—RESIGNATION OF PROFESSOR LUDWIG.

In January, a marble statue of the late Professor Riberi, raised by private subscription, was inaugurated amidst great ceremony in the courtyard of the Turin University. Perhaps the greatest Surgeon Turin has yet produced, Riberi, died some five or six years ago, possessed of great wealth, and left a large sum for the foundation of a Riberi prize, to be awarded by the Academy of Medicine. Instead of establishing a prize of moderate amount for perpetuity, he left a large sum to be divided into seven prizes of 20,000 lire (£800) each, one to be decreed every three years. This is a somewhat questionable procedure, as it is very doubtful whether Surgical works calling for so costly a recognition will appear at such short intervals seven times in succession. However, the triennial period for the second prize is comprised in the years 1865-67, and the Academy has announced that all candidates must forward their works or communications before December 31, 1867. Original manuscripts, whether with or without their authors' names, and any printed work upon *operative Medicine* which has been published for the first time during these three years, are competent to contend for the prize; but they must be written in the Italian, French, or Latin languages, and the authors are requested to point out to the Academy the portions to which they attach most importance.

An action brought by Dr. Dumont, of Caen, for the recovery of fees was decided the other day in his favour, and is of interest by reason of the liberal view which the Tribunal of Bayeux, before which it was tried, took of the elements which should be considered in determining the justice of a demand. Dr. Dumont claimed the sum of 2500 francs of M. Bannelois, the legatee of a lady who had been his patient. The original claim was 3500 francs, which was made up of 3200 francs for sixteen journeys from Caen to Isigny, a distance of sixty-four kilometres, at 200 francs the journey (£8 for about forty miles), and 300 francs for accompanying the patient to Paris in order to consult M. Nélaton. 1000 francs had, however, been paid, leaving 2500 francs, the subject of action. Bannelois declared that the price of the journeys was exorbitant, and refused to pay it. The Tribunal delivered the following judgment:—

"Different elements enter into the determination of what is just to pay a Medical Practitioner. For example, his position, his rank in the Medical body, the distances his patients compel him to traverse, and the prejudice to his ordinary practice caused by long and frequent journeys. Then we have the nature and gravity of the disease which he has undertaken to treat, and lastly the position and fortune of the person at whose hands the remuneration is sought. The distinguished position held by Dr. Dumont at Caen cannot be contested, and it is proved that his practice in that city is considerable. The disease from which the lady suffered was a severe one, necessitating much attendance, and especially frequent Surgical interference, an operation of great delicacy having been practised by Dr. Dumont. This operation, and the complications which followed it, compelled frequent absences from home, often for an entire day. With respect to Bannelois, of whom this payment is claimed, as the residual legatee of the deceased, he is a person in easy circumstances; and, moreover, it is to be borne in mind that he is not a direct heir defending his legitimate patrimony, but a legatee, a stranger to the family, and ought in any case to consider himself fortunate in any advantages he may reap from the succession. For these reasons Bannelois must discharge the claim made by Dr. Dumont, and pay all the expenses of this action."

The Professors of the Joseph Academy of Vienna have long felt it to be a great grievance at being peremptorily compelled to attend the meetings of the Military Sanitary Committee, where they have to consume much valuable time in considering details of which many of their number, such as the Professors of the Theory of Medicine, of the various Specialties, and of the Exact Sciences, are entirely ignorant. To such a point has this reached that the celebrated physiologist, Ludwig, who came from Zurich to Vienna, and has acquired

great popularity among the scientific circles of this last city, has found himself compelled to give up his chair and retire to Leipzig. The military authorities, who are paramount at Vienna, will hear of no compromise, and doubtless before long others of the Professors will follow Ludwig's independent course.

ROYAL EPSOM COLLEGE.

Although we do not agree with Mr. Cattlin in his self-abnegation, we willingly call attention to a letter from him, written with much good feeling, which will be found in another part of our columns.

REPORT ON CHEAP WINE.—NO. XI.

(By our Special Empirical Commissioner.)

(Continued from page 126.)

NOTE ON THE PHOSPHATES.

Phosphorus — Hypophosphites — Phosphoric Acid: its Use in Medicine—Phosphates side by side with Sulphates—Good enough for Physic, but too bad for Wine—Testimony of Dr. Wallace.

In compliance with the desire of some valued correspondents, I take the liberty of adding a few words on the compounds of phosphorus used in Medicine, and on the hypotheses on which that use is supposed to be founded; also on the soundness of making "richness in phosphates" a test of the goodness of wine.

Let me ask your readers to bear in mind the double class of virtues ascribed to this element and its compounds, viz.—1, a peculiar faculty of *stimulation*, and 2, peculiar *nutritive* virtues.

First comes phosphorus itself, a body which in the state commonly met with is self-inflammable in contact with air, and is, in any considerable dose, a most dangerous irritant poison. The highly irritant and inflammatory properties of phosphorus have caused it to be resorted to, on one of the commonest hypotheses of physic, in diseases which seem to be of an opposite class—as intense debility, paralysis, chronic rheumatism, and other *cold* diseases, the blue stage of cholera, and possibly as a random shot in other hopeless, or seemingly-hopeless, diseases. I believe that the administration of phosphorus is now almost unknown; it has died out through want of good results. And taking wine as the matter to which my observations have reference, probably no one, except by a juggle of language which Dr. Kletzinski, whom I have charged with it, would, like a man of honour, be the first to explain away, would affirm that he has found phosphorus, as phosphorus, in wine. My chemical friends tell me that there are processes of great certainty and precision for determining the existence of unoxidised phosphorus, such as distilling, and observing whether there is any phosphorescence in the distillate. I say, then, if any one finds phosphorus in wine, let him come forward and show it.

2. There is a set of compounds of phosphorus of unstable composition, because susceptible of further union with oxygen. Such are the *hypophosphites;* a set of compounds answering in their degree to the sulphites, hypochlorites (*alias* the well-known chloride of lime), etc. A Physician, who has conceived the idea that the tubercular diathesis depends on a want of phosphorus in the system, has, with considerable ingenuity, recommended the hypophosphites of lime and soda as medicines capable of communicating phosphorus somehow to the alleged insufficiently phosphorised tissues of the scrofulous and phthisical. Yet, as to the exact *modus operandi*, some of the devotees of this system hold opposite views. Monsieur Van Esschen believes that the hypophosphites, when taken into this air-breathing, oxygen-devouring system of ours, part with their oxygen, and give phosphorus in a nascent state to the tissues! Monsieur Churchill, on the contrary, believes that they communicate to these tissues a disposition to oxidation, or an affinity for oxygen, in which, he alleges, they are morbidly deficient.(a) Mighty tall talk, which will last a long time if it last till it is proved! Probably there are not many Physicians who put faith in the hypophosphites as specifics for phthisis; nevertheless, it is said on the testimony of patients—the only evidence which is worth anything in such a case—that the use of these substances, in *very small* doses, *with* gentian and other drugs, has seemed to invigorate the stomach and improve the appetite. And this is quite possible to believe, from the action of stimulating substances, without any notion of phosphorising the tissues. The taste of these hypophosphites is acrid and nauseous beyond all human conception, and if they do exist in wine, I should think it must be in such as they drink in the kingdom of Pluto. But no one, I believe, has yet produced any phosphide, phosphuret, hypophosphite, or other compound of phosphorus in an oxidisable state in wine. I am ashamed to hear that such things are talked of in Medical consultations. I have been told that an eminent Physician, in consultation, asked, "Don't you think we had better order our patient to drink Carlowitz wine?" "Why?" "Because it contains phosphuret of iron." "Who says so?" "Why, have you never heard that it was ordered for the Lady Dulciana, and for the rickety eldest son of the Marquis of Carabbas, because it contains phosphide of iron?" My informant bowed in grim silence, hoping the day would come when Physicians would discard the logic of Mrs. Gamp. For our parts, let us wait till the phosphide of iron is produced from wine.

Now we come to phosphoric acid, in which the element is combined with its fullest equivalents of oxygen. And what an instructive lesson! How it shows our utter dependence humbly, step by step, upon observation and experiment, and how surely we get bemired if we shut our eyes to fact, and trust to *à priori* speculation and rationalistic argumentation. Look at phosphorus and sulphur, two kindred bodies. One virulently poisonous in its common condition, the other so mild that it is a common physic for babes. Yet look at their analogous acids and salts. Sulphuric acid, however largely diluted, is austere, styptic, and pungent—a very valuable medicine in the right cases. Phosphoric acid, on the contrary, mild, more like a vegetable acid, soothing to irritated throats, useful in the coughs and ulcerated throats even of the phthisical, for whom the sulphuric would be too acrimonious. I have proved this over and over again; but it never could have been guessed *à priori*. Physicians have a most valuable remedy in phosphoric acid; but its value is just that which on hypothesis it ought not to have. It is mild, soothing, and quieting, whilst it might have been expected to be fiery, hot, and acrid.

Just in like manner is the contrast kept up between the salts of the sulphuric and the phosphoric acids in their reactions on the human body. The sulphates are, as a rule, bitter, austere, astringent; the phosphates, as a rule, mild, tasteless, and cold. Most likely these differences are founded on the fact that phosphates, as such, are present in the animal fluids, and, therefore, are not uncongenial to them. Sulphate of soda, or Glauber's salts, is a purgative so bitter that it has almost passed out of use. Sulphate of potass, or Polychrest salt, is a most valuable purge in small doses, as was well established by that eminent empirical Practitioner of the last century, Dr. W. Fordyce, but in large doses is so severe as to be employed for procuring abortion, and to be reckoned amongst poisons. Phosphate of soda is sold as the "Tasteless Aperient Salt," and can be taken in any dose without serious harm, though, if not enough to purge, it "sits heavily on the stomach," possibly through its very insipidity. Sulphate of iron irritates a ticklish stomach; phosphate of iron in any shape is as mild as a salt of a vegetable acid, and may be smuggled into an irritable stomach in almost any case in which iron is tolerated at all. If we want a still more conspicuous instance of the fact that the salts of phosphoric acid are, of all others, the most unstimulating, the most tasteless, characterless, and innocuous, let as look at the salts of ammonia. The chloride is a most pungent salt, and burns the tongue if a little crystal be tasted incautiously. The sulphate is bitter and

(a) See a pamphlet, "De la cause immediate de la Phthisie Pulmonaire, des Maladies Tuberculeuses, et de leur traitment specifique par les hypophosphites, d'aprés les principes de la medicine stoechiologique. 2e edition, par T. Francis Churchill. Analyse publiée dans le *Scalpel* par M. le Dr. Hippolite Bareller. Liège: J. D. Carmanne. 1864."

nauseous. The nitrate tastes cool. The phosphate very cool and almost insipid.

I am ashamed to say that I have heard of Physicians ordering *phosphate of ammonia* as a "stimulant"! as a "nervine tonic"! as "food for the nervous system"! &c., &c. Some may do so, on the notion that what phosphoric acid and ammonia each is alleged to do separately must be done by both in combination, just like the Practitioner who always gave sulphuric acid with lead because each would stop spitting of blood. Some may do so on some other theory, but will any one come forward with the results of practice? Even the rottenest theories may, like dung, promote good practice if they lead to repeated experiments and trials; but I ask again, has any one any experiments to record on this point?

All these things are humiliating enough when we discuss them in the innermost circles of Physic. They make one say to one's juniors, "Vides, mi fili, quantulâ sapientiâ curantur ægri." But we ought to sit in sackcloth and ashes when we find such hollow rationalisticism creeping out of the domain of physic and invading the counting-houses of our wine merchants by our vicious example. What will become of us if wine merchants take to arguing like Physicians!—if, when we remonstrate, and say that our wine is hot, or sour, or flat, or flavourless, or else perhaps polluted by some horrid earthy taste, we are presented with a certificate assuring us that the horrid liquid is perfectly good, because it is particularly "rich" in bone earth and in the salts that give its value to guano?

Alas! they have begun it, as I shall show directly. But now for a few words about "phosphates." Utterly devoid as they are of all stimulating properties, still they are, like many other mineral substances, absolutely necessary to animal and vegetable life; and without them no vegetables grow, nor can animals live on vegetables without them. But they are found everywhere; and in all common vegetables, as vegetables, and without reference to specific virtues. They are found by M. Terreil in mallows and dandelions. Bread contains much; bran more. The vine sap contains them; so does the grape juice; so does wine; but they are in wine as in all other vegetable juices in common, and are not the cause of the proper virtues which distinguish wine as wine. In fact, the more perfect the wine, the less does it contain of those earthy matters which cling to it through its vegetable origin.

In order to set my readers' minds at rest, I beg to subjoin two analyses, by Dr. Hofmann, the able director of the Royal College of Chemistry. One, of the Carlowitz, whose character has been damaged by injudicious Medical friends; another, of Como, a wine full of all the grape elements, but less perfectly fermented, fruity, and like young Port wine.

Max Greger's Carlowitz, selected, at 32*s.*

	Grammes.
I. Total solid matter (dried at 110° C) .	2·2720
Ash.	·29995
Phosphoric acid	·04162
Iron (met)	·0027

Denman's Como, at 20*s.*

	Grammes.
II. Total solid matter (at 110° C) . .	8·0216
Ash.	·5201
Phosphoric acid	·0735
Iron (met)	·0034

Of course the more concentrated grape juice shows itself in the Como, as it does in Tokay.

Now, what are we to think of the matter-of-fact character of a Profession which can recommend wine because of its phosphate of iron, and Carlowitz for its supposed excess of that salt?

I should not take up your time in demolishing this *phosphor myth* were it not that the ridiculous chemical eulogium of Kletzinski, and his use of the word "phosphor," backed, as they were, by the most unfortunate opinion of Liebig, as to the value of *richness in phosphates*, threaten to be the germ of a prolific crop of quackery.

The reputation of Tokay as a nervine stimulant is, I believe, established. Nor need I mince matters and refrain from saying that "when childless families despair" (I quote from Tate and Brady's version of the Psalms; Brady was chaplain to Apothecaries' Hall, *temp* William and Mary, and translated the Psalms as such), when January is wedded to May, and when old men wish to have the privileges of young ones, then Tokay is in request. It was, as I am told, a favourite drink at the court of King George the Fourth.

Well, by some absurd delusion, the restorative virtues of Tokay were inscribed to *phosphorus!* and hence the subtle attraction of the word. Any wine rich in phosphorus must be equal to Tokay at half the price! But there are lower depths still. As we displace Dr. Henery, up come another class of advertisements! See!

"The restorative effects of Tokay wine on impaired constitutions are well known, but its high price debars its use. A cheap but equally efficient substitute may be found in the celebrated Stogumber pale ale. In both the beneficial effect is due to the presence of phosphorus, Nature's great agent in the repair of the ravages of time and excess. This ale derives its remedial properties from the water of Harry Hill's Spring, from which it is brewed. While acting as a tonic and an alterative, it is unequalled for general use, being as grateful to the healthy sportsman as beneficial to the debilitated."—*Morning Star.*

Now, all this quackery has sprung up in Medical circles. We have ourselves to thank for it; and every one who has lauded Carlowitz wine because of its alleged phosphate of iron is an *à priori* ally of the gentry who puff their phosphorescent swipes.

P.S.—Let me quote from the last number of the *Dublin Quarterly Journal of Medical Science* what Dr. Wallace says in his *Contributions to the Volumetric Analysis of the Urine.* But now let us hear Dr. Wallace:—

"It has become the practice with some to give phosphates in cases of disease of nervous tissue, and the plan was followed at the commencement of the treatment of Case I. Further reflection, however, led to giving up the practice. If the phosphates are wanting in the urine, it is not because they are not supplied in sufficient quantity to the system, for there is always abundance of them in the food. Either they are not assimilated at all, and are passing off some other way, in which case there is no reason to suppose that phosphate of zinc or iron would be better assimilated than the phosphorus normally present in the food; or, possibly, they are being used up in the construction of some abnormal growth, as chloride of sodium seems to be in the hepatising lung of pneumonia, and then an additional supply of them would be positively injurious if absorbed at all. It may, however, be well doubted whether it is possible to supply phosphorus or sulphur to the tissue of either nerve or muscle by putting phosphates into the alimentary canal. It is probable that the phosphorus contained in the phosphates which are in the blood is on its way *out of* rather than *into*, the tissues, and that it is introduced into them as an elementary part of the albuminoid components which pass into the blood as chyle. If this be true, then the administration of phosphates with a view to their being assimilated is useless."

REVIEWS.

Statistical Report on the Health of the Navy for the Year 1861. [Ordered by the House of Commons to be printed, July 1, 1864.]

In some "Preliminary Observations" by Dr. Mackay, with which this Report opens, he dwells forcibly upon the paramount importance of those duties of a naval officer which are included under the term "sanitary duties;" and as might, after this exordium, have been anticipated, the Report is occupied to a great extent with questions relating to etiology and practical naval hygiene. To one or two of these questions we shall briefly allude.

It appears that during the year 1861, seventeen cases of tænia occurred on board the *Melpomene* on the Mediterranean station; and the following extract from the report of the Surgeon tends to confirm, if it now requires any confirmation, the current belief among European observers of the mode in which this parasite gains access to the human body:—"I was led to pay increased attention to the frequent occurrence of tænia in the ship, with the view of ascertaining the truth of a report that the water obtained from the Cat river at Beyrout contained the ova of the worm. The impression was derived from the fact that children, as well as adults, in the population of Beyrout are very commonly the subjects of the affection; but the practice of eating uncooked pork, to which our men in particular were addicted, I think explains the frequency of the complaint, and disposes of the belief that the water of Beyrout was the vehicle of its introduction."—P. 38. This gentleman gave to different patients the fresh ground root of the kousso and the oil of male fern, with a view to test their relative

value. He found that while with the former the disease reappeared after a few months, the very dose was so large as to produce vomiting, and its powerful action brought on troublesome prolapsus of the rectum. The male fern oil, on the other hand, he says, is free from the objections which lie against the kousso, and the worm and any joints expelled after the first portion showed no signs of vitality.

It is satisfactory to find that the system of inspection of prostitutes at Malta has been so successful that, although leave was twice granted to the crew of the *Agamemnon* at that place, not a single case of syphilis occurred. Contrast this with what we read of the condition of the men on the stations in China and Japan:—"The virulent character which this fearful scourge of the naval service assumes in China is probably dependent as much upon the more or less debilitated constitutions of the men who suffer as upon the miserably cachectic objects from whom the disease is contracted. Be this as it may, there is, perhaps, no place where, within the last twenty years, the reception of the syphilitic poison has been fraught with more disastrous results than on this part of the station; and it is therefore all the more necessary that there should be no relaxation whatever in the exercise of that wholesome surveillance which has been for some time instituted over the prostitutes in those localities where we can exercise any control. The Japanese local authorities may have the power, but they certainly do not as yet seem to have the will, to check the ravages of this disease, although the fact of prostitution being with them a government monopoly would appear to give greater facilities for almost entirely eradicating it than can be possessed by any other nation."—P. 178.

The portion of the report relating to the North American and West India stations contributes some important facts relating to the origin of yellow fever in certain ships on that station, in infection. We quote some remarks upon this outbreak, which also show some of the difficulties which surround the investigation of a subject which has given rise to much controversy, at the same time that they tend to explain the discrepant conclusions of the controversialists themselves.

"Such is the history," Dr. Mackay writes, "of the outbreak of yellow fever in these ships. The cases occurring in the *Rinaldo*, few though they be, are a very valuable addition to the numerous records which already exist demonstrating the infectious nature of this fearful disease. We have here an instance of a ship direct from England, touching only at Madeira on the way, arriving in a harbour in a temperate region (Halifax), the climate of which is looked upon as the antidote to which yellow fever-stricken ships fly. While there a ship (H.M.S. *Spiteful*, from the Havanna) arrived with many yellow fever cases on board. Every precaution that can possibly be taken to prevent communication with the infected ship is adopted; but from the nature and exigencies of the service this cannot be done effectually; working parties from the two ships meet in the dockyard, and the sick in hospital with ordinary complaints are brought into contact with convalescents from yellow fever. The result is, that a boy, one of the Dingey's crew, in constant communication with the shore, and mixing freely, doubtless, with the working parties from the infected ship—a man whose work was altogether in the dockyard, and who, although he denies having had any communication with the *Spiteful's* men, was doubtless in such circumstances as to render it more than improbable that he had not some intercourse with them—and another man, who had been a patient in hospital, and had only been brought on board his own ship on the day of her sailing for New York—are stricken down with undoubted yellow fever; and of these three two die, one on the third and the other on the fourth dry of the attack. Would these cases have occurred had not yellow fever been imported into Halifax? Reason and experience are alike opposed to such a supposition. That the disease did not spread amongst the ship's company is probably entirely attributable to the temperate climate of the locality in which it made its appearance."

"The difficulty of tracing epidemics to their sources is frequently very great; and, singular to say, on board ship it appears to be particularly so. Even when epidemics of such diseases as small-pox, scarlatina, and measles make their appearance, the source from which the first case derived the infection can, in a large number of cases, only be inferred. Sailors, as a race, are so thoughtless that some if they were disposed to give evidence as to where they had passed their period of leave on shore, it is very questionable whether they could accurately do so. Their tendencies are, however, to give a direct denial to anything which they think may implicate themselves; and viewing all questions of this nature with suspicion, even when the object of the inquiry is fully explained to them, they will often so withhold or vitiate their evidence as to render it utterly valueless. It may be accepted, however, as a general rule, that the haunts of the seaman on leave are those very localities in which pestilential diseases most frequently abound; and to these sources, therefore, in default of other evidence, epidemics of the exanthemata on board are commonly and with justice referred.

"When such difficulties are met with in tracing the source of disease familiar to every one, and which, in the majority of cases are marked by features easily recognisable, it will not be matter of surprise that the difficulties will be much increased in tracing such a disease as yellow fever, which need not present any other appearance than that of the most ordinary febrile seizure, and which may be closely simulated by another form of fever, not so fatal in its nature, and not capable of being conveyed by infection from one person to another. In the history of the epidemics on board these ships we have an instance of this difficulty. In the case of the *Firebrand*, that ship had for fifty-eight days been lying in the inner anchorage at Carthagena, where leave had been given, and daily communication was had with the shore. Fever, it was stated by the inhabitants, did not exist in the place, and had not for seven years. This statement may be taken for what it is worth; to an inquirer desiring accuracy it will be of little value.

"The Surgeon of the *Firebrand* states it as his opinion that the disease was contracted at Carthagena. On this point he has no doubt; but he says it was occasioned by malarious emanations from the neighbourhood of Carthagena. Malarious emanations, however, do not give rise to specific yellow fever. A reference to the state of the squadron on the West Coast of Africa in this report will afford abundant evidence to this effect;"—and a most interesting report it is, showing the powerful influence of quinine and careful guarding against exposure at night as prophylactics. "In the month of July," proceeds Dr. Mackay, "yellow fever was raging as an epidemic, not only in Havanna, but all over the island of Cuba. During this month the harbour was visited by the *Jason*, the *Barracouta*, the *Spiteful*, and the *Racer*, all of which ships contracted the disease. The *Mersey* contracted the disease there in September and the *Challenger* in December. It is not necessary to look to the offensive state of the harbour or the smell of bilge water on board ship as a cause for so specific a disease as yellow fever, when that disease was prevailing with such severity on shore. Even with the utmost care it is impossible to prevent a large amount of communication between ships' companies and the shore when ships are lying in harbour. Bumboats, washerwomen, the slaves employed in coaling, all form means of communication between the ships and the very localities on shore where the disease is most likely to be prevalent; and to these there may be added the daily communication on the part of officers, men-servants, and the crews of boats employed to convey them on shore."—P. 69.

The only other part of the report to which we shall now allude is that which relates to the outbreak of dysentery on board the *Gorgon* and *Lyra* on the Cape of Good Hope station. Twenty-five cases occurred on board the *Gorgon*, which the Surgeon attributes to the use of water from the Seychelles Islands at a time when the streams were low and a few heavy showers had stirred up the infusorial and vegetable matter in the water. It seems that the inhabitants were suffering in a similar manner. The dysentery on board the *Lyra* arose in a different manner. It seems that this vessel was employed in the suppression of the slave trade about Zanzibar, and had captured several Arab dhows engaged in the trade. "From the dhows taken at different times 200 slaves were removed to the *Lyra;* some of these were suffering from dysentery, and one or two were in a dying state. The dhows from which they were taken were reeking with the stench from their bodies and from the evacuations which had been suffered to collect in the hold in which the poor wretches were stowed. In the dhow which was sent away with the officer and crew the stench was so overpowering from the stirring up of the accumulated filth in the hold when the vessel began to roll about at sea, that every one on board was sickened by it, being seized with vomiting and purging. On board the *Lyra* every endeavour was made to keep the ship as clean and wholesome as possible, but the apathy of the slaves and their extremely filthy habits rendered this a most difficult and offensive task. From this time diarrhœa and dysentery became epidemic."—P. 153. Out of a complement

of 113 there were 58 cases of these complaints between April 1 and May 31. On arrival at Mahé, in the Seychelle group, on May 13, the slaves were landed, and the worst cases in the ship's company removed to sick quarters, and on this being done the disease was arrested.

There is very much in all these reports calculated to throw light upon those complicated questions of etiology which arise so often amongst ourselves on shore. The questions are often, indeed, identical which have to be solved by naval officers and by sanitarians labouring in large towns at home; but to the former the conditions bearing upon the outbreak of disease are often simplified, while the scale on which they operate is vastly greater. In fact, we are enabled to view many of our own problems thus almost ready solved for us.

FOREIGN CORRESPONDENCE.

AMERICA.

(Continued from page 129.)

Near Petersburg, Va., December 28.

We will now go to Rainey's, and ascertain how it fares with the operating staff of the Medical departments.

The scene here differs widely from that we have just left. There is no excitement here; there is collapse. The neighing of a restive horse or groan of a wounded sufferer is about all that breaks the silence. In front of the house, hitched to the rail-fence, are the horses of the Medical officers. Behind it the ambulances are drawn up in line. They are not in use; the distance between the Hospital and the front is so small that the stretcher-carriers can do the work more tenderly, and withal as expeditiously. Still further behind is an army of horses; they belong to the cavalry, who have dismounted to defend the line in front of the house.

The kitchen garden is filled with wounded, and every few minutes their number is increased by fresh arrivals. Poor fellows! Theirs is a dreary present, for their future is uncertain; and they are faint, chilled, and wet—yes, drenched to the skin. The excitement and suspense of the day has until now prevented us from observing it, but of a truth it is, and has been since early morning, raining heavily.

Most of the Medical officers are engaged in attending to the patients—in marking out those that must be brought to the operating-tables when their construction shall have been completed. One or two are under the porch, extemporising them from doors that have lately been wrested from their hinges. They are just about finished, when some scattered musketry rings sharply through the woods in front. Every hand is arrested, and every pulse beats quicker at the sound. Soon it swells into one loud, continuous rattle, while the song of travelling bullets throws a sense of danger over all the inmates of the Hospital, which the confusion among the cavalry horses, as they are being led out of the line of fire, does not tend to allay, nor the wild shrill yell of the rebel line as it strives to drive our gallant troopers back. What if they should be driven back? Yes; the wounded must be got out of this. Activity now prevails. The ambulances are ordered up, and each, as it is loaded, drives off to the right to be out of danger. It is soon evident, however, that the transportation is insufficient. Some of the wounded must be left. Three Medical officers volunteer to remain with them in case the worst anticipations should be fulfilled. Gallant fellows! Does not that yell, echoed from mouth to mouth along a line of foes, daunt you? It requires a bold heart or a bullet-proof shelter to carry one through what you volunteer to do—to lie tamely upon a contested field while friend and foe alike throw death towards you.

A new sound breaks through the confusion that fills the air; it is a lusty cheer,—a long exultant hurrah, that warms each drooping heart around the Rainey House, and tells of victory. The enemy have been repulsed.

As the infantry fall back after their unsuccessful attack, a rebel battery opens a spiteful fire of shell upon the cavalry line. Nearly every shot passes over the Hospital, and bursts harmlessly three or four hundred yards beyond. They fire too high, and have their fuse too long. One crashes through the house, and as it makes its exit explodes, sweeping a mass of withered leaves and twigs from a dwarfish tree that stands in its course, luckily without injury to the wounded man reclining at its foot.

Darkness begins to thicken; the explosion of each rebel gun lights up the horizon with a momentary flash, and every shell streaks the sky with a line of fire as it is hurled towards us. The firing slackens, and soon after ceases.

An hour and a-half drags tardily along. Nothing of importance could be done to alleviate the sufferings of the wounded, as the only orders the Surgeons have is to do nothing, but await further orders. They come at last. The struggle is not to be resumed on the morrow. The troops are to return to camp. The loaded ambulances will take the lead in the homeward route, accompanied by a regiment of infantry to protect them from straggling parties of the enemy's cavalry. They will halt at the Gurley House, where the medicine waggons are parked, and a temporary Hospital will be formed there. No time is directed to be lost after arrival at that point, as it is desirable that all operations be performed and the wounded lodged by rail at City Point Depôt without delay.

The wounded at Rainey's, for whom there is no transportation, are to be left there, under charge of the officers who volunteered to remain with them earlier in the day. The only supplies at their disposal are the contents of two or three of the field companions.

Nearly two hundred wounded were carried along; the number left to the care of the enemy is uncertain—perhaps a hundred and forty—perhaps not so many. The captured Medical officers are still within the limits of the confederacy.

One Surgeon was wounded in this affair, several stretcher men were hit; every member of the squad attached to one brigade was at one time during the first assault in the enemy's hands, but when their captors were thrown into confusion by our flank attack they, with the exception of two, succeeded in effecting their escape.

It is very gratifying to have to record that in the ingathering of the crop of laurels, of which this season has been so productive, the Profession has been well represented among the successful reapers. The following officers in the army of the Potomac have been appointed by the President to brevet rank for meritorious services rendered in the field during the present campaign before Richmond:—Major Y. A. McParlen, Surgeon, U.S.A., Medical Director A. of P., to be brevet lieut-col.; Major A. N. Dougherty, Surgeon, U.S.V., Medical Director 2nd corps, to be brevet lieut.-col.; Major J. J. Milhaw, Surgeon, U.S.A., Medical Director 5th corps, to be brevet lieut.-col.; Lieut. C. Smart, Assistant-Surgeon, U.S.A., Medical Inspector 2nd corps, to be brevet captain.

The Medical officers of this army are in expectation that Congress during its present session, by recognising in some way the services of those of their number who have been in the field since the commencement of the war, may succeed in retaining them until its termination. The best Professional men we have here connected with State organisation are those who, at the outbreak of the rebellion, from purely patriotic motives, threw up lucrative practices and volunteered for three years. This term has now expired, and they are being mustered out of service in squads. They prefer this course to volunteering for another term. They have had enough of war and its life of hazards and hardships, and long for the quiet and comfort to which they were accustomed before the commencement of this unexpected chapter in their lives. They consider they have done their duty to their country. "Let others go and do likewise." Were they by profession military Medical officers, as are the members of the Staff Corps, they would no doubt prefer to stay in the field in order to enjoy the opportunities of improving the art of military Surgery and themselves in it which the present offers, and which may, it is to be hoped, at no very distant day become unattainable. But they are not such. They are men who have heretofore driven around in their quiet practice, thoughtless of the mighty struggle in which they were soon to become participators. The long-gathering storm burst. Friends, country, humanity called upon them to haste to the succour of suffering thousands, and they did so. They served at first *con amore*, but as months rolled on changes took place in the regiments to which they were attached, and these very often exercised a most pernicious influence upon their future course. The colonel, lieutenant-colonel, and major became disabled or killed; so with the line officers. Campaigns such as that of the past summer make promotion wonderfully rapid. A former sergeant, wearing the silver leaf or outspread eagle of a field officer, may now command. A fine soldier he no doubt is and an honourable man, but a number of petty annoyances do come home to the Medical officers out of this state of matters. Although these be but trivial, it is such that during

the monotony of a winter camp make up the sum of life. Hence they become irritable; a distaste for their position creeps on them; they long for the expiration of their term; and although they do not fail in the line of duty, they do it simply because it is a duty.

No promotion is held forth to them as an inducement to perseverance in the cause. They commenced their career as majors, and as such it is ordained they shall terminate it. No higher rank, under existing circumstances, is before them, were they to serve for three times three years. Not that they are dissatisfied with a majority, They look upon that rank as the proper position for a Medical officer; it is their regimental connexion they dislike. They would have held forth to them as a reward for long service the probability of a staff appointment. They would wish a transfer to one or other of the Staff Corps, U.S.A. or U.S. Vols., without being subjected to the examination now required, and without loss of rank, for under the present rule Medical men joining these corps must enter as assistants, and serve anew for the Surgeonship.

In July of this year the War Department attempted to compromise matters by instituting an acting staff grade, for which all Surgeons who have been honourably reported after two years' service are eligible. The pay and emoluments of a Major of cavalry are offered, but no rank and no commission. The numbers that have remained under this order are fewer than could have been wished, for it is not a contract between Government and themselves as civil Surgeons that they desire.

Members of the Staff Corps feel this want of rank much less acutely than the State regimental officers. Their positions in charge of general Hospitals are more analogous to those of civil life. Yet those of them in the field do growl occasionally that they are but majors, while men holding similar positions in the Commissary and Quartermaster Departments are lieutenant-colonels. They also live in the hope that some Legislative Act during the ensuing session may affect their interests.

The Medical Department in the U.S. service is quite a complex structure. At the present time a new variety of the military Medical species is undergoing development at Washington. A body of troops is being organised and recruited, consisting of men who have seen at least two years' service, and have been honourably discharged. The Medical men to officer this force are required to be veterans also. They are to be commissioned by the President, and assigned to regiments,—this assignment constituting the difference between them and other officers commissioned by the same authority.

No less than seven classes of corps exist: four of these are commissioned by the President, one by the Governors of States, and two do not hold commissions.

1. Surgeons and Assistants of the U.S. army, the organisation that existed at the outbreak of the rebellion. These officers are now employed on staff duty.

2. Surgeons and Assistants of the U.S. Volunteer Corps.—A class of officers established for staff duty, when, after the war had fairly commenced, it was found that the regular army officers were insufficient to fill all the positions developed by its progress.

3. Surgeons and Assistants of coloured troops, commissioned by President, and on duty with the black regiment to which they have been assigned, ineligible for staff positions.

4. The officers of the veteran corps now in course of formation.

5. Regimental Medical officers of State organisations, commissioned by the Governor of the State to which their regiment belongs.

6. Acting-Staff-Surgeons.—Veteran Surgeons under contract as mentioned above.

7. Acting-Assistant-Surgeons, U.S. Army.—Civil Surgeons under contract, with pay of 1st lieutenant. No previous service is necessary to obtain this appointment. They are chiefly employed in Northern Hospitals.

The following story is told by Mr. G. A. Sala in his "Diary in America:"—"A Doctor went to settle in a village out West, and the first night of his arrival was sent for to attend a sick child. He looked at the little sufferer very attentively, and then delivered this oracular opinion,—'This hyar babe's got the small-pox, and I ain't posted up on pustules. We must approach this case by circular treatment. You give the little cuss this draught; that'll send him into fits; then send for me, I'm a stunner on fits.'"

GENERAL CORRESPONDENCE.

PRYCE *v.* BOWEN.

Letter from Mr. Essex Bowen.

[To the Editor of the Medical Times and Gazette.]

Sir,—It is my gratifying duty to ask for space in your columns for a word of true thankfulness to my Profession generally for its hearty sympathy and its most practical support in the difficulties and anxieties with which I have had so recently to contend.

I beg to express my gratitude for, and very high appreciation of, the ready and able advocacy of the cause of right which has been so generously rendered by your influential paper.

To the numerous members of the Profession, and others, both far and near, who, in addition to their kind sympathy and valued advice, have already completely indemnified me from the heavy expenses which the well-timed bankruptcy of my late adversary has rendered me liable to,—to these gentlemen I am most grateful; grateful not only for their pecuniary aid, but also for the assurance thereby given that those who are the only qualified judges hold me guiltless of the charge which has been thus maliciously brought against me. This assurance will henceforth enable me, as hitherto, fearlessly to undertake and conscientiously to perform every Professional duty which may devolve upon me. I am, &c.

Birkenhead, February 8. Essex Bowen.

ROYAL EPSOM COLLEGE.

Letter from Mr. W. A. N. Cattlin.

[To the Editor of the Medical Times and Gazette.]

Sir,—The interest you take in the prosperity and usefulness of the Epsom College has led you to place far too high a value on the part which I have taken in helping to bring about the alterations lately made in the "bye-laws relating to the school" of that institution. Having worked only as a member of a committee of some forty governors of the College, who were all as anxious and earnest in the matter as myself, and knowing as I do how much of the good effected has been due to the steady and long-continued influence in the Council of Mr. Ray, of Dulwich, Dr. Cholmeley, Mr. Hird, and other members of that body, it is with great pain and regret that I observe the marked prominence you give to my name in your last leader on the subject, or that you have mentioned me at all in connexion with it; and I earnestly wish that my rejection of the credit you have attributed to me could be made as prominent as was your award of it. I am confident that I may, at any rate, rely upon your courtesy for the insertion of this letter in your next number.

The Profession is deeply indebted to you for the untiring zeal with which the claims of its "less fortunate" members has ever been advocated in your valuable journal; nor will it be less grateful to the Council of the College for the boon which has been conferred upon it by the new bye-laws—bye-laws which, I hope, we shall all heartily and earnestly help the Council to make actively and efficiently operative.

I am, &c.

Islington, February 6. W. A. N. Cattlin.

OUGHT BUBO TO BE RESOLVED?

Letter from Dr. Harries.

[To the Editor of the Medical Times and Gazette.]

Sir,—Some time must necessarily elapse before we can derive the full benefit from the researches now being instituted into the nature and proper management of syphilis. I should wish, therefore, through your pages, to direct the attention of the Profession to what appears to me to be a great and widespread error of treatment; I refer to the usual management of the groin complication.

Whether or no there be at least two distinct lesions coupled under the name of chancre, the one infecting the bearer with syphilis, but never producing a suppurating bubo, the other not followed by secondary symptoms, and usually giving rise to a suppurating bubo, it is not necessary now to determine. Suffice it that it is a fact that a chancre followed by a discharging bubo is not followed by secondary or constitutional symptoms. The real exceptions to this rule are not more than occur to all fixed

laws. And it is at least as likely that the suppurating bubo prevents the passage of the poisons into the system, and thus decides that the chancre shall be a chancroid, as that the sore by this means proves its original nature.

The application of a certain material to the skin of the genitals produce a certain local change. This change is probably accompanied by the reproduction of the original poison, which, not being adapted for tissue building, is carried away by the lymphatics. These may or may not display irritation thereat. At the groin, however, the lymphatics communicate with a more complex gland, and here a new inflammation is set up. The self-made virus is to the lymphatic gland what the foreign poison was to the skin, and at this time the system generally is as little contaminated by the syphilitic poison as the skin of the penis was before its application. Practically it is still without the body, and now the question of syphilisation has to be decided. In one case the inflammation in the gland increases, the gland swells, matter is formed therein, the surrounding tissues are involved, the skin is reached, and the pus evacuates. The cavity then closes up, and the only mischief done is that an easily spared gland is destroyed. The extending inflammation has separated the sound from the unsound structures by an impervious wall of adhesion, so that not a trace of the poison has been able to pass into the system, and the mischief has begun and ended a local one. In another case the same course is pursued until the period when suppuration should occur; but instead of this, resolution follows, and the gland quietly subsides uninjured. Or suppuration may actually occur; and yet under the treatment employed, absorption and resolution may liberate the gland. What is the result? A poison that might have been thrown out here is allowed to enter the general system; a never-ending series of constitutional symptoms follows; and we remark that while that case was a chancroid, this must have been a chancre.

Seeing, then, that so much depends on the ejection or non-ejection of the poison at the groin, what would be the rational treatment? Clearly, by all means in our power, to promote suppuration there, and thus to save the patient from the other ills. When matter has fully formed, the sac should be fully laid open, and then stuffed with tow and kept discharging freely until it is entirely healed. There is no need for absolute rest. No mercury should be given for a sore on the penis as long as there is a chance of suppuration in the groin; for while removing the induration or inflammatory adhesion on the penis, it is also dissolving away the line of safety round the gland in the groin. The former is no harm; the latter is a great good. Some cases thus treated will, of course, do badly, but the percentage of secondary affection will be less than under the usual method.

Now refer to the treatment advocated by Surgeons generally. Druitt is a fair exponent of the most common views. In his "Manual," eighth edition, page 196, he thus lays down the law for the treatment of acute bubo:—"The first indication is to produce resolution by rest, aperient and saline remedies, low diet, leeches, and fomentations." "As soon as the tenderness is relieved, pressure by means of a compress and bandage, or by placing a weight on the part as the patient lies in bed, is useful. Even if matter does form and does not seem inclined to come to the surface, the iodine paint, cold lotions, aperients, tonics, and pressure will sometimes cause it to be absorbed." Is it credible that the "it" in this case is a deadly poison, whose absorption is the thing most to be dreaded? Fancy Surgeons laying down similar rules for ensuring the absorption of the poison of hydrophobia! Twenty years hence shall we find a man who bedaubs an advancing bubo with iodine?

To multiply quotations is useless; the same instructions you have in all the guides, the same practice you see everywhere. If by way of a change the Profession would but second the efforts of Nature to eliminate the poison—they have "promoted its absorption" long enough, goodness knows!—the melancholy ranks of syphilitics might be somewhat thinned. Craving their serious reconsideration of this point,

I am, &c. GWYNNE HARRIES, M.B. Lond.

NEW MEDICAL CORONER.—We are informed that Mr. Garrington has been elected Coroner for the Borough of Portsmouth.

THE Duke of Beaufort has lost nearly forty head of deer from their browsing on a yew, the boughs of which were bent down within their reach by the snow.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JANUARY 4.

Dr. OLDHAM, President, in the Chair.

THE following gentlemen were elected Fellows:—Mr. J. H. Bridgeman, Dr. E. Copeman, Mr. Fairbank, Dr. Hodder (of Toronto), and Mr. Whitehead.

Dr. PLAYFAIR read a case of Extra-uterine Fœtation, on which Dr. PRIESTLEY made some remarks.

Mr. WILLS, through Dr. GRAILY HEWITT, described the Mode of Birth of a Double Monster, and exhibited a photograph of the same.

Dr. PARSONS exhibited a specimen of Pulmonary Embolism, of the Tubular Kind, after Ovariotomy, and described the case.

Dr. RICHARDSON entered at considerable length into the question of these fibrous deposits.

Mr. NAPPER read a case of Amputation of Arm during early Pregnancy.

ANNUAL MEETING.

The business of the annual meeting then commenced. The report of the auditors of the accounts of the Treasurer for the year ending December 31, 1864, was read, from which it appeared that the balance in the hands of the Treasurer is £262 6s. 5d., and that during the year a sum of £181 10s. was invested in Consols in the name of the trustees of the Society, making a total now invested in Consols of £731 10s. The balance-sheet showed that the Society had received during the year the sum of £469 7s. as subscriptions from the Fellows, and £40 9s. 6d. from the sale of *Transactions*.

Mr. MITCHELL, in proposing the adoption of the report, congratulated the Society on its financial prosperity. Mr. NICHOLS having seconded the resolution, it was carried unanimously.

The SECRETARY having read the modifications of the laws rendered necessary by the opening of the library, Dr. MEADOWS proposed their adoption. This being seconded by Dr. HALL DAVIS, was unanimously adopted.

It was then announced that arrangements were now completed for the lending of the books of the library to the Fellows at Mr. Hardwicke's, publisher, 192, Piccadilly.

Dr. PRIESTLEY moved with great pleasure, and was seconded by the whole meeting, the following resolution:—"That the thanks of the Society be, and are hereby, given to the President and officers of the Society for their services during the past year. That they be particularly given to the retiring President, Dr. Oldham, for the able and efficient manner in which he had presided over the Society; and also to Dr. Graily Hewitt, on his retiring from the office of Honorary Secretary, for his zealous aid rendered to the Society from its commencement."

The list of donations to the library were then read.

The following gentlemen were then elected officers for the ensuing year:—*Hon. President*—Sir C. Locock, Bart., M.D. *President*—Dr. Barnes. *Vice-Presidents*—Dr. Gream, Dr. Greenhalgh, Mr. F. S. Haden, Mr. Robert Hardy (Hull), Dr. Tanner, Dr. J. G. Wilson (Glasgow). *Treasurer*—Dr. Graily Hewitt. *Hon. Secretaries*—Dr. Braxton Hicks, Dr. Alfred Meadows. *Hon. Librarian*—Dr. A. Meadows. *Other Members of Council*—Dr. Aveling (Sheffield), Dr. Clay (Manchester), Dr. John Hall Davis, Dr. Gervis, Dr. Alfred Hall (Brighton), Mr. I. Harrinson (Reading), Dr. Madge, Mr. Josh. T. Mitchell, Dr. Gustavus C. P. Murray, Mr. Edward Newton, Dr. Oldham, Dr. W. O. Priestley, Mr. Edward Ray, Dr. Samuel Richards, Dr. Thomas Skinner (Liverpool), Dr. Tyler Smith, Mr. Fred. Symonds (Oxford), Mr. James Reeves Traer.

The PRESIDENT then delivered the

ANNUAL ADDRESS.

He referred to the prosperity and activity of the Society, as shown by the balance-sheet, by the *Transactions*, and by the number of its Fellows, who now were to be found in Australia, New Zealand, India, and Canada. He lamented, however, the deaths of six Fellows during the past year. He congratulated the Society upon the formation of the Lending Library, which had long engaged the attention of the Council. The tone in which the discussions had been carried on in the Society was very satisfactory, although subjects had been brought before them upon which there had been strong diversity of opinion.

Dr. Oldham pointed out that it was to the interest of the Society to continue to maintain this spirit unimpaired. He thought it desirable to establish a committee of two *experts* to report to the Society upon the results of any new line of practice which might prove of serious consequence to the patient. It was one of the duties of the Society not only to bring forward new suggestions for improving practice, but, by the light of modern science, occasionally to revise the older rules and opinions; and he noticed, among other subjects, the advantage of the careful and intelligent investigation of the influence of the ergot of rye on the mother and fœtus, and on the uterus in functional or organic diseases. He alluded to the possibility of improving the education of women as nurses to the lying-in room, by instructing them in public institutions to a competent knowledge of their duties, which would save a vast amount of the injury and misery inflicted by incompetent nurses. Referring to the revival, in a recent case, of a jury of matrons to decide upon the pregnancy of a condemned criminal, he hoped the Society would take an early opportunity of endeavouring to induce the Legislature to alter this rule, and refer in future to obstetric Practitioners. The President, in conclusion, expressed his warm acknowledgments for the assistance rendered him by the honorary secretaries; and thanked the Fellows for their support, which had rendered the performance of his office one of the most agreeable recreations of his Professional life.

Dr. Tyler Smith proposed, and Dr. Greenhalgh seconded, a vote of thanks to the President for his valuable address, which was carried unanimously.

METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

At the meeting of this Association on Saturday evening, January 21, Dr. Druitt in the chair,

Dr. Letheby, gas analyst to the City of London, delivered a lecture, with experimental illustrations, upon the means of testing the illuminating power and chemical quality of coal-gas. At the commencement he stated that the object he had in view was not a scientific discussion of the various subjects which were to occupy their attention: his intention was to give a brief and simple account of the practical means to be used in estimating the illuminating power and chemical quality of coal-gas, so as to meet the requirements of recent legislation in this matter. The four points which were generally set forth with more or less precision in almost all modern Acts of Parliament relating to the supply of gas were—first, that when the gas is burnt in a particular manner, it shall have at least a certain minimum illuminating power; second, that it shall not contain more than a certain portion of ammonia; third, that it shall be free from sulphuretted hydrogen; and fourth, that it shall not contain more than a certain proportion of sulphur in any form. With regard to the means or appliances for estimating the illuminating power of gas, he observed that they were founded upon the principle that the intensity of light decreases as the distance of the luminous object from the observer increases, and, as the light radiates in all directions, the diminution of intensity is in proportion to the squares of the distance. Bearing this law in mind, the next and only remaining consideration was how to measure or judge of the relative intensities of two lights. Various modes had been adopted, the first being the simple plan proposed by Count Rumford, in 1794. It consisted in placing a rod before a white screen, and then so adjusting the position of the lights that the two shadows of the rod cast side by side on the screen are exactly of equal depth. The distances from the rod to the lights are then measured and squared, the numbers so obtained representing the relative intensities of the light. Another and common method of judging of the intensity of two lights was to observe at what distance from each of them a given object, such as small print, was clearly—equally clearly—perceptible, and then measuring the respective distances and squaring them. As far back as 1760, M. Bouguer directed attention to the fact that the eye could perceive very small differences in the intensity of the light from two objects, if the illuminated surfaces were close together; and the late Professor Ritchie, taking advantage of this suggestion, and improving the photometer of M. Bouguer, contrived an instrument for judging very accurately when the light from two objects is exactly equal. It consisted of two reflecting surfaces so placed as to throw the light from the two sources side by side upon a piece of tissue paper, and this being enclosed in a dark box, the equality of illumination could be accurately judged of. The lights being so arranged as to give a like intensity of illumination, the distances between them and the discs were measured and squared, as in the other cases. But the most ingenious of all the contrivances hitherto used was that of M. Bunsen. It consists of a piece of white filter-paper saturated with wax or spermaceti, except upon a small spot in the centre. When this paper is looked at by reflected light the centre spot is white, and the rest of the paper dark or greasy; but when looked at by transmitted light the waxed part is translucent, and the central spot dark or opaque. When this paper is held vertically between two unequal lights, it shows a dark spot and a light ground on the side of the lesser light, and a white spot with a dark ground on the side of the stronger light. By moving the paper nearer and nearer to the weaker light, the spot gradually disappears, until there is an exact equality of reflected and transmitted light on each side. The lights are then equal, and the distances of each from the disc being measured and squared, their relative illuminating power is determined. After referring to a contrivance of Mr. Wheatstone, in which the reflections cast by a silvered glass bead moving rapidly in a planed or eliptical direction between two lights was employed for a similar purpose, the lecturer stated that he had himself contrived, and was now perfecting, a photometer which, he thought, would enable them to dispense with a good deal of the complicated machinery required for testing the illuminating power of gas, and would enable them to ascertain the amount of light evolved from any gas flame in any position, as, for example, from a street lamp. It consisted of a wedge of dark glass, which was made to pass across an eye-piece placed at a given distance from the light; and according to the intensity of the light would be the thickness of the wedge through which it could be seen. This is graduated to a scale indicating the value of the light. After glancing at some other contrivances having the same end in view, the lecturer said the only two which were in practical operation were—1, A modification of Bouguer's and Ritchie's plan, which is in use in France, and the plan of Bunsen, most generally followed in this country, several forms of which instrument were employed. Having described and illustrated the mode of using the photometer, and indicated the standards of comparison, he proceeded to treat of the conditions to be observed in testing the illuminating power of gas for the purposes of the Metropolis Gas Act. In the 1st place, the gas should be accurately measured, and the rate of combustion should be steadily kept at five cubic feet per hour. This was best done by means of a contrivance by Mr. Sugg, of Westminster, in which a clock was introduced into a meter, the hand of the clock and the meter going together. 2. The gas should be delivered to the burner at a uniform pressure, which was effected by means of a governor, the invention of Mr. King, of Liverpool, and which was placed after the meter. 3. The gas should be burnt from an argand burner, having fifteen holes and a seven-inch chimney. The rule was, to select that burner which burnt the gas so as to bring the apex of the flame exactly on a level with the top of the glass. 4. To use a very delicate Bunsen disc; for although made in the same way and at the same time, not one in a dozen is sufficiently delicate to indicate the tenth part of a candle. 5. To have all reflected and diffused light completely excluded from the disc, which was best accomplished by having the disc in a dark box with conical ends. 6. To have contrivances, as small mirrors, for seeing both sides of the disc at the same time. 7. To have screens before the gas and the candle to keep the light from the eyes, and so to preserve their sensitiveness when viewing the disc. 8. To work with two sperm candles, taking care that they are free from paraffine, and that they burn nearly at the rate of 120 grains per hour each. 9. To light the candles as well as the gas ten minutes before making the experiment, and to balance the candles and weigh them while they are burning. 10. To continue the experiments for ten minutes, making observations of the disc every quarter or half minute. 11. To take care that the temperature of the room does not rise much above 65° F. 12. To reduce the experimental results to the required or standard proportion either by means of the printed tables or by multiplying the observed illuminating power by the observed combustion of the candles, and dividing by 120. The next consideration related to the means of testing the purity of gas. The Metropolis Gas Act of 1860 directs

that the gas shall be so far free from ammonia and sulphuretted hydrogen that it shall not discolour turmeric paper or paper imbued with acetate or carbonate of lead when these tests are exposed to a current of gas issuing for one minute under a pressure of $\frac{5}{10}$ths of an inch of water. These impurities were so easily recognised, and the process for detecting them so clearly described, that it was not necessary to make many observations upon the subject. He would only say that in order to obtain the required pressure, a small sheet governor, manufactured by Mr. Sugg and adapted by himself for this purpose, should be used; and that, in applying the turmeric test, care must be taken that the turmeric was of good quality and of a deep orange-yellow colour, and that it was melted with water immediately before being employed. When it was necessary to determine the exact amount of ammonia present the gas was made to pass through a glass tube about eight inches long and one inch in diameter, filled with fragments of broken glass, moistened with a known quantity of a solution of oxalic acid or dilute sulphuric acid. By having a piece of litmus paper in the distal end of the tube, the period at which the acid was saturated was readily seen; for while the ammonia was being absorbed the paper was red, but directly the acid was saturated the paper became blue. Thus by knowing the quantity of acid in the tube and the quantity of gas which had passed through it, the proportion of ammonia was easily estimated. A more accurate mode was to stop the process a little short of saturation, and then to estimate the quantity of unsaturated acid in the tube, and deduct it from the quantity originally used. This would give the exact proportion of acid neutralised by the ammonia of the gas, and, therefore, the quantity of ammonia present. In testing for sulphuretted hydrogen, the solution of sugar of lead should always be applied to one end only of a strip of white filter paper at the time of using; for unless there was a portion of the paper untouched by the lead, a slight discoloration from the presence of a small quantity of sulphuretted hydrogen would not be perceived. If, however, a part of the paper remained of its original whiteness, it gave by contrast a means of detecting the slightest discoloration of the lead. But as sulphur existed in coal-gas in other forms than as sulphuretted hydrogen, and was not discoverable by lead paper, the Legislature had in recent Acts provided for this impurity by fixing the proportion of it in gas, in any form, at less than a certain maximum amount. In the Newcastle-on-Tyne bill of last session the maximum was fixed at 10 grains per 100 cubic feet of gas, but in the Metropolis Gas Act it was fixed at 20 grains per 100 feet. Several processes had been contrived for the discovery of this impurity, but time would only suffice to refer to the process which Parliament had recently sanctioned. The gas was made to pass a very delicate meter, which registered accurately to the hundredth part of a cubic foot. After this it was delivered to a sensitive governor, constructed on Mr. King's principle. It was thence conducted to a Leslie burner, where it was consumed at the rate of not more than half a cubic foot per hour, and the products of combustion were carried by a bent trumpet-shaped glass tube into a glass cylinder, where they were condensed. As they passed from the burner through the tube, they met with a large quantity of ammoniacal gas, which was conveyed into the tube by means of an inverted funnel that passed up through the centre of the burner to about two inches above the flame. The ammonia was supplied by about two fluid ounces of the strongest liquid ammonia (sp. gr. ·880) placed in a beaker or wide-mouth bottle under the funnel. In this manner the sulphurous acid produced by the combustion of the gas was fixed by the ammonia and condensed in the cylinder. After burning the gas for twenty-four hours, the products of combustion were removed from the cylinder and put into a graduated glass. A given fractional quantity of the liquid was then taken, and evaporated in a beaker to dryness so as to get rid of the excess of ammonia. The residuum was a white crystalline mass of sulphate of ammonia. This was dissolved in a teaspoonful of water, and then treated with about three or four ounces of a saturated solution of nitrate of baryta in water, containing about a-tenth of its bulk of pure nitric acid. By this treatment a copious precipitate of white sulphate of baryta was formed, and on allowing the beaker to stand quiet for twelve hours, the sulphate of baryta would fall to the bottom of the vessel, leaving the liquid clear and colourless. This liquor was to be carefully poured off, and transferred to the solution bottle ready for another operation. The white precipitate must then be poured into a small bottle (three inches in diameter), placed on a funnel, and washed well with two or three drenchings of distilled water. When the filter and precipitate were quite dry, they were put into a balanced platinum crucible, and burnt quite white over a Bunsen gas-burner. The crucible with the white sulphate of baryta were then put into the balance, and the quantity by weight of the precipitate carefully ascertained. From this the amount of sulphur was easily calculated, for every 100 grains of the white sulphate of baryta represented 13·7 grains of sulphur. The lecturer then described the apparatus known as "Erdmann's gas-prover," and exhibited the magnesium light. He closed a very able and instructive address by expressing his obligations to Mr. Sugg, of Westminster, who had kindly placed upon the table and superintended the arrangement of the various apparatus by which the processes he had referred to were illustrated.

A conversation ensued upon the lecture, and many questions were proposed by the Medical officers present and replied to by Dr. Letheby.

The PRESIDENT, in the name of the Association, having presented a vote of thanks to Dr. Letheby, the proceedings terminated.

OBITUARY.

THE LATE R. D. GRAINGER, ESQ., F.R.S.

RICHARD DUGARD GRAINGER was born at Birmingham in 1801, where his father, Edward Grainger, Esq., long practised in repute as a Surgeon. At the Grammar School of King Edward in that town he received his early education. Having chosen the army for his Profession, he was sent to the Military Academy at Woolwich. He was, however, induced by circumstances, as well as by inclination, to abandon the military for the Medical Profession, and joined his highly gifted elder brother Edward, who had established a private anatomical school in the Borough, and rapidly attained extraordinary popularity and success as an anatomical teacher. Edward Grainger's brilliant talents, devotion to the science, and aptitude for the practice of his Profession, gave early promise of his attaining great future distinction as a Surgeon; but he was cut off in the bloom of his reputation and success. Thus, his younger brother Richard, when little more than 22 years of age, succeeded to the school and to the Anatomical Chair at Webb-street. Here Richard Grainger laboured long and successfully, for although as a lecturer he was inferior in brilliancy and eloquence to his more gifted brother, he was scarcely less popular with his large class of students. Associated with Armstrong, Southwood Smith, Marshall Hall, Pilcher, and Risdon Bennett, who, among others, successively lectured at his school, he maintained its popularity and usefulness till, like all the rest of the London private schools, it gradually succumbed to the superior advantages possessed by the large Hospitals. In 1842 he amalgamated his school with that of St. Thomas's Hospital, in which he occupied the Chair of Anatomy and Physiology until 1860. His labours in the dissecting-room and in preparation for his lectures during the period of his holding the Webb-street School were unremitting, and no man ever more conscientiously devoted himself to the welfare and advancement of his pupils. He had moreover, a pure and enthusiastic love of science and an ardent desire to extend its bounds. By his original investigations and experiments, especially in the departments of developmental anatomy, and the anatomy and physiology of the nervous system, he gained for himself a permanent place in the records of his favourite science. In 1837 he published his "Observations on the Structure and Functions of the Spinal Cord," and shortly after was elected a Fellow of the Royal Society. It would be impossible, in a brief sketch like the present, to attempt anything like an accurate estimate of Mr. Grainger's labours in connection with the intricate questions raised at the time of the controversy on Dr. Marshall Hall's doctrines of the nervous system. Suffice it to say that Grainger took no unimportant share in the investigations and discussions on the reflex theory, and contributed by his independent labours greatly to the elucidation of some of the most important points then warmly discussed.

Endowed with a spirit of warm and genuine philanthropy, he early ranked himself with the pioneers in the path of sanitary and social reform, at a time when such subjects met with little more than cold approval, and their advocates, for the most part, were viewed as little better than visionary enthusiasts On the appointment of the "Children's Employment Commission" in 1841, he was nominated one of the Inspec-

tors, and discharged the duties of an office demanding no small share of tact and discretion with equal zeal and ability.

In 1845 he was elected on the Council of the Royal College of Surgeons, and in 1848 he delivered before that body the Hunterian Oration. The subject which he selected for his address was "The Cultivation of Organic Science." It may be taken as a very fair illustration of his style of writing and of his philosophical spirit. It dwells chiefly on the importance of recognising "the triple combination of design, unity, and law" in all researches illustrative either of structure or function, and closes with an eloquent peroration claiming for the moral nature of man the application of the same principles.

In 1849 he was appointed, under the then Board of Health, as an Inspector to inquire into the origin and spread of cholera. His published reports to the Government on these subjects sufficiently prove the conscientious fidelity, as well as the intelligence, with which he fulfilled the arduous and often perilous duties assigned to him. In these, as well as in some of his public addresses on sanitary topics, there are some questions – *e.g.*, that of contagion—respecting which the soundness of his views may be questioned; but no one can fail to see and admire the manly honesty with which they were expressed.

On the passing of the "Burials Act," in 1853, he was again selected as one of the Inspectors for carrying out a measure, the importance of which he had long recognised and urged on the attention of the Government. This office he held up to the time of his death, and often fulfilled its duties in spite of languor and physical weakness, under which a less ardent and buoyant spirit than his would have succumbed.

On vacating the Physiological Chair at St. Thomas's Hospital in 1860 his former pupils and friends determined to present him (as had been more than once done before) with a testimonial. This, however, he declined to receive, desiring that it might be appropriated to the founding of a physiological prize in the School of St. Thomas's. To this testimonial Lord Shaftesbury and many other well-known philanthropists contributed, and the address presented to Mr. Grainger expresses the high estimation in which he was held, and the value entertained of his philanthropic labours.

In 1862 a second "Children's Employment Commission" was issued, and R. D. Grainger was nominated one of the Commissioners. This honorary appointment was a source of gratification to him, not only as being a graceful acknowledgment of his merits and the value of his services, but also as affording him opportunity for furthering by his knowledge and matured judgment the objects of the Commission, in which he took the deepest interest.

In the course of these his varied public and official duties, his attention had been strongly drawn to the evils and cruel consequences to the young females employed, attendant on the system pursued in the large milliners' and dressmakers' establishments. Having secured the ready co-operation of many of the influential members of the aristocracy, he succeeded in forming a society for the protection and succour of the young women employed in those branches of trade. To this institution he for some years devoted much valuable time and no little labour. Though grievously disappointed in not securing the full amount of success he hoped for, he received as his reward the blessing of many who were ready to perish, and obtained some diminution of the evils he had sought to remedy.

To those to whom R. Grainger was not personally known, it would be difficult to describe the peculiar charm of his private character. And it is not too much to say, that on those who knew him most intimately he exercised a species of fascination which almost unfits for making an attempt at a faithful portrait; the more so since this was the fascination of goodness, of love, proverbial for blinding the judgment. Numerous, indeed, were the friends that he made, amid all ranks and classes of society; but no one ever heard of his making an enemy, even in the discharge of duties calling for the exercise of firm, inflexible fidelity. Of tall and spare form, with an habitual stoop, his fine, expanded forehead and bright, quick eye betokened a man of superior intellect and culture; whilst his courteous, quiet, retiring, semi-bashful manner indicated the modesty and humility which are ever the associates of true greatness of mind. Once entered on conversation, for which he was always ready, he was lively, energetic, and earnest, always giving the impression that he was not only sincere, but even enthusiastic in his views. His peculiar, emphasised, earnest mode of speaking characterised his teaching, so that his pupils were always impressed with his thorough honesty and his own conviction of the truth and importance of what he was endeavouring to teach. This, though often giving a somewhat slow and laboured character to his speaking, not infrequently raised his public addresses and writings to a degree of eloquence, especially if the subject was one which called forth his deeper feelings of philanthropy or reverence.

His love of Nature amounted to a passion, and he took the deepest interest in every branch of natural science. Each new discovery was hailed by him with delight, and every new proof of unity of design gave him the most exquisite pleasure. The wisdom and goodness of the Creator as evidenced in all His works, Grainger delighted to discover and dilate on, and he could always find "sermons in stones, and good in everything." He was a man of decided opinions and deep convictions, but these he held in the utmost charity towards all men who might conscientiously differ from him. His love of truth, however, was paramount, and oppression, in every form, he hated. Those who would maintain their views at the expense of truth, and all who sought their own selfish ends and interests, regardless of others' freedom and welfare, he would denounce in no measured terms of indignation and scorn. In the discussion of scientific questions, he was eminently candid and discriminating, ever ready to acknowledge and proclaim merit in the humblest fellow-worker in the field of science or philanthropy. His liberality was bounded only by his means, and a poor brother or a struggling student he was ever ready to aid. Helpless misery and woe called forth his deepest sympathy and gave him unfeigned pain.

His health, never very robust, had for many years been failing, and latterly his life was one of great weakness and distress, though not of much actual pain. About five years ago he consulted his friend Dr. Risdon Bennett for dyspeptic symptoms, from which he had then suffered for some time, when it was discovered that he was labouring under renal disease, with albuminuria. The disease, however, for a long time appeared to make but little progress, and he pursued his avocations, with interruptions, increasing in frequency, till a few months before his death.

Fully aware that he was the subject of a fatal malady, his equanimity and cheerfulness of mind never forsook him. He was precluded from social intercourse (which he had always greatly enjoyed) except in his own house. There, however, amid languor and wasting sickness, painful to witness, he continued to manifest that humble, cheerful, consistent, Christian spirit which was at the foundation of his lovely character. For he had not contented himself with searching after scientific truth, but had long been a devout and earnest student of the Sacred Scriptures, had bowed his heart to their teaching, had sought to drink into the spirit, and walk in the footsteps of Him of whom they testify. They were not mere words of eloquence with which he closed the peroration of his Hunterian address, but were the expression of his deepest conviction, when he said: "We must turn to the sacred volume of revelation, wherein we shall discover laws as perfect, and principles as fixed, for the guidance of the spiritual nature of man, as those which rule the phenomena of the material world,—where, in fine, aided by the Divine grace, and prepared by a fitting humility, each and every one of us may hope to come to that 'true Light which lighteth every man that cometh into the world.'"

Heartfelt, though unobtrusive, as was his piety, he could not but recommend religion by his life and conduct. He was, however, too deeply impressed with its value and importance to admit of his failing on every legitimate occasion, whether public or private, to commend it to the attention of others. The warm and active interest which he took in the Christian Medical Association, and the beautiful, simple, and earnest addresses which he delivered before that Society, sufficiently testify how anxious he was that those who are entering on the study of that noble science to which he had devoted his life, and of which he was so great an ornament, should recognise and feel that the claims of revealed truth, whilst superior, are not antagonistic to scientific truth. His last end was not only peaceful, but cheerful and happy. He longed to be released, for to him the unseen world had no terrors. He died February 1, 1865, aged 63, and was interred at Eltham on the 7th inst. He left no children. But one survives him whose faithful love cheered his life and soothed his last hours, and whose deep sorrow may, perhaps, be in some small measure mitigated by the assurance, that not in her memory alone will Richard Dugard Grainger long live, as a bright example of all that was noble, and pure, "lovely, and of good report" in the Christian, philosopher, and friend.—J.R.B.

SECOND EXAMINATION
FOR THE
DEGREE OF BACHELOR OF MEDICINE.
OXFORD, DECEMBER 2, 1864.

Examiners.—Dr. Acland, Dr. Chambers, Dr. John W. Ogle.

PATHOLOGY.

Medical, Surgical.

1. Describe the microscopical appearances of typical specimens of encephaloïd carcinoma, and fibro-plastic growth.
2. Describe the condition called leucocythemia.
3. Distinguish between what are termed typhus and typhoïd fever.
4. What causes may produce general anasarca?
5. Under what several conditions is the urine found to contain (1) albumen, (2) sugar, and (3) pus globules?
6. By what conditions is jaundice produced? and in which may it be considered remediable either by nature or by art?
7. Enumerate the characteristics of what is termed "general paralysis of the insane;" and state the diseases for which it may be mistaken.
8. By what symptoms would you form a diagnosis of hæmorrhage into the spinal cord?
9. Enumerate the varieties of hernia that occur in the abdomen; and enumerate the swellings which may occur in the inguinal and scrotal regions, besides inguinoscrotal hernia.
10. Describe the various modes of growth in fibrous tumours of the uterus.

Materia Medica, Pharmacy.

1. What officinal preparations of the British Pharmacopœia contain opium, and in what proportions?
2. Mention the chief diuretics used in England, and give the doses of their several preparations.
3. Enumerate the "mixtures" for which directions are given in the British Pharmacopœia, and state their composition.
4. What is the composition of the pulvis jalapæ compositus, of the pilula scillæ composita, of the liquor morphiæ hydrochloratis, and of the liquor strychniæ of the British Pharmacopœia?
5. Name the medicines which impart colouring matter to the excretions.
6. What are the preparations of iron in the British Pharmacopœia? For what purpose is ferri peroxidum hydratum used? How is it ordered to be made?
7. What classes of medicines are fitted for preparation by means of decoction and of infusion respectively? How are liquid extracts made?
8. What is the temperature at which linseed, mustard, charcoal, and yeast poultices are to be made?
9. Explain the principle of volumetric analysis.
10. Give the equivalents of the weights and measures employed in the British Pharmacopœia in French weights and measures.

THERAPEUTICS.

1. Give an outline of the mode of treatment you would employ in a case of acute rheumatic fever.
2. How would you treat a case of pneumonia supervening upon delirium tremens, and what would probably be the result of your treatment?
3. What steps are required by the law of England to be taken before a person of unsound mind can be put under bodily restraint?
4. What would be your line of treatment in a well-marked case of pyæmia?
5. Bearing in mind the several causes of uterine hæmorrhage, what ought to be the treatment of the various forms of this affection?
6. What steps would you take if a woman, previously healthy, were seized with convulsions during labour?
7. What measures would you adopt in treating a case of spasmodic stricture of the urethra?
8. What are the indications for the use of, and contra-indications against the use of, elaterium, digitalis, aloes, and copaiba, severally in various diseases?
9. What are poisonous doses of the officinal preparations of opium respectively? How do you treat deep narcotism from that drug?

FORENSIC MEDICINE AND HYGIENE.

1. By what symptoms would you seek to form a diagnosis between intoxication from alcoholic drinks and concussion of the brain?
2. How would you proceed for the purpose of testing the contents of the stomach of a person suspected of having been poisoned by arsenic?
3. What are the symptoms of a poisonous dose of belladonna and of hydrocyanic acid?
4. What are the symptoms of poisoning by oxalic acid, and what the post-mortem appearances?
5. What evidence would satisfy you that an infant found dead had not breathed?
6. What are the several ways by which a room, or a ward, may be ventilated?
7. What impurities have been detected in the air of sick rooms?
8. How is typhoid fever said to be propagated?
9. Under what conditions is drinking water usually contaminated by lead?
10. Can you state any diseases which make butchers' meat wholly unfit for human food?

CLINICAL EXAMINATION.

(*a*) *At the Radcliffe Infirmary.*

1. Write a report on the case of
, Ward,
and
, Ward,
giving with care the history, diagnosis, and prognosis of the cases, and also the treatment you would recommend. Add such general remarks as occur to you by way of clinical comment on such cases.

(*b*) *At the Museum.*

2. Examine (writing a methodical account of your plan of examination) the urine marked A.
3. Describe and sketch from microscopical examination the object marked B.
4. Describe the morbid product marked C.

Translate from *Morgagni*. De Sed. Mor. II., 27, 8.

Relate any similar case which you may have seen or heard of; and state the probable condition of the cardiac muscular fibres.

LEGAL INTELLIGENCE.

COURT OF QUEEN'S BENCH.—MONDAY, FEBRUARY 6.

TAMPLIN V. COSENS AND ANOTHER.

THIS was an action by the eminent Surgeon, a Fellow of the Royal College and senior Surgeon of the Royal Orthopædic Hospital, against the executors of a gentleman of the bar to recover the amount remaining due for fees in respect of attendance upon his daughter. The young lady had laboured under the disease of "double lateral curvature of the spine," and in November, 1861, her father took her to the plaintiff (who, it appeared, had peculiar skill and experience in that species of disease), and placed her under his care in the hope of his effecting a cure. Mr. Cosens paid him the usual fee of a guinea, and nothing was then or at any time said as to fees. The plaintiff, however, intimated that his process of cure would probably take a considerable time—at least six months, if not longer. This was in November, 1861, and he continued to attend the lady until July, 1863, when her father died, and the claim in the present action, of course, could not extend beyond that date, though, in point of fact, the plaintiff continued to attend her, and in the result succeeded in effecting a cure, so that she had perfectly recovered, and, indeed, had since married. The peculiar feature of the plaintiff's process consisted chiefly in the application of a species of mechanical pressure, by means of a machine which required almost daily nice and skilful adjustment. Hence he saw her daily, inspected the spine, and adjusted the instrument. The total number of visits came to 218, for which he charged at the rate of one guinea for each visit. And thus the amount of his claim up to the father's death came to the sum of £228 14s. The executors, however, conceived that the deceased gentleman, whose income, it appeared, was limited, could not have intended to pay so much, and they, therefore, only acknowledged the claim to the amount of £129 13s. The principle upon which this particular sum was calculated did not appear. The plaintiff, however, declined to be satisfied with it, and prosecuted his action for the residue—about £100.

Mr. Lush, Q.C., and Mr. Needham appeared for the plain-

tiff; the Solicitor-General and Mr. H. T. Cole were for the defendants, the executors.

Surgeons of the highest eminence, such as Mr. Travers, Mr. Holden, etc., were called for the plaintiff, and stated that one guinea a visit was the usual rate of charge for a Surgeon of the plaintiff's undoubted eminence, and especially of his peculiar eminence in this kind of practice; and he himself positively stated that he never charged less, although in cases of poverty he would sometimes, out of charity, remit his fees and charge only for alternate visits. And, although he was pressed as to whether it was usual to let the fees run on so long, he stated that it was not usual to ask for the fees so long as the case continued.

In the result,

The Solicitor-General said he did not think that after this evidence it would be becoming in him to keep the case up longer, and he, therefore, yielded to a verdict for the sum claimed.

The Lord Chief Justice said he quite concurred in that course, which was such as might have been expected from the Solicitor-General. The case started with the payment of a guinea, and nothing had been said as to a reduction or abatement. In such a case the Medical attendant being a gentleman of high eminence, it could not be doubted that the charge was as stated, and if there were any reason, on account of the length of the case and the circumstances of the patient, to ask some abatement, it was for the patient or the relatives to request it, and throw themselves upon the liberality of the Medical man.

A verdict was then taken for the plaintiff for £99.

NEW INVENTIONS.

NELSON'S INHALER.

We have tried "Dr. Nelson's Improved Earthenware Inhaler," and believe it to be a cheap and convenient instrument. It serves both for simple hot water or for hot water medicated with the extracts of soothing plants such as are suitable for acute catarrh and quinsey, as well as for the various medicinal substances which are tried in the advanced stages of phthisis, in spasmodic asthma, etc. The instrument is easily cleaned, and cannot well be misused.

MEDICAL NEWS.

Royal College of Surgeons of England.—The following Members of the College, having undergone the necessary Examinations, were admitted Licentiates in Midwifery, at a meeting of the Board, on the 8th inst.:—

William Domett Stone, M.D. St. Andrews and L.S.A., Lincoln's-inn-fields, diploma of membership dated April 10, 1861; George Clements, L.S.A., Brixham, Devon, January 24, 1865; and Charles Edward Heron Rogers, Westmeon, Petersfield, July 27, 1864, Students of the Middlesex Hospital; George Cox Douglas, Ware, Herts, May 24, 1864; John Coryton Roberts, Peckham, July 26, 1864; and Henry James Dwelly Wandsworth, July 26, 1864, of Guy's Hospital; Patrick William Dillon, M.D. St. And., and L.S.A. Dub., Ennis, Co. Clare, July 11, 1851; Ferdinand Albert Purcell, M.D. Queen's University, Ireland, Cork, January 26, 1865; and Hutchins Williams, L.R.C.P. Ed., Southampton, May 27, 1853; of the Irish Schools; William Owen Jones, L.S.A. Bala, North Wales, August 1, 1861, of Manchester; Edward Hyde, Witney, Oxon, July 30, 1863; Walter Smith, Bognor, Sussex, May 11, 1864, of University College; Edward Roberts Smith, Dudley, Worcestershire, May 24, 1864, of St. Bartholomew's Hospital; and Henry Reginald Hatherly, Derby, November 16, 1864, of the Westminster Hospital.

Royal Colleges of Physicians and Surgeons, Edinburgh.—Double Qualification.—The following gentlemen passed their First Professional Examinations during the recent sittings of the Examiners:—

William G. W. Thompson, Ballymoney; J. Leman, Montreal; Albert W. Coppinger, Cork; Robert Stewart, Edinburgh; Arthur Roche, Cork; James Lindsay Mason, Montreal; John Thomas Richardson, Wotherspoon, umfriesshire; John T. Budge, Caithness; James Henry Oswald Goulden, tockport.,

And the following gentlemen passed their Final Examinations, and were admitted L.R.C.P. Edinburgh, and L.R.C.S. Edinburgh:—

Robert Beresford, Dublin; James Dods, East-Lothian; Daniel Mackay Forbes, Edinburgh; Robert Turner, Antrim; Samuel Hague, Ashton-under-Lyne; Alexander Hunter Miller, Edinburgh.

Royal College of Surgeons, Edinburgh.—During the recent sittings of the Examiners, the following gentlemen passed their Final Examinations, and obtained the Diploma of the College:—

Edward Hoggan, Meerut, India; Robert Thin, Kilconquhar; James Ingram, Orkney; Thomas James Higgins, Lisson; William Ellis, Clendinnon, county Wicklow; Alexander Wallace Jamieson, Derbyshire; James Mason, Rutlandshire.

Apothecaries' Hall.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, February 2, 1865:—

Arthur John Mahony, Glencarre, Co. Kerry, Ireland; James Francis Hamilton Richardson, Downe, near Bromley, Kent; Moreton Stevenson Wightman Wilson, Mowsley, Rugby; Tudor Hora, 27, Bloomfield-street.

The following gentlemen, also on the same day, passed their First Examination:—

George Crowe, University College; Robert Willmot, Sydenham College, Birmingham.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Davies, Redfern, M.R.C.S. Eng., has been elected Surgeon to the Free Surgical Cottage Hospital, Walsall.

Firth, J. T. Forbes, L.F.P.S. Glasg., has been elected Medical Officer to the Workhouse of the Parish of Rotherhithe.

Rigden, George, M.R.C.S. Eng., has been elected Assistant House-Surgeon and Dispenser to the Kent and Canterbury Hospital.

Roche, John, M.D. St. And., has been elected Medical Officer for the Workhouse of the Fermoy Union.

Sutton, Frederick, M.R.C.S. Eng., has been appointed Assistant Medical Officer to the Norfolk County Asylum, Thorpe, near Norwich.

Syme, Professor James, has been appointed one of the Examiners of the College of Veterinary Surgeons of Scotland.

Weller, George, M.R.C.S. Eng., has been appointed House-Surgeon to the London Hospital.

DEATHS.

Adams, George Hill, M.D. Edin., at 5, Mall-terrace, Notting-hill, W., on February 6, formerly of Geelong.

Bartlett, J. Bickford, M.R.C.S. Eng., at Teignmouth, Devon, on January 17, aged 72.

Campbell, Alexander, Surgeon, at Dunse, N.B., on the 30th ult., aged 56.

Conway, Joseph, M.D. Glasg., at West Blackhall-street, Greenock, on January 26.

Foxwell, James J., L.R.C.P. Edin., of Park-row, Bristol, on January 24, aged 33.

Girdwood, James, L.R.C.S. Edin., of Falkirk, Stirlingshire, on January 29, aged 67.

Gordan, Dr. J. A., at Fordanbridge, Fyvie, Aberdeen, on January 26, aged 58.

Hoile, Henry, M.R.C.S. Eng., at Market-street, Montrose, N.B., on January 31, aged 81.

Hoile, David Ogilvy, M.D. Edin, at Royal Victoria Hospital, Netley, on February 3, aged 34, Staff Assistant-Surgeon.

White, Dr. J., at Downpatrick, Co. Down, on January 19.

Wingett, William B., M.D. Edin., at Broughty Ferry, Forfarshire, on January 25.

At the last meeting of the Berlin Obstetrical Society Dr. Barnes was elected a foreign member.

The Late Mr. Belfour.—The remains of this gentleman were interred on Saturday last in the cemetery of Hackney old church. Beyond the immediate mourners, the only gentlemen who attended out of respect to the venerable Secretary of the Royal College of Surgeons were—Messrs. Arnott of the Council, McWhinnie of the Fellows, Fairless of the members, Lyne of the Medical students, and Messrs. Flower, Trimmer, and Stone of the College. *Sic transit gloria Collegii!*

Presentation to Dr. Anderson and Mr. Bracey.—Dr. Anderson having resigned his situation as Resident Medical officer of the General Hospital, Birmingham, and Mr. C. J. Bracey, who has filled the situation of House-Surgeon at the same institution for the last three years, having also vacated his office, the students of the Sydenham College and the General Hospital availed themselves of the opportunity of expressing their obligations to those gentlemen by presenting them with farewell testimonials. The testimonials consisted of handsome timepieces, and were presented at a social meeting of the students, held at Nock's Hotel. Mr. Hickenbotham, a late student of the College and Hospital, occupied the chair.

Death of Dr. Falconer.—We regret to have to announce the death of the eminent geologist, Dr. Hugh Falconer, F.R.S., F.L.S., F.G.S., etc., which took place at his residence in Park-crescent, on Tuesday last. Dr. Falconer was a native of Scotland, and graduated M.D. at the University of Edinburgh in 1829. He shortly afterwards accepted an appointment in the Medical service of the East India Company, and during a lengthened stay in Bengal devoted himself to those scientific researches, especially in connection with the fossil remains of the sub-Himalayan district, which have made his name so well known. He also held the post of Director of the Botanical Gardens and Professor of Botany in the Medical College of Calcutta. Since his return to England he has chiefly been engaged in investigating the geological evidence afforded by bone-deposits in caves, and within the last few months he made a voyage to Gibraltar for the purpose of examining, conjointly with Mr. Busk, the remarkable caverns recently opened in that rock. His knowledge of palæontology, especially of the higher forms of animal life, was most extensive, critical, and accurate, and his death will be a severe loss to science, as large stores of information, gathered through many years of an industrious life, are still unpublished, and will probably perish with him. The remains of Dr. Falconer were interred at Kensal-green on Saturday last.

Royal Institution of Great Britain.—General Monthly Meeting, Monday, February 6, 1865.—William Pole, Esq., M.A., F.R.S., Treasurer and Vice-President, in the Chair. The Countess of Tankerville; Francis Woodhouse Braine, Esq.; James Brogden, Esq.; William Henry Harrison, Esq.; Thomas Lucas, Esq.; John Lambert Mears, Esq.; William Miller, Esq.; James Romanes, Esq.; Edward Young Western, Esq.; and Henry Westropp, Esq., were elected Members of the Royal Institution. The Chairman announced a legacy of £100 to the Institution from the late George Dodd, Esq., and a donation of five guineas from Mrs. Barlow, and the following additions to "The Donation Fund for the Promotion of Experimental Researches:"—The Rev. John Barlow, second donation, £10; Henry Vaughan, £21; Edmund Packe, Esq., £5 5s. The presents received since the last meeting were laid on the table, and the thanks of the members returned for the same.

The Small-Pox and Vaccination Hospital.—The annual meeting of the governors of this Hospital was held on Friday last in the institution, which is situate on Highgate-hill. Mr. S. Turner occupied the chair. From the report it appeared that 836 patients had been admitted during the year—498 males and 338 females, of which number 728 had been discharged cured, and 108 cases had ended fatally. During the same period 268 out-patients had been vaccinated, and 648 charges of vaccine lymph had been supplied to Medical Practitioners. Dr. J. F. Marston, the resident Surgeon, reported that of the number of in-patients 17 were not cases of small-pox, and of the 819 cases of that disease 130 occurred to unvaccinated persons. The remaining 685 had been previously vaccinated; and the curious fact was shown that whereas there were 60 deaths among the 685 vaccinated patients, the vastly increased percentage of 47 deaths occurred to the 130 unvaccinated. It was stated that a sum of £187 10s. had been received from the Lords Commissioners of Her Majesty's Treasury, being a portion of the bequest of Mrs. De Lilley to Her Majesty, and Cardinal Wiseman, Captain Phillimore, and Messrs. W. Tomlin, J. Whittaker, and H. Herbert were elected life governors.

The Alleged Assault upon Mary Lamb by Dr. Carpenter.—The following letters have appeared in the *Durham Chronicle*:—

"*To the Editor of the Durham Chronicle.*

"Sir,—My letters to the Commissioners in Lunacy, published in your last week's *Chronicle*, relate a series of acts on the part of Mary Lamb which no sane man could attribute to a person 'not a lunatic.' As these letters follow one after the other, so do they contain a description of some insane act, not related before, and tending to show more strongly than its predecessor the unsound state of Mary Lamb's mind. That all these acts justify the conclusion that she is a lunatic must be evident to the meanest understanding, from the fact that the Commissioners in Lunacy formed an opinion upon only a few of them—communicated to them in my first letter—'That it was obvious she ought at once to be removed to an asylum.' That I was in regular attendance upon her from November 24 last, to the day after the alleged assault, and that the tying of her hands was by the express desire of her husband, who three days before had unsuccessfully attempted to do so himself, will be amply proved in two questions I am at once going to try. Until they are over I will refrain from all comment, being desirous of saying nothing which could create prejudice against the defendants. I therefore, for the present, simply enclose a copy of the letter I received from the Commissioners in Lunacy in reply to my first communication, and assuring you that all I have done for this poor woman has been with my best intention towards her, and for her sole benefit, I remain, Sir, your obedient servant,

"Carville, Durham. "R. H. S. Carpenter.

"P.S.—Mr. Sutherland deposed to having seen Mary Lamb and her husband at my house on the day following the alleged assault. I then dressed her finger as I had on several occasions previously done. The above fact is omitted in the published report of the case.

"[*Copy.*]

"Office of Commissioners in Lunacy, 19, Whitehall-place, London, 29th Nov., 1864.

"Sir,—I am desired by the Commissioners in Lunacy to thank you for your letter of the 25th instant, in reference to the case of Mary Lamb. From your statement it is obvious that she ought at once to be removed to an Asylum. It does not appear, however, that you have yourself given notice of the case to the relieving officer, and to place this officer's neglect beyond dispute, the Commissioners request you to be so good as to give notice to him in writing under the 68th section of the Lunatic Asylums' Act, 1853, that Mary Lamb is a person deemed to be a lunatic and not under proper care and control. Should he not within three days of receiving such notice take the necessary steps for bringing her before a magistrate with the view to her removal to an Asylum, on your communicating the fact, and also the name of the relieving officer, the Commissioners will themselves take measure to ensure his compliance with the law.—I am, Sir, your obedient servant,

"(Signed) "W. E. Spring Rice, Secretary.

"R. H. S. Carpenter, Esq."

The amount of absinthe drunk in Paris, with fatal effect on intellect and nerves, is hardly to be calculated. Switzerland alone sent last year 7,500,000 gallons to Paris.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

The late Dr. Jones Quain.—Many old pupils of Dr. Quain will be interested in the following additional facts as to the latter days of their distinguished teacher:—For three years, we have learnt, and until recently, he lived in the house of Dr. Marris Wilson, who formerly had been his prosecutor. During his residence in Dr. Wilson's house, and for many years previously, he had been in delicate health. The late cold damp weather severely distressed him, and kept him in his rooms. He had not been out for nearly a fortnight before his death, though actually unwell for no more than four or five days. The last time he left his residence was to go to church, where, when in London, he had long been noticed as a constant attendant. In his illness, Dr. Quain was attended, at his own request, by Dr. Marris Wilson. With respect to our notice of last week, we desire to state that we had no intention to attribute anything unbecoming to University College, or to any one connected with it, respecting circumstances which occurred nearly thirty years ago. Dr. Quain was never married. He was the eldest of many brothers, of whom three, all, we understand, that survive him, are members respectively of the clerical, the legal, and the Medical Profession.

Erinensis.—To Dr. Valentine Mott, of New York, says Sir Philip Crampton, is due the merit of having been the first to suggest, and the first to effect, the ligature of the common iliac artery.

The Royal Touch.—Consult Pettigrew's "Medical Superstitions." Aubre relates that Avise Evans had a fungous nose, and it being told to him that the King's hand would cure him, he awaited Charles in the park, kissed the royal hand, and rubbed his nose with it, which disturbed the King, but cured Evans.

Pryce *v.* Bowen.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—You will oblige me by stating that the following subscriptions have been added to the Bowen Fund, which is now closed.

I am, &c., H. D. Scholfield, M.D., Treasurer.

14, Hamilton-square, Birkenhead, February 7, 1865.

Dr. Garstang, Blackburn, 10s. 6d.; Joseph Toynbee, London, £1 1s.; Dr. M. Adams, London, £1 1s.; John L. Jardine Capel, Dorking, 10s. 6d.; Preston, per Dr. Hammond, £9 7s. 6d.; Messrs. Roberts and Williams, Festiniog, N.W., £1 1s.; Liverpool, per Dr. Stokes, £53 12s.; Dr. Dyster, Tenby, £5.

Candler *v.* Peat.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—We have the pleasure of forwarding you a list of the subscribers to the Peat Defence Fund, and a statement of receipts and expenditure. At Mr. Peat's request the subscription is now closed, and we append a note received from that gentleman.

We remain, Sir, your obedient servants,

C. R. Bree, M.D., Treasurer.
D. P. Morris, Secretary.

Colchester, January, 1865.

Manningtree, January 17th, 1865.

My dear Sir,—Allow me to offer you, and all the subscribers, my sincere and best thanks for the £100 received from you to-day, towards my law expenses in the late action, and for the great sympathy and kindness shown to me throughout the whole affair by my Professional brethren.

I remain, my dear Sir, yours sincerely,

Dr. Bree. Thos. Peat.

Army Medical Department.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—If there has been for some time past no external manifestation of dissatisfaction, but rather a studied suppression of latent discontent, it is to be ascribed to a general belief that certain measures are in contemplation intended to redress existing grievances and place the Medical Department of the Army more on a level with the Indian branch of the service, the position and prospects of which have lately been so much improved. A warrant, it is believed, is under consideration, the provisions of which will ensure promotion to Assistant-Surgeons after twelve years' service. There will probably be a retirement at twenty years, and, we hope, a full-pay retirement after thirty years' full-pay service; while promotion to the administrative ranks will be strictly guided by seniority, as in the scientific corps of Artillery and Engineers.

Such measures would afford general satisfaction to the executive ranks, and procure for the Director-General the lasting gratitude of his subordinates.

I am, &c, A Regimental Surgeon.

The New Medical Coroner for Portsmouth.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The election of a coroner for this borough took place to-day. Mr. Garrington, the Medical candidate, had at last no opponent, one other Medical and three legal gentlemen who started in the contest having, one by one, withdrawn from it. The contest here has not been between Doctor and lawyer in the usual sense, and therefore the election is not a triumph of a cause or principle. Mr. Garrington owes his election to his high character. The highest testimony that could be given to a public man from his own Profession was rendered to him, a few days before his election, when the Medical men free of the borough met, and by a resolution expressed "their sense of Mr. Garrington's fitness for the coronership, founded on their knowledge of his honourable reputation, both in Professional and private life, his sound judgment, independent character, and long experience in public affairs." This resolution was entrusted to one of his colleagues—Dr. Miller, a counsellor—to use in proposing Mr. Garrington to the Town Council. Happily, the retirement of the other candidates made it unnecessary to use this testimonial, which was well spoken to by the fact that neither of his most respectable opponents could make any head against him from the first; and therefore the judgment of the Town Council was one with that of the Medical Profession here. Mr. Garrington has been invited by the Medical men of the borough to a dinner, to be given in his honour, on the occasion of his election, on Tuesday next, which, if health allows it, will be presided over by Mr. Seale, the senior Practitioner in the borough, who is himself much respected, and an Alderman, Justice of the Peace, and past Mayor, like Mr. Garrington. Whilst the Council of the College of Surgeons are at their annual dinner, after the Hunterian oration, we shall be cementing the bonds of good fellowship, and doing honour to a worthy brother here. We have given up pretty much the practice of quarrelling with each other, which prevailed some years since here, and with scarcely an exception we meet in public and in private on the happiest terms. May this state of things continue and grow stronger, not only here, but everywhere! This is the devout wish of yours, &c.,

Portsmouth, February 6, 1865. Nemo.

P.S.—If any neighbouring Medical man who may see this has not received a private invitation to the dinner, and is disposed to come to it, he will be most welcome. We trust that this dinner may be the starting-point for an annual social gathering of the kind at Portsmouth.

Indecent Quack Advertisements.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I beg to enclose you an advertisement which has been put in each of the Manchester papers, and which you may, perhaps, think fit to reproduce by way of example elsewhere.

I am, &c.

184, Oxford-street, Manchester, Feb. 7. J. Thorburn.

"Manchester Medico-Ethical Association.—At the Annual General Meeting of the Association, held on Wednesday, the 25th inst., at the Clarence Hotel, Sir James L. Bardsley, M.D., President, in the chair, it was unanimously resolved:—

"'That this Association has great pleasure in publicly expressing its thanks to the Proprietors of the *Manchester Guardian* for having excluded licentious and immoral quack advertisements from a paper so influential and of such extensive circulation; also to the many other journals which have given up the somewhat lucrative but dishonourable practice. The Association begs to express its high sense of a proceeding which, though inseparable from an honourable press, has yet too few imitators.'

"Jon. Wilson, F.R.C.S., } Hon.
"Jno. Thorburn, M.D., } Secs."

The Treatment of Malarious Fever.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—While in a late communication, which you kindly gave room for in your valuable columns, I was desirous to correct the misapprehension as to the non-depletory and quinine mode of treating malarious fever in all its stages being of so recent a date as contemplated by Deputy-Inspector Hare, I had no wish to include what I conceive to be a very extravagant mode of exhibiting so scarce and valuable a medicine, believing that every advantage to be expected may be obtained from two-grain doses in clear solution, with the aid of dilute sulphuric acid; nor continuing it after two or three o'clock of the afternoon: it is by far most beneficial in the earlier parts of the day. It is not equally useful, however, in every variety of remitting fever, but the more these have a tendency to ultimately assume, as in the beginning of the cold season, the intermitting type, such as of Scinde and Ghuzerat.

Dr. Hare says he never saw abscess of the liver but as consequent upon ulceration of the colon. Dr. Harcourt could have set him right on that point—at all events, as to the inference. Nor does Dr. Hare seem to have noticed the vastly greater frequency of hepatic abscess in the older resident, increasing with the period of residence; in some years, too, without any obvious cause, and at certain seasons, rather than at others, except when a complication of fever. For instance, as we have elsewhere shown long ago,—from the time we joined the 2nd or Queen's Royal, in May, 1831, to the rainy season of 1836, with the exception of three officers, all over 40 years of age, who had previously served in the West Indies, there were not as many cases more in the regiment altogether. The average age was then about 26 to 31, and the period of tropical service five to eleven years. Yet from that period to the May following, at Bombay and Belgaum, there were not less than fifteen or twenty cases, including women and officers. The mortality in the regiment from fever that

year had been almost *nil* among the soldiers, and *nil* among the officers or their families, though prevalent and of bad type in November and December, several followers rapidly succumbing.

Nor did this inordinate loss by hepatic abscess in the winter months prove peculiar to the 2nd or Queen's. From a letter from Assistant-Surgeon Jackson, of the 6th or Royal Warwickshire, then stationed on the Island of Colaba, inquiring as to our experience on that island, it appeared they had lost about thirty by abscess of liver, I think he said, in the three months. Of course, he had included all—men and women of all ranks. In the 57th, too, at Cannanare, I found, after joining that regiment, the mortality from abscess of the liver that season had been nearly as remarkable there where there had been no unusual fever. The number, I think, was as great as they had previously lost by it altogether. Dr. Hare may have been misled by abscess of liver with dysenteries, as these occur as sequels of endemic autumnal remitting fevers, where both (separate and conjoined) are so numerous as to leave no doubt in my mind that they equally depend upon one and the same cause—the malaria with the asthenia from the preceding fever, which, as shown in a report from Deesa, in Vol. V. of the *Transactions* (not now in my possession) is usually favoured by depletory measures in those fevers. But abscess of the liver frequently occurs sporadically, without either previous fever or dysentery in the older residents, while amongst the younger, in the western coast dysenteries of the rainy season, even with extensive ulceration, we do not remember a case. Indeed, after seven years' residence in India the liver would appear to undergo changes of structure, rendering it peculiarly liable to abscess, even from slight causes. Nor does a change of climate to Europe of less than five years seem manifestly to diminish it; on the contrary, I have thought such persons more liable after their return.

Then as to remitting fever. So varied is this in its complications and tendencies, as well, perhaps, as in its hidden causes, that no stereotyped mode of treatment can be equally applicable in all times and localities. Statistics, too, are deceptive, and egregiously so, if the mortality be reckoned from the number of the admissions, as we showed in a report long ago from the West Indies, where one year in Demerara it exhibited no deaths from fever in 800 cases under the treatment then in vogue, of scruple doses of quinine united with calomel. That report is in the *London Medical Gazette* of August, 1849, page 191, and shows that with the strength only 200, and three fatal cases of complication and sequel, explained, as these had been, away, the mortality was above the average, both of the East and West Indies, exclusive of the pestilential yellow fever. In the Madras command I found, from documents furnished me by the Inspector-General (Nicholson) for statistical purposes, that the ratio of deaths from fever to strength was only 4·8 per 1000, for a period up to 1840 of sixteen or eighteen years, with an aggregate strength of 76,419 European troops, or scarcely one in 200 of strength. Were the strength shown in Dr. Hare's paper, with the number who died in May and June under the head of apoplexy, and in November and December of dysentery and abscesses of the liver, the main result might not be so favourable.

And now may I claim your further indulgence, for those who may not have access to the Bombay *Transactions*, and quote Vol. 1st, page 234, of a report for 1836-7? "In the gastro-hepatic (bilious remittent of Bombay Island), circumstances may no doubt occur which demand venesection; but more harm than good seems to us generally to accrue from it. . . In the catarrhal (constitution or tendency) we found the sooner the quinine was exhibited the better, even without perfect apyrexia; but in the gastro-hepatic it did not answer so well. When the mouth becomes sore, however, there is an apyrexial period, and if quinine is then administered convalescence proceeds rapidly." . . . . The Bombay fever, unlike the Ghuzerat, does not haunt the individual afterwards as an intermitting.

Vol. 3, page 175, for 1838-9, in Scinde and Affghanistan. (Prevailing tendency, diarrhœa and dysentery.) "The fever was treated upon similar principles, only after the first day or two, instead of the hyd. c. crêta and Dover's powder, calomel and opium and saline mixture (camphor mixture, with liq. acet. ammoniæ) during the paroxysm. In the intermission, quinine, even from the earliest period, not waiting for a perfect remission; and this seemingly with the very best effects. Sometimes, in the very bad cases, we mixed the quinine with hyd. c. crêta, or gave quinine and opium. This plan of beginning as early as possible with quinine in remitting fever I have been led into gradually for some years back." April, 1840.

Vol. 3, page 189. (Complicated with pleuro-pneumonia. At first very and quickly fatal, treated as idiopathic.) "We clearly perceived the chief part of the disease with which we had to contend was the fever, and, in consequence, immediately returned to the treatment by quinine on the least remission, preceding it, of course, by a moderate bleeding. . . . . But we had few cases that resisted the quinine for more than one or two paroxysms. . . . . The fever checked within the first two or three paroxysms, we found no difficulty with the pleuro-pneumonia—(a hint, perhaps, to our veterinary brethren, but where the quinine?) At least, as far as life was immediately concerned, nor has one died yet of the effects." (At this period three cases just convalescent, with whom we had suffered shipwreck the month previously, and who had been thus exposed for about ten days, only out of the water, without medicine, and partly without clothes, were in a very doubtful state, evidently with extensive adhesions, but they ultimately all recovered in four to six months.)

For complication with abscess of the liver, and that and dysentery as sequels, we must refer to the 5th volume.

Then, for the more healthy localisation of the European troops, beginning then to be agitated (1840), we might refer to a "Statistical Report," at the desire of Dr. Morehead, then the editor of the *Transactions*, quoting a single passage to show its drift. Here, however, we may premise the West Indian statistics of Tulloch we found subsequently to be erroneous when in the West Indies in 1848-9, owing to his tables having been made up from the official returns, where the pestilential yellow fever had been mixed up with the native remitting, and a number of cases of consumption, separated under pneumonia, bronchitis, and chronic catarrh. I carefully examined the records there with the autopsies, abstracts of which had regularly been attached to the quarterly reports or returns. This was from the practice of never changing the name of a disease after the first admission, when it had to be diagnosed, as it were, at the first glance.

Vol. 4, page 82. "Fifty miles from Deesa is Mount Aboo, a famous table-land, etc. Would any advantage be derived from having the military cantonment removed there? . . . . It would be *in fact* (as) a removing from Ghuzerat to the Deccan. . . . . It is true we might expect the mortality by consumption and liver (idiopathic) to be considerably increased—say, united, 5 per 1000 of strength annually. . . . . Fever, however, we find 15· to 20· with sequelæ, exclusive of invalided, but say 20· in all; from which deduct the estimated increase by liver and consumption, and we have a saving of at least 15 lives annually per 1000 of strength." . . . . .

In 1844 we recommended, in a similar way, Bangalore for the Madras troops, but to this it was objected that those already there were on sufferance of the Rajah of Mysore.

I am, &c.

Dollar, December 30, 1864. R. H. A. HUNTER, Staff-Surgeon.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29·144 in.
Mean temperature	39·3
Highest point of thermometer	52·1
Lowest point of thermometer	19·9
Mean dew-point temperature	36·7
General direction of wind	S W.,S.S.E.
Whole amount of rain in the week	0·43 in.

APPOINTMENTS FOR THE WEEK.

February 11. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Marshall, "On the Nervous System."

13. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

14. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ANTHROPOLOGICAL SOCIETY OF LONDON, 8 p.m. Meeting.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY (Ballot, 8 p.m.), 8½ p.m. Dr. Morell Mackenzie, "On Inhalation of Atomised Liquids in Chronic Disease of the Lungs." Mr. J. W. Hulke, "Ichthyosis of the Tongue." Dr. Hillier, "On Congenital Hydronephrosis."

ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, F.R.S., "On Electricity."

15. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

MEDICAL SOCIETY OF LONDON, 8½ p.m. Lettsomian Lectures—Lecture II. "On Stricture, Cancer, and Polypus of the Rectum," by Henry Smith, Esq., F.R.C.S.

16. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.: Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

HARVEIAN SOCIETY OF LONDON, 8 p.m. Mr. J. Z. Laurence, "On Certain Functional Diseases of the Retina;" and Discussion resumed on Dr. Drysdale's Paper on Phthisis.

ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, F.R.S., "On Electricity."

17. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 8 p.m. W. Huggins, Esq., "On the Physical and Chemical Constitution of the Fixed Stars and Nebulæ."

THE NEW SYDENHAM SOCIETY.

The Council has the great pleasure to be able to state that, in addition to the three works which have already been issued for 1864, the funds of the Society admit of the production of a small FASCICULUS of the ATLAS of PORTRAITS of SKIN DISEASES.

A FASCICULUS, consisting of Life-size Portraits, representing

LEUCODERMA, and | MORBUS ADDISONII.

will be ready in a few weeks, and will be supplied to the Members for the year just concluded (1864).

THE VOLUMES ALREADY IN THE HANDS OF MEMBERS FOR 1864 ARE,—

Vol. 21.—A HANDBOOK of the PRACTICE of FORENSIC MEDICINE, BASED upon PERSONAL EXPERIENCE. By J. L. CASPER, M.D., late Professor of Medical Jurisprudence in the University of Berlin. Translated by G. W. Balfour, M.D. Vol. III.

[The next Volume (Vol. IV.) will conclude Professor Casper's Work.]

"Casper's great work, based as it is upon a minute and laborious observation of facts, must prove the most trustworthy guide in the interpretation of the ofttimes difficult questions which the Medical jurist is called upon to solve."—Lancet.

Vol. 22.—ON the ANOMALIES of ACCOMMODATION and REFRACTION of the EYE; with a Preliminary Essay on Physiological Dioptrics. By F. C. DONDERS, M.D., Professor of Physiology and Ophthalmology in the University of Utrecht. Translated from the Author's Manuscript by W. D. Moore, M.D.

"This splendid monograph, from the hand of the accomplished Professor of Physiology and Ophthalmology of Utrecht, will be hailed as a boon by all lovers of ophthalmic science."—Lancet.

Vol. 23.—A YEARBOOK of MEDICINE, SURGERY, and their ALLIED SCIENCES, for 1863.

WORKS FOR 1865.

Vol. 25.—A YEARBOOK of MEDICINE and SURGERY for 1864.

Vol. 26.—THE FOURTH and CONCLUDING VOLUME of CASPER'S MEDICAL JURISPRUDENCE.

Vol. 27.—A FASCICULUS of the ATLAS of PORTRAITS of SKIN DISEASES.

Whether, in addition to the above, any other work will be brought out for the commencing year will depend upon the state of the Society's funds.

A List of Suggested Works is in preparation by a Committee of the Council, and will be submitted to the Members generally in the course of a few weeks, in order that opinions may be expressed. On this occasion it is intended to again take the votes of the Members as to the desirability of continuing the Yearbook.

The Council regrets that, notwithstanding every effort, considerable arrears still remain unpaid, and earnestly invites the attention of Local Secretaries and Members generally to this matter.

The subscriptions for 1865 (seventh year) are now due. All payments should be made to Mr. H. K. Lewis, 15, Gower-street North, the Society's Agent, who is empowered to receive subscriptions and give receipts. Cheques, money orders, and bankers' drafts to be made payable to the order of the Treasurer, Dr. W. Sedgwick Saunders.

Full sets of the Volumes published by the Society are in stock, and can be obtained by new Members. A Prospectus, containing list of Books, &c., can be had on application to Mr. Lewis, 15, Gower-street North, or to the Secretary.

4, Finsbury-circus, E.C., Jan. 20, 1865.

JONATHAN HUTCHINSON, Secretary.

ORIGINAL LECTURES.

LECTURES ON CHEMICAL AND MECHANICAL DISEASES AND THEIR RELATIONSHIP.

By H. BENCE JONES, A.M., M.D., F.R.S.

Lecture II.

DISEASES OF SUBOXIDATION—ON ACIDITY, OR THE ACID DIATHESIS.

Acid and sugar, chemically, are as closely related as parent and child; and hence a great similarity exists between the symptoms that arise from an excess of sugar and an excess of acid. The nature of the acid disease, the symptoms it produces, the means of detecting it, the consequences it occasions, and the treatment requisite to cure it, are all essentially chemical questions. A most important difference, however, exists between the sweet and sour disease, namely this: the sweet disease is mostly free from secondary mechanical diseases; whilst acidity continually gives rise to mechanical complaints. Two of these secondary mechanical, or mechanico-chemical, complaints—gravel and gout—are the frequent lot of those who, living more by nerve than by muscle work, disarrange the healthy balance between the carbon and oxygen which go in and come out of the body.

Acid is essential for the performance of the functions of the body. Without acid the albuminous food could not be dissolved; the excretions from the blood could not be safely removed. If no acid was produced in the body, there would be no digestion and no depuration of the blood, and probably bony matter would accumulate everywhere. The vinegar cruet is only less essential to man than the salt cellar, because the animal machine is itself an acid factory. Very often more acid is made than is useful or beneficial; then chemical errors occur, and these set up mechanical diseases as surely as the effect of the cannon-ball depends on the combustion of the gunpowder. The mechanical results are vastly more serious than the original chemical action; but they are directly proportioned the one to the other. As the motion of the mass depends entirely on the motion of the molecules, so the mechanical disease arises solely from the chemical disorder.

It would be useless, even if it were possible, to give a list of the mineral, vegetable, and animal acids, between carbonic acid (CO_2) and uric acid ($C_{10}H_4N_4O_6$), which may be formed from changes in the textures of the body, or from the food. It is far more important to consider how an excess of acid may arise or accumulate in the system. This may occur in two ways—1st, by over-production; and, 2nd, by insufficient evacuation. When these causes co-operate the excess of acidity reaches its maximum.

First, on the production of acid in the body from the textures and food.

The living human body is, chemically, a varying mass of more or less complex carbonaceous matter, each portion being exposed to the action of oxygen. The chemical products everywhere vary according to the substances acted upon, and according to the time during which the oxidation is continued.

Outside and inside the capillaries, in every part of the body, in cells and out of cells, chemical changes are taking place. The oxygen of the air, the organic fluid, the catalytic membrane, act and re-act each on the other; and the products of the chemical action are reabsorbed into the blood, or are thrown upon the inner or outer surface, to be taken up by the alimentary mucous membrane, or to be removed by the lungs, the skin, or the kidneys.

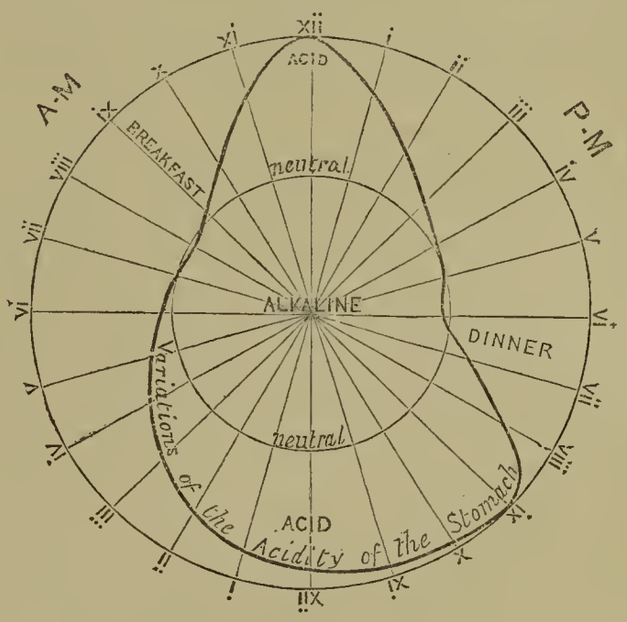
At present, the chemical changes which take place in the textures are very imperfectly known, and the variations of action which occur in health and disease are only beginning to be observed. The healthy muscle, during the circulation of the blood through it, has no acid reaction; but for a time after death chemical actions continue, and sufficient acid is produced, and remains unneutralised by fresh alkaline liquor sanguinis, so that markedly acid reaction can be obtained. Even during life, in tetanus, sufficient acid may be formed to give an acid reaction, and after violent epileptic convulsions excess of acidity may be found in the urine. Even the nerves and the electric organs of fishes show signs of acidity when the alkaline blood ceases to flow.

The production of some healthy and less complex secretion may enable us, from its chemistry, to obtain greater clearness on the production of acid in the body. The gastric juice furnishes by far the most striking example of the formation of acid in the body. Until the chemical acid factory in the stomach is fully understood, the chemical changes which are going on outside the capillary vessels throughout the body cannot be realised.

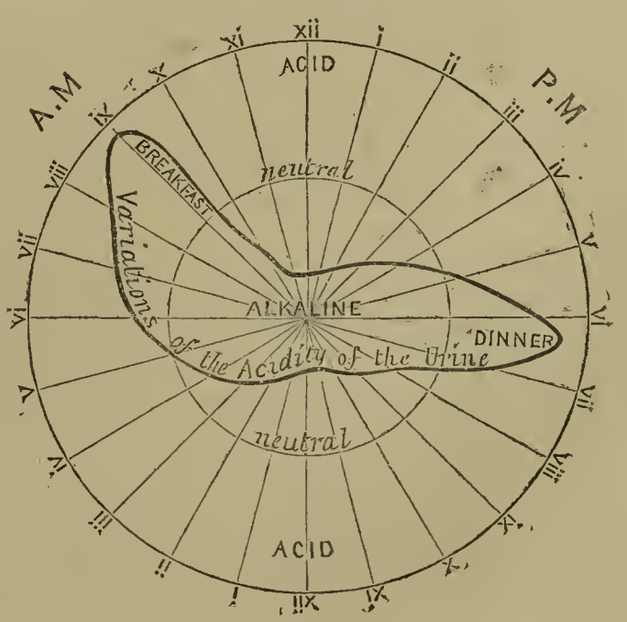
There can be no doubt that the formation of gastric juice occurs outside the capillaries of the stomach. Its rate of secretion depends on the rate of passage of the blood through the capillaries; and this is directly under the control of nerves that open or shut the blood vessels. In the fluid poured out of the capillaries chemical changes occur, acids are formed—perhaps Dr. Marcet's colloid acid; or by the oxidation of sugar, among other acids, oxalic acid may be produced, and this may decompose the chloride of sodium, and the most diffusible hydrochloric acid may be poured out on the free surface of the tubes; whilst the alkali passes with the organic acid, or its products of combustion, back into the blood.

That the blood increases in alkalescence during digestion can easily be proved by careful observation of the secretion of urine before and after food, or by the effects of severe or constant vomiting. The following diagram will best show you the contrast which can be traced between the acidity of the gastric juice and the acidity of the stomach. You will perceive that when the gastric juice is most acid the urine at that time is least acid, or most alkaline; and when all the gastric juice is absorbed, then the acidity of the urine is at its highest point.

Curve of variation of the acidity of the stomach.



Curve of variation of the acidity of the urine.



In the Medico-Chirurgical *Transactions*, Vol. 35, p. 41, you will find a paper "On the Alkalescence of the Urine from Fixed Alkali in Some Cases of Diseased Stomach." I shall here give you only one example in order to fix this inverse relationship of the acidity of the stomach and urine firmly in your minds. A man, aged 46, was admitted into St. George's Hospital with sarcinæ ventriculi. The eruption from the stomach occurred at irregular periods, once and sometimes twice daily; the quantity vomited each time was from one to four pints of intensely acid fluid. The urine was usually passed about six times in twenty-four hours, when the vomiting was most. The urine was acid twice, or at most thrice, daily before the sickness occurred; and for the rest of the day after the vomiting the urine was strongly alkaline from fixed alkali. The patient remained in the house for a month, and during the last week he had only one attack of sickness; then the urine became markedly acid each time it was passed, and remained so throughout all the day.

After digestion is finished, when the food is dissolved in the stomach, the intensely acid fluid is in part returned into the blood. The serum might almost cease to be alkaline but for the neutralising action of the bile; thus the degree of alkalescence of the blood must be continually changing, and the fluid effused from the capillaries, and out of which the secretions are formed, must become less alkaline after the food is absorbed than it is whilst digestion is going on in the stomach.

An oxidation similar to that which occurs in and around the stomach cells must occur to a greater or less degree everywhere throughout the body; carbonic acid or other acids, arising from a less perfect combustion, must be formed outside the capillaries of the body. In the muscles and nerves, and in every other texture, power must be set free by the mutual action of the carbon and the oxygen, and the acid products would quickly neutralise the alkalescence of the blood if the acids did not pass off by the lungs, the skin, and the kidneys.

On the Removal of Acid from the Body.

Without cessation night and day free acid continues to pass into the air vesicles of the lungs from the blood, thus rendering it more alkaline than it would otherwise be, and counterbalancing not only the acid produced by oxidation in the different textures, but also the residue of the acid from the gastric juice and food which is not neutralised by the bile.

If the combustion in the body were complete, the whole of the products, except the ashes, might escape by the lungs; free respiration might carry off readily all the acid produced in the system, but imperfect oxidations do occur, and then other acids besides carbonic acid are formed and give rise to neutral or to acid salts which are not volatile, and these being unable to pass off by the lungs are thrown out by the skin and the kidneys.

There can be no doubt whatever that acid is produced outside the capillaries of the skin and kidneys in the same way, although to a much less degree than in the stomach cells. The chemical composition of the substances that pass into the urine and the sweat depends not only on the amount of action of the oxygen, but also on the chemical composition of the fluid poured out of the capillaries to form the secretion.

If the serum of the blood is at its highest point of alkalescence, the acids formed by oxidation during the secretion of urine may be too feeble to neutralise the alkali poured out, and alkalescent urine may result. If, on the contrary, feebly alkaline or acid salts are effused from the capillaries, a very small amount of additional acid produced by oxidation in the secreting structure of the kidneys will set free some of the acid from the acid salts, and thus free uric acid may appear in the urine.

The same formation of acid occurs in the secreting structure of the skin, and although it is not possible to demonstrate the daily variations of the acidity of the sweat, yet the extraordinary increase in its acidity with strong exercise, or in some diseases, as in rheumatic fever, shows that it is subject to great variations.

The variations in the alkalescence of the saliva were long since shown by Dr. Wright to be influenced by the digestion. —*Lancet*, 1841, p. 787.

The smallest amount of acid is thrown out of the system when the respiration is impeded, whether from insufficient exercise or from imperfect supply of air; then carbonic acid accumulates, and the less perfect products of combustion are increased in the serum. If these can escape by the kidneys and skin the system is relieved, and no secondary symptoms are produced; but if these vents are closed, and if by acid diet and an irritable stomach an excess of acid is poured into the blood, then an outburst must take place, and chemical and mechanical diseases—that is, unusual molecular or massive motions—occur until the healthy condition of the blood is again reached.

Excess of acidity or the acid disease may shortly be defined to be a want of free oxidation and an insufficient escape of the products of imperfect combustion.

On the Means of Detecting Acidity.

It is not easy for the Physician to determine accurately the escape of an excess of acid by the lungs, and still less so by the skin; but by both chemical and microscopical evidence he can follow the minutest changes which occur in the acidity of the urine, and thus he may know something not only of the state of the blood from which that urine is secreted, but he may obtain some information regarding the activity of the processes of oxidation and nutrition outside the capillaries. Different litmus papers vary so much in composition and delicacy of reaction that no satisfactory conclusion can be reached by this test alone. A standard solution of soda furnishes the surest chemical proof of the amount of acid in a given quantity of urine, and thus variations may be proved and comparisons made with the utmost accuracy. But a readier method of coming to a practical conclusion exists in observing by the microscope the state in which the uric acid exists in the urine. The delicacy of this test for free acid far surpasses any other; indeed, litmus paper and standard solution cannot enable you to distinguish between acid salt and free acid; but the microscope by showing more or less free uric acid crystals tells at once the greater or smaller amount of free acid in the urine. As long as free uric acid crystals do not exist in the urine no very great amount of acidity is present. When acid urates alone are passed there may be very great effect on the litmus; but as long as the microscope and chemistry show that free uric acid is absent, the chief secondary mechanical disease, uric acid stone, is not likely to be set up.

Hence the determination of the presence or absence of free uric acid in the urine is a question of great importance.

A small bottle or test tube should be filled with fresh urine and examined by transmitted light. Uric acid crystals can be easily seen. If no red sand is present in twelve hours another examination should be made. Very frequently a deposit occurs as the urine cools, then the microscope must be used to see whether crystals of uric acid are mixed with the granular deposit. The amount of free acid may be known by the rapidity with which the uric acid crystals appear, by the size of the crystals, and by the more or less perfect decomposition of the granular urates.

When the free acid is in very great excess the uric acid may crystallise in the renal tubes or in the pelvis of the kidney or in the bladder. When very little free acid and very little uric acid has been present, I have seen the crystals of uric acid appear on the eleventh day after the water was passed.

Professor Scherer long since stated that an acid fermentation took place in the urine soon after it was passed; but I have been unable to satisfy myself that any increase of acidity occurs. His experiments were not made on healthy urine. When he made them, the state in which the uric acid existed in the urine was not known. The slow deposition of uric acid from a feebly acid solution of urates was not taken into account.

Very frequently, when examining the same specimen of urine day after day for uric acid crystals, I found that no free acid was deposited; until at last I was led to make exacter experiments to determine whether the free acid in the urine was increased after the water was made. But first a series of twenty-seven experiments were made on healthy urine to determine how often, and how soon on standing, uric acid crystallised out. Four times only were these crystals found by the microscope twenty-four hours after the water was made; and five times the acid crystallised out in two days. Eighteen times no uric acid was found free. In other words, eighteen times out of twenty-seven the urine under the microscope did not show this evidence of an increase of acidity. In the other nine times the uric acid might possibly have been set free by an acid fermentation, although another explanation was probable, namely, that the crystals only formed slowly because no great quantity of urates were present, and because the liberating acid was very weak. For determining between these views, a standard alkaline solution of caustic soda was prepared, and the acidity of the urine was measured as soon

as possible after the urine was made, and then from time to time afterwards the acidity of the same urine was again noted. Thus the following experiments were made:—

June 7,	Fifty cubic centimetres of healthy urine just passed were neutralised by	1·8	c.c. of standard solution of soda.
„ 10,	„	1·8	„
„ 12,	„	1·8	„
„ 14,	„	1·8	„
„ 17,	„	1·2	„
„ 19,	„	0·8	„
„ 13,	Fifty cubic centimetres passed by another healthy man neutralised by	1·5	„
„ 15,	„	1·5	„
„ 15,	Fifty cubic centimetres passed at different times neutralised	1·6	„
„ 17,	„	1·6	„
„ 19,	„	1·6	„
„ 21,	„	1·6	„

The total quantity of urine made in twenty-four hours was collected, and the acidity determined.

June 17,	Fifty cubic centimetres neutralised	3·8	c.c. of standard solution.
„ 19,	„	3·8	„
„ 21,	„	3·8	„
„ 22,	„	3·8	„
„ 27,	„	2·6	„

These are examples from many others, all showing that no change in the acidity occurs for some days after the urine is passed, and that then the acidity diminishes.

When it was proved that sugar existed in small quantities in healthy urine, I thought that some evidence for or against an acid fermentation might be got by determining the amount of sugar in the urine, first when fresh, and afterwards when it had stood some days.

Three litres of healthy urine were divided into two equal parts. The one half was examined for sugar immediately; and the amount of sugar was 2·4 grains. The other half was left for twenty-five days, until it became feebly alkaline, and then the sugar was determined, and the amount was 1·9 grain. A loss within the limits of error in the method of analysis.

These and many similar experiments are opposed to any acid fermentation; and when the formation of uric acid crystals in the urine occurs, it may be taken as a proof that same free acid is secreted by the kidneys, and that this, sooner or later, has set free more or less uric acid from the acid urates in the nrine.

The longest time in which I have seen uric acid crystallise out has been eleven days, but usually the first, second, or third day after the water is made the crystals form, if they form at all; and the formation of these crystals is the only certain and delicate test of the presence of free acid in the urine. I had hoped that the form of the crystals, varying as it does so greatly, might enable me to determine the nature of the liberating acid; but after a long series of experiments I can as yet come to no satisfactory conclusion in this respect.

(To be continued.)

THE PUBLIC HOSPITAL, JAMAICA.—The demon of discord seems to have crept into this establishment. The *Colonial Standard* of January 24 is filled with a letter from Mr. Alexander Fiddes, F.R.C.S.E., detailing the circumstances which led himself and Dr. Andrew Dunn, the other ordinary Medical officer of the Hospital, to resign their appointments. As we have only seen one side of the case, we are not in a position to offer an opinion as to the course pursued by Dr. Bowerbank and Governor Eyre. There can be no doubt, however, that Messrs. Fiddes and Dunn believed themselves to be aggrieved by the interference of Dr. Bowerbank, who was Chairman of the Board of Visitors, in Hospital matters; and injured by a judgment given by the Governor on statements made by Dr. Bowerbank. They believed that they could not, under the circumstances, continue to discharge their duties with honour to themselves, and they have, therefore, like high-minded men, resigned offices to which salaries were attached.

ORIGINAL COMMUNICATIONS.

ON THE

ADMINISTRATION OF CHLOROFORM IN OVARIOTOMY.

By E. PARSON, M.D., Lond.

SINCE the subject of administration of chloroform has been so recently and so ably discussed by the Committee for that purpose of the Medico-Chirurgical Society, and as the capital operation of ovariotomy is being almost daily performed, the results of my experience in the large number of cases performed by Mr. Spencer Wells at the Samaritan Hospital for Women, where I have had the subsequent care of the patients, as well as in many of Mr. Wells's private cases, may possibly be of some use to others in similar subsequent operations.

The apparatus I have used of late has been "Skinner's," consisting, as most people know, of a piece of domet flannel spread in a tent-like manner over a wire frame, the base of which is somewhat oval, so as to include the nose, mouth, and chin of the patient under this tent-like expansion. The handle is a piece of stout wire about seven inches long, bent into a loop, and can be moved and fixed at any convenient angle with the frame that supports the domet. Hence, the handle balancing the frame, the latter will generally lie easily wherever it is placed on the patient's face. This allows the right hand to hold the bottle of chloroform, enabling the left hand to feel the patient's pulse. The bottle containing the chloroform holds about two ounces, and allows the chloroform to escape drop by drop through a very small tube. This is Skinner's inhaler and dropping bottle, slightly modified for the Samaritan Hospital by Weiss and Son.

Its employment is equally simple; the tent-like inhaler is allowed to lie over the lower part of the face, and the chloroform is sprinkled drop by drop over it, and rarely does more than one minim of chloroform at a time escape from the bottle.

The advantage of this mode of giving chloroform appears to be that as only one minim of chloroform escapes at a time, and as the successive minims are distributed over the expanded domet, it ensures a much more regular dilution of the vapour with the air inspired than is usual with almost any other apparatus I have seen, except Clover's, whose methodical dilution is certainly the safest of any, and I know of no one who has presented anything as yet so decidedly accurate as his; but the incumbrance and the appearance of the large inflated bag, and the intricacy of the apparatus, will always, I fear, be an obstacle to its general adoption.

Now, the domet inhaler is possibly the next nearest approach to perfection in the simplicity of its use and regular dilution of the vapour, for it follows that if the drops fall regularly, and the inspirations be about the same in frequency and depth, that a regular dilution must be ensured, and hence a nearly equable inhalation, and those I believe to be very important facts for the safety of the patient.

The time usually required to produce anæsthesia thus, varies from ten to fifteen minutes, differing in different persons; but I observe in ovariotomy that the slower its administration the less is the subsequent distress after the operation; that a state of collapse rarely occurs, and the patients generally awake tranquilly and collected soon after the operation; and there is much less vomiting and retching (in no case is solid food allowed before the operation); the preliminary stage of excitement is also very much less; and lastly, there is rarely any spasm of the larynx, which, by the bye, does sometimes occur in hysterical women. The patients generally go quietly into a profound sleep without a struggle. Now, this infrequency of vomiting and retching is of immense importance to the ovariotomist, for vomiting tends to force the small intestines out of the abdomen through the wound, unless the wound be firmly grasped by an experienced assistant, or another assistant presses his hand upon the epigastric region to prevent the descent of the diaphragm, and the operator has to wait till the vomiting is over. And also after the wound is closed by the sutures and strapping, any effort of vomiting is exceedingly painful for the patient, by stretching the abdominal wound, straining the pedicle, and disturbing the small intestines and mesentery that have been more or less irritated by the necessary manipulation in the removal of the tumour and the subsequent sponging and wiping out the cavity of the peritoneum when necessary. Hence, the utmost quietude of the abdo-

minal viscera greatly increases the patient's chance of recovery after ovariotomy.

Cutting through the skin of the abdomen is certainly the most painful part of ovariotomy; next to this appears to be the sponging out of the pelvis; and hence the greatest amount of insensibility is required at the very outset of the operation, and very little chloroform is required whilst the adhesions are being broken down and the time occupied in tapping the cyst or cysts. During the sponging out the pelvis of any fluid that may have collected there, there is almost always a spasmodic action of the legs, which I believe is due to the direct pressure of the sponges over anterior crural nerves, and hold that chloroform should not be given to such an extent as to destroy the irritability of those nerves, and that an assistant should always be placed at the patient's knees to keep them down during this part of the operation. Possibly some of this spasmodic action of the legs may be reflex, and as the patient is unconscious of it, it is much better that those motions of the legs be restrained by an assistant than have the patient prostrated by chloroform. I have also observed that this very sponging the peritoneum has a very depressing effect on the heart's action; frequently the pulse sinks not only in force, but becomes small and slow. In one case I counted it only 30, whereas before it was beating at the rate of 68 in the minute. This woman, aged 32, had a mitral murmur and a large heart, and accompanying this failing of the pulse a death-like sweat broke out over her face; and as I have several times observed this, I fancy the hypogastric plexus has been pressed upon by the sponge, and that this dangerous state is through the medium of the sympathetic; and hence in those cases it becomes the more important not to have the circulation much reduced in power when there is this depressing ordeal to go through.

The chief drawback to chloroform in ovariotomy seems to be that the enormous distension of the abdomen so presses up the diaphragm that the apex of the heart is, I often find, tilted upwards and towards the left axilla—not unfrequently found beating under the third or fourth rib,—and the lungs so compressed upwards and backwards, that the power of making a deep and full inspiration is utterly impossible. I believe the muscular power of the diaphragm to be almost for the time paralysed, comparatively speaking; and hence in almost every case of ovariotomy there is an exceedingly feeble inspiratory power; and as ovarian cases are almost all greatly reduced in muscular power and tone, the state of the respiration during the operation is also a cause of great anxiety, for I have found that when the patient's mouth is shut, and she breathes solely through the nostrils, that the inspirations are less frequent and less deep than when the mouth is kept open; in fact, in some very feeble old women with ovarian dropsy of some years' standing, one can scarcely see that they inspire at all; and, further, I believe this defective inspiration to be greatly embarrassing to the right side of the heart, for I find that when the inspirations are shallow, the heart beats with less force and less frequency; and in those ovarian operations more attention should be even paid to the respiration than even to the pulse; and hence I have of late, when insensibility has been produced, slipped one of my fingers between the patient's teeth, and, throwing her head slightly backwards and to the right side, by this means the tongue does not fall backwards, and the stertor, if it has existed, is generally immediately prevented. I find also that where there is a tendency to spasmodic inspirations, too, and closure of the rima glottidis, it is very effectual in affording a free inspiration.

When the circulation is feeble, notwithstanding that air enters the chest freely, gentle rubbing the region over the apex of the heart is sure to increase its action; so, also, is rubbing the neck from the ear to the clavicle over the course of the phrenic and pneumogastric. But I find that this sometimes provokes vomiting; also a cold hand on the hot skin, or a rough, cold towel, has always been sufficient to stimulate the flagging circulation in even protracted operations. Occasionally, when the tumour is very large, immediately the abdomen is emptied the circulation has lost its accustomed pressure, and a temporary fainting occurs. Now this is best avoided by immediately removing one or two of the pillows that have been propping up the patient's head and shoulders, and allowing her to lie perfectly horizontal; and this has to be done whilst the operation is going on, for before removing the mass in the abdomen the patients cannot breathe at all if they are placed horizontally—their diaphragm cannot push down the mass in the abdomen unless their shoulders are raised, and the tumour allowed to gravitate away from the thorax. Mr. Spencer Wells, in a recent case, to avoid the chance of syncope, tapped the patient whilst on the table with a small trocar and canula, and emptied the largest cyst, and thus greatly equalised the pressure before any incision was made into the abdominal parietes.

The average amount of chloroform used is about three drachms. The objection that the chloroform thus administered affects the bystanders I have found to have been of very little importance, and is certainly more a theoretical than a practical objection.

Lastly, I beg to recommend operators *not* to have their patients too profoundly narcotised; for, however pleasant it may be for them, it is highly unpleasant for him who has the life of the patient in his more immediate charge, and I know of no cases so critical as those who are the subjects of ovariotomy.

3, York-street, Portman-square.

ON THE VARIOUS MODES OF ESTIMATING THE NUTRITIVE VALUE OF FOODS.

By JOHN BEDDOE, B.A., M.D., &c.,
[Physician to the Bristol Royal Infirmary.

In discussing before the Physiological Sub-section of the British Association the comparative merits of several modes of reckoning the nutritive value of foods, Dr. Edward Smith gave the preference to that which he has adopted in his official reports—viz., the statement of the quantity of carbon and of nitrogen contained. He advocated it as being at once most simple and most complete. Simple it certainly is; but I shall endeavour to show that in completeness and in general utility it is inferior to other methods.

I agree with him in reprobating the coarse, unscientific, and utterly misleading practice of estimating the value of food by its weight alone, with the slight discrimination of solids and liquids; and I find the method of reckoning the uncombined hydrogen as carbon, and adding it to the rest of the carbon, to be somewhat too clumsy and cumbrous for ordinary use, though its superiority in correctness to his own favourite plan is very marked when it is applied to dietaries abounding in vegetable or animal fats.

There remain two other methods. The first of these I will discuss briefly, as it has not met with general acceptance and was not mentioned in Dr. Smith's paper. It has, however, been employed by some German writers on dietetics. I may, perhaps, claim the authorship of it myself, as it was proposed by me to Dr. Robertson, of Buxton, about sixteen years ago, when he was publishing his work on diet. I subsequently communicated it to Professors Christison and Gregory; but do not think it was ever published in this country. This method is founded on the fact that almost all the carbon and hydrogen, and by far the greatest part of the nitrogen of the food, are excreted in the forms of carbonic acid, water, and ammonia, urea being equivalent, in this point of view, to a dehydrated carbonate of ammonia. Assuming that the calorific value of any substance is to be measured by the quantity of oxygen with which it will combine, it is only necessary to ascertain, in each instance, how much oxygen is required for the conversion of the carbon, hydrogen, and nitrogen into carbonic acid, water, and ammonia; and the respective quantities of oxygen expressed in terms relative to the weights of the substances examined will indicate, so far as elemental chemistry alone can do it, the respiratory value of food.(a)

For example, let the respiratory value of pure dry fibrin be required. It contains about 54 per cent. of carbon, 7 of hydrogen, $15\frac{3}{4}$ of nitrogen, and 22 of oxygen. Of the hydrogen, about 3·4 may be subtracted in order to convert the nitrogen into ammonia, and 2·75 to form water with the constituent oxygen. There remain 54 of carbon and about ·85 of hydrogen. These require for their conversion into carbonic acid and water 144 + 7 = 151 of extraneous oxygen; and 151 accordingly represents the calorific or respiratory value of 100 parts of fibrin.

Pure dry starch containing 44·4 per cent. of carbon requires for its combustion 118 per cent of oxygen (for 44·4 ÷ 3 × 8= 118·4); and 118 represents its calorific value. And if we take the composition of animal fat, in its purest forms, to be 79 of carbon, 11·5 of hydrogen, and 9·5 of oxygen, its value, similarly calculated, will be—

(79 ÷ 3 × 8=)210·4 + (11·5 × 8=)92—9·5=293.

(a) I purposely neglect the sulphur and phosphorus.

In the same manner may very easily be calculated the calorific value, expressed in terms of the oxygen required for its combustion, of any aliment, simple or compound, of which we possess either an ultimate or a proximate analysis. This mode of estimate (which I shall call for shortness "the oxygen way") is but little more troublesome than that of reckoning the free hydrogen as carbon ("the hydrogen way"), from which it differs considerably in its results when applied to nitrogenised substances, but not in other cases. The results of both differ widely from those obtained by the rude plan of reckoning the carbon only as calorific. This last I shall call Dr. Smith's, or "the carbon way." These differences may be most clearly shown by the following table, in which I have taken starch as a standard, and employed such quantities of it as will yield a calorific value of 100 on each of the three plans above mentioned:—

	Quantity of each substance.	Starch.	Fat.	Fibrin.
Oxygen way .	85	100	251	129
Carbon way .	225	100	179	123
Hydrogen way	225	100	251	151

All three methods agree in estimating the plastic value of substances by the amount of nitrogen; and all agree also in being based upon the results of ultimate chemical analysis. I shall now proceed to discuss two other methods, both founded on the results of proximate analysis; of these, one simply distinguishes the nitrogenised or albuminoid elements of food from the carbonaceous, and states the quantity of each, while the other further divides the carbonaceous elements into amylaceous or saccharine and fatty. The former has been employed by some of the best writers on the subject, but has little except its simplicity and easiness to recommend it; in accuracy it is inferior even to the coarse plan which I have called "the carbon way," for it altogether ignores the superiority, weight for weight, of fat over starch, which the other partially and imperfectly recognises. The latter is the most complete and perspicuous of all modes hitherto proposed; and I shall endeavour to show why I prefer it to all others, including the one described above, and to the invention of which I have laid claim.

In the first place, it not only does full justice to the higher calorific value of fatty as compared with starchy substances, in which respect it is equalled by the "hydrogen" and by the "oxygen" way; but it alone of the five methods enables one to see at a glance what proportion the former bears to the latter class of substances, thus affording us a kind of knowledge which is of much service in the estimation and formation of dietaries, and which may prove of still more use when we have more perfectly learned the respective parts played in the economy by the two classes. For though we know that among carnivorous races, such as the Eskimaws, the hydrocarbons may entirely replace the hydrates of carbon in the dietary, without apparent detriment, it has not yet been proved, nor does it seem probable, that the converse is the case. There are few vegetables copiously used as food which do not contain traces of some form of fat or oil, and in those who are usually confined to an almost exclusively amylaceous diet (*e. g.*, the cassava-eating tribes of central Africa) the longing for grease of some kind is, as I am informed by Dr. Kirk, of the Zambesi expedition, equally or more intense than that for albuminous food. And it is certainly not without good cause that the young animal of our own species, as well as of other mammals, has been so freely supplied with fat in the food of its infancy. But as the cereals most commonly used in this country (wheat and the potato) are extremely deficient in this respect, and as all fatty substances are comparatively expensive, so that there is some temptation for rigid economists to do without them; it is surely important to ascertain their presence and quantity in any dietary whose value we attempt or pretend to estimate. Again, the method under consideration enables us to exclude from calculation innutritious or indigestible substances, such as cellulose and chlorophyll, which according to Dr. Smith's method take equal rank with sugar and starch. These two advantages are sufficient to render this superior to any other method in accuracy and completeness; but its merits are not yet all told. In simplicity and intelligibility also it stands high; and its results can, I think, be carried in the memory with as much ease as those of any other plan. Thus it is quite as easy to remember that ordinary wheaten bread contains about 54 per cent. of amylaceous, 1 of fatty, and 8½ of albuminoid matter, as that it yields 28·3 per cent. of carbon and 1·29 of nitrogen; and the amount of information contained in the former series of statements is far more valuable than that in the latter, not to mention that is easy to deduce, with tolerable correctness, the elementary from the proximate constitution of a substance, while the converse process is impossible where fat is present in any quantity.

HOLIDAY NOTES ON CONTINENTAL SPAS.

(Second Series.)

ON SOME OF THE PRINCIPAL PYRENEAN SPAS.

By HERMANN WEBER, M.D., F.R.C.P.,
Physician to the German Hospital.

The Pyrenean Spas are by no means unknown in England; they are, however, as yet much less resorted to by English invalids, excepting those usually resident in the South of France, than the Spas of Germany. And yet it cannot be denied that in many conditions they offer advantages which are nowhere else to be obtained.

The number of mineral springs in the Pyrenees is very large; most of them are sulphurous or sulphuretted, but some of them belong to the muriated or the sulphated saline, the mixed saline, the carbonated alkaline, or the chalybeate waters.

The prominent feature of the Pyrenean spas consists, however, in the sulphurous springs, which are, with few exceptions, more or less thermal, some of them belonging to the hottest mineral waters in existence. My present notes refer principally to these sulphurous springs.

In order to avoid repetition, it appears advisable to premise some remarks on sulphurous waters in general, and especially on those of the Pyrenees.

The signification of sulphurous or sulphuretted waters is generally given to those waters which contain sulphur, sulphuretted hydrogen, or sulphurets of metals in perceptible quantities, which, however, may contain many other principles besides, but none of them in such quantity as to derive from it their predominant physiological or therapeutical action. They are divided, according to Fontan and other hydrologists, in *sodic* sulphuretted waters, containing sulphuret of sodium, and *calcic* sulphuretted waters, containing sulphuret of calcium; the former of these are also designated as *natural* sulphuretted waters, because their elements are considered as formed in the rock itself, without the intervention of decomposing organic substances; while the latter (the calcic) are regarded as *accidental* sulphuretted waters, because their sulphur is considered as derived from the decomposition of sulphates through the action of putrescent organic substances with which the waters have come in contact. Although Fontan's division is perhaps rather too systematical, yet the two groups offer marked differences in their character.

The Pyrenean sulphuretted springs belong almost all to the sodic or natural sulphuretted waters, and may be regarded as the principal representatives of this class of waters; in fact, almost all the known springs of this nature belong to the Pyrenees.

These waters are limpid at their origin, but become turbid through the contact of the air—some sooner, some later. When fresh, they do not exhale much sulphuretted hydrogen; most are even quite free from it at their source. The intensity of the odour, at all events, bears no relation to the amount of sulphurets they contain. The accidental sulphurous waters, on the contrary, as it is well known, emit a very strong smell of "rotten eggs."

The quantity of solid substances contained in the Pyrenean sulphuretted spas is very small, amounting only to a few grains in the pound. They are alkaline; and their principal basis is soda in combination with the sulphuric, silicic, muriatic, and hydrosulphuric acids. Almost all the sources contain also small quantities of potash, magnesia, chalk, iron, and organic substances.

Their composition is, however, as yet, not completely known, which is due in part to their rapid alteration under the influence of various agencies; and probably the very fact of this rapid decomposition is of great importance in their action on the animal organism.

According to the researches of Filhol, the presence of silica seems to be very important in this process of alteration. Thus it may be presumed that under the influence of the atmospheric air the silicic acid deprives the sulphuret of sodium of a por-

tion of its sodium, and that the sulphur in excess is transformed into sulphuretted hydrogen, which again, under the further influence of oxygen, may be changed into sulphur and water; but various ways may be imagined in which these alterations take place, and probably the decomposition is not quite so simple as it appears at first sight. The different springs exhibit considerable differences in this respect. Thus I have seen at Luchou a phenomenon which is called "blanchiment," the water becoming opalescent soon after exposure to the air, which phenomenon I have not seen either at Barèges, Cauterets, or Eaux-Chandes, and which seems to be due, according to Dr. Lambron and other hydrologists, to a precipitation of sulphur in substance. Filhol, who has examined this "blanchiment," found it caused by the suspension of sulphur, silicic acid in excess, and various silicates; and he ascribes its occurrence to the presence of a large proportion of silicic acid. The baths in the waters which offer this "blanchiment" feel softer to the skin than those in other sulphuretted waters. The manner and rapidity of decomposition which the waters undergo, it will be seen from this, is of some importance, and it is not the mere amount of sulphuret of sodium contained in them which is to be taken into consideration. Possibly some of the elements which are scarcely looked at in the analysis—as, for instance silica—exercise indirectly as great an influence as the sulphurets themselves.

From the changeable nature of these waters we must also at once conclude that their action must be very variable, according to quality and amount of decomposition which has taken place in the water when the bath is taken. The surrounding atmosphere, too, which is, no doubt, of great importance, the nature and influence of which has been, however, as yet, but little examined into, must widely vary according to the degree of the decomposition of the waters themselves.

The sulphuretted waters of the Pyrenees are all characterised by the presence of various organic substances, which, up to a very recent period, were thrown together under such significations as matière bitumineuse, humus, matière humique, matière gélatineuse, glairine, barégine, Pyrénéine, etc. The researches of Fontan ("Rech. sur les eaux minérales," 1853), Filhol ("Traité des eaux des Pyrénées," 1853), Lambron ("Annales de la Société d'Hydrologie," 1854), and others have shown the complicated nature of these organic substances, and especially the presence of the vegetable organism called "sulfuraire." It would be out of place to enter here into a description of the various organic substances, on the nature of which, as far as our present limited knowledge goes, excellent articles are contained in Lambron's valuable work, "Les Pyrénées et les eaux Thermales Sulfurées de Bagnères-de-Luchon" (vol. i., p. 473, 1862), and in the "Dictionnaire des eaux minerales" (vol. ii., p. 467, 1860). Lambron divides the organic substances into three groups: 1. Substance dissolved in the water, which is contained in all waters, but is different in the different kinds of mineral waters, and in the sulphuretted waters is called by him "sulfurose;" 2. Substance suspended in the water causing the various deposits of such waters, designated by him "sulfurine;" 3. Organised substance belonging to the vegetable kingdom, designated by Fontan "sulfuraire" (Leptomitus sulfuraria). The second kind of organic substance, viz., the "sulfurine," is, according to Lambron, the product of the transformation of the third, viz., the vegetable "sulfuraire."

Our knowledge of the physiological action of the sulphuretted waters is, as yet, very imperfect. Trustworthy researches on the action of these waters on the metamorphosis of tissue in healthy persons, on the elimination of carbonic acid through the lungs, or of urea, uric acid, and other products of tissue-change through the urine, are altogether wanting; and without knowing how these processes are influenced, we must consider ourselves ignorant as far as the physiological actions are concerned. Such researches are difficult, but they can be made, and ought to be made, and it would be very proper if the Société d'Hydrologie, or some other scientific society in France or Germany, would make them the subject of a prize essay.

It is, however, to be acknowledged as a valuable fact that the sulphuretted waters when taken internally in moderate quantities, and also when used as baths, do not, as was formerly believed, increase the frequency of the pulse, but, on the contrary, diminish it. Lambron says on this subject:—"L'elément sulfuré des eaux prises en boisson et en bain tempéré a une action hyposthénisante très-marquée sur le system circulatoire; les contractions du cœur sont moins énergiques et moins nombreuses, le pouls, pendant pleusieurs heures après être sorti du bain, offre une diminution de 5, 8, 10, ou 12 pulsations sur le nombre normal et habituel, compté soit au réveil, soit avant le départ pour le bain. Depuis 1855, j'ai maintes fois répété ces observations chez des personnes de deux sexes, de tout âge et de constitutions différentes et les résultats ont été les mêmes dans plus des $\frac{4}{5}$ des cas."—(L. c., vol. i., p. 526.)

Lambron quotes the researches of Gerdy on the calcic sulphuretted waters of Uriage; those of Hertwig, the Professor of Veterinary Medicine at Berlin, made with sulphuret of potassium and sulphuret of sodium; and those of Ferran (on the sodic sulphuretted waters of la Preste) as being in harmony with his own experience.

Although I place perfect trust in these researches for the special waters which have formed the subject of the examination, yet I hesitate in applying them to all the sulphuretted waters, as some of them, especially those of Barèges, have the general reputation, shared more or less by all the Medical men of Barèges, of being exciting to a high degree and unfit for cases prone to hæmorrhage or disturbance of circulation in general.

Filhol, Mialhe, Lambron, and others maintain that the sulphur, which is absorbed through the skin and intestinal mucous membrane, enters the blood and abstracts oxygen from the blood globules, forcing them through this to take up more oxygen from the air. Thus, the elements for an increased or more perfect tissue change are given, and this is probably the meaning of the expression generally used by the learned Physicians at the Pyrenean Spas, that their waters promote the "nutrition interstitielle," or that they exercise an immediate influence on the "fonctions plastiques."

I do not deny the probability of this theory, yet I can scarcely consider the view of the manner in which the sulphur acts on the blood, and through this on the tissue change, as sufficiently proved; and it would be, as stated before, very desirable if its correctness were to be examined into by researches on the products of this tissue change.

Some authors attribute to the sulphuretted waters also a fluidifying influence on the albuminous substances of the blood and tissues.

The more tangible excretions are apparently but slightly influenced by a moderate use of the waters. The fæcal excretions are, in some cases, at first retarded, but become afterwards more regular; only in few persons the waters cause colie and diarrhœa, perhaps, as Lambron suggests, on account of too great acidity of the intestinal secretions, which prevents the absorption of the sulphur. The appetite becomes in general increased.

The quantity of urine is said to be increased, but how much of this is due to the internal and external use of the warm water, and how much to the sulphurets admixed to it, is impossible to decide without a course of carefully instituted experiments. The same remark may be applied to the assertion "that the action of the skin is augmented, that the perspiration becomes increased, and that even copious sweats are produced," (Lambron, l.c. p. 540). There is, however, more proof of an increased activity of the skin, as the perspiration according to the author just quoted, contains sulphur, and the occurrence of cutaneous eruptions during the treatment is by no means rare. The mucous membranes in general, and those of the respiratory organs in particular, appear to be similarly influenced as the skin.

The action of the sulphurets on the nervous system is described as exciting, and has been compared to that of coffee. Lambron expresses his view on this subject in the following words:—"En fin, entré dans l'économie par n'importe quelle voie, le principe sulfuré excite à la manière du café (Bordeu) le système nerveux dans toutes ses parties, cerveau, moelle épinière, nerfs, et sans donté aussi le grand sympathique; mais it parait doué d'une action spéciale ou, tout au moins, plus prononcée pour activer les functions du cordon rachidien."—L. c., vol. i., p. 541.

A fact which has been mentioned to me by many—I may say by the majority of bathers—is a certain feeling of lassitude after the first three or four baths, which afterwards disappears, and is followed by a sensation of increased strength and activity. Another phenomenon, which is likewise often complained of, is a feeling of feverishness and nervous excitement a few days after the commencement of the treatment.

The question of the therapeutic actions of the sulphuretted waters I will discuss more fully in describing the principal Pyrenean Spas, limiting myself, at present, to merely naming

the morbid conditions for which these waters are most frequently resorted to. At the head may be placed diseases of the skin, and especially those which the French comprise under the term "diathèse herpétique," or "herpétisme" (Fontan); chronic affections of the respiratory organs and of the fauces; chronic rheumatism in its various forms; scrofulous disease; residues of traumatic affections; diseases of the bones; chlorosis; leucorrhœa from ulceration and abrasion of the os uteri; constitutional syphilis and mercurialism; chronic catarrh of the bladder and urethra; dyspepsia.

In how far the sulphuretted waters may be considered as real remedies against the pathological conditions just mentioned I shall endeavour to explain under the head of the different spas.

I shall begin by giving an account of Bagnères de Luchon, and intend to describe this Spa more fully than the others, because the beauty of its situation, the superiority of its accommodation, the composition, the variety and abundance of its springs, and the excellence of its bathing establishment, render it the Queen of the Pyrenean Spas, which will probably sooner or later become a favourite resort for English invalids as well as it is now for the French.

(To be continued.)

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

KING'S COLLEGE HOSPITAL.

LACERATION OF THE RECTUM—PERITONITIS—RECOVERY.

(Under the care of Mr. PARTRIDGE and Mr. SMITH.)

We are indebted for these notes to Mr. E. Atherstone, the dresser of the patient:—

William C., aged 25, on the night of December 25, 1864, climbing over a wall, against which a broom was standing, he slipped down, and the broom-handle pierced the seat of his breeches, entering his anus. He felt very faint for a few minutes from the intense pain, but recovering, he withdrew the handle, the blood flowing freely for a short time. He was soon afterwards brought to the Hospital, and seen by the Assistant House-Surgeon. There was no external laceration, but a small wound of the rectum about an inch and a-half above the anus. The hæmorrhage had ceased, and his pulse was very low and weak.

On the 26th vomiting set in, with pain over the hypogastric region. He had a natural motion, and passed no blood. His pulse 96, and weak. Ordered brandy, ℥ij.

27th.—Slight tympanitis set in, increasing on the 28th, when Mr. Henry Smith saw him, and made a rectal examination. He found a valvular wound of the rectum, sufficiently large to admit the index finger with ease, and extending upwards about an inch and a quarter on the right side, between the mucous and muscular coats of the gut. The vomiting still continued. Pil. opii, gr. j., t. d. s.

30th.—Pulse 85; vomiting gone; countenance free from anxiety; abdomen still tympanitic and painful.

31st.—The vomiting recommenced, and continued more or less every day until January 3, when it finally left him. Ices and effervescing mixtures were given to stay the vomiting; turpentine stupes and hot flannels applied to the abdomen; and ℞ Sp. ammon. aromat., ♏xx.; chlorodyne, ♏xv.; infusi. cinchonæ, ℥j. ft. mist., t. d. s., for a troublesome cough.

4th.—Pulse 90; tongue clean; abdomen very tense and tender about umbilicus; no vomiting.

9th.—Pulse 102; abdomen soft and of the natural size. An abscess has formed behind ramus of lower jaw. To omit pil. opii, and to take quinæ disulph., gr. iss.; acid sulph. d., ♏x.; infusi cinchonæ, ℥j. ft. mist., t. d. s.

14th.—The wound of rectum has almost healed, so that the tip of the finger cannot go into it. On pressing on back part of rectum there is hardness either from condensed cellular tissue or effusion of blood not yet absorbed. The abscess discharges freely.

18th.—Difficulty in passing water, most probably from nervous debility. Pulse 78.

23rd.—Site of wound in rectum barely to be distinguished in the form of a small depression. Abscess healed.

29th.—Abdomen tympanitic, with slight griping. ℞. Pil. opii, gr.j. Hot flannels to abdomen.

30th.—No tympanitis this morning; tongue clean; bowels open; pulse 62.

February 4.—Convalescent.

REMOVAL OF PORTION OF SCAPULA FOR FIBROID TUMOUR.

The patient whose scapula was partially removed by Mr. Fergusson, as described in a recent number of the journal, left on February 8, with the wound perfectly healed and in excellent health.

LIGATURE OF THE COMMON CAROTID ARTERY FOR A WOUND BEHIND THE RAMUS OF THE JAW — DEATH FROM ŒDEMA GLOTTIDIS — AUTOPSY.

(Under the care of Mr. PARTRIDGE.)

A man, aged 21, was brought into King's College Hospital on April 2, 1864, who had been stabbed behind the ramus of the jaw with a long, narrow, thin-bladed knife. Arterial blood was coming freely from the wound; at first the bleeding was arrested by a graduated compress, which controlled the bleeding for a few days, when one morning, whilst straining at stool, the coagulum gave way; a pulsating tumour formed, which was cut into, and the clot turned out, and an attempt made to secure the bleeding vessel or vessels, but without success. The hæmorrhage was controlled until Mr. Partridge's arrival at the Hospital, when he determined to ligature the common carotid. This was performed in the ordinary way by a longitudinal incision above the omo-hyoid. Some branches of the facial nerve were divided by the original wound, so that the patient could not close the eyelid. Pulsation was felt in the temporal artery two days after the operation. The ligature came away on the eleventh day.

The wound bled freely on the least exertion, and a severe attack of pneumonia came on. A large, deep-seated abscess formed behind the angle of the jaw; but it was not deemed advisable to open it at first, as its exact position was doubtful. He died suddenly, from suffocation produced by the pressure of the abscess.

Autopsy.—There was a large, deep wound behind the jaw, passing downwards and backwards. A large abscess was formed, extending deeply behind the ramus; considerable œdema of the glottis, involving the epiglottis. One of the larger branches of the external carotid to the parotid gland had been divided by the stab, but the trunk was untouched. The lungs were much gorged, the other organs were healthy.

GUY'S HOSPITAL.

LIGATURE OF COMMON CAROTID ARTERY FOR HÆMORRHAGE FROM A MALIGNANT TUMOUR OF RAPID GROWTH CONNECTED WITH THE SUPERIOR MAXILLARY BONE—DEATH FROM SECONDARY HÆMORRHAGE—AUTOPSY.

(Under the care of Mr. POLAND.)

For the following notes we are indebted to the operator, Mr. E. Reynolds Ray, late House-Surgeon:—

John T., aged 55 years, a farm labourer, admitted into Lazarus Ward, Guy's Hospital, October 26, 1864, under the care of Mr. Poland. Has had good general health; of steady sober habits, but of a malignant sallow aspect. About twelve months ago he felt a pricking sensation in the left eye which continued and increased. About six months ago he noticed a slight swelling of the left side of his face, and projection of the left eye, and found he could not see so well as formerly; the pain also increased about this time, and is now much more acute, extending down the face; at first there was a discharge from the nose, but there is an almost daily slight loss of blood. The left eye is now so protruded that the lids do not nearly meet when he attempts to close them. There is chemosis, the conjunctiva very injected, and the sight misty. On examining with the ophthalmoscope nothing is observed but a very injected state of the vessels. The nasal bone on the left side bulges, and the cheek rising to it, forms with it more or less a continuous plane, giving on manipulation a semi-elastic sensation. On looking into the left nostril, the septum nasi with bones attached are seen pushed to the right, out of the median line, the nostril itself being partially blocked up by the tumour. In the right nostril there is a polypus. On looking into the mouth the tumour is seen encroaching on the soft

palate, but limited to the left side, extending forward to the teeth, slightly loosening and displacing some of them, and again is felt in the angle between the lips and teeth, giving everywhere a hardened elastic sensation to the touch. On the left side the mouth is drawn up. The skin over malar bone and superior maxilla is purplish, and has given way in one small place below the inner angle of the eye, which place bleeds slightly from time to time.

On November 1 the glands below the angle of the jaw began to enlarge, though not rapidly. Several attacks of hæmorrhage from the nose occurred.

About the 10th the glands began rapidly to increase.

On the 11th there was a severe attack of hæmorrhage, checked by injection of a strong solution of alum up the left nostril. The man was suffering acutely, and daily becoming weaker.

At 5 a.m. on the 14th, Mr. E. Reynolds Ray, the House-Surgeon, was sent for to him; he found he had just vomited nearly two pints of dark-coloured blood (which afterwards coagulated), The patient said he had felt it trickling down his throat all night. He was faint; pulse rapid and weak. Though there was but little hæmorrhage then going on, it was thought advisable not to leave him with a chance of another severe attack, so Mr. Eastes administered chloroform, while the House-Surgeon proceeded to tie the common carotid. So rapid had been the growth of the glandular tumour that, though sixteen hours before it was thought possible to tie the artery in the upper part of its course, now it was found to be quite impracticable, the tumour extending nearly to a level with the cricoid cartilage. For this reason the artery was tied below the omo-hyoid muscle. Here but little difficulty was experienced, the patient losing during the operation but a few drachms of blood. The wound was closed by strips of plaster. 10 a.m.—Drowsy; has no paralysis either of motion or sensation; has great difficulty in swallowing; pupils equal and acting; has throbbing pain in head. 3.30 p.m.—Has sudden twitchings of his limbs, caused, the patient says, by sudden short paroxysms of pain in his head on the left side, causing him to jump; has occasional hiccough. 7 p.m.—Bowels have been twice relieved; passed water twice; swallows with less difficulty; motion and sensation perfect; pupils equal and acting; face has an erysipelatous blush on left side; has taken plenty of beef-tea; no paralysis.

16th, 3 a.m.—Sleeping; breathing easily. 9 a.m.—Quiet; no pain or paralysis; pulse 90, very small. Erysipelas has extended down his neck beyond the wound.

18th.—Better. There is a red, hot, painful swelling at the back of the right wrist joint and hand. The erysipelas about the face is dying away, though extending from the wound over the neck and chest.

24th.—An abscess over the back of the right hand opened; erysipelas gone.

26th.—An abscess opened below the jaw on the left side.

27th.—In pain last night about the right hand and arm. Fluctuation a little above the right wrist at back; opened; not communicating with former abscess; the wound is looking very healthy, and nearly closed. There is a strong pulse to be felt in the course of the carotid; less than an inch above where it was tied. There is also a very strong impulse to be traced from below quite up into the wound. Ever since the operation the man has been much more comfortable than before it. Is very anxious to get up. There has been no hæmorrhage; the glandular enlargement has been steadily decreasing, and the face is now much less distorted. He has since the operation had as much beef-tea as he could take, fish, chop, etc.; and after the first few days six ounces of wine daily, and from time to time a little opium. The erysipelatous surface was every day painted with the tincture of the sesquichloride of iron.

December 1.—Is not so well, weaker, pulse small, varying from 98 to 116: ordered brandy, 6 oz. Pupils equal; no paralysis.

2nd, 3·30 p.m.—While being lifted up to drink sudden arterial bleeding from the wound came on; died in two or three minutes; lost not more than two or three ounces of blood.

Post-mortem Twenty-three Hours After.—The artery was completely divided, though the ligature was still hanging by a few fibres to the upper extremity of the artery. The lower end was quite patent, and not the slightest appearance of a clot could be found in the lower part of the artery, nor was there anything like the cast of a vessel found in the blood lost at the time of death. The upper part of the artery was impervious to beyond the superior thyroid artery. The ascending pharyngeal and lingual and all other branches were free and looked enlarged. There was suppuration going on within the artery nearly up to the bifurcation. It is a strange fact that this man had no arteria innominata—the carotid and sub-clavian on the right side coming off direct from the arch of the aorta.

WEST LONDON HOSPITAL.

COMPOUND FRACTURE OF THE TIBIA, AND SIMPLE FRACTURE OF THE FIBULA—REDUCTION EFFECTED BY SAWING OFF THE END OF THE TIBIA—RECOVERY WITHOUT SHORTENING.

(Under the care of Mr. TEEVAN.)

For the notes of the following case we are indebted to Mr. Alderson, House-Surgeon.

David C., aged 49, a thin, wiry, and healthy-looking drayman, was, on September 17, thrown from his dray by his horses suddenly starting. When he was brought to the Hospital, it was found that he had met with a simple fracture of the right fibula in its upper part, and a compound fracture of the right tibia about the middle. The leg was greatly bruised and swollen, being nearly twice the size of the sound one, and it was evident that in several places the skin had lost its vitality. The fracture of the tibia was very oblique, so that, even after extension, the upper fragment continued to override the lower fragment considerably. The leg was placed in lateral splints; the wound was closed with a piece of lint; and an evaporating lotion applied to the limb. As the man was a free drinker, and it was clear that there would be considerable suppuration, he was placed on a liberal diet, and ordered brandy.

September 19.—On the night of his admission he slept well, and was tolerably comfortable the next day; but had no sleep last night, and complains of considerable pain at seat of fracture. The leg is in places of a deep purple colour, and has a shining look. The patient is suffering from considerable constitutional irritation. Ordered opium at bed time, and tonic infusion with sulphate of magnesia every day. The lateral splints were replaced by sandbags, and as the wound was inflamed a poultice was applied.

24th.—The constitutional irritation has subsided; the skin round the margin of the wound has sloughed considerably; and free suppuration is taking place, as also from two fresh wounds on the upper and outer part of the calf.

29th.—The patient has regained his appetite, and now sleeps well. Mr. Teevan effected reduction to-day by sawing off about one inch of bone from the upper fragment of the tibia. The leg was placed in a MacIntyre, and a pad put over the ends of the tibia, water dressing having been first laid on.

October 6.—Leg is still very boggy in places, and pus wells out freely from all the three apertures.

10th.—Granulations are now springing up from the periosteum and bare ends of the tibia, which had been denuded to the extent of about two inches, by the sloughing of the skin.

21st.—A mass of callus envelopes the bones. The wound is rapidly filling up. Limb kept well extended.

November 28.—Wound almost closed. Union seems tolerably firm. MacIntyre splint discontinued, and a short lateral wood splint applied.

At the end of December the patient left the Hospital, with the wound quite closed. He shortly afterwards was able to walk about with the aid of a stick only; and when he presented himself at the Hospital last week (February 8) there was no apparent shortening, and he declared that his leg was just as useful and as supple as the uninjured one.

A Doctors' Strike at Totnes.—The members of the Medical Profession in Totnes have declined to be any longer connected with the Phœnix Friendly Society in the capacity of Medical attendants, on the ground that the members of the Society generally are not the class of persons who ought to avail themselves of the boon granted by the Profession to the labouring and working classes. It is expected that similar notice will be given to the other societies.—*Western Daily Mercury.*

SATURDAY, FEBRUARY 18.

MEDICAL ERRORS.

The late terrible and fatal accident in Westminster has, very naturally, excited a great amount of public attention. Some hundreds of persons were assembled together in a school-room one evening, when suddenly part of the flooring gave way, and about an hundred and fifty men, women, and children were hurled pell-mell into the basement story beneath. Now, besides the pity and sympathy excited by such a calamity, nearly everybody is in the habit of more or less frequently attending gatherings together of different kinds in upper rooms, and nearly every one becomes, therefore, personally concerned in the trustworthiness of beams, girders, and other floor supports. We doubt not, then, that the inquiry into the cause of this accident has been very generally and carefully read. But Medical men must, we think, have perused it with special interest, and with, we venture to say, not a little amusement. We are, as a Profession, constantly taunted with the character of the evidence we give in courts of law and justice; it is confused, incorrect, theoretical, contradictory; all kinds of epithets expressive of ridicule and contempt are freely and constantly hurled at it. Well, very anxious to learn how to do better, we look out for examples that may teach us what evidence ought to be, and in the Westminster inquiry we expect to find a perfect lesson. The case is extremely simple. A beam of wood supporting a floor gives way under the superimposed weight of a crowd of people. Why did the beam break? Here are no conflicting forces to deal with, no unknown and mysterious powers and quantities, no complex combination of circumstances and influences, as there are in disease in the living body. All the elements to be dealt with here can be measured, weighed, and counted. The only laws to be considered are the laws of physics, which are well and accurately determined. Here, then, we naturally exclaim, we shall get a perfect lesson in scientific evidence. But lo! when we come to read, we find the professional evidence of the experts contradictory, theoretical, confused, and insufficient to a degree that no Medical evidence ever surpassed or equalled! Still, Medical men may, we think, learn a lesson from it, and we draw attention to it, not, as our readers may well suppose, simply to show that very bad "scientific" evidence may be given by others than Doctors, but because it seems to us the errors and fallacies of the evidence are just those to which Medical men are most prone—just those which vitiate so frequently our writings and arguments, and lead us to adopt ill-considered and really unfounded modes of practice. Let us look, then, a little at the evidence in this Westminster accident case. A beam of wood twenty feet long and a foot square, forming one of the supports of a room full of people, and which was calculated to support any amount of weight that could in the natural use of the room be put upon it, gave way; why did it break? An eminent architect gave evidence that he had examined the beam, and found that it was of American pine, while it ought to have been of Baltic timber; the contract under which the building was taken required timber of the latter kind to be employed, and a beam of such dimensions and of the right material would have borne a weight of forty tons, but American pine was utterly untrustworthy, and had broken down under a weight of less than four tons. The explanation seemed perfectly clear and simple. But the contractor and his foreman proved that the timber was actually Baltic, and not American! And then the architect having again examined the wood, confessed that he was "a little perplexed," that he was not quite sure about the matter, and that he thought the wood might really be genuine Baltic. Here, then, was an instance of hasty and imperfect observation. The architect's fact on which he based his whole theory and explanation was no fact at all; his reasoning was correct, but his premises were wrong. Is not this kind of error far too common in Medical reasoning? Do not Medical facts too often turn out to be not facts, and Medical arguments to be based on hasty and imperfect observations?

But the beam being of Baltic timber, it ought not, according to "Barlow's Tables," to have broken down under the weight it did. How did it come to contradict the standard tables? A builder and surveyor attributed its failure to the fact that the joists of the floor were morticed into it to a depth which reduced it to 12 inches by 6 in size, instead of 12 by 12. The "district surveyor" utterly repudiated this explanation. There was a stove in the room, and one authority thought that the heat of the stove had so desiccated the beam as to destroy its strength; but the "architect to the Committee of Privy Council on Education" rejected altogether this theory, as it is common enough for stoves to be used in such rooms, and the floors do not commonly give way. Both these explanations are examples of "post hoc ergo propter hoc" argument, which, we need hardly point out, is sadly too frequent with ourselves. The beam had been partly cut through for the morticing, and the accident followed; therefore, etc. The stove was there, and the accident followed, and therefore, etc.; but the morticing is common enough, the use of the stove is common enough, and the accident, happily, is not common; the cause alleged very frequently exists, the alleged result very rarely follows; so that the connection of the two as cause and effect is completely erroneous. But would it not be the easiest thing in the world to adduce examples of a similar hasty and imperfect argument from Medical writings? Or we might, perhaps, call the two last theories instances of generalisation from insufficient data; and this, again, is a most frequent error with us. A new or unusual means is tried in a few cases of disease, and recovery follows; and immediately they are published as proofs of the discovery of a new remedy. More extended experience shows the "remedy" to be utterly worthless, and, after vexing us for a longer or shorter time, it is consigned to oblivion. Everybody is but too familiar with instances of this kind.

We will not, however, any longer use the evidence given in the Westminster inquiry to "point a moral;" our purpose is only just to make it serve as an opportunity for pointing to some of the most common mistakes and shortcomings in Medical inquiries and arguments, and to direct the attention of our readers to Dr. Barclay's little work on "Medical Errors."(a) This is a reprint of Dr. Barclay's "Lumleian Lectures," delivered at the College of Physicians last year, and is well worthy of a careful perusal. It might, indeed, we venture to think, be, with but a little labour and trouble, made more generally valuable and useful, and we hope that when a new edition is called for the accomplished author will somewhat enlarge it, and will add to it a table of contents, and an index; at

(a) "Medical Errors: Fallacies Connected with the Application of the Inductive Method of Reasoning to the Science of Medicine." By A. W. Barclay, M.D. Cantab. and Edin, F.R.C.P, Physician to St. George's Hospital, etc. John Churchill and Sons. 1864.

present it has neither, and the want, we think, seriously detracts from its usefulness; but even as it is, and treating very briefly, in three hours'-time, so to speak, of a very large subject, it is a valuable and instructive work. Dr. Barclay speaks of the general "ignorance of the inductive method," of the "laws of induction," and of the "province of logic;" of "statistics and averages," of "the numerical method," "the application of statistics," the "legitimate inferences" to be drawn from them, and the common abuse of them. In treating of statistical investigations and the method of averages, he very truly, to our thinking, observes that "the fundamental error into which Medical writers are prone to fall is the idea that induction is almost synonymous with the enumeration of a large number of instances, and that any reasoning from such a collection of cases is properly called inductive reasoning." "A Medical treatise," he elsewhere remarks, "is too often estimated merely according to the number of cases, and especially successful cases, occurring in the author's practice." While the truth is that "from a very large number of cases trustworthy averages may be obtained, and that from these, under proper restrictions, correct inferences may occasionally be drawn; but that this does not give such collections of cases the character of inductions. A legitimate induction does not demand any lengthened series to prove its truthfulness, but while it assumes a certain familiarity on the part of the observer with the facts bearing on the subject, its distinctive character, as has been already explained, consists in the discovery of some law which will stand the test of experimental inquiry, and is found true for every case which comes under its operation. If the law fail in any case where the special circumstances to which it relates are present, we ought to be able to show that some higher law interfered with its operation, or else we must abandon the law, or at least hold it in suspense. This is never the case with an average; for, supposing we have ascertained that the basis of calculation is sufficiently large, and that the results are perfectly correct, we can still only say that in another series of a similar kind a like result will be obtained. It does not apply to individual instances. It is of the very nature of averages that certain circumstances are acknowledged to vary in most individuals in the series, and consequently that the majority of them are exceptions to the average result; and what is true of the whole is not absolutely true of any individual except by accident." The author also explains what is meant by a "law" and an "empirical law," and what is the value and use of each; and speaks of the employment and real worth of the deductive process of reasoning in Medicine.

This is enough to indicate the scope and aim of the book, and we only add that Dr. Barclay enforces and illustrates all that he says by telling examples drawn from Medical practice and Medical writings. The essay is, we fear, too compressed, and assumes too much previous familiarity with logic on the part of the reader to be of very wide usefulness; but perhaps these objections might be removed to a great degree if Dr. Barclay would add, in an appendix, the "canons of induction" to which he is obliged to refer his readers, and some definitions and explanations of the processes of induction and deduction.

THE WEEK.

ACUPRESSURE IN EDINBURGH.

It was some century and a-half after Paré proposed the arrestment of arterial hæmorrhages in Surgical operations by silken ligatures instead of red-hot irons, before the plan was adopted or even tried in the Hospitals of his own city of Paris. Acupressure, or the temporary metallic compression of bleeding arteries, seems destined to meet with a happier fate. In all his late operations at the Royal Infirmary of Edinburgh and at Chalmers' Hospital, Dr. Heron Watson, lecturer on Surgery, and one of the most expert and able operators in the Medical School of the northern metropolis, has employed acupressure to stem the accompanying bleeding. He has thus used it in amputation, excision of the knee-joint, extirpation of the mamma, etc.; and always, according to the reports of the eye-witnesses, with perfect facility and success, and with much greater expedition than he could have applied the ligature. Besides, the wounds themselves seem to be all healing with less irritation and more rapidity than when the ligatures and their inevitable arterial sloughs are left imbedded in the closed interiors of the wounds. Another Edinburgh Hospital Surgeon (Mr. Edwards) has used acupressure successfully last week in two cases out-of-doors—one of amputation and one of excision of the knee-joint. Professor Pirrie, and Drs. Leith and Fiddes, the Surgeons of the Aberdeen Infirmary, have, for some months past, adopted the practice with, it is stated, the most successful results, and have applied acupressure to the largest arteries opened in Surgical operations, as to the femoral artery in several cases of amputation of the thigh.

GEORGE VICTOR TOWNLEY.

The convict George Victor Townley committed suicide at the Pentonville Convict Prison on Sunday last. From what we have been able to gather, it appears that recently two letters addressed by him to his friends, in which he commented unfavourably upon the conduct of an officer of the prison, were not permitted to proceed to their destination. This seems to have annoyed him, and on Friday last he opened several veins in his arms while in bed. Having failed in his object in this way, he selected another more effectual method. He went to chapel as usual on Sunday afternoon, and, while coming out, leaped from the top of a staircase, upon which the door from the chapel opens, down to the asphalted pavement below, a distance of twenty-three and a-half feet. This was at five o'clock. Mr. Bradley, the Surgeon of the prison, was sent for, who found him unconscious, with symptoms of fracture of the base of the skull and of the left knee-joint. He died about eight o'clock the same evening. A post-mortem examination has been made. The skull was found badly fractured both over the frontal region and at the base, and the bones of the left knee-joint smashed. There was also some laceration of the brain at the base. With the exception of the lesions resulting from the fall, the organs of the body were found perfectly healthy, and there were no abnormal conditions either of the brain or its membranes, or of the bones of the cranium.

The tendency in the public mind to regard all suicides as the result of mental unsoundness is, doubtless, natural and charitable; but in such a case as this, which, a year ago, gave rise to much difference of opinion, it will be incumbent upon those whose business it will be to inquire into the cause of death, to sift with more than usual carefulness any evidence adduced in favour of Townley's insanity during the period of his residence at Pentonville, and prior to the fatal act.

COTTAGES IN CAMBRIDGESHIRE.

The following letter, which appeared in a late number of the *Times*, is additional evidence of the wretched sanitary condition of some agricultural districts, and of the passive resistance which the stolidity and short-sighted parsimony of small rural proprietors and parochial authorities oppose to any reforms which demand outlay:—

"Sir,—Mr. Clarke, the sanitary inspector, whose letter appears in the *Times* of the 7th inst., need not consider himself singular in the grievance he complained of, as there is a case here almost exactly similar to his. In June last I took a house in this parish, which contains about 185 inhabitants, and as I hold the curacy of it I soon became acquainted with the wants and sicknesses of the people. For the last two or three years there has been much illness in the place, chiefly diphtheria and malignant sore throat. Between June and October there were thirteen cases of the former, three of which proved fatal. Being anxious to get at the cause of this fearful disease in a parish which was formerly very healthy, I found on personal investigation that by far the

greater number of cottages had no privy accommodation whatever; and that in consequence small holes were dug in the ground, in some instances quite close to the doors of the cottages, into which everything in the shape of nightsoil and refuse was thrown, there to accumulate until considered sufficiently fermented to be laid over their different gardens.

"There is standing now in this parish a lot of thirteen cottages, many of which, from their dilapidated state, are wholly unfit for human habitation. To these there are only two privies pertaining. This fact speaks for itself. In order to get this state of things remedied, I wrote to complain of the danger to health caused thereby to the Board of Guardians of this district, upon which the parish Doctor was sent to make an investigation, and I accompanied him. This was thoroughly done, and the report sent in. One or two official warnings were then sent to the landlords, who, except in one instance, have done nothing. Finding no improvement, I wrote again to the Board of Guardians as well as to the magistrates' clerk. Official papers were then again circulated, and the matter dropped as before, while sickness goes on increasing.

"Will any of your readers, then, as nothing seems intended to be done, kindly tell me what steps ought to be taken in so disgusting a state of things, as it seems only through your powerful columns that those whose duty it is to remedy such evils can be induced to do so?

"I remain, Sir, yours obediently,

"Feb. 9." "W. J. Tillbrook, Curate of Newton.

THE METROPOLITAN SEWAGE.

Probably the most important work that Parliament will achieve this Session will be a thorough ventilation of the sewage question. The high hand with which the Metropolitan Board of Works have carried the matter, and the coolness with which they have sold the ratepayers of London to Messrs. Hope and Napier, has, at all events, had the effect of rousing a considerable spirit of resistance. The only fear we have is that the whole thing may be made a party question, and that the real scientific and economic character of the issue may be merged in the disputes of angry boards and rival engineers. Our readers will scarcely need reminding of the condition in which the question stands. The scheme of Messrs. Napier and Hope adopted by the Board of Works proposes to carry the whole sewage of the north of London to the sea coast of Essex, where it is to be expended in converting into grass land a large area of sands which is to be reclaimed from the sea, and to be defended from incursions of the watery element by the erection, at an enormous expense, of a huge sea-wall. This scheme is opposed by the Corporation of London and by Lord R. Montague, on the following grounds:—That the area over which the sewage is to be expended is vastly too small for its remunerative utilisation; that instead of its being poured by gravitation from an open culvert over an area of 20,000 or 40,000 acres, it should be distributed by pumps and hose over 500,000 or 600,000 acres. That such experiments as that at Rugby, by Mr. Lawes, prove that when liquid sewage is poured over a small area, instead of fertilising, it converts the land into a mere swamp. That the real value of the sewage of London has been entirely under-estimated by Messrs. Napier and Hope, but that, to obtain its value, it should not be expended on grass, but on arable land. These views are supported by the opinion of Baron Liebig, and it is to his conclusions, as embodied in the recent report of the Corn, Coal, and Finance Committee, that we now call attention.

"The Committee find that Baron Liebig's analysis of the various fertilising matters found in sewage and in Peruvian guano have led him to the conclusion that in 828 tons of the London sewage, taking its total annual amount at 266,000,000 tons, there is as much ammonia as in one ton of Peruvian guano; and estimating the value of the ammonia, phosphoric acid, and potash found in a ton of guano to be worth £7 14s., he is of opinion that the fertilising matter contained in one ton of sewage is worth 1·84d., and the annual amount of the metropolitan sewage is worth £2,049,715. He, however, further states,—'If the ammonia be reckoned at the price that the farmer pays at present for it in Peruvian guano, the ton of sewer water would be worth something more than the double of that price.' This would give £4,081,430 as the annual value of the metropolitan sewage—a sum somewhat larger than that arrived at by the Committee, basing this estimate on the analysis of Messrs. Hofmann and Witt and the present retail price of Peruvian guano, which price must necessarily rule that of every other manure. The Committee further find that Baron Liebig points attention to the power of soils to abstract from sewage the fertilising matters therein contained, but that of all soils pure sand possesses this power in the smallest degree; and with reference to the dilution of the sewage he states:—'A series of experiments with artificial sewer water proved that a dilution with water as great as that of the sewage of the metropolis in no wise diminishes the absorbing effect of the soil. I found, moreover, last summer, by experiments regarding the growth of plants, that a soil completely saturated with manuring matter did not, as might be supposed, further the development of the plants' growth, for to many, on the contrary, it was prejudicial.' The Committee also find that Baron Liebig conclusively proves the fitness of sewage as a manure suitable for arable land and general farming purposes, and emphatically points attention to the error of continually applying one description of manure to the land. He states:—'No one will ever think of supplying the full effect of farmyard dung by the employment of phosphates or guano; nor is it to be done either by the use of sewage. The chief value of sewage lies in this, that by its application the effects of phosphates, guano, and stable dung are made sure and lasting, and the crops raised to that maximum which the soil can produce, because, by means of sewer-water, those elements are given which are wanting in those other manures, or are present in them in but small quantities.' Baron Liebig, however, shows, by a comparison between the constituents of sewage and those required for the proper nourishment of grass, that although it will undoubtedly benefit that crop, yet that it is less suitable for it than for any other to which it could be applied, and will yield a much less profitable return, and that whereas the fertilising matter contained in a ton of the London sewage, if applied 'to arable land' would be worth 1·84d., taking guano sold at £7 14s. per ton as the standard of value, it would only be worth 2·8 farthings if used for grass, that being, as Baron Liebig states, 'three-eighths of that which I have computed its absolute value to be. The reason of this difference is that sewage water contains an excess of ammonia and phosphoric acid, which is without effect on the growth of grass, and for this reason is not paid for.' And further on, speaking of the application of sewage to the same crop, he states, 'In all localities which by nature are adapted for the employment of sewage, its use is unquestionably an advantage. But if a large capital be required, in order first to adapt the ground for this purpose, the speculation would hardly profit anything, even though he obtained the sewage for ¼d. a ton.' But, with reference to its peculiar fitness for general farming purposes, he observes, 'The full value of sewage, and of its separate constituents, can only be got out of it when it is employed on arable land. While, in the case of a meadow, the whole of that which has been taken from it in the harvest must be replaced in order to make the yield constant, it is sufficient in the system of farmyard manuring to give the farmyard manure those ingredients in addition which were taken from the ground in the preceding harvest in the seeds and meat sold. The component parts of the straw remain on the farm, and, therefore, need nothing to replace them. By means of Peruvian guano and phosphates, the farmer replaces only a portion of these constituents. By means of sewage, on the contrary, he is fully enabled, with the proper addition of phosphates, to restore all of them to his field, and to increase those particular ones which the field most wants, for giving higher and more constant crops. Sewage, as a never-failing source of ammonia, will prove to him of the greatest value when the supply of Peruvian guano is at an end.' Turning from the examination of the admirable report of Baron Liebig to the scheme of the Messrs. Hope and Napier, the committee find that they not only propose to apply the sewage in enormous and wasteful quantities to grass exclusively, for which crop, in their opinion, it is alone suitable, but that, as their plan is one of gravitation from first to last, the manure being applied by flooding the land from open gutters, it would be impossible by their plan to use it on arable land and for general farming purposes, as for such it must of necessity be applied by the hose and jet, which system those gentlemen entirely repudiate and hold up to ridicule."

*

PARLIAMENTARY.

On Thursday, February 9, in the House of Commons, Lord R. Montagu obtained leave to bring in a bill to amend and better to administer the laws for the protection of waters in rivers and streams in England; and a bill for facilitating the more useful application of town sewage in Great Britain and Ireland.

On Friday, February 10, Mr. Scully obtained leave to bring in a bill to amend the law of evidence in criminal cases.

On Monday, February 13, in the House of Lords, Lord Houghton moved for a return of the number of unions and parishes that have availed themselves of the new Act for the relief of the casual poor of the metropolis, and of the expenditure under the Act.

Lord Fortescue thought the relief of these classes of vagrants should be in the hands of the police. The system adopted had not worked well.

Lord Longford attributed the increase of the vagrant poor to the numerous evictions enforced by railway companies under the authority of the Legislature.

The motion was agreed to.

In the House of Commons, Viscount Enfield asked the hon. Member for Bath, as a member of the Metropolitan Board of Works, what progress had been made in the main drainage of the metropolitan district, and when the same would probably be completed.

Mr. Tite said that on the Surrey side the drainage works, with some slight exceptions at Putney and Crosness, were entirely completed. On the Middlesex side the high-level and middle-level sewers were finished, and were in complete operation, and carrying out the intentions of those who devised them. The only work remaining to be performed was the construction of the sewer under the Thames Embankment. A considerable length of that sewer had been completed, and upon their last inspection the Metropolitan Board passed through 300 or 400 feet of it. As to the exact time at which the works would be finished, the engineer stated in a report, dated February 2, that the works, both on the north and south side, would, with the exception of the low-level sewer, come into operation by March 29 next, but that the low-level sewer might probably not come into operation for a couple of years. The construction of the sewers was commenced in the year 1859, and they would cost about four millions of money.

Sir G. Grey moved for leave to introduce a Bill to consolidate and amend the law relating to prisons. He had bestowed, he said, much consideration upon this subject during the recess, and this Bill was the result of that consideration. It proposed to consolidate as well as to amend the existing law as regarded the construction of prisons, the appointment of prison officers, and the treatment of prisoners. He gave a general outline of the provisions of the Bill, especially as to the last-mentioned head—prison discipline, the definition of hard labour, an improved code of prison rules, the dietary of prisoners, and other points—observing that the details would be better understood when the Bill was printed. He proposed that it should be referred to a Select Committee.

After a short discussion, in which Sir F. Goldsmid, Mr. Norris, Mr. Walter, Sir B. Leighton, Mr. Neate, Mr. Adderley, and other members, took part, leave was given to bring in the Bill.

In the House of Commons on Tuesday, February 14,

Mr. R. Long asked the President of the Poor-law Board whether he proposed to re-appoint the Select Committee on the Poor Laws, with a view of further inquiry into the position and the grievances of Medical officers of Poor-law Unions.

Mr. Villiers replied in the negative. The Committee had before it the evidence taken in the course of two previous inquiries in that House, and came to the conclusion not to take further evidence.

It is clear that the Profession must exert the large amount of moral force they can unquestionably wield at the coming general election if the position of the union Medical officers is not to remain a disgrace to a civilised and wealthy nation. It is useless to expect anything from the present Parliament; but let it once be known that no candidate for borough or county, whatever be his politics, will receive the personal or collateral support of the local Medical Practitioners without a distinct pledge that the grievances of the union Medical officers shall receive at his hands the attention they demand, and that he will do his best to remedy them—and there will not only be a hope, but a certainty, that an active measure of reform will be carried by the next Parliament.

Mr. Vansittart asked the Secretary of State for India whether anything had been done to improve the sanitary state of Calcutta; if so, whether he had any objection to produce papers relating to the same; and whether it had been determined to relieve the European troops serving in India by the overland route; if so, whether any and what arrangements had been made for their transmission.

Sir C. Wood said, in reply to the first question, that a sanitary commission had been some time ago appointed, and that they had made a report on the subject to the Government of India. He, however, had as yet received no account of what had been done in consequence of that report. It was, he might add, the intention of the Government to send out the troops to India overland.

FROM ABROAD.—A HORSE-FLESH BANQUET—DISTRIBUTION OF PRIZES AT THE ACADÉMIE DES SCIENCES.

The grand "hippophagic banquet" has just been celebrated with great *éclât* at the Grand Hotel, Paris, under the patronage of the French Humane and Acclimatisation Societies. M. Quatrefages occupied the chair, and there were 130 guests present, a good 30 of these being members of the Medical Profession. In the face of the continued increase of the price of butchers' meat at Paris, these efforts of philanthropists to bring another variety of animal food within the scope of the poor man's purse are highly laudable. Of course, at this celebrated hotel all the resources of the culinary art could be drawn upon, and if palatable food could not be there produced from the material in question, it would be a hopeless task to seek to procure a general acceptance of horse-flesh as an article of diet by those whose means of preparing it are so limited. A chief point to be ascertained was the kind of soup it is capable of producing, this being an indispensable, and, indeed, the main, article in the dietary of the French lower classes. This was pronounced to be good; but M. Latour, who has, by perseverance, advanced himself to the position of a critical, and almost an epicurean, hippophagist, declares that he has tasted much better soup when this has been prepared for a smaller number of persons, and especially at snug little horse-flesh parties which he is in the habit of entertaining at his own house. The late M. Renault, indeed, at the celebrated Alfort dinner, made his guests the vehicle of exact experimentising, having soups prepared from horse and ox, in a manner precisely similar, placed before them in such a manner that they were not aware of which they had partaken until they had delivered their verdict. The horse won by a whole neck! At this banquet, where the cook had more scope, he evinced his power by producing boiled horse and cabbage and horse *à la mode*, which were pronounced perfect, and absolutely undistinguishable from beef similarly treated. But it seems that the more elaborate dishes, as the *hachis de cheval à la ménagère*, the *filet de cheval roti*, and the *paté de foie de cheval*, did not give the same amount of satisfaction as the simpler viands, possibly because the appetites of these hardy investigators had become by this time rather blunted. This is of little consequence, as these are not likely to be sought for by the poor, who, notwithstanding the eulogiums passed on the new food, will constitute the only hippophagists after the fashion has passed away. The banquet, upon the whole, was pronounced a splendid success, and the prefét of police has authorised the sale of horse-flesh, subject to the sanitary regulations which prevail in France with regard to the vending of flesh-food, and of which we stand so much in need in this country.

The Academy of Sciences made last week its annual distribution of prizes, and we may notice those of them which relate to Medicine. First, then, Prizes in Experimental Physiology have been awarded to three candidates—one of 1000 francs to M. Balbiani for his "Researches on the Constitution of the Germ prior to Fecundation;" a similar amount to M. Gerbe for his observations on the "Reproduc-

tion of the Colpodea;" and 500 francs to M. Sappey for his "Researches on the Structure of the Ovary, and especially the Seat and Number of the Ovules." An "honourable mention" is also decreed to M. Knoch, of St. Petersburg, for his researches on the *Bothriocephalus latus*, awaiting the completion of these. A prize would also have been certainly accorded to M. Leon Dufour for his great work on the "Anatomy of the Lepidoptera" had not the researches on which it is founded been already rewarded. This beautiful monograph will, however, be published in the *Memoires des Savants Etrangères* of the Academy. The Committee, with M. Claude Bernard as their reporter, preface the account of their award of the Montyon Prizes in Medicine and Surgery with the following remarks:—

"The Committee for these prizes receives and examines each year a large number of works and memoirs. Besides the services which these annual *concours* render to the progress of Medical science in stimulating by recompenses the zeal of labourers, they impart to the Committee itself a special interest and a species of instruction. It will, in fact, be understood that the choice of questions and subjects of the works transmitted each year to this *concours* being left free and spontaneous, the nature of these works themselves and the mode in which they treat of their subjects may, to a certain point, indicate the actual direction of Medical science and reflect its tendencies. Now, it is easy to perceive that the various portions of Medical science—physiology, pathology, and therapeutics—more isolated and separated in their origin, tend, in proportion as they augment and become developed, to come into closer approximation, so as to furnish mutual support in a common scientific conception. At the present time, more than at any other epoch, most of the pathological questions in human Medicine are treated by the light derived from comparative pathology and experiments made upon animals. The great majority of the works which the Committee is called upon to recompense this year present, in fact, this character; and the Committee congratulates itself upon this, as it is solely by means of analytical and experimental investigations that Medicine, the most difficult and complex of all the sciences, will become gradually extricated from the domain of empiricism, and brought within that of the experimental method which is the sole way common to all the Physical and Natural Sciences."

Three prizes, each of 2500 francs, are adjudged this year to M. Zenker for his investigations on Trichiniasis, to M. Marey for his work on the Medical Physiology of the Circulation, and to MM. Martin and Collineau for their memoir on Coxalgia. Additional recognitions, accompanied with 1000 francs each, are awarded to M. Ollivier for his Experimental and Clinical Researches on Saturnine Albuminuria, to M. Lemaitre for his on Atropine and Daturine, to M. Willemin for his experiments upon the Cutaneous Absorption of Water in Baths, to M. Lancereaux for his Anatomo-pathological Researches on Cerebral Thrombosis and Emboli, to M. Faure for his Experimental Researches on Fibrinous Coagula of the Heart, and to M. Grimaud for his works on Applied Hygiene. Other works deemed calling for simple honourable mention without recompense are M. Petrequin's memoir on the Treatment of Aneurism by Galvano-puncture, M. Abeille's treatise on Albuminuria and Glucosuria, M. Delioux's treatise on Dysentery, M. Courty's memoir on Organic Substitutions, M. Foley's memoir on Compressed Air, M. Millet's treatise on Laryngeal Diphtheritis, M. Jacquart's memoir on the value of the "Epactal Bone" as a character of race, and M. Schnepf's work on the Climate of Egypt. The Academy Prize of Medicine of 5000 francs is adjudged to M. Roussell for his History of Pelagra, a supplementary prize of 2000 francs being accorded to M. Cortallat for his work on the same subject.

While upon the subject of Academical prizes we may notice an action brought by M. Guillon against the Academy of Medicine in consequence of two of their awards. The Marquis d'Argenteuil instituted a valuable prize to be awarded every six years to the author of the greatest improvement in treating stricture of the urethra. In 1850, when M. Guillon was a candidate, M. Gerdy, the reporter, declared that the committee had not had time enough to sufficiently try the new procedures of M. Guillon. Again, in 1856, M. Langier, the then reporter, declared that no procedures or instruments which had been presented to the notice of preceding *concours* could compete. It is against these, what he considered contradictory decisions, that M. Guillon appealed. Moreover, he had another action in the matter of the Barbier Prize, the object of which is to recompense those who discover the means of curing a disease reputed incurable. M. Guillon was prevented submitting his claim for this prize by the decision that internal diseases, not Surgical affections, were contemplated by the testator. The Tribunal decided against M. Guillon with respect to both prizes, declaring that learned bodies should be allowed the free appreciation of the conditions necessary for a *concours*.

REPORT ON CHEAP WINE.—NO. XII.

(By our Special Empirical Commissioner.)

(Continued from page 151.)

Austrian Voeslauer Wine, Red and White—Mead or Metheglin —A Digression on Housewifery.

I was unwilling to put my notice of Mr. Schlumberger's very excellent Voeslau wines at the end of my last report, since they fully deserve a more prominent place. They also, as I believe, furnish an answer to a question which is sometimes put to me. It is all very well, it is said, to bring these cheap wines into notice, but the moment a public demand arises for them they will cease to be cheap, for the demand will be greater than the supply, and then prices will rise. Or else adulterations and dilutions will be perpetrated which will disgust the consumer, and so the public will be worse off than ever. To which it is replied, that even supposing the vineyards of France, and Greece, and Hungary were to fail—stimulated as their proprietors would be by the diffusion of greater taste and knowledge amongst the English—there is every probability that the Austrian vineyards at Voeslau would supply the deficiency. They belong to Mr. R. Schlumberger, who was one of the jurors of the International Exhibition, 1862, in London, and who is said to have devoted his life to the introduction of the best vines, the best vine culture, and wine making into his vineyards. Large quantities of these wines are said to be exported to Italy, the Danubian Principalities, Russia, etc., and it is my belief that they will meet with a steady sale in England so soon as they are sufficiently known. I am told that large quantities were taken in the Austrian frigate *Novara* in her cruise round the world, and that, after two and a half years in a great variety of climates, that part of it which was brought home was found greatly improved in flavour.

Of these wines, some are still, some sparkling. The subject of sparkling wines, and their use in medicine and diet, is serious enough to deserve a special article; and, as they do not come under the category of cheap wines, I must pass them by with the remark that the samples of Sparkling Voeslauer which I have tasted, and which range from 46s. to 64s. per dozen, will hold their own against any of the liquids called "champagne," of equal price; and that a man who does not want to give an extravagant price for "champagne," and who does desire the juice of the grape, and not of the rhubarb or gooseberry, will be well suited by Sparkling Voeslauer. It is really ridiculous to throw away money on a worthless liquid because it is called "Champagne," whilst a genuine wine may be had at less cost. The only way to check the fabricators of "champagne" will be to bring some other sparkling wines into vogue.

The Still Voeslauer wines are red and white; there is no complexity about them, and there are only three or four sorts of each.

The *Red Voeslauer*, the lowest quality, costs £15 per hogshead, in bond, or about 14s. 6d. per dozen, duty paid, but exclusive of bottles and bottling charges. It is 24s. per

dozen retail; but I need not repeat that the man who buys in *quantity* may save 25 per cent. It is a good stout, full-bodied, serviceable, and, I believe, economical wine, as its stoutness renders it more satisfying than most Bordeaux of equal price. There is no complaint of thinness, sourness, coldness, or poverty; it is a good sound wine, with just roughness enough to be clean.

The *Voeslauer Goldeck*, at £25 in bond, or 30s. per dozen retail, is a smoother, finer wine; whilst the *Goldeck Cabinet*, at £31 per hogshead in bond, or 27s. 10d. per dozen, minus bottles, or 42s. retail, is a much smoother, softer, more finished wine, which would be pronounced a "Burgundy," and would suit any roast meat at dinner, or might be sipped as an "after-dinner" wine.

What I have said of the red applies *mutatis mutandis* to the white. The *White Voeslauer* at 30s. is a good clean amber wine; very sound, not likely to offend John Bull by its acidity, and fit to appear at any dinner with fish and *entrées*, or at any evening party for young people *vice* Hambro' sherry, or at the family dinner in hot weather of economical persons, who think it bad economy to deny themselves the means of healthy nutrition. The white *Voeslauer Goldeck* at 36s. is a better wine, and the *Steinberg Cabinet* at 42s. fuller flavoured. Of course, large purchasers have the advantage of lower prices. The lower qualities possess *grapiness* (without too mueh perfume, without the muskiness of some light wines, which though agreeable in its place is not liked by every one at all times) with some vinosity; and some samples I have tasted of the higher kinds have a true Burgundiacal aroma. They would be ranked with Chablis, but are fuller. The agent for these wines is Mr. F. Andres, of 12, Mark-lane. I take the liberty of looking upon the occupations of human beings from a higher point of view than that of mere £ s. d. The man who makes two blades of corn grow where one grew before, or who introduees a new food or luxury, enlarges the field for the operation of the human mind, and helps forward the designs of Providence. If Mr. Schlumberger be ready to send us, as I am told, 1000 hogsheads of wine, let us think of him as a public benefactor, for it is quite as much to our interest to get good wine as it is that of the growers to sell it.

In the next place let me say a few words on that ancient liquor called *Meade*, *Meth*, or *Metheglin*. I do not want my readers to drink it, but some account of it may be a contribution to that part of anthropology which consists in the history of fermented liquors.

An American once asked me if the English knew a drink called *cider!* thinking it was peculiar to America! (He sent me, by the way, a cask of superb cider from New York, whieh, after a long voyage, turned out particularly well). Just so do I notice that Bence Jones's translation of Mulder's "Chemistry of Wine" says that "Honey wine or mead is prepared in Poland, Galicia, and some other parts (!!) from honey-water and ferment." Gracious heavens! is it come to this, that the drink of our Anglo-Saxon fathers, and of their British predecessors, which warmed them in fight and feast, and which they hoped to drink for ever in Hades out of their enemies' skulls;—the true wine of the English yeoman, shall be talked of as if it were peculiar to Poland, Galicia, and "some other parts" !!

Mead is one of the oldest drinks in the world. It forms one variety of the liquids classed together as *sicera* in the Vulgate, σἰκερα in the LXX. and Greek Testament, and under the name "strong drink" in the English Version. The Nazarites were forbidden to drink wine and "strong drink." Wine stands out by itself as the noblest of fermented liquors, as the highest gift of the kind to man, and as the type or symbol of the Divinest Influenees that ean be veiled under the Sacramental Elements. The "strong drink" or *sicera*, whence our word *sycer*, or *cider*, included every fermented liquor except grape-juice; such as palm wine, beer, cider, fruit wine, and mead.

Good mead is a liquid of very variable sweetness, according to the quantity of unfermented honey whieh may remain in it; if nicely made it is nearly dry, *i.e.*, not sweet. By age it aequires a remarkably luscious perfume, like that of Tokay. I have examined many specimens, *ex. gra.*:—

1. Mead sent me twenty years ago by a Medical friend in Hampshire. Most likely from having been boiled in an iron pot, it is so strongly impregnated with that metal that it has quite a chalybeate taste, and is undrinkable except to taste as a euriosity. Bottle after bottle has gone, as I have given it to some policeman or other person of West Saxon descent, who forgives the iron for the sake of the liquor. Carelessly corked, standing upright in my eellar for years, it is nearly dry, quite free from aeidity, sound as possible, and has alcoholic strength 20·5.

2. A specimen about five years old, vilely made, full of unfermented honey, also standing upright in a earelessly-corked bottle; very sweet; sp. gr. 1080; alcoholic strength 18.

3. A specimen from a Medical friend in Hampshire, made last year; sp. gr. 1020; alcoholic strength about 20; bright, clean, well fermented; strong tasting.

4. From a cottage on Poole Heath, made 1864; bad condition, actively fermenting, aeid, sweet and heady; sp. gr. 1050; alcoholic strength 23.

5. From a cottage in Holt forest, Dorsetshire, of 1864; clear and pleasant, not quite well fermented; sp. gr. 1027; alcoholic strength 24.

6. From a cottage on a heath near Cranborne, Dorsetshire; very clear, well fermented, and pleasant; too sweet for my palate, yet perfect as a specimen of a sweet fermented liquor, and very fragrant; sp. gr. 1050; alcoholic strength 22.

7. A magnificent specimen from an eminent tradesman at Christchurch, Hants, made in 1814, and consequently more than fifty years old; sp. gr. 1080; alcoholic strength 16. Marvellously soft, full flavoured, and fragrant; a little drop perfumes a glass so that it is diffieult to wash off.

Why, it may be asked, do I occupy your readers' time by deseanting on these barbarous liquors? Because they tell us two things.

In the first plaee, they set aside the notion that any large quantity of alcohol is necessary for the maintenance, or preservation, or development of a fermented liquor. When we think of these specimens of mead that have been literally lying about, without any eare, for periods varying from one to fifty years, and yet in perfect preservation;—and when I add to them two samples of *elder wine* which I received from the same gentleman that gave me the fifty-year old mead, one made in the year 1815 and one in 1818, each of low alcoholic strength, and yet perfectly preserved and marvellously nice, considering what they are—not to speak of cider from Ameriea tossing about for weeks in all weathers—when I add to these a specimen of Oxford ale that has been in my cellar for years, upright in bottle, alcoholie strength 19, we may well demand from the wine growers of Portugal, Spain, Sicily, and the Cape, that if they are to eontinue to supply the English market, they shall do upon scientific principles what the poor West Saxon peasants do by rule of thumb. Grape juice is but honey, and ferment, and water in a different shape; and what can be done with the one ought to be possible with the other. We ought to have firm and stable wines of the eountries above named, without the addition of brandy.

Secondly, it is worth while for the Medical philosopher to glance at the habits of a people, and at their luxuries, as evidences of their moral and social position. The cottager who ean brew a small stock of mead, and keep it for feast days, or friendly gatherings, cannot be very low in the scale of humanity. He has evidently a little surplus, a little fore-thought, and some notion of those snatches of rest and enjoyment which distinguish the labouring man from the slave or beast. But I suspect that the custom of making mead is, like other branches of housewifery, dying out amongst the West Saxon peasantry. When I was a boy, brought up in a part of the ancient Wessex, a drop of mead was offered on ealling at a better elass cottage. Now, it was with the utmost diffieulty that the messengers who were good enough to undertake the task, and who trudged long distances over a eountry less visited than usual by change, could collect a few driblets of the liquor. Bees are more scarce; cottagers, if they keep them, sell their honey, and buy beer; but in all these matters *housewifery*, or the cost of keeping house comfortably, is dying out. Homemade and homespun are displaced by manufactures (or machino-faetures) and shoddy. Formerly, *baker's* bread and *brewer's* beer were despised as unworthy to be set by the side of home made—*butcher's* meat, too, was distinguished, but as a thing of superior class from common meat, *i.e.*, pig meat—but the progress of events makes our whole population less housewifely, and more dependent on the shop. On this point Cobbett's "Cottage Eeonomy" deserves to be attentively studied. Young cottage girls had better brew or bake than do crochet. Cobbett says, with more than his usual elegance, "Give me, for a beautiful sight, a neat and smart woman heating her oven and setting in her bread! And if the bustle

does make the sign of labour glisten on her brow, where is the man that would not kiss that off rather than lick the plaster from the cheeks of a duchess?" We, as Medical men, may ask whether the woman who is accustomed to bake and brew, and who has a bottle or two of this fragrant honey wine to set before a guest, is not more likely to be self-dependent, able to nurse the sick, rear a family, and pay a humble Doctor's bill, than the woman who gets her cordials from the publican and her food from the shop, and who, when ill, goes straightway as a pauper to the parish or dispensary?

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF BATH.

The history of Bath is essentially Medical. It is based on the fame of the waters, around which the city has been built—their fame as remedies for mortal evils great and small. Whoever, therefore, would know Bath must know well all about its waters, why they were first rendered famous, why they are still famous, and on what their fame depends.

Connected with the discovery of the baths of Bath, legend, hard history, and harder science have many words to say. Legend travels through the air like a swift bird of fine plumage that now is here dazzling the eye with its simple beauty, and anon is gone cleaving its way in the invisible and leaving no track behind. History comes to us from and over the surface of the earth, toiling and toiling in packets and parcels, each labelled "with care," and filled too often, when opened, with broken bricks, singularly carved stone, or ancient pottery, not of much practical use in these days to any except the artist in clay, who is, and seems always to have been, busy at his wheel. Science, harder still, ascends to us from the waters under the earth, speculates as to the depth from which the currents rise, imagines gigantic subterrestrial furnaces, of which the mind can scarcely form a conception, in which the fluid is heated, and having taken the water as it flows out of earth, tears it to pieces and calculates its constituent parts.

All these phases in the history of the Bath waters have their interest, but the legendary is by far the most fascinating, haply because it is most imaginative; for we creatures of imagination love alway the wonderful beyond the actual, cling to it more closely in our heart of hearts, and build on it aspirations which cheer us when all else fails. Disbelieving, we are willing to believe, and laying down legend as unreliable, place it still within arm's length, and feel we would not like to lose it when the worst that may be said against it is said.

With regard to the legend—I may say the Medical legend of the Bath waters, for it is all connected with healing—there are many grim historians who dub it unreasonable, but who still, twisting according to their tastes, tell it reluctantly and with many apologies. I tell it neither reluctantly nor with apology; the legend is to my mind an exquisite little story, in which true and noble character is pourtrayed so simply, and a directing influence towards ultimate good is depicted so clearly that, whether fact or fiction prevail, I would not lose the narrative on any pretence, nor hesitate to record it in turn, according to my interpretation of it, as best I can, and in all its simplicity.

THE LEGEND HISTORY OF THE BATH WATERS.

To begin with the beginning, the reader must go back a long, long way in the marvellous past. He must stop only a century or two short of the siege of Troy, must imagine the Trojans still a race, but dispersed and conquered as the Poles are now, and must, for the moment, transport himself to Italy, then a young and rude country. The start will now be fair and the journey pleasant.

At the time named, then, there resided in Italy many fugitives—representatives of dismantled Troy,—and among them one Ascanius, a direct and immediate descendant of Eneas himself. The daughter of Ascanius married one Sylvius, and in due time was presumed to have conceived. Grandfather Ascanius, very proud of his origin, and anxious for an ancestral line in continuance, wished to know at once whether a male or female child was to come, and what was to be the fate of the expected stranger. To determine this point, therefore, he called together all his magicians, and bade them answer his inquiries. The magicians consulted and decided. They told their master the child to be born would be a boy, but, sad forecast! they added, he would cause the deaths both of his mother and father, would then suffer many troubles, but would ultimately become extremely wise and powerful, attain great glory, and be the founder of a new kingdom. Time went on, and a boy was born, but, in giving him birth, his mother died, and the first part of the prediction was thus fulfilled. The boy, placed in the care of a nurse, was named Brutus; he grew up a fine boy, and beloved. When he was fifteen he went out to the forest one day to hunt, and, in discharging a shaft, accidentally shot his father Sylvius, who died on the field. Thus the second part of the prediction came to pass.

The accident made known, poor Brutus, by virtue of the inexorable laws then in force, was expelled the Italian land as a parricide. He fled into Greece, and there, never resting, set himself vigorously to work in order to release the posterity of fair Helen from slavery. He raised an insurrection, fought Pandrasus, the King of Greece, on his own soil, beat him, made him captive, and took his daughter Imogen to wife. Brutus, however, was not a tyrant, and had no ambition to reign over Greeks; and so, after making Pandrasus liberate, with many presents, all the Trojan captives, he restored the crown to the defeated King, and with his wife and followers, entered on board a large ship, and set sail on adventure. After sailing three days and three nights, the adventurers came to anchor at an island called Laogecia, where Gerion, the first minister of Brutus, landed with a few men to make exploration. Gerion returned to report that not a living soul was to be found on the island, but that there existed upon it, in solemn and magnificent silence, a temple, with an oracle, dedicated to Diana. So soon as he heard this news, Brutus alone left his ship, and, proceeding to the temple, invoked the goddess to tell him his fate. Quickly, as he reclined on the green sward, sleep crept over him; and in a dream the oracular voice, in softest music, told him that if he proceeded beyond Gaul he would find in the Western Ocean a new land—an island rich in beauty and fertility—an island on which he would build a second Troy, and establish an empire the domain of which would know no limit, which time should never destroy, nor space confine.

On the following day Brutus and his followers re-started on their voyage; they passed the pillars of Hercules, and after a long journey landed in Aquitaine. There the King of the country—one Goffar or Goffarius—tried to make prisoners of the Trojan band, but the design failed; a battle occurred near to what is now called Tours, and Goffar was overthrown. Again Brutus and his band embarked, and making onward in their destined course came to Albion, where they landed at Totnes.

Wandering in the Island the exiles explored the banks of the Thames, and finding a favourable spot they rested and built a city which they named New Troy, and Brutus was made King. Over his kingdom thus founded Brutus reigned twenty-four years, and then full of days and honour died; so the last part of his horoscope was also fulfilled.

The King at his death left three sons all born to him by Imogen, the daughter of the Royal Greek Pandrasus; the sons were named respectively Locrin, Albanact, and Cawder. Locrin, the eldest, succeeded to the throne and reigned ten years; he was followed by his son, and from him a line of seven kings in direct succession. The eighth King of the line was named Liel, and was of great power; it is assumed that he was a contemporary of Solomon the Wise, and that while the hammers were ringing on the great temple of the Jews, Liel was the chief monarch in the White Island of the Western sea. Liel dying left his crown to Hudibras, his son, also a mighty potentate, very much loved for his virtues and feared for his justice. It was in this reign the curative qualities of the waters of Bath were discovered.

King Hudibras had one son, the Prince Bladud, who, young, handsome, generous, and just, was naturally the pride and pet of the court, and was very happy. While he was still a

youth, there came, with her retinue, on a visit to King Hudibras, from the court of the King of Aquitaine, a beautiful damsel, the Princess Tassel-Wassel. It was but for the Prince Bladud and the Princess Tassel-Wassel to meet to be enamoured of each other; and everybody said how fortunate their highnesses were, and what a glorious match theirs would be. Did everybody say so? No; unfortunately, that is not quite true. There was one man in the train of the Princess who did not think so, if he said so; for he, too, loved the Princess, and had reason to hope to win her. A noble by birth, this man had much influence, and he used it effectually. To oppose Prince Bladud directly were impossible, so he 'bided his time, and did nothing but watch and wait. At length he one day discovered that poor Prince Bladud had a spot of leprosy on his skin; and now it was time to act promptly. In those days the very name of leper was held in abhorrence; the leper was cast out of society as venomous, and his own friends forsook him. As quickly, therefore, as the rumour was set afloat that Prince Bladud was a leper the courtiers, one and all, claimed that his rank should in no way interfere, but that he should be exiled from his father's house.

On examination by the Physicians, the rumour was confirmed, and miserable Bladud was indeed pronounced a leper. He would infect the King, the Queen, the Princess, the court altogether; and so he must go. It was very hard for the King to say it, but he did. The court met in full assembly, and Bladud, in tears, bent his farewell. On his own part, he asked for no remission of his sentence, but held it to be a solemn duty to leave his home and be an outcast; but ere he left the Queen, his mother, not touching his body, poured into his hand, from a goblet, a ring: "That," said she, as she wept and still hoped, "keep very safely; if fate bring thee back well and cleansed of leprosy, how much soever thou art changed, I shall know thee, my dear son, by that token."

It is impossible to describe the emotions that were exhibited, and if not exhibited, felt, in the court when the Prince departed. The King, as was the custom then, turned his face three days to a blank wall, took no food, saw no dancing, and refused to let his royal bard even string the harp for the evening song: the bard himself composed what we now should call a dirge: the Queen and her train went into black, mourned for the living as for the dead, and to kill time and care, following the pattern of Andromache, took to the loom and spindle, and wove the battles of their ancestors in rich designs: the noble who had caused all this misery first rejoiced at the removal of his rival, and then sorrowed: while the Princess Tassel Wassel, unable to meet the blow, held on in silent grief, hating with all her heart the false suitor who craved her hand, and determining that when her years for waiting were past she would dedicate herself as a last resource to vestal rites. In course of time the external signs of sorrow declined, but the court of Lord Hudibras was no longer the same; their loss sat on the hearts of King and his Queen, and their smiles only gilded their despair. But we must return to the Prince, and follow him, poor leper, in his weary way.

Bladud, with his little wallet of cake and grout, and his dear mother's pledge, set forth on foot over the plains, he knew not whither, and cared little. For five days and nights he wandered on, and then, pining and drooping, he wished to die. In his despair he met a shepherd, who spoke kindly, asked him to eat, and gave him a bed in his mud hut. Next morning the shepherd, seeing he had a lad of good parts before him, but never dreaming of his rank, entrusted his sheep to the care of Bladud, and himself went to the forest to cut wood. This was continued for several days, and at last Bladud was installed as the servant of the shepherd, and much to his delight. Here, not far from his father's palace, he might, he hoped, pass in disguise until he was cured; and here he could now and then gather from the solitary traveller whom he had entertained with plain cheer and a merry song, something about the court and the King and the Queen and the Princess. Alas! the hopes were vain. Not long had the Prince held office as the servant of the shepherd when, to his horror, he discovered that his master was becoming affected with leprosy. Wretch that he was, not to have known that a leper is a curse to friend and foe alike! He would have wished to have told the good man of his offence, but his leprous tongue clave to his mouth, and so, leaving no sign or word, he fled.

He fled until he reached what is now called Keynsham, and there, as the lowest occupation he could hold, he took charge of swine. Four hundred swine were placed under his care by a swineherd named Norton; now he was free of communication from all human kind, and harm he could not do more. He was again deceived; not many weeks had he tended his herd when behold! the swine showed leprosy. In those days it was fully believed that swine could take the diseases of men, and Bladud had no doubt that again he was the offender. What should he do? He determined to try change of scene, and to take his herd over the Avon to some plains beyond where grasses and acorns were more abundant; there, perhaps, they might recover before his master should discover him. The Prince accordingly drove his swine over the Avon at what has since been called Swinesford, and having accomplished this difficult feat halted for the night. To his surprise, the next morning, as he was praying and adoring the rising sun according to his pious wont, his swine were all taken in commotion, sniffing and snorting as though consulting among themselves, and seeming to care not an iota for him. At last, to his still greater surprise, they set off in a body in one direction and at full run. The swine ran and the Prince ran; the swine snorted and the Prince shouted, but neither stopped until they came to, what is now called, Bath. There they all stopped very tired, the Prince angry and the swine apparently content.

On the following day, Bladud, who was an observant youth, noticed that a terribly leprous sow was moving about with her litter as if in search of some particular spot. At last she came to a pool in which water was issuing from the earth, and no sooner was she there than she plunged into the water with all her little ones, and wallowed for a long time with infinite satisfaction. As for the Prince, he merely noticed on the occasion that the water was warm.

Next, he saw that the sow at an early hour every morning returned to the pool with her young, and wallowed as before; and surely, said he, Nature must have given her a reason for going there; he therefore watched more closely, and discovered that under the process the animal and all her young were cured of the leprosy. To test the merits of the cure were a task speedily carried out: Prince Bladud drove daily all his sickly animals into the pool; he saw them, to his great joy, recover; then he himself bathed, and was soon free of spot or taint. His joy hereupon knew no bounds: to hasten back to his friend the shepherd, and bring him to the pool to be cured, was the work of a few weeks, and to restore to the swineherd his animals in sound condition was not less agreeable and easy.

But the wheel of fortune having once again turned in favour of Prince Bladud, went, as it usually does, turning on his side so fast that at last it gained a momentum which surpassed ordinary calculation. The Prince soon gained repute far and wide as a healer of lepers; outcasts from all parts rushed to him to be cured, and the name of Swineswick was given to his place. At length it became necessary to build a town, and Bladud was, of course, made first man, or Lud; and so he progressed until he promised to become, in his own province, as great as Lord Hudibras himself.

The court of Hudibras had meanwhile remained in the half desolate state in which we left it, for seven years; the King and Queen still mourned, the bard had failed to re-string his harp, and thumbed on three cords only; the ambitious noble had been sent to his own country to die broken-hearted on his journey; and the Princess, who would never return to Aquitaine, though still not more than twenty years old, was staid, womanly, and sad. Except during the time when, with due ceremony, the festival to Pan was held, mirth was rarely heard; but there was this that compensated for mirth, the King was always good and just, and the people asked but one question—Who shall succeed Lord Hudibras, and reign as he reigns? And every one answered with a heavy sigh—Who, indeed?

One fine night in the autumn the court had met before sunset in a small amphitheatre without the palace, in which in early days their majesties had seen Greek dramas enacted, and had themselves taken part in the sport. They had met now to sup, the King and Queen being in the places of honour, the Princess at their feet, and the courtiers around. For reasons that none could assign, the sadness that usually prevailed passed away; the King sent about the wine-cup to his friends, and conversation flowed until at a distance it was as a soft murmuring hum of Æolian sweetness. Suddenly, descending the steps of the amphitheatre, a group of boys and girls appeared. They bore in their hands wreaths of flowers, which they strewed before the dais, and then with one voice exclaimed, "Happy be thou, great lord and king! Timæus the Bard hath found his harp in the temple new strung and

attuned. Blest be Diana!" As they spoke they dispersed like shadows, and lo! on the upper steps of the raised mound stood the Bard himself, his harp in his hand. The rays of the setting sun clothed him in golden spray, and his face shone with joy that words cannot express. Straightway athwart the cords he drew his hand, and the sound that the instrument uttered was hardly mortal. He repeated the act three times, and then, while yet the whole court was motionless with wonder, and the very birds, it is whispered, ceased to twitter, he pointed into the distant space eastward, as though he descried something that to none other was visible, and, as if enchanted, sang,—

"Though fast sinks the sun to his glorious rest,
Let hope gild our brow and faith fill our breast.
Make merry! make merry! and spoil not the feast,
For he sinks in the west but to rise in the east.

And lo! as he goeth 'mid shades of the night
He knows that there cometh a brother of light.
Make welcome! make welcome! and keep up the feast,
For he who fled westward now comes from the east."

As the sounds died away, all rose and followed the eyes of the bard. Soon they saw a little cloud moving in the distance as towards themselves, and then it was discerned that over the plain men were advancing. Nearer and nearer they came, so that their voices were heard. A little longer, and in the presence of King Hudibras was another king with his retinue of great state and power. In simple words, Prince Bladud once more stood before his royal parents, but none knew him except Timæus the bard and the Princess, who leaned on him, and could not speak. Removing his helmet, the Prince approached the Queen, and, bending his knee, presented the ring that she had given him in a chalice of wine; then she, and the King, and the court, knew who it was that had returned, and had the sun actually re-arisen that night, he would not have caused greater wonder or more life.

The legend must soon close. The reader will feel assured that the Prince and Princess were married in due time; but he requires to be told a little more. The Prince, in order to gain wisdom at its prime source, travelled, refusing state and equipage, to Athens as a student. Returning home skilled in many useful arts, he ascended the throne on the death of his father, and reigned for twenty years. Cultivating the arts of peace only, he invited to his court all sorts of cunning and able workmen, and made various engines of singular power. At last he attempted to construct a flying machine, and succeeded so far as to make several voyages through the air. In one of these adventures he was lost or destroyed; some say that in his flight he was absorbed by the sun and was deified; others vulgarly affirm that he fell, broke his neck, and found his grave at a temple near a town afterwards named Solsbury. Anyway, in the course of his reign King Bladud proved himself very wise, very good, and generous to every one who had aided him. He gave Norton the swineherd an estate, from which sprang the place known as Hog's-Norton, and on the town of the waters he conferred special privileges. There he built proper baths or pools, a noble palace, and houses of state for his ministers. It is also said that he named the spot Caerbren; but it is more likely that having discovered the healing waters while offering his devotions to the god of day, he called them "the waters of the sun," whence afterwards the beautiful name long held to designate them and the town—Aquæ Solis.

THE COMMON HISTORY OF BATH AND OF ITS WATERS.

The belief in the legendary history of Bath, differing only in details, and founded on Prince Bladud, was accepted with little hesitation and little qualification until the present century. In guide-books and the local histories a hundred years old the legend is substantially given as matter of fact, and there can be no doubt that Leland, who travelled as Antiquary Royal in the reign of Henry the Eighth, accepted it with all his heart. The name of Bladud was thus retained as an ancient and respectable designation, and eighty years ago Dr. Falconer, then *the* Physician of Bath, resided in Bladud's-buildings. The tradition began to lose ground owing to a popular comedian turning the story into caricature; and in the first year or two of this century it was, *pro formâ*, excommunicated by an historian of repute, named Warner.

Unfortunately for the antiquarian scholar, the facts on which, exclusive of tradition, he would build a history of Bath are very few; and, indeed, I find little that is more reliable than the tradition. Leland heard or read that baths were first erected at Caer Baden, or Bath, by Julius Cæsar, but he repudiates the notion, and leaves the story of the old British origin unmolested, thinking, probably, that it was more natural for the warm springs to be known to the ancient native inhabitants of western Britain than for the Romans to have made the exclusive discovery of so remarkable a phenomenon. However, the first we really read of Bath belongs to the Roman period, and is from a writer named Solinus, who doubtless had visited the place, and who was well acquainted with the fountains or baths. Solinus probably lived in the reign of Titus Vespasian, but the springs had evidently been resorted to long before his time, since he found a town well constructed, with many architectural embellishments and a famous temple dedicated to Minerva. The fountains at that period also flowed into sumptuous baths, and the better classes resorted to them after the luxurious manner of wealthy Roman people.

The foundation of the city has been attributed to the Emperor Claudius during his short visit to Albion in the first century of the Christian era. But this statement, it must be admitted, is rather inferred than proved. Claudius visited Britain to second the labours of his general Plautius, who, landing in the year 43, defeated Caractacus and conquered a large portion of the western part of the island. Claudius marched triumphantly through the western district, and, it is assumed, became acquainted with the waters and built a town, or more correctly, ordered a town to be built near them. On this hypothesis, therefore, which is stoutly maintained, if not invented, by Warner, Bath came into existence in the year 44 of this era. Suffice it that previous to the close of the first half of the first century there was a Roman settlement or station at Caer Baden, Aquæ Solis, or, as we now call it, Bath. There is tolerable evidence that Agricola about the year 61 dedicated there a temple to Minerva, and that thirty years later Adrian had erected an armoury there at which the arms of the Roman legions were fabricated. Early, too, during the Roman occupation baths were formed such as were common in Rome, baths with the modern appliances of the hot-air bath and with more beauty. Four roads also were laid down, one leading to Cirencester, a second to Westbury, a third to Ilchester, and a fourth to Amesbury. Further, there was a large population governed by the laws of imperial Rome, and strong ramparts and fortifications of earthwork and stone around the town. It is probable that until the Romans began to leave Britain Bath continued to be a place of much importance, for in the year 208 Geta, the son of Septimus Severus, lived there in great state as a lieutenant or deputy ruler.

In the history of nations, no greater calamity is recorded than the cessation of Roman dominion in this island; every town, every man, felt the loss of that strong and wise government. In Rome itself, Roman rule was spoiled by the luxuries of wealth and power; in the provinces the law made itself known, and no luxury tainted or corrupted it; hence, when the Roman governors forsook their petty thrones there was political chaos, none to rule by right, and none to rule well. Bath, like other towns, suffered; when the last legions left, the old Britons who had been so long dispossessed resumed the right of government, and, under the famous King Arthur, they kept their foes the Saxons at bay for many years. At last Cuthween won the place from its native lords, and in the year 600 Caer Baden was a Saxon town, bearing the name of Akmanchester, or the city of sick people, the place being clearly at this time a centre whither the sick resorted for health.

In 676 we find the church of the Christian faith introduced, under the reign of Osric. Then on the site of the temple of Minerva, the abbey church of St. Peter and Paul raised its head, and hooded nuns took the places of the vestal servitors of the heathen goddess; later, the nuns were excluded, and secular canons were put in their stead; and, again, the canons had to give way to a levy of Benedictine monks, who remained in place and power until the monastic system was dissolved under the Tudor supremacy.

After the landing of the Conqueror, Bath easily fell under Norman rule. The Saxon kings had honoured it by repeated visits, and the Norman sovereigns were not backward to do the same; the result was that a bath, at a very early date, was set apart for the sovereign, and took the name of the king's bath.

Under the protection of John de Villula, Bishop of Bath and Wells, who flourished in the first part of the twelfth century, the state and reputation of the baths of Bath, or Bathes Ayde, as the place was also called, were transmitted downwards. In 1138, the then bishop built a leper house, and opened a leper's bath, which house, according to Dr. Falconer, remained until 1773. This Hospital, together with

all the baths, were held by the monks until the Reformation. My friend Dr. Falconer, in an excellent little work on the "Baths of Bath," gives us, from old Leland, a look at the town just prior to the dissolution of the abbey, and also tells us how the baths were disposed of when the dissolution had been effected:—

"There be 2 Springs of whote Wather in the West South West Part of the Towne. Wherof the bigger is caullid the *Crosse Bath*, bycause it hath a Cross erectid in the midle of it. This *Bath* is much frequentid of People diseasid with Lepre, Pokkes, Scabbes, and great Aches, and is temperate and pleasant, having a 11 or 12 Arches of Stone in the sides for men to stonde under y^{n} tyme of Reyne. Many be holp by this *Bathe* from Scabbes and Aches.

"The other *Bathe* is a 2 hunderith Foote of, and is lesse in cumpace withyn the Waulle then the other, having but 7 Arches y^{n} the Waulle. This is caullid the *Hote Bathe;* for at cumming into it, Men think that it wold scald the Flesch at the first, but after that the Flesch y^{e} warmid it is more tolerable and pleasaunt.

"Both these *Bathes* be in the midle of a lite streat, and joine to *St. John's Hospitale;* so that it may be thought that *Reginalde*, bishop of *Bathe*, made this Hospitale nere these 2 commune *Bathes* to socour poore people resorting to them.

"The *Kinges Bathe* is very faire and large, standing almost in the midle of the Toune, and at the West End of the Cathedrale Chirch.

"The area that this *Bathe* is y^{n} is cumpassid with an high Stone Waulle.

"The Brimmes of this *Bath* hath a litle walle cumpasing them, and in this Waul be a 32 Arches for Men and Women to stand separately y^{n}. To this *Bath* do Gentilmen resort.

"Ther goith a sluse out of this *Bath*, and servid in Tymes with Water derivid out of it 2 Places in *Bath* Priorie usid for *Bathes:* els voide; for in them be no springes.

"The Colour of the Water of the Baynes is as it were a depe blew Se Water, and rikith like a sething Potte continually, having sumwhat a sulphureus and somewhat a pleasant savor.

"The Water that rennith from the 2 smaul *Bathes* goit by a Dike into *Avon*, by West bynethe the Bridge.

"The Water that goith from the *Kinges Bath* turnith a Mylle, and after goith into *Avon* above *Bath*-bridge.

"In all the 3 *Bathes* a man may evidently se how the Water burbelith up from the Springes."(a)

"In 1542, Henry VIII., granted the 'late monastery or priory of Bath,' with all the property appertaining to it, to Humphrey Colles and his heirs: Colles disposed of it to Matthew Colthurst, whose son, Edmund Colthurst, gave the Abbey and a portion of the land adjoining it, to the Mayor and citizens of Bath; while the Abbey House and remainder of the property he sold to Fulk Morley in 1569, from whom it descended to the Duke of Kingston, and from him to the late and present Earl Manvers, who thus owns the Kingston or Old Roman Baths erected on the spot once occupied by the Abbey House. The King's, Cross, and Hot Baths appear to have been conveyed with the Abbey to the Mayor and citizens of Bath."

In the sixteenth century the celebrity of Bath and its waters declined. Towards the close of the century the mayor and citizens received from Queen Elizabeth a new charter of possession for the baths, and soon afterwards they built, or rather rebuilt two baths, known as the Hot and the Cross Baths. Later, in 1615, a Mr. Bellott, taking water from the King's bath, built a new bath, which took the name of the Queen's Bath, the wife of James I. having resorted to it. For nearly a century matters remained little changed. Bath was an important city, but not the Bath that it was to be—the Bath of fashion and beauty and wealth and wit, and, shall we say, wine? Yes, wine too. For these wonders it was forced to wait until 1704, in which year, long struggling for life, modern Bath was born. What it waited for is absurd: it was not for fresh air, not for curative waters, not for fine scenery—no, not for learned Doctors either, but for a pump-room. When Bath got a pump-room, it became Bath.

New Medical Knight.—Whitehall, February 11.—The Queen has been pleased to direct letters patent to be passed under the Great Seal granting the dignity of a Knight of the United Kingdom of Great Britain and Ireland unto Alexander Taylor, Esq., Doctor of Medicine.—From the *London Gazette*, Tuesday, February 14.

THE HUNTERIAN ORATION AT THE ROYAL COLLEGE OF SURGEONS.

February 14, 1865.

The biennial oration in honour of John Hunter was this year delivered by Professor Partridge, F.R.S., of King's College. There was, as usual, a fair muster of the Council of the College and of other Professional magnates. Amongst the orator's non-Professional hearers we observed the Chancellor of the Exchequer. The following is a condensed report of Professor Partridge's oration:—

Mr. President and Gentlemen,—More than half a century has elapsed since this Lectureship was founded; and addresses in connection with this subject have been delivered by no less than forty-one orators. The difficulty, however, in preparing a lecture of this kind arises not so much from the scarcity of material as in making a judicious selection from the abundance of matter.

John Hunter was born in the year 1728, and became anatomical assistant to his brother William. Although his early educational advantages were few, yet his Professional advantages were unusually great. He became the pupil of Cheselden and Pott, and extended his researches into comparative anatomy. He made astonishing progress; but his health being impaired by intense study, he entered the army in 1760 as Staff-Surgeon, and served at Belleisle and in Portugal. On his return to London, he pursued his inquiries into comparative anatomy, and erected a menagerie for that purpose at Brompton; he also gave lectures to his private class. In 1768, when he was forty years of age, he was elected one of the Surgeons of St. George's Hospital. His income arising from practice was not large; for he never made £1000 a-year until he was fifty. His genius was illimitable. He had intense application and a vivid imagination; but, like most men of genius, he was in advance of his generation. In disposition he was kind-hearted and liberal. Although, perhaps, his manners were somewhat rough, yet we may truly say of him, in the words of the Spanish proverb, "Better one diamond with a flaw than a thousand pebbles." He had a great taste for pictures, and in his letters to Jenner frequently alluded to paintings he had purchased. He died in the year 1793. In the days of Hunter there were very few facilities for the study of human or comparative anatomy, and the difficulty in obtaining bodies for dissection continued up to the passing of the Anatomical Act in 1858. In order to prosecute his labours in connection with comparative anatomy, he used to purchase wild animals, and when not required by himself lease them out to showmen.

Scientific Surgery dates from the labours of John Hunter, and since his time it has made more rapid advances than during any corresponding period. In aneurism, for instance, much has been done, viz., ligature on the distal side, compression, position or flexion (introduced by Mr. Ernest Hart), and manipulation. The failure of the early cases of compression was mainly owing to the instruments employed; but Ireland claims, and is fairly entitled to, the first rank for having introduced into modern Surgery the practice of treating cases of aneurism by compression. Hunter concluded that gonorrhœa and syphilis resulted from one and the same poison; but Ricord, by his experiments, has proved, beyond the slightest doubt, that the gonorrhœal discharge, when inoculated on the skin, never produces a chancre. While on this subject, I may mention that Government has lately appointed a Commission to institute certain inquiries into the venereal disease, more especially with regard to its effect upon the naval and military services of this country. This is decidedly a step in the right direction, for the condition of our soldiers and sailors in this respect contrasts most unfavourably with the condition of those in the service of Continental nations; and in order to remedy the evil, we must either admit a larger number of married men into the army, and allow their wives to accompany them, or else bring prostitution itself more under the control of the State.

Death has been busy amongst our ranks during the past year. The Profession and the College of Surgeons sustained a great loss in the death of Mr. Green; and this was felt the more, as it happened so soon after that of Sir Benjamin Brodie. Green was a pupil of Cline, and became Surgeon to St. Thomas's Hospital on Cline's death. In 1834, Coleridge died, leaving to Green the charge of his literary remains. Green

was twice President of this College, and twice delivered the Hunterian Oration. Though distinguished as a Surgeon, he left no important Professional work behind him; but he will best be known to posterity by his System of Philosophy, now in course of publication; it is entitled "Spiritual Philosophy," and will consist of two volumes, one on general, and the other on religious philosophy. As an illustration of Green's assiduity and application, I may mention that when he was sixty years of age he commenced the study of Hebrew, finding a knowledge of that language necessary to the prosecution of his work. Mr. Green is not the only member of our Profession who has devoted himself to general literature; and, in the words of a well-known writer, I may remark, "How useful, how grateful a resource it is to turn from perplexed thoughts to classic lore; it is the first impulse of instinct to acquire one's native language, and not the less is it the impulse of reason to acquire the languages of the day." The Profession has also met with another loss in the death of Mr. Edmund Belfour, who was for fifty-four years the indefatigable secretary of this College, and who always managed its affairs with good sense, temper, and discretion.

Since the last oration a marble statue of John Hunter, by Weekes, has been placed in the Museum. Mr. Weekes has chosen the attitude of the painter in the well-known picture of Hunter by Sir Joshua Reynolds, rather than attempt an original attitude. In this I think he has done wisely; for the picture will not last many years longer, and the attitude in the painting is the one best known to us. After the discovery of Hunter's remains in the place where they had lain so long, permission was obtained to inter them in Westminster Abbey, where they now lie, between the resting-places of Wordsworth and Ben Jonson.

Hunter's collection was purchased by Government for the sum of £15,000; it was offered first to the Royal Society, then to the College of Physicians, and was afterwards accepted by the Corporation of Surgeons. The catalogue of the Museum is now nearly completed; its compilation has extended over a period of thirty-four years. It is proposed to form a new osteological series, from skeletons now in the possession of the College; and for this two things are necessary—firstly, the appointment of an additional assistant; and secondly, further space, in the shape of new show-cases. The histological collection has undergone a complete examination; some specimens that were too old have been discarded; while several new ones have been added; and I should like to ask for more assistance from the Profession generally in adding new specimens to this series, which now forms the finest Museum of Anatomy and Surgery in the world.

REVIEWS.

A Manual of Materia Medica and Therapeutics; including the Preparations of the British Pharmacopœia, etc. By J. Forbes Royle, M.D., F.R.S., and Frederick W. Headland, M.D., B.A., F.L.S. Fourth Edition. Pp. 776. Churchill and Sons. 1865.

Manual of the Medicinal Preparations of Iron; including their Preparation, Chemistry, Physiological Action, and Therapeutical Use. By Harry Napier Draper, F.C.S. Pp. 131. Fannin and Co. 1864.

The preface to the fourth edition of Royle and Headland's Materia Medica states that the book has been remodelled throughout on the basis of the British Pharmacopœia; that it contains descriptions of all the medicines contained in that Pharmacopœia, and explanations of its formulæ; that it retains descriptions of the medicines and preparations of the London Pharmacopœia of 1851, and that it points out the differences between the two Pharmacopœias, and corrects the mistakes of the British; that it also furnishes notices of all non-officinal remedies of value, whether of established reputation or of recent introduction.

It is quite unnecessary to attempt a lengthened criticism of a work which has done such good service and stood such a lengthened test as Royle and Headland. The present edition, modified according to the announcement of the preface, is in no whit inferior to its predecessors. On the whole, Dr. Headland seems to have fulfilled his task most laboriously and conscientiously. For its size the book is undoubtedly the most complete and the fullest work on Materia Medica which we have seen since the publication of the British Pharmacopœia. It is much fuller if not so original as the work of Dr. Garrod, which, it will be remembered, appeared under the modest title of "Essentials."

In the chemical and botanical descriptions the work of Drs. Royle and Headland leaves little to be desired; the chemistry is generally most accurate, and quite up to the latest standard. The botanical portion is rendered more useful and comprehensible by a number of beautifully-finished wood engravings. With regard, however, to the therapeutical portion of the work, we think that sufficient prominence has scarcely been given to it. For instance, if we take so important an article as chloroform, its action and therapeutical uses are summed up in about seventeen lines; nothing is said as to the mode in which it produces its physiological effects, the symptoms of danger arising from its use, or the precautions which should be observed in administering it, although three pages are devoted to an accurate account of its chemistry, preparation, and tests. Again, if we look for information on the subject of stimulants, which occupies so prominent a position in modern therapeutics, we find that they are treated with the same brevity and meagreness, and the article on alcohol and its preparations by no means supplies the deficiency. We should not have ventured on these criticisms had not the book been called a Manual of Materia Medica and Therapeutics. The former it is, and a most excellent one; to the latter part of its title we do not think it can assert an equal claim. We are quite aware that these remarks would apply with equal justice to most works of the same class, but that a fault is general does not make it less in any particular instance; and when we remember that no human being would ever have studied Materia Medica had it not been for the sake of therapeutics, that the whole artificial collection of knowledge which goes under the name of Materia Medica would be a very dry and utterly useless farrago were it not for its subserviency to the science of healing, which alone gives it coherence and utility, we do think that, as a rule, architects of books on "Materia Medica and Therapeutics" have justly incurred the charge of paying more attention to the scaffolding than to the edifice.

We have, in addition, three small criticisms to offer before leaving this work. They are not important ones, and have only occurred to us in a cursory perusal. The first is, that the old symbols are retained for the new Pharmacopœia weights—a mistake, we think, tending to make pharmaceutists and prescribers forget the important difference between the apothecaries' and avoirdupois ounce. The second is in reference to the direction given to examine Bismuthum Album for arsenic by Marsh's test. Experience has shown that this test is inapplicable—in fact, that the presence of the trisnitrate interferes completely with the process. The third is the use of such a phrase as "the lining membrane of the *aërial* passages," which seems, to say the least, a somewhat airy flight in the way of scientific phraseology. Although, however, like every other book containing such a mass of information, sharp criticism may detect here and there a slight blemish, we can conscientiously state that this edition of Forbes and Royle is one of the best, if not the best, handbook of Materia Medica that can be given to the student.

Mr. Draper's "Manual of the Medicinal Preparations of Iron" is evidently the composition of a chemist rather than of a Physician. In its way, however, it is excellent. It gives a description of between forty and fifty chemical preparations in which iron is the most important, or at least one of the principal ingredients. The Practitioner of Medicine cannot but be obliged by receiving in a small compass and readable form information which enables him to vary in so many ways—to suit every variety of stomach, taste, and fancy—the administration of one of the most important medicines in the Materia Medica. We know that it may be said that some of the preparations are not wanted, that they are the mere luxuries of prescribing, and that everything which iron will accomplish may be done with two or three of the old preparations. We are by no means so sure of the truth of the latter allegation. Such preparations as the syrup of the iodide, the syrup of the pyrophosphate, the ammonio-citrate, and the potassio-tartrate, seem to suit peculiarly certain cases, and cannot be substituted for each other. We utterly repudiate the pseudo-chemistry which would prescribe an albuminate of soda and iron because albumen, soda, and iron are contained in the blood; or a phosphate because phosphorus exists in nervous matter; but we are clinically certain that in particular cases some preparations of iron and other minerals agree well, and answer our expectations; whilst others unquestionably do the contrary. And it is a

self-evident truism that he will be the most successful Physician who, in addition to a profound acquaintance with disease, has acquired the most varied and minute knowledge of the means by which it may be combatted.

The Diseases of the Ear; their Diagnosis and Treatment. Translated from the German of Dr. Anton Von Troeltsch, and Edited by D. B. St. John Roosa, M.D., Assistant-Surgeon to the New York Eye Infirmary. Illustrated with wood engravings. New York. 1864.

This volume in the German edition was reviewed in our pages for July 11, 1863, and we need not, therefore, revert to it at length. The translation is fairly, although not elegantly executed, and a good deal of interesting matter in the form of cases is added by the American editor; one of these we briefly extract, since it adds another to the instances on record of exfoliation of the labyrinth without cerebral lesion:—"W. C., aged 38, had suffered from discharge from the right ear for the greater part of thirty-two years. Lately an attack of inflammation had supervened, inducing a total loss of hearing, and paralysis of the portio dura on that side. Pain and dizziness of the head were increasing. There was great swelling, involving the entire auricle, and a large polypus protruded from the meatus. Under chloroform the polypus was removed, and there was then found a mass of loose bone occupying the position of the tympanum. The swollen meatus having been incised, the sequestrum was withdrawn, and found to contain the parts of the cochlea and of two of the semicircular canals. The patient rapidly regained his health, and eighteen months afterwards was doing well, with no head symptoms, nor discharge, and with a minute canal in the position of the external meatus."—P. 211.

We are glad to see Dr. Von Troeltsch's work made more accessible to the English reader. The author stands high in Germany, and his work shows a large amount of care and industry, with a genuine capacity and zeal for observation.

GENERAL CORRESPONDENCE.

ROYAL EPSOM COLLEGE.

Letter from Mr. Burford Norman.

[To the Editor of the Medical Times and Gazette.]

Sir,—Being a constant reader of your journal, and taking a warm interest in all that concerns the welfare of our Profession, I have read with much pleasure all that has again of late appeared in your columns touching that noble monument to Mr. Propert's care for the "less fortunate" members of our fraternity, the "Epsom College," by which name I speak of it, thoroughly acquiescing in all that you and Dr. Sieveking have said on this head, hoping never to hear the old title "Benevolent" used again, and believing that if those who agree with us adopt, on all occasions, this latter name, we shall help materially to hasten into oblivion that to which we so much object. With the view of helping forward either the building fund for lay scholars, or the fund established for exhibitions and scholarships, I have sent up ten guineas to my friend Mr. Cattlin, to be applied as he and the Exhibitioners' Committee think best, and shall gladly contribute something more annually, whilst health and work continue in me.

It would be well now for all who hold the same views, whether in the Council of the College or out of it, seriously to consider how best the *lay* element may be added to the school—a most important step, and I believe essential to a great and grand future for this institution; and the sooner a practical result is arrived at the better. It will be a starting-point for an onward course of prosperity such as has not yet been likely to be seen. One thing in reference to this branch of the subject should be borne in mind, as a first principle. The larger payment must not obtain for lay pupils greater advantages than those enjoyed by the foundation scholars or others; and if my friend Dr. Sieveking's idea of "a new and separate foundation" for carrying out this part of the scheme means that boys who pay £63 per annum are to live apart from the others, and to be a sort of aristocracy, the object of mixing different classes together in their pupilage will be defeated, and we shall have a college of nobs and snobs instead of a college of young gentlemen; but I do not suppose that that is his meaning.

Mr. Hird says the estimated (annual) cost of each boy at Epsom is £40. I feel sure that there is, somewhere or the other, an error in the calculation on which this estimate is founded, and that this matter requires a closer examination than it has yet received; for if the estimate is correct, then the rate of expenditure is needlessly high. To me it appears plain, as I endeavoured to show in a former communication upon this subject, that with reasonable economy the smallest payment now proposed to be made by an "exhibitioner" (£30 per annum) ought so much to exceed the cost of his maintenance as to leave a very considerable balance to go towards his other expenses for masters, servants, etc. Indeed (the College being rent free to the whole Profession), I had no manner of doubt that if the school were increased to 300 boys, all the sons of Medical men could be thoroughly well boarded and educated at £30 to £35 a-year each.

I am not well acquainted with the school buildings at Epsom, but understand them to be, so far as they go, fairly built and arranged for their purpose. What other are required for the carrying out of the recently-proposed alterations I am scarcely in a position to affirm; but a strong opinion prevails, which I share, that the accommodation for sick boys is not so good as it should be. The Infirmary, should, no doubt, be *entirely apart from the school*, which, I am informed, it is not at present. True, the College has hitherto been remarkably healthy, but it is still liable to all the casualties that befall other large schools, and from which even healthy families are not exempt. As the number of boys there is increased, the liability to these casualties and the tendency to spread of any contagious or infectious disease, which may break out there, will be augmented, too; so that the means of at once, and completely, segregating the sick should be at hand.

One part of the buildings, I think with you, had better never been erected. I mean the Homes for Pensioners, and glad indeed should I be to learn that they were to be turned to a better use than their present one, and that their aged occupants could depart in peace, and enjoy their pensions amongst their respective friends and familiar associations instead of being gathered together in a sort of almshouse. To sum up, I rejoice in what has been lately accomplished as the *auspicium melioris ævi*. I give my hearty assent to the views propounded by yourself and Dr. Sieveking, with other good friends of the College. I hope an unanimous feeling will animate the minds of governors to promote the prosperity of our College, and that those who from time to time direct its affairs, even if they regard "dissentient governors" as enemies, will remember "*fas est et ab hoste doceri*," and have their minds open and ready to receive and consider suggestions which may not originate with themselves. For Mr. Propert and his family, who have laboured as if labouring for their bread to promote this great undertaking, I earnestly trust there will be realised at Epsom such a measure of success as shall more than repay them for all they have done in its behalf. Looking anxiously forward to see in your next issue what form the Propert testimonial is to take,

I am, &c.

Southsea, February 12. H. Burford Norman.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

Tuesday, February 7.

Dr. Peacock, President.

CONGENITAL SYPHILITIC DISEASE OF THE TESTES.

Dr. Wilks brought before the notice of the Society a case of a child, 5 months old, suffering from congenital syphilis, and in whom both testes were enlarged. The left was the larger, and very hard, and divided apparently into two parts, as the epididymis and body of testis were equally affected. The disease is not very common, but clearly shows that the affection of the testes is of that kind which occurs in the internal organs, being a chronic disease dependent on a constitutional taint, and in no way the result of a testitis associated with the primary affection.

Mr. Holmes had seen several cases like that brought forward by Dr. Wilks. In one case it was found at the autopsy that all the hardness was due to deposit outside the

testis. In another, under the care of Dr. Ingram, similar appearances were found. Mr. Holmes, however, had no doubt that disease of the testis itself did occur as a result of congenital syphilis.

REPORT ON MR. WINDSOR'S CASE OF BLACK CATARACT.

Mr. HULKE, in reply to the President, said that the lens fibres exhibited the usual senile changes, but he had not been able to determine the nature of the pigment to which they owed their black colour.

Mr. HENRY THOMPSON showed, for Dr. Keith, of Aberdeen, a specimen of

CALCULUS WHICH HAD BEEN ADHERENT TO THE WALLS OF THE BLADDER.

In showing this specimen, Mr. Thompson remarked that the evidence on which it was stated that calculus was sometimes adherent to the walls of the bladder was generally obtained during life at operations. There was so little post-mortem evidence that some do not believe in its occurrence. In this specimen, taken from the bladder of a girl who died of typhus fever, there could be no question but that the calculus was actually adherent to the walls of the bladder. Of course, a real union was impossible, but the two were fixed together by processes entering the pores and fissures of the calculus.

Mr. HOLMES did not think from what had been stated that there was greater evidence in favour of Dr. Keith's opinion in his post-mortem than was to be obtained in the operation for stone during life. He remembered a case operated on by Mr. Mitchel Henry. In trying to get away the stone, it first came forward and was then pulled back.

Mr. HENRY THOMPSON thought that in Dr. Keith's case the evidence was much stronger, the bladder being widely exposed at the post-mortem. In the instance alluded to by Mr. Holmes, the retraction might have been due to sacculation.

Mr. HENRY THOMPSON then exhibited

A HAIR-PIN REMOVED FROM THE BLADDER OF A GIRL BY THE HIGH OPERATION.

It had been introduced fourteen days before she came under care. At first, there were scarcely any symptoms. After a few days' rest in the Hospital, a sound was passed, and the presence of the pin ascertained. It was easily got hold of, but from its position, and the force required to move it, it was not possible to remove it by the urethra; it was therefore removed by the high operation. Mr. Henry Thompson said that an instrument had been invented in Paris especially for the removal of such foreign bodies; but he had not found this instrument to be strong enough to bend a similar hair-pin which he obtained for trial.

Dr. PLAYFAIR showed a specimen of

EXTRA-UTERINE FŒTATION.

It was removed from the body of a woman whom he had not seen during life. She had been admitted into King's College Hospital for vomiting, and her case had been diagnosed as gastric ulcer. She had not menstruated for four months. She died in collapse a week after admission into the Hospital. On examination there was found a tubular fœtation. The right Fallopian tube was ruptured, and a large quantity of blood had escaped into the peritoneal cavity.

Dr. JULIUS POLLOCK showed a specimen of

ANEURISM PRESSING ON THE PULMONARY ARTERY.

The interest in this case was from the difficulty of diagnosis during life. The aortic valves were found to be diseased, and besides the aorta was pouched, and pressed on the pulmonary artery, nearly closing it.

Dr. J. E. POLLOCK exhibited

AN ENORMOUSLY ENLARGED LIVER,

from a phthisical patient. When admitted, he had pneumothorax on the left side, the heart was to be felt beating in the third intercostal space, and the liver was as high as the fourth rib; and, besides this, there was a cavity in the apex of the right lung.

Dr. MORRIS TONGE exhibited specimens from a case of

RIGHT HEMIPLEGIA, WITH LOSS OF SPEECH—EPILEPSY.

The great interest of this case was, that although the symptoms during life betokened disease of the brain, this part was found at the post-mortem examination to be quite healthy. Several parts of the cord were found to be in a condition resembling that termed by Mr. Lockhart Clarke "transparent granular degeneration." There were a few small fibrinous heads on the aortic valves.

Dr. GREENHOW exhibited the tonsils, larynx, stomach, and ileum taken from the body of a boy, aged 15, who had died of

DIPHTHERIA,

in the Middlesex Hospital, under his care. About the eleventh day of the illness, when the patient had seemed to be recovering, and the local disease appeared to have become limited to slight superficial ulceration of the tonsils, a change took place, the throat and soft palate again became deeply congested, a large amount of albumen was suddenly found in the urine, and vomiting of a glairy mucus tinged with blood supervened. The boy sank in a few days. At the autopsy the tonsils were found to be greatly enlarged and hard, presenting on section a brawny appearance, with sloughing in the centres. The under surface of the epiglottis was covered by a slightly adherent yellow-coloured false membrane; the trachea and bronchi were intensely injected, and there were several masses of pulmonary apoplexy in each lung, the intervening pulmonary tissue being congested, but crepitant. The stomach contained black altered blood, and its mucous membrane was coated with a layer of viscid mucus tinged with blood; this membrane was also injected in patches and of a dark red colour, with some small extravasations towards the lesser end. The mucous membrane throughout the small intestines was reddened, and towards the lower part of the ileum vividly injected, with here and there small ecchymoses in its substance. The solitary glands were somewhat prominent; Peyer's patches appeared to be normal. Dr. Greenhow remarked that the interest of the case lay entirely in the condition of the stomach and its association with vomiting—a not unfrequent symptom in the more asthenic form of diphtheria, which comes on, for the most part, rather late in the illness, sometimes when the patient has previously appeared to be going on satisfactorily, and is always an alarming, and often a fatal, symptom. In several cases he had seen it had supervened, as in the present instance during the course of the second week, coincidently with a highly albuminous condition of the urine; and most frequently the viscid glairy mucus, which forms a considerable portion of the vomit in such cases, has been streaked or tinged with blood.

Dr. GREENHOW also exhibited the

SUPRA-RENAL CAPSULES

taken from the body of a girl aged 12, who had died under his care in the Middlesex Hospital of Addison's disease. The deceased had returned from a visit in the country last summer apparently sun-burnt. This slight duskiness of the face, neck, and hands continued to the end of life. Her father had observed her to be drooping, though without any definite symptoms of illness for three or four weeks previous to her fatal attack. On Sunday, January 15, she was seized with vomiting, but continued to attend school until the following Wednesday, when the sickness returned. On that evening her mother gave her a strong cathartic powder, which purged her copiously and produced intense depression. When brought to the Hospital on Friday, the 20th, she was scarcely able to move, had an extremely languid, listless, exhausted aspect, a pallid countenance, and a remarkably small feeble pulse. Her breathing was frequently interrupted by sighing and yawning, and she retched on the slightest attempt at exertion. Her eyes were large and prominent, and the conjunctivæ peculiarly white. Her skin was cool, tongue clean and moist, and there being no signs of any other serious disease the case was diagnosed as one of Addison's disease, notwithstanding the absence of sufficiently marked discolouration to confirm the diagnosis. She gradually sank, and died January 28, having retained her consciousness to the last. At the autopsy the discolouration was more apparent than during life from the contrast presented by the dusky hue of the face, neck, hands, and abdomen compared with that of the chest and legs, which had remained normal. The axillæ and the areolæ were also slightly dark. There were no definite patches of discolouration on the skin, and the general aspect was that of a person with a naturally dark complexion, but with a fair chest and legs. There was a moderate amount of fat beneath the skin of the thorax and abdomen, the muscles were firm and red, and the blood under the microscope showed neither a deficiency of red corpuscles nor an excess of white ones. There were some deposits of tubercle in the lungs, but no cavities. Peyer's glands were more prominent than usual, the mucous membrane of the ileum was congested, the solitary glands were somewhat enlarged, and here and there one was opaque and slightly yellow. The supra-renal capsules were both much enlarged, their fibrous envelopes much thickened

and firmly adherent both to the capsules and to surrounding organs. No trace of normal structure remained; it was replaced partly by a greyish semi-transparent tissue of tough consistence and partly by opaque yellow matter of a cheesy consistence. A report and sketch of the microscopical appearances by Dr. Sanderson was appended.

Dr. Gibb brought forward a

PATIENT WHO HAD RECOVERED FROM NECROSIS OF THE CRICOID CARTILAGE.

He was aged 49, and had expelled portions of the ericoid cartilage that had undergone necrosis. The openings through which these had escaped were observed with the laryngoscope, and a sketch of them, with the patient's history, appeared in the fourteenth volume of the *Transactions* of the Society. In August last there was much swelling of the false cords, with stridor, cough, and dyspnœa, which necessitated tracheotomy. As was anticipated, the rings were ossified, and the necessary precautions were taken to obviate this. His subsequent progress was most satisfactory, for all the laryngeal symptoms subsided, and the larynx became clear, with cicatrical contraction of those parts through which the necrosed fragments of cartilage had extruded. The voice was good, clear, and loud, as was made manifest to the Society. Dr. Gibb did not think it prudent to dispense with the silver canula at present, owing to the inclemency of the weather; but in bringing the case before the Society he stated that it was one of extreme interest from the fact of the progressive stages of the necrosis, the manner which nature took to get rid of the detached portions of cartilage having been watched with the aid of the laryngoscope.

Dr. Gibb exhibited

PORTIONS OF OSSIFIED TRACHEAL RINGS

expelled some months after tracheotomy, which had been resorted to for chronic disease of the larynx, with obstruction. The operation was one of the most complicated and difficult he had ever witnessed, from the extremely ossified condition of the rings of the trachea, resembling steel almost in its degree of hardness. The patient, an elderly gentleman, is doing very well, and expelled the fragments exhibited through the mouth of the tube some weeks back.

Mr. Francis Mason showed a specimen of

SCIRRHUS CANCER OF THE PROSTATE GLAND.

The subject of the specimen was a man, aged 54, who had been a patient under Mr. Mason's care at King's College Hospital. Five years ago he fell from a ladder, and got severely bruised, although he received no direct injury to the pelvis or urinary organs. From that time he had had occasionally some difficulty in micturition; and three years after he noticed that a little blood came with the urine. At the date of his application in August last, he was suffering the most intense pain, and each attempt to pass urine was attended with the greatest agony. There was no family history of malignant disease. He remained under treatment for about three months, the remedies employed having little influence over the disease, and ultimately died exhausted. At the post-mortem examination, the body was found emaciated to the last degree. The prostate was extremely hard to the touch, and cut like, and had to the naked eye the appearance of, ordinary scirrhus disease. The pelvic and lumbar glands were infiltrated with cancerous deposit; and in each inguinal region several similar hard nodules were observed. Dr. George Johnson had kindly examined the specimen, and agreed with Mr. Mason as to the nature of the disease.

Mr. Henry Thompson said that scirrhus of the prostate was an extremely rare form of disease. Cancer of the prostate was generally encephaloid.

Mr. Henry Thompson, Dr. Murchison, and Mr. Mason were requested to make a further report on the specimen.

Report by Mr. Toynbee, Mr. Thomas Smith, and Mr. Hinton on Mr. Hinton's case of

SEBACEOUS TUMOUR IN THE TYMPANUM.

The tumours were found to consist of layers of flattened cells corresponding with those which constitute similar tumours on other parts of the body. The peculiarity of the case was, that besides a larger tumour which had apparently penetrated the membrana tympani from without, two smaller ones were developed entirely within the tympanum, partially embedded in a mass of effused blood and fibrine.

MEDICAL NEWS.

Apothecaries' Hall. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, February 9, 1865:—

Edmund Farrington Boult, Bath; James Mason, Barrowden, Rutland; John Roberts, Festiniog, North Wales; George Welland Mackenzie, Tiverton, Devon; Arthur John Watts, Alfred-road, Harrow-road; Francis Tuck, Oxford; Charles Edward Heron Rogers, Westmeon, Hants.

The following gentlemen, also on the same day, passed their first Examination:—

Walter Owen Withers, King's College; Frederick Barton, University College; Gilmore Winton Croft, St. Thomas's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Adair, Ponsonby, M.R.C.S. Lond., has been appointed by the Government of Bombay to be Medical Superintendent of Establishments of Submarine and Mekran-Coast Sections of the Government Indo-European Telegraph; head-quarters at Kurrachee, Scinde.

Bell, Joseph, M.D. Edin., has been appointed Assistant-Surgeon in the Surgical Clinical Wards of the Royal Infirmary, Edinburgh.

Coates, Frederick T., M.R.C.S. Eng., has been elected House-Surgeon to the North London Consumptive Hospital, Russell-place, Fitzroy-square.

Coppin, Morney, M.R.C.S. Eng., has been appointed Surgeon to the Royal South London Dispensary.

Etheridge, Charles, M.R.C.S. Eng., has been appointed Resident House-Surgeon to the Halifax Infirmary and Dispensary.

Hampson, John D. C., L.D.S.R.C.S Eng., has been elected Dental Surgeon to the Samaritan Free Hospital.

Harrison, Charles, M.D., has been appointed Resident Medical Officer to the General Lying-in Hospital, York-road, Lambeth.

Haward, John W., L.R.C.P. Lond., has been appointed House-Surgeon to the Hospital for Sick Children, Great Ormond-street.

Jones, Frederick C., M.D. Edin., has been appointed Consulting Surgeon to the Royal South London Dispensary.

M'Williams, Mr. J. Mc., has been appointed Assistant-House-Surgeon to the Halifax Infirmary and Dispensary.

Mills, S., M.R.C.S. Eng., has been elected House-Surgeon and Apothecary to the Lincoln County Hospital.

Sandell, Henry W. A., M.R.C.S. Eng., has been elected Resident Medical Officer to the National Sanitarium for Diseases of the Chest, Bournemouth, Hants.

Scott, Mr. Herbert, has been appointed Assistant-Surgeon to St. Peter's Hospital for the Cure of Stone in the Bladder and Urinary Diseases.

Wintle, H. J., M.R.C.S. Eng., has been elected one of the Surgeons to the Bristol Dispensary.

DEATHS.

Burke, J., Dr., at Mount St. Joseph's Monastery, Clondalkin, Ireland, on February 4, late of Roscommon.

Campbell, Alexander, Dr., of Dunse, Berwickshire, on January 30, aged 56.

Colbourne, Robert, M.R.C.S. Eng., at Great Marlow, Bucks, on January 20, aged 66.

Costello, John, M.D. Edin., at Green Lawn, Miltown Malbay, Ireland, on January 29, aged 58.

Lowe, William, M.R.C.S. Eng., at Warboys, Hunts, on February 8, aged 60.

Masfen, George B., Surgeon, Bengal Civil Service, at Gondah, Oude, India, on December 6, aged 39.

McLimont, Robert, M.D., at 15, Catherine-place, Bath, on February 8.

Munro, J., M.D., Deputy-Inspector-General of Hospitals and Fleets, at London-street, Edinburgh, on February 4, aged 60.

Nairne, John, M.D. Edin., at High-street, Perth, N.B., on January 30.

Nicolas, Thomas, M.D. St. And., at Portland, Dorset, on January 27, aged 42.

Raleigh, E. W. E., F.R.C.S. Eng., late of the Bengal Medical Service, on January 23, aged 62.

Tatterson, Joseph, L.S.A., at Lepton, near Huddersfield, on February 3, aged 65.

Wavell, Robert M., M.D. Edin., at Newport, Isle of Wight, on February 8, aged 67.

Wilkinson, Charles, M.R.C.S. Eng., at Southgate, Middlesex, on February 9, aged 73.

Willders, Frederick W., M.D., at Stamford-street, Blackfriars, S., on January 29, aged 36.

Medical Charities.—The following Institutions will benefit under the will of the late Mr. George Dodd, F.S.A., formerly M.P. for Maidstone, and late of Grosvenor-place, who, in addition to liberal sums to other non-medical charities, has bequeathed to the St. George's, Middlesex, and Lock Hospitals £100 each, and £200 to the Royal Humane Society. The following act of seasonable benevolence was reported on Friday last at a meeting of the Committee of Management of

King's College Hospital, when an old friend and liberal supporter of the charity, who requested that his name should not be mentioned, attended and handed to the chairman the munificent sum of £504; representing sixteen new life governors' donations at thirty guineas each, in aid of the current expenses of the Hospital.

THE BLANE MEDALS.—These naval prizes, founded by the late Sir Gilbert Blane, have just been awarded to Charles Forbes, M.D., M.R.C.S., of H.M.S. *Topaze* (1860), and Andrew Graham, M.D., of H.M.S. *Agamemnon* (1861).

THE forty-sixth anniversary of the Hunterian Society was held during the last week. The annual general meeting for the election of officers and other purposes took place on Wednesday evening, the 8th, when the following list was unanimously agreed upon for the session 1865-6:—*President*—Alfred Smee, Esq., F.R.S. *Vice-Presidents*—Robert Barnes, M.D.; W. Sedgwick Saunders, M.D.; S. W. Devenish, M.B.; Sigismund Sutro, M.D. *Treasurer*—William Cooke, M.D. *For the Oration of* 1866—D. de Derdt Hovell, Esq. *Librarian*—Stephen H. Ward, M.D, *Secretaries*—H. I. Fotherby, M.B.; W. Allingham, Esq. *Council*—Henry Blenkarne, Esq.; Thomas Brown, Esq.; P. Lodwick Burchell, M.B.; F. M. Corner, Esq.; Esquire Dukes, Esq.; J. Braxton Hicks, M.D.; Thomas Mee Daldy, M.D.; Thomas B. Crosby, M.D.; G. Nelson Edwards, M.D.; Robert Fowler, M.D.; G. Lichtenberg, M.D.; Buxton Shillitoe, Esq. After the business meeting the annual oration was delivered by Mr. Hutchinson, before a very full audience, consisting of the members and numerous friends who had been invited, and who listened with great interest to an eloquent address, which occupied more than an hour in the delivery. On Friday the usual dinner took place at the London Tavern, when the retiring President, Dr. Daldy, occupied the chair, supported on either side by Professor Owen and Dr. Greenhalgh, the President of the Medical Society; several other guests were also present, and enjoyed with the members the social pleasures of the evening. The usual toasts were given, and the speeches were interspersed with some exeellent singing by Messrs. Montem Smith and Ransford.

THE POOR-LAW BOARD AND THE HOLBORN UNION.—On Wednesday, at the usual meeting of the guardians of the Holborn united parishes, the letter of the Poor-law Board, published in the last number of the *Medical Times and Gazette*, on the late inquiry on the death of Timothy Daly, came on for consideration. The guardians resolved themselves into a committee, and the portion of the letter of the Poor-law Board which censured Mr. Norton for remissness in keeping his books came under discussion. A desultory conversation arose on the letter, and on the recommendation of Dr. Carr, the Medical officer who assisted Mr. Farnall—namely, that the drugs should be found by the parish, and that the Medical officer's salary should be raised from £100 a-year to £150—it was stated that this would be a double "rise," as the Medical officer now has to find the drugs out of his salary of £100, and two or three of the guardians were of opinion that the salary of £100 was sufficient, as the Surgeon had fees which amounted to upwards of £50 a-year additional. After a long discussion it was resolved to recommend the Guardian Board to reconsider the whole subject of the Medical relief, both indoor and out, and when the Board resumed this was adopted. On the motion of Mr. Cullen, it was carried that the clerk should write to Mr. Norton and convey to him the censure of the Poor-law Board, with the expression of a hope that in future he would attend to his duty in respect to keeping the books. The proceedings then terminated.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—At a meeting of this Society on February 6, a patient was introduced by Mr. Ramsay wearing the apparatus invented by Dr. Kingsley for cleft palate, with the view of allowing the members to see the improvement resulting from the use of the apparatus. The patient was requested to read and speak. Pathological preparations were exhibited by Mr. Ibbetson and Mr. Fletcher. The Secretary read a paper by Mr. Cartwright and himself "Upon the Skulls at Hythe Church, Kent." The writers, after stating how the bones were arranged at the above church, gave reasons for disbelieving the traditionary account of how they had been collected—viz., after a great battle between the Danes and Saxons; the appearance of the skulls, and the number of them that had belonged to children and probably to females, were contrary to such a view. The maxillæ principally occupied their attention; the alveolar arches were all well developed, and the teeth were in quality much finer than are usually seen in the present day. Irregularities of any kind were uncommon amongst them. In many cases they were much worn, probably from food containing much of the outer husk of the grain, and grit from the rude utensils used in preparing it. Caries existed, but to a less extent than is seen in the present day; it occurred generally on the masticating surfaces of the teeth, and was attended in most cases with alveolar abscess. Mr. Coleman read a paper "On Certain Forms of Irregularity and their Treatment." The object of this paper, as stated by the writer, was to bring before the Society certain views propounded by Mr. Cartwright at a former meeting, and which had not been fully discussed. Mr. Cartwright's opinion was, that the increasing prevalence of contracted dental arches were ascribable to increasing civilisation with selective breeding. This view was fully adopted by the writer, who adduced a large number of observations which told in its favour; he also agreed with the same authority in the treatment of cases of contracted maxillæ, with irregularly placed teeth; but in some cases he advocated a line of treatment not commonly pursued by Dental Practitioners. The discussion was adjourned till the next meeting.

LECTURE DELIVERED BY DR. BROWN-SEQUARD BEFORE THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—The President of the College, Dr. Beatty, took the opportunity of Dr. Brown-Séquard passing through Dublin on his return from America, to invite him to deliver before the College a Lecture "On the Physiology of the Brain and Nervous System." The lecture was delivered in the splendid new hall of the College on the evening of Friday, the 3rd inst. On this occasion all Graduates in Medicine and Surgery were admitted on presenting their cards, and the result was a large attendance. The learned lecturer gave a most able and interesting discourse, proving the importance of a thorough knowledge of physiology to the practical Physician. He first brought forward a number of types of hemiplegia, showing the light which is thrown on them by physiology, concluding this part of his subject with some observations on those forms of this affection which depend upon hæmorrhage in the cerebellum, and upon lesion of the anterior lobes of the brain. In the first of these we have vomiting, hyperæsthesia in some parts of the body, and amaurosis—the last-named symptom being due not to pressure on the tubercular quadrigemina, but to reflex action. As to the anterior lobes of the brain, it is known that phrenologists have considered them to be organs of speech; but there are many cases—and such a one had been mentioned to the lecturer by Dr. Stokes a few days previously to the lecture—where destruction of these lobes had taken place without any loss of speech. This symptom, also, Dr. Brown-Séquard looked upon as a reflex phenomenon. A remarkable peculiarity attending it is, that the loss of speech is usually unaccompanied by any difficulty of movement in the tongue; it appears rather to be the result of a paralysis of the "organ of expression of thoughts." The learned lecturer next passed to a class of cases characterised by pain in the back, a pricking sensation in both arms, with some degree of itching, burning, or by a strange sensation of heat and cold alternately in the skin of both limbs. Such symptoms depend altogether on inflammation of the nerves at their exit from the spine in the lower part of the cervical region, and may be removed, or at all events greatly mitigated, by active blistering of the spine in the region of the injury, dry cupping, etc. Dr. Brown-Séquard next proceeded to describe two very opposite classes of symptoms, both produced by fracture of the cervical portion of the spine. He then dwelt at some length upon the great variety of symptoms presented in brain disease, adding some remarks upon asphyxia and poisoning. He showed that poisoning often proved fatal by producing a diminution of temperature incompatible with life, and that if two similar animals poisoned with the same quantity of opium were placed in a cold room, one being carefully covered with warm clothes, while the other was exposed to the cold, it would be found that, *cæteris paribus*, the animal which was kept warm would survive, while the other would die. This fact obtains with almost every poison of an organic nature, that considerable diminution of temperature is produced, if not in itself sufficient to cause death, enough at least to add a powerful cause to the other causes existing. Now, this diminution of temperature is a feature which we can combat, and it is therefore of the utmost importance, in cases of poisoning, to use every means to keep up the temperature of the body. On the conclusion

of Dr. Brown-Séquard's able address, which was listened to with the greatest attention, a vote of thanks to the learned lecturer was proposed by Dr. Stokes, and was carried by acclamation.

Belfast Branch of the Royal Medical Benevolent Fund Society of Ireland.—The annual meeting of the subscribers to this branch of the above Society was held on the 8th inst, Dr. Patterson, in the absence of Dr. T. H. Purdon (the permanent president), presiding as chairman. Resolutions were adopted, amongst other important business, urging the continued exertions of the friends of the Society in support of its invaluable and truly benevolent objects, and calling, in particular, upon every member of the Profession not hitherto subscribing to its funds to do so as a bounden duty, and the nobility and gentry to aid also in furtherance of its increased usefulness; as upon them, and the wealthy portion of the community generally, the Medical Profession had the strongest claims, its members admittedly being so liberal in affording their services, without fee or reward, for the public weal. Deputations were also appointed to visit the principal towns in Antrim and Down on behalf of the Society, in order to increase the number of its supporters. A committee of management for the current year, to meet quarterly, was now appointed, consisting of Drs. T. H. Purdon (the permanent local president), Patterson, Drennan, Moore, T. H. Reade, H. S. Ferguson, Cuming, and S. Reid, as town members; and Drs. Spearing (Antrim), Musgrave (Lisburn), Filson (Portaferry), Keown, R.N. (Sydenham), and Surgeon Patrick (Carrickfergus), as country members. Drs. Browne, N.N., and Stewart were re-appointed treasurer and secretary respectively, and a vote of thanks passed to them for their past efficient services in the discharge of the duties of their offices. Some further routine business having been disposed of, and the thanks of the meeting given to the chairman of the day—Dr. Patterson—the meeting separated.

*** [In inserting the following, extracted from the *Hampshire Telegraph and Sussex Chronicle* of February 11th inst., we venture to think that Mr. Howell will be found to have repeated an exaggerated and *ex parte* statement, and that, before this, the affair has assumed a different complexion. In the meantime the editor of a local paper gladly hails every little incident in the Town Council, particularly if it can, by any possibility, be made to sustain a sensation heading:—]

The Contagious Diseases Prevention Act.—Startling Allegations.

Mr. Howell said it would be remembered, perhaps, that at their last meeting he directed attention to this Act, and expressed a hope that the wise and valuable decision of the Legislature might be strictly carried out, as it must be productive of considerable good; and it was now his duty to bring before the consideration of the Board a most flagrant case which had been communicated to himself and Mr. Wells, and which, he thought, deserved their most serious consideration. The circumstances of the case appeared to be that one of the metropolitan police, by virtue of the authority conferred by the Act, removed an unfortunate woman to the Hospital, and after she had been there about six or seven weeks, about half-past five o'clock one evening she was ejected from the institution, very little better than when she went in. Having directed attention to the clause which provided that no such woman could be even discharged from the Hospital until the expiration of three months from the date of her admission, he submitted that it was a very unkind and unnatural act to force, and actually with violence, a woman from the Hospital in the condition she was then in at half-past five o'clock on a wet evening. The consequence of the case was that she was taken to Mr. Way, the relieving-officer, who took compassion on her, and on the following day (which was the 25th of January) she was admitted into that Union-house. She entered the Hospital in the name of Ann Perrier, and was admitted into the Union as Emily King, being a young woman, and having come, as she said, from Southampton; and he thought it was a disgraceful thing, for he had questioned the woman very closely upon the point, and she declared most positively that she was ejected from the building with violence. The Clerk: By whom? Mr. Howell: Mr. O'Brien, the House-Surgeon. If such was the case he thought that some special notice should be taken of it, and he, therefore, proposed that a letter be written to Mr. O'Brien requesting that he would explain the cause of the same. (Hear, hear.) Mr. E. M. Wells said he did not think Mr. Howell had gone quite far enough. (Hear, hear.) He (Mr. Howell) had made a very serious charge against the House-Surgeon at the Hospital, and he thought that they should write to the authorities, for it was a very serious matter. Mr. Howell was much obliged to Mr. Wells for the suggestion, and thought that was the proper course after all. He really thought it was but just that the House-Surgeon should be called upon to explain the reason why he ejected this poor woman. Mr. Wells then seconded the amended resolution, and after some further conversation, it was adopted unanimously.

New Employment for the Medical Profession.—The following extraordinary statement, if true, does not speak highly for the public estimation of morality in which the district concerned is held, however it may testify to the sensitiveness of its fair sex on the subject of their reputations. "The following advertisement appeared in the *Inverness Courier* of Thursday last:—'To the Editor of the *Inverness Courier*. —'Dores Free Manse, Feb. 7, 1865.—'Sir,—Two females from Lochend called on me this night with a view to the publication of the accompanying document as an advertisement in the *Courier*. I hereby give my concurrence to the foresaid proposal. Have the goodness to send the document to Dr. Campbell, that he may insert one or two words which are wanting in his certificate, which must have been hurriedly written. Yours very truly, A. Macpherson.'—'A rumour having been circulated tending to affect the character of the fair sex of Lochend, in reference to the body of a child lately found in Loch Ness, the inhabitants of the district deemed it expedient to get their character adjusted by Dr. Campbell, from Inverness, who on Monday last met all the young and unmarried females of the place in the vestry of the Free Church, and certified as to their character being free from reproach. A reward of £5 is hereby offered to any party who can give correct information to the Rev. Mr. Macpherson, Dores, of any one attributing the perpetration of the crime to any of the females within the bounds of Lochend. Lochend, January 25, 1865.'—'I hereby certify I have examined a number of young women of Lochend, and have no reason to believe that any of them have been recently confined.—W. A. Campbell.'"

Scurvy.—An inquiry has been recently held by Mr. Humphrey, Coroner, at the Albion Tavern, Shadwell, touching the death of Heinut Popper, aged 40, one of the crew of the American ship *Santee*, from Calcutta for London. The ship in question sailed from New Hampton, and was commanded by Captain Parker, of whom personally the survivors of the crew speak well. Some fourteen months ago she took on board at Bremen a German crew of fifteen men, with whom she sailed to Calcutta. She sailed thence for London with a cargo of linseed. Julius Meenoot said that on leaving Calcutta, five months ago, the hands were all well. The provisions were not clean. No one could eat the meat, it was so bad. The coffee consisted chiefly of peas ground up. There was no fresh meat, but there was *boulli* once a week, and latterly oftener, and the pork was not bad. No lime juice was on board, but a winebottle full of vinegar was allowed to eight men per week. The steward was the first who fell sick; he died from scurvy. That was three months after leaving Calcutta. Several men were attacked with scurvy after that; among others the witness and the deceased. While witness was on deck he could get something to eat, but when below he could get nothing but hard bread. The sickness was caused from the bad provisions. Alman Dalahe said that he fell sick as well as the rest. The meat had a strong smell. The rice was good, but was so badly cooked that it was unfit to be eaten. John Brown, a Prussian, gave similar evidence, and said that the cook would sometimes give and sometimes refuse the necessaries to the sick men. There was no medicine for scurvy on board. Barrels of the meat had to be heaved overboard. It appeared that out of the crew of fifteen men two died on the voyage, two more in port, and that one or two others were in a hopeless state. Dr. D. Ross said that the ship came into the Victoria Docks on Wednesday night, and the next day witness was called to the deceased and others of the crew at Austemeier's lodging-house, Shadwell. Deceased and another died at once, from impoverished condition of the blood from scurvy. Limejuice was a specific for scurvy, and according to recent investigations scurvy did not arise either from contagion, impure air, or living on salt provisions, all which causes had been assigned to it; but from deprivation for a length of time of fresh succulent vegetables, causing the loss to the blood of an

essential element—the salts of potash—which was found in sufficient quantity in citric acid or lemonjuice. Therefore if there had been lemonjuice on board the ship, and if the rice and pork had been properly cooked, the lives of the deceased men would in all probability have been saved. The coroner said that the vessel being a foreign one she was not bound by the Act of Parliament compelling lemonjuice to be carried by British ships. The jury returned a verdict, "That deceased died from scurvy, from natural causes, accelerated by the want of properly cooked provisions, and by the total absence of limejuice on board the ship *Santee*."

THE GENERAL PROVIDENT ASSURANCE COMPANY (LIMITED).—This is a Society which seems desirous of enlarging its sphere of operations, and amongst other "features" advertises a homœopathic referee, as well as a Medical adviser. Query, do these gentlemen meet? Is any higher or lower value set on a homœopathic patient's life? Are there new Homœopathic Life Tables? Are the profits to match?

BULIMIA.—The *Patria* of Naples states that there is at present in the Hospital of Incurables in that city an old woman who is suffering from a strange disease. She every day eats at least five portions of roast meat, seventy eggs, several loaves, and other food, of course including a good quantity of maccaroni. When attempts are made to reduce her diet she raves like a mad woman. Professor Zamoglia has recently undertaken to cure the poor woman; but up to the present time her appetite remains unimpaired.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Unfortunate must be seen by a Medical man. We cannot prescribe.

Non-Existence of Syphilitic Virus.—We are sorry that we cannot insert the venerable Dr. Macloughlin's letter on the non-existence of the syphilitic virus. His arguments are of the verbal order, and put us in mind of the old proof of the non-existence of motion.

Nelson's Inhaler.—In our notice of the above, last week, we omitted to state that it may be obtained of Messrs. Maw and Son, Aldersgate-street, E.C.

Poitrinaire.—All the benefits derivable from inhalation are well known to Medical men. The quack advertisements referred to are not issued by persons within the pale of the Profession.

Received for Mrs. Walker and family, of Crick, near Rugby—Dr. Bisset Hawkins, second donation, £5.

The French Medical Association and the Prosecution of Quacks.—In the *Medical Times and Gazette* of February 4, 1865, it is stated that the Editor of the *British Medical Journal* had asserted that the French Medical Association did not give energetic support to the prosecution of quacks. We are informed that the real meaning of the Editor of the *British Medical Journal* was, that the French Association advised and patronised the prosecution of quacks, but that it left the doing of it to the Medical Practitioner at his own risk and peril, without contributing any money. We believe that the encouragement of prosecutions is considered of the greatest importance by the French Association, and that it does all short of finding money—gives advice, employs a standing counsel, etc.

Oriental.—The following are stated as properties of the betel nut:—

"Betel nut is bitter, hot, sweet, spicy, binding, alkaline,
An emulcent, an astringent,—foes to evils intestine;—
Giveth to the breath a fragrance, to the lips a crimson red;—
A detergent and a kindler of love's flame which lieth dead.
Praise the gods for the good betel! these be thirteen virtues given,
Hard to meet in one thing blended, even in the happy heaven."

Erratum.—Page 161, in the paragraph on the late Dr. Jones Quain, line 5, *for* "prosecutor," *read* "prosector."

THE GRIFFIN TESTIMONIAL FUND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The following subscriptions have been further received on behalf of the above fund:—Dr. J. Cogan, Wheatley, £1 1s.; Dr. F. J. Sandford, Market Drayton, £1 1s.; Dr. J. S. Belcher, St. George's East, 10s. 6d.; amount previously announced, £114 8s. 6d.; received at *Lancet* Office, £7 17s. 6d.

I am, &c.

ROBERT FOWLER, M.D., Treasurer and Hon. Sec.

145, Bishopsgate-street Without, January 25.

THE PUFF OBLIQUE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As a native of Maidstone, I occasionally see the local papers, and am surprised to see continual puffs of the Ophthalmic Hospital and its Surgeon, a specimen of which I enclose.

I am, &c.

Kennington, S. A MAN OF KENT.

"'EYES RIGHT.'—We are happy to be able to state that the epidemic at the Ophthalmic Hospital has entirely abated, thanks to the prompt measures of Mr. Adams, the very able and courteous Surgeon. He has taken procautions to keep the out-patients affected with it entirely separate from those not affected, and by these means every trace of it has vanished. This admirable Institution has relieved this year as many, or rather more patients than last year, and is very fortunate in having so valuable and attentive a Surgeon as Mr. Adams, who puts eyes right with the quickness of a drill sergeant."

APPOINTMENTS FOR THE WEEK.

February 18. *Saturday (this day).*

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Marshall, "On the Nervous System."

20. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Mr. De Meric, "Clinical Experience in Syphilis."

21. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ETHNOLOGICAL SOCIETY OF LONDON, 8 p.m. John Crawfurd, Esq., V.P., "On the History of Cannibalism in Reference to Social Progress." — Travers, Esq., "On the Destruction of the Aborigines of Chatham Island by a Maori Invasion."

PATHOLOGICAL SOCIETY, 8 p.m. Meeting.

ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, F.R.S., "On Electricity."

22. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

HUNTERIAN SOCIETY (Council Meeting, 7½ p.m.), 8 p.m. Mr. Maunder, "A Case of Pistol-shot Wound of the Chest Surgically and Medico-legally Considered." Mr. Couper, "Some Observations on Chloroform Inhalation, and Description of a New Inhaler."

MEDICAL SOCIETY OF LONDON, 8½ p.m. Lettsomian Lectures—Lecture III. "On the Treatment of Hæmorrhoids and Prolapsus of the Rectum," by Henry Smith, Esq., F.R.C.S.

23. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædie Hospital, 2 p.m.; West London Hospital, 2 p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, F.R.S., "On Electricity."

24. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 8 p.m. John Evans, Esq., F.R.S., "On the Forgery of Antiquities."

ORIGINAL LECTURES.

LECTURES ON CHEMICAL AND MECHANICAL DISEASES AND THEIR RELATIONSHIP.

By H. BENCE JONES, A.M., M.D., F.R.S.

Lecture II.

DISEASES OF SUBOXIDATION—ON ACIDITY, OR THE ACID DIATHESIS.

(Continued from page 167.)

On the Symptoms of Excess of Acidity.

As in diabetes, so in acidity, there are no symptoms when the disease begins. The over-acidity or the excess of sugar may come and go away without being observed. A little heartburn or a little urgency in passing water may last only for a few minutes, and be cured by nature as quickly as it was caused. Only when the skin or mucous membrane have become irritable by the continued action of the acid, do symptoms of acidity force themselves on the notice and require Medical aid. The amount of uneasiness or pain will vary with the sensitiveness of the membrane and with the degree of acidity. Slight degrees of acidity hardly irritate the skin; but itching, nettle-rash, eczema, and herpes are the outbursts of an over-acid state.

The mucous membrane of the stomach is less sensitive than that of the pharynx, œsophagus, and bowels. When 162 grs. or even 81 grs. of dry tartaric acid in four or six ounces of water are taken, the acid hurts the mouth and the upper part of the food-tube, and then ceases to be felt for three hours or more, when it causes violent griping pain for an hour or two. When the mucous membrane has become irritable the stomach becomes much more sensitive, and acidity causes pain, cramp of the muscular coat, and vomiting; the bowels feel more and move more strongly, and violent pain, colic, tormina and tenesmus come on.

If the sensitiveness of the mucous membrane of the urinary organs is increased, the nerves and muscles become irritable; urgency and frequency of passing water gradually increase into constant pain and violent spasm of the bladder. In the urethra a scalding pain is felt, and constriction of the mucous membrane causes a complete stricture whilst the spasm lasts.

When the acidity is excessive, the skin, stomach, and urinary organs may all be simultaneously irritated. In other words, the amount of acid formed may be so great that it is thrown out everywhere. Most frequently the acidity only shows itself in the stomach and in the urine; and the symptoms produced in the stomach and urinary organs are so closely dependent that the same treatment that does good to the one mucous membrane will be found to do good at the same time to the other.

I might here, if time permitted, give you innumerable cases of acidity illustrating the great persistence and intractability of the deposit of uric acid, and its great liability to return as soon as the alkalies are omitted, unless the strictest diet is observed. The resemblance of these cases to cases of diabetes is very striking; and, moreover, in slight diabetes or intermittent diabetes the production of excess of acid is very frequently to be met with.

I must, however, give you two cases illustrating the rarer consequences of this excess of acidity. A gentleman, aged 40, consulted me for constant deposit of urates and uric acid in the urine. He had been subject to these deposits for years; for the last few months occasionally, from one to five hours after a late dinner, he was attacked by pain in the stomach, which in a short time became intermittingly spasmodic. The intensest pain was reached in half a minute, it then relaxed, and returned as badly as before in two minutes. His suffering lasted about an hour, when the pain gradually abated, leaving a tenderness on pressure and an irritability after food for two or three days. The urine passed after the attack gave on standing uric acid crystals. I advised him when another attack occurred to fill the stomach with hot water and then to reject it. This he did, and a considerable quantity of nearly clear acid fluid was thrown up; on repeating the emetic later during the same attack, a much more intensely acid fluid was obtained, showing that probably an hour-glass contraction of the stomach had existed. By careful diet and anti-acid medicines the attacks entirely ceased. In another patient, six or eight hours after food, attacks of violent cramp used to occur in the rectum, and last from half-an-hour to an hour. Relief at the time was obtained by pressure on a hard seat, and by careful diet and alkalies the attacks entirely ceased.

Before speaking of the treatment, a few words must be said

On the Consequences of Excessive Acidity.

In all I have hitherto said of diabetes and acidity a parallel might be drawn between the two diseases, with this difference—that the bland sugar acts as a diuretic, whilst the irritating acid affects the nerves and muscles, causing pain and spasm; but in the consequences of the two diseases an entire divergence must be noted. Diabetes causes a painless weakness and atrophy. Acidity is the cause of from 60 to 50 per cent. of all the cases of stone that occur in England. Dr. Prout says—"If a uric acid nucleus had not been formed and detained in the bladder, two persons, at least, out of three who suffer from calculus would never have been troubled with that affection."—P. 583 "Stomach and Renal Disease."

In the 26th vol. of the Medico-Chirurgical *Transactions* for 1843, I have given the analysis of the calculi in St. George's Hospital. In 233 calculi, 89 consisted of uric acid alone; that is, 38 per cent. of these stones were caused *solely* by acidity. Whilst 135 consisted of uric acid; uric acid and oxalate of lime together; and of these substances mixed with urates; that is, 58 per cent. were wholly or *partially* caused by acidity.

Gravel is still more frequently caused by over acidity. Seventy-five per cent of all renal calculi are uric acid, caused by acidity alone. Hence three out of four renal attacks, giving rise to almost as violent mechanical suffering as the human body can endure, are caused by a slight chemical disorder which often continues unobserved until the mechanical disease is set up.

On the Treatment of Acidity.

The relation that exists between diabetes and over acidity is even more evident in the treatment than in the causes and symptoms of these diseases. The best diet for diabetes is the best diet for over acidity. The same medicines are most useful in both complaints. The same immediate effect can be produced by treatment, and there is the same disposition to a relapse after the symptoms have entirely ceased when wrong food is taken.

The treatment of acidity must be considered under two heads: First, the diet; and secondly, the medicines.

With regard to the diet. All that has been said against saccharine and farinaceous diet in diabetes might be repeated here, inasmuch as these substances give rise in the system to various acids in their progress to carbonic acid and water. Hence, as regards the action of sugar, dextrine, and starch, I may refer to the lecture on diabetes; but as the acid diathesis arises from a slighter check to the chemical actions of the body than the saccharine diathesis, therefore a less strict diet will give a greater improvement in this disease than in diabetes. Moreover, medicines effect a more decided good in over acidity than in the saccharine complaint, and on this account, also, greater liberty may be given in diet provided the acidity from the food is neutralised by alkaline medicine.

Another difference must be made in the diet of those who suffer from these complaints. In diabetes, fatty substances, cream, butter, fat, and oil check the wasting of the body; but in excess of acidity these articles of food often give rise to great uneasiness in the stomach; they are very liable to cause a peculiar feeling of irritation, which is known as heartburn. Thus, over acidity and heartburn often can be removed and kept away by leaving off sugar and butter. In severer cases, potatoes, rice, arrowroot, and a considerable portion of the daily bread must be given up. Fruits of all kinds are mostly highly flavoured ether mixtures of starch, sugar, and acid. Wines and beer chemically differ from fruit only by containing alcohol instead of some starch and sugar. Alcohol itself, very probably in the stomach as well as in the air, gives rise to acid, and the weak spirit and sugar of half-fermented beer and effervescing wine more easily undergoes this acid fermentation than fully fermented wine and pure spirit. Hence, in extreme cases of acidity small quantities of lean animal food, including fish, flesh, fowl, game, and eggs, and brandy-and-water, constitute the best anti-acid diet. All fluids containing sugar should be avoided; and alkaline gaseous mineral water, natural or artificial, will neutralise a portion of the acidity which the imperfect combustion continually produces.

Exactly the opposite diet was advised at the dawn of animal chemistry, on the ground that the ash of vegetables containing alkalies, these would neutralise all the acid that should arise from the starch and sugar. But take, for example, potatoes: the amount of acid-producing substances is from 20 to 30 per cent; the amount of alkali at most will not reach to 1 per cent. Or take bread: the ash of bread would neutralise at most 1 per cent. of acid. The amount of acid-producing substances in bread is 46 per cent. Any other fruit or vegetable would give equally good evidence against a vegetable diet in over-acidity.

The object of medicines in this complaint may be divided into—first, the removing, and secondly, the neutralising of acid.

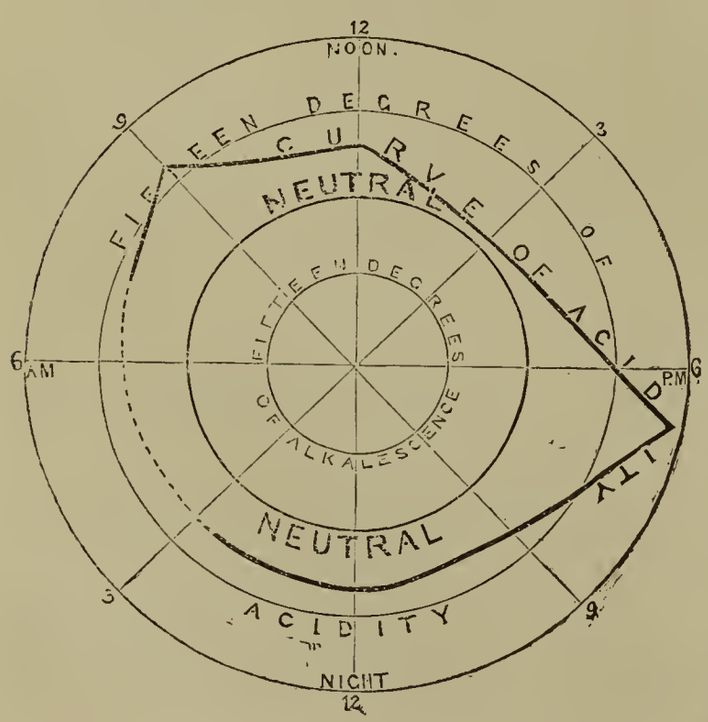
The removal of acid is effected most immediately and directly by emetics, emptying the stomach at the time when the greatest quantity of acid is present, that is, during the digestion of a full meal. In the treatment of the acidity of children, this is the shortest and readiest way. Hot water, mustard and water, ipecacuan will remove more acid than would be neutralised by the usual amount of alkali that could be taken daily. The repetition of the emetic should depend on the re-appearance of uric acid crystals in the urine.

The free action of the skin by baths, especially Turkish baths and vapour baths, or by strong exercise, removes acid quite as effectually, although more slowly, than by taking away the gastric juice. Moreover, an increased natural action disarranges the system less than a stomach catastrophe, which, though scarcely felt by the young, is a shock unfitted for advancing years. Of all the methods of exciting perspiration strong exercise is the best, because this generally implies a freer respiration, and this means the greatest possible conversion of acids into carbonic acid and water. The more bracing the air is, and the more free from mechanical and chemical impurities in the form of dust, smoke of all kinds, fogs, and noxious gases, the more vivid is the combustion, and the greater is the amount of acid that is removed from the system through the lungs.

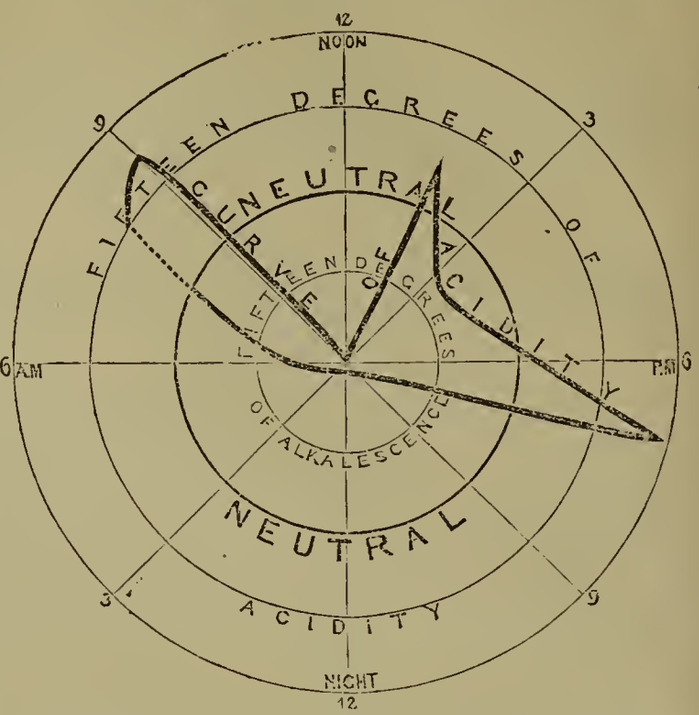
There remains to be considered the removal of acid by the kidneys. By increasing the action of the kidneys, an increased quantity of acids of many kinds, from carbonic acid to uric acid, is thrown out of the system. Diuretics thus become veritable anti-acids. Hence, pure water and nitre and mineral waters, by exciting diuresis, relieve the blood and textures of acid, but whilst promoting the action of the kidneys the acid may be neutralised, and this is the second object to be obtained by medicine.

In neutralising the acidity of the urine, by far the most effectual medicines are vegetable salines, containing fixed alkalies or earths. The following diagrams will show you better than any words of mine how differently salines containing volatile and fixed alkali act on the urine:—

Five drachms of tartrate of ammonia in the day.



Five drachms of tartrate of potash in the day.



Each degree of acidity or alkalescence was made equal to the twelfth of a grain of carbonate of soda. Although five drachms of tartrate of ammonia were taken in the day the urine was not made alkaline, not even neutral; whilst after the same quantity of tartrate of potass the urine was alkaline for the greater part of the day, and at one period reached as low as thirty-two degrees; in other words, a thousand grains of urine contained three grains of carbonate of soda. Moreover, eighty grains of carbonate of ammonia daily in three different experiments did not make the urine neutral, though it acts more strongly than most alkalies in neutralising the acidity of the gastric juice in the stomach. Three drachms and a-half of liquor potassæ, containing $6\frac{1}{4}$ per cent. of potass, taken in one day, though it lessened the acidity, did not cause alkalescence; still, no doubt, the action of this and other alkaline remedies, when long continued, produces very decided effects in neutralising acidity, the comparative worth of equal quantities of different alkalies may be determined by their combining proportions.

Thus 10 parts	lithia	= 12 parts	ammonia.
,,	,,	= 14	,,	magnesia.
,,	,,	= 19	,,	lime.
,,	,,	= 21	,,	soda.
,,	,,	= 33	,,	potass.
,,	,,	= 54	,,	bismuth.
,,	,,	= 25	,,	carb. of lithia.
,,	,,	= 27	,,	carb. of ammonia.
,,	,,	= 29	,,	carb. of magnesia.
,,	,,	= 35	,,	carb. of lime.
,,	,,	= 37	,,	carb. of soda.
,,	,,	= 48	,,	carb. of potass.
,,	,,	= 70	,,	carb. of bismuth.

In other words, fourteen grains of magnesia will neutralise as much acid as twenty-five grains of carbonate of lithia, or forty-eight grains of carbonate of potass, or seventy grains of carbonate of bismuth. One grain of carbonate of lithia is nearly equal to a grain and a half of carbonate of soda or two grains of carbonate of potass.

In ordering these different alkaline substances, their constipating or their aperient action must be considered; and beyond all this, the peculiarities of different individuals must be learnt by experience. That carbonate of soda to the amount of two ounces and a half daily may be taken for months with impunity may be seen in a case in Med.-Chir. *Trans.*, vol. v., p. 80. The blood had a strong buffy coat. The urine was alkaline. In speaking of the treatment of diabetes, I have dwelt on the alkaline action of different mineral waters. I must refer you to what I have already said. There is in the treatment of acidity an advantage in giving mineral waters which does not exist in the treatment of diabetes. In acidity pure water may be regarded as an anti-acid. It lessens the symptoms, and prevents the consequences

of the acidity; where strong acid irritates, weak acid has no effect. Strong acid quickly sets free uric acid; whilst weak acid has to make up by time what it wants in force, so that simple dilution, or the amount of water that exists in the mineral water, becomes an important means of relieving acidity.

When the acidity is excessive, all these different methods of lessening acidity must be used at the same time. To give acid in the food and to neutralise it by medicine is child's play, unless the amount of alkali taken exceeds the amount of acid eaten. The greatest possible effect can be obtained by stopping acid from going in, by removing acid by perspiration, and by the stomach, skin, and kidneys, and by neutralising the acid by lithia, ammonia, magnesia, or soda.

ORIGINAL COMMUNICATIONS.

ON NUTRITION.

By LIONEL S. BEALE, M.B., F.R.S.,

Fellow of the Royal College of Physicians; Physician to King's College Hospital; Professor of Physiology and of Morbid Anatomy in King's College.

Every tissue and every organ of the body, as is well known, is composed of a great number of small elementary parts or cells resembling one another. Moreover, the elementary parts of all tissues of all organisms, although differing from one another in structure, function, properties, and composition, nevertheless possess certain characters and properties in common. All exhibit the phenomena of growth, all form or produce certain peculiar substances, all appropriate certain materials and communicate to them properties or powers which they did not possess before. All are capable of producing new cells.

Now, a cell or elementary part of a tissue, though it be less than $\frac{1}{1000}$th of an inch in diameter, does not exhibit the same properties and composition throughout, but every living growing cell consists of matter in two very different states:—1. *Matter which is living;* and 2. *Matter which has ceased to live.* (See figures.) The living or germinal matter is within, and appears dark and granular in the drawings; the matter which has lived, or the formed material, is external to the germinal matter, and is indicated by a smooth tint. In the process of development, formation, and decay, the constituent particles of each elementary part or cell pass through certain definite changes, which always occur in the same definite order. In the process of nutrition the nutrient pabulum pursues the same course in all; it becomes changed in the same wonderful manner by the action of the living matter with which it comes into contact. This living matter passes through its various phases of existence like matter which lived before it, and perhaps it is to be followed by new matter, the particles of which will induce similar changes, and follow those which preceded them.

The nutrition of the monad, of the plant cell, or of the cell of any tissue of man, seems to be conducted upon the same principles. Nutrition cannot be imitated in inanimate matter, and seems to be due to the operation of a wonderful force or agency, of the nature of which we know nothing save that pre-existing living matter of the same kind manifested similar active phenomena. If, then, we desire to investigate the process of nutrition, and to account for the phenomena which take place in the nutrition of healthy or morbid structures, we must study the process as it occurs in a single component elementary part of a tissue or organ; in fact, *the nutrition of the cell.* When the changes occurring in one single elementary part of the tissue or organ are satisfactorily explained, those which take place in the entire tissue, organ, animal, or man will soon be understood.

This wonderful process of nutrition does not consist in the mere deposition of matter which was dissolved in a solution, or crystallisation would be a form of nutrition; nor is it an attraction of certain particles of matter for particles of a similar kind dissolved in the surrounding fluid, or the formation of a calculus would be due to nutrition. Neither is nutrition a chemical process resulting from the strong affinity of matter of one kind for matter of another kind which is drawn from its state of combination, for if this were so, many chemical operations would be illustrations of the process of nutrition.

Nutrition involves far more than takes place in these or any other phenomena occurring in inanimate matter. And no one has yet been able to bring about changes in inorganic materials at all resembling those which occur in the nutrition of the simplest living organism in existence (see Fig. 9, illustrating the phenomena which are comprehended under the term *Nutrition*). But it has been so frequently and so very confidently affirmed that the tendency of modern scientific discovery is to break down the barrier which it was formerly believed separated things living from things inanimate that some persons regard it as an opinion generally received by scientific men, and justified by observation and experiment, that the difference between the phenomena occurring in the inorganic world and in living beings is a difference of degree rather than a difference of kind. This view rests upon vague general assertions alone, and has as yet no real foundation whatever. Those who entertain such a doctrine should state in what particulars the lowest living form, such as a monad or a microscopic fungus, resembles inorganic matter, and in what particulars it differs from inorganic matter. It is time that earnest, unprejudiced men, who are willing to learn, should be simply told what is really known, and encouraged to inquire further, instead of being overwhelmed with mere high-sounding unsupported assertions, which in many ways retard the advance of true science. Those who have most earnestly and carefully studied the matter well know that many of those wonderful phenomena occurring in healthy and diseased structures cannot be accounted for, unless the operation of some force or power or agency, distinct from ordinary force or energy, is assumed, and it is mere trifling to assert that the tendency of investigation is to prove that vital force is but another mode of simple energy or motion, unless facts are adduced in support of such a view. Some may rest content and cease to inquire further when they are told that the human *machine* resembles a machine made by human hands; but any one who has actually studied even in a superficial manner the structures evolved during the formation of the human machine, the arrangement of a single tissue, the action of a single organ, or even of a single cell, to say nothing of the phenomena occurring during disease, will have seen sufficient to lead him to doubt if there exists any real analogy between man's machinery and the machinery constructed by man, and he naturally asks those who profess to see so much farther than he can see to show him in what particulars even a single simple living cell resembles the most perfect machine ever made by human hands.

The structural forces which lie latent in molten masses, to which crystallisation of amorphous drops of matter is due, are one thing, and the "structural forces" which lie latent in the drop of living matter, and cause the "crystallisation" (!) of matter in the shape of muscles and nerves and other tissues, are another. The "constructive force" of crystallisation which lies latent in the drop of water manifests its activity when heat is abstracted. The "constructive force" of living matter comes into operation only when heat has been added. Yet it is assumed that in each case the "constructive force" is a form or mode of heat itself; and although the assumption is unsupported by reason, it passes unquestioned, and is even regarded by some as a new scientific truth,—as an evidence of our progress towards what is called unity! One would have thought that the differences between crystallisation and the production of tissue had been shown often enough and clearly enough already to convince any impartial observer that crystallisation, and formation of tissue, were two very different processes; but is it probable that those who have embraced the dogma that the *only* forces operating in nature are derived from the sun can be influenced by argument or reason, or their faith shaken by the results of observation and experiment?

It has been assumed that the molecular forces of the crystal and the molecular forces of the cell are molecular forces of the same kind acting under different relations or differently conditioned; but we have not been taught in what the relations differ, or what is to be understood by the term "conditioned." According to some philosophers we might say, Here is a living cell, and there its pabulum. The forces of the latter, originally derived from the sun, become so "conditioned" by the atomic machinery of the cell as to result, in one case, in the formation of a cabbage, in another an oak, and in another a man, and so on! Force may be "conditioned" by machinery made by us so as to set in motion various wonderful instruments; but we know, or may learn, the structure and arrangement of the machinery by which the conditioning is brought about. Before we can understand what is meant by the word "conditioned" as applied to the atomic machinery of the cell, we

must be taught something of the structure of its *atomic machinery;* but upon this subject the New Philosophy maintains the most profound silence. It asserts largely, and, as smoothly as confidently glides with incredible swiftness from one position to another. Why should it pause to explain? Physiologists may ask in what points the living cell resembles the machine made by hands? and the conclusive answer is, that it does!

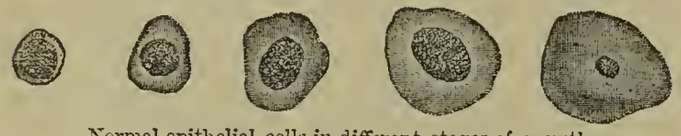
If, however, we inquire for ourselves, and examine the living matter in which this conditioning of force goes on, we find in it no evidence of structure at all; there is no *machinery* that we can see. A power of 10,000 diameters reveals no structure whatever, nor can we see any difference in different kinds of the living matter, although the conditioning is so widely different. The conditioning of force by a machine which has been manufactured, the structure of which is well known, must, therefore, be a very different process from the conditioning of force by living matter, the structure, composition, and arrangement of which are unknown. This living matter is all important to the nutritive process, but it has been ignored by those who consider all the changes to be due to physical force.

Let us now endeavour to ascertain simply what changes may be proved to occur during the nutrition of a cell. Whether vessels be concerned or not in the mere distribution of the nutriment is of no importance, as vessels have nothing to do with the process of nutrition itself. The thing to be nourished must be composed, at least in part, of living (germinal, protoplasmic, or nucleus) matter,—that is, of matter in a state or condition which, for the time being, differs in its properties, powers, or forces from every other state in which matter is yet known to exist. Formed or lifeless matter *alone* cannot be nourished without the agency of living matter any more than a crystal or a calculus can be *nourished*,—although matter may be *deposited* upon its external surface, or even in its substance.

If ordinary epithelial particles or cells be examined at different periods of growth, it will be noticed that the relative proportion of the *living matter*, to the *formed matter* varies considerably; and from these observations we can form a notion of the changes which occur in one cell as it undergoes development.

An epithelial cell at different ages is represented in Figs. 1, 2, 3, 4, 5. At first it consists of a mass of germinal matter,

Fig. 1. Fig. 2. Fig. 3. Fig. 4. Fig. 5.



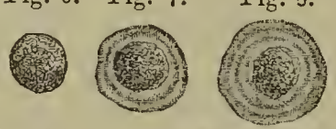
Normal epithelial cells in different stages of growth.

which was detached from a pre-existing mass, with a very thin layer of soft-formed material around it. This latter continues to increase in the manner I have described in my lectures at the College of Physicians in 1860.(a)

In such a simple cell, then, the phenomena of *nutrition, growth, and formation* may be studied.

In many cases an arrangement as of concentric zones (Figs. 6, 7, 8) around the mass of germinal matter may be observed. This does not arise from the deposition of layer

Fig. 6. Fig. 7. Fig. 8.

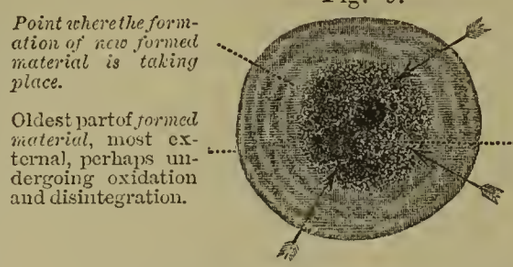


Deposition of formed material in concentric layers.

upon or *outside* layer, as in the formation of a calculus, but from the formation of layer *within* layer. This part of the subject has been worked out in other papers, and need not be further discussed here.(b)

In NUTRITION, certain constituents of the pabulum are not changed, or altered, or modified by the action of the nucleus or cell wall as is generally taught; but certain of the very constituents of the pabulum actually become the germinal matter, and this latter becomes resolved into formed material, which is added to that previously produced or compensates for what is removed by decay. The following figure shows the course which the pabulum takes during the process of nutrition:—

Fig. 9.



A living cell to show that the process of nutrition consists of

1. The passage of the pabulum through the formed material when it reaches the germinal matter.
2. The conversion of some of its constituents into germinal matter.
3. The conversion of some of the germinal matter previously existing into formed material which is deposited layer within layer, as it were, upon the *inner surface* of the formed material already produced. In many cases the successive layers are incorporated with one another.

The process of *oxidation* probably affects the outer and oldest part of the formed material chiefly, and, in some instances, occur in this situation only.

Nutrition, therefore, comprehends the appropriation of inanimate nutrient matter by living matter *which already exists;* the conversion of the nutrient matter into living matter, and the latter into formed matter, which may increase that which has been already produced (growth of formed material), or may compensate for that which has been destroyed or removed (maintenance).

The process of nutrition may be divided into three stages—

First Stage of Nutrition.—(*a*) The passage of pabulum in solution through the formed material. (*b*) Its contact with the living matter.

Second Stage of Nutrition.—The conversion of certain constituents of the inanimate pabulum into active living matter.

Third Stage of Nutrition.—The conversion of living matter into inanimate formed material.

(To be continued.)

THE TREATMENT OF ENTERIC FEVER WITH LARGE DOSES OF QUININE.

By JOHN FORMAN, M.R.C.S.

In 1837 and 1838 typhoid fever, so much more prevalent on the Continent than in this country, was treated with large doses of quinine. About this period it was administered in the Hospitals of Paris in 50 grain doses with the view of cutting short intermittents. In 1851 Professor Hughes Bennett used it in 10 grain doses in some severe cases of typhus and typhoid fever in the Edinburgh Infirmary, and although this was a very limited trial to warrant a judgment, the unfavourable opinion expressed at this time by this truly able teacher of Medicine led me to disregard this drug in the treatment of what we may now term our annual autumnal enteric fever. Until I observed the communication of Deputy-Inspector-General Hare, Bengal, in this journal (c) in November and December, 1864, "On the Treatment of Malarious Fever in India with Quinine." That gentleman's successful treatment of these tropical fevers led me to try the effect of large, frequently-repeated doses of this drug in cases of our enteric fever. The success I have met with during a short epidemic period of two months is certainly in the highest degree encouraging, and warrants a free and extended trial, and this communication is prompted in the hope that the success I have experienced may be endorsed by the practice of others.

Before commencing the quinine treatment, I have long been convinced of the efficacy of emetics as a premonitor to the general treatment of zymotic diseases, when administered at an early stage of the attack, and I am still inclined to precede the quinine by administering a mild emetic, particularly in subjects of a sanguino-bilious temperament; it is only natural to suppose that superfluous biliary matter must not only tend to increase the gastro-intestinal irritation, but also act as a barrier in some measure to the action of any remedy of a specific character.

I will illustrate as briefly as I can the treatment I have adopted by selecting promiscuously from my note-book three

(c) *Medical Times and Gazette.*

out of a considerable number of cases I have lately had under my care :—

Case 1.—Mrs. S., aged 53 years, assisted to nurse and sat up for several nights with family B., three of whom were ill of enteric fever. December 12, 1864, was the last night she sat up with the sick children, when she was seized with a chill and nausea. She continued to pursue her ordinary avocations, complaining of being out of sorts ; had impaired appetite, irregular chills, and headache until the 16th, when I saw her. She was then complaining of nausea, which had increased during the preceding night, attended with intense headache, sleeplessness, chills alternately with hot skin; pulse feeble and accelerated; tongue moist, red tip and edges creamy, fur in centre; thirst and retching; bowels relaxed after taking a dose of castor oil last night. She has severe aching pains in her joints and lumbar back. A mild ipecacuanha emetic was administered ; vomiting to be encouraged for two hours by warm diluents ; after sickness subsided to take 10 grains of quinine in half-drachm doses of phosphoric acid and water every three hours. After 40 grs. of quinine had been taken, deafness with considerable confusion in the head supervened; no decided impression produced upon the pulse (the great indicator for good or evil in fever) ; 20 grs. more were taken during the following eight hours, when the dose was reduced to 5 grs. every four hours ; this was continued until 120 grs. had been taken, when dilute phosphoric acid was continued only till the 20th, when all her fever symptoms had passed away. She was able to be about again on the 25th.

Case 2.—Mrs. B., mother of the sick family already mentioned, age 47 years. She has had eleven children; youngest four months, at the breast. During the night January 1, 1865, she was seized with prolonged shivering, accompanied with intense headache, sickness, and vomiting. I saw her during the day, and found her in bed along with two children very ill of enteric fever; the characteristic rose spots were developed in both cases. Another child had succumbed to the same disease a few days previously. (These children were treated with mineral acids and nutrients, with occasional mild doses of castor oil to assist the elimination of septicæmic excrementitious matter. They made a tardy recovery.) Mrs. B. had hot, pungent skin ; quick, feeble pulse ; nausea and thirst; her tongue had a dry, brown stripe down the centre, with red tip and edges ; bowels regular; intense headache; soreness over whole body, etc. Her child was sent out to be nursed, and after some directions being given about the arrangement of her room, ventilation, etc., the same treatment as in Mrs. S's. case was pursued, and on the evening of the fourth day after her attack all trace of fever had disappeared.

Case 3.—Mr. L., Excise officer, aged 38 years ; January 5, 1865, seized with a chill last evening, and continued to shiver during the whole of last night. This morning he has severe headache; neuralgic pains over the whole body, particularly in lumbar back ; conjunctivæ of jaundice tinge ; heavy expression of eyes, contra to his lively normal temperament; skin warm ; pulse 80, very compressible ; tongue coated with dry, brown fur ; insatiable thirst; bowels relaxed. After the nausea of an emetic had subsided, fifteen-grain doses of quinine were administered in dilute phosphoric acid every four hours. The physiological effect of the drug was distinctly manifested in eighteen hours, when the dose was diminished one-half. His attack was attended with violent bilious diarrhœa, accompanied with bloody mucus excrement, acute ileo-cæcal tenderness, etc. ; and although this patient is of the decided gastro-intestinal irritative diathesis, he was entirely relieved of his distinct fever symptoms on the fourth day after his smart invasion, and able to leave his room in eight days.

Remarks.—When symptoms of specific fever manifest themselves in the system, it is a rational inference to attribute this to the introduction of morbid matter into the blood. Our object, then, is clearly to administer an antidote energetically, and in sufficient quantity, on the same principle as we would administer sulphates in lead poison or prussiate of potash for hydrocyanic acid. The restorative and expectant methods of treatment seem to be as humiliative in the present day as the justly-abandoned antiphlogistic method of forty years ago. I am sanguine to hope that quinine will be endorsed as the future antidote for enteric fever, and bring it to its termination in one instead of three weeks, its ordinary course. As many months are frequently required to establish convalescence under the ordinary treatment.

In a future communication I will give a more extended trial of this drug, also the merits or demerits of muriate of cinchonine as a febrifuge and antiperiodic. The enormous demand for quinine, and the probable future diminished supply, may induce us to husband it for use in important cases only, also to test the efficacy of other medicines, such as muriate of cinchonine.

Fettercairn, Kincardineshire.

POISONING BY LAUDANUM TREATED BY ELECTRO-MAGNETISM AND BELLADONNA.

By PRESTWOOD LUCAS, M.D., M.R.C.P.,
Physician of the Brecknock County and Borough Infirmary.

A. P., aged 11, at 6.45 p.m. of December 15, 1864, swallowed an ounce and a-half of laudanum, sent to her by mistake for a black draught. She soon became very drowsy, and perspired freely. Her breathing gradually becoming very heavy and oppressed, her mother at length became alarmed, and Medical aid was sent for.

I arrived at the house at 9.15 p.m., and found my friend Dr. Davies already there, preparing to introduce the stomach-pump. The child had been kept walking about the room between two persons, who perseveringly employed the usual physical means of rousing her consciousness. Her face was cold and livid; hands, arms, and feet cold ; pupils contracted ; pulse 96. She could be roused by shaking and loud speaking, and then knew every one around her, looking at them with a half-intoxicated expression—understanding all that was said to her.

At 9.30 p.m. two scruples of sulphate of zinc dissolved in warm water were injected into the stomach. Only faint traces of laudanum were found in what was brought off the stomach, the remainder of that which had been swallowed having passed into the system.

The stomach was afterwards well washed out at intervals with repeated injections of warm water, each injection being followed by one of strong coffee. A sinapised foot-bath and, later, sinapisms to the calves of the legs were used.

Instead of being incessantly walked about the room, she was taken to walk for about a hundred yards and back in the open air, and allowed to rest in the intervals. The drowsiness, however, kept increasing. At one o'clock a.m. she was comatose; the breathing stertorous; face flushed; respiration only six in a minute ; pulse 100, small and feeble ; pupils much contracted ; could still be partially roused.

At 1.30 could not be roused by shaking or loud speaking ; occasional subsultus of the muscles of the arms and twitching of the eyebrows ; lower jaw dropped, showing an incessant to-and-fro motion of the tongue ; respiration 6 ; breathing stertorous.

2.40.—No improvement. Electro-magnetism applied at the upper cervical region and over the epigastrium, chest, and face. This soon roused her, so as to enable us to give her a teaspoonful of a solution of extract of belladonna of eight grains to the ounce.

2.55.—Electro-magnetism re-applied, and a teaspoonful of the solution given. Is more easily roused, but instantly falls asleep again ; breathing still stertorous.

3.20.—Electro-magnetism. An enema administered of gruel, with six drachms of brandy and a teaspoonful of the solution.

3.50.—Electro-magnetism and a teaspoonful of the solution. She now rose up to the sitting posture, and got off the couch to walk across the room supported by two persons, looking about her with an alarmed and bewildered expression, but apparently not recognising any one. She was, however, sufficiently awake to drink a cup of strong coffee, taking the cup in her hand. Face becoming more flushed ; pupils less contracted ; pulse 104 ; respiration 6 ; less stertor when asleep.

4.10.—Electro-magnetism and a teaspoonful of the solution. Is easily roused ; now sees and knows us.

4.40.—Enema as before, with the addition of two drachms of aromatic spirit of ammonia. Pulse 136 ; respiration 8 ; no stertor ; face highly flushed.

5.50.—Electro-magnetism and a teaspoonful of the solution. Has now received sixteen grains of extract of belladonna. No stertor ; respiration 8, attended with a soft sighing moan ; pupils moderately dilated ; is quite easily roused when spoken to ; answers questions and begins to notice objects.

From this time till 7 a.m. she was allowed to remain sleeping, reclining in an easy position on her left side, with her shoulders

and head raised. She was only spoken to occasionally, to ascertain that she could be easily roused. A diffused flush overspread her face and forehead, and a pleasant warmth and moisture the whole body. Pulse from 140 to 150; respiration 11. At 12.30 p.m. was sleeping, breathing softly; very easily roused, and perfectly conscious when awake. Respiration 12; pulse 150; pupils moderately dilated. Had much thirst, and some irritability of stomach and vomiting in the afternoon. Next day pupils were much dilated. She had slight diarrhœa, and afterwards speedily recovered.

In treating such a case as the one now detailed, of course the first and indispensable thing to be done must be to empty the stomach of its contents as speedily as possible, and then to wash its mucous surface thoroughly by injections of warm water. The usual methods of rousing the patient's consciousness by incessantly walking about, slapping their hands and limbs, etc., we soon forbade, believing that—owing to the fatigue and exhaustion produced by forced muscular efforts, much more harm than good would be done. With a like feeling we were very reserved in our use of electro-magnetism, apprehensive of the possible nervous exhaustion which a continued use of so powerful an agent might induce. Having first roused the patient out of the profound coma in which she lay, we afterwards applied it only just enough to enable her to take the solution which we gave her. We then allowed her to sleep until the next dose was to be given, and so on. We employed stimulants, external and internal, as has been described; but we could not help attributing the happy result in this case chiefly, if not altogether, to the influence of belladonna in counteracting the effects of the opium of which so large a quantity had been taken into the system. But at the same time, we found in electro-magnetism an invaluable resource; without it we could not have roused our patient to swallow anything.

One of our highest authorities on the subject of poisons, to whom the particulars of this case have been communicated, considers the result to be owing to the vigorous measures we adopted, and believes that the belladonna had little or nothing to do with it; but as regards vigour of treatment, the usual methods of rousing the patient by physical efforts and stimulants completely failed. The narcotism became more and more profound, until at length the child could not be roused at all out of her unconsciousness. It was not until we had recourse to electro-magnetism and belladonna that any signs of improvement took place. If recovery was solely due to electro-magnetism, a very moderate application of it was sufficient in this case, and it would be well to remember this in the treatment of similar cases. But it may be asked, how could a child of 11 years take sixteen grains of extract of belladonna in less than three hours, without experiencing any of its usual toxical effects, unless for the counteracting influence of the opium which had been previously taken? More importance might be attached to this argument had not Dr. Fuller shown, in a most interesting paper read by him to the Medico-Chirurgical Society, and published in the *Medical Times and Gazette* in July, 1859, the extraordinary tolerance of belladonna in young subjects. He described the tolerance of the drug as being so great, that "one child of 10 years took seventy grains of extract of belladonna daily, and a total amount of rather more than two ounces in twenty-six days. Another child of 14, to whom atropine was administered, took no less than thirty-seven grains in eighteen days! Whilst in adults two grains of the extract of belladonna daily would often induce vertigo and dizziness, and he found he could not establish a toleration of the larger doses, as in children."

This yet unexplained tolerance of belladonna in young subjects is, however, a question apart from that of its physiological relations to opium. The present case may not be considered as altogether fair evidence of the efficacy of belladonna, inasmuch as electro-magnetism was also employed in its treatment. But in Dr. Anderson's cases in India of opium poisoning, belladonna was the only remedy used. One of his patients in the course of thirty-six hours had swallowed two ounces of solution of hydrochlorate of morphia for delirium tremens. He was in a state of profoundest narcotism. He was made to swallow a drachm of tincture of belladonna in water every half hour. After the third dose the pupils began to dilate; in four hours and a half he was out of danger, having taken six drachms of the tincture. He also relates a similar case in which an ounce of the tincture in three ounces of water was given between 9 and 9.30 p.m., and in the course of the next half hour two drachms more were taken. At 2 a.m. all indications of opium poisoning had disappeared.

On the other hand, as to belladonna poisoning, Mr. Bell's two cases are most striking. His patient had had a fourth of a grain of sulphate of atropine in solution injected over the sciatic nerve. Its toxical effects in due time declared themselves, and the patient's condition became "altogether alarming," and was without any indication of improvement. A strong solution of morphia was injected into the gluteal region of the opposite side, which happened to be next to the edge of the bed. Almost immediately an improvement was perceptible. In two hours and a half his worst symptoms had disappeared, the next morning he was apparently quite well. The other case was less alarming, but equally displayed the influence of opium as an antidote to belladonna. Nor should the cases recorded by Mr. Seaton, of Leeds, be forgotten, of the ten persons poisoned by eating the ripe berries of the atropa belladonna, in which opium was given with such signal benefit.

REPORTS OF HOSPITAL PRACTICE
IN
MEDICINE AND SURGERY.

GUY'S HOSPITAL.

CASES OF TRICUSPID REGURGITATION.

We have been induced to bring forward the following cases of disease of the tricuspid valves, not so much because, compared with other forms of valvular disease, tricuspid disease has been, and still is believed by many to be rare, but because the following examples appear to illustrate some of the special circumstances under which tricuspid bruit may be produced. Further, they serve to assist in explaining how it happens that while there is good evidence from general symptoms of actual regurgitation through the orifice, yet there is no tricuspid bruit to indicate it:—

Case of Cirrhosis of the Lung, accompanied with Tricuspid Regurgitant Bruit—Death—Autopsy.

(Under the care of Dr. BARLOW.)

Richard B., aged 34, admitted into John Ward October 26, 1864. Occupation of late years a labourer, but in earlier life had been a sailor. His habits had been intemperate, and had been accustomed to drink freely of both beer and spirits. Could not give any account of his family history, other than that he believed his mother had died of dropsy. He left home when twelve years old and went to sea. Nine years ago was in St. Thomas's Hospital for five or six weeks with hæmoptysis, but he recovered from that, and was able to do his work much the same as usual until three weeks ago, when from severe pain over the region of the liver and between the shoulders he was obliged to give up work. Nevertheless he admitted that he had been subject to a cough and more or less shortness of breath, and moreover said that he had been getting thinner of late. He is a strong, powerful built man, and his muscles are apparently fairly nourished; he certainly cannot be said to be particularly thin. Skin moist, not hot; spots of purpura on the arms; face and lips bluish, and become livid on coughing; tongue white and furred; pulse regular; respirations 32. He lies most easily on his left side. Complains of his cough and great shortness of breath. Expectorates a quantity of tenacious mucus streaked with blood.

Physical Signs.—Dulness all over left side, with increased vocal resonance, and crepitation at the left apex. Expiration prolonged over both sides. Heart.—Rhythm regular. A systolic bruit heard with the greatest intensity a little to the left of the ensiform cartilage, but conducted best towards the right; not heard at the base of the heart nor in the axilla. Increased dulness over the hepatic region, accompanied by pain on pressure, and also by pain increased on inspiration. Urine not albuminous, acid reaction, and copious deposit of lithates. Œdema of feet and ankles.

In the clinical books there are full details of the further progress of the case, but want of space compels us to condense our report. He continued in much the same condition for three or four weeks, when symptoms of capillary bronchitis supervened, which seemed to be the immediate cause of death, on December 12.

Autopsy, by Dr. Wilks.—Face bloated and purple; general anasarca moderate in amount; abdomen distended; dulness over the whole of the left chest. Head not examined. Pleura:

Left enormously thickened, the costal unusually so, but the pulmonary was natural over a small part of the lower lobe, where it was to all appearance healthy; there was a circumscribed, keloid-looking patch on the right pleura, thick and puckered; no effusion. The right bronchus was natural; the mucous membrane of the left was of a rich red colour, and as thick as a peach skin; the secondary and all the smaller bronchi were shrunken and gristly, very red within; there were no dilatations. The right lung, though very large, was quite healthy in its texture; there was no emphysema, except a little of the interlobular sort on the diaphragmatic surface. The left lung, at its upper part—in fact, in its whole extent, except a piece the size of a pear—posteriorly, was converted into a gristly mass, which on section showed the cut ends of great vessels and shrivelled tubes, with a great deal of white fibroid tissue. In one or two places there was a piece of seemingly good lung, of the size of a broad bean, left as an islet in the fibrous mass. Glands normal. The heart was very large; left ventricle normal. The right side of the heart was much hypertrophied and dilated; and this was especially true of the auricle. The tricuspid valve was thickened round its edge. The aortic valves were thick, but were not puckered; there were no vegetations. Mitral normal.

In calling attention to this particular bruit, Dr. Barlow remarked that the question in his mind was whether it was due to regurgitation through the tricuspid orifice, or whether it was of exo-cardial origin. Whilst it is difficult to prove that such a bruit is not of exo-cardial origin, yet the following circumstances would favour the idea that it is due to regurgitation through the tricuspid orifice:—First, the point of greatest intensity of the bruit was near the ensiform cartilage, and, although not immediately over the sternum, yet it was conducted better and more distinctly in that direction and more feebly towards the left apex, and was not heard at all in the left axilla, nor at the angle of the left scapula. Secondly, there was visible pulsation in the jugular veins. Then, lastly, there was the evidence of great obstruction through the lungs and a dilated condition of the right side of the heart, as shown by the extreme lividity of the face and the œdema of the feet and ankles. But still, Dr. Barlow remarked, the bruit might have been an exo-cardial one, and one which he was in the habit of calling "a distension murmur." For, he said, the right side of the heart being much dilated, and, perhaps, also there being here (what has been noticed in many such cases) white patches situated especially over the surface of the dilated ventricle, the murmur might have been due to friction – a kind of murmur which, in many cases, it was very difficult to distinguish from an endo-cardial one. It will be remembered that Dr. Barlow, in his Gulstonian Lectures, called the attention of the Profession to some circumstances which seemed to show that many of the so-called "mitral" bruits had not an endo-cardial, but an exo-cardial origin; and Dr. Barlow is still of opinion that not a few of the murmurs which are confidently said to be due to disease of the mitral valves are produced either on the surface of the heart by friction or at the tricuspid orifice by regurgitation.

The second case is of somewhat similar character, and for the notes of it we are indebted to Dr. Wilks. Although it occurred several years ago, it has not been before published.

Chronic Pneumonia (Cirrhosis of the Lung)—Systolic Murmur Heard over the Ensiform Cartilage—Death—Autopsy—Disease of the Tricuspid Valves.

Geo. P., aged 62, a powerful-looking, well-built man, was admitted, October 12, 1859, into Job Ward, under the care of the late Dr. Addison. He was by occupation an engine-driver, and was said to have been troubled with a cough and shortness of breath for more than five years. When admitted he had well-marked physical signs of general bronchitis, with dulness and bronchophony on the right side. There was a systolic bruit, which was heard with greatest intensity towards and over the ensiform cartilage, and feebly conducted towards the left apex and to the left axilla. The patient remained in the Hospital for several weeks, and died November 19. As the chief interest of the case for our present purpose is simply in reference to the physical signs referring to the heart, we give no further details of the life history.

Autopsy by Dr. Wilks.—Body wasted; legs dropsical, and skin having a slightly yellowish shade. Head not examined. Lungs: Right universally adherent, and tissue so tough that the organ had to be cut out of the chest. The lung itself was consolidated from end to end, so that there were only a few portions left which were permeable by air. The pulmonary tissue appeared to be converted into a dense, tough, fibrous tissue, and this so hard that it could not be broken down by the finger. The induration, however, was not yet complete, for it was not uniform, some parts being harder than others, giving the section a knotted appearance, and as if the hardening process had begun in several distinct places at the same time. The colour of the section also was nearly black from a deposition of pigment throughout. There was no softening of any part except at the apex, where a very small cavity existed. The tubes were not much diseased, but at the upper part they were rather large, and their walls were thickened; elsewhere they were not affected. The pulmonary artery was very much diseased. It was, in the first place, considerably dilated, the branches throughout the tissue being much larger than natural. The coats of the vessel were also very much thickened, and the whole inner surface was covered with atheromatous deposits. The vessel, in fact, resembled very much a diseased aorta. Some of the smaller branches were entirely obstructed by ante-mortem coagula, as were also some of the pulmonary veins. In the main pulmonary vessel there was a layer of fibrine closely adherent to the walls of the vessel, and with difficulty separable. The left lung contained some indurated masses, showing the commencement of a similar disease to that in the right. Heart enlarged from hypertrophy of the right side. The auricle was distended and dilated, and ventricle much thickened and much dilated. The edges of the tricuspid were thickened. The left ventricle was of full size, as well as the auricular ventricular opening.

In this case Dr. Wilks stated that Dr. Addison, who did not believe in tricuspid murmurs, considered the murmur to be due to a mitral regurgitation. But from the fact that during life the murmur was heard loudest at the end of the sternum, and gradually diminished in intensity towards the left apex and left axilla, and, again, as the post-mortem examination showed there was no disease at the mitral orifice or valves, but very extensive dilation and hypertrophy of the right ventricle, and also great dilatation of the tricuspid orifice; and, again, that the right auricle was very considerably dilated and attenuated, Dr. Wilks concluded that there was little doubt but that the murmur had been produced by regurgitation through the tricuspid orifice.

Although in each of the above cases it is recorded that there was a systolic bruit heard most distinctly over the right apex, and that the general symptoms showed marked dilatation and hypertrophy of the right side of the heart, yet it is not to be denied that it is far from uncommon to find a great amount of dilatation of the right side of the heart and of the tricuspid orifice without a tricuspid bruit during life. But this difficulty seems to be explicable when we remember that in order that mere dilatation of the ventricle, and consequent widening of the orifice, may be accompanied by a murmur, it appears to be necessary that the regurgitating blood should be propelled backwards with a certain degree of force. This remark is illustrated by dilatation of the other ventricle. In regurgitation through the mitral orifice, there may be no bruit from mere feebleness of the left ventricle.

The histories of the two cases above recorded show that there had been great and persistent obstruction through the lungs for several years, by which the right ventricle had become gradually and at length highly hypertrophied, and in consequence the regurgitant current received a sufficient amount of force to cause bruit. Whereas in cases of chronic bronchitis with emphysema, in which it is not uncommon to find an equal amount of pulmonary obstruction and consequent dilatation of the right side of the heart, there is no tricuspid bruit, for the pulmonary obstruction is not persistent, nor is it continued over such a length of time as in cases like the two related. The same general principle is illustrated by what takes place in nutmeg liver. We have heard Dr. Wilks remark that it is the exception to find a well-marked appearance of nutmeg liver in cases of chronic bronchitis with emphysema for the simple reason that the cause of mechanical congestion constituting nutmeg liver is not persistent, whereas in cases of obstruction at the left side of the heart or of long continued and constant obstruction through the lungs, as in contracted lung after empyema, etc., it is usual to find the liver presenting the nutmeg condition well marked.

According to what has been above remarked, it is quite evident that the class of cases in which we are most likely to meet with tricuspid regurgitant bruit are those of mitral obstruction, of so-called cirrhosis of the lung, of contracted

lung from empyema, of atrophy and imperfect development of the lung arising from such cause as spinal deformity and from general and extensive dilatation of the bronchial tubes with condensation and atrophy of the pulmonary tissue around them and pressure of an aneurism or other intra-thoracic tumour on the pulmonary artery.

But even with evident obstruction in the lungs and with clear compensatory hypertrophy of the right ventricle, it does not necessarily follow that there should be a murmur to indicate the tricuspid regurgitation, for the ventricles may have undergone degenerative change, and may, although of large size, be of but little power.

In illustrating the most usual features of disease, we must carefully attend to the exceptional ones. Although the rule is, as we have said, that there is not enough hypertrophy in the right ventricle in cases of pulmonary obstruction from emphysema and bronchitis to cause a murmur during the regurgitation through the tricuspid orifice, yet now and then we meet with exceptions to this rule. Sometimes the pulmonary obstruction from the cause above mentioned does cause enough hypertrophy of the right ventricle to produce the murmur, and the following is a case in point. Perhaps absolutely there are more cases of tricuspid murmur to be found with emphysema and bronchitis than in the more marked cases of pulmonary obstruction, but we must keep in mind that emphysema and bronchitis are common and the other class of cases rare.

Tricuspid Regurgitant Murmur in a case of Chronic Bronchitis and Emphysema—Death—Autopsy.

(Under the care of Dr. GULL.)

Mary Ann S., aged 58, married woman, admitted April 30, 1864, into Mary's Ward, under the care of Dr. Gull, stated that she had generally enjoyed good health, with the exception of having had seven miscarriages and had once typhus fever, nineteen years ago. She said that two months ago she first noticed that her breath was very short, and that she could not lie down in bed; also a troublesome cough. One month ago her legs began to swell, and have continued so ever since; she suffered much pain in the left side.

Her chief complaint now is shortness of breath and swelling of her legs, and troublesome cough. Her face is blue and congested-looking. Tongue clean; bowels open; small, feeble, but regular pulse. Mucous râles heard all over the chest. No visible impulse between 5th and 6th ribs, over the left apex, but very distinctly seen in the epigastric region.

First sound, under the left nipple, is very feeble and indistinctly heard, and no murmur detected. At the extremity of the ensiform cartilage a loud, well-marked, prolonged systolic bruit is heard, which gradually becomes less and less audible as the left axilla is approached. No bruit heard at either angles of the scapula. Urine scanty and albuminous.

May 3.—Continued much the same.

6th.—Urine albuminous; sp. gr. 1025; legs much more swollen and œdematous. Dr. Gull ordered her legs to be punctured.

12th.—Seems more feeble; pulse slow and feeble; legs much swollen, and on the right leg there is a large purpurous patch, extending from the knee to the ancle.

13th.—She died.

We several times heard Dr. Gull call the attention of the students to the bruit in this case, asking them to contrast it with a mitral murmur in a patient occupying an adjacent bed.

Autopsy, by Dr. Wilks.—Heart small; right side hypertrophied. Right ventricle dilated and walls thickened. Right auricle very large. Tricuspid valve somewhat thickened at edges.

We could, if space permitted, give further cases of this kind.

We wish to draw attention to Dr. Barlow's opinions as to other modes of production of dilatation of the right side of the heart. He thinks that cases in which adhesion of the pericardium has occurred before growth is completed tend to produce it. He records a remarkable case which he had the opportunity of watching for several years. The patient had had pericarditis at the age of twelve years, continued dyspnœa, with slight alleviation at the time when menstruation was established, but with subsequent relapses. The patient died apparently from bronchitis. The autopsy showed small lungs, small trachea, small aorta, and small left side of the heart, but increased size of the pulmonary artery, and enlargement of the right side of the heart, all the valves being perfectly healthy. Dr. Barlow says:—"I would here remark that the adhesions of the pericardium could not have been the immediate cause either of the hypertrophy or the dilatation, since the adhesion was on the surface of the left ventricle, and the hypertrophy and dilatation were almost wholly of the right ventricle and auricle." He further says—"The explanation may be sought in the impediment afforded to the respiratory movements in the ascent and descent of the diaphragm, whereby in the young subject the development of the lungs are impeded."

While we take this opportunity of calling attention to Dr. Barlow's observations, the more general explanation of tricuspid regurgitation following pericarditis will be found, as might be expected, to be due to mitral obstruction.

Dr. Hope and other Physicians conceived that tricuspid regurgitation was comparatively very rare; but of late years the experience of different Physicians has tended to show that it is not nearly so uncommon as was formerly thought. In fact, Dr. Gairdner goes so far as to say—"Tricuspid murmurs you will find, if you examine carefully, to be nearly as common as other murmurs." And from what we have learned from other Physicians and from what we have observed, we have no hesitation in saying that they are not nearly so rare as was formerly thought. While it cannot be denied, as Dr. Gairdner so justly remarks, that this murmur is often difficult to detect and very liable to be confounded with mitral and exocardial murmur, at the same time there appear to be good reasons for thinking that not a few of the so-called mitral regurgitant murmurs are really tricuspid.

A woman, 53 years of age, was admitted under the care of Dr. Gull, November 16. Her case is recorded by the clinical clerk, Mr. Rootes, until December 1, when the report was continued by another gentleman, whose notes are not entered in the clinical book. The patient died several weeks ago.

In the winter of 1863-64 she began to suffer "from her breath," and had a bad cough, which she fancied was brought on by taking cold. The cough got well, but returned last autumn, and for two months she was very ill. She was, however, able to go out nursing, and was thus engaged on November 9 last, on which day she became so ill that she had to be taken home. Two days later she was brought to the Hospital. She had much dyspnœa, cough, and complained of abdominal pain and flatulence. She got little sleep, as she could not lie down at night on account of her breathing. Her expectoration was "purulent, tenacious, and rusty." The nature of the heart sounds are alluded to by Dr. Wilks in the following remarks, and their connexion with the appearances found postmortem is explained:—

CLINICAL REMARKS BY DR. WILKS ON DIRECT MITRAL MURMUR.

Post-mortem Examination.—The body presented most of the well-known appearances of those who have died of heart disease. The lungs were apoplectic; the liver in the condition known as nutmeg, &c. The heart exhibited in a marked degree the characteristics of obstructive mitral disease; the left auricle-ventricular orifice was so narrow that it would only just admit the point of the finger. This was due to the excessive thickening of the curtains and cords of the valve; the right side of the heart was somewhat enlarged; the left ventricle was about its usual size, whilst the left auricle was most enormously dilated, and at the same time its walls very tough and much thickened; the size of this cavity was even greater than appeared when the heart was removed, since the pulmonary veins were much increased in size and added to the capacity of the auricle. It contained a clot which had evidently been forming for some days prior to death.

Dr. Wilks made the following remarks to his class:—This case is of the greatest possible interest in connexion with the diagnosis of a contracted mitral orifice, and proves as nearly to demonstration as circumstances will permit the existence of a bruit produced by the blood passing through the narrow channel from the auricle to the ventricle, or as it is called a direct mitral murmur. In looking at this heart, you will see that every circumstance is present which is requisite for the production of such a sound. We know that fluid passing through a narrow channel is productive of a murmur as in the case of a constricted aortic orifice, and therefore you might feel some surprise at finding that many of the highest authorities have disputed and still dispute the possibility of a murmur occurring under the same circumstances at the mitral orifice. When a mitral valve is defective, it is admitted that a sound may be produced by the regurgitation of blood through it, but in many cases where a sound supposed to be dependent on such a cause has existed there is no proof that the valve has allowed such a flow of blood backwards; in fact, in very many cases, of

which this is an extreme instance, the appearance of the heart would prove the contrary, and thus you should always attentively examine the condition of the cavities in order to form a conclusion as to the interrupted circulation through them. In this instance, the small size of the left ventricle was a sufficient proof that a small amount of blood only had been sent into it, and the whole of this had been transmitted onwards; whereas the immense size of the auricle showed at once the obstruction which had existed to its discharge of blood, just as the bladder is seen to be hypertrophied in stricture of the urethra. Here, then, is clearly a case showing, without any possibility of mistake, that the blood had been driven through a narrow mitral chink with considerable force; also, it is tolerably certain that there was no regurgitation, for the edges of the valve closed well, and the heart was not enlarged in a manner to produce theoretically a pericardial sound. If, then, a bruit was heard, there could scarcely be a doubt that it was produced in the manner suggested by the passage of blood from the auricle to the ventricle, or that it was a direct mitral or systolic auricular murmur. Why, then, has this not been admitted by the highest authorities on cardiac disease? For the explanation we are indebted especially to Dr. Gairdner, who has put the matter in a clear light and shown that we do find a murmur where we should expect one under such circumstances as exist in the present case. The explanation depends upon the more correct method of regarding the heart's action. It had hitherto been supposed that the auricles and ventricles opened and closed alternately, and that it was during the contraction of the aorta and the second sound of the heart that the auricle contracted; consequently it was thought that if a direct mitral occurred it would be heard at the time of the diastolic sound and at the apex of the heart. It was denied that a diastolic mitral was ever heard in this position, and, therefore, that a sound was not produced by the transmission of blood through the auriculo-ventricular orifice. Dr. Gairdner, however, points out that the auricle contracts after the second sound and immediately before the first sound; and, therefore, a direct mitral murmur should be heard immediately preceding the impulse of the heart; that it is presystolic, although previously mistaken for a systolic. If this is proved, it would place the subject at rest. Now, this was done in the present case by Dr. Gull, who distinctly and repeatedly stated to his class that the bruit was presystolic, and that in consequence the mitral orifice was narrowed. Taking, therefore, the positive diagnosis made during life by Dr. Gull and the condition of heart found after death, no reasonable doubt can remain that in this instance the bruit heard was produced in the manner named. I have no doubt that Dr. Gull will afford you all details on the subject in his clinical lecture.

KING'S COLLEGE HOSPITAL.

ANEURISM OF THE AORTA PRESSING UPON THE PULMONARY ARTERY—DEATH—AUTOPSY.

(Under the care of Dr. JOHNSON.)

E. N., aged 38, admitted into King's College Hospital under Dr. Johnson, April 18, 1864. Has been troubled with palpitation of the heart occasionally for the last three months. Has never spat blood. Has pain in the left shoulder at times. Never had rheumatic fever.

Chest large, fairly expansive. Cardiac dulness extended, and lower down than normal. Chest resonant everywhere; respiration rather loud. The apex of the heart beats two inches below the left nipple, and there is pulsation in the scrobiculus. A loud systolic bruit, supposed to be mitral, is heard at the apex. Second sound very weak. Pulse wiry. The bruit is faintly audible behind. No albumen in urine. He is rather hoarse, and has been so for the last three months. Complains of difficulty in swallowing, the food seeming to be pushed to the right side of the œsophagus.

He gradually improved, and was discharged "relieved" on May 11.

Readmitted September 25, 1864. Has not been well since he left the Hospital, suffering from indigestion and palpitation. Dropsy came on a week before his readmission, and has steadily increased. The breathing has become difficult. His work has been light, and he has lived temperately. He now suffers much from dyspnœa. Expiration loud and rather prolonged. Chest resonant everywhere. The loud bruit is still heard at the apex. Pulse 100, small and weak. Since this attack came on his urine has been high coloured and scanty, containing about one-eighth albumen. He complained of pain in the scrobiculus cordis, which was relieved by dry cupping.

He became rather better for some time, but on October 5 his face was more swollen and blue. Bad cough; breath shorter; pulse 104; respiration 24, laboured. No abnormal sounds on auscultation over the lungs. Expectorates very little. Jugular veins distended. Lips blue.

He gradually became worse, without any special change in the symptoms, and died on October 14, 1864.

Autopsy by Dr. Julius Pollock.—The heart was large, the right ventricle being much hypertrophied and dilated, and forming the apex of the heart. The mitral valve was quite natural. The aorta, besides being much diseased and dilated, was pouched into a kind of aneurism into two or three places, and one of the pouches pressed upon and much narrowed the orifice of the pulmonary artery. The lungs were not at all gorged with blood, since probably very little blood could enter them. The bruit, supposed to be mitral, must have been due either to the dilated tricuspid orifice or to the pressure upon the pulmonary artery, probably the former. The liver, spleen, and kidneys were much congested.

SATURDAY, FEBRUARY 25.

THE SUICIDE OF GEORGE VICTOR TOWNLEY.

It is no enviable task, and certainly to us by no means an agreeable one, to revive the discussion of the sanity or mental unsoundness of the suicide and convicted homicide, George Victor Townley. It might be probably considered by some that the verdict of the coroner's inquest, in which this question was necessarily raised, should be left altogether unchallenged. And so, were we writing as mere chroniclers of current events, we should have left it; but, as guardians of scientific truth, we do not see what alternative remains to us, unless we are prepared to accept the sensibilities and instincts of the human heart as the final court of appeal in matters intellectual, where a cruel logic grimly prohibits the employment of any tools but her own in the painful search after such conclusions as she will recognise. The interests of the commonwealth can in no way that we can perceive be forwarded by pursuing the suicide to the grave, and hence we, as members of the commonwealth, should be well content if a verdict implying mental unsoundness were invariably pronounced in such cases. It is so pretty universally, and we concur in its reception, not because we hold a Coroner and a jury of laymen to be competent judges in the matter, but because we concur in the charity which dictates the verdict, —the charity "which thinketh no evil." As mere members of the State we concur also in receiving the verdict in the instance of Townley, notwithstanding that, as men of science, we are about to inquire, in the interests of science, whether the suicide of this man is in itself evidence of his mental unsoundness, and if not, whether there are any proofs that, up to the time of his committing it, he was the subject of any of the recognised forms of mental alienation.

Some stress was laid at the inquest, and at the trial for murder a year and more ago, upon the existence of hereditary predisposition to insanity upon the maternal side, no less than eleven members of the family being reported to have been insane at one period or another. Insanity is a disease, and admittedly an hereditary one; but, as with other hereditary maladies, the fact of its existence in a family is no proof of its existence in any individual member of that family. Hereditariness indicates a tendency, and that is all; and its value in diagnosis is just this, that where other proofs are sufficiently strong to support a diagnosis, it confirms the diagnosis in the minds of the observers. In the instance of insanity we will even go a step further, and say that members of families with such a tendency are not uncommonly eccentric in their modes of thought and conduct. Such eccentricity is the mental parallel to the bodily constitution, which, although not itself disease, we recognise in phthisical families, and designate by the term "temperament." If we adopt this phrase we may say that Townley exhibited the insane temperament in the peculiar ethical doctrines he held, and which we have been told on good authority he maintained during the whole period of his incarceration in Pentonville Prison. But as the bodily temperament most frequently met with in the consumptive is yet not consumption, so this eccentricity of Townley, though indicating his tendency to insanity, was not insanity itself. There are those, no doubt, who will demur to this view of the case, and who will maintain that Townley was "morally insane" on the ground of his differing from most other reasonable men, in the manner he did, upon questions which related to his moral responsibilities and his rights over the lives of other people. But such persons would forget one of the primary definitions in the Euclid of Medicine. A man is not bodily diseased because he differs from other men in the precise manner in which his bodily functions are performed; every man has his peculiarities in this respect which, for him, constitute health. It is the departure from the standard of his own sort of health which constitutes disease. Of course, we put aside here the consideration of congenital abnormalities. So, too, with mental health; a man is not mentally unsound because, from the time when his mind undertook independent action, it ran in a certain peculiar groove of its own somewhat different from that in which the minds of other men run; such persons, like those who have a tendency to phthisis, are proper subjects for preventive Medical art; they should be carefully looked after by their friends. To constitute disease, however, it must appear that the mind either gradually or suddenly departed from its own peculiar groove to run astray into an eccentric course; and, as with bodily disease, a departure from the normal state of the individual usually succeeds the application of some adequate disturbing cause, so too we naturally look for some adequate exciting cause for the mental aberrations of the insane. Throughout all the published evidence before us in the history of Townley, we fail to discover the time when his ethical views were other than they have been since under scientific observation; still less can we discover that such aberration succeeded the application of an adequate cause of mental disorder. The chaplain of the gaol stated that he regarded Townley as "morally insane" because, as at Derby, "he appeared quite insensible of the sin of the crime that he had committed." This argument we have disposed of, and neither the Coroner nor the jury were disposed to admit its validity. When questioned as to whether he had noticed any overt act of insanity, the chaplain replied that the only overt act that he could recognise was the act which terminated in his death. The Coroner very properly at once pointed out that in this he was simply begging the question which the jury was to decide. But the reply of the chaplain is one which we must not pass over, inasmuch as it involves the assumption that suicide is in itself an act resulting from mental unsoundness. No doubt self-preservation is one of the most powerful of human instincts, but that it may become inoperative to control the person who contemplates suicide on what he regards as an adequate motive is indisputable. The well-educated and perfectly sane Chinese mandarin who offends his Emperor commits the act almost as a matter of course, and our own law recognises the moral guilt of the *felo de se*, by the exaction of a barbarous vengeance. It is unnecessary to follow this subject any further. We proceed, therefore, to inquire, upon the basis of the facts in our possession, for the proofs either in the conduct, in the conversation, or in the correspondence of Townley of the existence of a condition of mental disease.

The history of Townley after his removal from Bethlehem was briefly as follows:—He was received at the prison on February 3, 1864. At that time he was in good bodily health, and at no time up to his death did he require Medical aid. The Surgeon of the prison states that during the whole year that intervened he observed nothing which could lead him to suppose that he was insane, and had anything strange in his conduct been observed by the warders or chaplain it would most assuredly have been reported to him. He states that nothing had ever been reported to him tending to show that Townley had any want of control over himself. He always found him cheerful. Townley's weight on admission was 12 stone 6 lb.; but at the periodical inspection of the prisoners in January last it had decreased to 11 stone 1 lb. There was nothing unusual in this; it merely indicated that the period had arrived for allowing him some extra diet, and accordingly 5 oz. extra bread were ordered, for which, on the first occasion that offered, Townley expressed his thanks politely to Mr. Bradley. The evidence of the Rev. Ambrose Sherwin, the chaplain of the gaol, confirmed that of the Surgeon. As a matter of course, he possessed higher opportunities of testing the condition of the prisoner's mind, and, being curious in the matter, he says that he observed him closely, yet could not detect any direct evidence of insanity except insensibility to the sinful nature of the act he had committed. He was always courteous, polite and gentlemanly, and ever ready to enter into conversation. During his incarceration he worked first as a weaver, but latterly as a shoemaker, being unhesitatingly entrusted with the sharp tools used in the latter trade. He was on the eve of being removed to the public works at Portland also, where equally dangerous weapons would have been entrusted to him. All this seems to show that to the minds of the prison authorities Townley possessed as much control over himself as other people in their sane senses, if he chose to exercise it. He was treated, in short, as any other murderer would have been under similar circumstances. On Friday, the 8th inst., letter paper, ruled with lines, was served out to him, and he wrote a letter to his friends. This letter has already appeared in the *Times*, and we refer to it because it has been wisely remarked that latent insanity shows itself more certainly in the correspondence than in either the conduct or conversation of the subject of it. This letter must be admitted to be perfectly coherent, and the only expression at all ambiguous about it is this—"The fact is, mum dear, as is usual with me, I am muddled. I turn my brain inside out, and there is nothing there—stagnant." Little stress, however, can be laid upon these expressions when we read the context—"It is true I find what some people would call kind wishes; but, then, that's all rubbish; so what can I do? I can only give you my best and kindest love, and tell you that I am just as usual—no difference whatever." And then follows an observation which is only confirmatory of the idea that his fatalistic notions still adhered to him—notions which he himself very properly designates as "trite." This letter was stopped by the Governor as written in contravention of the prison regulations, having not been written upon the lines only, but also between them. But he was permitted to write a second letter on Friday, the 10th. In this second letter, which we append to this article, he exhibits signs of mental irritation, comments severely upon the Governor as a man hardened by the office he held, and adds—"What can you expect from a pig but a

grunt?" The only sentences which could be tortured into any evidence of an abnormal mental condition are those in which, with a happy unconsciousness, the murderer criticises the character of the Governor as having lost all vestiges of humanity. On the other hand, it is clear, from the reference to his health, that he regarded his life as a burthen and its continuance a misfortune. The letter was, we understand, submitted by the Governor to the Director of Convict Prisons, who authorised its detention on the ground of its insolent tone. What passed between Townley and the Governor on the occasion of the announcement of the Director's decision did not come out at the inquest; but at the same time no evidence was put forward that during the Saturday or on the Sunday there was any remarkable change in the demeanour of the prisoner. All the chaplain tells us is that Townley was "annoyed;" and probably any other sane prisoner would have been equally annoyed under similar circumstances. He went to chapel in the afternoon of Sunday with his division, and the only unusual event was, that after sitting quietly, as was his wont, through the service, he took up his hymn-book towards the close of the concluding hymn, and sang in a full voice the last two verses. They were appropriate to a person about to die, and he probably knew their tenour from having heard them sung before. One prisoner said he had never heard him sing thus before, but another asserted that he recognised his bass voice as one he had formerly heard, and looked round to see whose it was. All this merely indicates, if it indicates anything, that Townley had made his mind up.

Now, with this history before us, on what hypothesis can he be scientifically regarded as a madman? Let us see. Dr. Tuke is a man of great experience in matters of this kind, and in his excellent work on insanity classifies suicidal mania. First, there is the suicidal monomaniac, whose temptation is to commit suicide as if in virtue of "a force acting automatically and superior to his reason and will." Such persons know that they cannot control themselves in this respect, and often seek to be restrained; moreover, these persons feel impelled to suicide apart from any circumstances reasonably moving them to put themselves out of life. Certainly this sort of insanity finds no example in Townley's case. To a mind ill regulated, as his was, admitting no moral responsibility to a higher being, it is the easiest thing in the world to comprehend what his motive to suicide was, just as it is easy to trace out the motive of the preceding homicide. Annoyance, the crossing of his plans in a manner which he could not rectify, seems to have operated on each occasion in bringing about the catastrophe. He could not and would not submit to what was unavoidable. There is no evidence that he was conscious of an impulse to suicide which he desired to control. Secondly, there is suicide the result of melancholia. There is no evidence of this; all the evidence adduced at the inquest is opposed to this hypothesis. Thirdly, there are the suicides which spring from illusions, hallucinations, etc. These, also, must be set aside in so far as Townley is concerned. Fourthly and lastly, there is suicide as the result of sudden and uncontrollable impulse. And this is the hypothesis put forward at the inquest by those who desired to uphold the theory of insanity; "his friends contend that he was subject to impulsive insanity." But in opposition to this must be placed the miserable truth that the suicide in Townley's case was most distinctly a deliberate act. Had there been no evidence of his having contemplated self-destruction up to the moment of the opportunity afforded by the gallery as he came out of chapel, this explanation of the act might have had some show of reason; but unfortunately there is the fact that Townley had attempted suicide at an earlier period of the day, by a different method, but had failed. He had endeavoured to bleed himself to death by opening three veins in his arms; but either he did not know the depth of the necessary incision, or his courage failed him, or perhaps he was interrupted. What hypothesis remains? God only knows the labyrinth of the human heart. The most experienced psychologist is lost amidst its mazes while he attempts to trace out the association of the thoughts out of which results a single action of the most rational and sane amongst us. How much sooner is he baffled when an abnormal intellect is submitted to his investigation. In this the friends of the unhappy convict may take refuge; it was in this that, however unwittingly, the jury and Coroner took refuge when recording their verdict that Townley's suicide was committed "whilst he was in an unsound state of mind." We have endeavoured to study the position of affairs with the aid of scientific experience; but science is not infallible, and "mercy rejoices over judgment."

TOWNLEY'S SECOND LETTER.

(Copy.)

10th February, 1865.

My dearest Mother,—The cause of the delay is as follows:—1st. Letter paper is now only issued on Wednesdays. 2nd. The governor has thought proper to stop a letter I wrote you last Wednesday, the writing not being to his taste. He also requires me to keep to the lines; which, as it is not specified, I was not likely to do. I am sorry for this extra delay, for I fear you will have been making yourself very uneasy the last two or three days. These sort of petty annoyances, contemptible in themselves, become more serious when they affect you through me, and *vice versâ*, unless, indeed, that be the object. Be this as it may, we must make every allowance for nature and education. One cannot expect good feelings or good taste from those whose very vocation has of necessity stifled whatever vestiges of humanity they may have originally possessed; in fact, to use a vulgar but expressive proverb, "what can you expect from a pig but a grunt?" But I must curtail, ruled lines being the order of the day; so here goes for a *resumé* of my first letter. Your birthday! I am afraid, my own mum, my hopes and wishes are but trash, and I would that my love and gratitude were in any way adequate to repay you for all you have gone through for me; I can only wish my darling mother as many happy returns of the day as possible with such an unlucky wight of a son. If you got the lock of hair I sent you, you must take that as the present. By the way, I did not forget dear Kate's birthday, though I fear she thought so. I had my reasons, though foolish ones. My health is good, as usual, so do not make yourself uneasy about that; besides, it is not of any material consequence to me. Indeed, considered as a life preserver, it may be said to be a nuisance. Many thanks for your last two letters, the carols, and magazines, which the authorities were good enough to let me have. I need not say how glad I am to hear of your meeting with kind friends. I won't say what comes uppermost in my mind, for this reason: I have found the Scotchman's prayer useful: by going on the opposite tack one only puts a stick into the hands of one's fellow Yahoos to break one's own head with, and you see whatever else one loses here one gains experience. About visiting: you must not for a moment think of it, mum dearest, especially now; besides, the mere thought of your being in contact with this place is hateful to me. I have other reasons, but no space. Pardon me, mother dear, the abruptness and apparent unkindness of this, but it must not be; and I can tell you how thankful I am for your even wishing it—I mean your kindness and sacrifice of self. And now I must thank you for the books, especially for "Gil Blas," "Silvio Pellico," and the magazines. "Silvio" I am particularly charmed with; he sometimes reminds me of you. "Gil Blas!" what a nice edition; so sorry you got it purposely, and the magazines." Will not name the others; all very nice." I think I have enough books for the present, and perhaps you had better not send me any more that have to be *returned*, excepting possibly the magazine, but will speak to the Governor on this subject, as well as about leaving the books behind me, etc. I don't think it will be necessary. I have been up before the Doctor for inspection, which, I believe, is a *sign* of going *some time*, though it may be a month or two yet. It is certain that I should not be allowed to write—indeed, there would probably be no time, you never know when you are going, and it would be useless asking. My best love to the dear governor—(I tried "father" at first, but it was "no go," though I am not quite easy about the other; in writing *to* him I should not think of it, but in speaking *of*, it is awkward; this is not lucid, but perhaps you have a glimmer)—also to Charles and Katy. Your letters and hers always make me laugh. I must not forget the dear aunts. Thank Aunt E. for the German, and whoever so

*

kindly did it (Mrs. E'hard?). And Dr. Wash, what of him? Remember all friends. And now, my own mum, good-bye. My letters for the future must be peculiar, as you perceive. Thanks for your dear ones.

Ever, my own mother, your affectionate son,
(Signed) GEO. V. TOWNLEY.

NOTES ON POST-MORTEM EXAMINATION OF GEORGE VICTOR TOWNLEY, FORTY-ONE HOURS AFTER DEATH.

(From a Correspondent.)

Exterior.—Body generally muscular and well nourished. Cadaveric rigidity everywhere strongly marked. Some lividity on posterior portions of trunk and extremities. Face generally tumid, most so on the right side. A bruised appearance above right eyebrow, extending up scalp about 3 inches; also of the lids and round about both eyes. Ecchymosis of conjunctivæ; corneæ flaccid; pupils dilated. Along the course of right eyebrows there is a horizontal cut, which in part reaches quite to the bone; in the rest very nearly to the bone: length, 3 inches. A vertical cut above inner extremity of left eyebrow; length, $\frac{1}{2}$ inch. A vertical cut above outer part of upper lip on right side; length, $\frac{1}{3}$ inch. A horizontal cut in corresponding part below lower lip, right side; length, $\frac{1}{3}$ inch. Blood lying in the hollow of right ear. Blood within both nostrils. Teeth and inside lips and gums stained with blood. Grazes on both knees. Crepitation felt on handling the left knee. In the bend of the right elbow there are two cuts about $\frac{1}{3}$ inch long—one where venesection had been performed by Mr. Bradley in median cephalic vein, the other a line to the outer side of it. On dissection, the latter cut had barely passed through the skin, and had not wounded vein. In bend of left elbow another similar cut over median cephalic vein, but, on dissection, was found not to have wounded it. About 3 inches lower a similar wound or cut over course of radial vein; on dissection, it was found to have passed through skin and to have very slightly wounded the vein. Height of the man, 5 feet, $9\frac{1}{4}$ inches; breadth across shoulders, 18 inches. Measurement of head with a tape—Across vertex from meatus auditorius to meatus, 15 inches; circumferential just above ears, $23\frac{1}{2}$ inches; from occipital protuberance to root of nose, 14 inches.

Head.—Tissue beneath scalp generally infiltrated with blood. Depth of infiltrated portion at vertex, $\frac{1}{4}$ inch. It was thicker more posteriorly. The only part free from it was about an inch above left eyebrow. It was thicker at vertex than more anteriorly. A starred fracture of calvarium. The centre of the star was situated a little to the right of the median line, and about $1\frac{1}{2}$ inch in front of the coronal suture. The rays of the star passed as follows:—One extended forwards and to the left side of root of nose; an offshoot from this about 1 inch long passed to the right side of nose, and this marked off a triangular space over right frontal sinus, where the bone was loose and depressed. Another ray passed forwards to right orbit at inner side of supra-orbital foramen. Another ran in a curved direction for 2 inches outwards towards right ear. Another backwards and towards left side for 5 inches. The principal depression was that over frontal sinus. At the centre of star the fracture gaped to the extent of $\frac{1}{8}$ inch. Coagulum of blood beneath right temporal muscle. Calvarium sawn round and removed. Bones were moderately but not abnormally thin. No glandulæ Pacchionæ discernible. Longitudinal sinus empty, as were other sinuses of dura mater, but not torn. Dura mater healthy. Cavity of arachnoid and upper part of spinal theca contained some drachms of bloody fluid. On right side a coagulum of blood above the tentorium cerebelli. Texture of arachnoid healthy; quite transparent everywhere. Dura mater torn away after removal of brain. Base of Skull.—Cribriform plate of ethmoid bone smashed and crista galli broken off. Roof of both orbits broken up. On left side a long fracture extended from middle of wing of sphenoid to base of petrous portion of temporal bone. On right side bones forming middle fossæ broken up a good deal and fractured in every direction. One large gap extends from carotid canal along anterior border of petrous portion of temporal bone quite to its base, where it curves somewhat upwards.

Brain.—Weight of brain as a whole, $55\frac{1}{2}$ ounces avoirdupois; cerebrum alone, $48\frac{3}{4}$ ounces; cerebellum, pons and medulla oblongata, $6\frac{3}{4}$ ounces. Specific gravity of brain as a whole, 1·042; cerebrum alone, 1·040; cerebellum, etc., 1·048. Laceration of the brain on right side at base of anterior lobe and anterior part of middle lobe. Pia-mater generally infiltrated with blood—most abundantly in the sulci between the convolutions, and between the laminæ of cerebellum. On slicing down the *brain tissue* from above, the white tissue was found to be very white; grey cortical tissue of usual colour. The whiteness of central tissue was evidently due to anæmia, the effect of large effusion of blood. Bloody points few and small. Near anterior extremity of anterior lobe, right side, small spots of interstitial hæmorrhage, extending down to lacerated part at its base, where the hæmorrhagic spots were closer, larger, and more numerous. With the exception of the parts absolutely lacerated, substance of brain was quite firm, but not more so than usual in health and in cold weather at this period after death. Right lateral ventricle contained about one drachm of bloody fluid; left, empty.

Chest.—Organs generally healthy; no fluid in pleuræ or pericardium; heart empty; moderate hypostatic congestion of posterior parts of both lungs; no tubercle or grit at apices.

Abdomen.—Omentum contained a moderate quantity of fat. Peritoneum healthy. Stomach much distended; contained several ounces of brownish black liquid — altered blood; mucous membrane healthy. Intestines slit up in whole length; jejunum contained some matters similar to those in stomach; colon contained some solid fæces; mucous membrane and glandular tissues healthy. Liver—Natural size and appearance, both externally and on section. Spleen small, flabby; no blood flowing on section. Kidneys healthy, except some dark discolouration on section. Behind left kidney cellular tissue showed some moderate effusion of blood. A similar effusion immediately in front of sacrum, behind peritoneum.

Left Knee.—Patella smashed; head of tibia fractured in the joint; considerable effusion of blood into and about the joint.

THE WEEK.

ARMY MEDICAL DEPARTMENT.

SOME seventy or eighty candidates, we understand, made their appearance for the competitive examinations for the Army Medical Service. Whether those gentlemen were in great part intended for the Indian branch of the Service, we do not know; if not, it must be a source of much congratulation to the Director-General and Horse Guards. What will be the effect on the future prospects and present condition of the Army Medical officers, we need not say.

SIR ALEXANDER TAYLOR.

WE inserted last week a paragraph from a recent number of the *London Gazette*, which stated that the Queen had been pleased to confer the honour of Knighthood on Dr. Alexander Taylor. Honours of this kind are not very plenteously bestowed on our Profession, and we have had many inquiries as to the position and claims of the gentleman on whom the distinction has been conferred. Dr. Taylor is a Physician practising at Pau, in the Pyrenees, and is known as the author of a very readable and instructive book on the climate of Pau. He formerly served in the Medical Staff of the British Legion in Spain, under Sir De Lacy Evans. The channel through which the honour descended, and the reasons for which it was awarded, are thus stated in the *Memorial des Pyrenées*:—

"In consequence of an application (unofficial) which the French Ambassador in London made by order of the Emperor to the Government of Her Britannic Majesty, Queen Victoria has been pleased to order letters patent to be made out conferring the dignity of Knight of the United Kingdom of Great Britain and Ireland on Mr. Alexander Taylor, M.D. This high distinction has been accorded to Dr. Taylor by the Queen in recompense for the services rendered by him to his countrymen and to the town of Pau."

PARLIAMENTARY.

IN the House of Commons on Friday, February 17, Mr. Bagwell inquired of the Secretary to the Treasury whether Her Majesty's Government proposed to adopt the resolution of the Select Committee of 1858, and place the Medical officers of Irish Unions on the same footing as similar officers in England and Scotland, one-half of whose salaries were paid from the public revenue.

Mr. F. Peel said that the Committee to which the hon.

gentleman referred seemed to have overlooked the circumstances, that while in England the Government paid but one quarter of the expense of the constabulary, in Ireland it defrayed the whole cost of that force; and that there was a special grant of £20,000 a-year for Hospitals in Dublin and certain officers of county Infirmaries. Except for those considerations, he did not see why the Government should not contribute to the payment of Medical officers of Unions in Ireland in the same way as it did to the payment of those in England and Scotland.

On Monday, February 20, Mr. Hibbert moved for leave to introduce a bill permitting capital punishments to be carried out, under certain regulations, within the interior of prisons. He thought it better that any discussion should take place on the second reading, which he proposed to postpone till some time after Easter.

Sir G. Grey said this question was under the consideration of the commissioners who were inquiring into the subject of capital punishment, and it would be desirable to have their opinion before the bill was read a second time.

Leave was then given to introduce the bill.

Mr. Villiers asked leave to introduce a bill for the better distribution of the charge for the relief of the poor in unions. After some prefatory remarks upon the law of settlement and removal, and its evils; upon the policy of compulsory relief of the poor, and upon the substitution of the union system for the parochial system, which had been attended with great advantage, he pointed out the reason of its comparative failure—namely, the continuance of parochial chargeability. He stated the results of the Act of 1862 in diminishing the evils of removals—results which, in his opinion, justified a further extension of its principle; and there was no proof that it would create any unjust or excessive charge upon the common fund. The bill, therefore, proposed to carry the principle further by making the common fund in future bear the maintenance of all the poor within the union. He dwelt upon the benefits which this change would confer upon the pauper poor, and the enormous evils connected with settlement and removal it would tend to cure, and cited testimonies in favour of the change.

Mr. Henley suggested certain points regarding which, he thought, information was required.

Mr. Locke observed that the bill would be of no advantage to the metropolitan parishes; that union rating would not meet the evils attending the displacements of population there.

Leave was then given to bring in the bill.

On Tuesday the House of Commons rejected by a majority of thirty the Cheltenham and Gloucestershire Water Bill. The object of this measure was to divert 1,000,000 gallons of water *per diem* from the Thames and to take it into the valley of the Severn for the supply of the town of Cheltenham. The good people of Cheltenham are said to have only four gallons of water per head *per diem*, and the water of the Severn is declared to be so completely befouled by the towns, and especially by the dye works, tan works, and other abominations on its banks that it is entirely unfit for use. The defilement of the Severn is only one instance of the spoliation of our rivers and streams which, with the increase of manufactures, has become one of the most crying evils of the age. We hope that before long the House of Commons will be induced to legislate on the subject; but the cool proposal of robbing the source of the Thames for the benefit of a district which has ruined its own water supply was very properly rejected.

Mr. Doulton moved for a Select Committee to inquire into the best means of preserving for the public use the forests, commons, and open spaces in and around the metropolis. The question, he observed, was one which did not admit of delay; the difficulties inherent in the question increased with delay, and unless some course was taken by Parliament with reference to it the question would settle itself by the disappearance of commons and open spaces altogether. His object in moving for a Committee was that the subject should be examined in all its bearings with a regard for public rights without encroaching upon private rights.

Alderman Rose seconded the motion.

Lord Bury replied to a remark of Alderman Rose with reference to the Wimbledon-common Bill. He supported the motion.

The discussion, which embraced collateral topics, was continued by Colonel North, Mr. Jackson, Mr. Locke, Mr. Bentinck, and Mr. Torrens.

Mr. Cowper approved the object of the motion, but protested against any proposal to meet the expenditure out of the Consolidated Fund.

After further discussion, in which Mr. Peacocke, Mr. Shaw-Lefevre, Mr. Marsh, and Mr. Cox took part, the motion was agreed to.

DE LUNATICO.

No Medical man who has not, by some means or other, acquired a knowledge of the Lunacy Acts can, when intervening to save a lunatic patient from the possible consequences of his melancholy state, be satisfied that he may not, in signing a lunacy certificate, sign the warrant for his own committal to prison, or that, on taking his fee, it may not be necessary to put it by as the nest egg of a fund for the payment of heavy costs in an action to be subsequently commenced against him.

Many Medical men have felt so strongly convinced of the risk run by those who sign certificates of lunacy, that, ignoring the loss of the fees which they would thereby obtain, they have from the outset of their Professional career systematically refused to sign such certificates. That they are right as regards their own interests there can be no doubt; but we cannot but think that it is open to grave consideration whether any man is justified in thus withdrawing from the public the benefit of his scientific opinion, which may, in many instances, by authorising the restraint of the lunatic, save him from the unhappy consequences of his own acts.

Only very recently we gave the particulars of a case in which a Medical man had unwittingly involved himself as defendant in an action for assault when interfering for the protection of an alleged lunatic; and of late years many cases more or less similar have occupied public attention, and have justly excited the alarm of the Profession at the risks to which they are exposed when called in by the friends of the insane. It was, undoubtedly, a sense of the risks run by his Professional brethren which caused Dr. Sutherland to express before the Select Committee of the House of Commons, in 1859, a fervent desire for a consolidation of the Lunacy Acts. Such a consolidation does not appear likely to be taken in hand for many Sessions to come, even if it be practicable.

Our attention has been drawn to this important subject by the perusal of a work (a) in which the position of Medical men in this matter is very clearly defined, and by which the practical consolidation of the statutes, so generally desired, has been, in our opinion, most successfully effected. Mr. Danby P. Fry, a barrister of long standing and repute, has given the subject much patient search and labour, and we consider Medical men owe him a debt of gratitude for the service he has done them in rendering in a familiar form the technicalities of the Lunacy Acts, and so arranging them that a rapid reference, even in the hurry of Professional engagements, will enable the Practitioner to ascertain at a glance what he may and what he may not do—what are his powers and what his perils when he is called upon to render Professional assistance to a lunatic patient.

In his preface to the work Mr. Fry says that it has been his desire and study to render it practically useful to all who are in any way concerned or interested in the class of afflicted persons for whom the Lunacy Acts make provision, whether as friends or relatives, or as members of the legal profession, or as justices of the peace, or as guardians of the poor or parish or union officers, or as superintendents or proprietors of public or private asylums, or persons otherwise engaged in the management of those establishments, or in the care of the insane, or *as members of the Medical Profession*, who may be called upon

(a) The Lunacy Acts: containing all the Statutes relating to Private Lunatics, Pauper Lunatics, Criminal Lunatics, Commissions of Lunacy, Public and Private Asylums, and the Commissioners in Lunacy; with an Introductory Commentary; Notes to the Statutes, including References to Decided Cases; and a copious Index. By Danby P. Fry, Esq., of Lincoln's-inn, barrister-at-law. London: Knight and Co., 90, Fleet-street.

at any moment to *give certificates of insanity*, as well as to undertake the care or to regulate the control of the insane, subject to legal in addition to moral responsibility. A very careful perusal of Mr. Fry's pages enables us to say that he has succeeded in realising the promise of his preface; not that the book should be referred to for the purpose of supplying the advice of a solicitor when such is really needed, but to enable the Practitioner to steer clear of the shoals and quicksands by which he is surrounded when he is called upon to deal with the insane.

FROM ABROAD.—THE PROSPERITY OF VICHY—THE BULLETIN DE THÉRAPEUTIQUE—PRIZE QUESTIONS OF THE ACADÉMIE DES SCIENCES.

Some notes derived from a visit made to Vichy last year by Drs. Körte and Göschen, two Berlin Physicians, supply some interesting facts with respect to this fashionable watering-place. Known in the time of the Romans, who had their *aqua calidæ* or *vicus calidus* here, Vichy seems to have been lost sight of as a curative place until the beginning of the seventeenth century, and did not attain any celebrity until the end of the eighteenth. Under the present Emperor, however, it has risen to the rank of the greatest watering-place in the world, as estimated by the number of visitors. These in 1838 were only 1940 in number, and even in 1854 only 6802; while from 13,332 in 1859, they have increased to the immense number of 24,000 in 1864. Everything that is possible, indeed, is done to tempt visitors by rendering their residence at Vichy agreeable and comfortable; and even the prices paid for accommodation are not so unreasonable as in a place of fashionable resort might be expected. Even in the height of the season, July and August, the price of board in the best hotels is only from 7 to 12 francs per diem, while in smaller establishments 5 or 6 francs per diem suffice. Connected now fully with the railway system, the town is easily reached from all sides, being within eight hours from Paris on the one side, and six hours from Lyons on the other. Of late years it has begun to be made also a place of winter residence for invalids, which the mildness of its climate well adapts it for. One great element of the recent and future success of Vichy has been the farming out for forty-one years the administration of its baths and the sales of its waters to a powerful company well provided with capital. By its aid suitable establishments for the comfort and enjoyment of visitors have been erected, and the preparation of the salts and waters for exportation are carried on with great energy. A few figures will give some idea of the activity which now prevails at Vichy, under the general supervision of the Director of the Company, Dr. Callou. During the season of 1863 there were 234,177 baths taken, 26,016 of the number being *gratis*. At the height of the season it is not uncommon for more than 3500 baths to be taken daily, from 12,000 to 13,000 towels and bathing gowns being washed at the washing department. So greatly has the export of Vichy waters increased that in 1863 there were expedited 1,502,940 bottles, together with more than a million boxes of lozenges. Crystallised sweetmeats are soon to be added to the other articles of export. The extent to which the company is carrying expenditure for the provision of reading, billiard, and concert rooms and the like may be judged of by the fact that they are now erecting a new casino which is to cost 1,000,000 francs. Drs. Körte and Göschen both agree that Vichy is a most admirably arranged place, the interests of the bathers and the public in general being far better considered than at the German watering-places.

That well-known bimensual publication, the *Bulletin de Thérapeutique*, has again changed hands in consequence of the death of its able editor and proprietor, M. Debout. Established by M. Miquel in 1831, it soon gained a large circulation, and had become a valuable property when its proprietor, seized with a fatal malady, placed its management in the hands of M. Debout, who from his active habits, love of work, great information, and loyal character was eminently qualified for the task. Debout was so well pleased with the prospects of the journal that in 1848 he purchased it for the handsome sum of 100,000 francs. That the journal did not lose prestige in his hands, and that he successfully made way against the difficulties which old journals have to contend with in the shape of new and vigorous rivals, and the dying off of old and attached subscribers, will be seen from the fact that he succeeded in disposing of it a few days before his death to M. Bricheteau, its future editor, for the 100,000 francs which he had paid for it eighteen years before. The journal, in fact, well deserves its success, for a more valuable repertory of Medical and Surgical therapeutics it would be difficult to find, and the frequency with which it is quoted in the English journals shows the estimation in which it is held in our own country.

The Academy of Sciences has announced the subjects of its magnificent collection of prizes in the mathematical and physical sciences for 1865 and 1866. We must confine our notice to the latter. 1. The Grand Prize (a gold medal 3000 francs in value) in the Physical Sciences for 1865, "The Comparative Anatomy of the Nervous System of Fishes." This prize, first proposed in 1859, has been postponed in 1862 and 1864 to 1865. The question for the same prize in 1866, "The Production of Hybrid Animals by means of Artificial Fecundation," has in like manner been postponed from 1861 and 1863 to 1866. Another Grand Prize of 3000 francs will also be adjudged in 1865, for "the osteographical work which will most contribute to the advancement of French Palæontology, whether by making better known the anatomical characters of one or more types of the vertebrata, and thus furnishing important elements for the study of the tertiary fauna, or by treating in a thorough manner of the fossils belonging to one of the least known classes of this great branch of the animal kingdom." 2. The Montyon Prize in Experimental Physiology, consisting of a gold medal 800 francs in value will be adjudged in 1865 to the author of the manuscript or printed work which appears to the Academy to have most contributed to the progress of experimental physiology. 3. The Montyon Prizes in Medicine and Surgery. The Academy will adjudge one or several prizes to the authors of works or discoveries which shall be regarded as of most utility to the art of healing, or have discovered the means of rendering an insalubrious employment less innocuous. The amount of the recompenses cannot be stated beforehand, the number to be rewarded not being known; but sufficient funds have been left by the testator to afford ample recognition of merit and to compensate for labour and expenses incurred. 4. The Academy Prize in Medicine and Surgery of 5000 francs, will be adjudged in 1866 for the best memoir on "The Application of Electricity to Therapeutics." 5. The grand prize in Surgery for 1866 of 20,000 francs has for its subject "The Preservation of the Limbs by the Preservation of the Periosteum." 6. The Cuvier prize of 1500 francs, to be adjudged in 1866, will be given to the author of the most remarkable work which has appeared between January 1, 1863, and December 31, 1865, either upon the Animal Kingdom or Geology. 7. The Bordin prize of a gold medal, 3000 francs in value, has been postponed from 1861 and 1863 to 1866, the subject being "Determine by anatomical investigation whether there exists in the stems of plants characters proper to the great natural families, and in accordance with those derived from the organs of reproduction." The Bordin prize for 1865, of the same value, "Determine experimentally the causes of the inequality of the absorption by different plants of the saline solutions of various natures contained in the soil, and ascertain by an anatomical examination of the roots the relations which may exist between the tissues that constitute them and the matters which they absorb or excrete." 8. The Breant prize of 100,000 francs will be adjudged in 1865 to the

discoverer of a cure for the Asiatic cholera. Awaiting the "coming man," the interest of this sum is available for rewarding those who may have most advanced our scientific knowledge with respect to cholera or other epidemic diseases. 9. The Jecker prize will be awarded in 1865 to he who has most accelerated the progress of organic chemistry. 10. The Barbier prize of 2000 francs is an annual award for whoever may have made a valuable discovery in Surgical, Medical, or Pharmaceutical knowledge, or in Botany in relation to the Healing Art. 11. The Godard prize for 1865, being the interest on 1000 francs, will be given for the best memoir on the Anatomy, Physiology, and Pathology of the Genito-urinary Organs. 12. The Savigny prize, being the interest of 20,000 francs, will in 1866 be awarded in aid of young travelling zoologists.

A KNOTTY POINT IN THE DIAGNOSIS OF SYPHILIS AND THE CURATIVE(?) EFFECTS OF SYPHILISATION.

(From a Correspondent.)

THE *Edinburgh Medical Journal* lately contained an interesting and important paper upon the curative effects of syphilisation. It was alleged that two patients suffering from very severe forms of constitutional syphilis were cured by Dr. Boeck by the above process. It so happened that one of these patients had been under Mr. Henry Lee for some time. Mr. Lee entertained the conviction that this patient was not, and never had, laboured under syphilis at all. He appears to have arrived at that conclusion chiefly from the consideration that no constitutional manifestations had appeared for some six years, when the patient in question exhibited the symptoms of the bone disease, for which he underwent syphilisation; and he conceived that the pus from an indurated sore could not have been used by Dr. Boeck, or the patient would have contracted a true syphilis. Mr. Lee finds a corroboration of his opinion in the fact that the father of the patient is said to have died of a "softening of the bones." To this Professor Simpson has replied on the part of his son—who was the author of the paper in the *Edinburgh Medical Journal*—in the pages of the *British Medical Journal*, where the correspondence has been carried on, that those Medical men who saw the primary disease entertained no doubt of its nature then, that others—including the Professor himself—equally thought the patient labouring under tertiary syphilis, before he went to Dr. Boeck. In addition to this positive observation he attempts to show that the non-appearance of secondaries does occasionally take place. Here the matter rests until Dr. Boeck's statements appear as to the source of the pus he used.

It must be a bold man who would venture to interpose a work on the subject; still, some important points have been lost sight of, it seems to us, in this correspondence between Mr. Henry Lee and Professor Simpson.

For example:—(1) On the interval of six years. Unquestionably, if this primary disease were untreated by any mercury and this period elapsed before the appearance of *any* general symptoms, then, the very great improbability and the extreme rarity of such an occurrence would suggest the idea that the nature of that primary affection was misinterpreted; for in every case where there have been opportunities for observing the course of syphilis, secondaries have appeared generally within five or eight weeks, and invariably within six months. But it seems to be taken for granted that in this case no such manifestations appeared, because none were observed. Secondary manifestations have been so mild in some cases that if the patients had not been in Hospital or under the daily inspection of a Surgeon, they might never have been observed; and it is a common thing for men, from ignorance, to deny the presence of any secondary symptoms when their persons bear unequivocal marks of the same. It is more than possible, therefore, that if the patient in question were actually syphilitic, some secondary symptoms did appear, but were not observed. (2) It seems that both father and son suffered from some affection of the bones—a softening of the bones! If this affection were the product of an *acquired* syphilis in the former, it *might* have been the effect of an *inherited* taint in the latter. Of course this is hypothesis only; but should it be proved ultimately that a remote and hereditary syphilitic taint could effect modifications in the degree and evolution of any subsequent attack, this will account for the non-appearance or slight manifestations of secondary symptoms in the first instance and subsequently, even if the artificial inoculations should turn out to have been made by Dr. Boeck with the pus of indurated sores.

If this hypothesis be a correct one, Dr. Simpson would be right in assuming that the patient had syphilis, and Mr. Lee might be right in assuming that no such disease had been acquired through the observed primary sore or, subsequently, through the artificial ones.

REPORT ON CHEAP WINE.—NO. XIII.

(By our Special Empirical Commissioner.)

(Continued from page 179.)

A Few More Hungarian Wines—Teteny, Diasi, etc.

IN order to do full and equal justice to all parties, I wish this week to mention a few additional Hungarian wines, *ex. gra.* :—

Red Tetenyi at 18s. I did not like this. It had a perfume of raspberries, and seemed too thin and acid.

Red Diasi, price 32s., bottles included, from M. Diosy, 123, Fenchurch-street. Very cheap for the money, satisfactory, soft, smooth, grapy wine. Alcoholic strength about 21·5.

Red Visontai, 1854, at 36s., from M. Diosy. This, like most other of the best wines, is said to be from the cellar of the Convent. Alcoholic strength about 27. This is a wine of striking character, dry, sub-austere, of potent vinosity; might pass for very light dry port.

White Tetenyi, 18s., from M. Diosy. A peculiarly nice grapy, well-flavoured, appetising wine. Very cheap indeed. It is said to be sometimes put into little brown flasks with handles, and sold at a high price as Stein Wein.

White Ruszti at 42s. Sweet, and undergoing transformation which might result in a delicious wine some years hence, but scarcely wholesome now. Sp. gr. 991; alcoholic strength about 27.

Bakator Muskat at 32s., and *White Diasi* at 36s., from M. Diosy, are grapy, muscat-flavoured, white wines.

Somlo', from the Bishop of Veszprém; price 60s., from M. Diosy, is a very delicate, fine-flavoured, first-class wine; well deserving the attention of the connoisseurs who do not hesitate to give from 5s. to 10s. per bottle for "Hock" for the earlier part of their dinners.

Tokay nearly white, from M. Diosy, at half-a-guinea a bottle; and Szamorodny, or *Dry Tokay*, from the same dealer, are wines which more than bear out what I have said before of their marvellous flavour. I learn that the word Szamorodny signifies "self-born," indicative of the spontaneity, vigour, and naturalness of the wine.

Dealers in French wines are Legion, and are well known and established; the Hungarian, Greek, and Austrian dealers are few, and as they are but beginning the honourable task of introducing the products of their native countries into England, and have to face an active set of competitors already in the field, it is right that they should be made known to the Medical Profession, through whom alone a salutary reform in the drinking customs of the country can be effected, and who alone can break through the prevalent superstition in favour of brandied wines and the fear of "acidity."

The following paper will refer again to Port and Sherry and their counterfeits, with a short notice of Oxford and Cambridge Wine, and Hospital Wine; possibly also Cheap Sparkling Wine.

SCHOLARSHIPS FOR NATURAL SCIENCE AT SIDNEY COLLEGE, CAMBRIDGE.—Among other Scholarships to be competed for at this College on October 10 next, are two of the value of £40 each annually, for Natural Science—electricity, chemistry, geology, anatomy; an intelligent knowledge of any one or two of which, added to a fair knowledge of classics and mathematics, would probably ensure a Scholarship. It may be held with another Scholarship if the candidate be fortunate enough to obtain another. Information, however, is to be obtained from the Rev. J. C. W. Ellis, tutor of the College.

THE ROYAL SOCIETY.—The President of the Royal Society will have *soirées* on the 11th of next month and on May 6, at Burlington House, Piccadilly.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF BATH.

(Continued from page 182.)

THE SCIENCE HISTORY OF THE BATH WATERS.

To few subjects have more extended labours been devoted than to the natural and science history of the waters of Bath. My friend Dr. Falconer, the present worthy representative of that distinguished name, has with great labour brought together two volumes, still unpublished, including merely the titles with short comments of the works that have been issued on this topic. He has been kind enough to place these volumes at my disposal, and a most valuable though formidable repertory of facts they present. The first writer seems to have been William Turner, M.D., Dean of Wells, who published a work first in Latin and afterwards in English in the year 1557. In 1562 the same author brought out a second volume in the black letter on the names and virtues of herbes, to which was joined a booke of the bath of Baeth in England and the vertues of the same. In 1568 a third part appears to have been added to the work. Turner was of opinion that the virtue of the waters lay in the brimstone which he presumed they held in solution. Turner was soon followed by other writers, who dwelt on various questions relating to the physical, the chemical, and the medicinal properties of the waters. The task would be too long, and the result I fear too barren, to allow of any attempt in this place to introduce an analysis of half that has been written. I shall, therefore, instead of following any chronological order, refer merely to the prevailing opinions and the facts that have been expressed:—1st. As regards the origin of the waters and their natural heat; 2ndly. As to their chemical properties; and 3rdly. As to the value which has been attached to them in respect to their therapeutical action.

The Origin of the Waters and the Cause of their Heat.

In the course of the seventeenth and the eighteenth centuries the prevailing idea as to the origin of the Bath waters and the cause of their heat was very primitive, simple, and not altogether wanting in scientific ingenuity. The supposed source of the water was rain, which distilled through two neighbouring hills, the hills of Claverton and Lansdown. It was assumed that from the supply derived from the Claverton Hill sulphureous constituents were obtained, while the water derived from the Lansdown mountain took up and conveyed ferruginous constituents. These two streams meeting in the valley beneath in subterranean caverns were the waters of Bath. The hypothesis respecting the cause of the warmth of the water was to the effect that as a due mixture of iron filings and sulphur, in water, produced heat by fermentation, so the two waters from Claverton and Lansdown meeting in the valley under the earth underwent there the necessary fermentation, and the hot water that rose from the springs was the result. I need scarcely add that this hypothesis is now exploded; indeed, it is proved, as I shall show, that there is in fact very little iron in the waters, certainly not sufficient to account for the development of heat on the supposition above described.

In course of time the hypothesis gave way, and the waters were held to be of volcanic origin, the volcano being presumed to exist beneath the point whence the streams issue from the earth. Later still the natural internal heat of the earth acting upon water derived from some deep source has been adduced as the cause of the phenomenon. Dr. Falconer writing four years ago supports this view. He says "it is more reasonable to attribute the heat of the Bath waters to a cause, to which both thermal and natural springs and volcanos may be satisfactorily referred, namely, the central heat of the earth."(a)

Within the last twelve months the question of the origin and the heat of the waters of Bath has received exposition from two of the ablest minds of the day: I mean Sir Charles Lyell and Dr. Daubeny. In his Presidential address delivered before the British Association for the Advancement of Science, last year in Bath, Sir Charles Lyell dwelt at length, and with wonderful clearness, on the cause of the constant eruption of water, which for so many centuries has been seen at Aquæ Solis. Sir Charles leans to the volcanic theory, and describes the issue of water as of the nature of a volcano absolutely. According to his view we have only to imagine the water rising into the air as clouds of vapour, and to suppose the eruption to be intermittent instead of constant, and the analogy is perfect. The springs or fountains of Bath are then easily defined as volcanoes of water issuing from a crater. The objection that might be urged against this beautiful and novel view is that, in the rise of the hot spring, that power does not seem at first sight to be presented by which vast masses of solid matter in the form of lava are thrown out when such mountains as Vesuvius or Etna belch forth their currents. To meet this objection, Sir Charles calls attention to the fact that the quantity of solid matter brought up by the waters is really, in the aggregate, enormous. He tells us Professor Ramsay has calculated that if the sulphates of lime and of soda, and the chlorides of sodium and magnesium, and the other mineral ingredients which the waters of Bath contain, were solidified, they would form in one year a square column, nine feet in diameter, and not less than 140 feet in height. All this matter, argues the writer, is now quietly conveyed by a stream of limpid water, in an invisible form, to the Avon, and by the Avon to the sea. "But if instead of being thus removed it were deposited around the orifice of the eruption, like the siliceous layers which encrust the circular basin of an Icelandic geyser, we should soon see a considerable cone built up with a crater in the middle; and if the action of the spring were intermittent, so that ten or twenty years should elapse between the periods when solid matter was emitted, or an interval of three centuries—as in the case of Vesuvius between 1306 and 1631—the discharge would be on so grand a scale as to afford no mean object of comparison with the intermittent outpourings of a volcano."

Perhaps the only difficulty that can be suggested, and that with great caution, against this beautiful and simple argument, lies in the one word *if*, which Sir Charles Lyell has introduced into the above quotation. It may be said, and with some justice, that the actual distinction between a volcanic eruption and the flow of water from the earth at Bath is—that the volcanic eruption is intermittent, while the waterflow is steady and continuous. The physical difference in the forces producing an intermittent and a continuous current may be conceived, not without reason, to be distinct and special; the first sudden, explosive, and, I had almost said, accidental; the second steady, and, as it were, a part of a continuous process going on in the bowels of the earth.

At the same meeting of the British Association for the Advancement of Science, Dr. Daubeny, in a remarkable paper, gave a different and original reading of the heating and raising of the waters. Dr. Daubeny's hypothesis is founded on the fact that nitrogen is evolved from the water in the free state. Whence, then, the nitrogen? It may, according to Bischoff, be derived from the decomposition of organic matter in the earth. It is, at the same time, scarcely probable that the supply of the gas would be so steady and so continuous as it is at Bath if the source were an accumulation of organic substance. Dr. Daubeny, therefore, is of opinion that the nitrogen is originally derived from the atmospheric air. He thinks that rain-water, which contains atmospheric air, in its descent through the earth, carries with it the oxygen and nitrogen of the air, but that low down in the earth's crust the oxygen, which we all know is held in very feeble combination with the nitrogen, is given up to substances eager for it, viz., to the metallic substances and to the non-metallic elements, such as phosphorus and sulphur; that the nitrogen is thus set free, and is forced upwards either by pressure of gas or by the heat—the same heat that causes the high temperature of the waters themselves. This theory, which is exceedingly rich in suggestion, opens up a wider field of thought than may appear on a hasty glance; it bears, in fact, as its learned author shows, on the first chemical changes which occurred in and on the earth. When the planet was a diffused vapour, held so by intense heat, it would be impossible for chemical combinations to occur at all; as the mass cooled down, there would be a point at last reached when the natural affinities between bodies would be exerted. In the gaseous condition all the elements present would be equally diffused; then, as cooling went on, the heavier elements would coalesce, first perhaps into a liquid, and afterwards in a denser form. At this point the influence of gravitation would be felt, and the heavier and lighter parts would be separated and laid down in concentric zones. The inner zones would consist of the metallic elements,

(a) Falconer on the "Baths of Bath." London: Simpkin and Marshall. 1860.

the outer ones of those of which water and hydrochloric acid are made up, and of those gases which produce the most external covering—the atmospheric sea. These external parts, reacting upon each other, and upon alkaline and earthy bases coming within their attraction, would generate the waters of the ocean and the salts contained in the ocean, while the redundant oxygen mixing with the negative and free nitrogen would constitute the atmospheric envelope in which we live and breathe. The atmosphere formed in the manner thus depicted, chemical changes on the surface of the earth would be inevitable, inasmuch as the oxygen of the air would be exposed to numerous substances for which it had much greater affinity than for nitrogen. But the change would not be confined to the surface; in time air and water would each penetrate into the earth, and then, whenever materials were met with which would take up oxygen, chemical action would ensue.

Carrying out this theory, Dr. Daubeny supposes that the processes which marked the occurrence of chemical changes on the earth's surface, and beneath its surface at the first, continue still; and in the production of the heated waters of Bath and other places he sees at work nothing more and nothing less than oxidation under the earth, generation of force, and upheaval of liquid collected at some point in open communication with what may be called the crater, through which the water issues so persistently.

In these brief descriptions I have included all that I can reasonably offer respecting the origin and cause of the heat of the Bath waters. Of the suggestions noticed, that of Dr. Daubeny seems to be most reasonable, but it does not fix the position of the vast chasm in which the great chemical changes are developed, neither does it say where the water finds its way into the earth.

The Physical and Chemical Nature of the Waters.

The waters of Bath come from four springs, and are received into the baths, which I shall describe in the sequel, only from these heads of supply. The water as it is fresh to hand is not to my taste pleasant; it is saltish and sharp, and creates a slight nausea. I was told that this unpleasantness would pass away in time after continued use, and I think the fourth and last dose was not quite so unpalatable as the first.

The temperature of the waters is very nearly the same—in the Hot Bath it is 120° F., in the King's Bath 117°, and in the Cross Bath 104°. Dr. Falconer gives the subjoined table of comparison of the waters of Bath with those of the thermal springs of other watering-places:—

Bath, Hot Bath, 120° F.	Vichy, 109° F.
Bath, King's Bath, 117° F.	Bath, Kingston Baths, 108° F.
Borcetta, 171° F.	
Wiesbaden, 158° F.	Bath, Cross Bath, 104° F.
Baden Baden, 153° F.	Warmbrunn, 99° F.
Aix-la-Chapelle, 130° F.	Pfeffers, 99° F.
Cauterets, 122° F.	Wildbad, 98° F.
Toplitz, 121° F.	Aigues Chaudes, 95° F.
Gastein, 120° F.	Schlangenbad, 88° F.

The annexed table gives the analysis of the waters of the Corporation Baths: the analysis was made from the King's bath:—

In an Imperial Gallon. 70,000 grs.	Phillips, 1806.	Scudamore, 1820.	Walcker, 1829.	Noad, 1844.	Merck & Galloway, 1848.
Carbonate of lime	7·680	5·280	10·667	—	8·820
Carbonate of magnesia	—	—	—	—	0·329
Carbonate of oxide of iron	0·274	0·200	0·243	0·521	1·071
Carbonate of soda	—	—	—	5·760	—
Sulphate of lime	86·400	98·320	81·624	96·240	80·052
Sulphate of potassa	—	—	2·927	—	4·641
Sulphate of soda	14·400	1·520	19 371	—	19·229
Chloride of sodium	31·680	12·240	15·122	27·456	12·642
Chloride of magnesium	—	15·360	13·339	7·142	14·581
Alumina	—	—	0·150	—	—
Silicic acid	1·960	1·920	3·233	3·360	2·982
	142·394	134·840	146·676	140·479	144·018
Quantity directly observed	144·125	—	147·622	149·072	—
Carbonic acid	11·25 c. i.	—	7·60 c. i.	—	26·45 c. i. at 115° F.

Of the gases evolved, viz., carbonic acid, nitrogen, and oxygen, Dr. Daubeny states, from direct analysis, that a variable quantity, rising sometimes as high as 13 per cent. of the whole, but in general amounting to 4·5, consists of carbonic acid, and 95 or 96 per cent. of the constituents of the atmospheric air; but the proportions of the two gases which enter into the composition of the atmosphere is very different from what is met in the air; in air, the oxygen exists in the proportion of 20·81, and the nitrogen as 79·19; but as evolved from the Bath waters, the proportions of these gases stand as oxygen 4 and nitrogen 96; the oxygen lost, according to Dr. Daubeny, has been used up under the earth in combining with oxidizable matter. The exact composition is stated thus:—Carbonic acid, 4·5; oxygen, 3·8; nitrogen, 91·7 (95·5); total, 100. Speaking of the water which supplies the King's and Queen's bath, the same author said that the spring which furnishes the supply, the most copious of any, discharges 128 gallons of water, or, in round numbers (reckoning 277 cubic inches to the gallon), 34,900 cubic inches per minute. Of this water, 100 cubic inches disengaged after long boiling 3½ cubic inches of air, yielding on analysis 2·9 cubic inches of carbonic acid, 0·4 of nitrogen, and 0·2 of oxygen; so that there is present in 34,900 cubic inches of the water 1012 of carbonic acid, 140 of nitrogen, and 70 of oxygen. These quantities, when added to the free gases disengaged from the spring, give the following totals:—Carbonic acid, 1024; nitrogen, 385; oxygen, 80; in all, 1489 cubic inches of gaseous substance. In a pint of the water there is present about three cubic inches of carbonic acid gas; the water, therefore, is sparkling, and, I had almost said, effervescent.

Professor Roscoe has recently discovered, by means of spectrum analysis, copper, strontium, and lithium in the Bath waters; and Merck and Galloway have found iodine and manganese. The iodine, however, is in such infinitesimal quantities, that it can hardly be noticed as a constituent; the same remarks apply, to the copper, the strontium, the lithium, and the manganese, and even to iron, which, though present, is in such minute proportions as to render accurate calculation of quantity impossible.

The specific gravity of the waters is 1·002.

(To be continued.)

De l' Ovariotomè. Par E. Kœberlé, Professeur Agrégé à la Faculté de Médicine de Strasbourg, &c. Pp. 88.

Opérations d' Ovariotomè. Par E. Kœberlé. Avec Six Planches Lithographiées. Paris: J. B. Baillière et Fils. 1865. Pp. 152.

On Ovariotomy. By E. Kœberlé, Fellow of the Faculty of Medicine of Strasburgh.

Operations of Ovariotomy. By E. Kœberlé. Paris: J. B. Baillière and Son. 1865.

The titles of these volumes sufficiently indicate their purpose. In one of them M. Kœberlé treats of the operation of ovariotomy, giving its history and statistics, the objections brought against it and the arguments in its favour, its indications and its contra-indications, and its prognosis. The other volume purports to be a simple detail of the cases in which M. Kœberlé has himself performed ovariotomy. In the historical sketch, an analysis of the well-known case of Laumonier, of Rouen, is given. In 1781, Laumonier performed gastrotomy on account of an abdominal tumour; the great bulk of the tumour was found to be due to a purulent collection in the Fallopian tube, but the ovary was enlarged to the size of a hen's egg, and was consequently twisted off. If this account of the case be the correct one, then Laumonier has the credit of having been the first to extract a diseased ovary, although, to be sure, he did it by chance. M. Kœberlé, of course, shows how much the present position of ovariotomy is due to English Surgeons, and he is rather unnecessarily acrimonious in referring to the different degrees of success with which the operation has met on the Continent and in Great Britain. It is not our intention to follow M. Kœberlé through his first volume, but we may give succinctly what he considers to be the contra-indications to ovariotomy.

They are,—(1.) All concomitant diseases necessarily fatal in a short time, and any condition of the patient (anæmic, for instance) which may have an unfavourable influence on the results of operation contra-indicate it. (2.) Small ovarian tumours causing no symptoms ought to be left alone. (3.) Suspicion of the tumour being of a cancerous nature contra-indicates operation. (4.) Extensive adhesions, especially if they be old, and therefore vascular. (5.) Great feebleness of the general health. (6.) Hectic fever, especially if the result of previous tapping; and (7.) Indocility of the patient, are all contra-indications. (8.) Patients in whom eructations are

difficult are generally unfavourable subjects, as in them tympanitis sets in after operation. (9.) When the disease is of long standing, and the patient has had attacks of peritonitis, we must expect adhesions. If the patient is old, and the progress of the disease slow, no operation must be performed; on the other hand, if the patient is young, the tumour must be extirpated at once, even although its progress is slow, as by operating early we have a better chance of success. (10.) When the neck of the womb is high and the tumour fills the cavity of the pelvis, there usually exist adhesions, which render the operation very laborious or impracticable. (11.) Too large a tumour is objectionable, even when it is unilocular. (12.) Ovariotomy must not be performed during the course of any epidemic. (13.) If the diagnosis is doubtful, the treatment must proceed on the supposition that the most unfavourable theory is the correct one. (14.) Pregnancy, or a suspicion that it may exist, contra-indicates the operation.

On turning to the introduction to his second volume, we find that between June, 1862, and June, 1864, M. Kœberlé has performed ovariotomy twelve times. All the operations have taken place at a *maison de sante*, situated in a faubourg close to the fortifications of Strasbourg, and which, the author is at some pains to inform us, is very far from being exceptionally healthy.

In the operation itself, which is always performed in a heated room, and while the patient is under chloroform, M. Kœberlé stands upon the right side; he makes the incision as short as is compatible with the extraction of the tumour; he evacuates cysts by means of a large trocar, and he takes care that no fluid falls into the peritoneal cavity. He is most particular as to the cleanness of his sponges, insisting that the water in which they are washed should previously be boiled, so as to destroy any animacules which it may contain. In sponging the peritoneal cavity free from blood, M. Kœberlé never washes the sponge which he uses, but merely squeezes it. He is of opinion that the small quantity of blood which is thus left in the abdominal cavity is useful, gluing the intestines to each other and to the abdominal wall, and thus provisionally performing the duty of the adhesions which are soon to replace it. When the pedicle of the tumour is long enough to permit of its being brought to the surface, a clamp is used which its inventor regards as superior to all others. It is a kind of forceps, the blades of which are separable, and are united by means of the ordinary lock of the French midwifery forceps. The part of the blade which is applied to the pedicle is in the form of a hook, the concavity looking inwards, and as the two hooks override each other, they necessarily enclose an oval space, which may be diminished at will by pressing the handles of the forceps together. In order to make the pressure continuous, a long screw can be passed from a socket in the right handle to another in the left; when the screw is turned the handles are necessarily pulled together or separated at pleasure. Attached to the convexity of each of the hooks is a flat iron ring about an inch and a-half in diameter, meant to prevent the instrument from slipping altogether into the wound. When the pedicle is too short to bring to the surface, M. Kœberlé ties it with iron wire, which is tightened by means of a *serre-nœud*, of whose mechanism we have a familiar instance in the ordinary wire écraseur. The *serre-nœud* is left attached, and the lower portion of the wound is kept open, while an attempt is made to carry off the pus by means of drainage tubes. In order to isolate the putrefying stump as much as possible, and to diminish the chances of purulent absorption, a sort of bivalve speculum made of lead and bent to the proper curves, is slipped over the *serre-nœud* and pushed down into the wound, so that the pedicle is, as it were, contained in a leaden cup, which separates it from the edges of the abdominal wound. The sutures for uniting the edges of the abdominal incision are of iron wire; the deep ones are quilled, and do not implicate the peritoneum; the superficial ones are twisted. No plaster is used. M. Kœberlé sometimes remains and compresses the abdomen manually for some hours; sometimes he places lateral bags of bran so as to press the abdomen together, and avoid any strain upon the ligatures. He believes in the beneficial action of pressure and of cold, and is in the habit of heaping three pounds of ice upon the patient's belly and keeping it there for days. Once he continued this treatment for eleven days after the operation. Still, his patient recovered. The end of the pedicle which is outside of the clamp or ligature, and therefore destined to mortify, is covered over with strong solution of the perchloride of iron, which has the effect of completely mummifying it. It is further dressed with solution of sulphate of iron, of whose disinfecting powers M. Kœberlé thinks very highly. When the sutures are removed they are replaced by the somewhat complicated process of gumming a row of threads to the skin on each side of the wound, and tying together those which are opposite. It is difficult to see what advantage this has over the far more simple plan of using strips of plaster; but perhaps the plaster might interfere with the ice treatment. Acetate of ammonia is freely given, and acetate of morphia when required. The patients are permitted to eat and drink, if so minded.

In his preface, M. Kœberlé informs us that he has performed ovariotomy twelve times, and has only had three deaths. On analysing the cases, however, it appears that two cases of incomplete ovariotomy and one case of extirpation of the uterus are included. There are nine cases of completed ovariotomy, and of these three died, giving a mortality of one in three cases. The right ovary alone was diseased in five, or if we include a doubtful case—that, namely, in which the uterus was excised—in six cases; the left ovary was the only one diseased in a single case; and in the remaining five both ovaries were affected. Of the five double ovariotomies three were completed, and of these two died; two were left incomplete, and the patients recovered.

M. Kœberlé's first case was a tolerably simple one: the pedicle was long enough for the clamp to be used, and the patient recovered. The second case was a difficult one, with extensive adhesions, and disease of both ovaries. The ligature, bivalve speculum, and drainage tubes were employed, and the patient ultimately recovered health, although now (three and a-half years after the performance of the operation) a drainage tube is still necessary in the fistula which remains. In the third case, both of the ovaries were diseased, the mass of the tumour being formed by the left ovary. Adhesions were very extensive; the right ovary was left untouched; and a ligature was put round the left ovary above its intimate adhesions to the rectum and uterus. Two thick pins were made to transfix the walls of the cysts, so as to keep it outside. The protruding part was well coated with muriate of iron, and drainage tubes were placed all round it. On the eighth day a canula was introduced through the centre of the ligature into that part of the cyst which was left in the abdomen, and three to four ounces of brownish-coloured, sour-smelling fluid were evacuated. On the thirtieth day, the suppuration being very abundant, iodine was injected. At the end of the second month a narrow fistula more than two inches deep still remained.

In the fourth case the pedicle was short, and a silk ligature was used. The ligature came away on the 11th day. On the 12th day the patient discovered that she was bleeding from the stump. Perchloride of iron had no effect, but the hæmorrhage was arrested by plugging the wound and applying pressure. Next day the bleeding recommenced, and on the 14th day M. Kœberlé was obliged to reopen the wound and tie the ovarian artery. The patient recovered, although a small fistula seems to have persisted at the lower angle of the wound.

In the fifth case the patient was 38 years of age and predisposed to hæmorrhage; the pedicle was short, and was therefore tied, the little bivalve speculum or dilator was used, and the abdomen was as usual kept covered with ice. The patient did not rally well after the operation, the pulse never rising above 75. She seemed, however, tending towards recovery, when at seven o'clock on the morning of the fourth day she suddenly became pale, burst out into a cold perspiration, and died in a few minutes. The post-mortem examination showed that there was no peritonitis of any consequence, nor was there fibrinous coagulation in the heart; the right lung was, however, intensely congested, and the right pleura contained eight or nine ounces of uncoagulated blood. M. Kœberlé concludes that the patient died of hæmorrhage, to which she was predisposed, and that the chloroform, cold caught during the operation, and the pressure on the belly, all conduced to the congestion which caused the hæmorrhage.

It seems to us that M. Kœberlé need invoke neither the action of the chloroform nor the cooling of the patient. Numerous facts have shown that after ovariotomy there is often a great tendency to apoplexy. The course of the circulation has been disturbed, blood is no longer required for the nutrition of the mass which has been removed, and for the moment the probability is that a state of true plethora exists. The plethora sometimes relieves itself by epistaxis, sometimes by a flow of blood from the womb; but if this relief be not afforded the lungs are often attacked,

and bronchitis sets in, occasionally accompanied with a little bloody expectoration. The effect of piling three pounds of ice upon the abdomen, and keeping it there, is necessarily to throw the mass of blood upon the thoracic viscera. The congestion becomes excessive, a blood-vessel gives way, and the patient, whose life is already trembling in the balance, sinks without chance of escape.

The sixth case is the one in which the uterus and both ovaries were extirpated. A strong, nervous woman, 31 years of age, had been married six years, and dated the commencement of her troubles from a miscarriage which occurred soon after the marriage. She soon observed a tumour in the abdomen, and she consulted many Medical men as to its nature, which, however, still remained doubtful. For two years before the lady came to M. Kœberlé, the tumour had increased rapidly, until at length it reached several inches above the umbilicus. Menstruation continued normal and regular, and the general health was very satisfactory. The patient, however, wished her tumour removed, and M. Kœberlé determined to operate. The tumour was found to consist of a fibroid outgrowth from the fundus of the womb: the pedicle was tied, and the tumour excised. It then appeared that there was a little fibrous nodule in the substance of the womb, and that the right ovary was somewhat larger than its fellow. M. Kœberlé therefore transfixed the cervix uteri, and tied doubly with iron wire in such a way as to embrace the ovarian vessels in the ligature. The whole of the womb and both ovaries were then removed. The ordinary treatment with ice, perchloride of iron and drainage tubes, was adopted, and the patient recovered.

We do not pretend to judge whether M. Kœberlé ought to have been contented with removing the tumour, or whether he was justified in unsexing the patient. His own defence of the major operation is, however, so good that we translate it literally, only premising that, according to M. Kœberlé's own showing, the simple removal of the tumour was a very much easier and safer operation than the other. At page 92 he says:—

"The patient has been practically cured of her tumour, and effectually guarded against any relapse by the amputation of the uterus. She need no longer fear any of those infirmities, so frequent in women, which have their origin in the womb—such, for instance, as leucorrhœa, polypi, hæmorrhage, prolapse. The extirpation of the ovaries, which had already been rendered useless by the existence of the large fibroid, which necessarily prevented the normal evolution of pregnancy, has relieved the patient of her menstrual periods, and of all the inconveniences connected with them, as well as from the diseases which spring from the ovaries themselves."

As these arguments apply with equal force to the healthy female, we can only conclude that M. Kœberlé regards the whole sexual organisation of the female as a mistake and a nuisance, which is to be removed at the earliest opportunity.

In the seventh case both ovaries were removed; one pedicle was ligatured, the other secured in a clamp. Tympanitis came on on the fourth day, and was treated by purgatives; the pulse gradully rose, and the patient died on the seventh day.

In the eighth case both ovaries were diseased, and adhesions in the pelvis were so extensive that a large multilocular mass had to be kept *in situ*. The wound was kept open, and for eight days the womb and the peristaltic motions of the intestine were visible. On the twenty-third day the patient was able to walk, but she died of cancer six months later.

In the ninth case both ovaries were removed, and the patient sank on the fourth day with symptoms of blood poisoning. In the tenth case the wire ligature was used, and the patient recovered. In the eleventh the ligature was also used, uterine colic came on immediately after the operation, and was combated by chloroform inhalation. The patient recovered. The last case was also successful; in it the clamp was used.

We have given this brief summary of M. Kœberlé's cases, because we are convinced that very few will care to read them in the original. M. Kœberlé has not the faculty of seizing the chief points of a case, and allowing secondary details to form the background of the picture. He has not studied perspective as applied to reporting, and consequently a mass of irrelevant matter is detailed with a verbosity which seriously impairs the value of the book. M. Kœberlé is certainly entitled to considerable praise in having given ovariotomy a fair footing in France. We think, however, that we detect in his style a certain arrogance which is scarcely worthy of a scientific inquirer. One of the deaths among his ovariotomy cases he directly lays to the charge of a colleague, while another he imputes to the obstinacy of the patient herself.

M. Kœberlé's successes have brought him great renown in his native country. After his second operation the Academy of Medicine voted him a sum of money from funds left by M. Barbier for discoverers of a cure for a disease previously considered incurable, or for a near approach to such a discovery. M. Kœberlé has also, we believe, been enrolled in the Legion of Honour.

When we consider the indiscriminate distribution of decorations in France, we may be tempted to agree with Metternich, that it is "*bien distingué*" not to possess one; but it certainly appears to us that some public recognition ought to be given to those who have signally improved the art of Medicine in its wider sense. In England we have no Academy of Medicine to pass votes of thanks or of approbation. The Medical man cannot, like the Churchman or the lawyer, look forward to a seat in the House of Lords. The only distinction to which he may aspire is to be allowed to enter a military order as a sort of supernumerary; and even this distinction has as yet been conferred for bureaucratic services rather than for scientific attainments. Until the system of life peerages has been extended to the Medical Profession, it will always be looked upon by a majority of the youthful population as standing on a lower level than law or divinity. It rests with Medical men themselves to say whether this disability is to be permanent.

It is certainly most unjust that, while national honours are heaped upon those who have distinguished themselves by military courage or by political talents, no public recognition is given to men who have been pre-eminently benefactors to humanity. A tardy and insufficient tribute has, it is true, been paid to the discoverer of vaccination; but there live at this moment men in our Profession who have done as much to deserve public gratitude as did Jenner. There are great men now alive who have robbed Operative Surgery of half its horrors by abolishing its pain; and there are those who have manfully overcome every opposition which prejudice threw in their way, and have triumphantly rescued one disease from the black list marked incurable. We believe that those men are themselves sufficiently repaid by the inward consciousness of having been pre-eminently useful to their fellow-men, and having added to the sum of human knowledge. But for the sake of others, and especially for the sake of those still hesitating as to the profession which they will embrace, it is extremely desirable that some tangible evidence should be given that the nation appreciates the sacrifices daily and hourly made by those who devote their energies and their talents to the promotion of its physical well-being.

FOREIGN CORRESPONDENCE.

GERMANY.

Berlin, February 3.

A discussion on diphtheria, which took place at a recent meeting of the Medical Society of Berlin, was sufficiently interesting to deserve being communicated to you, as Professor Virchow, Von Graefe, and other authorities took a prominent part in it. A paper was read by Dr. Veit, in which the author intended to prove that the morbid processes designated as croup and diphtheria were not so widely different as many pathological Anatomists and Professors of Clinical Medicine believed, since there was one common feature to both, viz., fibrinous exudation; and that it would therefore be better if we called the disease pharyngitis or laryngitis exudativa, and specified it according to the nature of the effusion as croupous or diphtheritic. As regards treatment, he recommended chiefly small pieces of ice to be taken every two or three minutes. In the discussion which followed, Prof. Virchow said that, previous to his having laid stress upon the difference between croupous and diphtheritic effusions, Rokitansky and the Vienna school had confounded the two under the name of croupous, while the French school had called them both diphtheritic. Both names had reference to the presence of a false membrane. There were, however, differences between the two conditions, as in one set of affections there were loose membranes adhering to the surface, and which might be easily be removed. Such affections had been associated with the name of croup, and it was, therefore, necessary to show that croup was very different from the pathological processes which

Brétonneau had observed in the mucous membrane of the throat, and his successors in that of the genitals and other membranes, for in the latter there was not mere deposition of a simple loose membrane capable of being at once separated from the surface without breach of continuity, but a process was going on in the very substance of the mucous membrane, and which resulted in ulceration, so that the false membrane could only come off in the course of some days. He was even now of opinion that this separation of the two processes was not only justifiable, but important in a pathological as in a clinical point of view, for the Medical Practitioner would always have to ask himself the question whether the process was one of gangrenous ulceration with breach of surface, or one where the surface was only covered with a loose, false membrane, but remained itself intact. He believed it would be best to confine the name of croup to the special affection of the larynx, and to distinguish its different degrees as catarrhalic, fibrinous, and diphtheritic. With regard to the pharynx, there was no such difference, as he had never yet observed free fibrinous false membranes on the surface of the pharynx and the tonsils; there was, therefore, no croupous angina or pharyngitis. The name of croup was, therefore, more a clinical than an anatomical expression; it represented anatomically three different pathological processes, which might exist together in the same person. Thus it was by no means rare that there was true diphtheritis in the pharynx and the upper part of the larynx including the vocal cords, while below these latter there were loose membranes which it was easy to separate, and further down ordinary catarrh, which might be set down as bronchitis. If, therefore, the name of croup were given up, and the gradual differences of the pathological process were to receive separate names, it would be impossible to get on with that in practice. "Croup" did not only mean certain anatomical peculiarities, but also a series of functional disturbances. Croupous catarrh was distinguished from simple laryngeal catarrh, not so much by anatomical criteria, but by the peculiar nervous symptoms observed during life. That the former was a more severe affection might also be shown anatomically, as there was swelling not only of the neighbouring glands, but also of the glands surrounding the jugular vein, and in grave forms of the disease even affections of the spleen, liver, and kidneys.

Professor Virchow then made some remarks about the pathological and clinical designations of disease. He said that there must always be a certain discrepancy between the two, as pathological anatomy had only to do with local processes; clinical medicine, however, with general conditions. Thus, in the same epidemic of cholera there might be cases which were, anatomically speaking, such of catarrh of the intestines, while others were such of true dyptheritis of the bowel. In certain cases of dysentery there was a dyphtheritic process, while in others there was nothing of the kind; and there were cases of intestinal diphtheria without dysentery. It would, therefore, be best to retain the old expressions giving the characteristic feature of the disease, while the minor features of it might be designated according to anatomical peculiarities. If every disease were reduced to local anatomical changes there would be great confusion, as there might be different stages, one passing into the other. By cashiering all the old clinical expressions all etiology would be lost, and we should no longer be able to group together diseases which have a common cause. In croup there would be positive danger in doing so, since cases of true croup might be anatomically nothing but laryngeal catarrh; and yet there was a danger inherent to these cases not at all peculiar to common laryngitis. In the same manner apoplexy was only a clinical, but not an anatomical conception. Apoplexy meant a sudden cessation of function, and more especially of that of the brain. This, however, did not give us any anatomical notions, since apoplexy was not merely caused by rupture of blood-vessels, but also by emboli, etc. If people talked of apoplexy of the lungs or the muscles, meaning with that hæmorrhage into these organs without cessation of function, confusion was produced. It was better to preserve the meaning of the word "apoplexy," physiologically and clinically, and to separate its different forms according to their anatomical nature—as hæmorrhagic, embolic, anæmic apoplexy, etc. If hæmorrhage were identified with apoplexy, this would be contrary to the facts, as hæmorrhage into the brain often occurred without causing the symptoms of apoplexy.

Professor von Graefe said that the type of croupous and diphtheritic diseases was very different, although they occasionally merged one into the other. He did not agree with Dr. Veit as to the effused fibrine being the connecting-link between the two. There was no effusion of fibrine in diphtheritic ophthalmia; in such affections there was only formation of pus and of a fine granular mass. Blennorrhœa might, by infection, cause croupous and diphtheritic processes in the eye, and diphtheria might produce blennorrhœa and croupous affections. The degree of contagiosity was, however, different, diphtheria being the most contagious.

Most of your readers will remember a series of experiments which were some years ago made by Signor Polli, of Milan, with hyposulphites, and the results of which seemed to prove that these salts possessed a special power in arresting putrefaction in the system. Signor Polli experimented with the hyposulphites of magnesia, soda, potash, and lime, and recommended them for typhoid fever, scarlatina, small-pox, septicæmia, and pyæmia. Professor C. O. Weber, of Bonn, who is at present occupied with very comprehensive experiments on inflammation, fever, putrefaction, etc., has quite recently repeated some of Polli's experiments, and has been, to a certain extent, as successful as the Italian physiologist. He gave two grammes of the hyposulphite of soda, for three days consecutively, to a large rabbit, and on the fourth day he injected a drachm of water, containing half a minim of sulphuretted hydrogen water, into the crural vein; twice this dose had, in a previous experiment, killed a cat. In the rabbit just mentioned, however, there was nothing wrong but accelerated respiration; it took food the same day, and moved freely about. There were no changes in the animal temperature. The animal now took for four succeeding days two grammes of the hyposulphite per diem, and was very well with it. The next day two drachms of water, containing two and a-half minims of sulphuretted hydrogen water, were injected, but caused no bad effects, while half that dose in another rabbit had caused convulsions and involuntary evacuations. The former animal continued cheerful, and took again one gramme of the hyposulphite. A fresh injection of $6\frac{2}{3}$ minims four days afterwards only caused rapid respiration; otherwise the rabbit was very well. Four days after, ten drops were injected, again causing rapid respiration and some sluggishness, but nothing further. The day after, however, the animal appeared decidedly unwell; it sat in a corner, and seemed to have the "blues." Respiration was accelerated; two and a-half grammes of the hyposulphite were given him the same day, but from that time nothing further was done. The animal ate, but became much emaciated, and partly lost its hair, so that its appearance was anything but prepossessing: it, however, appeared to be in pretty good spirits. The fæces were covered with mucus. About three weeks afterwards it was found dead. The post-mortem showed a moderate intestinal catarrh, but nothing else. There can be no doubt that the animal was essentially protected from the deleterious effects of sulphuretted hydrogen by the hyposulphite; and it would most likely have entirely recovered if the latter had been continued. Some other experiments with dogs, in whom putrid pus was injected, the hyposulphite having been administered for some days previously, were not so successful, as the animals died in spite of it; but perhaps a larger dose of the remedy might have had more effect. The hyposulphites are quite innocuous, their only unpleasant effects being slight diarrhœa.

I conclude by giving you the results of some of the experiments of Professor Weber on fever and inflammation. He found that if fresh, putrid, or dried-up pus was injected either into the subcutaneous cellular tissue or in the pleural cavity of animals, local inflammation and fever were produced. The latter, however, was not dependent upon the former, since it began immediately after injection, and reached its maximum a few hours afterwards. The effects of fresh, warm pus were chiefly striking. After the injection of such the temperature rose from 2° to 4° within an hour or two, more especially if it was injected in the pleural cavity. By repeating such injections artificial hectic fever might be caused. The loss of body-weight in consequence of this was far greater than could be accounted for by the withdrawal of food, which such animals instinctively refused. A fasting dog loses, according to the researches of Bischof and Voit about 1·8 per cent. of his body-weight per diem, while this loss in artificially produced fever amounts to 4 per cent. and more. What is called "Surgical fever," and which is a consequence of the injury caused, generally only sets in about the third day after injection. If pus is filtered, and the serum injected, the effects are much the same as with non-filtered pus, although not quite so striking. Professor Weber concludes from those

observations that in Surgical fever, pyæmia, and septicæmia, the blood is infected by the pus as by a ferment, and obtains "pyrogonous" (fever-producing) qualities. In order to test this supposition by experiment, defibrinised arterial and venous blood of such animals was injected into others; but without producing more fever or inflammation than might be readily accounted for by the injury. While in the experiments with pus the temperature increased 2° or 4°, in those with blood it only rose about 0·6° to 0·9°, and this was only the case on the third or fourth day after injection. Pus and other exudation fluids, if directly injected into the blood, have the same effects as if injected into the cellular tissue; but the rise of temperature appears to be a little higher in the former than it is in the latter. This increase is not at all due to the metastatic inflammations which are sometimes caused by emboli, or to the diffuse inflammation of the mucous membrane of the intestines, or to pleuritis and iritis, which latter are of very rare occurrence; for these only show their effects some days afterwards. If there is, however, violent diarrhœa, the temperature soon decreases; and this steadily goes on until death, just as in cholera. Embolism has nothing to do with this; for if small globules of wax are injected into the blood the temperature does not decrease. An emulsion of fat injected into a cat caused its death in a few hours, with simultaneous depression of temperature from 102° to 96°·8.

Diluted sulphuretted hydrogen water injected in the veins caused the temperature to increase immediately. After the injection of sulphuret of ammonium into the blood, the temperature rose for a time, but was afterwards diminished. Butyric acid seemed to cause the most marked diminution of temperature. In a cat in which ♏ 2½ of butyric acid, with one drachm of water, were injected, the temperature fell from 102° to 85° within five hours; and the animal died the following night. If the blood of such animals, in which pus injection had caused fever, was directly injected into the veins of other animals, fever was also caused in these latter. The temperature rose within a few hours by 2°5, which was accompanied with acceleration of the pulse. In one such experiment, however, there ensued violent diarrhœa and considerable diminution of temperature, which may perhaps have been due to the destruction of blood globules, which was shown to have occurred to a large extent.

It therefore seemed probable that in every inflammation the blood receives substances which produce fever as ferments would do. The blood of men suffering from inflammation could not be used in experiments tending to elucidate this point, as M. Panum has shown that the blood of one species is poison for another. Inflammation was, therefore, artificially caused in dogs, in order to exclude such errors. A fracture was produced and a good deal irritated, for the purpose of producing febrile reaction. Blood taken from such an animal, and injected into the veins of another, caused invariably a considerable increase of temperature, which sometimes even went beyond that of the animal first experimented upon. Fluid expressed from the lungs of a man who died of pneumonia was injected, after having been well filtered, and caused febrile symptoms. Even where there was originally no fever, but only rapid degeneration of tissue, fever could be artificially produced. Thus, it is known that after section of the vagi animals get inflammation of the lungs, but no fever. Blood taken from a dog thus treated caused fever in another. The same result was obtained with the blood of a dog who had been poisoned by cantharidine, but had had no fever previous to death. Fibrine is not the vehicle of fever in such cases, for in all these experiments fibrine had been separated from the blood. The quantity of blood injected having always been a small one when compared to the body-weight—viz., from three to eight drachms, its action certainly resembles that of a ferment. These experiments explain why fever is so very violent in certain diseases where the quantity of ferment passing into the blood is large, as, for instance, in peritonitis and acute rheumatic inflammation of the joints; at the same time, they give us a clue why it is that in other affections metastatic inflammation may be caused without the intermedium of emboli; as, for instance, endo- and pericarditis from rheumatic fever, parotitis from orchitis, and inflammation of serous membranes from pyæmia and septicæmia.

The Marquis of Westminster has presented the very handsome sum of £200 to the Great Northern Hospital, Caledonian-road.

GENERAL CORRESPONDENCE.

DR. BENCE JONES ON DIABETES.

Letter from Dr. Williams.

[To the Editor of the Medical Times and Gazette.]

Sir,—In the very interesting lecture on diabetes by Dr. Bence Jones, published in your periodical dated January 28, is the following sentence:—"The increased flow of urine produced by the diuretic action of the sugar compensates for the imperfect filtration effected by the diseased cortical structure of the kidneys, and for years I have watched the diabetes stationary or lessening, or occasionally disappearing, whilst the Bright's disease slowly increases and causes its secondary or tertiary symptoms, which gradually destroy the patient." Allow me to say that a private patient whom I have attended during the last four years died a few days ago. Her case illustrates precisely Dr. Bence Jones's experience as to the sequence of Bright's disease on diabetes and their contemporaneous existence, but with a slight variation as to the relative action of the maladies, which, although a provincial Physician, I may be excused for specifying. It is this:—Instead of "the increased flow of urine compensating for the imperfect filtration effected by the diseased cortical structure of the kidneys," I found that the diabetic urine, passed in excess for two years, although still rich in sugar, became gradually reduced in quantity; in fact, there was the same amount of sugar minus the diuresis, the other indications (cataract among the number) remaining as they were. At the end of the two years I tested for renal mischief, and discovered traces of albumen, which gradually augmented until the fatal issue, which was preceded by anasarca, bronchial congestion, somnolence, etc. The secretion of urine steadily diminished, and death was attributed to Bright's disease alone, which in this instance prevented not only the superabundant flow usually characterising glucosuria, but, notwithstanding the permanence of that condition, was productive of actual suppression. It is needless to point out the extreme importance, diagnostic and prognostic, of this complication and the practical difficulties associated with it. I will only add that my patient, a lady aged 66, did not lose flesh (although exceedingly stout) during any part of her illness.

I am, &c.

Philip H. Williams, M.D., M.R.C.P.L.

Worcester, February, 1865.

TREATMENT OF SYPHILIS BY ARSENIC.

Letter from Mr. Gaskoin.

[To the Editor of the Medical Times and Gazette.]

Sir,—I have had my attention directed to the following cases, which have excited much local interest. As I believe them to be of sufficient importance for more extended publication, I forward them to you with that view. I am, &c.

G. Gaskoin.

Pustular Syphilis treated by Mercury and Ioduret of Potassium without Alleviation of Symptoms—subsequent Recovery of Health under Arsenic.—(From the Clinique of Sr. J. A. da Silva, Surgeon 10th Infantry, Permanent Military Hospital, Lisbon.)

J. E., farrier, 3rd Company, No. 11, Cavalry 2, with chancres on the end of the prepuce and phymosis, of lymphatic temperament, 21 years of age. This patient came into Hospital December 18, 1862. The chancres were classed as hard, and the inflammation proved tedious in its duration. On December 30 the proto-ioduret of mercury was prescribed. On January 16, 1863, there appeared on the patient a general cutaneous eruption of papules and dark red maculæ, the chancres remaining as before. On the 21st of the same month he had conjunctivitis in the globe and lids of the left eye, which yielded to antiphlogistic and astringent topical remedies. On February 12 the cutaneous eruption assumed a pustular form, and small ulcers of a syphilitic character appeared on the patient's legs. His chancres were at this time healed. Ordered to continue the medicine, and to use plain water baths. By May 1 the eruption had increased; the proto-ioduret of mercury was, therefore, discontinued, and the prescription was changed to ioduret of potassium in the compound sarsaparilla syrup of Cuisinier. Ten days subse-

quently the patient's health was not improved. A consultation on the case occasioned his removal to a ward of different hygienic conditions; the ioduret of potassium to be continued, with substitution of the syrup of Gibert (deuto-ioduret of mercury) for the sarsaparilla syrup. On June 20, notwithstanding that the general health had improved, the cutaneous eruption was undiminished. General baths were superadded to the treatment. Embarrassed by the refractoriness of the symptoms, the Surgeon in charge recommended that the patient should join the detachment departing at this time of the year for the springs of Caldas da Rainha. This recommendation was approved of by the Health Committee. We are informed, however, that after the fifth bath the patient was obliged to abandon their use, from a febrile attack of some intensity, which lasted several days, and left the ulcers larger and deeper than before. A marked asthenia ensued on this attack, and he was too feeble to accompany the soldiers on their return to quarters. When he arrived at Lisbon, as late as October 24, he was in the condition following. He had yellowish-white incrustations largely and equally distributed over the surface of the body, but more of them in the face than elsewhere; on the removal of the crusts there appeared extensive ulcerations of some depth, possessing all the character of syphilitic ulcers; his general health was somewhat improved. All along during his stay at the springs he had been under strict Medical surveillance. In reflecting on the efficiency of the mercurial treatment in this case, I could not but call to mind the success which attends the use of arsenic in skin affections, hence I was led to attempt the cure by that line of treatment. I began by prescribing two milligrammes of arsenious acid, to be taken daily in divided doses dissolved in a decoction of sarsaparilla. The result was most satisfactory; the crusts became detached; the ulcers progressed towards cicatrisation, and left merely copper-coloured stains. On November 22 I suspended the medicine, finding that the patient had difficulty in passing urine, with forcing pains at the neck of the bladder; this inconvenience, however, lasted but a few days, being removed by fomentations.

On December 2 I renewed the use of the arsenical preparation, and on the 21st of the month the patient was considered cured. He was referred to the *Junta da Saude*, and by them excused from further military service.

The result of the case before us is extremely satisfactory. By the time he received benefit from the arsenic he had already been a year in Hospital. Subsequently to this happy result obtained by me, certain of our colleagues have employed a similar treatment in cases of consecutive syphilis with equally advantageous results. I have myself more recently found occasion to prescribe arsenious acid for a patient with syphilitic ulcers in the legs after I had found that mercurial treatment had failed to make any impression. And in this case fifteen days' treatment by arsenious acid, prescribed identically as above, was sufficient to change the character of the symptoms, and the man got perfectly well.

Pustular Syphilis—accompanied by Other Symptoms of Syphilitic Infection—no Improvement under Ioduret of Potassium or Mercurial Preparations—Cure established by Means of Arsenic.—(From the Clinique of Sr. Dr. F. de Sousa de Castello Branco, Lisbon.)

J. C. B., an infantry corporal, of sanguineo-lymphatic temperament and deteriorated *physique*. Has been in Hospital since September 26, 1863, suffering from an inveterate syphilitic affection, characterised by us as pustular syphilide. The patient has suffered on repeated occasions from primaries: he now appears with ulcers, which are concealed by more or less firm and adherent crusts. They are seen on the body generally, but especially on the face, where several of the ulcers by their union form large incrustations, and implicate no insignificant amount of surface. The integument bordering on the ulcers is of reddish brown or mauve colour. There is a large excavated ulcer in the throat, which occupies the posterior wall of the pharynx impeding deglutition. In the long bones, especially of the lower limbs, he has pains of an acute character, with night exacerbations, accompanied by febrile reactions which denote irritation in the gastric tract. My predecessor in this clinique had submitted the patient to anti-syphilitic treatment by ioduret of potassium, in doses at first of twelve grains, and subsequently of twenty-four grains daily. It was found necessary to suspend the medicine from time to time as contraindicated by the condition of the *primæ viæ*, and we substituted for it the syrup of iodurated deuto-ioduret of mercury of Gibert: at the same time we prescribed for the throat the use of corrosive sublimate in gargles of a compound decoction of hemlock, with opiated fomentations to the limbs.

Notwithstanding the employment of these therapeutic means for the period of two months and a-half, the patient experienced no real alleviation; every flattering expectation of improvement was followed by speedy exacerbation of the disorder. Under these circumstances, and having in view the successes detailed above in the practice of our colleague, Sr. Silva, I determined to submit the patient to the therapeutic use of arsenic. Accordingly, omitting all mercurials, on the 3rd of December I prescribed one milligramme of arsenious acid to be taken in a pint of decoction of sarsa. daily. A large amount of relief was, so to speak, immediate. The ulcers showed a tendency to close and heal; in the face there was a diminution in the red brown colour, which had stained the nose, and formed a border to the superficial incrustations existing there. These last very speedily began to detach themselves, the throat also took on a more favourable appearance; the osteoscopic pains had in some measure ceased; there was appetite for food, the general condition was more promising, and everything encouraged the hope that the sufferings of the patient, previously so refractory and resistent, would yield eventually to the means employed. Two milligrammes of arsenious acid were now administered daily in the same amount of decoction as above. On the 20th of the month the incrustations had fallen, leaving parts of the skin strongly marked with a bronze colour; the pharynx inclined to heal, and the patient swallowed much better; the pains, too, in the bones were nearly gone. We now ventured to raise the dose of arsenious acid to five milligrammes, in divided doses, daily. On the 26th of the same month the patient was completely cured, only some marks of bronze stains remained to show where the ulcers had been. All medicines were omitted on the following day, and he was allowed a slight term of indulgence for convalescence.

The remedy was all along excellently well borne, without irritation of any kind. Under experience of so positive a result in the above case and of that related by my colleague, I cannot but express a decided opinion that arsenic should be more generally employed in treatment of inveterate forms of syphilis, especially if, as sometimes will occur, all other therapeutic means have been exhausted.—From the *Escholiaste Medico*, No. 230, A.D. 1864.

THE PRODUCTION OF AN INVERTED IMAGE BY A CONVEX LENS.

LETTER FROM DR. W. ZEHENDER.

[To the Editor of the Medical Times and Gazette.]

SIR,—When I read the first letter of Mr. John Cresswell, published in your valuable journal (No. 751, 1864), about the production of an inverted image by a convex lens, I was much astonished to learn that one of the best established optical statements could be denied. I also, like Mr. Cresswell, had devoted a fair share of my leisure to the study of optics, and flattered myself, like him, that I had some knowledge of that science; but if it is true what Mr. Cresswell tells us about the situation of the inverted image produced by a convex lens, all we know about optics is erroneous.

Though Mr. Laurence, to whom the objection was addressed, had answered in a very polite style, and in a manner that was fitted to convince everybody, Mr. Cresswell tells us in a second letter (No. 754) that he has again carefully tried to see the inverted image in the focal point, but that to his eye it always "appears painted on the lens."

I pray you, Sir, to ask Mr. Cresswell whether he has ever tried to see the inverted image with both his eyes (binocularly). I am very sure that if he would endeavour to do so he would soon retract his most extraordinary statement. Indeed, it is a well-known fact, and I am afraid Mr. Cresswell will think it also one of those of which every schoolboy is aware, that, seeing with both eyes, we are much more fit to judge of distances than closing the one and seeing but with the other. Everybody knows that it is rather difficult to snuff a candle, looking at it with only one eye, because we are not able to ascertain exactly the distance of it. Do not you think so? Well, close one of your eyes, and let another man hold a candle without your seeing at what distance it is held, and try to snuff it with one eye closed. I think you will not very quickly succeed.

Now, look at the inverted image of a convex lens with both eyes. I suppose it will appear to you double in the first moment; you can only see alternately each one of these two images clearly and distinctly; you cannot judge exactly about the distance at which it appears to you to be; but cross now your visual lines at the focal point of the lens, and try to unite the two images in a single one, as you ought to do in looking at a stereoscopic apparatus, and you will clearly and undoubtedly see it "floating in the air." If I do so, and if now I take a pen and try to point out in what place this image appears to me to be, I always point at the very focus of the lens, and I am sure not to be mistaken more than about one-twentieth of an inch; and if Mr. Cresswell will try the same, I am sure he will succeed quite as well, or perhaps even better, than I can.

This little experiment seems to me sufficient to prove that the inverted image of a convex lens really appears (floating in the air) in the focus, and not, as Mr. Cresswell asserts, painted on the lens.

Will you ascertain yourselves the truth of this fact in another way, and only with the help of one of your eyes? Then place a second strong convex glass close to your eye, and endeavour to see at what distance you can clearly see any object through it. If your eye is emetropic, or, at least, neither short nor long-sighted, you will see through this second glass nearly at a distance that is equal to the focal distance of your lens. Now, look with this glass at the inverted image produced by your first convex glass, and when you have found the distance you want to see it the best, I can certainly tell you both your lenses will be distant from each other the total number of their separate focuses added together; hence it follows that the inverted image really appears in the focal distance of the lens —*q. e. d.*

Excuse, Sir, my bad English. I am German; and if I should not succeed to convince Mr. Cresswell that his statement is erroneous, I am very sure I would if I could explain to him the facts in my own language. I am, &c.

Bern, January 15. W. Zehender.

The Streets of London.—In a return just issued, as a summary of the *Weekly Returns of Births and Deaths in London*, a publication full of interesting details on the subject to which it relates, the Registrar-General makes the following opportune remarks on the atmosphere and thoroughfares of London:— "If coal were cheap, the greater command which the poor would have over that commodity would materially help to reduce the winter rate of mortality; and if smoke were abated at domestic fires, as well as at bakers' ovens and public furnaces, by more thorough combustion of fuel, the carbonaceous particles which they emit would not darken the air and pollute whatever they touch, nor, by forcing a passage into the throat and lungs, aggravate or excite fatal pulmonary complaints in human beings. Given, a broad river, with a temperature at the time above that of the air; let there be another vast moisture-exhaling surface on its banks sixty or more square miles in extent, and this area covered with houses which pour smoke from a million chimneys into a still atmosphere, and the result is that almost impervious fuliginous mass called 'a London fog.' But London has acquired almost as much fame for that highly agglutinative compound, its mud, as for its fogs; and perhaps there is more connexion than is generally supposed between them. It would be a humble but invaluable sanitary work if the streets were subjected to a perfect system of purification; if they were frequently and thoroughly cleansed and dried. The attention of Boards of Works may be well directed to this end. The present expedient by which householders who pay rates for parochial management are expected to clean the pavement in front of their own houses is unjust in principle and futile in practice. The whole width of thoroughfare from frontage to frontage should get the benefit of the same brooms and shovels. Old persons whose avocations compel them to be much out of doors, in feebly urging their steps over filthy streets, waste much of that strength which should be husbanded for the employment by which they live. And how can poor people be expected to keep the inside of their houses free from damp and dirt when all the adjacent exterior is a 'mud ocean?' A good scavenger is a practical teacher of that cleanliness which is said to be next to godliness; and if the streets were well kept the crowds who frequent them would read excellent plain sermons in the stones."

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, February 14.

Dr. Basham, V.P., in the Chair.

A paper, by Dr. Morell Mackenzie, was read on

THE TREATMENT OF CHRONIC DISEASE OF THE LUNGS BY THE INHALATION OF ATOMISED LIQUIDS.

The author, after an elaborate description of the various instruments invented for the purpose of introducing medicine by means of inhalation, enters into an account of the apparatus invented by Dr. Siegle,(a) of Strasbourg, and himself, which he thus describes:—It consists of a little kettle with a horizontal spout, in which there is a very fine opening. Placed at right angles to the horizontal spout is a vertical tube which dips down into the kettle, with a spirit-lamp beneath it. As the steam issues from the spout it causes a vacuum in the vertical tube, and the medicated liquid rising up becomes mechanically incorporated in the steam. The dilution of the medicated liquid which takes place is very slight, as the conversion of a drachm of water into steam will take up three drachms of medicated liquid. The temperature of the steam is lowered by the incorporation of the liquid, so that at the end of the cylinder it has only a temperature of about 70°. In this apparatus there is, of course, no current of cold air. The amount of liquid taken up varies—that is, it depends on the amount of heat applied, on the height of the column of liquid, etc. This is not an important defect, but when it is thought desirable to take up a definite quantity of liquid the author uses the following apparatus:—A graduated glass tube, about eight inches high, has from its lower part a fine piece of tubing, which is bent round and up again, and then extends about an inch horizontally, and ends with a minute opening. In the vertical portion of the fine tubing there is a stop-cock. The small aperture of the tube is placed at right angles to the spout of the kettle, and as the liquid emerges it becomes incorporated in the steam. By means of the stop-cock the amount of liquid which passes from the tube can be regulated, so that the same amount can always be taken up in the same time. Dr. Siegel's simple apparatus is an excellent one, and the author stated that he had often used it with great advantage. The author observed that his own atomiser is very simple, and can be used very easily. The liquid is driven from a fine glass pipe on to a projection in a bell-shaped tube, by the descent of a piston. The piston is drawn up without any exertion by a wheel and rack, at its upper part, and is forced down by a circular spring which surrounds the cylinder. The apparatus is filled with liquid by a funnel in its top, and all the spray except that which is inhaled passes back into the apparatus. The advantages of his (Dr. Mackenzie's) atomiser are:—1st. Its simplicity, requiring only a few turns of a handle to set it in operation. 2nd. The extremely fine state of subdivision which it effects. 3rd. The uniform pressure exerted. 4th. The fact that the waste liquid returns into the apparatus. 5th. The ease with which it can be taken to pieces and cleaned. After enumerating the Physicians and physiologists who had worked at the subject on the Continent, the author analysed the experiments which had been performed by Demarquay, Fournié, Brian, and others, on rabbits and dogs. He then related his own experiments, which had been carried out in conjunction with Dr. Duchesne, of Woodford. After detailing various experiments performed on pigs and dogs, Dr. Mackenzie thus sums up the results:—Leaving Demarquay's rabbits out of the question—it having been shown by Claude Bernard that as those animals in their normal state breathe through the nares when their nostrils are covered, and they are made to breathe through the mouth, the conditions are not physiological; and by Fournié that any solution (not atomised) injected into a rabbit's mouth passes into the lungs—there are (1st) Demarquay's and Brian's experiments on dogs; (2nd) his (Dr. Mackenzie's) on pigs and dogs; (3rd) an experiment performed by Demarquay in the presence of numerous witnesses on a woman with a tracheal fistula, in which it was shown that the inhaled liquid penetrated to the trachea, though there was a great obstruction at the upper

(a) This admirable apparatus has unfortunately been patented by Dr. Siegle.

opening of the larynx. This experiment, which had been previously unsuccessfully performed by Fournié, has since been repeated by Lieber, Schnitzler, and others, with results similar to those obtained by Demarquay; (4th) the fact first shown by Bataille, and since by Moura-Bourouillon, the author, and others, that after the inhalation of a coloured atomised solution the sputa remained tinged long after the employment of the laryngoscope could detect any traces of the material used. On the one hand there were an immense number of positive proofs of the penetration of atomised liquids, on the other hand there were a few experiments performed with negative results. It was scarcely necessary to remark that any experiment might be performed—the most simple chemical test employed—in a manner to ensure failure. But a few experiments of this sort could have little weight against the mass of evidence on the other side. The author stated that the greatest benefit from this system of therapeutics might be expected, and had resulted in bronchitis, asthma, and hæmoptysis. He brought forward twenty-two cases treated between October, 1863, and January, 1864. There were ten cases of bronchitis, six of phthisis, two of hæmoptysis, three of asthma, and one of whooping-cough. The author did not believe that in phthisis the treatment would have a positively curative effect, but was beneficial in cutting short intercurrent bronchitis. Of the twenty-two cases detailed, only two were unable to make use of this curative process. Of the ten cases of bronchitis, eight were cured, one relieved, and one obtained no benefit. The average duration of the time required for curing these cases, though most of them were severe and of long standing, was only fifteen days and a quarter. The shortest time was six days (a severe case, No. 4); the longest forty days. The duration of treatment was not in proportion to the severity of the disease, one mild case requiring twenty-eight days to get well. Of the six patients labouring under consumption, two were unable to use the inhalations on account of the irritation which they caused. Of the remaining four cases, whilst the physical signs did not undergo any material alteration, the local symptoms (expectoration, pain, and cough) were greatly relieved. The general health was much improved in two cases, Nos. 11 and 15; slightly in a third, and not at all in a fourth. In two cases of hæmoptysis, one severe, the other slight, the atomised liquids rapidly stopped the bleeding. In three cases of asthma—one a very severe case, which had obstinately resisted the ordinary treatment—this system of therapeutics soon gave relief. In one case of whooping-cough (in an adult) the inhalations gave immediate relief, and quickly effected a cure. The author stated that during the past year he had used atomised liquids in more than eighty cases of diseases of the lungs, and that he had found the plan of treatment no less successful than was detailed in this paper. The various instruments referred to in the communication were brought before the Society, and likewise diagrams illustrating their action and method of employment.

Dr. Gibb said that the subject of the author's paper was one of the highest importance, and in which he took the greatest interest. In the earlier part of his Professional career he (Dr. Gibb) had looked forward to the time when some means might be devised for introducing fluid in a minute state of division into the interior of the bronchial tubes, which would prove more certain in its effects than the vapour inhaled from certain substances. The instrument contrived by Dr. Sales Giron seemed to answer the purpose intended, but many others had been contrived since his invention. He had employed one manufactured by Weiss which readily answered the purpose, yet, as it soon got out of order, he had latterly given a preference to the fluid atomiser of Lewin, of Berlin, which, notwithstanding what the author had stated in favour of Siegle's and his own, he believed the most useful and convenient from its simplicity and readiness of application. In employing Siegle's, the temperature of the steam could not always be relied upon with any amount of adjustment of the cylinder for its diffusion, although it had decided advantages for introducing small quantities of certain agents. From the evidence brought forward by the author, illustrated by experiments of his own and Continental investigators, he had not the slightest doubt that any atomised fluid reached the minutest bronchial tubes and air cells, and from his own experience of the inhalation of fluid thus atomised or pulverised he was quite satisfied such was the case. With Siegle's atomiser he had caused the inhalation of a solution of the iodide of silver for a few minutes only in a case of rapid phthisis in the second stage of the disease, with profuse expectoration and laryngeal mischief. The effect of this was a general feeling of warmth throughout every part of the chest and the subsequent diminution of the expectoration. This feeling of warmth so generally diffused convinced him that the atomised fluid had reached the minutest bronchi. As a palliative in some cases of phthisis, and as likely to diminish the amount of expectoration, the inhalation of atomised fluids would prove useful, but it never could be relied upon as a curative agent in this disease. With regard to bronchitis, the chronic form especially, asthma, and hæmoptysis, his own experience agreed with that of the author, and showed that in many cases the greatest amount of relief could be obtained. Indeed, he had been surprised at the good results which sometimes followed, in the two former especially. He accepted the author's term atomised as preferable to pulverised in its application to fluids, and had no hesitation in adopting it. As furnishing an additional and most useful therapeutic agent in the treatment of laryngeal and chest diseases, the inhalation of certain atomised fluids must be regarded as one of undoubted value, and he (Dr. Gibb) gladly bore testimony in its favour.

Dr. Williams (of Swansea) said that, although a stranger to the Society, he could not help making some remarks on the valuable paper just read. He considered that Dr. Mackenzie stood in the very highest scientific position, and he (Dr. Williams) entertained the very highest opinion of him as an observer. Yet he wished to express his dissent on some points in the paper. He (Dr. Williams) had studied and had had opportunities of seeing disease of the lungs in all forms, and he believed that atomising fluids was unnecessary, on the ground that they could be introduced in the simplest manner by ordinary inhalation. He had himself gone through many experiments to prove the rate the air travelled to the air-cells, and he had found that it travelled in the slowest possible matter, and that attempts to make it pass more quickly simply excited spasm, and diminished the speed. He thought that, allowing time, simple inhalation would be as effectual as with force supplied by instruments. In the ordinary act of inspiration the air was only carried as far as the secondary bronchial tubes; the air below being nearly stationary, and being changed by a molecular process. Therefore, although force might be of service in bringing atomised liquids or vapours to the larynx, trachea, or larger bronchi, it could be of no value in treating disease of the more interior parts. Moreover, the absorptive power of mucous membrane, the speaker remarked, was not great. He had under his observation many patients who had worked in arsenic. They suffered from skin disease only—from the local action of the poison,—and not from general poisoning by it, although large quantities must have been inhaled. He (Dr. Williams) had tried the plan of inhalation of remedies, but believed internal treatment in the usual way was preferable. In conclusion, he wished again to thank the author for his highly philosophical paper, and to express a hope that he would go still further in his scientific researches.

Dr. Semulhof had arrived at the same conclusion as the last speaker, but for different reasons. Whilst admitting the great value of experiments, practical men must look to the end. In listening to the author's able paper, he came to the conclusion that the atomised substances did penetrate the lungs, and that such treatment was of benefit. But he thought that form of treatment was not necessary, and that the author had not attained any end not otherwise achieved. Some of the cases related, as hæmoptysis and whooping-cough, could have been well treated by ordinary means. Whilst he should read the paper, and, indeed, anything written by the author, with great attention, he was not quite so sanguine as Dr. Gibb as to the practical results.

Dr. Morell Mackenzie, on being called on to reply, said that the hour was so late, and that his paper had already occupied so much of the Society's time, that he felt it was impossible either to defend or explain the points on which there seemed to be some difference of opinion. With regard to Dr. Williams' remarks, he might say, however, that with the instrument he recommended, the atomised liquids were not accompanied by any current of air, nor had the atoms or molecules of the medicated liquid any force of their own. They were simply small particles floating in air. He was not prepared to discuss the question of the velocity with which air travelled down the smaller bronchi, as there was experimental evidence to show that liquids in a state of fine subdivision could penetrate to the pulmonary air-cells of the lungs of animals. The system of inhalation which he recommended was not meant to enter into competition with the ordinary modes of inhalation, but was intended to enable people to

inhale drugs which could not be volatilised. Those who thought that constitutional treatment was important could combine it with the local therapeutics. It was a mistake to suppose that there was anything antagonistic in the two methods.

NEW INVENTIONS.

AN IMPROVED CAUSTIC CASE.

The accompanying engraving represents an ingenious caustic-case made by Mr. Matthews, at the suggestion of Mr. Francis Mason, of King's College Hospital.

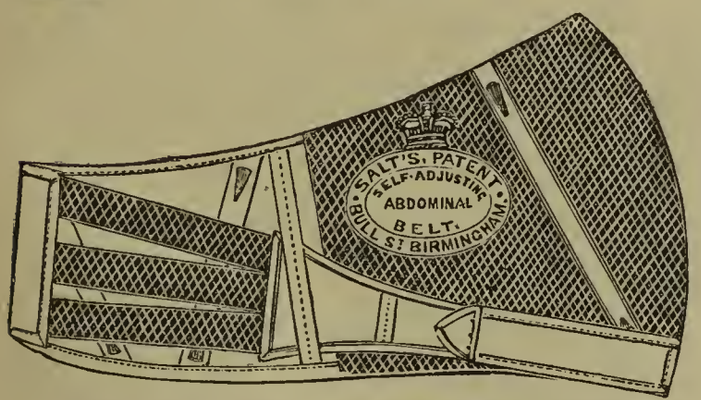
It will be observed that, in addition to the grooved needle and caustic-holder, there is attached a small spud for removing foreign bodies from the eye, and which may be made available for other purposes. As an appendage to the ordinary pocket-case the utility of the eye-spud is acknowledged by all practical Surgeons. In this instance the length of the caustic case is not increased, and the spud being affixed thereto obviates the necessity of carrying it as a separate instrument.

NEW ABDOMINAL BELT.

Mr. Salt, of Birmingham, has devised an ingenious belt for cases of enlargement of the abdomen from whatever causes. It appears to us to possess the following advantages :—

1. It adapts itself accurately to the figure, affording an equable and yielding support, which, by a simple contrivance, accommodates itself to the increasing dimensions of the abdomen, and renders an additional belt of larger size altogether unnecessary.
2. It can be applied without assistance.
3. It is extremely light and durable, and, being of pervious texture, is not unduly heating to the body.

We have lately had an opportunity of trying it in a case of enlargement of the abdomen from obesity, with the result of completely relieving many of the symptoms which had previously caused the patient pain and annoyance.



MEDICAL NEWS.

Royal College of Physicians of London.—At a general meeting of the Fellows, held on Monday, February 20, the following gentlemen, having undergone the necessary Examination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practise Physic as Licentiates of the College :—

George Lamb, Hull; John Bunyan Foster, 66, Upper Charlotte-street, Fitzroy-square; Thomas Robinson Glynn, 35, Canonbury-road, Islington; John Hudson, Rochester; William Griffith, Oswestry; J. Wm. C. Neynoe Murphy, Aldershot; Charles Theodore Günther, M.D. Tübingen, Hampton Wick; John Marshall.

At the same meeting, the following gentlemen were reported by the Examiners to have passed the First Part of the Professional Examination for the Licence :—

William Jennings Burt, St. George's Hospital; William Harris Butler, Guy's Hospital; Thomas Morgan Joseph, University College; Edwin Renshaw, St. Bartholomew's Hospital; Charles Lyon Redout, St. George's Hospital; Francis William Underhill, St. George's Hospital; Geo. Samuel Watson, St. George's Hospital; Walter Owen Withers, King's College.

Apothecaries' Hall. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, February 16, 1865 :—

Franklin Gould, 26, Charlotte-street, Bedford-square; Robert Robertson, North Dispensary, Liverpool; Charles Carr, Newcastle-on-Tyne; George William Rigden, Bargate-street, Canterbury; Ralph Burnham, Preston, Holderness.

The following gentleman, also on the same day, passed his first Examination :—

Ridgway, R. S. C. C. Lloyd, Guy's Hospital.

Pharmaceutical Society of Great Britain.—Names of Candidates who passed the Examination, February 22, as Pharmaceutical Chemists :—

James Barrett, Leicester; John Currie, Glasgow; John Francis, Wrexham; James Isherwood, London; Joseph C. Preston, London; William H. Tugwell, Greenwich; William H. Whiteway, Torquay; James Williamson, Edinburgh.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Barnes, Henry, M.D. Edin., has been elected Resident Medical Officer to the General Hospital for Sick Children, Manchester.

Edgeworth, Henry, F.R.C.S.I., has been appointed Surgeon to the Constabulary of Longford.

Macloghlin, Robert H., M.B. Dub., has been elected Medical Officer to the Dunfanaghy Workhouse and Fever Hospital.

M'Manus, John, L.A.H. Dub., has been appointed Apothecary and Secretary to the County Infirmary, Longford, and Apothecary to the Gaol.

Powles, Mr. R. C., has been elected House-Physician to King's College Hospital.

Seller, William, M.D. Edin., has been appointed one of the Medical Examiners in the Edinburgh University.

Watkin, Thomas L., M.D. Edin., has been re-appointed one of the Physicians to the Durham County Hospital.

DEATHS.

Cæsar, John A., M.R.C.S. Eng., at Cork, on February 10, aged 33.

Catherwood, Alfred, M.D. Glasg., at Charles-square, Hoxton, N., on February 19, aged 62.

Crawford, James, L.F.P.S. Glasg., at Kincardine, Perthshire, on February 6.

Fisher, J., M.D., at Bailieborough, Co. Cavan, recently, aged 25.

Golland, Walker, M.R.C.S. Eng., at 7, Cavendish-street, Manchester, on February 5, aged 52.

Gratiolet, Professor, the well-known Anatomist, died last week in Paris in consequence of a stroke of apoplexy.

Loadman, Robert M., L.S.A., at 1, St. Alban's-terrace, Hammersmith, on February 8, aged 67.

Magrath, Miles M., Assistant-Surgeon R.N., at Hong Kong, on December 16, aged 30.

Marshall, William, M.R.C.S. Eng., at Antwerp, on February 1, aged 39.

Martin, John F., M.R.C.S. Eng., at Abingdon, Berks, on February 14 aged 60.

Rix, Samuel B., Surgeon, at Zwart Kei River, South Africa, on December 18, aged 23.

Taylor, John Hollamby, M.D. Aberd., at Guildford, Surrey, on February 13, aged 80.

Williamson, William, M.D. Edin., at Union-street, Aberdeen, on Februar 16, aged 40.

Woodman, William, M.R.C.S. Eng., at 16, Bedford-circus, Exeter, on February 9, aged 63.

Young, William, M.D. Glasg., at Maryhill, Glasgow, on February 10.

Conversazione at the King and Queen's College of Physicians in Ireland.—On Monday evening last, February 20, the splendid new College, of the laying of the first stone of which we gave a full report in our impression of July 12, 1862, was properly inaugurated by a most brilliant *réunion*, which took place on the invitation of Dr. Beatty, who, having some years ago filled the same office in the College of Surgeons, was, on last St. Luke's Day, elected President of the King and Queen's College, in the room of Dr. Corrigan. In addition to the great majority of the Fellows and Licentiates of the College, there were present on this occasion—His Excellency the Lord-Lieutenant; the Right

Honourable the Lord Mayor; the Right Honourable the Lord Chancellor; the Right Honourable Joseph Napier, ex-Chancellor of Ireland; the Right Honourable the Attorney-General; the Honourable George Handcock; Sir William R. Wilde; the Very Rev. Dr. Graves, Dean of the Chapel Royal; and a very large number of Professional and non-Professional guests. Dr. Beatty wore his official costume as President, which resembled that of the Chancellor of the University. The Fellows also appeared in their usual academic dress, and wore the hoods of their several degrees. His Excellency arrived at about half-past nine o'clock, and was conducted by the President to the hall, the band of the 84th Regiment, stationed on the staircase, playing the National Anthem. The hall, a noble apartment, fifty-eight feet by thirty in width, and thirty in height, was well furnished with objects of historic and scientific interest, supplied by the Fellows (their contributions included the original grant of arms temp., 1667, etc.), the President, Dr. Carte, Prof. Beete Jukes, George O. Wilson, Esq., Dr. E. Perceval Wright, Dr. Wm. Barker, and Dr. John Barker. At one end of the room was suspended a portrait of Sir Patrick Dun, President of the College in 1692, and opposite to it was placed a splendid portrait of Dr. Corrigan, just completed by the distinguished artist, Mr. Catterson Smith, Pres. R.H.A., which has been painted at the expense of the College to commemorate Dr. Corrigan's five years' presidentship, from 1859 to 1864, during which time, and mainly owing to his clearsighted and liberal exertions, the new building was commenced and completed. Having examined most of the objects of interest in the hall, his Excellency and as many as could be admitted were conducted to a small darkened apartment, where a series of most interesting electrical experiments was performed by Mr. Robinson, of Grafton-street, exhibiting the passage of the current through tubes filled with various gases. Mr. Robinson exhibited also the light of the new metal, magnesium, and several large revolving stereoscopes. The guests then adjourned to the library, 58 feet by 18 feet, where refreshments were liberally supplied, and after some time separated, having spent a most instructive and agreeable evening, the pleasure of the latter having been considerably enhanced by the opportunity of meeting old friends from the country, who had come up to town to do honour to the worthy President's hospitable invitation. A well-chosen selection of music was performed during the evening by the military and string bands of the 84th Regiment.

PRESENTATION.—At the last meeting of the South London Medico-Ethical Society, the members presented to their worthy Honorary Secretary, Dr. Swallow, Kennington-park-road, a very handsome silver cup, which bears the following inscription:—"Presented to James Dodd Swallow, M.D., by the members of the South London Medico-Ethical Society, as a token of their esteem and appreciation of his valuable services as Honorary Secretary of the Society.—February, 1865."

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Dr. Elliott's case of Imperforate Rectum is intended for publication, and shall appear shortly.

A Member.—Professor Fergusson's lectures at the College of Surgeons will be resumed some time in the ensuing summer.

Erinensis.—Yes. Dr. Brady, the M.P. for Leitrim, is a member of the London College of Surgeons. He formerly practised in the Blackfriars-road.

Veritas is entitled to the patient as long as she may feel disposed to employ him. At the same time, we think it would have been the more generous course to have acted in this instance *for* his brother.

A Fellow of the College.—The information you require shall be obtained. The gentleman to whom you allude is one of the "honorary" Fellows; the number, from a careful analysis of the list, is reduced from 542 to 275.

Dr. Davis.—Yes; Dr. Shebbeare was condemned to stand in the pillory at Charing-cross for publishing "An Eighth Letter to the People of England."

M., Margate.—In early life, Sydenham left Magdalen Hall, Oxford, to serve in the Parliamentary army.

A Fellow.—On inquiry we have ascertained that the executors of John Hunter left a certain sum, the interest of which is supposed to pay the expenses of a festival alluded to by "A Fellow."

M.D., Kennington.—Dr. Dominicetti established medicinal baths at Cheyne-walk, Chelsea, for the use of all disorders just a century ago, 1765. Soon after he took a house at Millbank, and had 16,000 people under his care. He, however, became bankrupt and disappeared.

Indian Surgeon.—We have received from our correspondent copies of articles from the *Calcutta Englishman* and the *Madras Athenæum*, republished in the *Homeward Mail*, containing some adverse comments on the new Medical Warrant for India. We can only say that, in our opinion, they do not in any degree affect the conclusion at which we arrived as to the substantial benefits conferred on the service by the new Warrant. We have already noticed several of the points urged by the writers in the Indian papers. It could not be expected that any measure would give equal satisfaction to all ranks in the service.

A file of the *Nelson Examiner*, of November and December, 1864, has been forwarded to us, containing a set of letters signed *Canis Senex*, which we do not hesitate to say are disgraceful to the anonymous writer, as well as to the newspaper in which they were permitted to appear. The Profession, unfortunately, is discredited, also, by the unworthy conduct of one of its members, if, as is said, the writer be a member. A man who writes anonymously in a newspaper, bitterly criticising the Professional proceedings of one of his brethren, and then heaping scurrility on the head of respectable Medical writers whose books were quoted against him, but who have nothing to do personally with the point in dispute, can have as little idea of the conduct of a gentleman as he has of the etiquette of a learned Profession.

THE LATE CHARGES AGAINST THE MEDICAL OFFICER OF THE HOLBORN UNION WORKHOUSE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg to inform you that the inhabitants of the Holborn district are endeavouring to raise a subscription to defray Mr. Norton's expenses (between £50 and £60), and it is proposed that if the sum raised exceed that amount, the Committee intend to form with it the nucleus of a Medical defence fund, as the enclosed circular will show. The Committee will feel greatly obliged if you will kindly mention this in the *Medical Times and Gazette*.

I am, &c.

55, Guildford-street, February 21. WM. C. HUGMAN, Hon. Sec.

(Circular.)

"THE CASE OF TIMOTHY DALY.

"In consequence of the general feeling of sympathy for Mr. Norton which has been excited by the injurious and unfounded charges recently brought against that gentleman, a meeting of the ratepayers of the Holborn district has been held for the purpose of taking into consideration the best means of relieving him of the heavy expense which the recent prolonged investigation by Mr. Farnall has entailed upon him. The gentlemen attending this meeting have ascertained to their entire satisfaction from inquiries made of several members of the Board of Guardians, also of the pauper inmates of the house, and from other sources, that his duties as Medical Officer of this Union have been most diligently and skilfully performed during the past ten years he has held the appointment; and confidently appeal to the ratepayers and the public to contribute by a small subscription, as widely extending as possible, as an expression of their sympathy and confidence.

"Owing to the general interest which this case has excited, and the publicity given to it by the public press, this meeting feels that it is unnecessary to enter into a lengthy detail of its merits, but beg to enclose a copy of the report just issued by the Poor-law Commissioners, and refer you to the strongly expressed opinions of the two London Medical journals (*Medical Times* and *Lancet*) upon the subject.

"It is resolved that a Committee shall be formed to carry out the above object.

"The following gentlemen have consented to act in that capacity and receive subscriptions:—Dr. Septimus Gibbon, Medical Officer of Health, Finsbury-square; Mr. Morson, Southampton-row and Queen-square; Mr. E. Taylor, Lamb's Conduit-street; Mr. Hagger, Lamb's Conduit-street; Mr. Holden, Lamb's Conduit-street; Mr. Yarde, Lamb's Conduit-street; Mr. Hanson, Red Lion-square; Dr. Robinson, Lamb's Conduit-street; Dr. Roberts, Lamb's Conduit-street; Dr. Stevens, Bloomsbury-square; Mr. Stagg, Great Ormond-street; Mr. Prosser, Holborn; Mr. Garlick, F.R.C.S., Great James-street; Mr. Cuff, F.R.C.S., Guildford-street; Mr. Kempe, 8, Keppel-street; Mr. Gibson, F.R.C.S., 10, Russell-square, Surgeon to Newgate.

"*Treasurer*—R. Sykes, Esq., Manager of the London and County Bank, Holborn Branch, by whom also subscriptions will be received.

"*Hon. Secretary*—W. C. Hugman, F.R.C.S., 55, Guildford-street, London, W.C."

*** We hope that the Committee will be completely successful in carrying out their object. Mr. Norton was made the victim of most unjust accusations, and we trust that his brethren in the Profession will unite with the ratepayers to bear him harmless from pecuniary loss. If the Committee obtain sufficient money to form the nucleus of a Medical Defence Fund, they may confer a great benefit on the whole Profession.

UNION OF FRACTURED RIBS AT 94.—OVARIOTOMY IN SWITZERLAND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—A not very common case of consolidation of fractured bones occurred to me lately. On January 1, 1865, Mrs. G., a lady, 94 years old, fell from her chair on her right side. The fourth and the fifth ribs of the left side broke in the fall, in the middle of the bone, probably from forced extension. I applied a large pitch plaster, and over it a *bandage d'corps* to maintain the fragments. The consolidation is now complete; plaster and bandage have been removed ten days ago; Mrs. G. is as well and free in her movements as if nothing had happened.

An operation of ovariotomy has been practised at our little Samaritan Hospital with a full success. It was a multilocular tumour, containing about twelve litres of liquid. It was operated by Dr. De Montel, who had the case in his charge. Everything went on most favourably, and the patient is now entirely cured. It was the first operation of ovariotomy practised in our canton, and it excited no little interest among the Medical men of the neighbourhood, who were all present.

Perhaps, Sir, you will think this to be of some interest to your readers.

I am, &c.

Vevey, February 17. J. C. GUISAN DUY.

Right of Recovery for the Services of an Unregistered Assistant.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I was the plaintiff in an action lately tried in the County Court of this town, in which I sought to recover for Professional attendance and medicine rendered and supplied by my assistant, who conducts a branch surgery for me five miles distant from my own residence. I am registered as an Apothecary, Surgeon, and Doctor of Medicine. The judge, after a few minutes' consideration, gave a verdict, with costs, for the defendant, based on the ground that, according to the Medical Act, no qualified Medical practitioner could recover for cases which had been attended by an assistant *(sine* diploma) resident five miles distance from the principal.

I beg to submit the above to the readers of your widely-circulated journal, many, no doubt, of whom have branch practices, as I think it involves a question of great importance to the Profession generally.

I may add that, having conducted this branch practice for a considerable time, I might be a considerable loser should this decision hold correct.

I am, &c. John Willett, M.D.

Northwich, Cheshire, February 13, 1865.

P.S.—Your opinion, as an addendum, would much oblige.

[We are of opinion that the decision of the County Court judge was clearly wrong. Supposing the Medical Act never to have been passed, there could be no doubt of Dr. Willett's right to recover, presuming that the branch practice is conducted in his name, and the assistant was accepted by the patient as Dr. Willett's representative. Now, what is the effect of the 32nd section of the Medical Act on that right? That section enacts that no person shall be entitled to recover for any Medical attendance, etc., unless he shall prove upon the trial that he is registered. Dr. Willett, we presume, did prove that he was registered; and his case would then be complete. We may add that the right of a qualified Practitioner to recover for work done by an unregistered assistant is expressly recognised by Chief Justice Erle, in his judgment in Turner and Smith *v.* Reynall, 32 L. J. C., p. 164, although the point in question was not raised in that case.—Ed.]

A Midwifery Question.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I should be glad to know, through your correspondents, especially from some leading Practitioners in obstetric practice, whether the repeated application of the hand dipped in cold water and applied to the abdomen is a safe means of inducing uterine action, or whether, in short, it can be regarded as "meddlesome Midwifery." I have always used this method in preference to ergot of rye, and have never regretted its employment. It is a natural remedy, always at hand. With the same intent, I constantly adopt the plan of making my patient drink the coldest water; the effect is immediate, and often of great value. By this means, also, I have determined the existence of pregnancy, beyond a doubt, when the flattest denial was given. The motions thereby communicated to the fœtus are readily felt by the hand, both through the vagina and the abdominal wall.

The application of the cold hand (made so by water) is no new method of producing action in the uterus. I have seen it used in Dublin, and I have also seen a cloth, well wetted, thrown forcibly on the abdomen, and with the result of speedy pain in the uterus. I learned my cold water plan from a Dr. G. J. Morris, who was a most excellent Midwifery Practitioner, and I never regret its adoption. Of course it is inadmissible when there is an inclination to rigor, and I never employ it when the patient objects to cold. Its sudden use is its very recommendation.

I am, &c. Henry Ussher, M.B., Surgeon,

February 15. Medical Officer, Wandsworth Dispensary.

The Value of the Microscope as a Test for Forgery.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I shall be much obliged by your kindly inserting the following queries in your valuable journal, an answer to which, from some of the members of the London Microscopical Society, will be much prized. I will trouble you with the full particulars of the case, as you will then judge better of its real interest:—

Within the last few days a very respectable and well-to-do merchant in this city was accused by a country farmer of the crime of forgery in three notes of hand which had passed between them in 1859. It was alleged by the farmer that the notes were drawn up to bear no interest, and that the merchant had inserted the following line—"with interest at 20 per cent. until paid"—some time after he had signed them. To prove this, he produced four other persons, who, along with himself, swore positively that the line was a forgery. The only evidence that the merchant could fall back upon was the microscope; by its aid he thought that it could be certainly ascertained which was written last, the man's signature or the line in question, as some of the letters of both were not only in contact, but crossed each other.

The case has been investigated very carefully, the investigation having lasted two whole days before three magistrates, who unanimously decided on its dismissal. The farmer, however, is determined not to allow the matter to rest, but to bring it before the next Spring Assizes.

At the investigation the merchant produced fifty or sixty witnesses, who, on looking through a No. 1 Smith and Beck microscope, all swore that they had not the slightest doubt that there was no forgery, as several letters of the signature appeared to be distinctly over those of the "line." Amongst these were three or four who are constantly using the microscope. The farmer, however, produced one gentleman, himself a microscopist, who alleged that he considered it by no means a certain test.

You will see that this is a most interesting and important case. I am not aware of ever having seen a similar one recorded. The following are the queries to which I solicit replies:—

No. 1.—In cases of suspected forgery, where proof rests on one line, or words, written above one another, can the microscope be considered a certain test in cases where the ink of both words is very distinct? can it positively tell which is written last? also in cases where tracing has taken place?

No. 2.—If so, must the examination be conducted by microscopic experts? or can any ordinary person describe what he sees with certainty when the object is placed for him in the field of the microscope by an expert?

No. 3.—In such examinations, what object-glasses are the best to be used—those of a high or low power? and why?

No. 4.—What light is best to be used—incident or transmitted?

No. 5.—Before a correct opinion can be given, is it necessary to cut the paper in two, where the words cross one another or are in contact, in order to place the cut edge in the field? and why?

I am, &c.

J. A. Brown, M.B.T.C.D., L.R.C.S.E.

London, Canada West, January 27.

APPOINTMENTS FOR THE WEEK

February 25. *Saturday (this day).*

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

27. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

Royal Institution, 3 p.m. Prof. Tyndall, F.R.S., "On Electricity."

28. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

Anthropological Society of London, 8 p.m. Meeting.

Royal Institution, 3 p.m. Prof. Hofmann, F.R.S., "An Introduction to the Study of Chemistry."

Royal Medical and Chirurgical Society, 8½ p.m. Meeting.

March 1. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

Royal Institution, 3 p.m. Prof. Marshall, "On the Nervous System."

Royal Medical and Chirurgical Society, 8 p.m. Anniversary Meeting.

2. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Harveian Society of London, 8 p.m. Dr. Griffith, "On a New Method for the Arrest of Uterine Hæmorrhages." Also, a Clinical Discussion "On the Use of Alcohol in Fevers."

Royal Institution, 3 p.m. Prof. Hofmann, F.R.S., "An Introduction to the Study of Chemistry."

3. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m. James Fergusson, Esq., F.R.S., "On the Temple at Jerusalem."

Western Medical and Surgical Society, 8 p.m. Dr. G. F. Blandford, "On Melancholia."

ORIGINAL LECTURES.

LECTURES ON CHEMICAL AND MECHANICAL DISEASES AND THEIR RELATIONSHIP.

By H. BENCE JONES, A.M., M.D., F.R.S.

Lecture III.

DISEASES OF SUBOXIDATION—ON THE OXALIC ACID DIATHESIS.

On the Oxalic Acid Diathesis.

Strictly speaking, the oxalic acid diathesis is included in the general expression acid diathesis, for the oxalic is only the last acid in the descending scale of ternary organic substances that is produced before perfect combustion sets free carbonic acid and water. Still I shall treat of oxalic acid separately, partly for the sake of clearness, and partly because, being a very strong acid, it will probably be found, in the progress of animal chemistry, to play an important part in the healthy chemical actions that take place in the body.

As oxalic acid is only a special instance of acidity, much that was said in the last lecture applies to the production of an excess of this acid also. To avoid useless repetition, I shall now confine myself to that which belongs specially to oxalic acid as distinguished from other acids.

The production of oxalic acid in the body is a purely chemical process. Certainly it would have escaped notice if the compound which it forms with lime had not been very insoluble in dilute acid. This chemical cause leads to the secondary mechanical disease, mulberry calculus, and this complaint is so frequent and so serious that the primary chemical disorder hence rises to an importance which it would not at all reach by itself.

To make the production of oxalate of lime depend on an oxalate of lime diathesis, so far, at least, as the lime is concerned, is only giving a hard word to the chemical affinity of oxalic acid for lime which partly depends on the insolubility of the compound produced.

If perfectly healthy action is marked by the production of carbonic acid and water .	CO_2HO
The first and slightest arrest of oxidation will be marked by the production of oxalic acid	$C_4O_6 2HO$
The higher degrees of arrest of oxidation of sugar and albumen will produce other acids, as acetic acid	$C_4H_3O_3HO$
Or hippuric	$C_{18}H_8NO_5HO$
Or uric	$C_{10}H_2N_4O_4 2HO$
The highest degree of arrest of sugar will give diabetes; grape sugar . . .	$C_{24}H_{28}O_{28}$

Hence oxalic acid is related to over acidity and to diabetes in that it is the lowest of a series of imperfect oxidations, whilst diabetes is the highest term of the same series. Moreover, it will be seen that between the oxalic and the saccharine diathesis there is a resemblance not only in the causes of these diseases, but also in the treatment.

Oxalic acid, like sugar, can arise from two sources—first, from the food; and secondly, from the textures.

Of all the acids that exist in the vegetable kingdom, the most widely present is oxalic acid. Schleiden even states that oxalate of lime, either in needles or octohedra, is present in every plant; in some, as in rhubarb or sorrel, oxalic acid is present in very large quantities. It is formed out of carbonic acid and water by the hydrogen of the water combining with the carbonic acid while the oxygen is given off; thus, $C_4O_8 + 2HO = C_4H_2O_8 + 2O$. As this oxalic acid is mostly combined with potassa or lime, it is not likely to escape oxidation in the body before it passes out of the kidneys, and hence probably from this source oxalate of lime rarely occurs in the urine.

All the hydrocarbons, as starch and sugar, that exist in the food, and most of the vegetable acids, when oxidised out of the body by nitric acid or by fusion with hydrate of potassa, give oxalic acid; if fully oxidised, they would give carbonic acid and water.

In the oxidising action which is going on in the body, the starch, sugar, and vegetable acids may all stop in their progress to carbonic acid and water before their final change takes place, and thus give rise to oxalic acid; and this will combine with any lime that happens to come within its reach, and will pass out as oxalate of lime in the urine. Moreover, in addition to these vegetable sources of oxalic acid, there may be two sources from animal substances. The sugar that has its origin in the muscles and in the liver may, by arrest of oxidation, furnish oxalic acid.

Moreover, there can be no doubt that albuminous substances, whether of vegetable or of animal food, give rise to uric acid when an excess is eaten; and when uric acid is imperfectly oxidised, it divides into oxalic acid and urea: so that oxalic acid may be produced even from the albuminous constituents of the different organs and textures themselves. In the process of disintegration different portions of the albuminous matter may stop at different degrees of oxidation, when from any cause that action is incomplete. Hence uric acid, or urea and oxalic acid, instead of urea and carbonic acid, may be thrown out of the body. Thus, then, there may be not less than four sources of oxalic acid in the urine—two in the food and two in the textures.

That oxalic acid does come from the textures is rendered more likely by the fact that when the strictest possible diet is observed oxalate of lime may occasionally still be detected in the urine. In this respect, as in others, the parallel with diabetes is very close; the difference being that the sugar causes diuresis, and implies a greater loss of force, whilst the oxalic acid, in consequence of the insolubility in dilute acid of the oxalate of lime, gives rise to a serious mechanical disease, which requires severe mechanical treatment for its cure.

It is highly probable that oxalic acid, though not so widely diffused in animals as in vegetables, may be much more frequently present in different secretions and textures of the body than is yet proved to be the case. Already it has been found in the blood, in mucus, in saliva, and in perspiration. Its occurrence in the urine implies no disease, but only a slight error of deficiency in the chemical changes in the body.

It is twenty years since I was consulted by a Medical gentleman, who said he had been greatly alarmed by being told that the oxalate of lime in his urine indicated serious and, possibly, malignant disease. I advised him to examine the water passed by apparently healthy people. In a very short time he wrote to me that he found octahedral crystals in the urine of the most healthy of his friends.

On the Means of Detecting Oxalic Acid.

At present oxalic acid is most readily detected by means of the crystals it forms with lime. It requires no skill and no preparation of the urine to find the oxalate of lime. The urine should be left to stand for twenty-four hours in a bottle or tall glass; the upper part of the fluid should be poured off, and the last few drops remaining should be examined. A magnifying power of 320 times is generally sufficient, but the crystals are sometimes so small that more than this power is necessary to determine the form. Generally oxalate of lime octohedra are thus found without the least difficulty—sometimes in large single crystals, very frequently in aggregations of small octahedra forming microscopic calculi.

Dr. Golding Bird was the first who stated that these crystals, which had for some time previously been observed in urine, were oxalate of lime.

It is only in rare cases that so many crystals can be collected from the urine as will furnish the chemical proof that these octahedra are oxalate of lime; this proof may be obtained. Moreover, artificially formed oxalate of lime, which is generally an amorphous powder, can be made to crystallise in octahedra by dissolving it by the aid of heat in very dilute hydrochloric acid, and setting it aside for many days, when octahedral crystals will very frequently be formed. The less oxalate of lime present and the more acid the solution, the slower the crystals form. In no experiment have I succeeded in forming the crystals which Dr. G. Bird has called dumb-bell crystals of oxalate of lime. They do not very frequently occur in the urine, and I cannot say that their appearance gives any important indication. Oxalate of lime occurs in the urine in a third form, which M. Donné has also observed; and as the microscopic appearance may lead you to a wrong diagnosis, it requires to be mentioned here.

I sometimes find, with or without octahedral crystals, little flattened discs, the size of very small blood globules. When rolling over, they may very easily be mistaken for blood globules. They vary much in size, some being much smaller than any blood globules. I have seen these discs mixed with octahedral and dumb-bell crystals—in fact, the smallest dumb-

bell crystals form minute flattened discs. They are not soluble in water as blood globules are; they have a different appearance in the centre, and the eye, by practice, can learn to distinguish certainly between blood globules and oxalate of lime.

On the Symptoms of Oxalic Acid.

The most common symptom of the oxalic acid diathesis is flatulent dyspepsia; frequently before food considerable uneasiness is felt, and eructation occurs. Eating for a time removes the symptoms, often only to return in an hour or two with increased intensity. The pain sometimes is so severe, persistent, or intermitting, that it can only be produced by actual cramp of the muscular coat of the stomach. This state of suffering may last from half-an-hour to three or four hours, and then cease to return after some days or months or years.

In the urine the presence of oxalate of lime may be suspected when sudden changes in the quantity made in twenty-four hours are observed.

A slightly dyspeptic gentleman was passing urine giving a thick deposit of urates only on cooling. The amount made in twenty-four hours was twenty-nine ounces, specific gravity 1023·8. The following day, without any change of diet, or increased quantity of fluid drunk, or medicine of any kind, he passed fifty-four ounces, specific gravity 1018·1, and on examination myriads of octahedral crystals were found to be present.

Usually an increased urgency and frequency of making water accompanies this increased flow, and there is a general feeling of irritability of the nervous system, exaggerating external and internal annoyances to a degree far beyond that to which they would rise if no dyspepsia existed.

W. S., aged 64, had all his life been dyspeptic. For twelve years he had had dry and moist eczema. For seven or eight years he has had sleepless nights; so excessively nervous he could not go to bed. Has had violent pains on the top of the head, and spasms of the stomach, lasting half-an-hour or an hour, relieved by an escape of wind. For the last two years he has had frequent calls to pass water at times. Has never had a distinct attack of gout, but frequently has flying pains in the joints. Without known cause, he frequently, for some hours, passes large quantities of water, with increased frequency in the morning, but not in the evening. For example:—

On Feb. 13 he passed—	ozs	On Feb. 14 he passed—	ozs.
At 2 a.m. . .	4	At 7 a.m. . .	8
3.30 . . .	5	8 breakfast.	
7.30 . . .	6	10. . . .	2
8.30 . . .	6	2 p.m. . .	4
10 breakfast.		Dinner.	
12 noon . .	7	5.30 . . .	4

	45 sp.gr.1015.		26 sp.gr. 1026.

In the water passed on the 13th I found plenty of octahedral crystals; in that of the 14th I found free uric acid and urates. There was no other disease detectable.

(To be continued.)

The Late Dr. Hawkins, of Hitchin.—Dr. Hawkins was the fourth son of Major Hawkins, of Laurence End, Herts. He graduated at Edinburgh, and there formed an intimacy with the late Sir J. Forbes, which continued through life, and whose opinions on the incurability of disease, embodied in his memorable work on the "Nature and Art," etc., he fully shared and openly professed. On settling at Hitchin, in 1820, one of his first acts was the opening of a dispensary for the relief of the poor. From this small beginning sprang, by his persevering efforts, the present noble building, which was opened in 1842, under the name of the North Herts and South Beds Infirmary. Till October, 1863, he continued to fulfil the office of Surgeon to the institution, when a paralytic seizure forced him to resign; on which occasion the subscribers, to mark their sense of his valuable and long-continued services, presented him with 1000 guineas. Dr. Hawkins died on November 27, 1864, from a second attack of his former complaint, in his 69th year.

ORIGINAL COMMUNICATIONS.

ON NUTRITION.

By LIONEL S. BEALE, M.B., F.R.S.,

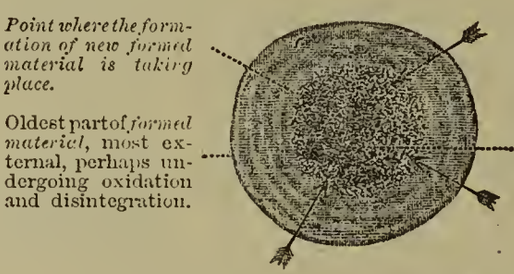
Fellow of the Royal College of Physicians; Physician to King's College Hospital; Professor of Physiology and of Morbid Anatomy in King's College.

(Continued from page 194.)

From what was stated in the last paper, it appears that the first stage of the process of nutrition of a cell or elementary part comprehends (*a*), The passage of the dissolved pabulum through the formed material already produced, and (*b*), The contact of the solution which has passed through with the living matter. Up to this time the chemical composition of the pabulum has not been changed. The passage of the pabulum through the formed material is probably a *physical process*. It is likely that the formed matter, in many cases, acts the part of a filter, and its properties may be such as to allow some solutions to pass through it, and to interfere with the passage of others.

But in the second stage of the process of nutrition alterations occur which cannot be explained by physical laws. No such changes are known to occur except in the case of *living beings*, and we know of no means of producing them, save by bringing inanimate pabulum into relation with matter which already lives. I, therefore, speak of these as *vital changes*, and I shall endeavour to describe as far as I am able what probably occurs in the matter in this living state.

Before we can understand the real nature of the process of nutrition, we must learn what goes on this germinal or living matter when new pabulum comes into contact with it and undergoes its marvellous change. Atoms of matter, formerly in combination, are silently and quietly released. They are made to alter their positions; to move in a manner which we cannot explain; to take up altogether new relations, and acquire new properties. The ordinary attractions and affinities seem for the time being to be overcome, and there is no evidence that while the matter lives its particles enter into combination at all.



A living cell to show that the process of nutrition consists of

1. The passage of the pabulum through the formed material when it reaches the germinal matter.
2. The conversion of some of its constituents into germinal matter.
3. The conversion of some of the germinal matter previously existing into formed material which is deposited layer within layer, as it were, upon the *inner surface* of the formed material already produced. In many cases the successive layers are incorporated with one another.

The process of *oxidation* probably affects the outer and oldest part of the formed material chiefly, and, in some instances, occur in this situation only.

In the process of nutrition nutrient matter, pabulum, with its latent force, passes into this living matter; but who will affirm that the force thus latent in the pabulum is the force which causes the living matter to move and to draw new particles towards it—the force by virtue of which the elements of which it consists arrange themselves in a special manner?

It would seem rather as if there existed in relation with the living matter some power which compelled the elements of matter to take up certain definite relations to one another—some power which caused matter to arrange itself in a definite way, which controlled the matter and the forces latent in the matter. For how can the power which directs and controls force, be of the same nature as force? Nor is there any evidence of the manifestation of force or ordinary affinities while the matter remains in this temporary living state. The ordinary affinities and forces seem to be actually suspended, and do not again come into play until the matter has ceased to live.

Such wonderful power is not confined to the germ, as some have said, but it exists in relation with every particle of living

matter in every tissue in every organism. It has been called "directive power or agency," and has been compared to the direction of machinery by man, as the organism itself has been compared with a machine. If every lever and wheel moved itself, built itself up, and possessed in every part the power of forming other levers and wheels from crude materials whilst it still performed its proper offices, then some sort of comparison might fairly be made between inanimate machines and living things.

This power of self-construction is peculiar to matter which is alive, and there is no living thing in which it is not manifested; but there is no other force in nature which can be compared to it. It seems, therefore, correct to call the actions which go on in all living matter, but in living matter alone, *vital actions;* and to speak of the power to the influence of which these actions are supposed to be due, as *vital power*. If any physicist can explain these actions by any known laws of Physics, then we must cease to talk of vital power. But some physicists, who have ventured to discuss very freely certain physiological problems, have not even alluded to the real phenomena which distinguish things living from things inanimate.

In nutrition, some constituents of the pabulum have conferred upon them the same powers as the living matter already existing, and thus the latter *increases*, or is *nourished*, or "*grows*." But the pabulum is pabulum no longer; it has lost its old characters and has acquired new ones. Its particles are differently arranged; they do not combine to form compounds. There is reason to believe that they actually move in a direction *from* the centre at which they acquired their new properties. It is for the Physicist to prove that they do not move *from centres*, or, if he admits that they do, to explain *why* they move in this direction. This tendency to move *from* a centre seems one important character in which every kind of living matter differs from matter in every other known state. This *centrifugal* movement will enable us to explain how the pabulum is drawn towards the living matter; for it is obvious that if the various particles of which a spherical mass is composed exhibit a tendency to move *from* a centre, the fluid (pabulum) around will be caused to move in the opposite direction, and currents will flow *towards* the centre. Thus, upon this view of the constitution of living matter, something like an explanation of the cause of the passage into its substance of matter from without is afforded.

Now, of the chemistry of this matter, which performs all these active processes and possesses such marvellous powers, nothing whatever is known, save that by its death we can obtain a substance which we call fibrin, another we call albumen, a little matter we call fat, water, and salts. A chemist might say the living matter is composed of these things; but who can prove that these substances actually exist *in* the living matter? On the contrary, they seem to be but *products resulting from its death*, under certain conditions. So that there is nothing in this second stage of the process of nutrition which resembles any chemical process known. In no case does food become converted directly into tissue, or into the products of secretion, or into blood. In no case does food, as food, become oxidised; but it always becomes *germinal*, or *living matter*, the products resulting from the death of which are applied to the nutrition of the germinal matter of the blood, tissues, secreting organs, etc.

Surely, then, we may consider it established that in the nutrition of every living structure all pabulum passes through the state of germinal matter before it assumes the condition of formed material, and that the character, composition, and properties of the formed material are the consequence of certain changes occurring during the temporary living or germinal state. (See Fig.)

In every kind of nutrition it is this germinal matter, and this alone, which plays the most important part. Without it no formed material can be produced. Formed material (cell wall, intercellular substance) has no changing, metabolic, converting, or catalytic power. It cannot make new formed material. It cannot alter, modify, change, or convert. It is passive. But the germinal matter does all these things, and its powers are conveyed to new matter without loss, and this extension of power from particle to particle seems to be infinite.

Let it not be supposed that I am discussing any unusual or exceptional process. I am speaking of changes which occur in every living cell of every living growing tissue in nature. Nor are the statements I have made applicable alone to the healthy condition. They apply to morbid changes.

The phenomena of inflammation are mainly due to the increased access of pabulum to living germinal matter. In mortification, in fever, in chronic structural changes in secreting organs — such as cirrhosis and chronic renal disease — in cancer, in fatty degeneration, and in many other changes, germinal matter is involved. The growth of germinal matter, which in the normal state is slow, may be accelerated in consequence of the access of an increased supply of pabulum; or the growth of germinal matter, which in the normal state of things is very rapid, may be interfered with by the formation around each separate mass of a thick layer of hardened and slightly permeable formed material. Not one of these phenomena can occur without germinal matter, nor is any one of them simply a mechanical or chemical change. Those so-called morbific agents, or morbid poisons, which are capable of being transferred from a diseased to a healthy organism, are minute portions of living or germinal matter. A living pus corpuscle, or perhaps a very minute portion of such a corpuscle, from the eye of a person suffering from purulent ophthalmia, coming into contact with a conjunctiva in a certain state will grow and multiply, and thus cause the disease in a person not previously affected. An active living corpuscle from the gonorrhœal discharge will, as is well known, grow and multiply if transferred to a conjunctival mucous membrane.

These and many other morbid poisons are, in fact, masses of living germinal matter detached from the germinal matter of a living organism. The active matter of small-pox and vaccine lymph is probably of the same nature, and so, too, the poison of typhus, scarlatina, and some other fevers. These living particles, unlike the germinal matter from which they have descended, retain their vitality, and often for a very considerable time, under conditions which would destroy the germinal matter in the cells of a healthy organism.

The life of the rapidly-growing pus corpuscle is not so easily destroyed as that of the more slowly growing mass of germinal matter of the epithelial cell from which it was originally derived, and the cancer cell flourishes where the normal tissue cells had grown very slowly. Germinal matter seems to gain in its tendency to very rapid increase as it loses its power of evolving special and important structures. The power of growing and multiplying under a vast number of different conditions, producing little formed material, and no lasting structure whatever, and the power of evolving definite structure to fulfil a definite purpose seem opposed.

Vital phenomena ought not, therefore, to be ignored in the healthy or diseased *nutrition* of any single cell or tissue, and it is as unjustifiable to speak of any morbid condition as a *chemical or mechanical disease* as to attribute the phenomena occurring in a living being to mechanical and chemical operations alone. Disease involves more than mechanics or chemistry, or both combined. Altered external chemical and mechanical conditions imply a modification in the vital changes going on in the living matter, and the disease is the consequence; but it is as impossible to explain the nature of the diseased action without referring to the vital phenomena occurring in the living matter, as it would be to give a true account of the process of nutrition without referring to vital changes. A cell without living matter is incapable of exhibiting any of the phenomena characteristic of and peculiar to living things, and the results of any mechanical or chemical changes induced in healthy living tissues are seen in modifications in growth, etc., dependent upon *vital changes* in the germinal matter of the affected tissue.

I have endeavoured to show that in all cases the tissue or structure of a living being is composed of matter which *lives* and matter which *has lived*, and that in the first *vital changes* as distinguished from mere physical and chemical phenomena occur, and that this living matter alone is essentially concerned in *nutrition, formation, and growth*. This living matter is all important in the changes occurring in all parts of the body in health and disease, and it differs from matter in every other known state, in its power of converting new matter into matter like itself, and of communicating to it powers and properties in all respects similar to those it possessed before the new matter came in contact with it. Every kind of living matter known is colourless, and possesses certain characters in common with other kinds, but there is the greatest difference in power—a difference which cannot be accounted for by difference in chemical composition, or attributed solely to the conditions under which life is carried on, etc. It has been suggested that since this apparently simple, colourless, soft, plastic matter endowed with all these wonderful powers consists of nothing but a little carbon, hydrogen, nitrogen, oxygen,

with one or two other elements of less importance, in some peculiar state of combination, it may be possible to discover the conditions under which these simple elements may be made to combine, and so to form artificially a particle of living matter! If, however, we consider the actual processes which occur in the nutrition of the simplest living particle, or if we observe for ourselves the changes which may be seen in living matter under the higher powers of the microscope, as in a mucus corpuscle or a pus corpuscle, we shall be led to study and investigate still further the wonderful phenomena which characterise living matter, and the nature of the changes which occur in the process of its nutrition; and we shall soon be convinced that the vague and oft-repeated assertions with reference to the identity of *vital* with chemical and physical actions rest upon no scientific foundation whatever; that they are opposed to the results of careful observation and experiment, and have arisen from a most incomplete examination of actual facts, many of which are open to the observation of all.

(To be continued.)

ON THE USE OF HOT WATER AS A REMEDY FOR PROFUSE PERSPIRATION.

By ROBERT DRUITT, M.R.C.P. Lond., etc.

I WISH to call the attention of my Professional brethren to the use of hot water as a remedy for profuse perspiration.

If a part of the body that is perspiring be bathed with quite *hot* water till it becomes decidedly hot and *red*, the skin will become dry, and will continue so for a greater or less period of time.

If *cold* water be used, the part remains cool for some time and then becomes gradually warm or glowing; if *tepid*, it is usually made unpleasantly chilly and flabby; if *warm*, it is left perspiring; if *hot*, it is left hot, red, and dry.

The terms cold, tepid, warm, and hot are merely relative; what would be warm to one would be lukewarm to another person; but when I say *hot* water for our present purpose I mean water as hot as can be borne without pain. It may be used by sponging or immersion, and must be continued till the parts treated are hot, red, and *tingling* with heat—almost scalded, in fact. A good wipe with water at 130° is easily borne; for immersion the heat must be less; but the feelings are the only guide.

The circumstance which led me to recommend this remedy was the observation of the painful dryness of a hot skin in feverish attacks, and of the dryness produced by using too hot water in a bath, and by the clumsy use of the lamp-bath, which may make the skin dry instead of moist if not well managed.

The cases in which I have recommended it with benefit are —first, those of general tendency to perspire to a distressing degree in hot weather, the patient being in good health. If a man who has thoroughly used a cold bath in the morning be obliged to change his shirt in the middle of the day, for example, he will keep his skin comfortably dry for a certain time by a good wash with very hot water.

The next class of cases are those in which, with or without tendency to perspire over the body generally, but most probably without, there is a tendency to distressing perspiration of some particular part; as the axillæ, hands, feet, etc. Patients who seek relief for this are generally young persons from 13 to 20, and they often endure great misery and persecution in consequence of this symptom, which really admits of easy Medical treatment. The health is sure to be improved by free purgation, and by quinine, air, exercise, etc. But the distressing local symptom may be got rid of for hours at a time by the thorough application of the hottest water to the offending part until it is red, hot, and tingling as if scalded.

Thirdly, there are the cases of true hectic; diurnal shiverings, followed by heat, and drenching perspiration of an earthy, sickly odour, and depending (as we suppose) on absorption of decaying pus from some internal organ, probably lung, etc. In these cases I have tried every remedy I know of without result. I have caused profuse perspiration by the lamp-bath in the afternoon without preventing the access of hectic and perspiration in the evening; and confess my remedy inert—or next to it—in these cases.

But there is a fourth variety—the ordinary night sweat of the phthisical, not preceded by regular hectic paroxysm, but induced by all that relaxes, lessened by all that strengthens, and coming on when the patient falls asleep. For many of these cases the hot water gives relief, to a certain extent, especially if the perspiration begin, as it often does, on one special part of the body by preference, as the chest, hands, or feet. In such cases I have the testimony of patients that the hot water greatly helps to control the sweat. The way is, when the patient goes to bed, to have the chest reddened with hot water, and wiped dry. One patient, whom I see daily, and who is confined to his bed, calls out for it so soon as he perceives the dampness beginning, and has it used to chest, hands, and feet, and by this means often, not always, passes a night without being obliged to shift his linen.

In conclusion, let me say that I only offer this as a contribution towards the relief of an unpleasant symptom, and not as a cure for a disease; and that whoever uses it must recollect that it is not *warm*, but *hot* water, just below scalding point, that is to be employed.

37, Hertford-street, Mayfair, W.

METHOD OF APPLYING THE GYPSUM BANDAGE.(a)

By T. E. STARK, Army Medical Officer.

Gypsum.—The water must be expelled from the gypsum. By exposing the gypsum, $SO_3CaO + 2HO$, to a temperature from 100° to 120° Celsius, it loses about $1\frac{1}{2}HO$. The boiled plaster, $SO_3CaO + \frac{1}{2}HO$, is to be got at a plasterer's. An inferior quality, being not quite white, used by plasterers for making rough forms, is preferable. The gypsum must be well pulverised, and should be preserved in air-tight bottles or tin boxes; such gypsum mixed with two parts of water forms a cream-like material, and becomes hard in from fifteen to twenty minutes. The temperature of the mixture rises as soon as crystallisation sets in, the hardening of the mixture being an imperfect crystallisation.

Flannel.—Of all materials flannel is the best for gypsum bandages; the thin, coarse flannel called "demi-caine" must be cut into bandages about two yards and one foot in length, and one and a-half inches in breadth. Those bandages should be spread on a table and rubbed in with gypsum powder; in order to rub the gypsum well into the weft of the flannel, a tightly rolled up cotton bandage should be used; the gypsum powder must be well worked into the flannel, first on one side and then on the other; it must not be rubbed backwards and forwards, but always in the same direction, according to the thread. After the process one ounce of flannel must contain nine ounces of gypsum powder.

The bandage after being well rubbed in with gypsum should be rolled up loosely. It is unnecessary to spread gypsum on the bandage before rolling it up, as the gypsum powder alone contained in the weft of the flannel gives consistence to the bandage when applied. The gypsum bandages must be kept in air-tight bottles, tin cases, or boxes.

Application of the Bandage.—It is applied directly to the skin; the limb or part should be shaved if required, and then rubbed with a little oleum olivarum, or ung. simpl.

The bandage must be first soaked in luke-warm water for two or three minutes, and being thoroughly wet it should be carefully passed round the limb, care being taken not to make *renverses*, the turns covering each other to a depth of two-thirds or three-quarters of the roller.

According as the turns cover each other to a depth of about three-quarters, or two-thirds, the bandage will be more or less firm. The bandage should be applied so that a gentle pressure is exercised; the uniform circular pressure being one of the most important qualities of the gypsum bandage. Prominent parts —for instance, the heel and elbow—should be covered by narrow lengths cut from the bandage, in order to cover them better, and to prevent the accumulation of turns on the opposite side.

In case some parts of the bandage should not be thoroughly wetted, a stream of water must be directed upon it. During the application of the first bandage, a second should be soaking, and when this is taken out for application a third should be soaking, and so on. The beginning of the second bandage must join the end of the first, and so on in succession, in order to make the surface uniform. After applying one or two bandages, the whole is sponged.

(a) An abstract from "Mathüsen's Gipsverband en zijne laasste Wüzigingen." Medeqedeeld door Dr. W. Kral. Utrecht. 1863. "Mathüsen's Plaster of Paris Bandage and its most Recent Modifications." By Dr. W. Kral. Utrecht. 1863.

Many-Tailed Bandage.—The lengths cut from the long bandage being put on a waterproof sheet, covering each other from two-thirds, three-quarters, etc., are to be passed beneath the limb. Five or six bandages are to be thoroughly wetted at the same time by a small watering pot, and then carefully applied round the limb, from below upwards, the ends of each bandage overlapped in front. Of the first and last turns the edges must be folded back to prevent them, when hard, from being sharp and causing excoriations.

The gypsum bandage, having been applied, should be left to itself until it is hard by the crystallisation of the gypsum. It becomes hard in fifteen or twenty minutes, and then the turns being firmly united together in the flannel gypsum bandage, we may operate on it: cut it open; make valves. It requires some hours before it is dry. If there is no particular hurry to cut the bandage open, we may as well wait until it is dry.

The hard and dry gypsum bandage being pervious, does not interfere with the functions of the skin. The bandage is a good conductor of heat, and being directly in contact with the skin, it is easy to observe the pathological process under the bandage. The thermometer will indicate the temperature of the part affected.

If required, we may apply cold lotions to the bandage, for the above mentioned reason of its being a good conductor of caloric.

The gypsum bandage may be directly applied to sores. The hard and dry bandage, being pervious, will imbibe the matter. In case all the matter should not be imbibed, it will flow between the bandage and the skin; but there is no occasion to fear that the skin will be affected. The gypsum bandage being directly in contact with the skin, neither wound secretion nor matter affects it. Even in a case of compound fracture, where the whole bandage was soaked by ichor, and on that account removed, as it was feared that the skin might be affected; it was, however, found in a healthy state.

Should the gypsum bandage be required to cover a wound, for instance in a case of compound fracture, the wound should be covered with lint and linen, to prevent the wound secretion from coming in contact with the wetted gypsum bandage, as it might interfere with the crystallisation of the gypsum. The hard and dry gypsum bandage will resist wound secretion, matter, etc.

The gypsum bandage will withstand water; it does not lose its hardness either by baths or cold or warm irrigations.

In order to prevent stiffness of the articulations and weakness of the muscles, the gypsum bandage may be applied so that it allows of gentle movements of the joints. On the extension side of the joint a length of adhesive plaster, about one and a-half or two inches broad and surrounding two-thirds of the joint, should be applied to the gypsum bandage, the adhesive side outwards.

The gypsum bandage should further be passed over this piece of adhesive plaster and round the limb. The bandage being hard and dry allows of movements. On the extension side two turns do not adhere to each other, being separated by the adhesive plaster, to which the gypsum bandage does not stick, the turns on the flexion side forming a kind of hinge.

Having made use of this joint of the bandage, it may be closed by passing a thoroughly wetted gypsum length round it; this on becoming hard prevents any voluntary movements. In order to make the wetted length stick well, we have to wet that part of the bandage where it is to be put on.

The gypsum bandage not only exercises an uniform circular pressure and relaxes the muscles, but maintains, if well applied, extension and counter extension. The gypsum bandage does not change after crystallisation has set in. If during the application of the bandage a proper extension and counter extension is made, and maintained until the bandage is hard, the bandage will keep up a state of permanent extension and counter extension.

To obtain a more perfect state of permanent extension and counter extension, the gypsum bandage may be applied as follows:—For instance, in case of a fracture of the forearm, the gypsum bandage should be applied from the middle of the forearm to the middle of the arm. The lower part of the bandage is now to be covered with a double layer of blotting paper. Then a gypsum bandage must be applied from the wrist upwards as far as the blotting paper extends. The gypsum bandages separated by blotting paper do not adhere to each other. On making extension and counter extension the lower part of the bandage will slide from the upper. The limb having been restored to the required length, the lower part of the bandage, where it slides from the upper part, must be cut open and adapted to the other part, and fixed with gypsum lengths.

How to make Incisions in the Gypsum Bandage.—The bandage must be opened with a strong pair of blunt-pointed scissors. The opening of such a hard bandage may be considerably facilitated if we proceed in the following manner:—The blunt-pointed blade is to be passed between the bandage and the skin; the pair of scissors should be held in the right hand, on the thumb and fourth finger, the left hand must exercise the required force, by placing the left thumb on the right holding the scissors, and the other fingers underneath. The right hand directs the scissors, the left hand forces them through the bandage. We use two sorts of scissors, Mr. Mathysen's pair of scissors, and Mr. Szymanowski's, the latter from the principle of an American pruning scissors. The bandage should always be cut open on that side of the limb where the bone is covered by soft parts—for instance ,on the outer side of the crista tibiæ, not on the inside. The gypsum bandage is to be cut open in order to make it bivalvular, to make valves, and to remove it.

Suppose we are treating a fracture of the centre of the femur with a gypsum bandage; it should be opened by an incision carried along the inner side of the thigh, as far as, or below the knee-joint. In a fracture of the tibia the bandage should be opened by a longitudinal incision down a line on the outer part of the leg, as far as the ankle-joint. In every case where swelling is to be expected, the bandage must be opened in the direction of the longitudinal axis of the limb. The bandage on being cut open will adapt itself to the swollen parts, and no unpleasant symptoms, caused by too tightly tied bandages, will arise.

When the size of the limb decreases, by the disappearance of the swelling or the emaciation of the limb, the bivalvular gypsum bandage may be moulded to the limb, and the margins immovably connected with each other by means of gypsum lengths. According as the valves of the bandage project more or less over each other, it adapts itself to a smaller or larger volume of the limb.

The above-mentioned operations on the bandage do not diminish its firmness. The bandage having been moulded to the part and secured with gypsum lengths, affords the same uniform support and circular pressure.

Percussion will decide whether the gypsum bandage is too large for the limb. As soon as we find that the bandage is no longer in contact with the skin, we have to cut it open, make it bivalvular and overlap the margins. In case the bandage is already bivalvular, we have only to overlap the valves farther, the whole adapting itself to the decreased size of the limb.

Valves.—In order to make a valve in the bandage, we proceed in the following manner:—Suppose we require a valve corresponding to the middle third of the leg. The heel being covered by narrow lengths, the gypsum roller is passed round the foot, the ankle joint, the lower third of the leg as far as the middle third. Then a piece of paper, as broad as the lower border of the valve which we have to make, is to be put between two turns, and then the bandage passed upwards as far as or above the knee.

The bandage being hard, we draw with a pencil the outline of the valve, the paper being the lower border.

The paper prevents the turns from sticking to each other, so we have only to cut open the sides; the upper border being continuous with the bandage, forms the hinge. Oval valves are the best, the long axis corresponding to the longitudinal axis of the limb. Oval valves have the lower border and the upper border small, the latter forming the hinge.

Having made the whole bandage bivalvular by a longitudinal incision, we can easily make quadrilateral valves by carrying two incisions transversely; the free border of the valves will then correspond to the longitudinal incision. In case the bivalvular bandage has already been overlapped, we shall, of course, make the incisions in that margin of the bandage which projects over the other.

To make the bandage soft where it must be cut, we may use acidum hydrochloricum concentratum, one-third; mixed with water, two-thirds. Having drawn the line where the bandage is to be cut open, we apply the diluted hydrochloric acid on the line with a brush. This must be repeated several times; in about eight or ten minutes the bandage is quite soft, as far as the hydrochloric acid has been put on, and may be cut open by an ordinary pair of scissors, rubbed with unguentum simplex.

REPORTS OF HOSPITAL PRACTICE
IN
MEDICINE AND SURGERY.

GUY'S HOSPITAL.

CASE OF GLANDERS—DIFFICULTY IN DIAGNOSIS—DEATH—CLINICAL REMARKS.

(Under the care of Dr. HABERSHON.)

This case was one of great obscurity, and when first admitted the symptoms were regarded as those of bronchitis, with slight pleurisy consequent on exposure to cold. After a short time pain in the joints came on, and suppuration took place, preceded by erysipelatous inflammation at the parts. Scattered pustules then appeared on the body, and it was evident that severe disease existed, closely allied to pyæmia; still the cause was not evident, and the whole case was involved in much obscurity. The first symptoms were those of inflammatory disease about the chest, and at the end of fourteen days phlegmonous erysipelas with suppuration was found at the right foot, then at the left elbow; there were febrile symptoms, with great prostration and delirium. Six or seven days later pustules appeared on the body, and this fact tended to confirm the idea of pyæmia. The typhoid symptoms increased in severity, and no hope was entertained of recovery.

On June 9, the twenty-fourth day of his illness, and three days before death, a watery discharge took place from his nose. The true character of the disease was then seen as glanders, and especial inquiry was made in reference to to contact with any diseased horse. It was not ascertained till after death that the horse he had driven four weeks previously had been affected with glanders, and had died from that affection.

The pain in the joints in this case was not likely to be mistaken for rheumatism, from the erysipelatous redness and rapid suppuration. No tumours were present, as have been sometimes described in glanders, nor did the pustules appear till the 21st day after exposure to the diseased horse. The comparison to the pustules of small-pox, or those produced by tartar emetic, was not borne out in this instance. They had the character of the sero-purulent blebs sometimes seen in pyæmia; vesicles appeared first on the back, then on the extremities, and lastly on the face; they were isolated, like those of rupia, without inflammatory base; they soon became larger and prominent, and were filled with pus, the pus assuming a deeper colour as the pustule enlarged. It was only a short time before death, the 24th day, that the mucous membrane of the nose and the nasal sinuses became affected, the face then became swollen, and pustules appeared upon it. It was impossible to ascertain how the man had become affected, whether from any wound upon the hands, or from applying diseased secretions inadvertently to his own face, or whether the breath of the horse had been sufficient to contaminate the blood.

James F., aged 37, a master tailor by trade, living at Deptford, was admitted, under the care of Dr. Habershon, into the clinical ward on May 27, 1863. He has generally enjoyed good health—indeed, this is the second illness he has ever had; the former he calls inflammation of the lungs; but his habits have been very intemperate, and he states that he has been subject to a winter cough for some time.

The present illness, he says, began with a cold. On Sunday, May 16, he hired a conveyance to take himself and a few friends out of town. When driving home he felt very chilly; but he did not begin to be actually ill till the following Tuesday. He then felt great pain in his back, and on that evening his left side became very painful: the pain he compares to being "pierced by daggers." On the Friday following he attended as an out-patient, under Dr. Pavy, but could not then make it convenient to come into the Hospital. He has been getting worse till the present time.

Present condition.—He has an anxious, rather worn-out appearance. The skin is hot and rather dry. The tongue is furred and dry, and somewhat fissured. The appetite is very indifferent, and he has taken but little nourishment for the last week. The bowels are relieved daily. The pulse is accelerated—100 per minute, and is compressible. The heart sounds are normal. The chest is broad and well formed. On percussion, there is somewhat more than the natural amount of resonance. Rhonchus and sibilus are heard all over the chest. Resp. 20 p.m. He complains of pain in the left side at the base of the lung; much increased on inspiration, and also when he coughs. An indistinct pleuritic rub is heard at the base posteriorly. He cannot lie well on either side; the most comfortable position is on the back. He has a short cough, and expectorates mucus, which, however, is scanty; and complains of severe pain in both elbow-joints on extension; but no swelling or redness can be seen.

28th.—The urine is high coloured; it forms no deposit on standing; is not coagulable by heat or nitric acid. ℞. Pil. colocy. c. cal. gr. x., statim; cataplasma lini, lateri simistro applic.; pulv. Doveri, gr. v., ter. die. c. J.A.A., ʒi.; vinc, ʒvi.

29th.—To-day no pleuritic rub can be detected. Sibilus is very well marked. He complains much of his right foot, which is inflamed, but not very tender. No fluctuation. Lotio alba has been applied, but it was afterwards changed for a poultice, which gave some relief, but it still continues painful. He is ordered to take the pill of Dover's powder night and morning.

30th.—Rhonchus and sibilus are heard all over the chest, accompanied by some mucous râles. The expectoration is increasing. His foot is still painful, and now looks as if affected with phlegmonous erysipelas. He complains also of pain in the lower part of the back, which is red. He has had distinct rigors to-day.

June 1.—℞. acid hydrocy. dil., miij., ex. mist. cornüi. co. sextâ quâque horâ sum.

2nd.—Last night the pain in the foot was so great that, although no distinct fluctuation could be detected, an exploratory incision was made, and afterwards enlarged, from which a quantity of pus was evacuated. A hemlock poultice was afterwards applied, and to-day he feels considerably relieved. The back, over the lower part of the sacrum, and on the inner edge of each buttock, is red and fissured, with a tendency to an eczematous eruption; it is of an erysipelatous hue. Cotton wool with oil is to be applied. The left forearm just below the elbow-joint is very painful, but there is no marked redness; the temperature of that part of the forearm is decidedly higher than that of the arm. The pulse is weak and compressible, 100 per minute. There has been slight delirium during the night, but this morning he is quite sensible. Rhonchus and sibilus still heard all over the chest, accompanied in some parts with mucous râles. No pleuritic rub audible. He has had no shivering to-day or yesterday. Respiration laboured, and accompanied by great wheezing; 20 per minute. The tongue is flabby and rather furred. The bowels are regular. The skin is above the normal temperature, and his expression is more depressed. He is ordered to take, in addition to his six ounces of wine, eight ounces of brandy.

4th.—The patient continues delirious at night. There is less cough, and but scanty expectoration.

5th.—This morning he is in a semi-delirious state, and constantly wants to leave his bed; he is not conscious that he is in a Hospital. Pulse fluttering, 104 per minute; rhonchus and sibilus are still heard, but hardly any mucous râles. Eruption of vesicles all over the back; the lower part of the back is, he says, less painful; indeed, to-day he does not complain of any pain, but is evidently worse. Respirations, twenty-eight per minute. Both pupils are contracted. The urine is scanty, of a brownish colour, but it contains no albumen. ℞ Tr. hyoscy. ætheris chlorici āā ʒss. ex. mist. camphoræ statim, et repetatur hac nocte. On the back of the right hand there is a swelling, having an erysipelatous hue, painful on pressure. A poultice is to be applied to the foot and to the elbow.

6th.—Pulse 116 per minute, feeble; respirations laboured, twenty-nine per minute. He has rested better last night. Sililus and rhonchus audible all over the chest. Coughs a little, and expectorates a little frothy tenacious mucus. Tongue moist, but he complains of thirst. The swelling on the hand is to be enveloped in cotton wool and oil, and a poultice is to be continued to the elbow. Repetatur haustus hac nocte, et ℞ quinæ disulphatis gr. iij., ter die in formâ pilulæ. Wine, ʒxij.; brandy, ʒviij.; milk, Oij.; beef-tea and arrowroot; four eggs.

8th.—Respirations twenty-nine per minute; pulse 120. The right hand is more swollen, and very red; numerous pustules appear on the calves of the legs, and between the shoulders, most of which are about three-quarters of an inch in circumference, though some are much larger. There is subsultus

tendinum, and also picking of bedclothes. He mutters almost incessantly, but when spoken to he answers questions. Complains of much nausea. Capiat. olei. ricini. ʒss. si opus fuerit.

9th.—Respiration 44 per minute; pulse 134. The elbow and back of the hand are not so swollen, but pustules appear on various parts of the body. His lips are parched, and his tongue is dry. His bowels have been freely relieved without taking the castor-oil. He has rested badly during the night. A thin, watery discharge was to-day, for the first time, noticed from the nostrils. Subsultus tendinum, and floccitatio. He is much more delirious. 8 p.m.—Continues much the same; pulse 130. Seems conscious for a minute or two, and is again quite delirious. His whole face seems swollen—a bloated appearance. He has a great aversion to his friends sitting around his bed; mutters continually. Mist. ammon. effervesc. quartâ quâque horâ s. Omit the brandy.

10th.—Has rested a little better during the night, but this morning he presents a sad appearance; his face is much swollen, and is marked in various places with pustules, which also are found all over the body; on each leg and thigh there are about twenty, and several on his back and arms. Local suppuration in the neighbourhood of smaller joints. The swelling on the back of left hand has greatly subsided, except in one position, where fluctuation is detected, and into which an opening is made, and pus evacuated. Respiration 44 per minute; pulse 120; respiration spasmodic. Bowels freely relieved this morning; subsultus tendinum continues. 5 p.m. —Pupils contracted. The discharge from the nostrils still continues. The pustules in some places discharge their contents. The urine is of a dark brown colour; it is not coagulable by heat or nitric acid.

11th.—Day and night he remains in much the same position, on his back, and mutters incessantly. There are still more pustules seen on various parts of the body, accompanied by local suppuration, and they are apparently indiscriminately scattered over the body. The lips and teeth are covered with sordes. He takes no notice of passing events. ℞. Misturæ vini. gallici, ʒss. secundâ quâque horâ sum. He is to continue with his nourishment, which he takes very well.

The patient continued alive till 2.30 a.m. on Friday, the 12th. No post-mortem examination was made. The back and posterior aspects of legs and arms were very black.

Mr. Phillips, to whom we are indebted for the above, adds, —"Both the patient and his friends were in vain interrogated with a view of obtaining a history of contagion from a glandered horse; but we have since his death ascertained that the horse he hired for the Sunday before he was taken ill had glanders then, and has since died of that malady."

THE LONDON HOSPITAL.

REMOVAL OF A LARGE CALCULUS FROM A YOUNG GIRL BY RAPID DILATATION OF THE URETHRA.

(Under the care of Mr. CURLING.)

The following case is one of considerable practical interest, and tends to confirm the views of Mr. Bryant respecting the treatment of stone in the female.(a) The patient was rapidly relieved from a state of great suffering to health. Mr. Curling made the case the subject of some clinical remarks, of which the following is a very brief note:—

Those who saw the girl when she was first admitted would have observed that she was extremely ill—so ill, indeed, that as soon as it was discovered that the cause of her symptoms was calculus, Mr. Curling did not like to defer the operation, even for twenty-four hours, and therefore operated at once. The result of speedy dilatation was most satisfactory. Before chloroform was introduced, Mr. Curling remarked, the practice was to dilate very gradually by sponge tents or by instruments, so that twenty-four hours or more were occupied in stretching the urethra. Patients were not able to bear rapid dilatation without chloroform.

When he had ascertained the large size of the stone, Mr. Curling had some doubts as to whether he could dilate the urethra sufficiently to extract it, but the passage yielded more readily than he had expected. In about ten minutes he was able to introduce his forefinger and then the forceps.

In some cases of stone in the female bladder, Mr. Curling remarked, lithotrity was of great use in reducing the stone to fragments small enough to pass the urethra easily. This case, however, was quite unfit for that operation. The patient could not retain her urine, and the bladder contracted round the calculus so as to leave no room for manipulating with the lithotrite.

The chief point of interest after the operation was whether the patient would recover power of retention. In extracting the calculus, which required some force, no doubt the urethra was slightly lacerated, causing some bleeding. In the report of the case it will be found that power of retention was gradually and completely regained. Mr. Curling added that, as regards this power, dilatation was much more promising than the cutting operation, and he quite condemned vaginal lithotomy.

For the notes of the case we are indebted to Mr. Rogerson.

Sarah B., aged 12 years, a thin, spare girl, much prostrated by prolonged suffering, was admitted December 20, 1864, having been sent up from Dover. About sixteen months ago she was taken with a sudden stoppage during micturition, and continued to endure pain and inconvenience without mentioning it to her parents. She gradually became worse, and four months ago was confined to bed. Her urine had a strong ammoniacal smell, was of a dirty white colour, with much sediment, and a thick secretion or mucus which adhered to the utensil, occasionally blood, causing during its exit severe smarting pain in the passage, followed by severe pain near the pubes. A month afterwards her urine commenced to dribble from her, and has continued to do so for three months; the sufferings being periodically the most agonising and distressing, causing her to cry for hours, and even to scream.

A fortnight before her admission she had bed sores, ulcerated in two or three patches over the spinous processes of the lumbar vertebræ, the surrounding integument of the loins and buttocks was inflamed and excoriated mostly from the urine.

Mr. Curling saw her at half-past one p.m., and found her in a precarious and depressed state. He directed her to be at once conveyed to the ward, where he passed a sound, and readily detected a large stone in the bladder. He thought it advisable, from the distressing condition of the child, to remove the stone without any delay. Chloroform was administered. The patient was placed at the edge of the operating-table; the legs were flexed, and held apart. Weiss's three-bladed dilator was passed into the urethra, and about half a dozen revolutions of the screw were made in the space of five minutes. The instrument was then withdrawn, and the forefinger was introduced into the urethra, but could not be easily passed onward into the bladder from the still narrow and tight condition of the urethra. The dilator was re-introduced with the prongs closed, and the dilatation was carried on steadily for three or four more minutes. Mr. Curling's finger then passed with the greatest of ease into the bladder, and he discovered the stone to be a large one. He then passed a small pair of curved lithotomy forceps into the bladder, caught the stone by its long axis within the blades, bringing it down by detraction and an oscillatory movement from side to side until it was successfully extracted. The bladder was then washed out with tepid water.

The stone was remarkably large, of an ovoid form, measuring an inch and a half in length, and one inch and an eighth in diameter, or more at its widest part. The patient was conveyed to bed, and shortly after recovering from the influence of chloroform ten minims of laudanum were given; a warm hip-bath every night.

The dilatation and extraction did not occupy more than fifteen minutes. A small quantity of blood—a few drachms only—escaped during and after the extraction of the stone.

On division of the stone into two symmetrical halves, it was found to be composed of a lithate of ammonia nucleus with concentric laminæ of oxalate of lime surrounding it, with phosphatic deposit intervening between them. All the outer part and by far the greater part of the calculus was composed of phosphate of lime. The day after the operation the patient slept nearly continuously throughout; pulse quick, 108; voice feeble; pain in the passage; otherwise comfortable. On the second day, forty-nine hours after the removal of the calculus, pulse 120, full; tongue furred on each side of the sulcus; skin hot; mouth and tongue dry and thirsty.

Third day, pulse not so frequent, 108; tongue cleaner; smarting pain in passing water.

24th.—The inflammatory symptoms disappeared; tongue moist; pulse better, 96.

(a) Med. Chir. *Trans.*, vol. xlvii.

To-day, the 25th, is cheerful; takes her food, including ʒiv. wine, milk, and beef-tea. Five minims of tincture of opium in an ounce of camphor mixture three times a-day, and the warm hip-bath every night. Sat in a chair by the fire with a blanket round her for some hours, and retained her water for an hour.

26th.—Her urine still continues dribbling from her. She is much more cheerful in aspect. On Mr. Curling's visit to-day she was sitting up in bed, the improvement in her general appearance being most marked.

28th.—She retained her water during nearly the whole of the day.

On the 29th she was dressed, held her water, passing it with a good force.

31st.—Water remains neutral, a little thick, with some sediment; passes in the day, but in the night is still plagued with incontinence of urine.

January 3, 1865.—Mr. Curling recommended her to go into the garden of the Hospital, and requested the nurse to arouse the child twice during the night. From this date the power of retaining her urine gradually increased, and she frequently gets up, and micturates by voluntary efforts.

10th.—Her general health greatly improved; countenance cheerful; urine slightly acid; retains it six hours in the day; and no incontinency at night. Discharged cured.

ST. GEORGE'S HOSPITAL.

HYSTERICAL (SO-CALLED) PARAPLEGIA.

(Under the care of Dr. J. W. OGLE.)

The patient, Anne C., aged 21, from Kensington, having the teeth much decayed, was admitted October 19, 1864. It was said that she had had diphtheria at Christmas, but there was no certainty of this. She had been for five or six weeks, it was said, the subject of "fits," and had had two on the day of admission. These had come on first after she had attended her father's funeral, she having on the day following experienced much numbness and chilly feelings in the legs, which so increased that on the third day afterwards she could not walk at all. She was brought to the Hospital in a cab, and lifted upstairs. There was then complete loss of power in moving both legs, and the sensibility of the skin of those limbs at every part below the knees was absolutely wanting; it was not so in any other part of the body's surface. On tickling the sole of either foot a very slight but yet actual reflex action was induced. She asserted that at times the legs were wont to jerk up involuntarily. Her feet were lower in temperature than the other parts of the body. On pressure, the upper part of the dorsal region of the spinal column proved to be tender, and at one spot pain was produced thereby.

The urine was natural, and free from either albumen or sugar. She stated that at times she was unable to "hold the water." This was never so with the alvine evacuations. She was ordered to take ammonia and citrate of iron with aromatic spirits of ammonia, and to be purged, and to have good diet. Four days later she was put upon quinine and iron with one-sixteenth of a grain of strychnia, and the compound galbanam pill (gr. xii.) every night. After taking this for four days she expressed herself as decidedly better in the legs, especially across the front of the ankles. The feet were still clammy and cold, and I ordered a hot-water-bottle to be kept always in bed. The feet did not, however, feel cold to the patient. On the 27th I ordered the legs and length of the back to be galvanised for ten minutes every morning; and three days later, the medicine being continued, the strychnia to be increased to one-twelfth of a grain. During this time she gradually improved, and the power over the legs was so much restored that on November 2 I found her walking about in the ward. She quite recovered in a few days longer as to her legs, but experienced a very severe attack of bronchitis, which kept her in the Hospital three or four weeks longer.

EPILEPTIC ATTACK—NUMBNESS IN EXTREMITIES—HALF-COMATOSE STATE AND SINGING DELIRIUM—STRIDULOUS RESPIRATION OWING TO FIBRINOUS EXUDATION INSIDE THE LARYNX--DISEASED KIDNEYS--UNDISCOVERED ABSCESS OF LIVER.

(Under the care of Dr. J. W. OGLE.)

T. W., aged about 45, a thin, pale, yellowish-faced man, came to me as an out-patient, but was so ill that I admitted him into the Hospital, on October 14, 1864. He had been ailing seven months, and of late had had anasarca of the face and feet. Two weeks previously he had had a "fit," which was followed by hæmoptysis. For two weeks he had complained of numbness in both feet and legs, and in both hands and fingers. For several days he had vomited all kinds of food. When I first saw him he was suffering from a distressing stridulous cough, and was exceedingly hoarse. Nothing wrong in the throat could be seen as far down as the epiglottis. The respiratory murmur was very feeble at the back of the lungs. Heart-sounds natural. He had been a very dissipated, intemperate man as a soldier in India. Had never had rheumatic fever or jaundice. The urine contained a considerable amount of albumen.

Two days after admission he was in a very heavy state,—in a kind of half stupor. The pupils were equal, but somewhat smaller than before, possibly from the opium in his medicine.

On the 22nd vomiting of a quantity of green stuff had set in, and he was very faint. The lips were much swelled. The stridulous noise of inspiration was much diminished. The vomiting continued, and in his state of half-stupor he was, on the next day, constantly moaning or singing in a low tone, the pulse being very small. He fell into a sleeping condition, the respiration being slow and snoring, but could be roused, when he always said he was in no pain, excepting that he was rather sore in the belly. He refused food, and so went on, vomiting at times, moaning, and in a half-stupor for two or three days, and gradually sank and died.

On post-mortem examination extensive disease of the kidneys was found; also, quite unexpectedly, a considerable sized abscess of the liver. Marks of former dysentery were met with in the bowels. On removing the larynx a slight layer of fibrinous exudation was found lining the upper part of the larynx.

KING'S COLLEGE HOSPITAL.

EXCISION OF A PORTION OF THE SHAFT OF THE HUMERUS FOR A LARGE BONY TUMOUR CONNECTED WITH LOWER THIRD—CASE NOW UNDER TREATMENT.

(Under the care of Mr. FERGUSSON.)

The following is a good example of Conservative Surgery. The case had been deemed one in which amputation of the arm was necessary, but as the joint did not seem implicated in the disease, and the forearm was perfectly healthy, Mr. Fergusson determined to remove only that portion of the bone directly connected with the tumour. The history of the case is briefly as follows (from the careful notes of Mr. W. Bell):—

A. W., aged 24, a weak, sickly-looking woman, was admitted February 9, with a large hard tumour growing from the lower third of the shoulder humerus, somewhat spindle-shaped, and about the size of a large orange. She states that about two years ago her arm became very painful, and grew more so, until it was so violent she could not bear it. For some time it was treated as rheumatic, but when she first noticed the swelling, about eighteen months ago, she went to one of the London Hospitals, when it was considered a case for amputation of the arm, being malignant. Latterly, the shaft of the bone was thrown out of the right line and distorted, and felt, on manipulation, like an ununited fracture. This distortion came on gradually.

On February 18 the patient was placed under the influence of chloroform. Mr. Fergusson made an H incision at the back of the arm over the tumour, and, dissecting back the flaps, exposed the mass and a portion of the shaft above and below. He next sawed through the bone above and below the tumour about one inch above the joint, and then dissected it out. There was but little hæmorrhage, the parts were brought together by sutures, and the arm placed on an angular splint.

On section, the external part of the tumour was very hard and dense, and the compact tissue much thickened. In the centre was a plane of cheesy, broken-down substance, extending downwards and forwards.

Mr. Fergusson, in some clinical remarks made after the operation, said that the forearm being so perfect and the joint apparently healthy, some splint or other contrivance might be made which would keep the humerus fixed and yet allow of the patient making great use of the forearm and the fingers.

Up to this time (February 25) the patient has been getting on extremely well.

The tumour was divided, and part of it placed in the College museum, and part in that of the College of Surgeons.

Mr. Fergusson did not consider that the tumour was malignant. The patient was not cachectie-looking, and there were no enlarged axillary glands.

SATURDAY, MARCH 4.

QUACKERY AND LEGISLATION.

It would be mueh to be regretted if publie attention should cease to be directed to the subject of quackery before some effective Legislative measures are adopted for the repression of the evil. We have lately endeavoured to exhibit the "noxious trade" in all its enormity, and done our best to check the proceedings of the offenders by giving them publicity. But in doing this we labour under two disadvantages. First, our readers, as a matter of course, consist chiefly of men who need no enlightenment whatever in matters wherein the general public, for want of seientific knowledge and training, are too easily duped; and secondly, a Medical journal giving vent to its indignation against irregular Practitioners is always considered by the ignorant to be open to the imputation of interested motives.

It is, therefore, a subject of more than ordinary interest and gratification to see the matter taken up in a quarter where the suspicion of self-interest can have no place, and brought under the notiee of a class which, though equal to the Medical Profession in general education and intelligence, would not otherwise necessarily have their attention directed to the point.

The *Solieitors' Journal*, a paper of almost universal circulation amongst the London members of the legal profession, publishes in its impression of February 11 an article on quackery, strong and to the point, and having, moreover, the merit of making some attempt, albeit a slight one, at propounding a *seheme* for legislative interference. After regretting that public health and the purses of individuals should not be protected in England as in Franee, the writer proceeds:—

"Doubtless there is this grave difficulty. According to our English mode of thinking, it is a serious and generally reprehensible interfereuce with the liberty of the subject to extinguish a profitable trade, as this is, by legislative enactment, and there must be a very clear and cogent case of public benefit to compensate us for the sacrifice of personal liberty. 'What!' say the objectors, and not without force, 'interfere with the right of a British subject to make any eontract respecting his own pocket or health that in his own discretiou he himself may please? Why should the Legislature interfere to protect men against their own folly? In seeking to suppress these publications, we may prevent scientific and Medical inquiry. Why should we, in effect, revive an obsolete monopoly? This would be a gross, wanton, and un-English interference with that which is most dear to us—our free, uncontrolled, unfettered liberty;' and so forth. And it is not enough to say that similar objections may be and have been made to every project of reform brought under the consideration of the Legislature, and that, nevertheless, the reforms have been effeeted with advantage to the public. The real question at issue here is, not whether the arbitrary suppression of these quacks would or not be a public benefit—no one ean deny that it would be so, except the quacks themselves—but whether there is or not involved in this suppression a principle so fraught with danger as to render its adoption a greater evil than the nuisance it is desired to suppress. We cannot deny that to watch over the moral conduct of the population by law savours somewhat suspiciously of 'paternal government.' When the New England colonists declared adultery to be a crime punishable with the pillory, few people in this country doubted that, however excellent the morality of the statute in question, it was, practically, tyrannical. The question for us, then, is, have we, declamation apart, a right to prevent the open exercise of this most 'noxious trade?' and we do not hesitate to say that we have.

"Why is cheating a criminal offence? Because it is the duty of law to protect *property*, and cheating is an invasion of the rights of property. Is it, then, less the duty of law to prevent the weak and credulous from being deceived out of their health, which is property, and made furthermore to pay their money for that which cannot be taken to be 'valuable consideration.' Moreover, public decency is within the proper scope of the law, and these exhibitions and advertisements offend against public decency.

"We admit freely that the task is not an easy one; but that is no reason why the attempt should not be made. Lord Campbell, in dealing with the Holywell-street obscenities, had similar difficulties to encounter, yet he made the attempt, and practically succeeded in his object.

"The failure of the Medical Registration Act to suppress these evils is another proof of the necessity of a public prosecutor. The Medical Council consider, and probably with justice, that they are not called upon to institute proceedings, at their own risk, against quacks, who, by their assumed titles, hold themselves out to the public, who have no means of knowing better, as duly-qualified Medical Practitioners; and a kind of sanction is believed to be added to this representation by the appearance of their advertisements in respectable newspapers. As the law at present stands, there is no person or body compelled to prosecute.

"The first step necessary sounds a strong one, but it is really right on principle. Let it be made a misdemeanour to assume the title or qualification of a Medical man, unless authorised by the diploma of some recognised or legalised body or institution; then appoint a public officer bound to institute legal proceedings against all persons who violate the law in this respect, on a proper *prima facie* case being shown; next prohibit any man from practising Medicine in any place until his diplomas have been submitted to some magistrate, and a proper opportunity afforded for any person who may be so minded to test their genuineness. Let the presentation of a false diploma be declared a misdemeanour, and power of summary conviction (subject to the right of appeal) given to the magistrates; next the magistrates should be invested with power to close those museums that disgrace our leading thoroughfares, wherever found, and the provisions of Lord Campbell's Act should be extended to the circulation of those filthy publications.

. . . . . .

"It is not neeessary here to enter into the details by means of which these provisions might be carried out, as they will easily suggest themselves to every experienced draftsman. Let the principle but be admitted that the men are public nuisances, as deserving of being stopped as unqualified solicitors or unauthorised brokers, and that the publications are an offence against public deeency, and the rest will follow upon well-established precedents almost without the necessity of consideration."

We are glad to have the benefit of competent legal opinion, however general in its terms, as to the nature of the enactments required; but we must, nevertheless, express our regret that the writer of the above should not have condescended rather more to particulars, so that the details of the much-wanted measure might have been discussed. It may be, as above stated, that the carrying out of these suggestions would be a matter of no difficulty. If this be the case, we can only congratulate ourselves and the public on the fact, and remark that our legislators will have no excuse if a repressive bill be not passed this session. It is said that any

amount of money can be obtained amongst the fraternity of quacks for opposing any such measure, and the system is, we fear, not easy to put down. We are in a bad way, however, if the united force of the country is unable to prevail in so vital a matter against the interest of the "dirty quacks."

MODERN SYPHILOGRAPHY.—No. VII.

THE CAUSE, VARIETIES, AND PATHOLOGY OF SYPHILIS (INTERNAL SYPHILIS, ETC.)

The whole tone of modern thought is eminently critical and experimental. The inconveniences and evils attending that disregard of authority which is so characteristic of our age, in matters of belief or of some branches of study, is the main source of our strength and progress of Medical science. Neither authority nor the dictates of the keenest intellect can any longer impose upon the present or future a verdict of the past. History does not actually repeat itself, for we do not move in perfect circles, but in spirals, and the ascent is a very gradual and progressive one. Beliefs which were the intellectual property of past ages have now assumed a defined and settled position, and we have seen how light has been shut out or obscured by imperfect or false observation, and have learnt not to be dogmatical over much.

Thanks to the labours of Virchow, Wilks, Professor Simpson, Aitken, Hutchinson, and many other observers, we are beginning to possess a clearer knowledge of syphilis, and to learn that the external manifestations of it form a part only of a series of morbid phenomena induced by the syphilitic virus. "After a period, indeed, of scepticism and doubt," says Dr. Aitken, "we are now confirming, by actual observations, aided by all the advanced knowledge and appliances of the day, the crude surmises of the early physicians regarding the pathology of syphilis." The Physicians of the 16th and 17th century not only recognised syphilis as the result of a specific poison or virus, but they firmly believed that it was capable of profoundly affecting the system, and of giving rise to many and specific internal derangements, as well as of combining with and modifying other diseases. Here, again, Edinburgh was in advance of the London schools. Benjamin Bell (a) was the first writer who laid to the charge of syphilis a number of general and internal diseases, and supported his statements by a series of clinical observations. Syphilitic lesions of the nervous system were very clearly recognised by the late Dr. Todd, and cases of intra-cranial and nervous disease, in connection with syphilis, have been described by numerous observers, particularly by Lallemand, M. Lagneau, fils, Bonet, Brown-Séquard, Wilks, Roberts, Hutchinson, and many others. It is now known that the lungs, liver, kidneys, spleen, lymphatic glands, and muscular organs may, one or more of them, become affected in subjects of the syphilitic taint. The pathological course of syphilis in these cases, as Dr. Aitken well remarks, is seldom a pure and unmixed one, but is generally overlaid and intermingled with other diseases.

If our readers have followed us thus far, they will have learnt that we regard true syphilis as at once a contagious and constitutional disease, taking its place, in these respects, among diseases such as variola, vaccinia, hydrophobia, etc., and that syphilis no more frequently doubles itself in the body than do other constitutional maladies which depend upon the effects of an animal poison.

This virus—for we presume no one, except our revered and bold friend the member of the Legion of Honour, would deny that there is a something—a very peculiar and specific property or agent—as thousands of unfortunate patients know to their cost—in this material which engenders syphilis—the virus, then, of syphilis contrasts with other animal poisons as remarkably in the slowness of development and evolution of the symptoms to which it gives rise, as in the cyclical characters by which these are characterised; pursuing a course marked by alternate periods of activity and latency or dormancy. There is the period of incubation, preceding the appearance of its primary symptoms, to be succeeded by another before the evolution of its secondary stage, and by a third prior to the appearance of its so-called tertiary symptoms. Nay, more; in almost all cases of syphilitic infection we may observe a remarkable tendency in the disease to progress by a series of curves, as it were; the ascent from latency of the symptoms to their appearance being rapid, and the descent towards inactivity, dormancy, or health, slow.

If we group together a large number of cases, what do we find? That there is a period of incubation, varying commonly from one to four weeks; that this is followed by a lesion at the point of implantation of the virus, and in the neighbouring lymphatic glands; that the morbid principle appears to undergo multiplication during another interval of from one to three months, and that its effects are seen on the lymphatic glands and the complexion of the patient; and then we have an exanthem, with or without throat affection, general malaise, rheumatismal pains, sometimes slight fever of a remittent type, and occasionally some catarrhal symptoms, marking the secondary stage. Beyond this there may be recurrences of the so-called secondaries of a different type in the mild, or the occurrence of other and more severe forms, or of tertiaries in the severe cases. This evolution of syphilitic phenomena is much more regular than is generally believed, and it has not yet been proved that we can avert their occurrence at the beginning by any remedies, and we can only artificially shorten their duration or prevent their recurrence by constitutional ones. If so, the terms primary syphilis, infecting and non-infecting sores, etc., which we have used to render ourselves intelligible, are very improper and unfortunate ones,—improper in implying a false pathology; unfortunate to the patient, in leading to the use of mercury in many doubtful cases, and in others with the view of *preventing* secondary manifestations, instead of limiting our views to healing the chancre, dissipating the induration, and preventing a patient's spreading the contagion. Again, primary and secondary are terms which should be used to express the *order* of evolution or the chronometry, and not the *nature* of the disease; for it is certainly constitutional long before the occurrence of the secondary phenomena.

To what is the evolution of syphilitic phenomena due? Is the blood contaminated by a something which undergoes and induces zymotic changes in it, gradually increasing in amount out of the blood elements? the manifestations of the disease being only the expressions, signs, and effects of the elimination of the virus from the system. Or does the blood draw its supply of the virus from the separate diseased products in the solids? the localised syphilitic growths, whether in glands, skin, or elsewhere, acting as so many foci for the reproduction and maintenance of the poison in the system. The last is the view which Virchow (b) so strongly upholds, and it has this support of our observations, viz.,—that the smaller the amount of induration in the chancre and glands, the less severe commonly are the subsequent manifestations; and, we think, we have perceived the absorption and resolution of indurations to advance more rapidly immediately before, and during outbreaks of, general syphilitic symptoms.

Supposing Virchow's hypothesis to be correct, we conceive that the peculiar pigmental deposits so common to syphilitic lesions (such as are seen upon the cicatrix of a chancre on the skin of the penis, and which discoloration, according to our observation, is removed in the course of eight to twelve months, and replaced by a white patch) must also be sources of the blood contamination. The question is not altogether devoid of practical interest, because, if his view be well founded, the excision or destruction of a chancre at early dates

(a) "Treatise on Gonorrhœa and Lues Venera," Second Edition, vol. ii., pp. 139, 147, 463, *et seq*, which are well worthy of perusal.

(b) "Every dyserasia is dependent upon a permanent supply of noxious ingredients from certain sources"—the lymphatic glands, etc., for example, constituting "the local depôts from which new quantities of noxious matter are continually being introduced into the blood."

might *modify* the subsequent severity of the disease, by cutting off a main source from which the contaminated blood is recruited. Meantime, two things are evident—viz., that the poison may be long latent to manifest itself at very distant and uncertain dates, and that such manifestations appear to be often excited by debility or causes of ill health unconnected with syphilis.

Of the chemical and other physical changes in the blood we possess no trustworthy data. The analyses made by M. Grassi, under the direction of Ricord, are corroborative of what the anæmic aspect of the patient suggests—viz., that there is a diminution in the number of the blood globules.

A very short experience of this disease will teach the observer a fact which is too much disregarded—viz., that there are several types or degrees of the syphilitic infection.

We all recognise that small-pox, scarlatina, etc., may assume different forms, and, according as these approach the benign or the malignant types do we group them in separate divisions, as varieties or forms of the same disorder. It would be strange indeed if it were otherwise with syphilis. Analogy and experience teach us that it is not. The recognition of this does not involve a question of theory only; but it must exercise an important influence upon our prognosis, treatment, and proper appreciation of the pathology of the disease. The *quantity* and the *quality* of the effused products will differ at different stages in the same individual; but still more these will vary in the different forms of the disease witnessed in several individuals.

Let us, then, endeavour to express our own opinions—with the understanding, however, that we only intend them to be received as *approximations* to the truth.

1st. The greater the induration, and the longer the period during which primaries remain unhealed, the more probable it is that the constitutional infection will prove severe.

2nd. The amount of ulceration, phagedena, etc., of the primary sore stands in some relation to the more intractable forms of secondary affections—the pustular, ecthymatous, rupial, unhealthy ulcerations, nodes, and gummatous tumours.

MM. Bassereau, Diday, Langlebert, and others, have shown that superficial erosions, with concomitant induration, are far more common than the true Hunterian chancre, and the chancre with phagedenic ulceration. Bassereau, in 170 cases of syphilitic erythema, found that the first form occurred 146 times to 24 of the two latter.

Phagedena, to any extent at least, is a very uncommon complication of true chancre in this country. The majority of cases in which it is present are those of the local soft sore; and from all we can learn it is more frequently seen abroad, in the persons of our soldiers and sailors, recalling to our minds the old story of the Lisbon opera dancer and the havoc she made amongst our countrymen. Be this as it may, when a phagedenic action appears in the primary chancre it is commonly an indication that the quality of the syphilitic products subsequently effused will be cacoplastic, albuminiform, prone to early degeneration, softening, or suppurative action. The impression made by the poison, or the behaviour of the constitution of the individual under its morbid influence, is thus ofttimes early expressed.

Babington, in his edition of Hunter, has indicated the relation between the severity of the subsequent phenomena and the unhealthy phagedenic action in the primary sore. Bassereau, likewise, has clearly expressed the same thing as the result of his extensive experience; and M. Diday, in his recent work, has still more strongly and practically enunciated it. So far for the primary lesion. Now let us turn to the secondary symptoms.

The evolution and succession of the stages under ordinary circumstances may be very regular, as we have said, and the recurrence of syphilitic manifestations ensues—not in one continuous unbroken chain, but in succession—the links of which are interrupted by the interposition of intervals of comparative health (as the observations of M. Diday have done so much to demonstrate)—until the syphilitic poison would appear to have reached the natural length of its tether, and to have exhausted itself. Such is a rough expression of the course pursued in very many cases. With others it is far otherwise: mercurial treatment, exposure to changes of climate, the occurrence of other diseases, differences of constitution, poverty, with all its train of concomitant evils; these are so many disturbing causes, so difficult to calculate, and their influences so difficult to gauge, that we can only expect to reach approximations to truth.

The so-called constitutional symptoms may be ranged under two types, which contrast with one another.

Thus, a cutaneous syphilide, early in its appearance (from thirty to fifty days after the appearance of the chancre), wide in its extent and very superficial in character, denotes the milder degree of constitutional infection; while the discrete and localised morbid processes, affecting the deeper tissues of the skin and mucous membrane, have the opposite character of a severe degree of syphilitic infection.

When the "secondaries" are rather late in appearing, when they at first or speedily assume particular and mixed forms,—such as *large* papular elevations of the skin, which suppurate—when numerous superficial pustules or vesiculo-crustaceous scales form upon inflamed patches of skin, accompanied by similar affections of the scalp, when the engorgement of the throat is well marked at first,—not a mere snail-tract throat—and when there is an elevation of the mucous membrane about the palate, as if from a product effused into its substance or underlying its surface,—these symptoms express differences of severity from the first type every bit as great as between the throat affection of the severe and of the mild types of scarlatina. The gravity of the prognosis increases according as we perceive, by the early and subsequent softening and degeneration of these lesions, that the lymph is more or less destitute of plastic elements. The marasmus of the patient only too often advances, *pari passu*, with the degenerate actions going on in his tissues. The above expresses, in its worse forms, a profound syphilis, or a bad constitution such as the strumous; but there is another type which is difficult of cure out of proportion to its apparent effect on the constitution. When the induration of the chancre spreads out, ulcerates afresh at one part, throws up redundant rosy granulations at others—becomes, in short, transformed into a secondary lesion, a mucous plaque; or when a large papular elevation appears at some part (say the groin), inflames, softens, and becomes an ulcer, it assumes very peculiar characters, and exhausts our ingenuity to heal it. Such cases are not very common, perhaps, but the writer has seen them on more than one occasion. The ulcer exhibits two very different processes in action at the same time: phagedena, in that there is a slowly-advancing, painful, and unhealthy ulceration, with ichorous discharge at one part, and rosy, spongy, vascular redundant granulation out-growths at another.

The tubercular eruptions are among the latest secondary manifestations, but not invariably so. We have witnessed large wheal-like, rounded, or oval patches of skin, of a dull red colour, upon the face, etc., from three to nine months after the date of the primary disease. These elevations were distinguished from lichenous or herpetic eruptions seated upon circular or crescentic patches of inflamed skin, by the swelling and elevation of the dermis from infiltration into its substance. When occurring at these dates they generally desquamate on the surface, the ulcerated tubercles belonging to the later manifestations, and never being accompanied by the diffuse superficial eruptions. Like the pustular syphilodermata, they either indicate a severe form of syphilitic infection or a defective constitution. It is in these cases that the appearance of severe throat affections, and disease of deep structures and internal organs are to be feared.

The experience of the best modern syphilographers is tolerably uniform on some of the above points. The macula syphilitica (roseola, etc.), says Professor Zeissl, and the sub-

cutaneous or submucous tubercle represent the two poles of syphilitic exudation. But, it may be urged, we are confounding different stages of the disease with one another, for it is generally allowed that the early syphilides appear very diffused and superficial in their character when contrasted with the later manifestations. While we allow this to have its full weight, the impressions left upon our minds from our own observations are, that the early roseoloid or erythematous eruptions are not usually the precursors to the severer manifestations, and that the early eruptions have had from the first, or have speedily assumed, a mixed character—erythema, lichen, or acne at one part, thickened elevations of congested skin at another, or pustules—in those cases which have proved severe.

(To be continued.)

THE WEEK.

PROFESSOR SYME, AND THE PAMPHLET ON ACUPRESSURE.

We have often been obliged in the interests of the Profession to criticise the proceedings of Professor Syme, and to lament the bitterness too often displayed in his treatment of his colleagues. But we do not a bit the less admire the boldness, the originality, and skill with which Professor Syme has devised and performed new operations, and has revived old ones, to the great credit of that Northern School of Surgery which so well rivals the schools of London. We heartily regret the ebullition of bad taste which is described by our Edinburgh correspondents, and do not wish to make matters worse by any comment of ours. Would that men of science could "agree to differ," and treat all matters of difference on scientific points as so many accidents of their Profession, which need not interfere with the courtesies of life, public, or private.

THE PROCEEDINGS AGAINST A MEDICAL MAN FOR APPLYING MECHANICAL RESTRAINT TO A LUNATIC PATIENT.

The case of Mr. R. H. S. Carpenter, who was fined by the Durham magistrates £5 for applying mechanical restraint to one Mary Lamb, an old woman who was in the habit of breaking windows and threatening to take the lives of her neighbour's children, will be in the memory of most of the readers of this journal. Mr. Carpenter has taken the only course open to him to vindicate his Professional character in the matter. He brought an action in the County Court against the husband of his patient for fees for his visits and for the certificate he signed. We are happy to say that he has recovered the full amount claimed. Mr. Carpenter proved by the evidence of several witnesses that he had been employed by the defendant to attend his wife, that the defendant wished his wife sent to a lunatic asylum, and that on the night of the alleged assault Lamb had "asked Mr. Carpenter if he could not get a strait-jacket for his wife; if he could not he would not stay in the house with her." All this evidence was either ignored or not taken by the Durham magistrates. Although Mr. Carpenter's treatment of his patient is thus set in the right light, we should be very glad to hear that the decision of the magistrates could be appealed against in a higher court. It seems so monstrous that a Medical attendant who takes the enormous responsibility of superintending a case of insanity should be liable to fines and penalties when interfering to prevent the patient from injuring himself and others, that we should like to hear the opinion of one of our judges on the case. Did the magistrates of Durham in fining Mr. Carpenter act in conformity with the law of England? If so, it is high time that the Medical Council should take action on the matter, and either by introducing a clause in the proposed amended Medical Act, or by framing a separate measure for the consideration of Parliament, should endeavour to protect the registered Medical Practitioners of the United Kingdom in the performance of their imperative duties.

"ST. BARTHOLOMEW'S HOSPITAL REPORTS."
