PROFESSOR PETE (UNIVERSITY, PESTH) ON THE NATURE AND USE OF WINE, SPIRITS, AND ALCOHOLISED WINES.

In the last number of his periodical, *Tandesadi* ("Medical Adviser"), Professor Pete has a few observations on the above subject, which may not be out of place in the *Medical Times and Gazette*.

Pure wine—that is, the pure juice of the grape—possesses, through its simple fermentation alone, a sufficient degree of natural alcoholic strength to render it a wholesome, mild stimulant, and a sufficiently potent dietetic means for the physical and moral restoration of man. Distilled spirits, on the contrary, and, in some degree, also alcoholised (fortified) wines, may answer medicinal purposes, and act beneficially as a remedy in certain abnormal conditions of the human system, but are too powerful stimulants to be dietetic. They are to be compared in this respect to our common mineral household salt,—an indispensable condiment in small doses, a remedy in larger quantities, and a poison if in excess.

The natural alcohol inherent in wine is widely different in every respect from that alcohol which is artificially introduced into wine; the mixture will always remain a mechanical, and not a chemical one,—that is, this alcohol will remain hanging as a foreign body in the wine. Chemistry will prove this. For if you submit pure wine—be it ever so strong—to slow distillation, you will obtain as a first product, water, then alcohol, then water again. On the contrary, if you carefully distil mixed (alcoholised, fortified wines), the first drops will be alcohol; this is the alcohol that had been mixed into the wine, then water, then again alcohol,—the natural alcohol of the wine—and, lastly, water.

Pure wine assists digestion and the formation of blood; it promotes the nourishment and invigorates the system; distilled spirits, whether taken alone or mixed in wine, hinder the formation of blood and the nourishment, because they paralyse and benumb, with the whole nervous system, those nerves which are the instruments to nutrition.

We need not go out of our own country (Hungary) to find striking illustrations of the above truth. Compare the healthy looks and appearance of the rural population in our wine-growing districts,—Tokay, Somló, or in our plains (pusztas) the ancestral habitation of the true wine-drinking Magyar race—with the sallow complexion, hollow checks, and sickly appearance of the spirit-imbibing Sclavonians and Wallachians in the Carpathian mountains.

There is still another remarkably distinguishing peculiarity to be noted: distilled spirits, as well as alcoholised wines, will be the more intoxicating the higher the degree of their alcoholic strength; the intoxicating effect of pure wine, on the contrary, does not depend on its strength. Wine drinkers know very well that young, coarse wines will sooner set the head turning old than matured, although chemically much stronger, wines. Roussillon, of 12 or 14 degrees alcoholic strength, will sooner intoxicate than Lafite of 18 or 20 degrees, or Tokay of 23 degrees.

Alcoholised wines—Port and Sherry—are rare in Hungary, and indulged in only by the upper ten thousand. Is it not a strange coincidence that he gout is also at home only in the palaces of our rich? (we call the gout the ailment of the wealthy) and is not the more general prevalence of gout in England to be partly ascribed to the greater consumption of distilled alcohol taken either by itself, or in the shape of sherry and port?

ORIGINAL LECTURES.

ON

THE FOOD OF MAN IN RELATION TO HIS USEFUL WORK.

By LYON PLAYFAIR, C.B., LL.D., F.R.S.,
Professor of Chemistry in the University of Edinburgh; Vice-President of the Royal Society, Edinburgh; Vice-President, and formerly President, of the Chemical Society, London, etc.

DELIVERED AT THE ROYAL SOCIETY, EDINBURGH, APRIL 3, 1865, AND ROYAL INSTITUTION, LONDON, APRIL 28, 1865.

1. THE great generalisation of Liebig, that food contains two chief classes of organic ingredients,—one class consisting of nitrogenous substances which give the plastic materials for the formation of tissues, while the other class contains the amylaceous and saccharine bodies destined to support the heat of the animal body—has met with general acceptance, notwithstanding the objections entertained by some physiologists to the general terms of the division. They state that the nitrogenous aliments may also support animal heat, as well as fulfil their special function of forming the tissues. But the distinguished author of the classification admitted this fact in his first work,(a) when he pointed out that the carnivora must waste their tissues in the support of animal heat. The recent experiments of Bischof and Voit,(b) and of Pettenkofer and Voit,(c) in feeding animals on flesh from which all fat had been removed, completely prove that nitrogenous substances can act as heat-givers as well as flesh-formers. But the converse of the classification is not true, for we have not the slightest evidence to show that alimentary bodies free from nitrogen can build up any organ of the body. It is known that a small quantity of fat is always present in healthy tissue, but it may be wholly removed by ether without injury to the organic structure. The same experiments which proved that flesh-formers might, when necessary, act vicariously as heat-givers, have also proved that the nutrition of carnivora may be effected without the supply of fat or any other non-nitrogenous body.

2. The chief object of this lecture is to examine the function of nitrogenous ingredients of food as a magazine of force for the production of dynamical effects in the animal. The consideration of the animal body as a machine, and of the food in the light of fuel supplied to it, has already engaged the attention of philosophers. Rumford,(d) Joule,(e) Mayer,(f) Helmholtz,(g) Dumas,(h) Hirn,(i) Fick,(k) and Carpenter (l) have published their views on this important subject; but all of them, so far as I know their writings, have looked upon food in its aggregate, applying their calculations to the total carbon and hydrogen contained in it, without discussing the influence exerted by its separate constituents in the production of force.

3. The Rev. Dr. Haughton, of Dublin, has been an exception in this respect. He has endeavoured to find in the urine the representative of the mental, vital, and mechanical work of the human body, and gives the following equations (m):—

Opus Mechanicum, or 150 lbs. raised one mile	= 136·5 grains of urea.
Opus Mentale, or five hours of study	= 217·0 „ „
Opus Vitale	= 297·0 „ „

He then draws the conclusion that in manual or routine bodily labour, men are sufficiently well fed when they receive as much food as will discharge 400 grains of urea daily (the product of 2·8 oz. of flesh-formers), of which 300 grains are spent in vital work, and 100 grains (the product of less than three-fourths of an ounce of flesh-formers) in mechanical work. But when the work is of a higher order, Haughton states that a better quality of food must be supplied, sufficient to allow a discharge of 533 grains of urea daily, of which 300 grains are spent as before in vital work, and 233 grains in the mental and mechanical work necessary to keep the body in health.

4. If we are to understand these numbers of Haughton as being true exponents of the quantity of tissues necessary to be transformed for the production of force, the latter can readily be calculated and compared with that necessary to effect the work. Urea can only be an exponent of work, inasmuch as it shows us the quantity of tissue which has become oxidised in its production, and thus enables us to express the amount of energy stored up in that tissue, and in the oxygen which transformed it. Now, as 136·5 grains of urea are said to be equal to 150 lbs. weight raised to the height of one mile, we ought to find at least this amount of potential energy in the 405 grains of tissue from which the urea must have been derived, and in the oxygen required to convert it into this diamine. After deducting the hydrogen which may be supposed to have already met with oxygen in the tissues, we have available for transformation—

190·6 grains of carbon.
12·5 „ hydrogen.
5·1 „ sulphur.

These numbers, by the usual formula, would give 498·8 lbs. of water raised 1° F., and this, converted into its mechanical equivalent by the co-efficient 772, represents 385,073 lbs. raised to the height of one foot. This, then, represents the total potential energy, while the actual work realised by the man is more than double this amount, or is 792,000 foot-pounds. It is clear, then, that Haughton cannot have meant the equations given by him in the mathematical sense of equality, but only in the general sense of representation. In fact, in a further paper (n) he points out that the combustion of the carbon and hydrogen of the proteine compounds can only account for 54 per cent. (misprinted 34 per cent.) of the work ascribed to the urea. Hence we are obliged to class Haughton with the other writers, who consider that the transformation of the nitrogenous tissues is insufficient to account for the dynamical movements of the body.

5. In discussing this subject anew, I divide the work performed in the body as follows:—

1. Mental work.
2. Calorific work.
3. Internal dynamical work.
4. External „ „
5. Digestive or assimilative work.

With the two first divisions we have little to do in the present lecture; with the three last divisions we shall be fully occupied.

6. It will be convenient to proceed in the following order:—

DIVISION I.

A. To ascertain the amount of food necessary for mere subsistence without exercise.

B. To determine the amount of food required for complete heath, with a moderate exercise of from five to seven miles daily.

C. To fix the amount of food suited for active work, such as is represented by a man walking twenty miles daily continuously.

D. To find the amount of food consumed by labourers with very arduous occupations, such as navvies engaged on railways.

Having ascertained these preliminary facts, which are altogether independent of theory, we shall then be in a position to proceed to

DIVISION II.

A. To discuss whether there be sufficient potential energy in the nitrogenous tissues, or of the food representing them, and in the oxygen required for their transformation, to account for the dynamical actions within or without the body.

B. To consider whether the fatty and amylaceous or saccharine ingredients of food are employed in this mechanical work.

Having discussed these points, we should then be in a position to proceed to

DIVISION III.

A. To inquire whether the secretions of urea and uric acid *per vesicam* are sufficient representatives of labour performed.

B. To consider what is represented by the nitrogenous materials secreted *per anum*.

Division I.

Food Required under different Conditions of Work.

7. In determining the amount of food required for mere subsistence, we ascertain, at least approximatively, that necessary for internal dynamical work. By that we mean such work as is carried on within the man independently of the will, and in the direction of which he is an unconscious agent. The heart beats, the blood circulates, the lungs play, the diaphragm acts, the intestines exert their peristaltic motion, by an inner directive movement. In the exercise of these motions a certain amount of force is expended, but it is ultimately converted into heat, and aids the *opus calorificum*, which is chiefly produced by the combustion of the non-nitrogenous parts of food.

In looking for a purely subsisting diet, we naturally turn to the experience of Hospitals having convalescent patients unable still to take exercise. The following is the dietetic value in ounces of the "common diet with bread" employed at the Infirmary in Edinburgh(o).

Flesh-formers	2·06 oz.
Fat	0·58 ,,
Starch	11·33 ,,
Starch equivalent of heat-givers	12·69 ,,
Mineral matter	0·35 ,,

In this diet the amount of carbon in the flesh-formers is 1·08 oz., and in the heat-givers 5·57, or together 6·58 oz. This amount of carbon fairly represents that required to keep up the vital actions, for Dr. E. Smith (p) found, in his own case, that 6 oz. of carbon were exhaled by him during one day's starvation, and Ranke,(q) in a three days' trial, found 6·4 oz. every twenty-four hours. We may therefore assume that 6·5 oz. of carbon are required to support the life of an adult man without exercise. In the following table are some recorded instances of deficient dietaries, although in some of the cases they were only defective because work was expected from the persons living upon them. They are, therefore, generally sufficient for mere subsistence during rest, but insufficient for the performance of labour.

An examination of the information furnished by this table will justify the conclusion, that though 2 oz. of flesh-formers, 0·5 oz. of fat, 12 oz. of starch and sugar, containing a total amount of 6½ oz. of carbon, will suffice for a man to support the internal dynamical motions and other vital necessities of his body when he is at complete rest, they are not compatible with a moderate amount of exercise; so that, even in the condition of low health without activity, 2·5 oz. of flesh-formers, 1 oz. of fat, 12 oz. of starch, and 0·5 oz. of mineral matter are necessary. This diet contains 7·44 oz. of carbon.

Table I.—Subsistence and Low Dietaries.

Dietaries.	Flesh-formers.	Fat.	Starch, etc.	Starch, etc.	Carbon.
Contractors' insufficient prison diet, Bengal (r)	2·05	0·73	17·84	19·58	9·585
Dundee prison diet, treacle substituted for milk, 50 per cent. of prisoners lost weight (s)	2·87	0·87	13·41	15·41	8·168
Needlewomen in London (t)	1·90	1·04	10·29	12·74	6·392
"Common diet," Edinburgh Infirmary (u)	2·06	0·58	11·33	12·69	6·585
Average diet during cotton famine in Lancashire, 1862(v)	2·72	..	..	..	9·540
Diet of the prisoners in Libby prison, Confederate States(w)	2·41	0·98	5·62	8·01	4·546
Mean subsistence diet	2·33	0·84	11·69	13·68	7·469

8. We have now to get a mean dietetic value for the food of an adult man in active health, but without hard labour. The dietaries of soldiers during peace offer us a large experience. I have recalculated the following table, which was published formerly by me in a less complete form,(x) taking bread as containing 37 per cent. of water.(y) The data for the calculations have been obtained from the sources quoted below.

Table II.—Dietaries of Soldiers during Peace.

	Mean Dietetic Value. oz.
Weight of solid food	51·0
Flesh-formers	4·215
Fat	1·847
Starch, sugar, cellulose, etc.	18·690
Starch equivalent of heat-givers	22·059
Mineral matter	0·714
C Carbon in flesh-formers	2·267
C′ Carbon in heat-givers	9·720
Total carbon, C + C′	11·987
Ratio of C : C′ C : C′ : : 1 : x	4·290
Ratio of flesh-formers to starch equivalents	5·237

The mean of this table may fairly be taken as representing the value of food required to keep adult men in good health. Army Surgeons state that the diet of our own soldiers, which does not differ widely from the mean, is not sufficient for recruits during their drills, though the sergeants fatten upon it. As the average value is also nearly the same as that of middle class diets,(z) we may safely assume it to be a correct expression of the diet of men who live well and take moderate exercise, of from five to seven miles daily.

9. Before we discuss the dietetic value of food required for men engaged in labour, we must define what we understand by a full day's work. We take such work, when performed continuously throughout the year, with rest on Sundays, to be represented by a daily walk of twenty miles. The experience of postmen in rural districts shows that more than this amount of work cannot be executed without the man breaking down. As the co-efficient of traction is nearly $\frac{1}{20}$th the weight of a man's body, the work which a standard man of 150 lbs. has to perform is 792,000 foot-pounds. That this is a full estimate will be apparent from the following table (a) of the work of a man under different conditions:—

Kind of Labour.	Amount of Work in ft. Tons.	Authority.
Pedestrians	353	Haughton.
Pile-driving	312	Coulomb.
,,	352	Lamande.
Turning a winch	374	Coulomb.
Porters carrying goods and returning unloaded	325	,,
Porters always loaded	303	,,
Porters carrying wood up stairs, descending unloaded	381	,,
Paviours at work	352	Haughton.
Prisoners at shot drill	310	,,

Mean, 340·2 tons = 105,605 metre kilogrammes.

The mean of this table gives 762,048 foot-pounds. A man's labour differs within a tolerably wide range, according to the manner in which it is exerted, for while it may not exceed 480,000 foot-pounds in hammering, it may reach to 1,500,000 foot-pounds when pushing or pulling horizontally.(b) Hence the amount of 792,000 foot-pounds taken for a day's work, may be considered a full, though not an excessive amount.

This estimate receives further support when we examine the work performed by soldiers in war. In Sherman's famous march from Atlanta to Savannah, twelve miles daily were accomplished. In war, the Prussian army walks fourteen miles daily, resting every fourth day. In our Indian marches, twelve miles daily, with the same rest, is the rate of work allowed to the troops. Hence, if we take full war work as represented by fourteen miles' daily continuous marching, the soldiers being laden with 60 lbs. weight of accoutrements,(c) we have a full estimate of labour work. This is found by the following equation—

$$\left[\frac{150+60}{20}\right] \times 73{,}920 = 776{,}160 \text{ foot-pounds.}$$

The weight of the man and of his accoutrements, divided by the co-efficient of traction, and multiplied by the number of feet traversed, thus leads us to a result rather less than that found for the pedestrian. The following table gives the

(o) The ounce used in this lecture is always 437·5 grains, or 28·35 grammes, the gramme being taken at 15·43 grains.
(p) Smith, *Trans. Roy. Soc.*, vol. cxlix., p. 681.
(q) Ranke, Müller's *Archiv.*, 1862, S. 342.

dietetic value for soldiers engaged in the arduous duties of war :—

Table III.—Dietaries of Soldiers During War.

	Mean of War Diet.
	oz.
Weight of solid food	46·0
Flesh-formers	5·41
Fat	2·41
Starch, sugar, etc.	17·92
Starch equivalent	23·48
Mineral matter	0·68
C carbon in flesh-formers	2·90
C′ carbon in heat-givers	9·81
Total carbon, C + C′	12·71
Ratio C : C′ : : 1 : x	3·37
Ratio of flesh-formers to starch equivalent	4·35

Hence it will be observed that about 5·5 oz. of flesh-formers, and 23½ oz. of the starch equivalent of heat-givers, are required by the soldier to enable him to withstand the fatigues of war.

10. We possess in the English army a corps of soldiers who are labourers even during peace. I allude to the Royal Engineers, who, while in the depôt at Chatham, are actively occupied either in constructing field works, or in pursuing their avocations as artisans, from which class they are all selected. Desirous to obtain the dietaries of these men, I applied to Colonel Collinson, R.E., the second in command at Chatham, and he, with the consent of Colonel Harness, instituted a careful inquiry into the actual amount of food consumed by 495 men for twelve consecutive days. Quartermaster Conolly took an active part in the inquiry, and the captains of each of the companies became responsible for the accuracy of the returns, which were made with all the detail and care to be expected from this highly scientific corps. These returns were then reduced to their dietetic value by myself, so that we may consider them as affording the most complete evidence which we possess of the requirements of food for labouring men during a fair but not an excessive amount of work in twenty-four hours.

Table IV.—Dietaries of the Royal Engineers from January 1 to 12, 1865.

	Mean of all Returns.
Number of men giving returns	495
Weight of solid food	oz. 66·97
Flesh-formers	,, 5·08
Fat	,, 2·91
Starch, sugar, etc.	,, 22·22
Starch equivalent	,, 29·38
Mineral matter	,, 0·93
C carbon in flesh-formers	,, 2·730
C′ carbon in heat-givers	,, 12·113
Total Carbon, C + C′	,, 14·844
Ratio C : C′ : : 1 : : 1 : x	,, 4·45
Ratio of flesh-formers to starch equivalent	,, 5·82

There are several points of interest shown by these reductions. The working soldier finds it necessary to take about five ounces of flesh-formers daily. The only notable exception is in the case of a detachment of the 38th Company, stationed at the South Kensington Museum. This exception furnishes a ready explanation, for although these soldiers are even better paid than those at Chatham, their work is of a less laborious character, being chiefly that of draughtsmen, photographers, etc; with this work they do not require a larger quantity of flesh-formers than is consumed by soldiers of the line, and accordingly we find that their diet sinks to this level.(d) Omitting this exceptional case, we find a singular uniformity in the starch equivalent of heat-givers. It is higher than that of soldiers engaged in war, but this is doubtless due to the ease with which potatoes are obtained in garrison, and to their being always in considerable quantity in the diet.

11. We do not possess many well-recorded instances of labourers' diets, by actual weight and measure. The approximative returns obtained by Dr. E. Smith, in his report to the Privy Council on the diet of the working classes, are valuable for what they profess to be as giving us an insight into the mode of living of artisans; but they can scarcely be considered as presenting us with data of weight and measure, ascertained with any further degree of precision than could be obtained by conversation with working people. I append a few instances of working dietaries, which have been determined by actual weights of the food consumed :—

Table V.—Examples of Labourers' Dietaries.

Class of Labourer.	Flesh-formers	Fat.	Starch, Sugar, etc.	Starch equivalent.	Carbon.
English sailor (fresh meat)(e)	5·00	2·57	14·39	20·40	11·05
French sailor(f)	5·74	1·32	23·60	26·70	14·58
English navvy (Crimea)(g)	5·73	3·27	13·21	21·06	11·46
,, ,, (Rouen Railway(h)	6·84	3·82	27·81	37·08	18·96
Hard-worked weavers(i)	5·33	1·53	21·89	25·42	13·76
Fully-fed tailors(k)	4·63	1·37	18·47	21·64	11·74
Blacksmiths(l)	6·20	2·50	23·50	29·50	15·69
Mean working diet	5·64	2·34	20·41	25·97	13·89

I have not quoted in this table the well-known allowances of 910 lbs. oatmeal given annually to our Scotch agricultural labourers on the bothy system, and 60 oz. of milk daily. This diet equals 8¾ oz. of flesh-formers, 4·5 oz. of fat, and nearly 27½ oz. starch. I attach little importance to this, because it is well known that the labourer sells nearly a quarter of the oatmeal to buy spirits and other luxuries. A man training for prize fighting, (m) and who walked seventeen miles daily for exercise, was found to eat weekly 269 oz. of mutton, without bones, 14 oz. of bread (only 2 oz. daily at dinner), and 170 oz. of ale. The food of this prize-fighter had therefore the following dietetic value :—

Flesh-formers	9·8 oz.
Fat	3·1 ,,
Starch	3·27 ,,
Starch equivalent	10·70 ,,

This result, however, is certainly not an average case, although interesting as showing the conditions employed in training a man to the extreme of muscular activity.

12. From the preceding data we propose to take the following general averages in our calculations :—

	Subsistence Diet.	Diet in Quietude.	Diet of Adult in Full Health.	Diet of Active Labourers.	Diet of Hard-worked Labourers
	oz.	oz.	oz.	oz.	oz.
Flesh-formers	2·0	2·5	4·2	5·5	6·5
Fat	0·5	1·0	1·8	2·5	2·5
Starch	12·0	12·0	18·7	20·0	20·0
Starch equivalent	13·2	14·4	22·0	26·0	26·0
Carbon	6·7	7·4	11·9	13·7	14·3

(To be continued.)

(d) For this return I am indebted to Captain Donelly, R.E., Inspector of Science to the Department of Science and Art.

ORIGINAL COMMUNICATIONS.

ON A

SIMPLE METHOD OF TREATING CERTAIN KINDS OF EPILEPSY, DEMENTIA, AND OTHER CHRONIC HEAD-AFFECTIONS.

By THOMAS LAYCOCK, M.D., etc.,

Professor of the Practice of Medicine and of Clinical Medicine, and Lecturer on Medical Psychology and Mental Diseases in the University of Edinburgh.

The prescription of errhines and sternutatories has almost wholly ceased, although they are occasionally referred to by writers. Valleix mentions the breathing of ammonia as being sometimes useful in epileptic fits, but systematic writers in general on epilepsy recommend all kinds of derivants and counter-irritants except these. Professor Hasse, indeed, notices them, but only to say that they are more likely to be hurtful than useful. The current doctrine, that epilepsy is due to "excitement of the brain" or reflex irritability of the medulla oblongata, is obviously opposed to the notion that irritants to the nostrils can be of service.

Nor is it generally known or even suspected that various chronic cerebral affections may be relieved and sometimes cured by this method of treatment. And yet it was anciently very popular. The *pulvis asari compositus* of a former Pharmacopœia was the last of various formulæ long abandoned, which were thus commonly used in both mediæval and archaic medicine. The Greeks distinguished the irritants that caused a flow of mucus (errhines), in accordance with an ancient humoral theory of phlegm, from those which excited sneezing or sternutatories. Both kinds were prescribed in cephalæa, amaurosis, lethargy, vertigo, epilepsy, and other head-affections.

Some years ago, when reflecting upon the probable cause of epilepsy, and more particularly of the sensorial and mental symptoms as distinguished from the convulsive and motor, I was led to the conclusion that stimulants to the nostrils would be found useful in a certain class of cases in warding off the attack, in shortening the duration of the comatose condition, and in diminishing the susceptibility to returns. I was enabled, through the kind assistance of my friend, Dr. James Saidler, now resident superintendent of the private asylum at Gilmour House, Liberton, near Edinburgh, to try the effects of various such stimulants on insane epileptics at that time under his care in the Millholme Asylum, Musselburgh. Subsequently I extended the theory to cases of headache, loss of memory, hallucinations, and the like, in which I had reason to think the circulation and state of nutrition of the encephalon was disordered. I now put together some rough notes of the results of treatment of these affections specially with the hope that the Physicians and Assistant-Physicians of asylums may be induced to try the method of stimulation or counter-irritation of the nostrils in this numerous class of cases, and report results in a more complete and satisfactory manner than I am able to do.

1. Epilepsies and Epileptic Seizures.

The pathology of epilepsy and epileptic seizures is so obscure, and the entire class of diseases have such varied relations to sleep and its morbid states, as well as to almost every form of morbid mental condition, that a few brief remarks on the theory which led me to make the trials described, may serve to facilitate the selection of the kind of case in which the plan of treatment may be reasonably attempted. We know well that there are exciting causes of epilepsy, which can be removed or obviated, and the disease thus cured. There are also known predisposing causes, which are necessary to the action of the exciting causes, and which can be obviated. But the proximate cause, or that condition of the brain which immediately precedes the fit, and without which neither predisposing nor exciting causes can take effect, is still unknown. Now, as this is the disease, it is clear that until we know its true nature, we cannot reasonably attempt a rational prevention and cure of epilepsy. To determine this proximate cause, let us select the primary, essential, and pathognomic mental condition for consideration. We know that in the typical epilepsy this consists in the instantaneous and total abolition of consciousness, upon which abolition convulsions of a particular kind supervene, and then coma upon these. If there be no precedent abolition of consciousness the convulsions are not strictly epileptic. What, then, is that condition of the brain in which total and instantaneous abolition of consciousness occurs? It can only be such a state suddenly induced as renders continuous consciousness impossible. Now, we know that for continued consciousness two things are needed; namely—first, a proper circulation of blood through the encephalon; secondly, a proper transformation of the cerebral tissues, so that the vital functions of that tissue, in so far as they minister to consciousness, may go on. I write thus generally of the encephalon, or the whole contents of the cranium, to avoid all anatomical theories as to the special seat of consciousness, and of the functions of particular portions of it, and which, in fact, have little practical bearing on the points in question.

Granted these two propositions as to consciousness, we may conclude *that the proximate cause of an epileptic paroxysm is a sudden cessation of the circulation through the encephalon, or some portion of it, and of the proper metamorphosis of the cerebral or encephalic tissue*, in so far as it is the seat of consciousness. Consequently, if we could obviate these conditions we arrest or limit the fit.

These propositions apply to the typical fit exclusively; there are, however, epileptic seizures in which the abolition of consciousness is not instantaneous, but preceded by disorders of the consciousness, such as vertigo, headache, aura, hallucinations, delusions and illusions, delirium, and even mania. There are, moreover, imperfect fits, in which there is no convulsive condition, or in which those disorders of the consciousness which are premonitory of a complete paroxysm constitute the only phenomena. We can explain these, however, on the same principles by assuming that the morbid encephalic changes, which, in the complete fit, are too rapid and instantaneous to give time for these morbid mental states to be expressed or fixed on the memory, come on more slowly in the fit with premonitory sensorial symptoms ending in unconsciousness and convulsions. In the imperfect fit the changes do not pass on to the abolition of consciousness; and before the paroxysm is complete there is a return to healthy or normal action. So that *the various kinds of epilepsies differ in this, that their phenomena are dependent upon different degrees of intensity of a common proximate cause.*

There are, however, differences in individuals as to the particular kinds of premonitory symptoms and as to the particular results of the convulsions. In one there may be visual hallucinations; in another, auditory; in a third, maniacal delirium; in another, irritable temper; and one may bite the tongue, and another may not; and a third may be convulsed on one side only. But these differences do not interfere with the practical application of the principles I have laid down. If we assume (as we must if we would theorise at all) that these individual differences are due to anatomical differences, arising either in a special predisposition to take on morbid action situate in a particular portion of the encephalon or from the action of exciting causes, specially operative on such portions, then it follows *that all the premonitory symptoms and the symptoms of the minor and incomplete epileptic paroxysms, however varied, are due to the same proximate cause as those of the typical fit.* The functional activity being more imperfect locally than generally in the encephalon, it follows that the exciting causes of the epileptic fit will act primarily, or predominately, or exclusively on them to the special and local derangement of the circulative and nutrient activity, and the manifestation of special symptoms differing according to the portion of the encephalon involved.

Starting from these propositions as to the proximate and predisposing causes of epilepsy and epileptiform seizures, let us next inquire how the circulation and the tissue-changes within the encephalon are disordered? In the typical fit the disorder occurs instantaneously; the exciting cause must therefore act instantaneously. Now, if we look to the sudden occurrence of other nervous symptoms with which, in respect to the suddenness, we can compare the seizure,—such as palsy, sneezing, or spasms—we can conclude that it is due to the sudden excitation or injury of a regulating nerve-centre. Applying this to epilepsy, we can conclude that the same thing happens at the seizure, and it consequently follows that there is a regulating centre for the circulation and nutrition of the encephalon, and for the particular ganglionic centres of which it is made up; or, to put the proposition in another form, just as there are ganglionic centres for maintaining and regulating muscular nutrition and metamorphosis, and combining groups of muscles in action, so also there are centres for maintaining and regulating encephalic nutrition and metamorphosis, and combining the various subordinate centres into that unity of action which correlates or corresponds with the unity of consciousness. When these functions fail as to the whole encephalon, then there is abolition of consciousness; when as to particular portions only, then there is disorder of the senses, perceptions, and intellect;—so that if we would prevent a fit of epilepsy, or abate hallucinations, delirium, and other mental disorders, we must act directly on these hypothetical centres of regulation, so as to to prevent defect of their functions, or cause it to cease.

But the question next arises, which is that centre, if there be one? so that anatomy and physiology and experience may teach us how to act upon it.

My researches upon this point have led me to the conclusion that the cerebellum is the chief regulating centre, but that the cerebellum, acting as such, is itself acted upon, and regulated by impressions reaching it from two wholly different sources,—namely, inferiorly from the medulla oblongata, or great spinal centre proper of the body, and superiorly from the encephalic centres of emotion, perception, and thought. I simply state the hypothesis, however, because a detailed exposition of the facts which support it would involve the whole question of cerebral physiology, and because, for pathological reasons, the cerebellum and medulla oblongata are now con-

sidered by pathologists to be the seat of epilepsy. Starting, then, from these physiological, anatomical, and pathological conclusions, what means (we ask) can be made available for removing the morbid conditions of those centres upon which epilepsies and epileptiform seizures depend?

Analogy, fortunately, can be our guide in the inquiry, either with or without the aid of the hypothesis. In sleep we witness a condition more or less like that dependent on the proximate cause of epilepsy. There is a more or less sudden abolition of consciousness, with premonitory delirium in the form of dreaming, and in morbid states of the brain with premonitory vertigo and other sensations, ending at last in a physiological palsy or paresis. In sleep, too, we know that there is at least a slowing of the circulation and an arrest of brain-metamorphosis, so that force-materials may accumulate. Dreaming is also the analogue of insane delusion, and in syncope, whether from pain, or emotion, or loss of blood, there is a sudden loss of consciousness, with at least a slowing of the cerebral circulation. The class of means, therefore, which serve best to rouse from deep sleep, or syncope, or dreaming, would be most available in preventing the epileptic seizure altogether, in abating the premonitory symptoms, and in shortening the duration of the comatose state. Now, although impressions through the cerebral nerves of sense may be effectual in rousing from sleep and syncope, yet the most simple and most certain are those means which are excitants of the medulla oblongata through the afferent nerves of the respiratory system, and more particularly the nasal branches of the fifth pair. In short, I was led to the conclusion that irritants applied to the nostrils would be the best means of exciting the activity of the medulla oblongata, and, through it, of the cerebellum in cases of epilepsy. I therefore first experimented with strong liquor ammoniæ and snuff.

I will now give the results of some trials made upon epileptics according to the foregoing views, as stated by my friend Dr. Saidler in a letter to me, dated Millholme House Asylum, September 18, 1860:—

"According to instructions, I have tried the plan you recommended for the epileptic fit with the following results:—In the case of Rogers (who does not snuff), ordinary snuff liberally applied has no effect. Ammonia seemed to do more good, but his fits vary so much in intensity and duration that he is not a fair subject for the experiment. In the case of the female patients the result seems to have been more marked, and in several in which the ammonia has been used, it seems to cut short the fit, speedily restoring the patient to consciousness, and preventing to a great extent the torpor and semi-comatose state so protracted after a fit. In one respect, at any rate, its value is undoubtedly great—viz., in detecting the malingerer. One woman (erotic), who used to have fits three or four times a-day, has only had one since its application, and that when she supposed the attendant to be absent. It speedily put an end to her fit."

I now suggested, as we had felt our way in the matter, that the snuff should be made more irritating by drugs, and given regularly. The powder of the root of white hellebore is a most powerful irritant, and cayenne pepper little less so. These were tried. The results are detailed in the subjoined letter from Dr. Saidler, dated October 29, 1860:—

"After many experiments of various kinds as to the different strengths of ingredients and the results of snuff and ammonia during the epileptic fit, I commenced, on the 22nd, a regular trial of the following mixture—viz., common snuff, white hellebore, and cayenne pepper. At first I gave only one pinch in the morning to our female epileptics, seven in number; and certainly the result was surprising. On the 22nd there was not a single fit; on the 23rd, only one pinch in the morning, and not one fit; on the 24th, snuff in the morning and forenoon, not one fit; on the 25th, snuff three times, not one fit; on the 26th, the same dose and result; on the 27th, the same dose, one patient had a very severe fit in the afternoon, and ordered her to have the snuff more frequently; on the 28th, the same patient had a fit at the same time as the day before, but was quickly brought out of it by the use of ammonia. I need scarcely say that I have been highly surprised, and at the same time gratified, at these results. Before commencing the trial of the snuff and the ammonia, not a day passed without at least one, but generally two or three fits. The attendant is quite surprised, and enters so zealously into the plan of treatment that I have every confidence in the facts being so, more especially as I watch the cases with great care and considerable anxiety, being afraid that we are only postponing the fits, and that the time will come when we can no longer avert them, and that then they will be all the more severe. This is as to the female patients. As to C—— R——, I have failed in the meantime. The first day I gave him the composition he had three very severe fits, and the next he was as bad. I have never ventured to try it again; but I think he has had fewer since he had the snuff than he used to have. I may state that I think the snuff, though causing sneezing, is the best for keeping off the fit, whilst the strong liquor ammoniæ is the best for bringing them out of it. I am more convinced than ever of its efficacy in shortening the paroxysm and the comatose state after it. I shall be very glad to hear from you, and try anything you may suggest. Meanwhile, I shall carry on the experiments with the greatest interest and pleasure."

Doubtless, it is very necessary to be slow in drawing conclusions as to the results of treatment in epilepsy. Experience amply proves that the hope and mental excitement which the trial of a new remedy excites in the patient are of themselves, for a while at least, powerfully curative; hence the multitude of infallible remedies for epilepsy. In few, if any, of the cases referred to was a cure expected; they were all too complicated and of too long standing. But the experiment proved, in the case of C—— R——, a sort of *experimentum crucis* as to the influence of the method of treatment, in some cases at least. His was apparently of the worst kind; the fits were of long standing and very frequent; no means had been of use; and he was, in fact, reduced to such a state of dull stupidity that he could have no knowledge that a new method was being tried; and it was tried, indeed, with hardly the slightest hope of benefit resulting. Hence any good he derived could only be referred to the treatment. His nostrils were so anæsthetic that the ordinary mixtures had no effect in producing irritation. I therefore cautiously placed some of the pure powdered white hellebore just within the nostrils, and thus caused free sneezing. Dr. Saidler repeated the doses from time to time. The result was that when I introduced him to my clinical class in the following May (1861) he had not had a fit for six months, and was transformed from the stupid drivelling epileptic to a joyous "master merryman," and repeated some comic verses to us with much humour. He remained well for about a year, when he gradually relapsed into his old state, and died about two years after.

I now sent to Dr. Saidler packages of purely medicinal snuffs, compounded of asarum, or hellebore, or arnica, so as to try whether different results would follow. Generally, they failed to produce sneezing, and the good effects were not so marked as when sneezing resulted, but still "sufficiently hopeful." After various trials, I have found the following a safe formula for a sternutatory:—℞ Pulveris cinchonæ, ʒss. Pulveris hellebori albi, gr. x., misce intimè. Signa. "The *sneezing powder*.—A very small pinch to be placed just within the nostrils three times a-day, so as to excite frequent sneezing for ten minutes. To check the sneezing, if necessary, wash out the nostrils with cold water snuffed up." I have seen dangerous sneezing excited by the powdered hellebore. It would be easy to devise other formulæ. The Greek Physicians prescribed pepper, euphorbium, soapwort, gith (or *nigella sativa*), elaterium, and castor in powder. They also injected the nostrils with the juices of pimpernel, leeks, and other plants, and mixed the juice of elaterium with milk for an injection. Aretæus mentions in his chapter on the treatment of cephalæa a syringe with two delivery pipes, made expressly for the nostrils. He also blew powders up the nostrils through a reed or quill, and applied ointments and liniments within the nostrils by means of a feather. Any irritant thing easily removed and manageable as to its effects on the mucous membrane would, doubtless, serve the purpose. Aretæus ascribes, however, valuable uses to powdered castor beyond its mere effects as an errhine or sternutatory.

Mechanical Irritation of the Nostrils.—In so far as the irritation of the nostrils by irritant drugs is curative, we can substitute mechanical irritation for them. The act of sneezing requires a co-ordination and harmonising of numerous groups of muscles, and probably the change in the nerve-centres that induces this arrests also the defect in the regulating centres, which I have shown to be the chief element in the production of epilepsy. I have accordingly tried irritation of the nostrils with a feather or a quill. A young lady had an attack of the *petite mal* while seated at table. I instantly irritated the nostrils mechanically by scratching them, and in a few seconds she was restored, but without the slightest knowledge of what had happened. On a previous occasion a like attack

had passed into convulsions. A young gentleman had a very similar attack in my presence, but with slight facial convulsions, and the fit was ended in a few seconds by the same means. That the irritation is the effective element in the treatment, is further shown by the fact that the *throat* may be irritated with advantage in other paroxysmal affections. There is a kind of hysteric fit in which the patient seems to be strangling, for she "fights" with her hands about the windpipe, and also appears to be partly unconscious. In these cases I have found it successful treatment to irritate the throat with a feather, so as to excite retching. So soon as this happens, the patient heaves a deep sigh, and is at once relieved from the fit, much to her apparent surprise. I have tried this plan for many years, and I conclude from certain statements made by Aretæus and Paul of Egina that a like procedure was anciently found of use in certain head-affections—viz., epilepsy, tetanus, and vertigo. The burnt feathers and the fetid things used from time immemorial may have a double effect. They may excite the same nausea and retching which tickling the throat excites, and thus harmonise the disordered nerve-centres into a physiological act. And they may also act as irritants on the pulmonary membrane, for I have reason to think that bronchial irritants may be beneficially used in these cases. It is necessary to remember, in treating epilepsy by nasal irritants, that the nostrils have often such a dull sensibility that sneezing cannot be excited, and that this state is worse just before, or on the accession of, the fit. The inhalation of the vapour of ammonia is a wholly different thing, and has probably a different mode of action on the medulla oblongata, since the vapour must, in part at least, reach the laryngeal or bronchial mucous membrane, and act through that on the medulla oblongata.

(To be continued.)

CASE OF

APOPLEXY, WITH PARALYSIS OF THE RIGHT SIDE, CURED BY APPLICATIONS OF HEAT AND COLD ALONG THE BACK.

By JOHN CHAPMAN, M.D., M.R.C.P.

W. H., A GENTLEMAN, aged 55, suffered during the evening of December 2, 1864, from an attack of diarrhœa—a malady to which he is peculiarly liable, and which in his case seems to be of a peculiar character: it is accompanied with extreme and remarkably persistent abdominal pain, which, so far as I can learn, is not of a spasmodic kind.(a) The pain continued from 9 p.m. to 1 a.m. Late at night the diarrhœa was followed by vomiting, which occurred about ten times. At 2 a.m. he said that he was paralysed, and requested a Medical man to be sent for. He became rapidly worse, and very shortly after having expressed a wish for Medical aid lost the power of speech. As the Physician sent for resides near the patient, he speedily arrived. He surrounded the patient's feet with mustard plasters; gave, I believe, some homœopathic medicine, and pronounced the case a very serious one. At his suggestion my advice was requested; he then ceased to visit the patient, whom I saw for the first time at 9.30 a.m., December 4. I found him in a state of profound stupor. He did not respond in any way to the questions put to him, and could not be roused up. The right arm and leg were paralysed; the leg less completely so than the arm. If the forearm were raised vertically it immediately fell like a dead mass, and when the hand was pinched severely there was no evidence of sensibility; only when I made my thumb and finger nails nearly meet in the skin was there the faintest sign of feeling. The sensibility of the leg was much more obvious. The left hand was of a markedly dusky hue; the nails of the same hand were slightly purple; the temperature of the left side was considerably lower than that of the right; and the pulse, which was 82, was much feebler at the left than at the right wrist. The head was hot. Both eyes were closed; the left one was protruded abnormally, and slightly lacrymose; the face was drawn to the left side.

The patient's wife stated that about seven years ago he became giddy on two or three occasions while on the top of an omnibus, and nearly "fainted;" that once he did actually "faint;" that he was known to have had like attacks, approaching to fainting-fits—in all, about six, at different periods during the last seven years. After smoking he often became "ghastly pale, and, indeed, perfectly blue." It is unknown whether on these occasions he ever lost his consciousness. Fifteen months ago he was troubled with attacks of "giddiness" six or seven times a-day; the attacks began to be frequent, his wife thinks, about a year previously. Latterly, they have been less frequent. Two years ago he had a slight attack of paralysis while at his office, but speedily recovered.

I removed the mustard from the feet at once, every vestige of it being carefully washed away, in order to prevent any centric irritation from that source. I then applied a spinal water-bag, small size, the temperature of the water being about 120° Fahr., to the cervical and upper dorsal region of the spine. In less than twenty minutes the head had become much cooler than before. The bag was ordered to be refilled at frequent intervals with water at 120°, and to be applied continuously during the day so long as, or whenever, the head should be found hotter than natural. A spinal ice-bag was also ordered to be applied at once to the lower dorsal and to the lumbar region, to be kept on during three-quarters of an hour, and to be re-applied during the same length of time in the afternoon.

On revisiting the patient at 7 p.m., I found the head comfortably cool. He evinced the presence of some degree of consciousness by making a slight voluntary co-operative effort when his body was raised to apply the bag, and again when he was moved from one side of the bed to the other while the bed was put in order. The water-bag was ordered to be applied as before, every two hours throughout the night, and the ice-bag also as before—once the same evening.

Dec. 4, 9 a.m.—Head cool; face much less drawn to left side; for the first time since the attack the bladder has been relieved copiously, the urine being of a very high colour. Evidences of the return of consciousness are increasing. To continue the application of the water-bag whenever the head becomes hot; to apply the ice-bag as before, twice during the day; and to give an enema of warm water with a little soap dissolved in it. ℞ Liq. am. acet., ʒjss.; mag. sulp., gr. xv.; ammonii brom., gr. v.; ammoniæ sesquicarb., gr. ijss.; pot. bicarb., gr. v.; aquæ, ad. ʒj.; sextis hôris.

5th, 10 a.m.—The face is nearly symmetrical; the tongue is freely protruded; bowels have been opened twice; urine of natural colour, or even paler than natural. The patient's son, who sat up with him last night, is astonished by the power of the water-bag in reducing the heat of the head, and volunteers the statement that when his father's breathing was stertorous, the application of the bag speedily caused it to become quite tranquil. The ice-bag to be continued as before; and the water-bag when its need is indicated by the temperature of the head. Repeat the saline mixture, omitting the sulphate of magnesia, and half the bicarbonate of potash.

6th.—Is decidedly better; he answers questions rationally, though chiefly by "No" and "Yes," and bade me "good morning." The head is normally cool, and has never been so warm during the night as to necessitate the use of the water-bag. The dusky colour of the left hand has disappeared; the pulse, which is 72, is nearly as strong in the left wrist as in the right, and a difference in the temperature of the two sides of the body can no longer be detected. Bowels open; urine natural. To continue in all respects as before.

7th.—Improves steadily; asks and answers questions intelligibly, although there is great mental feebleness. Can open and shut his right hand fairly well, but cannot bring the tip of the forefinger in apposition with the thumb. Head, and body generally, cool; pulse 72. To omit the saline. ℞ Ammonii bromidii, gr. v.; ammoniæ sesquicarb., gr. iii.; infusi calumbæ, ʒj., ter die. To give freely of nourishing food.

10th.—Talks with increasing facility. The temperature of the whole of the body is lower than hitherto; pulse 62. To apply ice along the whole spine during fifteen minutes three times a-day, and to continue giving ample nourishment: meat three times a-day.

13th.—Got up and sat in his chair about a quarter of an hour yesterday, and was up an hour to-day. Power of right hand so improved that yesterday he became enabled to button his left wristband; pulse 74. Treatment as before.

15th.—Still better; dressed and undressed himself to-day; read *The Times* for half an hour—evidently understanding, at least in part, what he read. Pulse 80; urine of deep colour. To apply the spinal ice-bag only twice a-day. ℞ Liq. ammon. acet., ʒij.; pot. iod., gr. ij.; pot. bicarb., gr. v.; aqua ad., ʒj., ter die.

(a) The patient's mother was liable to precisely the same kind of diarrhœa, and his brother, a Medical man, died of it.

28th.—Is physically stronger; walked about the dining-room easily and steadily; he talks more freely, and answers questions with facility; pulse 84; bowels open. Treatment as before.

January 23.—Walked between one and two miles two days in succession; urine turbid; pulse 84. To apply ice in each cell of the ice-bag only once daily—viz., during half an hour before rising; to continue the saline mixture each evening only, and to take ferri et quinæ citratis, gr. v., each day at noon.

30th.—Reports himself very well, and looks so; can now stand some seconds on his right leg; still a little awkward with the right forefinger and thumb, although they can now be brought into firm opposition with each other; cannot shave the upper lip, and hold his knife at table as a child does; has now become impatient at wearing the ice; the very slight remnant of paralysis in the right forefinger and thumb makes me wish that the ice-bag should be continued once daily a short time longer; but I assented to its discontinuance, ordered the medicines last prescribed to be taken during a few days more, and on this occasion took my leave of the case.

February 25.—He called upon me; reported himself quite well; impressed me as being so both mentally and physically. During the whole period of convalescence he has not had a single attack of "fainting" or "giddiness," although previous to treatment such attacks, as already stated, occurred with alarming frequency.

I have now under my care a case of apoplexy, the symptoms of which contrast in a striking manner with those of the case just described, and the treatment of which has been correspondingly different. The patient, a stout woman, aged 60, had several attacks of what were described as "something like fainting fits," and one of deep drowsiness, from which she could only be roused with difficulty, and which lasted the whole day. She also suffered great pain on the left side of her head. Her malady was regarded by her Medical attendant as neuralgia, and was treated as such, quinine and wine being given in large quantities. Having previously become considerably better during a few days, she was taken down to Brighton. In the train she complained again of violent pain in the head, was excessively flushed, had a dull, heavy expression, and at 7 p.m. of the same day (March 13), while staggering towards the bed, exclaimed, "Oh, my head! my head!" and fell into the arms of two women who happened to be near her. The Physician who was immediately called in said she was dying. He stayed with her till 3 o'clock of the following morning, and, on leaving, sent a woman to "lay her out." As stated by a spectator, "she gasped, seemed to breathe only at intervals, was blue round the mouth, clayey looking, the whole features seemed to sink, her head, shoulders, arms, and legs were quite cold, and her face was covered with clammy sweat." She remained in this state during forty-eight hours. At the end of that time I visited her. The head and face were strikingly cold and death-like; the eyes exuded a thick gluey fluid; the left pupil was dilated and immoveable in the presence of light; the right pupil was contracted; the right side was more dusky and somewhat colder even than the left; the face was drawn to the left side. On tickling the soles of the feet there was very slight movement of the left foot; none of the right.

In treating the case reported above, my object, in the first instance, was to effect the contraction of the cerebral blood-vessels, and thus to lessen the amount of blood in the head; but in this case my whole effort was directed to produce alternate contraction and relaxation of the blood-vessels, in order to effect movement of the stagnant blood within the skull. As the case is still under treatment, I defer publishing a detailed account of it until further progress has been made; meanwhile, however, I may state the chief results which, up to this date, have been obtained. Within fifteen minutes of my first application to the spinal region, an area of about two and a-half inches in diameter in the middle of the forehead became quite warm. Before twelve hours had elapsed the whole head and face became warm; and within twenty-four hours, or by the evening of March 16, her whole body was warm. On this day she saw a cup of beef-tea in the hands of an attendant, and opened her mouth as if asking for it. The same evening she was believed to have recognised her daughter.

On the 19th, when asked whether she would have some broth, and whether she knew her daughter, she answered "Yes."

26th.—A gentleman who went to see her asked her if she would shake hands with him; she unmistakeably put out her hand, and said "I will;" and when the Medical attendant told her to put out her tongue, she made an attempt, though rather unsuccessful, to do so.

29th.—The report says,—"Her eyes are clear and bright; she eats well of chicken and lamb. She appears to understand all that we say to her, and she will smile at a little joke."

April 3.—Is still progressing; looks intelligent; shows decisive likes and dislikes of the different kinds of food offered to her; she put out her tongue, and moved it about at my request, and, when I left her, grasped and shook my hand. The whole body continues warm: during the last ten days it has not once been necessary to apply warmth to the feet. The left pupil appears to me as small as the right, and is equally contractile.

May 1.—I received a report that she is improving in all respects. She has now voluntarily moved her paralysed arm and leg. The writer adds:—"I saw her move her fingers. She is much more intelligent than when I saw her rather more than a week ago."

25, Somerset-street, Portman-square, W.

REPORTS OF HOSPITAL PRACTICE
IN
MEDICINE AND SURGERY.

ST. BARTHOLOMEW'S HOSPITAL.

CEREBRO-SPINAL MENINGITIS (?) IDIOPATHIC.

(Under the care of Dr. MARTIN.)

The following case will be read with interest at the present time in connexion with the reports of recently prevailing epidemics of cerebro-spinal meningitis in Prussia and America. Dr. Murchison thinks these epidemics are really epidemics of typhus. For his opinion on this subject we refer our readers to the report of the Pathological Society, p. 479. In the following case, however, Dr. Andrew, to whom we are indebted for the following report, tells us that, after the most careful investigation, there was not the slightest evidence of any source of infection. Inquiries were made at the model lodging house from which the patient was brought, but there had been no case of typhus in that institution. It was also ascertained that no one had been admitted from it into the London Fever Hospital. Meningitis of any kind is rare in a patient 16 years of age; but cases of this kind in which there was not only no tubercle in the brain, but also in no other part of the body, are exceedingly rare. The rapid course of the disease is also very remarkable.

Clara L., aged 16, admitted into St. Bartholomew's Hospital, under Dr. Martin, April 13, 1865.

History.—Was quite well up to April 10; on that day was obliged to leave her work at a sewing-machine about 11 a.m., in consequence of headache and sickness, but was still able to walk home, though with difficulty, from Hoxton to St. Pancras-square, near King's-cross. According to the statement of her sisters, she complained in the course of the day of feeling cold; towards evening vomited frequently; and, the next day, the 11th, she became violently delirious, so that they had some trouble in keeping her in bed. The sickness ceased on the morning of the 11th; the delirium continued. She was the youngest of five children, the other four all healthy. No history of exposure to any infection could be obtained; but she had been greatly heated and fatigued on the 9th. No detailed note was taken on the day of admission, but her general condition and decubitus were apparently the same as on the following morning. The temperature in the axilla was 103 F.; pulse 105, small; the bowels acted twice within an hour of admission, the motions scanty, dark, and powdery. She answered questions readily and sensibly, but had completely forgotten all that had occurred between her reaching home on the 10th, and her arrival in the ward, not knowing where she was, or remembering even her being brought to the Hospital.

April 14.—A well-nourished girl, of fair complexion, frequently changing her position in the bed, but lying generally about two-thirds turned over towards the left, with the head drawn backwards as far as possible between the shoulders, the back also being slightly arched. Her friends first noticed this peculiar position on the 12th. The head retains this position

during sleep, but during the act of deglutition is brought somewhat forwards. She is unable to remain for any length of time on her back, on account of the increase of pain which any strain upon the muscles at the back of the neck occasions. She occasionally wanders, talking incoherently; complains of continual pain at the nape of the neck, and of intermitting pain in the head. There is no tenderness over the spinal column, but slight over the abdomen. Face flushed; eyes slightly suffused, with slightly dilated pupils, both equally so; respiration hurried, shallow, interrupted by a slight dry cough; lips dry and peeling; tongue dry, and thickly coated with yellowish-brown fur. Has taken milk, beef-tea, etc., readily and with ease. Bowels have acted once in the course of the night, motion relaxed; has passed a fair quantity of urine voluntarily; slept quietly, not wandering or talking; heart and respiratory sounds natural.

15th, Saturday.—Decubitus the same as yesterday; still complains of the pain. Bowels acted twice; motions relaxed, of a bright yellow, and slimy (had taken a grain of calomel the previous evening); is thirsty; swallows easily. Skin hot; pulse 96, of greater volume. Catamenia appeared early this morning (she expected their return in the course of this week). Passed a very bad night, screaming continually till about 5 a.m., when she dozed for a short time, and has since been less violent. About 3 p.m. the respiration became embarrassed and noisy. She could still swallow easily; the feet cold, the face gradually more and more livid. A few minutes after 6 p.m. she was attacked by slight convulsive movements, most marked in the muscles of the face, which lasted up to her death at 6.50 p.m. The face became of a livid purple. She retained consciousness almost up to the setting in of the convulsions, requesting that her father might be sent for, and giving his correct address to the sister of the ward. The sphincters retained their power to the last. The most careful examination failed to detect any rash during the time she was under observation.

Autopsy Forty Hours After Death.—Rigor mortis well marked. The thumbs slightly flexed upon the palms; muscles of back natural; scalp congested and œdematous. The sheath of the cord contains apparently about the usual quantity of fluid, but what there is is milky and opaque. The membranes of the upper portion of the cord are greatly congested; at the level of the foramen magnum is a little greyish transparent lymph on the posterior aspect, and there are numerous delicate adhesions in the spinal arachnoid in the upper cervical region. The cerebral convolutions are slightly flattened; in the right hemisphere, about its centre, a considerable tract of the white matter presents a yellowish tinge. The septum lucidum and pillars of the fornix are soft, but entire; the vessels of the thyroid plexus and velum interpositum greatly congested; the walls of the ventricles appear natural, and they contain about the usual quantity of clear fluid. There is some slight opacity of the arachnoid at the base; no tubercle detected anywhere, except perhaps in a gland by the side of the trachea, which contains a putty-like mass. The spleen weighed 5½ oz., was pale and soft, almost pulpy; liver and kidneys greatly congested; supra-renal capsules natural; no change in Peyer's patches. In the right ovary there was a small recent clot, and also in the interior of the uterus. There were loose clots present in the heart and large veins, but the greater portion of the blood was fluid.

SAMARITAN HOSPITAL.

CASES OF OVARIOTOMY.

(Under the care of Mr. SPENCER WELLS.)

Case 1.—*Multilocular Ovarian Cyst—Once Tapped—Ovariotomy—Septic Peritonitis—Tubular Clot in the Heart.*

On the 8th of August, 1864, an unmarried servant, 21 years of age, was sent to Mr. Wells by Mr. Cooke, of Charlwood-street, and admitted into the Samaritan Hospital suffering from ovarian disease. She had a cheerful face, and did not appear much brought down by her disease. The appetite was bad and the bowels confined; the nervous, respiratory, and circulatory systems were in good order. The urine was normal in quantity, and contained no albumen. The girth at the umbilical level was 35 inches, the distance from the ensiform cartilage to the umbilicus 7 inches, from the umbilicus to the pubic symphisis 8 inches, and to each iliac spine also 8 inches. The abdomen was occupied by a large fluctuating tumour. There was a little tenderness on pressure, but no crepitus. The abdominal parietes were of the normal thickness, and neither showed traces of lineæ albicantes nor of dilated veins. The tumour was quite unattached to the abdominal wall. The catamenia had always been regular, neither in excess nor scanty; there had never been any sudden suppression. The uterus was far back, but moveable; the tumour could be indistinctly felt in front of it. The patient was born at Brighton, of a healthy stock, and for the most of her life had acted in the capacity of housemaid in a gentleman's family. She never had any serious illness, but, on the contrary, was habitually in the enjoyment of good health. On June 13, 1864, she experienced considerable pain in the left iliac region; the pain was, indeed, so severe that she was confined to bed. There was no pressure on the bladder, no constipation, no fulness in the breasts; nothing but pain and a sense of weakness and numbness in both legs. On June 20 the patient discovered a tumour in her abdomen. At first on the left side, it quickly gained the median line, and at the same time increased very rapidly in size. The treatment which had been pursued was entirely Medical. In order to see what could be gained by tapping, on August 11 Mr. Wells removed twelve pints of very thick fluid, evidently ovarian. The patient was relieved, and was discharged three days after the tapping. The cyst refilled, and she was re-admitted on December 6. Mr. Wells wrote down this diagnosis in the Hospital book:—"Ovarian cyst. One large cyst refilling after tapping. Secondary growths both in right and left ilio-lumbar regions. No important parietal or pelvic adhesions. Uterus healthy."

On December 14, 1864, he extirpated the tumour. Dr. Wilson, of Glasgow, and others were present. Dr. Parson gave chloroform. The incision extended downwards four inches from one inch below the umbilicus. There was a thick layer of fat both beneath the skin and between the peritoneum and recti muscles. There were no adhesions. The pedicle sprang from the left side of the uterus; it was three inches long, and was easily secured in a small clamp, and fixed externally without causing traction. The right ovary was found to be healthy. There was no hæmorrhage; and the wound was closed by one deep and two superficial sutures below the clamp, and three deep and two superficial above it. The only peculiarities of the operation were the thick layers of fat in the parietes and the fact that the stump of the pedicle lay in the middle of the wound instead of, as usual, falling into its lower angle. During the operation five to six pints of very viscid dark fluid were drawn off, and the remaining mass weighed from three to four pounds. The operation was performed at 2.30. Four hours later the pulse was 100, the urine clear and plentiful, and there was slight pain. At half-past 8 the patient was sick once. The pulse was 112. Twenty drops of opium were ordered. During the whole of the next day the state of the patient was most satisfactory. The skin acted well; there was no great pain; and the urine was abundant. At night the pulse had risen to 130; the patient complained of thirst and some flatulence, but seemed very well.

On the second day the urine was loaded with purplish lithates; there was no sickness nor tympanites; but thirst was troublesome. At 8 p.m. there was a good deal of oppression, flatulence, and thirst; the pulse was 140; the respiration 36; the tongue coated, but not dry. Champagne was given; it relieved the thirst; and at 11.30 p.m. the pulse was only 128. The patient slept a little during the night, having taken twenty drops of laudanum. Next morning she was worse. The pulse was 150; the abdomen tympanitic; the vomiting frequent. At 1 p.m. the pulse was 148, very irregular in force; the respiration shallow. Mr. Wells opened a vein, and drew five ounces, by weight, of blood, which coagulated with a firm clot, having a slight coating of fibrine on the surface, and very little serum separating. Poultices were ordered to the abdomen and mustard to the back. A one-grain opium pill was given, but was immediately vomited. The urine was now scanty and albuminous, containing excess of uræmatin. After the bleeding, the pulse became feebler and more rapid. It rose to 160. The urine, however, contained less albumen and uræmatin. Vomiting became more frequent, the gradually darkening hue of the rejected matters showing how much the stomach was suffering from its efforts. A vain attempt was made to keep up the strength by nutritive and stimulating enemata. The patient dozed a little after having had twenty drops of laudanum by the rectum and a plentiful sprinkling of the same on the poultices. The pulse became almost imperceptible. There was a slight discharge from the abdominal wound, and Mr. Wells took off the clamp, after having secured the stump with

a ligature. No more fluid came away, although he introduced an elastic tube into the peritoneal cavity, and tried to pump it out with a syringe. The patient died on the morning of the fourth day, ninety-three hours after operation.

The body was examined twenty-two hours after death by Dr. Parson. He reported as follows :—"Body well nourished, fat plentiful, muscles averagely red. The wound had not united, and looked sloughy on its peritoneal surface. The pedicle was long and thin, and sprang from the broad ligament, and was well secured. The uterus was normal, the left ovary apparently so. The intestines were distended with flatus, and very vascular. The peritoneum was covered all over with recent lymph, which in some places was a little tough and organised, but in the majority thin and purulent—so much so that about a teacupful of this sero-purulent fluid was diffused in the belly. The descending colon, sigmoid flexure, and rectum were very small, and contracted. Heart. —Valves normal, nothing in left side, a clot in right side. Substance of heart perfectly firm. A good deal of dark blood in the cavæ semi-clotted, and some in the right auricle. The clot is greater in the auricle than in the ventricle; it is of ante-mortem nature. Cause of death.—Diffuse low peritonitis, possibly of septicæmic origin, with fibrinous deposition in heart."

Dr. Parson exhibited the heart at the Obstetrical Society as an excellent example of ante-mortem clot. The mass of fibrine was distinctly tubular, the current of blood from the ventricle into the pulmonary artery having clearly passed through the clot. Mr. Wells stated at the Society his opinion that the low form of peritonitis and septicæmia in this case partly depended on the low vital powers of the patient, and partly on the state of the Hospital at the time. In an adjoining ward a patient had erysipelatous phlebitis after removal of part of a uterine growth, and in a ward below, scarlatinoid pyæmic fever followed amputation of the cervix. There was nothing observed at the post-mortem connecting the death with ovariotomy, except indirectly through this septic peritonitis. The only object of the bleeding was in the forlorn hope of giving mechanical relief to the lungs and kidneys. The latter object was effected, for the urine at once became more copious, and the quantity both of albumen and uræmatin lessened. The progress of the deposit in the heart was traced very accurately from failure in intensity of the first sound till it became quite inaudible.

Case 2.—Adherent Multilocular Cyst—Four Tappings—Ovariotomy—Recovery.

On December 29, 1864, an unmarried schoolmistress, 24 years of age, who had been sent to Mr. Wells by Dr. Robbs, of Grantham, was admitted for ovariotomy.

The patient was feeble and strumous-looking, with a hectic flush on each cheek. Her extremities were habitually cold, but there were no night sweats, no eruption, no œdema, and no varicose veins. She occasionally had a troublesome cough, and expectoration was free, especially at night. On percussion, the left side of the thorax was duller than the right, and expiration was a little prolonged in the left lung. Dr. Parson, who examined the chest, thought that there was "no tubercle, unless in small quantities and scattered." The heart's sounds were normal, but the heart was evidently displaced upwards, the apex being felt between the third and fourth ribs. The liver was displaced upwards, as was also the stomach and the transverse colon. The urine was of specific gravity 1015, and contained no albumen. The girth at the umbilical level was thirty-six and a-half inches, the distance from the umbilicus to the ensiform cartilage nine inches, to the pubic symphisis eight and a-half inches, and to either ilium eleven inches. The whole abdomen was occupied by an irregular tumour, which in some parts was fluctuant.

Her parents were healthy; but three of her sisters had died of phthisis. She herself had always enjoyed good health, and had regularly menstruated up to Christmas, 1863. About this time the body began to enlarge without any appreciable cause. Pain was felt in the left side, tolerably constant, and acute occasionally. By March, 1864, the swelling was chiefly felt on the right side of the abdomen. It steadily increased in size, and became fluctuant. In October, 1864, and again in November of the same year, Dr. Robbs tapped, drawing off on each occasion about twelve pints of thick clear fluid.

After her admission into the Hospital there was a little swelling observed in the left leg. Other symptoms were become urgent, and on January 4, 1865, Mr. Wells tapped and removed seventeen pints of fluid. After the tapping the crural phlebitis on the left side increased, and the leg and thigh were much swollen. The heart and liver descended a little, and the general health improved. The cyst, however, refilled, and on January 30 Mr. Wells tapped again, and removed eighteen pints of white glutinous fluid, similar to that which had before been evacuated. After the tapping, groups of cysts, irregularly disposed and evidently adhering in many places to the parietes, were felt filling the whole of the epigastrium, and, on the right side of the median line, reaching several inches above the umbilicus. The uterus was high, and to the left side; its mobility was restricted. The os was small and virginal. The tumour was felt on the right side of the uterus, pushing that organ to the left. The tumour was scarcely below the brim of the pelvis. Mr. Wells's diagnosis was, "Multilocular ovarian cyst; parietal adhesions; pelvic attachments possible, but doubtful." He thought that ovariotomy was the only resource, but that the feeble state of general health and displacement of thoracic viscera lessened the chance of success. After the last tapping the heart beat a full inch lower than it had done before; but the apex of the left lung was still duller than the right.

Mr. Wells performed ovariotomy on February 15, Dr. Dehn, of Hamburgh, and other visitors being present. Chloroform was given by Dr. Parson. The incision was carried downwards for five inches from one inch below the umbilicus. There were extensive adhesions above and to the right side as well as to the brim of the pelvis, and, in one place to a piece of omentum. They gave way easily to the hand. Having tapped a large cyst, and broken down a second inside the first, the tumour was drawn out. The pedicle was three to four inches long. It sprang from the left side of a very long thin uterus. It was secured in the smallest clamp, and kept outside without traction. There was a very little oozing from from the adhesions. The blood was carefully sponged away, but no vessel required ligature. The right ovary was felt to be healthy. The wound was closed with five deep and three superficial silk sutures. About twenty-two pints of fluid were evacuated at the operation, and the more solid remainder of the tumour weighed seven pounds.

The patient rallied well, complained of little pain, and only required a single opiate. The stitches were all removed on third day, when there was a little tendency to prolapse of the pedicle. Mr. Wells removed the clamp on the eighth day. The bowels acted for the first time on the thirteenth day. There had been no uneasiness from the prolonged constipation. The patient left the Hospital four weeks after the operation, and called on Mr. Wells on March 16 in excellent health. She then returned to Grantham, and has been heard of since as quite well. The diagnosis in this case was well borne out. The adhesion low down to the right side quite explained the pushing of the uterus upward and to the left.

(To be continued.)

ST. THOMAS'S HOSPITAL.

TYPHLO-ENTERITIS—DEATH—AUTOPSY.

(Under the care of Dr. PEACOCK.)

The following case affords an example of perforation of the appendix vermiformis, leading to a communication between the cavity of that body and the peritoneal sac, and so inducing fatal peritonitis. In the majority of such cases the perforation is due to inflammation set up by the presence of some foreign body, as when a mass of indurated fæcal matter becomes imbedded in the appendix. No such foreign matter was found in this instance; but it is possible that a stercoraceous mass might have existed, and have become broken down so as to escape observation. The occurrence of marked symptoms of obstruction of the bowels on two occasions without any mechanical impediment having been met with is a noticeable feature in this case.

A boy, aged 10, was admitted into St. Thomas's Hospital, under the care of Dr. Peacock on January 2, 1865. He was then labouring under symptoms of peritonitis, with obstruction of the bowels, and stated that he had been suddenly seized on December 28 with pain in the abdomen, sickness, and vomiting; and as his bowels were confined, a powder was given to him. This produced no effect, and was repeated the following day, and as no satisfactory result ensued, castor oil and an injection were subsequently administered. No evacuation was, however, obtained, and the pain and vomiting continued, and he was sent to St. Thomas's. When seen by Dr. Peacock he was greatly exhausted, the pulse at the wrist was

scarcely to be felt, and the extremities were cold and livid; his face was flushed, and he had constant vomiting and great pain in the stomach, and the abdomen was tumid and very tender; the matters vomited were fluid, and of a brown colour, apparently containing bile and blood, but had no fæcal smell. He had passed but little water. Leeches and fomentations had been applied and he had taken some calomel, but without any action being produced on the bowels. He was directed to have opiates, which relieved the pain and sickness, but were not otherwise beneficial, and he died on the second day after being seen.

It appears that he had previously, in August, 1864, been in the Hospital, under the care of Dr. Bristowe, and then laboured under similar symptoms, which were relieved by aperients and opiates.

The post-mortem examination was performed by Mr. Rayner, the Medical registrar of the Hospital, after the body had been removed to the boy's home, and the following are the notes he took:—

Autopsy.—Heart, lungs, kidneys, liver, and spleen, healthy; the abdomen was tumid, and the great omentum was adherent by its edges to the abdominal wall, the cavity being thus divided into two portions—an upper which was free from all traces of inflammation, a lower which contained fluid not in large amount, but thick and creamy, equally diffused, nowhere tinged with fæculent matter. The intestines in the low parts were covered with recent lymph, by which they were slightly adherent to one another. On examining the vermiform appendage its extremity presented an opening communicating between the intestine and peritoneal cavity; the extremity of the appendix seemed to have had its cavity dilated, but no foreign substance could be found either in it or in the abdominal cavity; fæcal matter was traced through the whole length of the intestinal canal; the head of the colon contained some, but was not distended.

WESTMINSTER HOSPITAL.

VARICOCELE TREATED BY PERMANENT SUBCUTANEOUS LIGATURES.

(Under the care of Mr. CHRISTOPHER HEATH.)

Obliteration of the spermatic veins for the cure of varicocele is now a frequent operation; but the mode in which the result is effected is modified by different Surgeons. Mr. Holt has lately, in several instances in the Westminster Hospital, employed the subcutaneous ligature, which has been left permanently *in situ* with the best effect. We publish to-day a case in which Mr. Heath adopted the same plan with success.

G. W., aged 35, admitted into Mark Ward, December 12, 1864, with varicocele of left side, which had existed some years. Masturbated when a boy, but married at 23, and has had seven children. Has noticed enlargement of left side of scrotum for last ten years, but has had no pain except in very hot weather and when he walks very much.

On admission, the left spermatic veins were much enlarged and the vas deferens thickened. The left testicle hangs much lower than the right, and is softer, but not smaller, than the right.

December 13.—Mr. Heath ligatured the spermatic veins subcutaneously in two places. The upper ligature was of silkworm gut, the lower of silver wire. Both were cut close and drawn entirely under the skin.

15th.—Complains of pain in the abdomen and up the cord, but no signs of inflammation present. Veins of cord smaller than before.

26th.—Able to walk about. Great induration of cord between the two ligatures, which are now buried beneath the skin.

January 3, 1865.—Discharged.

February 10.—Came as out-patient. The thickening has nearly disappeared, and the veins of the cord appear to have returned to their normal condition. Has no inconvenience from either of the ligatures.

Deaths of Scientific Men in France.—To the already numerous list of these which have occurred recently we have now to add the death of M. Valenciennes, Professor of Zoology at the *Muséum d'Histoire Naturelle*, and of M. Léon Dufour, so well known by his writings on Botany and the Anatomy of Insects.

SATURDAY, MAY 6.

THE LAST HOURS OF PRESIDENT LINCOLN.

Since that sad Sunday morning in December, 1861, when the whole English people awoke to learn the calamity that had befallen us in the loss of the Prince Consort, there never has been so wide-spread a sense of grief as that occasioned by the death of President Lincoln. Grief, too, embittered by the deepest humiliation at the idea that amongst any people of English lineage, amongst any free, out-speaking, self-governing race, there could be found any so base as to resort to the weapons of the assassin in a cause only to be settled by open debate or the still fiercer arbitrement of war. Not that we for one moment believe that the heroic people who have followed Stonewall Jackson and Lee could be guilty of a crime so base and cowardly. Certainly, too, nothing in the tone of English education, society, religion, manners, or sentiments can be in the least accused of fostering the sentiments of the assassin. True, schoolboys read of Harmodius and Aristogeiton, but they are never held up as models; whilst the very fact that a man or his father could bear such names as Junius, Brutus, Wilkes, shows that his sentiments may be in accordance with those of the baser populations of Southern Europe, certainly not with that of the English people, from the Queen over us to that of the lowest cads who make a ring in the streets for the love of a "fair fight."

The assassin, Wilkes Booth, son of Junius Brutus, tells the world, in a document (which some psychologists would probably consider as satisfactory a proof of insanity as the letters left by Townley), that he "waited," "hoped," and "prayed." It never seems that he worked or fought. Whilst others were sacrificing their lives, he was nursing his sentiments. Doubtless, like many other misguided creatures, whose ideas of glory are founded on French novels, he considered any powerful emotion a thing to be yielded to, and a justification of any crime he might commit. We earnestly hope that the doctrine of "doing duty" and of controlling passion will take the place of that of "irrepressible emotion."

Certainly no crime was ever arranged with more minute precautions to ensure the destruction of the victim and the escape of the murderer. Having access to the theatre by day, he deliberately surveyed the premises, placed the chair in which his victim was to sit, and made arrangements for opening the door of the lobby of the President's box himself and for barring it against entrance of others from without. Then at the fatal moment he got access to the lobby of the Presidential box, barred the outer door, shot the President *through the inner door*, rushed into the box past his bleeding victim, stabbed Major Rathbone, who tried to arrest him, and jumped upon the stage, making his escape with the theatrical flourish which we now know but too well.

The President, as we are told, "fell back in a state of syncope, totally insensible, and breathing slowly. The blood oozed from the wound at the back of his head. His eyes were closed and injected with blood, both the lids and the portion surrounding the eyes being as black as if they had been bruised by violence. For several hours the breathing continued regularly, and apparently without pain or consciousness. But about 7 o'clock a change occurred, and the breathing, which had been continuous, was interrupted at intervals. These intervals became more frequent and of longer duration, and the breathing more feeble. Several times the interval was so long that we thought him dead, and the Surgeon applied his finger to the pulse, evidently to ascertain if such was the fact. But it was not till 22 minutes past 7 o'clock in the morning that the flame flickered out. There was no apparent suffering, no convulsive action, no rattling of the throat, none of the ordinary premonitory symptoms of death. Death in this case was a mere cessation of breathing.

"On the next day, Surgeon-General Barnes, Dr. Stone, the late President's family Physician, Drs. Crane, Curtis, Woodward, Toft, and other eminent Medical men performed an autopsy on the body of the President.

"The external appearance of the face was that of a deep black stain about both eyes. Otherwise the face was very natural.

"The wound was on the left side of the head behind, on a line with, and three inches from the left ear.

"The course of the ball was obliquely forward, toward the right eye, crossing the brain obliquely a few inches behind the eye, where the ball lodged.

"In the track of the wound were found fragments of bone which had been driven forward by the ball.

"The ball was found embedded in the anterior lobe of the west hemisphere of the brain.

"The orbit plates of both eyes were the seat of comminuted fracture, and the orbits of the eyes were filled with extravasated blood.

"The serious injury to the orbit plates was due to the centre coup, the result of the intense shock of so large a projectile fired so closely to the head.

"The ball was evidently a derringer, hand cast, and from which the neck had been clipped.

"A shaving of lead had been removed from the ball in its passage through the bones of the skull, and was found in the orifice of the wound. The first fragment of bone was found two and a-half inches within the brain; the second and a larger fragment about four inches from the orifice. The ball lay still further in advance. The wound was half-an-inch in diameter."

Thus fell Abraham Lincoln, at the moment when he had achieved unexampled greatness. Not merely that he had commanded the largest armies in the world, or had subdued an heroic people of his own race, fighting for their very homes and liberties, but that in the moment of victory he thought of mercy. His best epitaph would be an admonition to his successor to follow his example.

MODERN DERMATOLOGY.—No. IV.

Though no one will dispute the assertion that the great majority of skin diseases are not mere local affections but own a constitutional origin, yet, as we have seen, it is as indisputable that it is not often possible either to say to what particular constitutional vice, defect, or taint a skin disease is due, or to use etiological affinity as a basis of classification for these affections. The modern French dermatologists have advanced farther in this direction than the English, and in addition to "scrofulous" and "syphilitic" affections, or, as they term them, "scrofulides" and "syphilides," recognise the "dartres" or "herpétides," and the "arthritides" as distinct and definite classes. M. Bazin is the special patron of the last-mentioned group; he affirms that "les affections cutanées d'origine arthritique constituent une famille tout aussi naturelle que elle des syphilides ou des affections parasitaires," but, notwithstanding his confidence that this opinion would be quickly shared in by all enlightened observers "de bonne foi et sans prévention," the arthritic group has not yet been nearly so generally recognised, even in France, as that of the "maladies dartreuses," "herpétides," or "dartres," and we think that no one will be surprised at this who will read M. Bazin's account of the "arthritides," or Mr. Williams's reproduction of it; the list of arthritides is a very long one, and includes, among others, erythema nodosum, urticaria, herpes, herpes zoster, pemphigus, intertrigo, pityriasis, psoriasis, prurigo, lichen, eczema, ecthyma, and furunculus: the simple truth, and the whole truth, is, we believe, that skin diseases are somewhat modified in appearance, course, and duration when they appear in persons of a gouty or rheumatic habit, and any Practitioner who has the sense to treat the patient, and not merely a disease of a given name, will recognise this, and regulate and vary his means accordingly.

M. Hardy's views have met with more general acceptance than M. Bazin's. His sixth class of skin diseases, "les dartres," comprises eczema, lichen, psoriasis, and pityriasis, which, according to him, "dépendant d'un état particulier, d'une disposition générale de l'économie, que l'on appelle diathèse dartreuse." The old French word *dartre*—whence our *tetter*—originally replaced the term *herpes*, and was employed to indicate "les affections cutanées chroniques ayant de la tendance à récidiver et à se généraliser," and popularly was applied to all inveterate and constitutional diseases of the skin. Willan and Bateman, finding the word had such a vague and indefinite meaning, rejected it altogether. Alibert attempted "de le zéhabiliter dans le langage scientifique," but it continued to have only a very vague and popular signification; scientific writers not making much use of it, partly because of its very general and undefined application, and partly because old authors had spoken not only of a *vice dartreux*, but also of a *virus dartreux*, manifestly a very incorrect expression, seeing that the dartres are not transmissible by inoculation. M. Hardy, rejecting altogether the idea of a dartrous virus, adopts the existence of a dartrous diathesis, of which eczema, lichen, pityriasis, and psoriasis are different expressions. How, then, does he describe this diathesis? "Nous appellerons *dartres*," he says, "affections de la peau à lésions élémentaires différentes, non contagieuses, se transmettant souvent par voie d'hérédité, se reproduisant d'une manière presque constante, présentant pour symptome principal des demangeaisons, disposées à s'étendre, à marche habituellement chronique, et dont la guérison a lieu sans cicatrices, bien qu'elles s'accompagnent souvent d'ulcérations:" these eruptions are due to the *dartrous diathesis*, which, indeed, "is often completely latent, but which, in a great number of cases, may, by careful observation, be recognised, even in the absence of any eruption, by particular characters and special accidents; its victims may possess apparently all the attributes of good health, but are nevertheless in a peculiar condition which is not perfect health; their general surface is dry, perspiration is with difficulty excited and quickly ceases; the skin is frequently the seat of severe itching, especially around the anus, even without any eruption, and it is extremely sensitive, so that very slight and passing causes, either general, such as alcoholic excess, coffee, shell-fish, etc., or local, as friction by the dress, the application of a plaster, etc., will excite an eruption, which, though ephemeral and not a dartre, reveals a peculiar predisposition of the economy and the existence of a latent defect which only awaits a favourable opportunity to manifest itself clearly; this arriving, the diathesis bursts forth:—"Elle est alors caractérisée par diverses sortes d'éruptions cutanées: vésicules, papules, squames, mais ces lésions élémentaries ne sont jamais isolées, de manière à former des éruptions à caractéres anatomiques constants. Le plus souvent, elles sont associées et unies, soit momentanément, soit pendant tout le cours de la maladie." Besides the characters already mentioned of the eruptions, they are marked by a great tendency to spread, and by itching, they generally affect a considerable amount of surface, either continuously or in patches; they often appear at several different parts at the same time; they are mostly symmetrical, and they often affect the mucous membranes. They run an essentially chronic course, and their cure is difficult.

It must be admitted that, apart from the actual presence of the eruptions, the "dartrous diathesis" has but a very vague and shadowy outline, and must be difficult to recognise and appreciate; and, even were the term accepted, it must not be forgotten that it is a mere phrase, arbitrarily employed to express a belief in the existence of a something of whose real nature we are absolutely ignorant — a convenient concrete expression of a theory. At the same time, it is undeniable that there are certain very common skin diseases, of which eczema is at once by far the most common, and *par excellence* the type, which, in their general characters, their natural course, and their behaviour under treatment, do present a very close family resemblance, and they may be very usefully and justly classed together; but, in the present state of knowledge, we prefer Mr. Wilson's mode of doing this; it is safer, we think, and quite as practically useful, to bring them together as "eczematous affections"—*i. e.*, "diseases having the character of eczema," than as so many expressions of the "dartrous diathesis." It is to be noted, in passing, that most of these modern dermatologists employ the term *Eczema* in a different sense from Willan, for they deny that it is essentially a vesicular disease; Hebra, Hardy, McCall Anderson, Wilson, and others teach that its elementary lesion "is not of necessity a vesicle, but may be an erythematous state of the skin, a vesicle, a pustule, a papule, or a fissure." It is only just to state that Dr. Tilbury Fox ably and very earnestly opposes these views, but we are disposed to side with those who give to the term eczema "a larger meaning and wider applicability" than it bore of old.

We have said that the skin diseases classed together by Mr. Wilson as eczematous affections are closely allied in their behaviour under treatment; and, in fact, when an eruption has been diagnosed as belonging to this class, the treatment required for its cure is at once known. In no part of dermatology has more marked, decided, and satisfactory advance been made than in its therapeutics. As skin diseases have been gradually rescued from the hands of empirics and mere specialists, and been recognised as diseases of the system, and worthy of the best attention of the accomplished Medical man, their treatment has become more and more scientific, and more and more simple; they are acknowledged to be constitutional as well as local affections, and the patient is examined and treated instead of only the cutaneous manifestation of his disorder, and it is now fully felt that to treat skin disease rightly requires a thorough knowlege of all Medical science; as Mr. Wilson puts it, "to treat the constitutional affection, the Practitioner must be an enlightened Physician; to treat the local disease he must be an accomplished Surgeon."

In the management of the eczematous affections, a degree of unanimity prevails among modern dermatologists that we must call really remarkable in these days. All recommend purgatives and depressants, arsenic, iron, cod liver oil, and sulphur, given in degrees and combinations varied according to the age, condition, constitution, and temperament of the patient. M. Hardy well describes the various means to be employed as belonging "à la médication dérivative, à la médication substitutive, ou à la médication reconstituante." Purgatives occupy the first place among *les médicaments dérivatifs*. Arsenic and sulphur he places in the second group of medicines, together with tincture of cantharides and the balsam of copaiba, which he has found useful in some obstinate cases, "Nous considérons," he remarks, "ces médicaments comme des modéficateurs de cette membrane (la peau) et nous expliquerons leurs effets par une action substitutive qui, amenant dans le tissu cutané une modalité nouvelle, fait disparaitre l'altération intérieure." The direct action of arsenic on the skin is evident, he observes, "non-seulement par les effets thérapeutics, mais encore par les taches grises qu'il n'est pas rare de rencontrer chez les malades qui ont pris pendant un temps assez long des préparations arsenicales, et qu'on serait tenté d'attribuer au dépôt et à la présence reelle de l'arsenic dans le tissu même de la peau."

Bitters, cod liver oil, iron, and some iodides are useful "by their effect on the constitution and the whole economy. . . They are chiefly indicated when the eruption appears in persons of the lymphatic temperament, and those with a deteriorated constitution; they evidently operate by their reparative act;" they are "les médicaments reconstituents."

In English we should call these two latter groups simply *alteratives* and *tonics;* but our readers will doubtless appreciate the trouble we have taken to give them the benefit of M. Hardy's longer description of their mode of action, as the increased number of words *must* seem to carry with it a fuller and more real degree of explanation? For the principles of the local treatment we may quote Mr. Wilson:—"Causes of irritation are to be removed; inflammation and pruritus are to be subdued; excoriated and weeping surfaces are to be soothed; crusts and sordes to be cleared away; dry and desquamating parts are to be softened; and irritable and chronic states of the tissues to be stimulated to a more healthy action." We cannot here go into details; but we may allude to the great value of stimulating applications in some varieties and conditions of eczema. "There is nothing that brings a weak, and irritable, and angry eczema—an eczema that does not seem to quite know whether to be itchy or exudative, or otherwise rebellious—so speedily to its senses as one of these stronger remedies; it seems to act the part of a local tonic, and substitutes sthenic action for asthenic action." For this purpose a solution of nitrate of silver in nitric ether (gr. i.—xx. ad ℥i.) is found of great value; and in eczema sclerosum, eczema fissum of the palms of the hands and of the fingers, and in any of the very chronic or very obstinate forms, an application first employed by Hebra is of very high value—viz., a solution of potassa fusa (℥i.—iv. ad ℥i.). For the same purpose Dr. M'Call Anderson also speaks highly of the use of acetum cantharides prepared with glacial acetic acid. When irritability and pain are very predominant, in *eczema neurosum*, Mr. Wilson has found the nitrate of silver solution of the greatest value.

It is scarcely necessary to add that attention must be paid to diet; food must be simple, nutritious, and unstimulating, and "the patient warned to eat very moderately and slowly, and to masticate his food well."—(Anderson.)

Most of our authors allude to the vulgar idea that it may be dangerous to cure, or, at least, to cure quickly, a skin disease, especially one of the eczematous affections, and all reject it as a fallacy. Dr. Hillier observes, "this idea has originated from the fact that, often coincidently with an attack of some internal disease, many chronic skin diseases disappear in part or wholly. It does not necessarily follow from this fact that the acute disease is the effect of the disappearance of the chronic disease; it is probable that the disappearance of the skin disease is an effect rather than a cause, or else the two results are produced by some common cause. We know of no remedies that act so powerfully on skin diseases that we run the risk of curing them too quickly." So, also, Mr. Wilson:—"We have no reason to fear re-percussion; our fear should be rather our incapability of mastering the disease; and we neglect our duty when we allow the disease to run on for months and years without attempting a cure, placing our reliance on morbid nature, and hoping, if the patient be an infant, that the cutting of the teeth, or the development of puberty, or menstruation, or manhood, will eventually bring about a cure. There is another evil in deferring a cure—namely, the setting up in the constitution of a tendency or diathesis. Diathesis is of two kinds, *hereditary* and *accidental*. The latter is the consequence of a protracted continuance of the disease, and in another generation may become hereditary." M. Hardy holds the same opinion on this subject; but, with Dr. Hillier, thinks that in some few complications caution is required; in some patients suffering from eczematous affections, and from asthma or chronic bronchitis. "On remarque que les accés de suffocation sont plus rares et plus légers tant que l'éruption est en pleine efflorescence, et qus les

étouffements reviennent au contraire plus fréquents et plus graves, quand l'affection extérieure est guérie ou seulement diminuée d'une manière notable ; dans ces circonstances le médecin devra toujours respecter l'affection cutanée, au moins dans certains limites ;" and a like caution is to be observed in some cases of gastralgia and neuralgia.

THE WEEK.

THE ROYAL COLLEGE OF PHYSICIANS AND THE ARMY MEDICAL DEPARTMENT.

It is not likely that the Royal College of Physicians can acquiesce in the decision of the small meeting of Fellows who contemptuously rejected the Report of their Committee, and decided not to help the Army and Navy Surgeons. If the College be really in earnest in its wish to put itself at the head of the Medical Profession, it can scarcely plead "that it is not the province of the College to interfere" in a matter in which the comfort and respectability of the Medical officers of the Army and Navy are directly, and the welfare of both services indirectly, concerned. An attempt has indeed been made by a contemporary to lay the blame on the Report presented to the College by its Committee, alleging that the Report was too long, and contained matter that was irrelevant and that could not be substantiated or could be explained away. We would observe first that the names of Black, Gavin Milroy, Sibson, Markham, Armstrong, and A. P. Stewart are not those of men apt to indulge in assertions which they cannot prove. Secondly, that if these gentlemen have erred, it has been in goodly company. They have but repeated the assertions of the Royal Commission appointed in 1857, and presided over by the late lamented Lord Herbert, and re-affirmed what was stated emphatically by the late Lord Dalhousie in the following terms :—

"It is impossible to imagine what serious justification can be offered for a system which, in respect of external position, postpones service to experience, cunning to ignorance, age to youth—a system which gives a subaltern who is hardly free from his drill precedence over his elder, who, perhaps, has served through every campaign for thirty years—a system which treats a member of a learned profession, a man of ability, skill, and experience, as inferior in position to a cornet of cavalry just entering in the study of the pay and audit regulations—a system, in fine, which thrusts down grey-headed veterans below beardless boys."

Such is the system as described by Lord Dalhousie, but which the College is too courtly to interfere with.

As for the Report itself, we pronounce it carefully drawn and temperately worded. If there be any sting, it is in the facts. If it were not the province of the College to interfere, it is a pity that they took the matter up. But having begun, they can hardly rest where they are. They cannot suppose that the six men whose names we have given above, and the Profession at their back, will acquiesce in this accidental stultification. It is clear that the Medical officers of the army and navy, unlike all other officers of Her Majesty's service, have at present no definite *status;* they are treated not according to a definite written code, but according to the whims of the Commander-in-Chief. No gentleman would venture to treat his own servants with the disrespect and contumely which is shown towards the Medical officers of the army.

RADCLIFFE INFIRMARY, OXFORD.

At a special General Court of the Governors, held on April 29 ult., Mr. John Briscoe was unanimously elected Surgeon to the Infirmary, in room of Mr. James T. Hester, resigned. This is the second vacancy within the last few years, in the staff of this Infirmary, which has been filled by one of its ex-House-Surgeons ; Dr. Gray, the last elected Physician, having, like Mr. Briscoe, served that office in former years. The Governors of a Hospital are wise thus substantially to recognise the claims of those who have already deserved well of them in a subordinate position. The well-being of a provincial Hospital generally depends so much on the personal and Professional character of the House-Surgeon, that the Governors cannot be too careful to get a good man and to keep him as long as possible. These ends will only be gained by making the post worth his keeping—that is to say, by giving him a good salary and snug home, treating him like a gentleman, and letting him see in his office not a mere means of livelihood, but a possible stepping-stone to a higher Professional position.

THE CROONIAN LECTURES.

Dr. Lionel Beale will give the Croonian Lecture at the Royal Society, on Thursday, May 11, at 8.30, "On the ultimate nerve-fibres distributed to muscle and some other tissues, with observations upon the structure and probable mode of action of a nervous mechanism."

THE "DUBLIN MEDICAL PRESS" ON THE PURE WINE QUESTION.

We have great pleasure in quoting the following friendly piece of criticism from the *Dublin Medical Press* of April 26, because it shows that the editorial staff of that journal approve and that their large circle of Medical readers are likely to join in the movement in favour of pure wines, which our Commissioner set going through our columns :—

"We have devoted a good deal of our space to extracts from a very excellent series of papers on 'Cheap Wines' which have appeared from time to time in the *Medical Times and Gazette*, because the information which they convey is not only something new, but very startling, and of great importance to the Profession. If we are to believe the author, and as far as we are enabled to judge his statements appear perfectly reliable, very few of us have ever drunk any quantity of real, genuine, unadulterated, and undoctored wine, and, as a rule, those of us who cannot afford high prices are confiding their digestion to the tender mercies of wine-makers, and are drinking stuff in some instances not containing one drop of wine. The author recommends us to fall back on the lighter Continental wines, and gives us an ample choice.

"It is strange if wine-drinkers, with their eyes fully opened to the disclosures of the author, will continue to confine themselves to the old hot-brandied mixtures called sherry when they can get real wines more agreeable, more healthful, and more economical."

OVARIOTOMY IN AUSTRALIA.(a)

On March 10, 1864, Dr. R. T. Tracy performed ovariotomy on Mrs. G., aged 29, married, and mother of three children. Five small omental arteries were tied, and the pedicle secured by a clamp. Recovery in a month. On October 27, Mrs. C., aged 46, married, no children, underwent the operation for a tumour of nine years' growth which had been tapped six times. There were no adhesions. Recovery in twenty days. On November 9, Dr. P. H. MacGillivray operated at the Bendigo Hospital on a married woman, aged 37, with a tumour of seven years' standing, which had been tapped forty-three times. On laying open the peritoneal cavity—

"A large nodulated tumour was found, into the nearest cyst of which a trocar was inserted. A small quantity of thick fluid escaped, but it was found that its contents were too viscid to be evacuated in this manner. The same was found to be the case with other cysts which were tried. The tumour, which was about the size of a man's head, consisted of an aggregation of an immense number of cysts of all sizes, from a pea to an orange ; was adherent in various directions to the uterus, the omentum and pelvic fascia. The adhesions were torn through with the fingers, considerable force being required, especially in the pelvis. In separating the adhesions here, the iliac vessels were exposed and distinctly visible. Several small vessels which bled were tied with fine silk, the ends of the ligature being cut short. The pedicle was fixed with a pair of callipers, a double ligature of whipcord passed

(a) *Australian Medical Journal* for July and December, 1864, and February, 1865. Melbourne: Wilson and Mackinnon.

through it, and tied on each side. It was then cut through above the callipers. The edges of the wound were brought together in the usual manner.

"Forty hours after the operation, there was a sudden flow of blood from the lower part of the incision, coming out by the side of the pedicle. By putting on additional padding and tightening the bandage, it was easily checked, but returned again in about an hour to the extent of three or four ounces. It was again stopped, and the bandage firmly tightened. The small quantity of blood lost, however, told at once on her feeble strength, and she rapidly sank and died at three in the afternoon, forty-six hours after the operation.

"The post-mortem examination showed that the diseased mass had been entirely removed. There were about two pints of bloody fluid in the abdomen and pelvis, and death was evidently caused by the hæmorrhage, which was found to have proceeded from some vessels in the divided adhesions, which had not bled at the time of the operation, and consequently had not been secured."

MR. CHADWICK ON DEFENCES AGAINST EPIDEMIC VISITATIONS.

Mr. Chadwick has lately delivered an address at Salisbury on the new drainage works in that city, and on the best means of meeting epidemic visitations. The lecture was, as might be expected from the known eminence of the lecturer in hygienic science, full of apt illustrations in proof of the validity of sanitary principles and the utility of sanitary practice. We do not agree with Mr. Chadwick in his estimate of the value of quarantine, but, with that single exception, we are glad to meet with a popular address so true, so practical, and so thoroughly to the point. Mr. Chadwick draws a glowing picture of the present drainage of Salisbury, and the present immunity of that city from preventible disease. *En passant*, he indicates a new use for sewerage, which we commend to the notice of our piseiculture societies. He says, if town sewage be allowed to stagnate and become putrid, it will destroy animal life in rivers, but, on the contrary, that, if fresh, it will nourish fish.

"The putrid sewage discharged from old large man-sized sewers of deposit killed fishes. The fresh sewage which is yet improperly permitted to escape from direct application to the land feeds them and improves their quality. I am told that the largest trout—thirteen pounds weight—have been caught at the mouth of your new outfall sewer."

We should like to know what Mr. Chadwick means by *quality*. We confess to seepticism on the point of flavour in trout so fattened.

The following account of an epizootie in the wilds of Brazil is curious:—

"Mr. Bates, in his travels in the Brazils, gives an account of a choleraic visitation amongst the animals of the forests there, which is so instructive that I give it in his own words:—'The first symptoms of the epidemic appeared among the crocodiles, whose hideous carcases might then be seen floating down the stream in such prodigious numbers that both the waters and air of that fine region were tainted with their effluvium. It was observed that they were first seized with a violent fit of coughing, followed by a black vomit, which compelled them to quit their watery home, and finally find a grave amongst the thickets on the river banks. The disease next attacked the fish and other inhabitants of the water with equal violence, until it was feared the streams would be depopulated. The fearful mortality among them can be better estimated from the fact that, for more than a month, the rippling waves of that noble river, the Apure, were constantly washing down masses of putrefaction, its placid surface being by them actually hidden from view for several weeks. The next victims were the pachydermata of the swamps, and it was a pitiable sight to see the sluggish *chiguires* (capyvaras) and the grizzly wild boars dragging their paralysed hind-quarters after them; hence the name of *derrengadera*, applied to this disease. Not even monkeys in their aërial retreats escaped the contagion, and their melancholy cries resounded day and night through the woods like wailings of the eternally lost.' The most destructive of fishes of prey called the Caribo, suffers from a special and constantly-recurring visitation, these fish being subject to a yearly mortality during the heats of summer, when the water is deprived of a portion of the air it holds in solution. 'Their carcasses,' says Don Ramon, 'may then be seen floating on the water by thousands, while the beach is strewn with their bones, especially their bristling jaws, which render walking barefoot on the borders of lagoons extremely dangerous.' The observation of the effects of impure water in epidemic periods is the foundation of a popular belief at those times that wells have been poisoned, which is true, but it is by the atmosphere, by decomposition of the animal and vegetable matter contained in the water."

We subjoin one more passage, as a specimen of the practical part of Mr. Chadwick's address:—

"We have various leagues—temperance leagues and others—to promote social reforms; but in my view the most important league we could have would be a national league for the enforcement of personal cleanliness, teetotalism, and regular personal ablutions, as means of protection from epidemics, as well as for promotion of general health. It is only Physicians who are aware of the personal filth of the great mass of the population. The Medical officers who have to perform the duty of vaccination will tell you how horribly dirty they commonly find the persons of children. The Surgeons who examine recruits for the army, though they examine them singly, and frequently in open rooms, before the day is over are overpowered by the effluvium. I am told of a militia colonel who a short time ago put his men into square to address them, was overcome by the surrounding stench, and vomited. Personal cleanliness, more than hands and face washing, amongst the populace is the exception. The person who succeeded best in preserving children from epidemics, and from the supposed inevitable children's diseases, and maintaining their highest degree of health, was the late Mr. Aubin, the manager of the Central District School of London, and his distinction in practice was to maintain the highest degree of personal cleanliness by the daily complete ablution of the children with tepid water. Being remonstrated with for the luxury of cleanliness of the clothes of the children of that class in giving them clean pinafores every day, his answer was that 300 soiled pinafores made an appreciable difference in the air they breathed, and in proportion would 300 soiled or dirty skins. The death-rate in some children's establishments has been reduced by about one-third by the ventilation of the dormitories, and the drainage of the premises, and by another third on the introduction of complete regular head-to-foot daily ablution. A schoolmaster of a ragged-school resorted to the practice of the daily ablution of the scholars at the school defensively against the horrible stench of the assemblage of them. At first the practice was introduced with difficulty when cold water was used; and he observed to me that it was apt to be overlooked that children of that class are generally of a low circulation, and that cold water is really painful to them, but we passed some steam through the water and made it tepid, when the difficulty was removed, the ablution was made agreeable, and the practice was introduced, and with the removal of the filth and the foul smell there was the removal of much disease, and the reduction of epidemic attacks. The difference in appearance of school children who are washed and of those who are unwashed is very striking. Into the district schools children are brought who are horribly squalid, whose aspect is gradually changed; the skin is altered and cleared, the hue of health is imparted, exercise is added; for these are half-time industrial schools, and shortly the child is another creature, it may be added, morally as well as physically, and so it might be with the entire population. With the health and strength of cleanliness they have, when properly set up, an immunity from epidemics."

PARLIAMENTARY. — THE CASE OF MARY GREEN—THE BUDGET, CONSUMPTION OF BEER IN ENGLAND.

On Thursday, April 27,

THE CASE OF MARY GREEN.

Mr. Hennessy, who had given notice of his intention to ask the President of the Poor-law Board a question with reference to the conduct of the parochial authorities in refusing Medical aid to a woman named Mary Green, who died in childbirth, said that, according to the published account of the case, the husband of the woman sent for a Doctor named Butler, who had purchased the practice of a former Doctor. Mr. Butler came to the house and looked around, but seeing that the people were very poor, and that he was not likely to get his fee, he left the place, recommending the people to send for the

parish Doctor. The man went to the Workhouse at Islington, stated the case, and asked for the assistance of the parochial Doctor. ("Order," and "Hear, hear.") The man was told that Medical assistance would not be afforded to the woman unless he produced the marriage certificate. He then secured the services of another Medical man, but by the time that the latter had arrived, the child was dead, the woman herself dying shortly afterwards. He wished, therefore, to ask whether it was the rule of the Poor-law Board that the Medical officer should not attend poor women under similar circumstances, without the production of marriage certificates, and also, if such were the rule, whether her Majesty's Government would take any steps to have it repealed.

Mr. Villiers said that he had seen the report of the case in the newspapers, but he was not yet perfectly informed as to the details; but he had already sent for the depositions taken before the coroner, and should shortly know precisely what had occurred. As soon, however, as he saw the report, he had requested an inspector to make inquiry at the workhouse at Islington, to know more of the matter, and though he learnt that the case was substantially as described by the hon. member, yet it did not appear that any authorities at that house had been to blame. The poor man who had applied for Medical assistance for his wife was not a pauper, but an independent artisan, and he had never intended seeking relief. On the contrary, expecting his wife to be confined, he had made an arrangement with a Medical man to attend her during her confinement. In the meantime, however, the Doctor had sold his business to another Doctor, and with it transferred all the engagements he had contracted. When, therefore, this poor woman was taken ill, she sent for the Doctor who had purchased the business, and it was true, he believed, that being struck with the apparent poverty of the people, he declined to attend her, and said it was a case for the parish. Upon which the husband went to the workhouse, and applied for Medical relief; but unfortunately he only applied to a man standing at the gate, who was no officer, but a pauper and inmate of the workhouse, and he told the man that they would not give him Medical relief unless he produced his marriage certificate; on which, unfortunately, the man went away. It so happened that the relieving officer was always at the workhouse, and his directions were to provide Medical relief immediately in all cases of emergency, and in this case that relief would certainly have been provided, had he been apprised of the matter. The man, upon leaving the house, called upon another Doctor, who readily went to the poor woman's assistance; but when he arrived it was too late, and shortly afterwards the poor woman died.

It will be seen that Mr. Villiers, in his reply to Mr. Hennessy, contented himself with giving the husband's *ex parte* statement. It does not seem to have struck him that it was due to the Medical man to suppose that his account, which, we are informed, placed the whole affair in a very different light, was at least as worthy of credence as that of the husband.

It is unnecessary to give an abstract of Mr. Gladstone's Budget. All of our readers have, no doubt, heard with satisfaction that the inquisitorial Income-tax is to be reduced twopence in the pound, and that half the present duty is to be taken off tea. We give, however, the following *morceau* on the consumption of beer, from that part of Mr. Gladstone's speech in which he disposed of the claims of the malt-tax:—

"But what, let me ask, is now the consumption of beer in England? In some instances it is astonishing. I am about to relate an anecdote in connexion with this point, which I may preface by saying that I have many good reasons to look upon it as authentic, though I confess I was disposed to be a little incredulous for the moment when I first heard it. The authority from which it came, however, entirely forbids the continuance of any such feeling. The subject of my tale is a labouring man, whose ordinary avocations are on the river Thames, and require great muscular exertion. An accident occurred to this man's hand, and he went into an Hospital at the East-end of London. One of the Surgeons there dealt with his case, but the result was not quite satisfactory. The Surgeon accordingly said he should wish to open his hand, but that before he performed the operation he was anxious to be assured that his patient was in every sense of the word a temperate person. He asked some persons who knew him whether he was temperate, and they informed him that he was. He put the same question to the man himself, and he said, 'Certainly, I am temperate, and have always been so.' 'What quantity of beer do you usually drink?' asked the Surgeon. The reply was, 'Never more than eight quarts a-day.' (Loud laughter.) I inquired, that being the consumption of a temperate man, how much an intemperate man might be supposed to drink, and I was told that the quantity ran from twelve to sixteen quarts a-day. (Laughter.) But if, including the whole population of the country, hon. gentlemen will have the goodness to take the number of barrels of beer brewed annually in England, to reduce them to quarts, to make a fair deduction for the population of Scotland and Ireland, who drink but little beer, for women, who drink but a small proportion relatively to the men, and for young persons under 15, who likewise drink but a very small proportion of the quantity consumed, they will find that every adult male in England consumes not far short of 600 quarts every year; and when you take into account the pauper, the criminal, the sick, the wealthy, too, and that very large and respectable class who pass under the *sobriquet* of 'teetotallers,' all of whom come more or less into the calculation, I do not think the demand for the repeal of the malt-tax can be supported by the argument that access to a sufficient quantity of beer is extremely difficult, or that the consumption of it is gradually dying away. (Hear, hear.) More than £40,000,000 sterling is, as far as we can learn, laid out by the population of England every year in the purchase of this valuable beverage. So much, then, for the consumption of beer, which I think I may fairly say is not declining, but is steadily on the increase."

On Friday, April 28, the Courts of Justice Building Bill was read a second time in the House of Lords.

FROM ABROAD.—LOCALISATION OF THE FACULTY OF LANGUAGE.—RESULTS OF REVACCINATION IN THE PRUSSIAN ARMY—EFFECTS OF THE INJECTION OF SULPHURETTED HYDROGEN.

SOME time since (*Medical Times and Gazette*, December 24) we quoted the somewhat extraordinary report made by M. Lelut on a memoir submitted to him by the Academy of Medicine. The memoir was that of a M. Dax, having for its objects to show the constancy of the coincidence of derangements of speech and lesions of the left hemisphere of the brain. M. Lelut said the inferences of the author from his numerous cases would lead to phrenological conclusions, and that as his mind was long since made up as to the fallacy of these, he altogether declined to discuss the paper. Other members of the Academy have not felt disposed to accept this dictum as final, and have insisted that the paper should be submitted to discussion. M. Bouilland, who for the last forty years has advocated the localisation of the faculty of articulate language in the anterior lobes, naturally makes much account of the confirmation of his views furnished by M. Dax' numerous cases, but he does not feel justified in localising with M. Broca this faculty in the third convolution of the left lobe. While he does not contend for the truth of craniology, too, he maintains that phrenology, properly so called, possesses a really scientific foundation. M. Trousseau, in a remarkable discourse, which, though prolonged over two meetings, held his audience entranced by its power, lucidity, and admirable delivery, recalled attention to the precise objects of the paper on which the report had been made, and entered into a complete exposition of the disturbance of articulated language which he indicates by the term *aphasie* in preference to that of *aphémie* suggested by Broca. Aphasia may affect any or all of the four signs by means of which man represents his ideas—*i.e.*, speech, gesture, writing or drawing; and M. Trousseau cited numerous cases from his abundant clinical resources exhibiting this general or partial privation of the means of communicating ideas. In some of these instances the aphasia proved quite transitory, undergoing rapid relief on blood-letting. Essential differences exist between this condition and the impediment of articulation, consequent on paralysis. At first sight the asserted localisation of a function in one side of an organ so apparently symmetrical as the brain, seems highly improbable; but singular as it may seem it must be accepted if facts can be adduced in sufficient number in proof of its exactitude. This, however, M. Trousseau does not believe is the case. That one side of the

body may become much more frequently than the other subject to certain affections is shown by the greater preponderance of neuralgia and hysterical paralysis on the left side. Such preponderance is, however, far from being so constant in aphasia; for while of thirty-two examples collected by M. Trousseau, fourteen favoured Broca's doctrine of its dependence on a lesion of the third convolution of the left lobe, eighteen contradicted the theory. Taking the more general statement of MM. Bouilland and Dax that the anterior lobes are those in which the faculty of language is seated, M. Trousseau is able to adduce eighteen cases favouring this view, while in sixteen others either disease of the frontal lobes existed without the occurrence of aphasia, or aphasia coincided with disease of other portions of the organ. As to the nature of the lesion which gives rise to aphasia, in a vast majority of cases, this is *ramollissement*, some cases of transitory aphosia being dependent upon cerebral hæmorrhage. In almost all cases the *ramollissement* is due to obstruction by thrombosis or emboli of the middle cerebral artery or the artery of the fissure of Sylvius. The general clinical conclusion to be drawn from these facts is, that apoplexy with aphasia is to be attributed to a *ramollissement* of the brain, which, if there exist any affection of the heart or vessels, may be referred to arterial obliteration. We may also prognosticate that the *ramollissement* will proceed slowly, allowing the patient to live for a considerable time, differing thereon from the diffused *ramollissement* described by Rostan.

The Prussian Government has just published its annual report on the results of re-vaccination in the army. During 1864, re-vaccination was performed upon 69,560 soldiers; and of this number 59,396 exhibited distinct cicatrices from former vaccination, 7265 had them only indistinctly, and 2899 were devoid of them. In the 69,560, the vaccination ran a regular course in 43,596, and an irregular course in 10,508; while in 15,459 no result followed its performance. These last being tried again, 4897 were vaccinated with success and 10,392 with no result; so that in 48,493, or nearly 70 per cent., of those re-vaccinated the vaccination ran a regular course. Of these successfully re-vaccinated persons, 3 became in the course of the year the subjects of varicella, 22 of varioloid, and 1 of variola. In the entire army there occurred 27 cases of varicella, 83 of varioloid, and 10 of variola. Of these 120 patients, 64 had not been re-vaccinated, 30 had been re-vaccinated without success, and 26, as stated above, had been successfully revaccinated. The number of variolous diseases has been greater in 1864 than in former years, which may in part be due to these having prevailed epidemically in regions near which the military were stationed. In almost all the cases the disease was of most trifling importance, 1 soldier only dying from this cause.

M. Demarquay, pursuing his researches on the influence of the various gases upon the economy, has performed several experiments with that highly deleterious substance sulphuretted hydrogen. M. Claude Bernard, in a memoir published in 1857, has shown that when injected in moderate quantity in the veins of dogs it produces little effect, being eliminated from the bronchi in from three to six seconds, according to the vein selected. He has also shown that when injected into the arterial system or the splanchnic centres the gas becomes partly absorbed, and symptoms of poisoning of varied intensity result. From these experiments it results that the action of the gas upon the venous blood was not sufficiently prolonged to induce grave alterations, its elimination taking place rapidly from the pulmonary surface. Injected into the arterial system, the gas, pursuing a longer course, had more time to act intimately, and operates upon the most vital element—the red globules of the blood. All who have related cases of poisoning by its agency agree in stating that the blood becomes thick, viscous, and black, the tissues also presenting characters corresponding to this condition of the blood, being of deeper colour than normal, and more or less softened.

For the purpose of still further investigating the action of this gas, M. Demarquay instituted fourteen experiments on rabbits, injecting it generally into the cellular tissue of the abdomen or back, and sometimes into the peritoneum. The quantity injected varied from ten to fifty centilitres, but there was no sensible difference in the rapidity with which death was produced, whether the quantity injected was large or small. The dangerous character of the gas is proved by the promptitude with which death ensued, this taking place from two to five minutes after the injection. Within twenty-five seconds after the injection elimination by the lungs commences; but it is a very curious fact that no traces of the presence of the gas can be discovered by means of test-papers in the kidneys, liver, spleen, heart, or even the lungs themselves; and after death free sulphuretted hydrogen cannot be found in the blood. On opening the body promptly after death, a striking degree of turgescence of the laryngeal, tracheal, and bronchial mucous membrane is observable; and if the experiment be so managed that death do not take place so suddenly, a true phlegmasia of this membrane is developed. This M. Demarquay regards as a constant alteration produced by the elimination of sulphuretted hydrogen; and he believes that some of the benefit derived from the use of sulphurous mineral waters in the treatment of chronic inflammatory affections of the air-passages may be due to the substitutive action produced by their elimination. It is well known that these patients often suffer from more or less acute inflammatory action, congestion, or hæmorrhage after the use of such mineral waters, and before a beneficial result is produced.

THE IMPULSE TO KILL.

*** In giving insertion to the following paper from one of the most gifted members of our Profession, we must beg our readers to remember that we do not coincide in the views there expressed, and that we have uniformly in this journal upheld what we venture to believe a stronger and sounder view. We hold that man's responsibility extends to the operations of his own mind. We uphold the doctrine of "self-control" to the utmost, and desire steadily to inculcate this doctrine as an essential part of morality, side by side with a trust in the guidance and faith in the goodness of the Deity, and to repressing all systems which lead people to yield to emotion, or even to value themselves for the intensity of their *emotions*, after the doctrine of French novels. Thus we believe that the impulse to murder self or others would be greatly decreased. Further, we do not believe that *work*—*i.e.*, steady, plodding work for a settled end or purpose—is killing. Too often it is the irregular kind of work, done on the spur of urgent necessity, and alternating with idleness—an idleness fostered and rendered luxurious by narcotics and stimulants—which is exhausting. The hare can't beat the tortoise, and then dies of spite, or a man goes on working spite of warnings. In saying this we also reverently admit that it is not for man to say where responsibility ends in any particular case. We judge no one. But we uphold the general doctrine of responsibility to the utmost as a part of education, politics, and morality.—Ed.

Public attention is at present naturally directed to the extraordinary amount of mortality from exceptional causes which the journals of even the last few months record. When every Sunday we pray for deliverance from "battle and murder and from sudden death," how distant they seem to us; and yet, as "black Care sits behind the horseman," so they are ever occurring and reminding us that a man, mentally and physically, is very brittle.

It is now several years since the writer of this article went to Edinburgh, and there saw the great stonemason, Hugh Miller, with shaggy hair and compressed lips, striding to the *Witness* office, or at evening in exactly the same dress, plaid and all, discussing the old red sandstone at the Royal Society. People wondered at his excited manner; but they forgot that out of that shaggy head were coming every day newspaper leaders and copy for the printer of all kinds. The public demanded it, and the strong man did his best.

One day a friend of ours, when walking on Arthur's Seat, saw Miller suddenly stop among the whins, kneel down and pray. He was probably struggling even then with the impulse to which he a few days afterwards succumbed. For he was found a few days afterwards shot through the heart, and some

writing by his own hand—some wild words—told that in a state of morbid terror at some fancied danger he had killed himself. How well we remember the morning when we entered the room at Portobello—an uncarpeted little chamber full of books, which, indeed, seemed its only furniture, except a table and chair and a sponge-bath, at the bottom of which was a revolver and a little blood. Now, what could have induced Hugh Miller to shoot himself? The readiest answer is, "disease of the brain;" but we took out his brain, and, except a little thickening of the arachnoid, there was no disease. It was a large, firm, heavy brain, weighing about sixty ounces. So for an explanation we must go elsewhere. One who assisted us in this examination has recently died,—not exactly by his own hand, but he would have, except for the watchfulness of his attendants. He had no cerebral lesion visible to our eyes; did he die of disease of the brain? If he did, we could not see it, even when handling and slicing it. What was there to account for a good man, leading a virtuous and prosperous life, wishing to kill himself? How shall we explain the terrible delirium, or, stranger still, when the apparent madman becomes suddenly tranquil and sane, says "Good bye," and dies? Within the last few days the death of Admiral Fitzroy has been mourned over and wondered at—here is one useful, respected, and prosperous cutting his throat! We have seen poor street-walkers hanging to the knockers of doors, seen them dragged from the river. We knew a clergyman who hanged himself to escape lithotomy, and a boy did the same to escape a flogging at school. It would be natural to say that want caused some to kill themselves, and terror caused the others. But after a little consideration we see that mental excitement is the cause alone; and whether induced by hardship or overwork, it is the same poison which kills the poor girl who leaps over London-bridge as that which killed Admiral Fitzroy, Hugh Miller, Lord Castlereagh, and Chatterton—

"The sleepless soul that perished in its pride."

And why? Because it was a "sleepless soul." So was the poor prostitute's and the others we have named. People do not kill themselves because they have no dinner, but because their minds are exhausted — the ψυχη and the πνεῦμα have it all their own way, and, as it were, wishing to be free, tempt their poor prison to destruction. All this may seem paradoxical, but it is no less true. Man is a killing animal, and is only separated from other beasts of prey because he does not eat what he kills in anger. We have numberless instances of men killing because they could not help it. Take the case of the sailor who had bought a new knife, and when walking into Portsmouth saw a portly gentleman with a tight-fitting coat; the back was too tempting, the knife went into it, and all the prisoner's defence was, "*he couldn't help it.*" Captain Gronow tells a story in his delightful "Reminiscences" of a party at Paris after Waterloo; one of the party rose, exclaiming "J'ai envie de *tuer* quelqu'un." He went out, met a man, insulted him, and killed him.

Now, that brings one's mind naturally to the question what you are to do should you be inclined to kill yourself. The Frenchman answered that with "tuer quelqu'un"—an answer which, as Byron says, is "convenient, but immoral." This case of Miss Kent's is especially painful to Medical men; there are so many reasons for believing her morally innocent even if she did do what she says she did. Have not we all known young girls do the queerest things when, as the phase is, they are "not well?" Have we not known grown women say wonderful things? and is there any Doctor who has not heard confessions of obviously imaginary crimes? but still, the irritable condition of a young lady may suggest to Mephistopheles the whisper, "J'ai envie de tuer quelqu'un," and she may do it; and many a one has. Some years ago a nursemaid who was quietly sewing, but had a great deal to attend to, put down her work, cut the child's head off, and carried it down to her master and mistress, who were at dinner. It was found that she was suffering from uterine irritation. When James, the murderer of Mr. and Mrs. Bonner, was asked why he had hurt such kind employers, he said, "I fell asleep on the bench in the servants' hall, and I wakened up wishing to kill somebody." Now, what is the physical difference between suicide and murder *per se?* Who are the people that kill themselves? They are the very clever or the very stupid. The class between these limits seldom do. The "perfervidum ingenium" of the genius makes his mind so impatient of restraint that he yearns for freedom from, perhaps, a starved and aching body. The passionate and jealous man, who sees circumstances keeping him from worldly success, kills himself as a scorpion does when surrounded by a flame from spirits of wine on fire.

Now, how is this terrible "envie de tuer quelqu'un" to be cured? What causes it? The last question is the easiest to answer. For many centuries neither murder nor suicide have been otherwise than execrated and despised; both deeds are so cowardly. The smallest "gamin" in London would readily face the murderer of Lincoln; because he shot a man behind his back, and why? He had a *craze* to kill *some one*, so he killed the most conspicuous man. There was a clergyman on the Continent who paid butchers to allow him to kill their beasts; the desires are analogous. Macaulay sings:

"Woe to these cruel eyes
Who love to look on torture,
But dare not look on war."

Napoleon said that all conspiracies were made up of knaves and fools: the knave finds a fool with the tendency which is most convenient. The fool may have many good qualities, but they are jumbled in his unsteady, paradoxical head.

"His honour rooted in dishonour grew,
And faith, unfaithful, kept him falsely true."

It may seem harsh to say it, but who can doubt that the tendency to kill is common to both the philosopher and the fool? though the one generally acts by an impulse from within, when the mind is rendered susceptible to the poison "tuer quelqu'un," and so he kills himself. The fool, who has no real mental inside, whether it is by bodily irritation, or by some temptation, or the influence of any person, —all of which are external irritations—generally slays somebody else, and then is aghast at what he has done; he runs away, but the chances are that ere many hours are over he will be found somewhere near where he committed the crime, wondering if it be really true.

The more one ponders over the subjects murder and suicide, the more marvellous they appear; and the more murderers' and suicides' brains we examine, the more we feel how idle it is to seek for a reason in morbid appearances of the brain.

We cannot conclude this article without a comment upon that terrible condition most Professional men now are in, namely, *overwork*. It is very pleasant to think of a youth of labour ending with an age of ease. But how few reach the latter? over how many hard workers are the spring flowers now blooming? how many, too, are in lunatic Asylums? Not long ago we saw a middle-aged man lying on the grass at an Asylum, surrounded by books (he liked to have his old friends by him). I could scarcely recognise in his expressionless face the author of one of the most erudite articles in "Todd's Cyclopædia of Physiology;" he had *read* himself into a madhouse.

It may be argued that one who dies as Admiral Fitzroy has done is but a martyr to duty. Undoubtedly he is. So, too, would be a general dying in battle; but the general is expected to keep out of fire, as, though death to him might bring glory to his army, it would bring disaster; and so, as Nelson rashly exposed himself to French bullets, Fitzroy, who for several years has been busy saving the lives of his brethren, and warring, not with man, but with the elements, has allowed his enthusiasm in a good cause, and his zeal for science, to overmaster him, and render his brain susceptible to the poison of killing, to which it seems, in certain states of health, we are all so liable.

REVIEWS.

Essays and Reports on Operative and Conservative Surgery. By R. C. Butcher, M.R.I.A., Surgeon to Mercer's Hospital, Dublin. Illustrated by sixty-two lithographic plates, coloured and plain, and several engravings on wood. 8vo, pp. 933. Dublin: Fannin and Co. London: Hardwicke.

On several occasions we have had to take favourable notice of the essays on Operative Surgery which have been published by Mr. Butcher, and which have deservedly made him known as one of the most prominent Surgeons in the sister kingdom. The work now lying before us consists in great part of the essays in question which have been brought together so as, with some new matter, to form a very imposing-looking book. In the Preface the author takes especial care to mention the fact that the work is not intended by any means to be a "System of Surgery," but "it professes simply to record some of the actual experience of one who, commencing as an Hospital pupil at an early age, has been for the last quarter of a century assiduously employed in the field of practical Surgery, and who has endeavoured to exhibit the work of a Surgeon as it presents itself at the bedside and in the operating theatre."

The reader will thus be prepared to find the work of somewhat a discursive character; but still it is eminently practical, and a glance at its contents will at once show what very important subjects connected with the domain of practical Surgery have been considered by Mr. Butcher. Thus, he commences the work with the question of excision of the knee-joint—a matter upon which Surgeons are not yet quite in accord. Nearly a fifth part of the entire volume is dedicated to this recently-revived operation. To the subjects of excision of the elbow, wrist, nipple, and lower jaw, as well as other similar operations, a large portion of the work is devoted; also, then, the important subject of wounded arteries is considered. Amputation of the foot at the ankle by Syme's and Pirogoff's methods respectively is discussed, and there is a very good chapter on "Amputation at the Knee-joint." The treatment of fractures of the thigh and leg, and injuries to joints, have received considerable attention, and the operation for hare-lip is treated of at great length, numerous coloured drawings assisting the reader very materially in this part of the work especially. Lithotomy in the infant and child has a chapter devoted to it, and the treatment of severe deformities from cicatrices is illustrated by some very interesting cases; and after having touched the various subjects of hydrocele, tetanus, and aneurism, Mr. Butcher concludes his laborious work by detailing some interesting cases of enormous tumour which he has removed by operation.

We may thus see that nearly every important department of practical and conservative Surgery has been considered, and very fully, too, in the work before us, which reflects the highest credit upon the author, who seems to have spared no pains to advance the art of which he is such an enthusiastic follower. Surgery has possessed great names in the Irish capital during the present century, and that of Butcher may be well classed amongst them. He is evidently a man who keeps pace with the times, and is an ardent follower of what is very properly termed conservative Surgery, And there is one feature of a pleasing character to which we gladly point, and this is the ready willingness of Mr. Butcher not only to be fair but to be generous towards others in appreciation of their labours—a remarkable contrast to this spirit has, we regret to say, been exhibited in some recent works, the authors of which might with propriety follow Mr. Butcher in this respect.

It will be impossible for every one, of course, to agree with the author in all he says, or to endorse his opinions on some of the more debateable subjects here discussed; for instance, they who are opposed to the treatment of diseased knee-joints by excision will consider Mr. Butcher's advocacy of this operation is much too warm, and they, even, who are not adverse to it will doubt the correctness of his views as to the comparative danger of this operation and of amputation of the thigh. Nevertheless, it is very evident that Mr. Butcher has devoted a great deal of attention to this highly important subject, and he is quite justified from his own success—deservedly great—in speaking so highly as he does of the proceeding in question. Considering all the opposition which has been raised against it, it is wonderful that excision of the knee-joint has stood its ground; but it may with truth be affirmed that the powerful advocacy of Mr. Butcher has in a large degree contributed to the almost general recognition of the operation as a legitimate proceeding in Surgery.

Some discussion is raised on the very important question of the relative merits of amputation of the foot by Syme's and Pirogoff's methods. Mr. Butcher enters very fairly into the matter, but leaves the impression very evident on the mind that he is favourable on the whole to the procedure of the Russian Surgeon; and with all due deference to Professor Syme, who will have always the great merit of originating amputation at the ankle, there cannot be a doubt that the patient is better off after Pirogoff's method. Let any Surgeon accustomed to look at stumps examine a case of each when twelve months have elapsed after a successful operation, and he cannot hesitate for a moment as to which he should perform. He will find that the stump after Pirogoff's proceeding will come into contact with the ground without the intervention of any artificial substitute, and that the limb is altogether much stronger and more adapted for movement than when the os calcis has been taken away. Of course there are a few cases when even the back part of the os calcis cannot be preserved in consequence of disease, and in such a case the operation of Syme must be substituted, but in nearly every instance falling under our own notice the disease in the os calcis has been so limited that the amount necessary for forming the prominence of the stump could readily be preserved.

The author speaks highly in favour of another conservative proceeding in Surgery, which we are glad to see is steadily gaining ground. We allude to amputation of the thigh at the knee-joint; it is an admirable operation, and should be selected in all cases when it is possible, as much safer and better than amputation through the lower third of the thigh. A very good case is related by Mr. Butcher where he performed this operation, and the illustration accompanying it shows well the character of the long and well-formed stump.

A very interesting and remarkable series of cases of complicated hare-lip are related, and we find that Mr. Butcher has achieved considerable success in this department of what may be called decorative Surgery. Certainly, some of his cases were as bad as they could well be, and the ingenuity and care required in bringing about the restoration of the deformities must have been great. He is in favour of operating at an early age, and we are glad to see does not use the simple suture, but trusts to the needles and twisted suture, in complicated cases at least.

We are not aware that there are any other controversial points in this work to which we need refer. There are many practical matters of the very highest interest to the Surgeon discussed in a very able manner; and, indeed, the enthusiasm of the writer renders his descriptions of his operations so clear that the reader is, as it were, translated to the bedside of the patients themselves. Mr. Butcher, in collecting these materials together, has executed a most laborious task. He may rest assured that his efforts to favour the spread of Conservative Surgery have already borne much fruit; and this will now be increased in a tenfold degree.

The Personal Responsibility of the Insane. By James F. Duncan, M.D., T.C.D., M.R.I.A., Physician to the Adelaide Hospital and to Simpson's Hospital, etc. Dublin: Fannin and Co. 1865. Pp. 98.

The author starts with the axiom that the difference between insanity and crime is, that the former is a morbid condition, and is associated with some disorder of the *material organisation* connected directly or indirectly with the mind, while crime is a perverted action of the mind itself, independently of bodily disease. And when the question arises as to whether any mental condition is indicative of insanity, Dr. Duncan properly holds that the standard of comparison is "not some arbitrary model of supposed human excellence, but the natural condition of the individual himself, as ascertained by personal observation of his previous habits and acquirements." Any alteration is more important if it comes on suddenly. It is not necessary that we should find bodily disease in such cases in the brain itself, but it may be situated elsewhere; and the teaching which insists upon its presence is based upon general experience, in the first place; next, upon the known efficacy of bodily Medical treatment; thirdly, upon the effects of certain material agents, such as opium, Indian hemp, in disturbing the operations of the mind; fourthly, upon the effects

of ordinary disease in altering the feelings, affections, etc., of an individual; and, lastly, upon the phenomena of sleep and somnambulism. Another axiom is, that "to create responsibility there must be both power of action and liberty. . . . No man can be held accountable for not doing what he is unable to perform, or for doing what he is unable to resist doing."

One of the principal causes of disagreements between counsel and judges on the one hand and Medical men on the other in our courts of law is, that the latter hold commonly the doctrine of *partial* insanity, whilst the former deny it, holding that a man must either be sane or insane; if sane responsible, if insane irresponsible; and that this connexion is to be practically relied upon, even though the insanity be such as leaves the sufferer quite free to judge between right and wrong, and with full liberty and power to refuse to do the evil and choose to do the good. And thus, while Dr. Duncan maintains and illustrates the doctrine of partial insanity, he attaches to it as a necessary corollary the doctrine of partial responsibility. "The plea of irresponsibility can be pushed no further than the corresponding insanity extends, either directly *per se* or indirectly by the morbid influence it may exercise over the other faculties, so as to interfere with their free action." He then goes on to show that this sort of partial responsibility certainly exists among the undoubtedly insane, and lays down some rules by which its amount and degree may be determined. This leads him to discuss the old dictum of Lord Chief-Justice Mansfield, that a person to be irresponsible must be incapable of judging between right and wrong, and its modification by Chief-Justice Tyndall, limiting its application to the specific act in question. We believe that Dr. Duncan touches the very core of our own Medico-legal controversy when he writes thus:—"The question of the personal responsibility of the insane for criminal actions may be viewed in two distinct aspects—viz., as they may be made the subject of judicial inquiry in our courts of law, and as they ought to be regarded by the individual himself *in foro conscientiæ*. This latter aspect of the question appears to me to be almost completely ignored in treatises professing to treat of the subject. The effect of it is, to some extent at least, to mislead the victims of partial insanity into the belief that if human tribunals hold them excused for their criminal actions, they must be so in reality. Against this idea it is necessary to enter a distinct caveat." The distinction which he draws between eccentricity and insanity is thus summed up:—"So long as the conduct is innocent in itself, and the result of mere whim or caprice, however absurd it may be considered, it cannot be looked upon as insane. But let this eccentric conduct be the result of some fixed idea that it is in any way necessary for him to act as he does, either for his own benefit or that of others, and it alters its complexion, and it must then be looked upon as partaking of the character of insanity." Having discussed his subject in its relation to insanity in general, Dr. Duncan proceeds to consider responsibility in its relation to certain forms of insanity. First, as it relates to those forms characterised by *delusion*. Now, in order to a delusion being accepted as evidence of an unsound mind, he lays down the three following necessary features—namely, a certain degree of permanence, its remaining proof against conviction and argument, and its influencing the conduct; and as regards the doctrine that for a delusion to confer irresponsibility for criminal acts only when there is an obvious connexion between the two, he says that to limit irresponsibility strictly to such cases, would be unphilosophical and unjust. "There may be a real, though a latent bond, sufficient to account for the occurrence, if it could only be traced; and while the mere fact of the possibility of such a connexion existing ought not to be held sufficient wholly to exculpate the party charged, it ought to make caution doubly necessary on the part of those who investigate the case, and where the truth is doubtful to mitigate the punishment."

As respects "moral insanity," Dr. Duncan says—"The proper responsibility of these cases is a very difficult question. Legal authorities will not admit, in the absence of disease of the intellectual faculties, that there is any excuse for crime. They think that were they to do so, it would be opening at once a wide door for every excess, inasmuch as it would be impossible to refute the hypothesis whenever put forward. But this is going too far. The evidence of real co-existing disease, and the history of the individual's habits and condition previous to the commission of the crime, as well as the nature of the act itself, and its attending circumstances, would guard against abuse. The absence of all proof of a co-existing morbid state ought to go a great way to fasten accountability upon the person charged." He meets the difficulties of legal writers again, as to admitting "impulsive" insanity, thus:—"When it is recollected that the frenzy of which this is but a symptom, though of short duration anteriorly to the commission of the act, is usually well marked, that it seldom passes rapidly away, and that the attending circumstances are entirely different from ordinary murder, there seems really no reason for disputing its occurrence." . . . "The plea of an unaccountable and sudden impulse prompting to the commission of an act of violence ought not to be admitted, when there has been no distinct evidence of insanity immediately preceding or following the act; more especially when the weapon employed has been deliberately provided for the purpose." He then proceeds to discuss insanity as characterised by various morbid propensities, the plea of hereditariness, and the verdict of "insanity" as given in cases of suicide by coroners' juries, and concludes with the following summary:—"1. Persons labouring under ordinary mania, where there are incoherence, excitement, and the general symptoms of complete mental estrangement, are thereby rendered entirely irresponsible for whatever criminal actions they may commit in that state. 2. Persons labouring under the various forms of partial insanity are irresponsible for the criminal actions they may commit which are plainly traceable to that condition, even though such actions may not admit of justification on the hypothesis of the cause which provoked them being real instead of imaginary. 3. Where criminal acts are committed by persons partially insane, although no connexion may be traceable between those actions and their insanity, their condition must be looked upon as a ground of mitigation of punishment, and treated accordingly. 4. Where persons convicted of crimes are exculpated, either wholly or partially, on the ground of insanity, their condition requires them to be transmitted to a proper Hospital or Asylum for their immediate Medical treatment. 5. That, subject to proper precautions, as soon as such patients are restored to health, reason and humanity require that they should be set at liberty unless there should appear to be a special risk of a relapse. 6. That where unoffending persons have suffered personal injury from the violence of insane persons, reasonable compensation should be made to them out of the lunatic's estate. 7. That coroners' juries should not be expected or required to append to their finding in cases of suicide the usual formula 'when labouring under temporary insanity,' unless some urgent necessity arises to require the person's state of mind to be carefully investigated, and the fact of such condition existing has been clearly established. 8. That, unless in clear cases of positive mental derangement, some modified form of the obsolete mode of unchristian sepulture should be maintained as a means of checking the too prevalent tendency to suicide."

The Surgery of the Rectum: being the Lettsomian Lectures on Surgery delivered before the Medical Society of London, 1865. By Henry Smith, F.R.C.S., Assistant-Surgeon to King's College Hospital. London: John Churchill and Sons. 1865. Pp. 127.

This is a very small book, but very complete in its way. It contains just three lectures, delivered before the Medical Society of London, and as the whole Surgery of the rectum could not be discussed in so small a compass, the author confined himself to certain points on which he had the fruits of his own experience to lay before his auditors. The first lecture treats of fistula in ano, and more especially of certain complications which are occasionally met with. Mr. Smith ignores the theory that there is always an internal opening in this affection, and gives gratifying proof of it in the fact that he has treated cases, and caused them to get well by good diet and stimulating injections, without the use of the knife. Loss of power in the sphincter after division next engages his attention. In small degree this is very common, and the question might be put, not how many patients suffer from it, but after what time do they regain their power? When permanent, Mr. Smith believes it to arise from too free division of the internal sphincter and fibres of the rectum itself. The combination of stricture with fistula is next dwelt upon, and in the second lecture the history of stricture, cancer, and polypus. Stricture is in many cases referred by our author to pre-existing ulceration of a syphilitic character; and in a few cases to over solicitude on the part of inexperienced Surgeons to remove piles too completely; so that healthy skin and mucous membrane are abstracted, and tight contraction the result. The last lecture treats of piles and

prolapsus, and gives the author opportunity for developing the advantages of a clamp with a screw which he has devised for seizing and holding the fold of mucous membrane to be removed whilst it is cut off, and the raw surface seared with the cautery. The cases which Mr. Smith gives bear out his claim for this process as being a safe and speedy cure; we might almost say an agreeable one—at any rate, by comparison—for the transitory smart and three days in bed are not to be compared to the constant drag upon health and upon mental capacity caused by habitual bleeding and prolapse of the rectum.

Handbuch der Allgemeinen und Speciellen Chirurgie.
Handbook of General and Special Surgery. First Part of First Volume. Erlangen. 1865. 8vo. Pp. 352.

This handbook bids fair to be the best exponent of the most advanced school of German Surgery. Edited by Pitha and Billroth—who are assisted by such men as Esmarch, Nussbaum, Simon, Wagner, Weber, and others almost equally well known here—illustrated by excellent woodcuts, and accompanied by an atlas of 136 copper-plates and 52 lithographic plates, the work must be looked forward to with interest. There will be about eight parts of six shillings each, and the atlas will cost about eight shillings. Each part will be about 350 pages, if the first is to be taken as a specimen of its successors.

This part, after a short introduction on the history of Surgery by Dr. Haeser, is entirely taken up by a series of admirable articles by Dr. Weber, of Bonn, on Hyperæmia, Inflammation, Anæmia, Gangrene, Hypertrophy, and Degenerations. We shall only give one extract—and that one on Acupressure, which will delight the heart of Mr. Syme, and no doubt call forth a long series of experiments from Dr. Simpson. Dr. Weber says:—"I shall only remark as to acupressure, that experiments on the lower animals have shown me that when it is really efficient it cuts through the vessel just as the ligature does, and that this division takes place much more rapidly than when the ligature is employed. I have assured myself by unprejudiced experiments, that suppuration through the arterial coats takes place much more quickly by this method. Sometimes forty-eight hours is sufficient. It is evident that no extra security is given by this. On the other hand, if we take away the needles too soon, we cannot be certain that the arteries are firmly closed. I have several times after taking away the needles before the second day seen such violent hæmorrhage that I was forced to ligature."

A Manual of the Practice of Surgery. By William Fairlie Clarke, M.A., F.R.C.S., Surgeon to the St. George's and St. James's Dispensary and Assistant-Surgeon to the West London Hospital. Henry Renshaw, 356, Strand. 16mo. Pp. 352.

This work is intended for those who desire brevity; whether because they are beginning study, and wish first of all to see the general outlines of Surgery before they plunge into the details, or whether they are finishing and in want of a work that shall prepare them for examination. To write a short book that shall not be obscure, the writer must possess the gift of method, and must further have the power of seizing the main facts—the kernel, as it were—of every subject, so as to present it stripped of all the husks. Mr. Fairlie Clarke seems to have both qualities, and has presented the student with a work which will go into his waistcoat-pocket, and which gives in a clear intelligible way the very pith or marrow of Surgical practice. The author wastes no space on theories, or "the most advanced views," he quotes no authorities, and indulges in no controversy, but gives a good practical account of the chief Surgical subjects, and contrives to say a great deal in a very limited space.

Observations on Medical Education: being the Introductory Lecture in the Faculty of Medicine of University College, London, for the Session 1864-5. With additions by Richard Quain, F.R.S., Holme Professor of Surgery. London: Walton and Maberly. 1865. Pp. 61.

The central topic in this lecture and in the additional notes is the practical aim which all teaching should have, and to the encouragement of which the regulations of the licensing boards of the Medical Council ought to be directed. What Mr. Quain seems to advocate is a thoroughly good preliminary education, and then a good practical system of instruction in the subjects which are to be to be the daily work of the Medical man. He thinks that the accessory subjects should be taught so as not to constitute a burden to the mind, as they are apt to do now, when distinguished chemists, physiologists, comparative anatomists, etc., are engaged in lecturing to Medical students. He seems to hint at these gentlemen reducing their teaching within more moderate limits, and such as shall embrace those matters which bear most distinctly upon the future occupation of their hearers. We think he is right here. We have expressed similar views ourselves. We think that it is outrageous to demand from a Medical student a knowledge of chemistry, for example, which with the other subjects he has to study, can be nothing else than crammed book-learning, and so certain to be forgotten as soon as the exigencies of the examination-day are over; but still, he should know all that is essential to qualify him to search for a poison in the dead body, and to enable him to understand the nature of the medicines he employs and the operation they and disease both exert upon the human body.

The Handbook of Dining; or, Corpulency and Leanness Scientifically Considered; comprising the art of dining on correct principles consistent with easy digestion, the avoidance of corpulency, and the cure of leanness, together with special remarks on those subjects. By Brillat Savarin, author of the "Physiologie du Goût." Translated by L. F. Simpson. London: Longman. Pp. 170.

Brillat Savarin's "Physiologie du Goût" is one of the most charming books that ever were written. Lively, satirical, treating with an inimitable air of seriousness of all the little comforts of life, its exquisite wit would have preserved it from decay, were not its physiological principles so well founded in experience, that in every page the practical Physician may pick up some hint which will be useful to the dyspeptic or valetudinarian. Mr. Simpson has given us an abridgment of the work, freely translated, but not destitute of the vivacity of the original. The original work, as is well known, contains the best directions possible for the cure of both obesity and leanness, and it is to these that the translator has devoted much space. We advise our readers to have Mr. Simpson's abridgment for the weaker vessels in their families, and the original for themselves. It is inimitable as a model of polished sarcasm. The author's moral reasons for adding to the embonpoint of meagre women are admirable. The spare forms, he says, of certain of the fair sex should be clothed with real flesh and blood, instead of those curious contrivances of silk or cotton (he refers to the aids to beauty which were in vogue in the precrinoline age) that are displayed in the *magasins des nouveautés*, to the great scandal of the virtuous, who turn from them "avec autant et plus de soin que si la réalité se présentait a leur yeux."

GENERAL CORRESPONDENCE.

CASE OF SUICIDE AT DAWLISH.—SIMPSON'S AND BATTLE'S VERMIN KILLERS.

*** Dr. Herapath has written us the following letter in reference to a case in which death was produced by some powders sold as Simpson's and Battle's vermin killers. The deceased person was the wife of a tradesman at Devonport, who in a fit of insanity poisoned herself at an hotel at Dawlish. Two points are worth notice in the case. First, that the condition of the body (extreme rigidity, bending back of the head, clenched hands, etc.) was strongly suggestive of poisoning by strychnia, although arsenic and not strychnia was found in the stomach. The second is as to the propriety of a Medical Practitioner obtaining the aid of an expert to make an analysis without the coroner's order. In this case the coroner objected to pay Dr. Herapath's fee, as he had not requested Dr. Baker, who had made the post-mortem examination, to obtain chemical assistance. Dr. Herapath met the difficulty by foregoing his fee, but the result of his analysis showed clearly that a chemical examination was necessary.

[To the Editor of the Medical Times and Gazette.]

Sir,—I send you the published reports of an inquest and its adjournment on the case of Mrs. Williams, who has com-

mitted suicide in a very extraordinary manner at Dawlish recently, as you will see on perusal of the enclosed. She had three or four parcels of rat poison in her reticule, or about the room, some of which were empty, others in reserve. Two papers of Simpson's vermin killer had been disposed of, and one parcel of Battle's (a powder of a blue colour, containing strychnia) had apparently been used, "some blue stains being found in the mouth and at the angles of the jaw, whilst the pocket handkerchief was marked with blue stains also." The rigidity and contortions of the dead body led Dr. Baker to infer strychnia as the cause of death. He sent the viscera to me, and I proved arsenic in abundance in the mucus present in the stomach, which was very scanty. The fluid which had escaped into the jar from an opening made in the walls of the stomach by the scalpel also contained abundance of the metal arsenic, but strychnia was not in either of these materials. I also found traces of arsenic in the liver. If strychnia were taken, it never got into the stomach at all. It is probable, however, that the two first packets did not kill her as quickly as she expected, and she took the third packet, but the contents never went further than the mouth, some being ejected in consequence of the bitter taste, and an almond was taken to get rid of this, but enough remained to kill by absorption from the mucous membrane of the tongue.

The coroner would not have my evidence, as he had given no order for a chemical analysis, but I made a voluntary statement, of which you now have the substance. I have sent to Exeter for Simpson's papers, and after having analysed them I will again communicate with you. Battle's of course contains strychnia; the other I presume to consist of arsenious acid. She was a great believer in alcohol, and that accounts for her nervousness and depression of spirits.

April 28. I am, &c. W. Bird Herapath.

"LINIMENTUM BELLADONNÆ, Ph. Br."

Letter from Dr. S. Martyn.

[To the Editor of the Medical Times and Gazette.]

Sir,—It may be worth while to make public the following note of a circumstance which has just occurred in a case under my care:—

A young married lady, who for many years has had a small tumour of some sort floating freely in the left abdomen, and attached to the uterus, suffers occasionally from inflammatory conditions set up in the surrounding parts, especially on over-exertion at the menstrual periods. She is at present recovering from a somewhat severe attack of metroperitonitis arising in this way, and on the 22nd inst. was well as to febrile signs, tongue, pulse, and abdominal tenderness (except on very deep pressure). There was, however, one exception: she had for three days suffered from a pain diffused over the sacral region, and which, on the day named, had become very intense. For this I prescribed moist heat, and, if that failed, a liniment consisting of ♏ xxx. of "Lin. Bellad. Ph. Br.," with a very small addition of opiated soap liniment, to enable the whole to be rubbed in.

The next morning I was called hastily to the case, the course of events having been as follows:—In the evening the liniment had been applied with the effect of entire and almost instantaneous relief from pain. Shortly afterwards a sense of alarm came on (the lady has no hysterical tendency, and was quite ignorant of the nature of the application), then repeated tremors or shivering, general throbbing, swimming in the head, dimness of sight, and intense thirst. There was entire absence of sleep, and towards morning a feeling of tightness across the epigastrium, with a sense of impending suffocation. This last was, however, a little relieved by mustard plasters applied by the nurse.

At 7½ a.m. I found her much flushed, and with headache and mental confusion. Eyes very open and yet somewhat intolerant of light, pupils dilated, pulse 140, weak and variable, surface dry, tongue thickly coated, throat parched, breathing gasping and irregular. Recognising the effect of belladonna, I raised the head well, applied cold to the scalp, and administered a strong ethereal stimulant, followed by effervescing draughts and castor oil. The same evening there was very little improvement. Next day (yesterday) she felt better, and in the evening her pulse was quiet and tongue cleaning rapidly. She had slept almost continuously, taking beef-tea and cream and water at intervals. There has not been the slightest return of sacral pain. I need add no comment except that the chemist is entirely trustworthy. I am, &c.

Clifton, April 25. S. Martyn, M.D.

THE MEDICAL PROVIDENT SOCIETY.

Letter from Dr. Alexander Henry.

[To the Editor of the Medical Times and Gazette.]

Sir,—I have the pleasure of sending you a copy of the rules and tables of the Medical Provident Society in connection with the British Medical Association, and shall feel much obliged by your allowing me to inform the Profession, through the columns of your journal, that I am ready to receive applications for admission from all duly registered Medical Practitioners residing in the United Kingdom, and to furnish them with the necessary forms of examination paper and certificate.

In accordance with the decision of the Board of Directors, the Society has been registered under the Friendly Societies' Act. The tables have been approved by Mr. Finlaison, Actuary to the National Debt.

The difficulties under which Medical men often labour when prevented by illness or accident from attending to their Professional duties must be well known to you. You will therefore readily perceive that an institution like the Medical Provident Society, the financial calculations of which have been approved by the highest actuarial authority, must, if well supported and judiciously managed, be at once safe in its operations and highly beneficial to the contributors.

Allow me also to remind the more wealthy members of the Profession that they can give material aid to the Society by donations to its auxiliary fund. The sum of £700 has already been subscribed, and the larger this fund becomes the more stable will be the Society and less likely to suffer from extraordinary pressure on its sick fund. By the rules of the Society, every registered Medical Practitioner, being a donor of ten guineas or more, is eligible as an honorary member for life.

I am, &c.

Alexander Henry, M.D., Secretary.

15, George-street, Portman-square, W., April 25.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

Tuesday, May 2.

Dr. Peacock, President.

SPECIMENS FROM CASES OF THE EPIDEMIC OF CEREBRO-SPINAL MENINGITIS RECENTLY PREVAILING IN THE NEIGHBOURHOOD OF DANTZIG.

As this subject is one of unusual importance, and as it excited very great interest, we anticipate our report of the Society's proceedings. A report of the previous meeting is in type, and will appear next week with a report of the other specimens exhibited at the present meeting.

Dr. Sanderson, on behalf of Mr. Simon, who was unavoidably absent, exhibited the pathological results of two cases of the so-called epidemic cerebro-spinal meningitis which has recently prevailed in the neighbourhood of Dantzig.

One of the specimens was the spinal cord of a child, aged 3½ years, who died on the eighteenth day of the disease. The illness commenced in the usual way on March 26th, with flushing of the face, intense pain in the head and back of the neck, obstinate and repeated vomiting, which symptoms were soon followed by unconsciousness. Since the beginning of April there had been strabismus.

When first seen by Dr. Sanderson on April 11th, the patient was lying on her side, with the head retracted and the lower limbs drawn up. The general surface was pale, and the body much emaciated. The pulse and breathing were rapid, and the latter embarrassed. The pupils were insensible to light. The eyes, which were usually open and lustreless, squinted inwards. The patient gave no sign of consciousness when addressed by name; but when she was lifted in bed pitiful cries of pain were uttered, the countenance became distorted, and it was observed that the head remained fixed in its original position of retraction. On the 12th the breathing was more rapid and difficult, and the physical signs of hypostatic congestion were ascertained to exist. On the following morning the child died.

The principal lesions discovered after death were the following:—The pons Varolii was covered with a thick layer of concrete exudation, consisting entirely of pus-corpuscles,

which extended forwards to the chiasma, backwards to the anterior surface of the medulla, and laterally to the inferior surface of the cerebellum and into the Sylvian fissures. The ventricles were distended with purulent fluid containing flakes of concrete pus. Under the arachnoid covering the convolutions on the convexities of both hemispheres, some of the intergyral spaces were occupied with similar concrete exudation. The posterior aspect of the spinal cord was covered with a layer of similar character, which extended from the cervical swelling to the cauda equina. The anterior surface of the cord was free from exudation. With the exception of collapse and excessive hyperæmia of the bases of both lungs, the other organs were healthy.

The particulars of the second case were not communicated in detail. It was stated that the patient (an adult male, aged 42) was admitted into Hospital on the second day of the disease, and died on the tenth day. After the usual initial symptoms, rigor, vomiting, intense headache, and pain in the back of the neck, the patient became delirious, and subsequently passed into a state of stupor, from which he could be roused without difficulty. Dyspnœa came on about the seventh day, and gradually increased till death. In this case, as in the other, there was little pain, excepting when the patient was raised in bed. The head was constantly retracted, but there was no tetanic contraction of the muscles of the nape. The characteristic eruption of herpes labialis appeared on the seventh day.

The post-mortem appearances, as regards the brain and spinal cord, resembled those already related, with the exception that here there was very little exudation on the base of the brain, but a considerable deposit on the pia mater covering the upper surface of the cerebellum, from which point it extended forwards to the velum interpositum.

In answer to many questions from the President, Dr. C. J. B. Williams, and others, Dr. Sanderson stated that the facts observed at Dantzig afforded no ground for believing that the disease was communicable from person to person, or that it had anything in common with typhus fever, excepting in so far as each disease was no doubt dependent on a specific poison; that no eruptions resembling those of typhus or typhoid fever were observed; that impairment of the respiratory function was usually the immediate cause of death; and that, in general, the blood was found uncoagulated after death. In two cases, the spleen was excessively hyperæmic and soft as in typhus.

Dr. Murchison's attention had been devoted to the subject of epidemic cerebro-spinal meningitis long before the epidemic at Dantzig had been heard of. He thought that the appearances described by Dr. Sanderson left no doubt as to the existence of inflammation of the membranes of the brain and cord in the specimens which he had exhibited. But the important points to determine were whether this inflammation was primary, or whether it was merely a local complication of some general abnormal condition, and in the latter case what was the real nature of the primary disease. Most pathologists admitted that there was such a disease as primary inflammation of the brain and cord, independent of tubercle; but all Practitioners knew full well that the disease was extremely rare, and that when the lesions in question were found after death they were most commonly due to some blood disease. Dr. Murchison had found these lesions in cases of typhus fever (see *Lancet*, April 22), scarlet fever, and pyæmia, and a gentleman was present who had found similar appearances in a large number of cases of yellow fever. When, therefore, we heard of so many as 1200 persons dying of this affection in Dantzig and its neighbourhood within a few months, there could be no doubt that the lesions of the nervous centres were secondary to some general disease of the system. The question then was, what was this general disease? Was it, as had been stated, a disease which of necessity gave rise to inflammation of the cerebro-spinal membranes, and which had scarcely before been known in Britain? Dr. Murchison believed not.

The epidemic at Dantzig had been stated on good authority to be the same as the "epidemic cerebro-spinal meningitis" which had been described by many French and American writers, and which had been so common in America during the present war. Assuming this to be the case, we had ample materials for forming an opinion. Dr. Murchison had studied the accounts of these epidemics with great care, and had come to the conclusion that it was more than probable that most of them—he did not say all—were typhus fever complicated with meningitis, such as he had witnessed at the London Fever Hospital. This opinion, moreover, was the same as that held by some of the highest authorities on fever in America and France, such as Drs. Upham and Gaultier de Claubry. The signs of inflammation of the membranes of the brain were as marked in the American cases as at Dantzig; but this important observation had been made in American, that these signs were not always present, even in cases where their existence had been suspected from the previous symptoms. The other post-mortem signs were those of typhus, viz., a fluid condition of the blood, enlargement and softening of the spleen, and hypostatic congestion of the lungs. Dr. Murchison would be glad to know what was the condition of the blood, the spleen, and the lungs in the cases observed at Dantzig. A rash had also been noted in a large number of the American cases, many of the descriptions of which corresponded in every particular with the eruption of typhus—(see *Lancet*, April 22, p. 418). The etiology of the two diseases constituted another most important point of resemblance. Both in America and on the Continent of Europe the intimate relation between the occurrence of epidemic cerebro-spinal meningitis and overcrowding with bad ventilation had been a matter of general observation. If this remark did not apply to the Dantzig epidemic, then it differed not only from typhus, but from most epidemics of cerebro-spinal meningitis on record.

Dr. Murchison then proceeded to notice some objections which might be raised to his view of epidemic cerebro-spinal meningitis.

First, he had heard it said that the symptoms and whole course of the disease differed from those of typhus. After considerable experience in typhus fever, he could not assent to the soundness of this argument, and it must be borne in mind that typhus fever complicated with meningitis presented different symptoms from typhus fever not so complicated.

Secondly, it might be argued that inflammation of the cerebro-spinal membranes had been the rule at Dantzig and elsewhere, whereas in English typhus it was undoubtedly a rare exception. But it had been shown that in the so-called "epidemic cerebro-spinal meningitis" of America, cerebro-spinal meningitis was not always present; and with this fact before him, Dr. Murchison was not prepared to admit that six or eight autopsies, which were all that had been made out of 1200 fatal cases, were sufficient to decide the question in reference to the Dantzig epidemic. A more important fact remained to be stated. Outbreaks of undoubted typhus had been known to occur in England, in which almost every fatal case had been complicated with cerebral meningitis. About thirty years ago, a remarkable outbreak of this sort had occurred in an asylum for seamen in the East of London. The epidemic had been described by the late Dr. Roupell, the author of an excellent work on typhus. Dr. Roupell's description of the rash and of the other symptoms made it clear that the fever was typhus. Many of the cases proved fatal, and they were dissected and recorded by an eminent pathologist, Mr. George Busk, who had assured Dr. Murchison that Dr. Roupell's description was perfectly correct, and that in almost every one of the cases, lymph or pus was found on the surface of the brain.

Thirdly, it had been stated that there was no evidence of the disease at Dantzig being "personally communicable." Contradictory statements, however, had been made on this point, and it was worthy of consideration that many cases had proved fatal at Dantzig before the stage at which typhus probably becomes contagious. The communicability of typhus varied greatly according to circumstances. Dr. Christison and the late Dr. Alison had attended upwards of 280 cases of typhus in private houses, and in only one instance had the disease spread. Few Medical men, however, would be induced by this fact to subscribe to the opinion of some persons that typhus was not contagious. But, after all, if the disease at Dantzig was not communicable, then it unquestionably differed from many of the epidemics of cerebro-spinal meningitis already on record.

Lastly, it had been argued that typhus was unknown at Dantzig; but one of the most frightful epidemics of typhus ever known had occurred there; and it was a remarkable fact that the present epidemic had appeared almost simultaneously with an epidemic of typhus and relapsing fever in the adjacent country of Russia.

In conclusion, Dr. Murchison observed that if he had ventured to express his views in opposition to those of his friend Dr. Sanderson, he had done so solely with the hope that by free discussion light might be thrown on a disease which still required elucidation.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners on April 27 :—

Edwin Charles Garnsey, Wells, Somerset; George Lamb, L.R.C.P. and L.S.A., Hull; Bryan Holme Allen, L.S.A., London; Robert Croft Beck, Louth, Lincolnshire; Joseph Thompson, Nottingham; and John Hackney, Myddelton-square, students of University College. John Holden Webb, Tunbridge Wells; Richard Samuel Purnell Griffiths, Cheltenham; Sydenham John Knott, Jamaica; and Benjamin Bingay Thurgar, M.D. Edinb., Torquay, Devon, of St. Mary's Hospital. Herbert Lucas, Hitchin, Herts, and George Rendle, Newington-causeway, of Guy's Hospital; Frederick Barham Nunneley, Burton-on-Trent, and Edward Francis Jenkins Cole, St. Helena, of King's College; Thomas Harrison Tidswell, Spalding, Charing-cross Hospital; Thomas Lloyd Place, Wickham Market, of St. Bartholomew's Hospital; William Griffith Jones, Llanelly, Carmarthen, of the Middlesex Hospital; Frederick Knowlton Hampshire, Kensington, of St. George's Hospital; William Knight Treves, Dorchester, of St. Thomas's Hospital; and Charles James Cullingworth, Leeds.

Admitted members on April 28 :—

Frederick William Humphreys, Trinity-square, Tower-hill; Robert Woodings Sutton Barraclough, Streatham-hill; George Warcup Malim, Grantham; John Battison, Chesterfield; and John Arthur Ensor, L.S.A., Exeter, students of Guy's Hospital. Ralph Gooding, B.A. Lond., and L.S.A. Ipswich; Arthur Armistead Corte, Blackburn; and Edward Living Fenn, Nayland, Suffolk, of King's College; Harry Davenport Dod, Macclesfield; William Jeremiah Wane, Lancaster; John Haigh Tarleton, B.A. Cantab, Birmingham; William Taynton, Commercial-road; and John Rogerson, Bow, of the London Hospital. Walter Lattey, L.S.A., Clapham, and Charles Edward Hocken, Chelsea, of St. George's Hospital; Alfred Marchmont Watson, M.D. Edin., Peterborough, and Myrry Clarke, Jamaica, of the Edinburgh School; Frederick Isaac Flower, L.S.A., Codford, Wilts, of the Middlesex Hospital; and Henry Hargreaves Birtwell, L.S.A., Blackburn, of St. Thomas's Hospital.

It appears that out of the ninety-five gentlemen who offered themselves for examination only twelve were referred back to their studies for six months.

The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 2nd inst., and, when eligible, will be admitted to the Pass Examination :—

John Jenkins, William Spratt, J. C. Chester, Walter Greene, Richard Tudge, Charles Nutt, Christopher Lordison, W. B. Giles, W. C. Toulmin, Henry Warlow, and John Williams, Students of Guy's Hospital; W. G. Maddox, Stammers Morrison, G. H. Maasdrop, C. A. Robinson, and L. M. Le Grand, of the University College; Arthur Waller, Frederick Stocks, and Thomas Baron, of St. Thomas's Hospital; Richard Kinneir, C. H. Orfeur, and W. A. Richards, of King's College; Arthur Jackson and L. E. Evans, of St. Bartholomew's Hospital; J. C. McDonald, of the Westminster Hospital; C. H. Dawson, of the Bristol School.

The following passed on the 3rd inst. :—

S. W. Arundell, E. H. Addenbrooke, H. F. Marshall, G. P. Hadley, and Thomas Sansome, of the Birmingham School; William Davies, G. V. Poore, F. W. Young, and Nicholas Marshall, of the University College; C. W. Eccles, Charles Hedley, and Charles Gurdon, of Guy's Hospital; William Naughtin and Ellery Turner, of Charing-cross Hospital; George Bishopp and G. C. Parr, of St. George's Hospital; W. E. Williams and Mowbray Jackson, of St. Bartholomew's Hospital; J. J. Ilott, of the London Hospital; T. J. Fawcitt, of Newcastle; James Howard, of Manchester; Isaac Taylor, of Sheffield.

The following passed on the 4th inst. :—

W. H. Moore, N. E. Davies, A. H. Smee, F. C. Shaw, Frederick Oke, and Henry Sedgwick, students of St. Bartholomew's Hospital; O. H. Foster, William Stanger, T. C. Marsh, and Henry Lyne, of Guy's Hospital; William Monckton, C. W. Philpot, and R. G. Boulton, of King's College; J. B. Withington and J. S. Wyman, of Birmingham; Thomas Conry, of Dublin; J. W. Marsh, of the London Hospital; E. N. Smith, of St. Mary's Hospital; R. C. Newton, of Newcastle; C. H. Spooner, of St. Thomas's Hospital; J. T. D. Hughes, of Glasgow; Charles Grindrod, of Manchester; and J. M. Creed, of University College.

It is stated that out of the 104 candidates who offered themselves for examination no less than thirty-three were referred back to their studies for three months.

APOTHECARIES' HALL. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, April 27, 1865 :—

William Hoffmeister, Cowes, Isle of Wight; Nathl. Thos. John Haydon, Bovey Tracey, Devon; Thomas Dick, Harrington, Cumberland; James Fernie, Kimbolton, Hunts; Brownlow North Hyatt, 49, Doughty-street.

The following gentleman, also on the same day, passed his first Examination :—

Shirley Woolmer Arundell, General Hospital, Birmingham.

PRELIMINARY EXAMINATION IN ARTS.—The following gentlemen passed this Examination on April 28 and 29, 1865, and received Certificates of Proficiency in General Education :—

Frederic Byres Taylor (Certificate of Honour); John Adams, Newcastle-under-Lyne; F. G. Alleyne, 27, Gloucester-place; H. F. Baker, 6, Furnival's-inn; John R. Bayley, Holt, near Winchfield; Geo. Robt. Beswick, Brick-lane, Spitalfields; W. L. H. Penkarne, College-hill, E.C.; J. A. Calentarients, 43, Camden-road; R. Caldecott, Rugby; J. G. Colborne, 53, Tachbrook-street; Lee F. Cogan, Greenwich; W. B. Davies, Chelmsford; Saml. Evans, Llandovery; W. A. D. Fasken, Norwood; Wm. Hy. Gilkes, Hereford; Clement F. Gray, Holmes Chapel; Geo. Granslade, Stoke-sub-Hamdon; T. H. Hendley, Charlton; R. C. Holman, East Heathly; Donald N. C. Hood, Croydon; J. A. Jackson, South Ockendon; Alfred A. Kidger, King's College; Walter Kitching, York; Saml. Lee, Savile-row; Aug. E. B. Love, Canterbury; Jas. McDougall, Shobdon; Herbert Norton, Springgrove; Edwd. Palk, Totness; W. A. Patchett, Mottram; F. J. Pearse, Regent-street, Westminster; A. P. Penrose, Amwell-street, E.C.; W. Perkins, Malmesbury; G. H. Phillips, 29, St. Peter's-square; Allen Sewell, 17, Euston-square; Chas. W. Smith, Douglas-road, Canonbury; Herbert A. Smith, 28, Hatton-garden; F. E. Taylor, Norwich; H. A. Turner, Brighton; F. H. Truter, 5, Manchester-street; G. H. Wade, Littlehampton; C. P. S. Wayman, Great Thurlow, Suffolk.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ANDERSON, A. M., M.D., has been appointed Physician and Medical Superintendent of the Fever Wards, Town's Hospital, Glasgow.

ANDERSON, JOHN, M.R.C.S. Eng., has been reappointed Medical Officer for Peterhead, Aberdeenshire.

ANNANDALE, THOMAS, F.R.C.S.E., has been appointed Assistant-Surgeon to the Royal Infirmary, Edinburgh.

ARMSTRONG, THOMAS, M.R.C.S. Eng., has been appointed Medical Officer for the Workhouse of the Brecknock Union.

ASHFORD, EDWIN C., L.R.C.P. Edin., has been elected Medical Officer for the Workhouse of the Tiverton Union.

BILLING, ARCHIBALD, M.D. Oxon., F.R.S., has been elected Consulting Physician to the Free Dispensary for Diseases of the Throat, King-street, Regent-street.

BOGG, THOMAS W., M.R.C.S. Eng., has been appointed Surgeon to the Louth House of Correction.

BROWNE, J. CRICHTON, M.D. Edin., has been appointed Medical Superintendent of the Newcastle-upon-Tyne Borough Lunatic Asylum.

BRYANT, WILLIAM H., M.R.C.S. Eng., has been appointed Resident Surgeon to the Great Northern Hospital, Caledonian-road.

FRASER, PATRICK, L.R.C.P. Lond., has been elected Physician to the Free Dispensary for Diseases of the Throat, King-street, Regent-street.

GREWCOCK, GEORGE, M.R.C.S. Eng., has been elected House-Surgeon and Secretary to the Stamford and Rutland Infirmary.

HACKNEY, JOHN, M.R.C.S. Eng., has been appointed House-Surgeon to the Royal Free Hospital, Gray's-inn-road.

KEELE, GEORGE T., M.R.C.S. Eng., has been elected Surgeon to the Holloway and North Islington Dispensary.

LYNCH, J. ROCHE, M.R.C.S. Eng., has been appointed House-Surgeon t St. Mary's Hospital.

OWENS, HENRY, M.D., has been appointed one of the Resident Surgeons at the Birmingham Lying-in Hospital.

PERCIVAL, Mr. T., has been elected Assistant Resident Medical Officer to the Leeds General Infirmary.

ROPER, CHARLES H., M.R.C.S. Eng., has been elected Surgeon to the Devon and Exeter Hospital.

WILLETT, CHARLES V., M.R.C.S. Eng., has been appointed House-Surgeon to the Brighton and Hove Dispensary.

WORGER, THOMAS H., M.R.C.S. Eng., has been appointed one of the Resident Surgeons at the Birmingham Lying-in Hospital.

DEATHS.

ARMSTRONG, GEORGE D., M.R.C.S. Eng., at Cockermouth, Cumberland, on March 9, aged 39.

CROWDY, CHARLES W., M.R.C.P. Lond., at Beaufort-buildings, Bath, on April 25.

HIFFELSHEIM, the distinguished man of science, who has of late paid much attention to the practical application of dynamic electricity, has just died at Paris at the early age of 37.

MOREL-LAVALLEE, the well-known Surgeon of the Beaujou Hôpital, Paris, has just died.

ROSS, SAML., M.R.C.S. Eng., at Haxey, Lincolnshire, on March 23, aged 44.

STANLEY, JOHN, M.D. Edin., at Belle Vue, near Whitehaven, on April 28, aged 89.

TOMKIN, W. BRYCKWOOD, M.R.C.S. Eng., at Witham, Essex, on April 16, aged 44.

WRAGG, CHRISTOPHER, M.R.C.S. Eng., at 198, Goswell-road, London, on April 26, aged 40.

NEWCASTLE AND GATESHEAD OBSTETRICAL SOCIETY.—A new society has been formed with the above title, the objects of which are sufficiently explained by its first law—viz., "that the objects of this Society are—the advancement of obstetrical science, the promotion of all that relates to the knowledge of all that relates to the knowledge of the diseases of women and children, and the maintenance of Professional etiquette amongst its members." The following is the list of the first officers :—*President.*—W. Dawson, M.D. *Vice-Presidents.*—A. S. Donkin, M.D.; G. Y. Heath, M.D.; B. Barkus, M.D.; J. Jobson, F.R.C.S. *Committee.*—L. Blumer, M.D., Sunderland; Richard Clarke, M.R.C.S.; J. C. Preston, L.S.A.; W. C. Nesham, M.D.; T. H. Pyle, M.R.C.S., Earsdon; J. Russell, M.R.C.S. *Hon. Sec.*—R. Ellis, L.R.C.P. Ed., 36, Hinde-street, Newcastle-upon-Tyne. We heartily wish the Society a successful and useful career.

University of London.—The Senate, at a meeting held on the 26th inst., elected the following gentlemen as examiners for the ensuing year, commencing 1st July next:—*Chemistry*—Henry Debus, Esq., Ph.D., F.R.S., and Professor A. W. Williamson, Ph.D., F.R.S. *Botany and Vegetable Physiology*—Rev. M. J. Berkeley, M.A., and Thomas Thomson, Esq., M.D., F.R.S. *Geology and Palæontology*—Archibald Geikie, Esq., F.R.S. Ed., F.G.S., and S. P. Woodward, Esq., F.G.S. *Practice of Medicine*—Professor Edmund Alexander Parkes, M.D., F.R.S., and Francis Sibson, Esq., M.D., F.R.S. *Surgery*—Professor John Eric Erichsen, and John Hilton, Esq., F.R.S. *Anatomy*—Professor George Viner Ellis, and Professor Peter Redfern, M.D. *Physiology, Comparative Anatomy, and Zoology*—Professor Thomas H. Huxley, Ph.D., F.R.S., and William Scovell Savory, Esq., M.B., F.R.S. *Midwifery*—John Braxton Hicks, Esq., M.D., F.R.S., and William Overend Priestley, Esq., M.D. *Materia Medica and Pharmaceutical Chemistry*—Frederick J. Farre, Esq., M.D., and Samuel Osborne Habershon, Esq., M.D. *Forensic Medicine*—Professor William Augustus Guy, M.B., and William Odling, Esq., M.B., F.R.S.

Royal College of Surgeons in Ireland.—At a meeting of the College held on Tuesday, May 2, the following gentlemen were elected Examiners for the ensuing year, viz.:—Examiners for Letters Testimonial and Fellowship.—Christopher Fleming, Jerome Morgan, George H. Porter, Benjamin W. Richardson, M. Harry Stapleton, Edward A. Stoker, T. Jolliffe Tufnell. Examiners in Midwifery.—James Isdell, Alfred H. M'Clintock, Edward J. Quinan. Examiners in General Education.—Thomas Byrne, John Murray, George F. Shaw.

The Académie Francaise.—The forty "*immortels*" who constitute this Academie, to which even the Emperor Napoleon is stated to be so desirous to belong, are thus distributed, according to age:—There are 5 octogenarians, 10 septuagenarians, 13 sexagenarians, 8 quinquegenarians, 3 quadragenarians, and 1 trigentenarian. Their combined ages constitute a sum of 2611 years.

The Zoological Society.—At a meeting of the Council of this Society on Wednesday last, Dr. James Murie was elected anatomical prosector in the gardens, at a salary of £250 per annum. Educated to the duties in question under Professor Quekett, in the Museum of the Royal College of Surgeons of England, there is no doubt Dr. Murie will thoroughly justify the rather difficult duty of selection made by the Council from the twenty-nine good men who offered themselves for the appointment. To the Society itself great credit is due for creating an office calculated to be of as much benefit to the scientific public at large as to themselves. Our readers will be glad to learn, from the annual report just published, that the receipts of the Society for the past year from all sources amounted to £21,713 13s. 10d.

Popular Scientific Lectures on the Continent.—These lectures, which, under the name of "conferences," are now quite the rage in France, have been taken up with great zeal in Italy, and it seems that at Naples a Mademoiselle Royer—a French lady, we presume—has met with splendid success in her conferences on some of the most important questions of natural science, especially spontaneous generation and the origin of species.

The Royal Free Hospital.—The biennial festival of this Hospital was held at the Freemasons' Tavern on Monday, May 1, E. Masterman, Esq., treasurer, in the chair. Among the donations and subscriptions announced was £1000, the second donation of that amount, by a lady anonymously; £500 by Sir Rustomjee Jamsetjee Jejeebhoy, Bart.; George Crawshay, Esq., a fourth donation, £325. The total amount announced during the evening was £4430.

Hospital for Women (Patron: Her Royal Highness the Princess of Wales).—*New Wing for Paying Patients.*—Several ladies having suggested the expediency of admitting paying patients into the Hospital, thereby supplying a want which has been long and extensively felt, the general committee have engaged to carry this suggestion into effect by the addition of a new wing, to be devoted exclusively to this purpose. The benefits of the Hospital for Women have, for the last twenty-two years, been extended to the indigent poor only, to the necessary exclusion of a large class of sufferers, such as the impoverished gentlewoman, the wives, widows, and daughters of Professional men, and needy and over-worked governesses, who, though unable to incur the expense of protracted Medical treatment at home, yet shrink from the want of privacy and repose which is common to the wards of a general Hospital, and are thus entirely debarred from the advantages which the rich and the destitute poor alike enjoy. The sum of £5000 will be required, of which £2550 must be paid on July 5 next, to complete the purchase of the new wing, and it is calculated that the remainder will be fully sufficient for necessary repairs, alterations, furnishing, etc.; after which it is hoped that the paying wing will keep itself, as the present arrangements of the Hospital will be sufficient for the double institution, extra nurses only being required for the additional patients. The patients will be accommodated, as far as possible, with separate rooms, and as they will probably each pay from 10s. to £1 per week, it is hoped that the current expenses will be met by the funds accruing from this source. Her Royal Highness the Princess of Wales has graciously signified her pleasure to become the patron of the Hospital for Women, and has given a donation in aid of the proposed new wing.

The North Staffordshire Infirmary.—The Proposed New Building.—Mr. C. Lynam, the architect, has published an account of the building which is to be the new Hospital for the Potteries. The Hospital is to be built on the pavilion principle, and the buildings are to be arranged round a central garden 140 feet long and 70 feet wide. Communication between the buildings is to be furnished by a glazed corridor which is to surround the garden. Amongst the buildings we observe that a separate ward is allotted for burn cases—a dire necessity in the Potteries.

The Adulteration of Medicine with Methylated Spirit.—An inquiry has been held by Mr. Richards, deputy-coroner, at the Crown Tavern, Charles-street, Mile-end, respecting the death of a child named John R. Lawson, and in the course of the proceedings a very abominable sort of adulteration of medicines was made known. Mrs. Lawson, the wife of a beer-shop keeper, said that deceased was ailing with the whooping-cough, and she took him to a Surgeon in Newington-causeway. The name "Tanner" was on a plate outside the door, and the house was a private one. Mr. Tanner said the child had chicken-pox, and was very dangerously ill. He gave a bottle of medicine, and some ointment, for which he charged 1s. 3d. She gave the medicine three times, and each time he was violently sick from it. The next morning she removed from Southwark to James-street, Mile-end, and as the child seemed dying she called in Mr. Reilly. Mr. F. J. Reilly, M.R.C.S., said that the child died from acute bronchitis. He had made a slight chemical analysis of the medicine produced, and found it to contain poppies and iron prepared with methylated spirits of wine. Methylated spirits of wine was used by French polishers as a substitute for naptha, which destroyed their eyes. The Government allowed spirits of wine to be sold free of duty if it was methylated or adulterated by some naptha being passed through it to render it unfit for drinking purposes, and consequently it could be bought for 6s. 6d. a gallon, while spirits of wine unsophisticated cost 22s. a gallon. It was most improper to use methylated spirits for medicine—it would sicken any patient, but it had not caused the deceased's death. The jury said that even the smell of the medicine was disgusting; it was like bad naptha. Mr. Reilly said that he could not find the name "Tanner" in the "Directory." The jury returned a verdict that the deceased died from bronchitis from natural causes, and the jury strongly deprecated the use of methylated spirits for medicine in the place of pure spirits of wine.

Death of Mark Kebbell, Esq.—"Very seldom before have we known such a feeling of deep and wide-spread regret to exist in the community as that which was caused by the sudden and untimely death of the late Mr. Mark Kebbell. The Physician, in virtue of the important duties which he has to perform, is brought in daily, almost hourly, contact with the members of the community in which he resides, and is often present at moments when not only the exercise of his skill is required, but when those at whose bedside he stands feel deeply the need of that kindness and sympathy which he can afford. Mark Kebbell, who has gone from amongst us, was one to whom it has been vouchsafed to perform such duties to suffering humanity, and hundreds can now testify to the zeal, the skill, and the fidelity which he displayed in his onerous task. To every one—to the poor as well as to the rich—were his services willingly tendered, and it is to this circumstance we partly attribute the deep and general mark of respect to his memory which was shown on Sunday, when his last mortal

remains were conveyed to the grave. When the procession started, upwards of 250 people took their place in the solemn procession, and these again were followed by many additional spectators. On reaching the churchyard, the Bishop of Wellington, accompanied by the Rev. W. Andrews, commenced to read the touching burial service, as contained in the ritual of the English Church. For a few seconds all uncovered, as the voice of the clergyman was heard. Thus the procession advanced till a quiet nook was reached, backed by an amphitheatre of hills, and presenting in front a panoramic view of the bay and its outlet. Here they halted, and gathered round the new-made grave, close to which the officiating clergyman, in calm and clear tones, continued the performance of his office, while hundreds of spectators on the hills, with bared heads, gazed on the affecting scene. At the words, 'We consign his body to the dust,' the coffin was lowered, and immediately afterwards the rattle of the handful of earth thrown on it was heard. A little time more and the service concluded, when friends, and those who were nearer and dearer, came forward to take a last sad look into the pit which would soon shut out from sight all that was mortal of a good and worthy man. 'Mark Kebbell, died on the 3rd of February, 1865, aged 38 years.' Such was the simple inscription on the coffin, such the epitaph on one whom we could have ill spared, a warm friend, a skilful Physician, and a man whose memory will long outlive his good deeds."—*From the Wellington Paper.*—[Mr. Mark Kebbell formerly resided in Brighton, and received his earlier Professional education at the Sussex County Hospital. He had been at Wellington about eight years, where he was very successful in practice. The cause of his death was malignant scarlet fever, which he contracted from his patients, and he died in the faithful discharge of his duties.—*Brighton Gazette.*]

Death after Operation for Cataract in a Child.—M. Warlomont related an interesting case at the Ophthalmological Congress at Heidelberg. A healthy infant, 11 months old, was brought to him with congenital cataracts. The capsules were punctured with Hay's needle twice at a month's interval, absorption going on slowly but regularly; so that at the end of four months there remained only fragments of the opaque capsule floating within the pupil, those of the left eye being free and of the right adherent to the iris. A third operation was required to remove these fragments from the field of vision, the right side offering a little resistance to this on account of the adhesions. After this last trifling operation, however, the child became sick and restless, while the right eye was much inflamed, iritis arising. Increased vomiting followed, together with cerebral symptoms and febrile action, and two days afterwards the infant died.—*Annales d' Oculistique*, June, p. 240.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Dr. W. Clarke, Tweedside, Barbadoes.—The enclosed has been received with thanks.

Stockton-on-Tees.—Our present arrangements do not permit us to insert announcements of marriages.

The Abbey, Hexham.—Our obituary notices are strictly confined to members of the Medical Profession.

A deputation of Medical men interested in preventing counter-practice of chemists will wait on Sir F. Kelly in a few days respecting the proposed Chemists and Druggists Bills. The day is not fixed, but any gentleman interested and desirous of going may apply at the office of this journal, or to Dr. S. Gibbon, 23, Finsbury-square, E.C.

Payment of Gaol Surgeons for Attendance at Inquests.—Our legal adviser sends the following:—"I think that the Surgeon of a gaol is not entitled to a fee for giving evidence before a coroner's inquest on the body of a prisoner dying in the gaol. The Act 6 and 7 Will. IV., c. 89, s. 5, provides that in the case of an inquest on a person who has died in a public Hospital, or Infirmary, or any building or place belonging thereto, the Medical officer whose duty it was to attend the deceased as such Medical officer shall not be entitled to the fees given by the Act. I think that the death of a prisoner in gaol is within this clause."

The Case of Mary Green.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Two very severe articles have appeared in the *Daily Telegraph*, holding Mr. Butler up to public execration for his conduct in the affair of Mary Green. Now, taking Mr. Butler's facts to be correct, I do not myself see that the least blame was to be imputed to him. He surely had a right to decline the case, and he appears to have pointed out to them where to obtain the assistance they required. It is always a rule with me never to go to a labour unless previously specially retained (or as substitute for a Professional brother).

The public have a very firm-rooted, but mistaken, idea that we are their servants, bound to come whenever they call, be the matter light or grave; but remuneration for services rendered is the last thing thought of. This idea has been fostered to a great extent by a false philanthropy practised by the Profession, in too many instances self-seeking and egotistical. Should this idea be extended to midwifery, and should the public believe they could get the services of a qualified Medical man on the spur of the moment without previous engagement, those of us who practise among the poor would be literally robbed of our fees to an enormous extent.

I know nothing whatever of Mr. Butler, but I look to you, sir, to vindicate the honour of the Profession in this matter; and so convinced am I that he has been misjudged and injured, that, if you think proper, I will forward to you £2 2s. as the beginning of a fund to aid him in prosecuting the author who has so grossly slandered him. I am, &c.

M.B. Lond.

A Liverpool Coroner and Beadle on Sudden Death.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The following report of an inquest, held before the deputy-coroner for Liverpool, is extracted from the *Daily Post* of to-day. I send it to you merely to show how such an inquiry (so-called) is conducted by a law coroner, to whom it seems it never occurred that when "there is no suspicion—nothing improper," that when a case "is one of those sudden deaths which arise from natural causes," surely no inquest is required. I may mention that the learned official, whose very lucid dicta on Medical matters appear to carry such authority, is an ex-policeman. I am, &c.

Liverpool, May 3. E. H. J.

"An inquest was held yesterday, before Mr. Wybergh, deputy borough coroner, on the body of Robert M'Dougall, 36 years of age, a fireman on board a steamer, who lived in Haddock-street. The deceased had often complained of giddiness in the head, and it was stated that he had received a sunstroke while abroad. On Monday afternoon he had suddenly fallen down dead in Regent-road. The jury seemed to have some difficulty in agreeing upon their verdict, and the foreman said a majority thought it requisite that a post-mortem examination of the body should be made. One of the jurymen explained that they desired this particularly, because shortly before his death the deceased had eaten heartily of his dinner.—The Beadle here interrupted by saying: There is no poison that would kill a man as quick as this man had died.—The Juryman: If he had fell and hurt himself we would be satisfied, but a person falling down there could not be injured.—The Beadle: If he had poison before he left his own house it would have acted upon him before he got there.—The Deputy-coroner: If you cannot come to a conclusion, the only effect will be that I shall have to adjourn the case till to-morrow, and we shall have to pay a Doctor two guineas to say whether it was disease of the heart or whether it was apoplexy. What matter will it be? It would still be natural disease. There is no cause for suspicion—nothing improper. It is simply one of those sudden deaths which arise from natural causes.—After the lapse of a few moments, the Foreman said: There is only one outstanding, Mr. Coroner, the other eleven agree.—The Deputy-Coroner: I shall have to lock you up.—Another short interval elapsed, and the Foreman then cheerfully announced: Mr. Coroner, he's given in.—A verdict of 'Natural causes' was then recorded."

Surgeon-Major Hare in Reply to Dr. Macpherson.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir.—In reply to Dr. Macpherson's letter, dated January 18, which was sent to me by the last mail, I hope you will allow me to make the following remarks:—

In my papers it will be observed that I have most carefully avoided referring to any figures which I had myself compiled. The tables which Dr. Macpherson refers to were those published as the result of the experiment by the Committee appointed by Lord Dalhousie to arrange it. I was not allowed to select my patients, nor did I keep, or ever see, the Hospital Registers. This was all arranged by Sir James Thomson and the Hospital authorities. I simply treated the patients which were sent by them to my ward; and every grain of medicine which I prescribed, and every death, was recorded by them. The public, therefore, must decide for themselves whether they will credit Dr. Macpherson or the Committee of three Medical officers, high in rank, appointed by the Government to manage the experiment, in concert with Dr. Nicholson, the Surgeon of the Hospital.

Dr. Nicholson's name is well known in India as the most successful Practitioner that ever appeared in Calcutta. He prophesied from the commencement the success of my experiment, always gave me his full support, and never sanctioned the opposition of his assistant, which he knew was only and solely caused by Dr. Macpherson's vexation in finding that the results of my practice were compared with his own, and his mortality thus proved to have been very great. I would willingly have avoided such an invidious comparison, but I was not consulted, and obliged to do as I was ordered. Dr. Macpherson did, I believe, write to the Committee some letters very early in the experiment, when he saw what the result would probably be; but I never read them, and was not consulted. They were, no doubt, what he says of them himself, "curiosities of Medical statistics." The Committee decided for themselves.

But the argument of my papers does not rest on figures. In mentioning my experiment I was obliged to give its recorded results, though I know myself that the success shown in the tables is considerably below the reality, from the determination of the Committee to publish under their authority nothing that was doubtful. The real proof of the success of the experiment is the revolution(a) which it has caused in practice throughout India, the certainty of which the reader can see for himself in the steady and large increase in the expenditure of quinine(b) ever since its date. Lord Dalhousie foresaw this, and took immediate steps to introduce the cinchona tree.

Dr. Macpherson's remarks, that the contents of my papers are "old and stale," may be noticed as a sample of the correctness and the spirit of his other objections. Can this be said of the great facts which I have proved, —viz., that quinine can be given during the hottest stage of the paroxysm of remittent malarious fever, and even in continued malarious fever, not only with impunity, but enormous saving of life; that malarious fever is not an inflammatory disease, and that in the very large number of dissections recorded during more than twenty years in the General Hospital, not one appearance of inflammatory result is found after fever, while they are constantly described by the same Practitioners in their examinations

(a) See Dr. Ewart's History quoted, p. 647, *Medical Times and Gazette*, December 17, 1864; also Ranking's Abstract, vol. 39, 1864, p. 43.

(b) See Table No. 6, p. 674, *Medical Times and Gazette*, December 24, 1864.

of the deaths from dysentery; and lastly, the curious and important proof of the immense majority of malarious fevers over every other form in Calcutta, and the clear deduction that the result of malarious poisoning is not necessarily intermittent or remittent fever, but that it is sometimes no fever at all, but icy coldness throughout, like the collapse stage of cholera; that the poison, therefore, of malaria is a direct sedative which injures the vitality of the blood, and thus stops the capillary circulation, which requires vital powers for its continuance;—the blood therefore accumulates, in what is called congestion, in the great viscera of the body, the liver, spleen, brain, etc., and the salutary efforts of Nature to overcome this stagnation we have called fever, and have been treating it hitherto most fatally as an inflammatory disease?

Also, if I were reviewing my own papers, I would add that, as the proof of error never appears so practically convincing as when we are able clearly to view its cause, so it will be seen how important my arguments are on the past practice of Drs. James Johnson and Twining, where I show that the remedies they used were truly successful, but wrongly applied, from the prevalence of false inflammatory theories, and dread of the supposed stimulating effects of bark. These facts Dr. Macpherson asserts to be "old and stale," yet I know not where else, except in my papers, they can be found; and they are truths which will benefit the human race wherever civilisation can extend itself. I am, &c.

E. Hare, Deputy Inspector-General of Hospitals, Bengal.

Agra, Bengal, March 22.

BOOKS RECEIVED.

Report on the Health of Liverpool during the Year 1864. By W. S. Trench, M.D., Medical Officer of Health for the Borough. 1865. Pp. 59.

*** The greater part of this Report is occupied with a consideration of the several conditions which have appeared to promote the spread of typhus fever in Liverpool, which, commencing to be in excess during the latter months of 1861, steadily increased in the borough, until, during the last quarter of 1864, it attained the gravity and extent of a destructive epidemic. In 1864 the deaths numbered 1774, the numbers each quarter being 307, 539, 595, 753; so that this disease gave rise to 10.5 per cent. of all the deaths registered. The conditions dwelt upon in the report are contagion, indigence, overcrowding (in Liverpool very much due to the arrivals of emigrants for embarkation at that port), filth, and drunkenness. He traces very fully the influence which the American blockade of cotton ports has had in throwing out of employment a vast number of the labouring population. Taking the cotton porters alone, it seems that in 1860 and '61 there were as many as 6000 or 7000 persons engaged in this occupation alone, and the losses which fell upon these people must have been felt likewise by the whole body of unskilled operatives. The standard by which Dr. Trench judges of overcrowding is the cubic capacity of rooms, his minimum being 300ft. for each individual. This is the customary minimum in London. He is in error in thinking that more is demanded, except by one or two of the health officers. We agree with him, from practical working of this standard, that as things are at present it could not well be raised; and it is pretty certain that even thus there are abundant instances which escape the eye of health officers and sanitary inspectors in which even this minimum is not attained. Dr. Trench has a section devoted to the subject of "sub-letting" in poor tenements. He agrees with Mr. Godwin's suggestion, that houses sublet should be registered in some way, and the landlords obliged to comply with some simple hygienic requirements. This is the plan proposed also by the Metropolitan Association of Medical Officers of Health. It seems to us a very practical one, and such as Parliament should find no difficulty in sanctioning. Dr. Trench does not find that there was any increase of intemperance prior to the outbreak in 1861, and the excess subsequently he attributes to the depression of trade and its moral and physical concomitants—anxiety, idleness, and destitution. There is a report appended "On the Prevention of Contagion," from which it appears that shortly after Dr. Henry, of Manchester, published his papers in the *Philosophical Magazine*, the Liverpool Town Council erected an apparatus for disinfection by means of steam, which has been in constant use in the borough gaol since. The ordinary working is 210° Fah., equal to 8lbs. pressure on the square inch; but it is capable of being raised to 9 or 10 lbs. without danger. Dr. Henry suggests the erection of a public disinfecting apparatus, on a scale sufficient to meet the requirements of the humbler classes of the community, and also of an air-tight dry-room, in which all woollen cloth might be subjected to the action of chlorine.

Indian Emigration: Where to Settle in Western India, with Hints on Cotton and Sheep Farms. By Lieut. T. Prendergast B. Walsh, 1st Bombay Grenadier Regiment. London: Saunders, Otley, and Co. 1864. Price 1s.

*** A very interesting pamphlet, giving advice to persons proposing to settle in Western India as cotton or sheep farmers. Such a scheme is well worth thinking of by any Englishman who does not desire absolutely to expatriate himself. He recommends certain sites in Western Bombay, and gives instructions for intending settlers, with estimates of cost, etc. He looks forward to a larger consumption of animal food by all classes in India. "Meat is much used by natives in all the large towns I have visited in India, and in villages where I have put up I have been repeatedly asked for meat when I have killed a sheep. Brahmins of course I except; but the entire Mussulman population, the Mahrattas, the Rajpoots, the Coolies, and all low castes, and many other persuasions of Hindoos, eat the flesh of sheep. Beef is certainly regarded with disgust by most natives, and a Dher will not eat swine's flesh; but I have seen Bheels eat both in Goozerat."

Odds and Ends. No. 2. Convicts. By a Practical Hand. Edinburgh: Edmonstone and Douglas. 1865. 6d.

*** A thoroughly practical and interesting account of a very painful subject.

On Intra-Thoracic Cancer. Part the First. Introductory and Historic Sketch. By John Cockle, M.D., Physician to the Royal Free Hospital. London: Churchill. Pp. 34.

*** We presume Dr. Cockle intends to publish a book in the form of a series of pamphlets. If so, we should like to suggest that it would be better to change his plan, and let the Profession have all he wishes to say in a mass. It is so difficult to judge of what a book is likely to be which is published in this form, that we would rather reserve criticism until the whole series is before us.

The Annual Report of the Committee of the Manchester and Salford Sanitary Association; being the Summary of their Proceedings for the Year 1864.

*** Dwells again upon the importance of having a place to which children with contagious exanthemata may be removed from the dwellings of the poor.

Anuual Report of the Cumberland and Westmoreland Lunatic Asylum for 1864.

*** Contains an important and interesting account of an outbreak of dysentery in the Asylum.

VITAL STATISTICS OF LONDON.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29·967 in.
Mean temperature	54·2
Highest point of thermometer	81·5
Lowest point of thermometer	36·1
Mean dew-point temperature	43·9
General direction of wind	Variable.
Whole amount of rain in the week	0·00 in.

APPOINTMENTS FOR THE WEEK.

May 6. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m. Royal Free Hospital, 1½ p.m.

Royal Institution, 4 p.m. Prof. Bain, "On the Physical Accompaniments of Mind."

8. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

Royal Institution, 2 p.m. General Monthly Meeting.

9. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

Ethnological Society of London, 8 p.m. Rev. F. W. Farrar, "On Language in Relation to Ethnology." Sir Woodbine Parish, "On the Indians of South America."

Royal Medical and Chirurgical Society, 8½ p.m. Mr Henry Lee, "On Acute Inflammation of the Veins." Dr. George Harley and Dr. Dickinson, "On Intermittent Hæmaturia."

Royal Institution, 4 p.m. Professor Frankland, F.R.S., "On Organic Chemistry."

10. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

Microscopical Society, 8 p.m. Meeting.

11. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Royal Institution, 4 p.m. Professor Frankland, F.R.S., "On Organic Chemistry."

12. *Friday.*

Operations, Westminster Ophthalmic 1½ p.m.

Royal Institution, 8 p.m. Frederick Field, Esq., F.R.S., "On Magenta and other Dyes."

ORIGINAL LECTURES.

ON

THE FOOD OF MAN IN RELATION TO HIS USEFUL WORK.

By LYON PLAYFAIR, C.B., LL.D., F.R.S.,
Professor of Chemistry in the University of Edinburgh; Vice-President of the Royal Society, Edinburgh; Vice-President, and formerly President, of the Chemical Society, London, etc.

DELIVERED AT THE ROYAL SOCIETY, EDINBURGH, APRIL 3, 1865, AND ROYAL INSTITUTION, LONDON, APRIL 28, 1865.

(Continued from page 461.)

DIVISION II.

Application of the Preceding Data to Elicit the Source of Useful Work.

13. The common experience of mankind teaches us, that when work is to be obtained from an animal, it must be supplied, in proportion to the labour, with food rich in flesh-formers. Thus a horse, when at work, must be fed with oats or beans, both rich in flesh-formers; a supply of potatoes or turnips, both abounding in heat-givers, would not enable it to do its work. Professor Dick, the head of the Veterinary College in Edinburgh, tells me that a horse may be kept without work, but taking a little exercise, in fair condition, on 12 lbs. of hay and 5 lbs. of oats; but if a good amount of work is to be got out of it, the horse should get 14 lbs. hay, 12 lbs. oats, and 2 lbs. beans. These diets reduced, as regards their flesh-formers, are as follows:—

Horse at rest .	.	29·2 ozs. of flesh-formers.
Horse at work	.	56·2 ,, ,,
Diff. for work .		27·0 ,, ,,

The labour of a horse is generally taken as equal to that of between seven and eight men; and as the working food of a labourer is $5{\cdot}5 - 2{\cdot}0 = 3{\cdot}5$, the proportion

$$3{\cdot}5 : 27 :: 1 : x.$$

in which $x = 7{\cdot}7$ leads to the same result. Again, if we compare the labour and food of a horse and of a man when doing the same kind of work—that is, pulling weights horizontally—we have the following ratios, which, from the different character of their food and assimilative processes, must be made upon the flesh-formers actually expended on work external to their body:—

Work of horse, Morin(n) $\frac{12{,}400{,}000}{1{,}500{,}000} = 8.$
Work of man, Rankin(o)

Labour flesh-formers in the food of horse $\frac{27}{3{\cdot}5} = 7{\cdot}7.$
,, ,, ,, food of man

These ratios are as near as we can expect with animals of such a different character. If we take again two labouring animals of the same herbivorous nature—the ox and horse,—we can compare their labour and food without complicating the question by deducting the quantity required for *opus vitale*. The Sussex farmers find that an ox is well fed on 50 lbs. mangold-wurzel, 3 lbs. beans, and 17 lbs. wheaten straw, the flesh-formers in this food being 38·6 oz. Muschet (p) has given us the labour of an ox, from which we obtain the following ratios:—

Work of horse in foot-pounds, $\frac{12{,}400{,}000}{8{,}640{,}000} = 1{\cdot}43.$
Work of ox ,,

Plastic food of horse, $\frac{56{\cdot}5}{38{\cdot}6} = 1{\cdot}46$
,, food of ox,

14. These numbers, so far as they go, appear to indicate that the external dynamical work of animals is proportional to their plastic food. But this is only the common experience of man. The miners in Chili, who work like horses, also feed like them, for Darwin tells us that their common food consists of bread, beans, and roasted grain. During our harvest in Scotland, the reapers consume about eight ounces of plastic nutriment daily (Christison). Our railway contractors know this necessity of the system so well that they are accustomed to discharge labourers when their appetites fail (Lankester). And, generally, the previous diet tables prove this amply, by showing a constant increase of 30 per cent. of flesh-formers in a labouring diet over one fitted for health without hard work, as contrasted with a varying increase of from 5 to 20 per cent. in the heat-givers.

15. Having thus rendered it probable that we are to look to the plastic ingredients of food as exponents of dynamical action, both internal and external to the body of a man, let us now examine the transformations which they suffer. All chemists are agreed that the final transformation of plastic matter in the body yields carbonic acid, water, urea, and sulphuric acid. Those who believe that the transformation takes place in the blood, agree on this point with those who consider that it is effected in the tissues.

If we take the simplest possible *empirical* formula for albumen, or of tissue formed by it, one representing analysis merely, and not constitution, our views may be more easily understood. Such a formula is $C_{24}H_{38}N_6O_{16}$, in which the 1·2 per cent. of sulphur is for the present supposed to play the part of oxygen:—

		Calculated.	Mean of analysis.
24 C, . . .	288	53·55	53·8
38 H, . . .	38	7·06	7·0
6N, . . .	84	15·61	15·7
16 O, . . .	128	23·78	S 1·2 O 22·3
	538	100·00	100·0

The transformation of this generic tissue-forming body, still omitting the sulphur, would be as follows:—

Albumen. Urea or amido-carbonic acid. Carbonic acid. Water.

$$C_{24}H_{38}N_6O_{16} + 10O = 3(CO_2(NH_2)_2) + 21(CO_4) + 13(H_2O_2).$$

The simplicity of the transformation is remarkable. Water and two forms of carbonic acid are alone produced; of the latter amido-carbonic or urea is secreted with water *per vesicam*, and the gaseous carbonic acid, accompanied by watery vapour, passes away *per halitem* or *per cutem*. If this empirical formula be a fair representation of analysis, and it claims to be nothing more, then, as the result of the transformation, *seven* times as much carbon should escape by the lungs and skin as by the urine. We can only test this when animals are fed on a flesh diet free from fat. Luckily there are two classes of experiments of this kind, one of them being by Bischof and Voit,(q) and the other by Pettenkoffer and Voit.(r) The results of the former, omitting the starving experiments on the dog, are as follows:—

	Grammes of Flesh.	C in Urea. Grammes.	C in CO_4. Grammes.
First Series . .	1800	24·2	180·8
Second ,, . .	1500	21·6	162·1
Third ,, . .	1200	17·7	132·6
Fourth ,, . .	1800	24·9	186·5
Fifth ,, . .	1800	25·6	223·3
Sixth ,, . .	2000	30·3	228·5
Mean . .	1383	24·0	185·6

Before using these figures, we must correct them for the one per cent. of fat which, according to these authors, still remained in the flesh. If we suppose the fat to contain 77 per cent. of carbon, then 13·83 grammes of fat, in the average daily supply of 1383 grammes of flesh, would contain 10·6 grammes of carbon. Hence we have in reality 175 grammes of the carbon in the carbonic acid due to the flesh alone. From this we obtain the ratio—

$$24 : 175 :: 1 : x \ . \ . \ . \ . \ x = 7{\cdot}29.$$

In Pettenkoffer and Voit's experiments, conducted in a like way, but where no correction requires to be made for fat, 21·6 grammes of carbon were found in the urea, and 148 grammes in the carbonic acid, and small quantity of carburetted hydrogen, which escaped by the lungs and skin. Hence we have—

$$21{\cdot}6 : 148 :: 1 : x \ . \ . \ . \ . \ x = 6{\cdot}85.$$

The mean of these two independent series of experiments shows that 7·07 times as much carbon passes away in the form of carbonic acid as we find in urea, our equation having required 7·0.

16. Having established the fairness of the equation of transformation, we have to ascertain its calorific value. Although

(r) *Ann. der Ch. and Phar.*, Supp. Bd., 1863.

we are well aware, as has been shown by Berthelot(s) and others, that this depends for absolute truth on a thorough knowledge of the rational constitution of a body, this need not prevent, until the progress of knowledge teaches us this, our use of approximative numbers. These we can obtain by the following scheme :—

21 C becomes 21 CO_4, carbonic acid.
3 C ,, 3 CO_2, carbonic oxide.
26—16 H ,, 5 H_2O_2, Water.

In this scheme the hydrogen is reduced to ten atoms, because there are already sixteen atoms of oxygen in the tissue, which may be supposed to have united with that element without increase of temperature. The calorific units employed are those of Andrews—viz., 7900 for carbon, 33,808 for hydrogen, and 2307 for the 1·2 per cent. of sulphur in albumen. We do not know experimentally how much heat is given out when carbon unites with oxygen to produce carbonic oxide; but as we do know how much the latter gives out on becoming carbonic acid, it is easy to calculate how much heat a gramme of carbon would evolve on becoming carbonic oxide. The unit of heat by this calculation would be 2227·7. It will now be convenient to ascertain by these numbers how much heat would be given out by the transformation of one ounce or 437·5 grains (t) (28·35 grammes) of tissue. A little calculation shows that this quantity would yield as much heat as would raise 126·5 kilogrammes of water 1° C. This, converted into its mechanical equivalent, gives :—

126·5 × 425 = 53,762 metre kilogrammes.

17. These numbers can easily be applied. Thus we have seen that a labourer receives 5·5 oz. (155·92 grammes) of flesh-formers in his food. The potential energy represented by this quantity is 295,691 metre kilos.; while the man's labour of raising his own weight one mile high per day is 109,496 metre kilos. But we have not yet deducted the amount of energy required for *opus vitale*, in which we include internal, dynamical, mental, and assimilative work. Concurring estimates of the force exerted by the heart have been made by Helmholtz (u) and Haughton. (v) The latter estimates it at 122 foot-tons, or 273,280 foot-pounds, which is more than one-third of the useful work done out of the body. Now, although the motion of the blood in the human body depends almost entirely upon the heart, there are at least indications in man, and clear evidences in plants, (w) and in the lower animals, that there are other movements in the system without any *vis a tergo* from an impelling body. If the heart do not use the energy placed at its disposal more economically than the conscious man does the amount with which he works, then it would require nearly one ounce, or exactly 1·20 oz. (theoretically, 0·702 oz. should suffice) of the plastic food. This is very nearly one-half of that which is required for subsistence. The two ounces of flesh-formers used in subsistence would yield by their transformation 253 units of heat, or a mechanical equivalent of 107,524 metre kilos., while the work of the heart is only 37,781 metre kilos. But in addition to the other dynamical work within the body, there is also included in this subsistence quantity both a limited amount of mental work and a full proportional of assimilative work. In the dynamical work, besides the cardiac movements, there are those of the respiratory apparatus, of the diaphragm, of the intestines, and of the arteries. All these in the aggregate represent a considerable, though numerically unknown, demand upon plastic food. And finally, we have the mental work, not considerable certainly in a man fed upon a minimum diet, but probably requiring a certain amount for the manifestations of mind to the material world. We cannot therefore be surprised to find that double the amount of energy necessary for the cardiac movements is supplied for the whole functions included in *opus vitale*.

18. The *opus mechanicum* or external dynamical work done by the body of a hard-worked labourer, is to be sought in the 3·5 ounces (99·2 grammes) of flesh-formers which remain after deducting the amount required for *opus vitale* from the total plastic food. But of this quantity one-twelfth appears in the alvine evacuation, without being formed into tissue, and the remainder yields 405 units of heat, or its mechanical equivalent of 172,125 metre kilos.; while the actual amount of useful work performed by the man is 109,496 metre kilos.

19. When we contrast the useful work of a steam-engine with the potential energy supplied to it, this economy of force on the part of the man must appear surprising. But even in the rough mode of calculation available to Scoresby and Joule, to Dumas and Helmholtz, before our knowledge of dietetics had enabled us to consider this question in a more precise way, the relative economy of the human machine excited their surprise. And yet our demand for economy is much greater than they supposed to be necessary, for we require that more than half of the potential energy should be converted into useful work.(x) It may be therefore necessary to adduce general arguments in support of the view that the dynamical action of the body depends wholly on the transformation of the tissues.

20. Nothing is better established in physiology than that muscular activity is dependent on a free supply of arterial blood to the muscles. When a ligature is applied to a large arterial trunk, the action of the voluntary muscles depending on that vessel is either wholly or partially arrested, at least until the collateral circulation is developed. Thus when the abdominal aorta is tied in animals, their hind legs can scarcely be dragged along (Segalus).(y) Such experiments only prove that a free supply of arterial blood to the muscle, to promote its transformation and to restore its waste, is necessary for the production of muscular action. Anything that interferes with the oxidising influence of the blood upon the substance of the muscle affects the power of movement. In the cerulean disease, when venous and arterial blood become mixed, the patient shows both indisposition and inability for muscular exertion. Like difficulty is observed in the thin air of mountain tops, until the lungs become suited to it. Certain substances which retard the oxidation of phosphorus or phosphuretted hydrogen, even in the presence of oxygen (Graham), such as ether and chloroform, seem to act in a like way on the tissues of an animal, by arresting muscular effort. The proof that there is diminished oxidation in such cases is found in the presence of sugar in the urine. The wayward gait of the drunkard under the influence of alcohol is probably the result of a similar obstacle to change.

Gustav von Liebig (z) has demonstrated that the oxidation of tissue is quite essential to muscular irritability, which ceases when the access of oxygen is prevented, and is again manifested when it is supplied. Scelkow's (a) experiments on the gases of the blood are particularly interesting in this point of view. Arterial blood contains 17 vols. of oxygen and is reduced to 8 vols. in coursing through a muscle at rest, and to between 1 and 2 vols. when the same muscle is in action, the volume of carbonic acid augmenting from 24 to 34½ at the same time. These experiments prove clearly that oxidation and contemporaneous production of carbonic acid attend the transformation of tissues, a fact which other physiologists had shown with less numerical precision formerly. Thus Matteucci,(b) in confirming the fact that muscular contraction is dependent on the presence of oxygen, showed that the evolution of carbonic acid is proportional to the amount of contraction, a result which has been confirmed by Valentin.(c) We need scarcely adduce proofs that the oxidation and production of carbonic acid proceed simultaneously in the substance of the tissue and not in the blood, for as long as the muscle is contractile, after it has been cut off from the blood, the

(s) Acad. de Science, January, 1865.

(t) The details of this calculation are as follows :—
One ounce of albumen contains—

Carbon	235·37	grains
Hydrogen	30·62	,,
Nitrogen	68 68	,,
Sulphur	5·25	,,
Oxygen	97·56	,,
	437·48	

This, treated according to the equation given :—

C.	201·75 ×	7,900	= 1,593,825
C.	33·62 ×	2,227·7	= 74,895
H.	8·05 ×	33,808	= 272,154
S.	5·25 ×	2,307	= 12,111
			1,052,985

$\frac{1,952,985}{1 \text{ kil.} = 15,432 \text{ grs.}} = 126{\cdot}5$ kilogramme units. To convert this into mechanical force :—

126·5 × 425 = 53,762 metre kilos.

same changes go on. Again, in insects which have no true blood, carbonic acid is produced by muscular activity (Newport.(d) Valentin (e) observed that when muscular contraction takes place a greater volume of oxygen is absorbed than of carbonic acid evolved, a result to be expected when we know that hydrogen is oxidised and urea is formed. Helmholtz attempted to follow the changes in a contracting muscle, and found evidence of increasing lactates, but could find no diminution in the fat contained in it, a fact of great significance, as we shall see hereafter. Brown-Séquard (f) by producing a circulation of arterial blood in the body of an animal which had assumed cadaveric rigidity, showed that muscular relaxation and contractility was restored and preserved for a long time, the blood issuing as venous; and he further proved that the elongated condition of muscles required the presence of oxidised blood. I have made experiments along with Mr. Turner, the Demonstrator of Anatomy in the University of Edinburgh, to ascertain whether oxygenated water (peroxide of hydrogen), or a solution of permanganate of potash, would cause relaxation in the muscles of rabbits after *rigor mortis* had set in, as Richardson found. In four rabbits these supplies of oxygen had no effect whatever, either in preventing the access of *rigor mortis* or in relaxing it. I believe, therefore, that this relaxation is not due merely to the oxidation of the muscle, but to its nutrition by the arterial blood, which feeds it while it removes the effete matter. It will be obvious from the tenor of my remarks, although I am unwilling to complicate the present question by a theory, that I agree with Draper (g) and others, in considering the contraction of a muscle due to a disintegration of its particles, and its relaxation to their restoration, agreeing also with Dr. Radcliffe (h) as to the active state of the relaxed muscle and the exhausted state of the contracted, without assenting, however, to his torpedo discharges as the causes of these states.

21. All these facts prove that transformation of the muscle through the agency of oxygen is the condition of muscular action. Most likely intermediate products are formed before the final forms of carbonic acid and urea are reached. If these graduated changes take place in the muscle itself, the same amount of potential energy will be available as would be if the simplest forms of oxidation were reached at a bound. If lactic acid be the intermediate product of oxidation before carbonic acid, its passage into the latter must be very rapid, for that is continually eliminated from a muscle during its action. And if we thus constantly find that carbonic acid, the highest oxidised form of carbon, is manifested in the substance of muscle during its activity, it is certainly to be expected that the less oxidised form of amido-carbonic acid should be simultaneously produced. In those cases of disease where elimination of urea is retarded, it is found abundantly in the muscles. Thus, in cholera, especially in the muscles which have been severely cramped, urea is detected with ease. In this disease there is a small amount of chloride of sodium in the blood, and its solvent action on the urea is thus reduced. In uræmia, also, it can readily be extracted from muscular substance.(i) Although in the muscles of certain kinds of fish, as in the *Plagcostomata* (Frierichs and Städeler), urea may be always found, yet Liebig (k) searched for it in vain in the muscles of healthy mammals. Yet this is not surprising when we consider how long search was made for urea in the blood without success. Although the blood contains the sum of the urea of all the transformations proceeding throughout the body, yet as Marchand (l) has shown, the quantity of it which can exist in the blood at any one time is so small that it may readily escape detection. If this be true in regard to blood, it is *à fortiori* true in respect to flesh from which the blood is rapidly removing waste matter in the process of the reparation of the exhausted muscle. It may be possible that creatin(m) is intermediate between tissue and urea, but this is a pure speculation; for although we are acquainted with process by which it can be split into sarkosin and urea, we know of no simple oxidation which will effect this change. Let us inquire how much urea we may expect to find in flesh in a given time, and it will not appear wonderful that it has escaped detection even in the skilled hands of Liebig. In an adult man, 520 grains of urea are secreted in twenty-four hours; hence in one hour $\frac{520}{24} = 22$ grains. Now, although we know that blood is incessantly and promptly removing waste material from the muscles, let us suppose that a quarter of an hour elapses without any of it being taken up, and that the man is killed at this period. Distributed through all the muscles of his body, there would be about 5 grains of urea; and in 10 lbs. weight of fresh flesh, the quantity operated upon by Liebig, there could not be more than 0·4 grains of urea, or 0·026 gramme. In this estimation we take the weight of fresh flesh at 1800 ounces. In our present state of analysis for urea this small quantity could not be detected.

22. In considering the origin of energy in the muscles, one of three sources is alone conceivable—(1.) The energy might arise in the circulating fluid itself; or, (2.) The oxygen of the blood might consume the fat deposited in the muscle; or (3.) The substance of the muscle must be transformed to provide the energy.(n)

We have already (§ 20) shown that the changes which take place in muscle during contraction occur in its substance, and not in the circulating fluid of the capillaries, for irritability continues for a considerable time after the blood has been cut off; and we might here recall the well-known fact, that in spite of a larger quantity of oxygen being taken into the lungs than of carbonic acid evolved, and consequently a necessary evolution of latent heat, the blood of the left side of the heart is 0·2 degrees cooler than that of the right side, showing that oxidation of material is not largely effected during aëration of the blood. We may therefore proceed to the second possible source of energy—the combustion of the fat in the substance of muscle.

23. The usual function of fat is unquestionably, like that of starch or of sugar, to keep up the heat of the animal. When they have served this purpose their physiological work is completed, and the *opus calorificum* cannot be changed into *opus mechanicum*, for that must be due to converted heat, or to force, which has never assumed that form. We know that all the fat and starch in food is required to account for the animal heat, because it has always been a difficulty to reconcile the experimental heat actually generated by an animal with the amount available in the food-fuel supplied to it. In fact, until the researches of Andrews, and of Favre and Silberman, gave to us higher calorific values for hydrogen and carbon than formerly, there was no possibility of accounting for the heat actually given out by animals in the experiments of Dulong.(o) And even with these increased coefficients, we require the combustion of all the non-nitrogenous constituents of food to enable us to account for animal heat. But although this is the case, we must bear in mind that only a small quantity of converted heat is theoretically necessary for mechanical work. The energy available in 22 oz. of a starch equivalent of fuel, consumed by a healthy man, would correspond to 2187 kil. units of heat; while the transformation of the muscles of that man, required for mechanical force, yields about 543 kil. units. Although nearly one-half of the latter is spent in internal dynamical work, and passes into heat within the body, still we cannot afford to subtract any of the available work from the heat-givers. Taking it in round numbers, we have 2500 kil. units of heat available from them and converted vital work, and 2700 kil. units are required, according to the estimate of Helmholtz, to account for evaporation, heating of the ingesta, and radiation. The

(n) We do not consider it necessary in the present state of science to present a fourth alternative of the origin of the energy from "nervous force." Some old experiments of Matteucci are still, however, constantly quoted in support of this view. He says ("Phys. Phen. of Living Beings," p. 325) that the chemical action of three milligrammes of zinc, oxidating and converted into nervous force, in a frog, produced a muscular power equal to 5·419 metre kilos. But the current emanating from the zinc could only have exercised a directive action on the muscle which it affected. The total energy derivable from the zinc can be found as follows:—

$$\left(\frac{003 \times 1301}{1000}\right) \times 420 = 1{\cdot}64 \text{ metre kilos.}$$

Deducting this from 5·42, actually got in the experiment, 3·78 metre kilos. of work must have been obtained from some other source of energy beyond the zinc. There is no other source than the substance of the muscle itself. So long as a muscle is alive and in contact with oxygen it can contract under electrical excitement, and the difference between the work which could be done by the exciting force and the useful work obtained, must be the measure of the energy rendered available by the structural and molecular change of the muscle itself. In a later memoir (*Phil. Trans.*, 1857), Matteucci compares the exciting current to the spark which ignites gunpowder, and would seem to have abandoned his former ideas.

(o) Berl. Med. Ency. art., "Thierische Warme;" compare also Fick, Med. Physik. S. 175, *et seq.*

diversion, therefore, of the ordinary ingredients of food, whose proper function is *opus calorificum*, to the production of *opus mechanicum*, is not probable from *à priori* considerations. But it is nevertheless a fact that fat is always present in healthy muscle, and it is desirable to consider its relation to muscular action.

24. The experiments made by Bidder and Schmidt(p) on starving cats, and by Bischof and Voit on a starving dog,(q) throw light on this subject. From these we learn that during the whole course of starvation fat disappears from the muscle in a regular manner, while there is no such regularity as to the waste of the tissues. The amount of urea falls to one-half in two days; then remains constant for a week, falling again rapidly and considerably two days previous to death; during all this time the daily waste of fat remains nearly constant. Nor is there anything surprising in this difference. As the animal becomes weaker, the internal dynamical or vital motions decrease, and their representative in the urine naturally falls. But the fat continues to burn in the living lamp as steadily as the lungs afford to it oxygen.

When Bischof and Voit supplied their starving dog with fat, the waste of the body, as evidenced by the lessened amount of urea secreted, was diminished, because the fat supported the respiration, which before had partially to depend on wasting tissues. The fat cast over them a protective influence, and limited their waste to the support of their own dynamic functions. And in this fact would seem to be the use of fat after it is stored up in the muscle. We allude to its chemical use; for its mechanical advantage in lessening friction, and its possible histogenetic employment in the formation of cells, are not under consideration. Fat does not form a portion of an organ, for ether can extract it without any lesion of the organic structure. In wild animals the muscular fat is present in only small proportion—not exceeding 2 per cent. of the muscle. In the muscle of an active man the fat amounts to 2·2 per cent. A man in ordinary health and activity wastes daily 1750 grains of dry flesh, or 7000 grains of fresh muscle, which would contain 150 grains of fat. The total amount of heat which this quantity could yield by its combustion is 87 kil. units, while the flesh in which it resides would give by its transformation about 506 kil. units. We need not, therefore, look for the source of potential energy in a minor when we have a major source quite sufficient to account for it. The human heart weighs, on an average, 9·4 oz., and contains, according to Böttcher, a mean of 1·7 per cent. of fat. On the extravagant supposition, in § 18, that it destroys more than half its substance daily in movements, it would use 147·7 grammes, containing 2·5 grammes of fat. This quantity could, by its combustion, give 23·9 kil. units of heat, or 10,157 metre kil. of mechanical force. But we have shown that the useful work of the heart is 37,780 metre kils. So that the fat cannot account for the work performed. In these calculations we refer to fat distributed in and inherent to healthy muscle, and not to masses of fat in adipose tissue, such as we find in fattened animals or obese men, for no one pretends that such separate fat can be the cause of movement in any other sense than that starch, sugar, or other body extraneous to the muscle, may, by some unknown or inconceivable method, have this force transformed from *opus calorificum* to *opus mechanicum*. The chemical use of fat deposited within the muscle may be to protect it from the assaults of oxygen during its repose. A muscle, even at rest, gives out carbonic acid, which is no doubt partly due to the oxidation of its effete particles, but also to the oxidation of fat. The conception that the latter is the source of muscular action can only have arisen from the false analogy of the animal body to a steam-engine. But incessant transformation of the acting parts of the animal machine forms the condition for its action, while in the case of the steam-engine, it is transformation of fuel external to the machine which causes it to move.

25. From the considerations which have preceded, we consider Liebig amply justified in viewing the non-nitrogenous portions of food as mere heat-givers. They never can act vicariously for albuminous bodies as tissue-formers, although tissues may and do evolve heat by transformation when required to do so. That heat-givers do operate indirectly on the waste of tissues cannot be questioned. They facilitate transformation by keeping up animal heat and by the promotion of circulation. Cold-blooded reptiles become more active when artificial warmth is supplied to them, and conversely, warm-blooded mammals become more sluggish when the heat of their bodies falls, as during hibernation. Such dependencies of different groups of food, acting co-ordinately, are incessantly found, but nevertheless each group has its own specific work to perform.

26. While we have been led to the conclusion that the transformation of the tissues is the source of dynamical power in the animal, we have yet to examine whether the appearance of heat, and electro-motive force current in the muscles, may not be evolved from, and thus absorb the force on which we have relied. The muscle during contraction is certainly hotter than at rest, about 0·5° C. warmer, according to Becquerel and Brechet. In fever, the temperature of the muscles rises sometimes to 40° or 41° C., and in tetanus to 44° C. (Ludwig); while Fick has shown that in these cases the muscles are hotter than the circulating blood. But the experiments have been made when the waste of tissue is not producing useful work, and must therefore necessarily pass into heat. Beclard (r) found, in fact, that the heat developed in a muscle is in inverse ratio to the mechanical effects produced; for example, in trying to raise insuperable weights, more heat is evolved than in lifting lighter weights. Hirn(s) also ascertained, by direct experiment on a treadmill, that less heat is evolved for each gramme of oxygen taken into the body when hard work is done outside the body. In fact, the heat developed in muscles, when not due to the combustion of fat, is probably only the result of lost work, just as we find that the electro-motive force disappears almost entirely during the active work of a muscle or nerve (t) (Du Bois Ramond). Even with the wonderful economy of force which the animal as a machine exhibits, we cannot be surprised that some of the lost work is manifested in the forms of heat and electricity. We know, for instance, that all the potential energy rendered available for internal dynamical work must assume ultimately these forms.

ORIGINAL COMMUNICATIONS.

ON A

SIMPLE METHOD OF TREATING CERTAIN KINDS OF EPILEPSY, DEMENTIA, AND OTHER CHRONIC HEAD-AFFECTIONS.

By THOMAS LAYCOCK, M.D., etc.,

Professor of the Practice of Medicine and of Clinical Medicine, and Lecturer on Medical Psychology and Mental Diseases in the University of Edinburgh.

(Continued from page 464.)

2. Headaches and Delirium.

Hemicrania may also be relieved by these means. This kind of headache, known as sick headache, *migraine*, the *megrims*, seems to be rather a neuralgia of the cranium, or dura mater, or the scalp than of the encephalon, when it occurs in its simple paroxysmal form unassociated with any structural disease of those parts. Some difference of opinion is expressed as to its nature, but there seems little doubt that it is of vascular origin, for the chief characteristic is the intensely painful throbbings of the temporal and other arteries, aggravated by any movement. That it is also centric seems probable from the symmetrical distribution of the pain and from the concurrent affection of the stomach, in which there is often the production of an intensely acid fluid as well as nausea and vomiting. Dr. Brown-Séquard thinks the symptoms affecting the face, ear, and eye indicate a palsy and not an irritation of the sympathetic or vaso-motor nerves. Prof. Du Bois-Reymond (who has published his own case) is of opinion, on the contrary, that there is a sort of tetanic contraction of the blood-vessels from irritation of the sympathetic system. But neither palsy nor contraction explains the distressing *pain*, for both conditions of the vessels notoriously occur without any pain whatever. It is, therefore, a sensory and not a purely motor affection of the nervous system. Now, I have found that the smelling of strong smelling salts or liquor of ammonia far more certainly alleviates, and even cures, than ammonia and other stimulants taken internally. Some of these, indeed,

make matters worse by exciting vomiting when the head feels to split at every strain on the stomach. I therefore think the action of the irritant is directly on the medulla oblongata.

In hallucinations and delirium the mental disorder seems to be proximately due to a loss of that co-ordination of the various encephalic centres engaged in perception and thought upon which the unity of consciousness depends. It therefore seemed to me to be *à priori* probable that the same class of means which co-ordinate motor centres when disordered would restore the balance of the sensorial centres. I have long demonstrated this to my clinical class as to delirium when opportunity served. It not unfrequently happens that a delirious patient cannot be got to take his medicine or attend rationally to things necessary for his benefit. Now, irritating the nostrils will often serve to recal the patient, temporarily at least, to reason, so that time is given for the administration of the dose or for other matters. In like manner, when a patient awakes out of sleep in a state half way between delirium and hallucination, this very simple means will be found more available than shouting to him, shaking him, or the like.

3.—Chronic Mental Defects and Dementia.

The results of nasal irritation in relieving the hebitude of the epileptic suggests its application to states of mental apathy and torpor in which it is reasonable to conclude that there is defective nutrition and circulation of the encephalon, whether with or without defective co-ordination. I subjoin a case of mental torpor, in which the helleborised cinchona(a) seemed to have a singularly rapid effect, together with the particulars of the morbid changes discovered after death. I am indebted to my friend, Dr. Herbert Taylor, of New Barnet, formerly one of my clinical clerks, for the details:—

Case of Apathy and Somnolency Consecutive to a Blow over the Occiput, Successfully Treated by a Sternutatory—Death Five Months Subsequently—Deposit over the Commissure of the Cerebellum.

Mark S., a coachman, aged about 40, was admitted October 10, 1863, into the "Skin Ward," or Ward 2 of the Clinic of the Edinburgh Royal Infirmary, under the care of Dr. Laycock, suffering from extensive scabies, especially severe about the nates. This was speedily cured, and he was about to be discharged, when Dr. Laycock's attention was called to the circumstance that, except at visit (when he was roused up), the patient was constantly in an apathetic, sleepy state, although quite intelligent when spoken to. This was diagnosed as due to a morbid cerebral condition, the consequence of a blow upon the occiput. A dose of a sternutatory powder was ordered to be taken three times a day; each dose excited sneezing for several minutes, and in a few days the apathy was cured. No particulars were recorded at the time, but in March, 1864, the patient was again admitted into the Infirmary, under Dr. Laycock, when the following history was obtained from him:

Patient states that he has been always a healthy man. When 19 years of age had gonorrhœa; but he stoutly denies any attack of syphilis. He was never a drunkard, and for the last ten years has been a total abstainer. Five years ago, however, while engaged as a stoker on a railway engine, he fell from off the engine, and struck his head about the occipital protuberance against a metal plate. The engine was stationary at the time. He was unconscious in consequence, and remained so for four or five days, but was shortly afterwards able to resume his work. Ever since, at the spot struck, he has "off and on" experienced uneasiness, which seldom amounted to pain. He is now constantly giddy; and the least sudden movement, such as looking up quickly or abruptly stooping, increases this sensation of giddiness. His own expression is, he feels like a drunken man, unable to keep his feet. This condition has increased up to the present time. The drowsiness which annoyed him before the treatment in October was then entirely removed, and he has had no return of it since. Since leaving the Hospital, the head-symptoms have increased, and during the last six weeks his memory has become shorter; although ever since his fall it has been somewhat impaired, and never was very good. Patient was found to suffer from aneurism of the arch of aorta on his second admission to the Hospital; and of this, with other complications, he died on March 28, 1864. Examination of the brain and membranes revealed the following appearances:—Dura mater thickened, and Pacchionian bodies numerous; convolutions of cerebrum not flattened, or, at all events, but little; a good deal of sub-arachnoid fluid; but vessels on the surface not particularly congested. Pia mater distinctly opaque and thickened. Section: "Red points" more numerous than they ought to be; consistence of brain substance not altered; cortical portion rather paler than natural; lateral ventricles contain more fluid than they should—serous in kind; choroid plexus of right side very pale; on membranes covering pons Varolii are seen little deposits, whitish in colour, opaque, and clustered together, the membrane at this point and around being thickened.

Comment.—The patient died of spurious aneurism of the aorta, which ulcerated into the trachea and stretched to paresis and finally to paralysis the vagus and recurrent nerves. The deposits on the membranes covering the pons and the thickening thereof might be reasonably supposed to so far influence the functions of the crura cerebelli and their commissure as to interfere with the locomotive functions of the cerebellum; hence the staggering, etc. Probably the vaso-motor functions were involved in the apathy and drowsiness.

I have tried sternutatories in cases of insanity with general palsy, but with no beneficial result. They were all such that degeneration of the cerebral vessels was probably the proximate cause; and I should hardly expect much benefit from excitement of nutrition and of the circulation in this kind of mental hebitude. But that there are various forms of insanity and dementia which a permanent excitation or modification of the cerebral circulation and nutrition artificially induced by this kind of treatment would cure or relieve, seems fairly deducible from various cases in which improvement has originated spontaneously. Dr. Skae mentions instructive examples in his report of the Royal Edinburgh Asylum for 1859. A patient who had been ten years in the institution, and in a very imbecile state, appeared to be remarkably sensible for two days before his death. In two cases of chronic mania there was also a remarkable interval of sanity extending to several hours, which occurred immediately before a fatal apoplectic seizure. This illustrates the nature of the cerebral change to which the change in the mental state is due. In persons predisposed to apoplexy an analogous condition is sometimes seen. After suffering from various head symptoms, they go to bed, feeling better than they have felt for a long time, and during the night have a fit. Perhaps the most striking example of this kind of change in dementia is recorded by Dr. Skae:—"A lady, whose residence extends to forty-six years, was lately seized with an illness which threatens to be her last. She has not been known, in the memory of the oldest officer or servant, to answer a question or to speak at all, except to swear or talk to herself incoherently while being undressed. On recovering from the immediate effects of the invasion of this illness, she conversed very coherently, asked a portion of the Bible to be read to her, and mentioned the chapter she preferred. She named parties connected with the Asylum twenty years ago, and spoke intelligently of events previous to that period, but seemed quite ignorant of any of the present officers." (Report, 1859, p. 29.) The therapeutic problem for solution is—how to induce artificially that change in the encephalon which in these cases follows upon disease? I think excitation of the cerebellum and medulla oblongata is the chief point to be aimed at, so as to induce at once both a better co-ordination of the encephalic centres and an increased activity of circulation and nutrition. In cases of so-called hysterical palsy the effect of emotional changes in this way is often very striking; and even in other cases of a more organic kind they are powerfully curative. I knew a gentleman suffering from hopeless paraplegia, believed to be dependent on cerebellar disease, who rose from his chair and walked freely under the influence of a painful hallucination. Febrile diseases, such as scarlatina or measles, occurring to the insane sometimes restore them to sanity, during at least the course of the fever. My friend, Dr. Rorie, of the Dundee Asylum, mentions the case of an aged female, the subject of recurrent mania, who was restored to reason in proportion as a disease of the liver advanced, and which finally caused death. The restoration of reason in acute head-affections for a few hours before death is not at all uncommon, and is, indeed, prognostic of a fatal issue. How, then, can we induce similar changes therapeutically, so as to secure their permanent curative effect? In all these instances there is probably at first an increased activity of the encephalic circulation, due to that kind of change in the vessels which follows upon lesion of the cervical sympathetic, together with an evolution of heat. It would be hardly possible to act upon that system directly, but perhaps drugs may be discovered which have indirectly this effect. At present we are too

(a) This powder is composed of ten grains of powdered white hellebore and sixty grains of powdered cinchona. In the first part of this communication the proportion of the latter is erroneously put at ʒss.

much in the dark as to the action of opium, strychnine, and the like, on the cerebral circulation to use them rationally. Excitation of the nerve-centres directly may be, however, available, and the means thereto are very various. Thus I have found that the stimulus of a cold douche to the face has instantly removed defective co-ordination in melancholia, and relieved a patient from depressing delusions; and nothing in these cases is so exhilarating as breathing cold air. Some curious illustrations of the tonic effects of cold on the nervous system have been lately published by my friend, Mr. Roberton, of Manchester, in the form of eases of child-crowing in infants cured by exposure of them to a cold dry wind.(b) So important is this remedy in certain forms of melancholia and dementia, that I believe the cure of such cases is hopeless in the crowded dormitories and wards of Asylums. Local excitation through the skin, nostrils, and lungs, of the encephalic centres, conjoined with a rational treatment in other respects, may do much; and perhaps we may yet discover drugs or other means by which we can excite artificially that encephalic condition which is sometimes so curative in apparently the most hopeless eases as to the merely mental states.

Should any of your readers try the means recommended above they would oblige me much by eommunicating with me.

Rutland-street, Edinburgh.

ON THE RAPIDITY OF THE PASSAGE OF CRYSTALLOID SUBSTANCES INTO THE VASCULAR AND NON-VASCULAR TEXTURES OF THE BODY.(c)

By HENRY BENCE JONES, M.D., F.R.S.

Dear Dr. Sharpey,—I am anxious that you should read to the Royal Society a short note containing the results of some observations I have lately made on the rapidity of the passage of crystalloid substances into the vascular and non-vaseular textures of the body.

It occurred to me that it might be possible to trace the passage of substanees from the blood into the textures of the body by means of the spectrum-analysis, and with the assistance of Dr. Dupré some very remarkable results have been obtained.

Guinea-pigs have chiefly been used for the experiments. Usually no lithium can be found in any part of their bodies. When half a grain of chloride of lithium was given to a guinea-pig for three successive days, lithium appeared in every tissue of the body. Even in the non-vascular textures, as the cartilages, the cornea, the crystalline lens, lithium could be found.

Two animals of the same size and age were taken; one was given three grains of chloride of lithium, and it was killed in eight hours; another had no lithium; it was also killed, and when the whole lens was burnt at once no trace of lithium could be found. In the other which had taken lithium, a piece of the lens, $\frac{1}{20}$th of a pin's head in size, showed the lithium; it had penetrated to the centre of the lens.

In another pig the same quantity of chloride of lithium was given, and in four hours even the centre of the lens contained lithium.

Another pig was given the same quantity, and it was killed in two hours and a quarter. The cartilage of the hip showed lithium faintly, but distinctly. The outer portions of the lens showed it slightly; the inner portions showed no trace.

To a younger pig the same quantity was given, and it was killed in thirty-two minutes. Lithium was found in the cartilage of the hip; in the aqueous humour; distinctly in the outer part of the lens, and very faintly in the inner part.

In an older and larger pig, to which the same quantity was given, lithium after one hour was found in the hip and knee-joints very faintly; in the aqueous humour of the eye very distinctly; but none was found in the lens, not even when half was taken for one trial.

Chloride of rubidium in a three-grain dose was not satisfactorily detected anywhere. When twenty grains had been taken, the blood, liver, and kidney showed this substance; the lens when burnt all at once showed the smallest possible trace; the cartilages and aqueous humour showed none, probably because the delicacy of the spectrum-analysis for rubidium is very much less than that for lithium.

A patient who was suffering from diseased heart took some lithia-water containing fifteen grains of citrate of lithia thirty-six hours before her death, and the same quantity six hours before death. The crystalline lens, the blood, and the cartilage of one joint were examined for lithium: in the cartilage it was found very distinctly; in the blood exceedingly faintly; and when the entire lens was taken, the faintest possible indications of lithium were obtained.

Another patient took lithia-water eontaining ten grains of earbonate of lithia five hours and a half before death: the lens showed very faint traces of lithium when half the substance was taken for one examination; the cartilage showed lithium very distinctly.

I expect to be able to find lithium in the lens after operation for cataract, and in the umbilical cord after the birth of the fœtus.

I am yours truly,

H. Bence Jones.

A patient of Mr. Bowman's with a double cataract was given lithia-water with twenty grains of carbonate of lithia seven hours before the operation on one lens. Lithia was present in each particle of it. After seven days the other lens was examined, and no trace of lithia could be found in it.

ON SOME OF THE

MORE FREQUENT COMPLICATIONS OF INTERNAL HÆMORRHOIDS.

By W. ALLINGHAM, F.R.C.S.,

Surgeon to the Great Northern Hospital; Assistant-Surgeon to St. Mark's Hospital for Diseases of the Rectum.

There are few operations which can offer a more satisfactory result, both to the patient and the Surgeon, than the removal of internal hæmorrhoids; and, paradoxical as it may appear, the worst cases generally do best, the relief afforded being more marked, and a recurrence of the disease much less frequent. But there are eases we see every now and then which do not by any means turn out so well, unless their nature is thoroughly understood and the proper treatment adopted; and these are the cases to which I wish, in a few words, to call attention.

One of the most frequent complications of internal hæmorrhoids is fissure. When examining a ease of piles, I always inquire whether the patient has pain in passing a motion, or after doing so. If these questions are answered in the affirmative, I expect to find a fissure or small ulcer, and I am rarely deceived. Simple cases of hæmorrhoids are not attended with pain; there may be a fulness and discomfort, with some smarting at the time of defeeation, but eertainly not pain.

A very careful examination is needed to deteet a small fissure when it is conjoined with hæmorrhoids, for frequently a hæmorrhoidal tumour will overlap the fissure, and so conceal it as almost to defy detection, unless the investigation be conducted with certain precautions.

Before proceeding to an examination to determine the operation required, the patient should have the bowels thoroughly cleared out by an aperient and a copious warm water injection; the part should then be protruded by straining over hot water, if the injection has not sufficiently accomplished it. Each pile should be examined, and separated from its neighbour, to see if any fissure or ulcer exists between them; then the finger should be passed into the rectum, to ascertain the condition of the mucous membrane, and to see that there is no ulceration or stricture above the hæmorrhoids.

Frequently one is led to discover the whereabouts of the fissure by observing one or two little papillæ of muco-cutaneous structure, which grow at its margins. When a fissure is found, be careful to see that no polypus co-exists, for if it does, and the fissure be divided, the polypus being left, the wound will certainly not heal. To effect a cure, the polypus must be removed at the time of operating for the fissure. We frequently learn more by our failures than by our successful cases. A young woman was operated upon by me for fissure, and apparently with success. However, six or seven weeks after the operation she returned complaining of the old pain, and, on examination, I found the wound had not healed. This led to a further and more careful search, resulting in the discovery of a polypus at the upper end of the wound. I, therefore, removed it, re-incised the fissure, and she got rapidly well. In operations where you have to divide a fissure as well as ligature piles, there is more tendency to hæmorrhage than in simple cases. Possibly the division of the sphincter may in

some measure account for this. Be that as it may, it is a practical point that these patients should always be watched with extra vigilance.

Sometimes it is a small ulcer with thickened edges which complicates hæmorrhoids. To this most of my previous observations respecting fissure will also apply. Occasionally these ulcers are of syphilitic origin. I have now under my care two cases of hæmorrhoids in which syphilitic ulcers exist. Here, I think, it is better to wait until the ulceration is cured, or nearly so, before proceeding to operate upon the hæmorrhoids.

Fistula in conjunction with hæmorrhoids is not so common as fissure, although by no means an infrequent complication. My colleague, Mr. Lane, and myself operated on the same day at St. Mark's Hospital on two cases of this description only a few weeks ago. If the fistula be well marked, there is no difficulty in the diagnosis, but if it be of the blind internal variety, or the external orifice be very small, it may be overlooked by any one not very conversant with rectal disease or not exceedingly careful. Such a case I saw a couple of months since, and I have at various times met with several examples of this oversight.

A gentleman came to me and stated that three months before he had been operated upon for internal piles. He had done very well after the operation, and had been pronounced cured, but he still had occasional throbbing and pain, particularly on passing a motion. There was also a constantly-recurring discharge, which stained his linen; it might cease for a day or two, but then returned. He had consulted the gentleman who operated upon him, and had been told that he was only suffering from a little weakness of the bowel, which would right itself soon. Of this, however, the patient could not feel convinced. The frequent discharge and soiling of his linen gave him the greatest concern, and worried him to a degree which seemed almost absurd and quite disproportioned to the gravity of his case. And this I have often observed in patients of the better class, while the majority of Hospital patients think nothing of a rectal discharge unless it is attended with pain or is very copious. On a careful examination of this case, I detected just at the very verge of the anus, and concealed between two of the natural folds of skin, a very small orifice. A fine probe passed into it, and through a short sinus not quite three-quarters of an inch long, into the bowel. Here was an explanation of the whole matter. From the history of the case, there was no doubt that this slight fistula existed with the hæmorrhoids, but the major malady masked the minor one, and so it had escaped detection. I divided the fistula, and in a week the patient was perfectly well and cured of his annoying discharge.

Before operating for piles, be certain that no stricture of the rectum exists. I saw a patient a few days ago at St. Mark's who had been operated upon in one of our London Hospitals for hæmorrhoids only six or seven weeks ago, and had been rendered worse rather than better by the operation. On examining him, I found extensive ulceration and stricture, commencing about an inch and a-half up the rectum, and extending higher than the finger could reach. This was evidently of long standing, and the patient's history clearly showed that he had been suffering from stricture and ulceration for at least eighteen months or two years.

It can scarcely be necessary to observe that these are cases which do not admit of any operative interference. It is well to remember when we have discovered the presence of a disease in an organ that we have still something more to do in the way of diagnosis—viz., to determine whether any other malady co-exists.

In the above observations I have purposely avoided noticing the methods of treating the complications I have described, as I intend in a future paper to enter fully into that part of the subject.

The Jubilee of the Vienna University. — The University Consistorium has averted the disgrace which would have attached to this body had Virchow's name been omitted from the list of those upon whom honorary diplomas are to be conferred. The list at present comprises twenty-four names—viz., Baer, Baum, Baumgartner, Dubois-Reymond, Bruns, Bunsen, Carus, Chelius, Donders, Frerichs, Graefe, Helmholtz, Langenbeck, Liebig, Middeldorpff, Mitscherlich, Pettenkofer, Purkinje, Reichert, Ruete, Scanzoni, Schönbein, Virchow, and Weber—a galaxy of talent of which Germany may well be proud!

REPORTS OF HOSPITAL PRACTICE
IN
MEDICINE AND SURGERY.

SAMARITAN HOSPITAL.

CASES OF OVARIOTOMY.

(Under the care of Mr. SPENCER WELLS.)

Continued from page 467.)

Case 3.—Adherent Multilocular Cyst—Four Tappings—Ovariotomy—Death on the Fourth Day.

In October, 1864, a married sterile woman, 50 years of age, came from Leeds to consult Mr. Wells by the advice of Dr. Braithwaite. Her habits were very sedentary; she was rather fat, and had a brownish complexion. Her feet were habitually cold; she always perspired freely about four o'clock in the morning. The appetite was tolerably good; her bowels regular. She was prevented from sleeping by a fixed pain in her right side; she had a slight cough, which had lasted two months, but there was nothing wrong with the chest; she habitually slept on the right side. Her pulse was 100; there was no bruit, but the sounds of the heart were very feeble, and there was a suspicion of fatty heart. The urine contained no albumen; its specific gravity was 1012; thirty-six ounces were passed daily; it usually contained much urates and mucus. The girth at the umbilical level was 40½ inches, the distance from the umbilicus to the ensiform cartilage 9½ inches, to the symphisis pubis 8 inches, and to either ilium 9½ inches. The liver and spleen were in their normal position. The whole abdomen was filled with a tumour which reached as high as the epigastrium. Fluctuation was distinctly perceptible in that portion of the tumour which was above the umbilical level, less so in the portion beneath that level. The parietes were of the normal thickness; there were numerous lineæ albicantes. The right loin was clearer than the left on percussion. No pain nor tenderness on pressure was felt, except in the right iliac and lumbar region. The ribs were slightly pushed outwards. There had been no catamenial discharge for two and a-half years; there was no leucorrhœa. The uterus was central and mobile. The os was large, and unusually patent, considering that the patient has never been pregnant. No hereditary predisposition to disease could be traced. When 20 years old the patient suffered from amenorrhœa and palpitation, and for the last seven years she had been subject to headache. Three years before Mr. Wells saw her, she felt a dragging at the navel, with a "pressure forwards," and at the same time observed that her size was increasing. Up to Christmas, 1863, she increased in size without discovering a distinct tumour. She observed, however, that the swelling was confined to the lower part of the belly, just as if she had been in the family-way. At Christmas, 1863, she had a great deal of pain for five days, at the end of which time the swelling had disappeared. In about a month's time it began again to be visible, springing up from below and in the mesian line, though, perhaps, slightly inclined to the right side. The swelling increased more and more rapidly. During the three months immediately previous to her first seeing Mr. Wells, the tumour had doubled its size. His diagnosis was "Multilocular cyst behind uterus, not attached there." The patient not being anxious for ovariotomy, he tapped and removed sixteen pints of whitish opaque fluid, whose colour was due to the presence of fat.

The patient was discharged on October 19, having recovered well from the tapping. On December 9 she wrote to say that she was suffering much from her tumour, and was very anxious to have it removed. It was arranged that she should come to London, but she was at that time so unwell that she could not bear the journey. On December 14, Mr. Braithwaite tapped and reported, "After tapping the second time, the tumour fell down low in the abdomen, so that there were probably not yet any adhesions at the upper part; liquid extremely thin, almost like water, but rather 'milky.'"

The patient was readmitted into the Samaritan Hospital on December 27, 1864. On the 9th of January, 1865, as the general health was not satisfactory, Mr. Wells removed fifteen and a-half pints of opalescent, excessively fœtid fluid, full of pus corpuscles. A part of the tumour appeared to adhere behind the left false ribs. On account of the fœtor of the fluid, Mr. Wells, after emptying the cyst, threw a little tincture of

iodine into it. The pulse remained feeble for several days; so quinine was given, and the patient went to Eastbourne. She returned to the Hospital on February 1. She appeared in better general health than before, but was beginning to suffer from distension; and on February 6, there being much heat of the skin and tenderness over the upper part of the cyst, Mr. Wells tapped again and removed fourteen and a-half pints of whitish, curdy fluid, not at all fœtid. This relieved her much; it was thought that ovariotomy might be performed, and Mr. Wells operated on February 23, Dr. Reinhardt, of Munich, Dr. Playfair, etc., being present. Dr. Parson gave chloroform. The incision was begun an inch below the umbilicus, and was carried downwards five to six inches through a very thick layer of fat and œdematous cellular tissue. Two veins were compressed to stop bleeding. There were extensive adhesions in front, but they yielded easily to the hand; on separating them near the scars of tapping the cyst wall gave way, and some ovarian fluid escaped in the peritoneal cavity. The tumour was easily withdrawn, a large piece of omentum being separated from its upper portion; the pedicle was slender—three to four inches long—and sprang from the left side of the uterus, which was globular, and at least twice as large as natural. The pedicle was fixed in a medium sized clamp, and kept out without difficulty; the right ovary was healthy. A good deal of peritoneal sponging was necessary. The wound was closed with silk sutures, deep and superficial. The patient rallied well, but required a good deal of laudanum; 110 drops were given in the six hours following the operation. She passed an excellent night; there was no sickness, and no more opium required. The pulse was 108; the skin moist; the urine full of urates. During the second night there was some pain, and twice there was bilious vomiting. At 10 in the morning on the second day the pulse was 116; the aspect cheerful; the tongue coated with yellowish mucus; the urine loaded with lithates; at night the pulse rose to 120. On the third day there was occasional vomiting of greenish mucus; the pulse was 108; the clamp and stump were quite dry. Mr. Wells removed one deep stitch and changed the plaster. The tongue was cleaner; the urine rather less loaded; pain began in the abdomen in the afternoon, and at night vomiting became frequent.

At 5 a.m. on the morning of the fourth day the pulse was 140, the respiration 20, the urine scanty, the belly tympanitic. Stimulants were freely given. At 8.30 the pupils were closely contracted, the urine almost suppressed, the pulse scarcely perceptible. A long tube was introduced into the rectum, but nothing came through it. The patient died ninety-five hours after the operation.

At the post-mortem examination the body appeared rather fat; the abdomen distended; the pedicle well secured; the wound partially united—the inner as well as the outer surfaces well approximated. The peritoneal edges were so well united that the stitches could not be seen. The whole descending colon was empty and spasmodically contracted, and the small intestines were slightly inflamed, and were distended with flatus. There was little serum in the peritoneum. The opposite ovary was normal; the uterus large, its cavity not elongated; a small mucous polypus in the cavity of the cervix. In the fundus uteri was a fibroid tumour as large as a child's fist. The liver was large and very fatty; spleen very small; kidneys pale and flabby; lungs normal. The heart was very thin, fat, pale, and dilated, left ventricle scarcely thicker than right; some dark blood in right side; left side empty; a fibrinous clot in the right ventricle, interlaced with the chordæ tendinæ, and extending into the pulmonary artery.

Case 4.—Non-adherent Cyst—Twice Tapped—Ovariotomy—Recovery.

On December 16, 1864, Mr. Wells was consulted by a patient who had been under the care of Dr. Hare, in University College Hospital, suffering from ovarian disease. She was single, a housemaid, and 25 years of age. There was little emaciation, but the patient looked sickly. Some of the veins of the legs were slightly varicose, and the legs themselves became œdematous at nights. The mammary areolæ were somewhat dark. The tongue was clean, the appetite poor, the bowels regular. There was often a good deal of pain in the hypogastrium after walking. There was a slight cough, but no expectoration. The physical examination of the chest showed nothing abnormal, except that the lower lobe of the left lung was evidently somewhat compressed. The pulse was 112; the heart's sounds normal. The urinary organs were healthy. The girth at the umbilical level was 37¼ inches, the distance from the ensiform cartilage to the umbilicus 8 inches, to the symphisis pubis 10½ inches, and to either ilium 10½ inches. The abdomen was filled with a fluctuating tumour, which extended from the brim of the pelvis to the epigastrium. The right loin was clear; the left dull on percussion. The abdominal parietes were not excessively thick; there were no dilated veins; there was no crepitus nor tenderness to the touch. The stomach and liver were evidently somewhat displaced upwards by the tumour. The catamenia were regular, and rather more abundant than they usually had been. The uterus was central, freely moveable, five and a-half inches long. The condition of the os and cervix was virginal.

No hereditary disposition to disease could be traced. Two years and a-half before Mr. Wells saw the patient, she had a fall and hurt her knee. Even before this she had observed that her abdomen was increasing in size, but it was only six months later that the swelling became hard and that pain began to be complained of after exertion. The pain was in the right iliac region, and was often accompanied with vomiting. There was no vaginal fulness, no bearing down of the uterus, no pressure on the bladder. The tumour increased gradually in size, and the symptoms became aggravated. On four separate occasions attacks of circumscribed peritonitis occurred in the right iliac region.

In July, 1864, the patient entered University College Hospital under the care of Dr. Hare. Her health greatly improved under his treatment, but the tumour continued to increase, and she was tapped. The operation was performed in July, 1864, and gave her great relief. The fluid removed was quite clear, and after the tapping scarcely a trace of the tumour could be felt through the abdominal walls. About two months after the tapping the cyst began to refill.

The patient was admitted into the Samaritan Hospital on the 1st of February, 1865. She was then suffering so much from distension that Mr. Wells tapped at once, and evacuated thirty-two pints of clear limpid fluid. On the 5th of March the patient was as large as a woman in the seventh month of pregnancy, and increasing. She was most anxious for ovariotomy. Mr. Wells's diagnosis was "Cyst of left ovary nearly unilocular; no close connection either to abdominal wall, pelvis, or uterus." He performed ovariotomy on the 20th of March, in the presence of Drs. Doniges (Breslau), Sirelius (Helsingfors), Marion Sims, Hare, and others. Chloroform was given by Dr. Parson. The incision was made midway between the umbilicus and the pubic symphisis to the extent of five inches. There were no adhesions, except to a long narrow slip of fibrous tissue running close to the pedicle. After separation, it was secured temporarily in a clamp, but it was found not to bleed and was released. The pedicle was secured in the smallest sized clamp and kept outside. There was no hæmorrhage except from the edges of the wound. The opposite ovary was healthy. The wound was closed with five deep and two superficial silk sutures. The cyst consisted of several large loculi, some of which intercommunicated.

The whole operation only lasted eight minutes. The patient rallied well, and only required two doses of opium. On the first morning she twice vomited some bile. There was no pain; but the tongue was white and the breath offensive. In the afternoon the pulse was 120, and there was a wheezing cough. On the second day there was a good deal of restlessness, the urine was scanty and high coloured, the pulse was 140, and, although there was no tympanites, no flatus had passed by the bowels since the operation. Mr. Wells removed two of the deep stitches. The pulse at ten in the evening had fallen to 128. Per vaginam the uterus was felt pressing against the rectum, and there was a sensation as if some of the small intestines had fallen into Douglas's space.

On the third morning there was still some bilious vomiting, and the urine was much loaded with pink sediment; the pulse was 124. There was still the sensation as if some of the bowels were in Douglas's space; but some flatus passed after the examination. In the evening Mr. Wells removed another deep suture. The chest was easier. There was still considerable thirst, but the tongue was less loaded. On the fourth morning the patient appeared to be quite out of danger. The pulse was 96. She had begun to feel better in the middle of the night, after passing much flatus. Just before this she had drunk a little brandy and iced water. Shortly after this uterine epistaxis was observed. The discharge lasted three days, and both in duration and quantity resembled the patient's ordinary catamenia. Mr. Wells removed the clamp on the eighth day. The bowels acted easily on the twelfth day, after a warm water injection. No inconvenience was experienced

from this long period of constipation. The patient gained strength rapidly, left the Hospital on April 13, and has since obtained a situation as nursemaid.

(To be continued.)

ST. BARTHOLOMEW'S HOSPITAL.

FIBROUS TUMOUR GROWING FROM THE LOWER BORDER OF THE PECTORALIS MAJOR, IMMEDIATELY BEHIND THE MAMMA, SIMULATING SCIRRHUS OF THE GLAND—REMOVAL.

(Under the care of Mr. SAVORY.)

JOHN B., aged 22, an ill-nourished, sallow-looking man, applied to Mr. Savory on February 29 for advice respecting a tumour in the left mammary region. On examination the growth was found to be situated immediately behind the nipple. In general outline it was egg-shaped, with a long diameter, taking the line of the lower border of the pectoralis major, of nearly 3 inches, and a transverse measurement of about 2½ inches. Wide at its base of attachment, it gradually rose to an oval prominence in front, on which the nipple was seated. It was distinctly circumscribed, somewhat irregular on the surface, of an almost stony hardness, and so firmly fixed to the muscle beneath as to be scarcely at all moveable. The skin, however, covering it was not adherent, and there was no retraction of the nipple. Some slight enlargement of the axillary glands could be detected, and a hard cord, formed by some thickened lymphatic trunks, was felt running towards the arm-pit from the upper and outer border of the tumour. The man stated that he first noticed the growth seven months previously, and that it had since been steadily increasing in size. It was not painful except when he struck or otherwise injured it while at his work. He could assign no cause for its formation, and denied having had syphilis. He was admitted into the Hospital.

The interest of this case rested chiefly in the question what the nature of the growth would prove to be. Looking at the extreme hardness of the mass; its firm connection with the parts beneath, and its situation in the immediate neighbourhood of the mammary gland; and also at the affection of the axillary lymphatics, and the cachectic appearance of the patient, the question was raised whether this could be an example of scirrhus of the breast. The well-known rarity of this disease in the male, particularly during the early period of life, made Mr. Savory hesitate to adopt this view, especially as some other circumstances seemed to point to an opposite conclusion. Thus, although the tumour had attained a considerable size, it had not involved the skin, which was freely moveable over it; there was no retraction of the nipple; and on very careful examination it appeared doubtful whether the mammary gland could not be felt thinned out and carried forward on the surface of the mass. The difficulty of arriving at an opinion as to the precise character of the tumour was of little importance practically, as the proper treatment evidently was to excise it.

Upon proceeding to operate, Mr. Savory found that the growth was connected with the lower edge of the pectoralis, so that it was necessary to cut away some of the fibres of the muscle along with it. The mammary gland was not involved in the mass, but was only carried forward in front of it. The wound was closed, and it subsequently healed without complication. By the aid of the microscope the tumour was seen to be composed entirely of dense fibrous tissue, strong bands of which crossed each other irregularly in various directions. Muscular fibres traced to its surface were there abruptly lost; none could be found entering its substance.

Fibrous tumours of voluntary muscles are rarely met with—indeed, so rarely that they are scarcely mentioned in the ordinary handbooks of Surgery and Pathology. A recent notice of them may be found in Mr. Teevan's paper in the *Medico-Chirurgical Review*, lxiv., October, 1863, in which reference is made to seven published cases.

THROMBOSIS OF CEREBRAL SINUSES, WITH APOPLEXY OF OPTIC THALAMI, CONSEQUENT ON ANÆMIA.

(Under the care of Dr. JEAFFRESON.)

This case is very interesting, as showing effusion of blood in nervous tissue from an unusual cause—viz., venous obstruction. Apoplexy of the optic thalamus is rare in patients twenty years of age, and apoplexy of both thalami rarer still. As regards treatment, of course the general condition of the patient was most important. She was liable to thrombosis almost anywhere, and its occurrence in the cerebral sinuses, if not a matter of accident, is one which it would be difficult to explain. The case is an interesting clinical record, as showing one of the dangers of anæmia.

Eliza S., aged 20, admitted into St. Bartholomew's Hospital, under Dr. Jeaffreson, March 29, 1865. She had enjoyed good health up to twelve months before her death, when, without any apparent cause, the catamenia suddenly ceased, and she began to suffer from anæmia. On admission, she was very feeble and anæmic; ankles œdematous; pain in left side; anæmic murmurs in neck, etc. She complained of slight headache, at first frontal, which gradually became more intense, so that on the night of April 3 it kept her awake. On April 4 she vomited several times, was delirious during the night, and on the 5th became gradually insensible and comatose, the pulse varying from 90 to 120, and being slightly irregular. She died at 10.30 a.m. on the 6th.

Autopsy, Twenty-six Hours after Death.—(By Dr. Andrews, to whom we are indebted for this report.)—Brain: Convolutions somewhat flattened, particularly on the right side, and marked by impress of fibres of dura mater. In the white matter of the posterior part of each hemisphere, about half an inch from the upper surface, is a dark clot the size of a pea. Both lateral ventricles contain a considerable quantity of blood-stained fluid; in the right one is a long thin dark clot lying upon the surface of the corpus striatum and optic thalamus. The septum lucidum is entire, but soft. The optic thalami are unusually prominent; on section, œdematous, and filled with numerous firm, dark clots, by which their tissue, greatly softened, is broken down. These characters are more marked in the right than in the left; but the left corpus striatum presents numerous dark red points, apparently small clots. The veins of the choroid plexus and velum interpositum, together with the venæ Galeni are distended by firm, partly yellow, and fibrinous clots. These extend continuously along the straight sinus, and for about one inch into the commencement of the lateral sinuses, a little further down the right than down the left; but in the lateral sinuses they do not entirely fill the vessels, whilst the straight sinus and the smaller veins are greatly distended by them. The oldest portion of the clot appears to be at the junction of the straight with the lateral sinuses. It is here of a dull pinkish tint, and somewhat soft. The blood in the other sinuses was almost entirely fluid; no disease of any of the cerebral arteries was detected. The substance of the brain was throughout a little soft and watery. No tubercle was detected in any organ. Several of the branches of the pulmonary artery in each lung were obstructed by old clots, some of which were breaking down in their centres. There were numerous large ecchymoses immediately beneath the endocardium of the left ventricle, which was very firmly contracted, and in the jejunum there were three recent intussusceptions.

ST. GEORGE'S HOSPITAL.

CASE OF ANEURISM OF THE BASILAR ARTERY — EPILEPTIFORM CONVULSIONS — DEATH — AUTOPSY.

(Under the care of Dr. FULLER.)

THIS patient died of apoplexy, but the cause of it was an unusual one. Had the patient been much younger, one would have felt pretty confident that the apoplectic symptoms were due to rupture of a cerebral aneurism, but, being 37 years of age, he was liable to rupture of vessels in the usual way—*i.e.*, without previous aneurismal dilatation. The case is of great interest also as showing how cautious we ought to be in making a prognosis when we are called to a patient in an epileptiform paroxysm. We ought to be especially careful when the fit is the first the patient has had, but sometimes death from rupture of a cerebral aneurism will occur when a patient has long been subject to epileptiform attacks. Mr. Squire, Dr. J. W. Ogle, and Dr. Murchison, have recorded cases of this kind in the Pathological Society's *Transactions*. For the notes of the following case we are indebted to Mr. Heywood Smith, Dr. Fuller's clinical clerk:—

A man, G. W., aged 37, was admitted into the King's Ward of St. George's Hospital, February 22, 1865, under the care of Dr. Fuller, when the following history was given of him. Five days ago he was attacked with diarrhœa, and the following day he had five fits of a convulsive character, which lasted from 1 to 12 p.m. Last evening he had another fit of a similar character, which lasted an hour and a half, since which he

has not regained consciousness. Has not been subject to headache; he is reported to have had a blow on the head when in the Crimea. Has had a large blister applied to the neck, which is now discharging freely.

On Admission.—There is no loss of power on either side in the upper extremities; there is no œdema of the legs; skin cool; pupils somewhat contracted, both equally so; pulse 84, regular; tongue slightly coated; bowels costive. Enema terebinthinæ vesp. Decoct. aloes co., ℥jss.; potass. nitratis, gr. xx.; ter quotidie. Hydr. chlor., gr. x., in pulv. stat. His bowels were not open. At 10 p.m., he said a few words to the nurse, shook a little, but was not convulsed, and died at 4 a.m. on the 23rd.

Autopsy Thirty-four Hours and a-half after Death.—The external appearance of the body was natural. Head: On opening the head the convolutions were seen to be very much flattened all over the vertex; the large vessels were more than usually injected. At the base of the brain was a thick layer of black coagulum in the arachnoid and sub-arachnoid cavities. The pons Varolii and medulla oblongata were deeply imbedded in clot; the fourth ventricle was filled, and the spinal cord was surrounded inside its dura mater to the cauda equina. There was a rounded clot, like a leech, at the bottom of each lateral ventricle, in connexion with the choroid plexus. It was found after a more careful examination of the base of the brain, that the blood had proceeded from a small aneurism of the basilar artery, about as large as a small bean. This projected from the right side of the vessel, very near the junction of the vertebrals. It had burst by an opening almost as large as could be made in so small a sac. The aneurism was completely imbedded in coagulum. There was atheroma of the cranial vessels. Chest: There were a few old adhesions of the pleuræ. The lungs were natural. The left ventricle of the heart was somewhat contracted; the valves were natural; the aorta was somewhat atheromatous. Abdomen: The abdominal viscera were natural, excepting that there was a considerable cyst in one kidney.

SATURDAY, MAY 13.

MEDICAL ETHICS AND THE ISLINGTON INQUEST.

Just as the ordinary courtesies of life are based upon the principles of Christian ethics, so, too, are the relations between Professional men and the public. What we call etiquette, and Professional etiquette in particular, is nothing else than an unwritten code of laws for the guidance of conduct under certain circumstances which experience shows are of common occurrence, and these rules are of no value whatever, except as they embody moral precepts. Were we all living in a condition of absolute perfection, no such concrete laws would be necessary. But, unhappily, personal interests and personal feeling often run counter to abstract right, the wellbeing of society, and the maintenance of the true balance between man and man. But society does more than inculcate regulations for the conservation of order and propriety, for it takes upon itself the performance of certain duties which, if not performed by the aggregate body, would be liable to suffer, either from the wilful negligence of individuals, or from the inconvenience which would result were each of its members called upon to carry them out in his own person. And while doing this it relaxes, *to a certain extent*, individual responsibility. That is, while leaving unrepealed the moral law of charity, it provides for its execution in the general, but not for its execution in exceptional contingencies. Such contingencies it leaves to individual responsibility. Thus, for instance, it deals with the command—"Give to every one that asketh thee." Providing a system of public relief for the poor and unfortunate, it meets all ordinary necessities of an extreme nature; instituting charitable establishments, it provides for other cases which, from one cause or another, the arrangements of the State fail to include; but after all this is done, there remains much distress and trouble which private philanthropy alone can relieve. No man who possesses the means of relieving it can shift upon society in such cases the responsibilities which bear upon the individual. And, on the whole, this sort of combined action of society works satisfactorily, charity is exercised with discrimination, fraud is defeated, and the convenience of social and individual life maintained undisturbed.

Thus it is that society at large dispenses to the necessitous the worldly goods which Providence has placed in its hands. And thus, too, that section of society to which Medical men belong dispenses to the necessitous sick the resources of art which it alone possesses. We are prepared to maintain that there is no class of men which, as a body, exercises a larger, more extensive, and more bountiful philanthropy than our own Profession. Witness the hours spent day after day and year after year, at the risk of life and health—hours which others devote to the prosecution of schemes for personal aggrandisement—by the most distinguished and learned of our body, in Hospitals and Infirmaries, and in visiting the wretched hovels of the sick; and even putting these aside, the labour and self denial of the miserably paid Poor-law officers. Yes; these too are doing a work of charity; let the public hug itself as it may in the fancy that they only do what they are paid for doing. They are not paid, if by this is meant that they are adequately remunerated for all that they do and suffer for the poor. It is for the public convenience, no less than for the convenience of the Profession, that this order is established; and private Practitioners have, as a rule, been absolved from individual demands upon their service in the sense that the public have any absolute claim that under ordinary circumstances, such demands shall be necessarily complied with as of right. Under ordinary circumstances, no one can go to a Medical Practitioner and claim as his right his Professional aid. We put the question of fees apart altogether. We say that it is only on the ground that we have taken, or on the plea of absolute incapacity, preoccupation, or ill health that any Medical man can ever retire from the practice of his Profession so long as there is a sick person whom it is possible for him to relieve. But society and the arrangements of the Profession relieve him from this inconvenience, and permit him to retire from practice whenever it may please him to do so. They enable him also to dictate the conditions upon which he will exercise his art, and to say to the public, "Such and such are my conditions; if you are willing to conform to them, well and good; if not, I must beg you to seek the advice of some one else."

We are led to make these remarks because it appears that the general public are somewhat mystified upon this subject. And it seems desirable not only to set them right, but to place before our Professional brethren an answer to an absurd doctrine put forward by a portion of the non-Medical press. The occasion was the unfortunate death of a woman named Mary Green in childbirth. It was stated at the inquest that a Dr. Gardiner had engaged to attend her, but that he subsequently sold his practice to a Dr. Butler. Both these gentlemen deny the engagement; and as we would not affix upon the Greens the stigma of perjury, we can very well understand that from some mistake in the matter they imagined that one or other of these gentlemen was bound to attend. Of course,

had there been an engagement, this would have been the case. Being applied to in the middle of the night, Dr. Butler visited the woman. He might have refused, but he did not; he went, and in this he exercised his discretion. Had he been told that the case was urgent, that there was danger in any delay, of course he would have had no choice; no right-minded man would have desired even the power of declining to attend in any such emergency. And here it is that we disagree with the doctrine set forward by a local paper while commenting upon this case: "Women in childbirth must be attended. Fee or no fee, a Doctor who is summoned in this extremity must come." We say that he need not come unless he chooses; we say that an ordinary case of labour is not an "extremity;" neither is it an emergency. The lowest of the low are perfectly well aware of the rule which requires the pre-engagement of a Practitioner or midwife, and there are nine months in which to provide for the coming need. Even where parish aid is sought some notice is expected, in order that the necessary attendance may be at hand when wanted; and no one has a right to demand a Professional man's services (except under circumstances of immediate danger) when this ordinary precaution has not been taken, and when no preparation has been made to comply with the conditions on which he may choose to practise. But we say in this case there was no such emergency. Dr. Butler visited the house, and says that, perceiving that the case was not sufficiently advanced to render his stay necessary, he left, giving the Greens to understand that he declined the case, and advising them to apply to the parochial authorities for the attendance they were unable to pay for. He had a perfect right to do this. As it happened, however, in consequence of some mistake or supposed informality, for which the parish authorities of Islington are responsible, the husband failed in obtaining the services of the parish midwife, and on his again applying to Dr. Butler he was not at home. The mistake of Dr. Butler was this, that having once visited the case, and so knowing that sooner or later Professional aid would be required, he did not voluntarily call in the morning to see if the application for the parish midwife had been successful. Still, we do not know what took him away from home so early as nine o'clock; it might have been some case to which he was engaged, so far as we know; at any rate, there was abundance of time between one and nine o'clock for the communication to be made to him that the application to the parish had failed. He very fairly supposed that it was successful; and he seems to have gone out with that idea. Still, we say that, had nothing intervened to prevent his doing so, a call for the purpose of inquiry would have been wisely made. It would have been an act of kindness, and its neglect has rebounded unmercifully upon Dr. Butler. It would have been prudent, more especially as he had not determined the presentation in his first visit—a circumstance which brings the possibility of a cross birth to every accoucheur's mind. If he had paid a second visit out of charity or policy, early in the morning, he would have satisfied himself as to the presentation, and would have turned and delivered: he would have had one or perhaps two hours of hard work unpaid, but he would have enjoyed the gratification of saving two lives, and of having had an opportunity of performing one of the nicest operations in the whole range of Medicine; and he would have avoided all the waste of time at the Coroner's Court, and all the obloquy hurled at himself and at his Profession. Or if unable to devote the time himself to this operation, we will undertake to say that fifty accoucheurs—in general practice or in consulting, in private practice, or officers of public institutions—might have been found who would have been on the spot in half an hour, and have performed the operation. We confidently assert that if notice of such a case—a poor woman likely to perish from unusual presentation—had been given to any member of the Obstetrical Society, from the President downwards, she would have been relieved instantly. Whatever the shortcomings of our Profession, any unwillingness to come forward at such a juncture is not amongst them. Dr. Butler did not call a second time. We repeat that he was not obliged to do so, though it would have been a kind and prudent act; no doubt he had a reasonable excuse; but, all things considered, it is a pity, for the sake of himself and his Profession, that he did not. After all, gratuitous Medical aid is such a drug in London that the possibility may never have occurred to him that the poor woman was perishing for want of it!

Let us sum all this up. The Profession has its rights as well as its duties. It is the duty of any Medical man who is not disabled by circumstances to give his aid in an emergency, whatever that emergency may be. Under ordinary circumstances, in a society where he is not the sole representative of his order, and where proper provision is made for the poor, he is not bound to grant his service to any one who may choose to ask for it. He may decline to attend a labour if he pleases, unless pre-engaged. Many Medical men never attend labours at all, although perfectly competent and even highly qualified to do so. A Medical man may make any conditions as to his ordinary services that he chooses; he may decline to attend, for instance, at night, or unless conveyed to the patient's house in a cab, or for less than his own customary fee, and so on. Having visited a patient once and exercised his art, he is not compelled to pay a second visit; but then he must make it known that he declines to do so. Even in the progress of a confinement, on any good and sufficient reason, as where his directions are not obeyed, or he is subjected to insult, etc., he may decline further responsibility; but in this case he must remain until a successor has been found, and until he has handed over the case to him. In all cases a man of proper feeling will not allow any silly notion of dignity to intercept the performance of an act of Christian kindness, or mere pique to hurry him into conduct incompatible with Christian forbearance. Even on grounds of common self-interest, a man who hopes to get on in midwifery will rather encounter an unpaid attendance than let a poor woman run the risk of losing her life.

THE WEEK.

THE PROBABLE SUCCESSOR TO ADMIRAL FITZROY.

Our readers will be gratified to know that there is every reason to hope that Her Majesty's Government will confer on Mr. Glaisher the superintendence of the Meteorological Department of the Board of Trade, vacant by the lamented death of Admiral Fitzroy. We believe that Mr. Glaisher at present holds an appointment in the Observatory at Greenwich, under the Astronomer Royal, the duties of which he discharges with zeal and efficiency quite sufficient to merit promotion. But it is the vast amount of extra-official and gratuitous labour which he has undertaken for the pure love of science which has rendered his name so truly a household word amongst us, and which demands some public recognition and reward. Besides doing his own work, Mr. Glaisher lends a hand to assist every other meteorological worker, by his services in correcting instruments and comparing them with the standards, and by his collation and publication of results. We say nothing of the balloon ascents, or of the element of danger to life which they superadd to Mr. Glaisher's other assiduous and interesting labours; but feeling, as all Medical Practitioners must, how many unsolved problems there are of the influence of weather upon human life and upon the production of food by agriculturists, and upon the production or transport of epidemic disease, we hope that the man who has done so much to advance our little stock of knowledge will be rewarded with a position which we feel sure will be to him an incentive and opportunity for researches still more laborious and fruitful.

MORE PAPERS ON MODERN SYPHILOGRAPHY.

Our readers will be glad to learn that the able writer of the articles on "Modern Syphilography" which have lately appeared in our pages, and which we know have been eagerly perused by all who are diligently working at that subject, has furnished us with a series of "Rough Notes from the Life"—on all the most vexed questions in syphilography, which we shall begin to publish next week. "Abortive treatment," "Modifying effects of tissue on character of sores," "Suppurating bubo," "Characters of constitutional sores," are the titles of the earlier papers. They will be what they profess—not polished theoretical essays, but rough notes from the life.

LOCAL METROPOLITAN MUSEUMS.

The permanent buildings which have lately been erected at the South Kensington Museum have superseded the unsightly structures with which we have all been long familiar, and which are commonly called the Brompton boilers. The boilers—as all boilers should be—are made of iron; and the question arises, What is to be done with them? Are they to be taken down and sold as old iron? That were indeed a degradation! Can they not be turned to some better account? It appears that they are separable into three portions, and that they could be converted at a trifling expense into three distinct buildings, each capable of containing a small collection of objects of scientific interest or works of art. At a meeting held a few days ago, Earl Granville intimated that the Government were willing to dispose of them in this way at a nominal price to any of the metropolitan districts which would undertake to provide a suitable site and to raise the necessary funds for their erection. Several gentlemen who were present at the meeting immediately set forth the claims of the districts which they represented, and begged to be allowed to participate in the boon. In fact, the boilers, for the first time in their lives, were quite in favour. Thus it seems probable that these "ironsides," after having done their duty manfully at South Kensington for twelve years, notwithstanding many scoffs and taunts, will ere long be disbanded and marched off separately to suburban districts, there to enter upon a fresh career of honourable usefulness and to protect the rising local museums of science and art.

INSTRUCTION IN MENTAL DISEASES A RECOGNISED BRANCH OF MEDICAL EDUCATION.

At the annual meeting of Convocation of the University of London, held on Tuesday last, the following resolution was passed unanimously:—

"That it is desirable that a certificate of having attended a course of clinical instruction in mental diseases should be required from all candidates for the Second M.B. Pass Examination, and that the examination should necessarily embrace the subject of insanity."

The University of London has always taken the lead in the promotion of Medical education, but, perhaps, on no occasion has a step been proposed more calculated to confer a lasting benefit on the Profession, and, through them, upon the public. The senate to which this resolution will now go cannot fail to give it effect, and when once the importance of the study of insanity is thus recognised by the University of London, other examining bodies in the metropolis will insist upon the candidates for a licence possessing, at least, clinical acquaintance with this important class of maladies. We may hope then that the deplorable blunders sometimes fallen into by members of our Profession who have to certify or give evidence in our law courts in cases of insanity will be of less frequent occurrence than hitherto. Besides, as was well pointed out by a member of Convocation in the discussion of the subject, it will be no small point gained that the general Practitioner of Medicine and the Physician in ordinary practice will be in a position to meet the specialist upon something like an equal footing. The immediate advantage which the public will gain by the adoption of this resolution by the University of London is, that there will be at once provided for the service of Asylums a class of graduates the most highly-educated of any sent forth by any licensing body in the United Kingdom.

GOVERNMENT RECOGNITION OF PROFESSIONAL SERVICES.

Tuesday's *Gazette* contains the following:—

"*General Order.—No.* 865.

"Dated Horse Guards, May 9, 1865.

"In consideration of the highly meritorious services rendered during the prevalence of the yellow fever in Bermuda by the undermentioned officers, Her Majesty has been graciously pleased to command that they shall be promoted as herein stated:—

"Staff Surg.-Major T. W. Barrow to be Deputy Inspector-Gen of Hospitals.

"Surg. F. Cogan, 2nd Foot, to be Surg.-Major.

"The Rev. J. Virtue, Fourth Class Roman Catholic Chaplain to the Forces to be Third Class Chaplain.

"The conduct of the following officers during the epidemic was likewise conspicuous and praiseworthy:—

"Brevet-Major J. E. Hope, Royal Artillery; Capt. F. N. Cromartie, Royal Artillery; Capt. D. C. Walker, Royal Engineers; Brevet-Major W. W. Lynch, 2nd Foot; Capt. J. Armstrong, 2nd Foot; Staff Assist.-Surg. F. J. Shortt; Staff Assist.-Surg. F. Pennington; Assist.-Surg. B. Burland, M.B., Royal Artillery.

"By command of His Royal Highness the Field Marshal Commanding-in-Chief,

"James Yorke Scarlett, Adjutant-General."

We congratulate the recipients—Medical and lay—of these honours. The Horse Guards, with its accustomed liberality to Medical officers, and with that sense of the value of Medical lives and services which has ever so conspicuously distinguished it, has granted two promotions for Professional services during an epidemic in which nearly half the Surgeons employed lost their lives.

THE CHEMISTS AND DRUGGISTS BILLS.

We understand that a deputation from the Parliamentary Committee of the Metropolitan Counties Branch of the British Medical Association, consisting of C. J. F. Lord, Esq., of Hampstead; Mr. Martin, of Hammersmith; Dr. Seaton; and Dr. Septimus Gibbon have had a conference with Sir F. Kelly, M.P., on the subject of the bills now before Parliament for promoting registration of chemists and druggists. Dr. Druitt was also present. We believe that the deputation expressed themselves as favourable to the principle of the bills, so far as they would secure a better education and more scientific status for the chemist and druggist, but they objected that whereas these bills propose to protect the public from persons who shall carelessly or ignorantly make up prescriptions of duly qualified Medical Practitioners, they run the risk of sanctioning a worse evil—viz., the practice of Medicine in the form of "counter practice" by chemists destitute of any Medical qualification whatever. They doubted the mischiefs of careless dispensing, except as most rare instances, but believed the evils of unqualified practice by chemists to be daily and hourly palpable. They spoke of cases of disease which might be checked in the bud by early and judicious treatment, allowed to go on from bad to worse, whilst the chemist was giving his "bottle of stuff," instead of referring the case to a Practitioner. It appeared clear to the deputation, from the observations which fell from Sir F. Kelly, that in the minds of some members of the Committee of the House of Commons the object was not so much to advance a knowledge of scientific pharmacy and of the natural sciences on which it rests, amongst chemists, as to supply the poor with Medical advice for slight ailments. "What a benefit to the poor, who go to a chemist for some

slight ailment, to have an educated man," etc., etc. This is the real sting of the Bill, and of the efforts of its promoters. These Members of Parliament forget that pharmaceutical chemists learn nothing and know nothing of the Healing Art; whilst the General Practitioners of England do exactly, as matter of skilled practice, what the prescribing chemists do irregularly and ignorantly. If the poor man do not like to knock at the private door of a "Doctor" or "Surgeon," or if he do not care to go to a charitable institution, there is no district which has not an "open Surgery," kept by some rising Practitioner, who contents himself at the outset of life with the small profit derivable from charges for medicine, in return for the skilled treatment of disease. It is in vain to raise the apothecary if he is to be supplanted by the chemist. We believe that the deputation intends to petition the House of Commons on the subject of the injury which the Bills are likely to inflict on the General Practitioner in poor and populous neighbourhoods. As we have before admitted, it is not the really scientific pharmaceutist who is to be dreaded as a rival to the Medical man; he is really an ally, working in a different path; and it is admitted that the leading men in the Pharmaceutical Society, whose zeal and acuteness in promoting the interests of their own body well deserve to be imitated, not only do not desire counter practice, but desire to put it down, and are ready to consent to the enactment of a clause by which a penalty shall be inflicted on any of their body who practise Medicine. The subject of Patent Medicines was discussed by the deputation; and here also we believe that the sentiments of the enlightened members of the Pharmaceutical Society are at one with those of the Medical Profession. The deputation expressed themselves as highly gratified by the attention which Sir F. Kelly paid to their observations, and the suggestions he offered for attaining the ends desired.

THE SUPPLY OF EXPENSIVE MEDICINES TO THE POOR.

At length the Poor-law Board have taken the initiative in regard to the supply of cod-liver oil and other expensive medicines to the sick poor; they have issued to Boards of Guardians the following circular letter on the subject:—

"Poor-Law Board, Whitehall, S.W., April 12, 1865.

"Sir,—I am directed by the Poor-law Board to state that they are desirous of drawing the attention of the Guardians to the question of the supply of medicines for the sick poor.

"The Board transmitted to the Guardians a copy of the Report of the Committee of the House of Commons on Poor Relief shortly after it was printed, with the view of informing them of the opinions and recommendations of the Committee on the several points to which their inquiries had been directed.

"The Board think it right, however, now to bring more particularly under the notice of the Guardians the following resolution of the Committee relating to Medical relief, viz.:—

"'That there are no sufficient grounds for materally interfering with the present system of Medical relief, which was made the subject of special and lengthened inquiries by select committees of this House in the years 1844 and 1854.'

"That the recommendations of those committees were for the most part carried out by the orders of the Poor-law Board, and the system of Medical relief appears to be administered with general advantage. Your Committee, however, recommend that in future cod liver oil, quinine, and other expensive medicines, shall be provided at the expense of the guardians, subject to the orders and regulations of the Poor-law Board.

"The Board have repeatedly considered the recommendation of the Committee relative to the supply of cod liver oil, quinine, and other expensive medicines, with the view of determining what measures should be taken by them to carry it into effect.

"It does not appear to the Board that they can, with advantage, issue any general and positive regulation on the subject; and they are of opinion that much difficulty and embarrassment might arise from a compulsory interference with the arrangements for Medical relief which are in force under the existing contracts. They request the Guardians, however, to be good enough to consider whether an alteration in those arrangements as regards the supply of the medicines referred to cannot be made whenever a new appointment of a Medical officer may become necessary; or, with the consent of the present Medical officers, during the continuance of their existing contracts.

"With regard to the mode in which the proposed object can most conveniently be effected, the Board are of opinion,—

"1. That it may be advisable to provide a store of cod liver oil at the workhouse, or at some other convenient places of deposit in the union, and to supply it to the sick poor on the prescription of the Medical officers, through the relieving officers, in the same way as wine, or other extras recommended by the Medical officers in the way of nourishment, are now supplied.

"2. That quinine and other expensive medicines may be supplied,—

"Either by an order of the Medical officer on a chemist, the cost of the medicines so ordered being paid for by the Guardians to such chemist as goods or provisions supplied in relief;

"Or, by the Medical officers themselves, who may send in an account, quarterly, to the Guardians of the cost of the medicines in question which they may have supplied to their pauper patients.

"The former plan may probably be convenient in the town unions; the latter in the country unions.

"Cod liver oil and any other medicines intended to be so supplied should be specified and excepted from the provisions of the Medical contract, which require generally that Medical officers should themselves provide the requisite medicines and medical appliances for their pauper patients.

"I am, Sir, your obedient servant,

"Enfield, Secretary."

This does not go so far as many members of the Profession engaged in the care of the sick poor would, we believe, have desired; but, on the principle that "half a loaf is better than no bread," we should hail it with satisfaction, as affording evidence that the Central Board are anxious to exert themselves for the benefit of the poor and of Medical officers (the interests of both classes being equally in their care) to such extent as the Report of the "Select Committee on Poor Relief" will permit. At the end of last year, when commenting on Mr. Griffin's proposed Bill for Poor-law Medical Relief, we stated our opinion that there existed no necessity for *directing* the establishment of Dispensaries; it now remains to be seen whether a *recommendation* that the Guardians should supply medicines of exceptional cost will not be equally efficacious as a means of relieving Medical officers from incurring, as at present, either the cost of providing them for their poorer patients, or the conscience-reproach of omitting to order them when necessary. We believe that we shall be borne out by all classes in a position to judge—Professional or lay—when we state that the cases have been few in which a Medical officer has been deterred from recommending quinine, for instance, on account of its cost to himself, although we do know there are cases in which arsenic is substituted; but very many indeed are the instances in which a large share of a quarter's salary has been disbursed for expensive drugs. We have learnt with great pleasure that, although the above circular is only dated the 12th ultimo, in numerous Unions the Guardians have responded to it with proposals to relieve their Medical officers from the charge of supplying the medicines to which it has reference, and we also understand that in very few cases has there been any suggestion to reduce the salaries in consequence of such relief. We doubt very much whether Guardians of the Poor (who are not, as a rule, the meekest of mankind) would not, had they been *directed* to adopt the measure recommended in the circular, have made a point of at once proposing to reduce the salaries of their Medical officers; and therefore we consider that the course adopted by the Central Board in adopting a *recommendation* in lieu of a *direction* will, on the whole, prove the more beneficial to the interests of the Profession.

THE ROYAL ALBERT VETERINARY COLLEGE.

We understand that the new Veterinary College of Edinburgh, including its eminent head Professor John Gamgee, with the whole staff and apparatus, of professors, teachers, students, museum, library, diagrams, etc., is to be transferred to London, and to be established at Chelsea, under the title of the Royal Albert Veterinary College. There will be no attempt to displace or injure the Royal Veterinary College, which is working so energetically at Camden Town; for London is large enough to admit of two such colleges working in harmonious and honourable competition. To quote from the prospectus:—

"A preliminary contract has been concluded for one of the most desirable sites in the West-end of London, adjoining the new Chelsea Barracks, facing the gardens of Chelsea Hospital, situated about a mile from Hyde Park-corner, and in the immediate proximity of Belgravia.

"The great wear and tear amongst horses in the metropolis, their increasing value and number, and the enhanced price of cattle, sheep, and other domestic quadrupeds, for our rapidly increasing population, render it of paramount importance that no effort should be spared to secure the most approved mode of veterinary teaching and practice.

"The number of Veterinary Surgeons in the United Kingdom is lamentably deficient: though this country possesses the finest animals in the world, there are fewer skilled persons to attend to their health than in most parts of Europe.

"Notwithstanding the far greater value of stock in England than in France, we find that the whole of Her Majesty's possessions have less than 1500 Veterinarians engaged in their profession, whereas France alone without her dependencies has upwards of 3000.

"*With a view to relieve the sufferings of sick animals belonging to the humbler classes, an early portion of each week-day will be set apart at the College for affording gratuitous advice.*

"Owing to the great desideratum of a course of scientific education for agriculturists in the metropolis, arrangements have been made on the plan which has worked so successfully in Paris and elsewhere, of combining a course of agriculture with the curriculum of veterinary studies.

"The Committee have great pleasure in announcing that they have for this purpose secured the services of a gentleman so eminent in the department of agricultural education as Professor Coleman, late of the Royal Agricultural College, Cirencester.

"It is believed that many interested in farming pursuits, whether in London and its environs or elsewhere, will avail themselves of the great privileges thus afforded them, preparatory to or after a course of practical training in the country, and no effort will be spared to render the agricultural curriculum complete in all particulars."

We are sure that the advent of so energetic and original a worker as Professor John Gamgee will be welcomed by every scientific man in London.

THE COLDSTREAM MURDER.

A short time ago we called attention to the case of a Medical Practitioner who, for imposing personal restraint upon a dangerous and violent lunatic, was fined £5 by a Durham bench of magistrates. The following case affords a more striking commentary on the present state of the law in reference to the responsibilities of Medical men who are called to to take charge of lunatic patients than any we can offer. A few more such ghastly examples, and the public will perhaps learn that it is better a violent person, who is not insane, but simply wicked, should occasionally be restrained in error than that madmen should be allowed to murder and destroy whilst the Doctor can only interfere at his own peril.

"At the Jedburg Circuit Court on Wednesday, May 3, before Lord Ardmillan and Lord Jerviswoode, Alexander Thomson, lately residing in Church-lane, Coldstream, was placed at the bar charged with the murder of his wife in his own house on the 4th or 5th of December last. The prisoner had given himself into custody on the morning of December 5, to the sheriff-officer at Coldstream, who on repairing to the house found the deceased Margaret Dickson or Thomson barbarously murdered, eleven of her ribs being fractured and her body showing many frightful injuries. The panel pleaded 'Not Guilty,' and a special defence was put in to the effect that he was insane at the time the act was committed. The Medical witnesses called for the defence were allowed to sit in court to hear the evidence. It was proved that the prisoner was usually a person of very quiet and inoffensive temper, and that he and his wife usually lived happily together, but that he took to great fits of drinking, which gave rise to acts of violence bordering on if not producing insanity. Sometimes he had been chained to the bed to prevent him getting out of the house to satisfy his craving for drink, and altogether he appeared to have been a pitiable victim of that propensity. On the night in question there had evidently been a great conflict, and the woman, who was spoken of as a very quiet person, would appear to have used either poker or tongs in her defence. She had, however, been overpowered by the husband's fury, and the Medical witnesses who examined the body expressed their opinion that several of the wounds separately were sufficient to cause death. The evidence of the murder was quite conclusive, and the contest of evidence related rather to the question of the prisoner's responsibility as a sane person for the act. The local Medical witnesses deposed that several times he had suffered from delirium tremens, and on one occasion, at least, had showed symptoms of acute mania. On the night before the murder Dr. Turnbull had advised restraint, on account of old symptoms reappearing, but Mrs. Thomson expressed her confidence in being able to manage him. The doctor, not quite satisfied, had applied for the use of leg-irons, but the constable declined to lend them. The Professional witnesses examined for the defence thought the prisoner's violence was attributable to an attack of acute mania, followed by a gradual return in the morning to consciousness."

After hearing counsel and the Judge's charge, the jury returned the following verdict:—"Not Guilty, in respect that at the time of his committing the act he was temporarily insane."

PARLIAMENTARY.—WORKHOUSE NURSES—THE CONDITION OF THE NATIONAL MUSEUMS—PRECAUTIONS AGAINST RAILWAY ACCIDENTS.

In the House of Commons on Friday, May 5,

Mr. A. Mills asked the President of the Poor-law Board whether Government intended to adopt the suggestions contained in the evidence given before the Select Committee on Poor Relief, respecting the employment of trained and competent nurses in workhouses, and whether it was intended to carry out the recommendation embodied in the report, that quinine and other expensive medicines should be provided, when required, by the guardians.

Mr. Villiers said he believed the evidence to which the hon. member referred was that of a lady, Miss Twining, who appeared as a witness before the Poor-law Committee. She referred to the great want of improvement in the system of proper nurses for the sick poor in the workhouses of London, and said that in most of these workhouses there was no such attendance at all. This was an overstatement of the case. The Metropolitan Poor-law Inspector had always urged the guardians to employ competent persons as nurses for the sick, and the fact was that, upon inquiry, which he (Mr. Villiers) had directed in consequence of this evidence, he found that there were no less than ninety-three paid nurses in the different houses in London, and that out of the thirty-nine workhouses there were only eight without them. There was, however, great reason to doubt whether they were efficient for the purpose for which they were employed, and there was no doubt a great difficulty in proving who were competent persons; but, in consequence of communications lately received at the Poor-law Board from Miss Nightingale, who superintended establishments for the purpose of properly training nurses, and who was now taking much interest in the state of these houses, there was every reason to suppose that well-qualified persons could be obtained, and in number equal to the demand for them, should the guardians be willing to engage them. The Poor-law Board had already issued a circular to the guardians of all unions and parishes in London urging them to employ such persons, together with proper assistants, and it was to be hoped that they would now exercise their discretion in doing so. With respect to the supply of expensive medicines, such as quinine, etc., which the hon. member inquired about, the Poor-law Board had

issued a circular to all the unions in England and Wales on this subject, suggesting the propriety of their making arrangements with their Medical Officers forthwith for this purpose, and he was glad to say that many unions and parishes in the metropolis did supply those medicines, and found no difficulty in doing so.

Mr. Gregory called the attention of the House to the condition of the British Museum, the National Gallery, and the Kensington Museum. These collections of the treasures of nature and art were grossly neglected, though acquired by great expenditure. This neglect had been attributed to the parsimony of the House of Commons, but he rather ascribed it to the conduct of the Government, which had shaken the confidence of the House. He believed the House was prepared to vote the money that might be required, but the attempts of the Government to remove these collections to South Kensington had excited suspicions and made the House distrustful. He ascribed the defects in the management of the British Museum to allowing it to continue under the control of trustees. The collections ought to be placed under one head, who should be made responsible to a Minister. At present the collections were in a state discreditable to the wealth and intelligence of the nation.

Mr. Cowper agreed with much that Mr. Gregory had stated, but the different proposals of the Government for disposing of the national collection of pictures had been overruled. They had therefore been abandoned.

Mr. Walpole denied that the present state of the British Museum, which he admitted to be discreditable, was the fault of the trustees, who had added so largely to the collections. Things had reached a point at which the Government must interfere. They were exactly in the same position in which they stood ten years ago. The necessary space might be provided by purchasing the ground in the vicinity of the Museum, but the houses only to be pulled down for the gradual additions to the building. The Government would take the clear decision of the House on the question of keeping the collections together, and then act on that decision.

Sir G. Bowyer thought that, as the great fault of the National Gallery was want of height, it might be improved by adding another storey to it. In the same manner space might be gained at the British Museum.

Mr. Tite could see no difficulty in effecting the desired object of keeping the national collections together, if the Government determined to propose a good plan for the purpose.

The Chancellor of the Exchequer said the House had rejected every plan of the Government, but had never come to any decision of its own. He pointed out the enormous expense of purchasing the eight acres of ground in the neighbourhood of the Museum, which Professor Owen stated the collections would require. This would surely be inexpedient when seven acres of land had been purchased at a moderate rate at Kensington.

Mr. Ayrton denied that eight acres were wanted. But with respect to the British Museum the Government had always persevered in the plan the House had condemned.

Mr. H. Seymour feared the Government intended to make another attempt to drag the British Museum collections down to Kensington. That plan had prevented all progress since 1862.

Sir W. Gallwey moved as a resolution, "That the safety of the public requires some immediate provision should be made for compelling railway companies to establish a proper communication between guards and passengers." He referred to the numerous railway accidents that have lately occurred, and the alarm they have excited, as fully justifying some interference.

Mr. Milner Gibson said the Government had been in communication with every railway company in the kingdom on the subject, and a plan was then under trial by which passengers could arrest the attention of the guard, who would be instructed to stop the train at the next station protected by a fixed signal. This plan would do much to remedy the evil, and while the experiments were in progress it would be inexpedient to pass the resolution.

The resolution was withdrawn.

FROM ABROAD.—PROFESSIONAL ADVERTISING—ALCOHOLISM AT HAVRE—CONDENSED MILK.

In the laudable desire to prevent indiscriminate advertising and puffery, the question arises whether the Profession has gone too far in prohibiting it in any mode or degree whatever. At all events, the editor of the *Boston Medical Journal*—a sound reasoner on most matters that come before him—thinks that there is something to be said on the other side. He bases his argument upon the great development which has taken place in specialities in modern times, which in the opinion of some would be only to justify one abuse by another. Still, right or wrong, these specialties do thrive apace, and are pursued by men of high principle as well as great repute, and here is the suggestion:—

"It is certainly important for the Medical Profession and for the public at large to know who those Physicians are who have determined to occupy a restricted field of labour, and what are the special subjects to which they confine their attention. No more ready means occurs to us of making such a decision publicly known than through the medium of a modest advertisement in a Medical periodical. So presented, it is addressed almost exclusively to Medical readers, and the advertiser hardly lays himself open to the charge of mercenary motives. No Physician in general practice can expect at the present day to keep up his knowledge to the highest standard of progress in the diagnosis and treatment of diseases of the eye, for example, and the advertisement of one who restricts himself to the treatment of this class of disease tells him where he may send his obscure or doubtful cases for relief. The relief is twofold, for the Physician and the patient, and the result is a positive public benefit. . . . . It would seem, then, if we judge rightly in this matter, that the simple statement of a specialist in a Medical journal that he has chosen a particular department of Professional labour should not only not lay him open to animadversion, but is probably to some extent a public advantage. It has not the character of a newspaper puff of a tradesman in any sense, where the advertiser plainly designs to recommend as strongly as possible the wares which he offers for sale. Its publication should be limited, however, to the Medical press. Advertisements of such a nature in the daily newspapers savour very strongly of a hankering after the gains which are supposed to reward the enterprising advertiser of the last new nostrum, and are not to be thought of for a moment. The only advertisement in a daily newspaper which occurs to us as being in keeping with strict Professional propriety, is that of a change of residence, and even this may be allowed to stand so long sometimes as to present a most unwholesome look."

It is evident from this statement of our *confrère* that advertising exists already to an extent in the United States not known to ourselves. Not that we are so free from its practice as at first sight seems, for although neither qualifications nor address can be advertised even in the Medical journals, let alone the political ones, yet the frequent advertisements of Medical works that we see in these latter are certainly addressed to the public and not to the Profession, which is possessed of ample sources of information in the Medical journals.

John Bull has got such an inveterate habit of speaking of his own defects, and so loudly calling attention to them, that he really sometimes seems worse than he is. Now, in the matter of drink, how often has he had the sobriety of the Continent pointed out to him as worthy of his imitation, forming, as it does, such a contrast to his own disgraceful habits! It is true that persons acquainted with the beer-drinking in Germany, and the quantity of brandy and absinthe consumed by the lower classes in France and Switzerland, have had their doubts as to the comparative amount of the abuse of alcoholic drinks in this country; but the undeserved stigma attaches to us still; in spite of the efforts of our numerous temperance societies. However, one of the towns of France—Havre—must run us pretty close, if we are to believe the testimony of a thesis just published by M. Piasecki, on alcoholism as observed among the working-classes of that seaport. From the octroi returns, it appears that its consumption of alcoholic fluid far exceeds that of any other town in France, reaching the enormous quantity of 16 litres per head per annum. It seems it is a place in which labour is very highly paid, but is liable to frequent intermissions. M. Piasecki furnishes a statistical account of some of the results of such dissipation as observed at the Hospital during the years 1858-63. During this

period, 6175 males were admitted into the Physicians' wards, and of this number, 301 were suffering from alcoholism, death resulting in 56, as compared with 827 deaths from other causes. During the same period, among 3101 females admitted, there occurred 147 cases of alcoholism, followed by death in 19 cases, as compared with 529 deaths from all other causes. Of the 301 cases of alcoholism in males, 135 were cases of delirium tremens, 67 of insanity, 2 of alcoholic vertigo, 1 of chorea, 1 of pneumonia, 44 disease of the liver, and 42 disease of the stomach. Of the 147 female cases, 56 were delirium tremens, 37 insanity, 2 chorea, 22 affectious of the liver, and 21 affections of the throat. In the first category, suicide was either accomplished or attempted in 9 instances, and in the second in 6 instances.

A recent number of the *Boston Journal* contains an interesting account of the preparation of condensed milk, which during the war has been consumed in enormous quantities. At one of the factories in New York State, described in the article, there is a daily reception of 10,000 quarts of milk from more than fifty farmers, at three cents per quart. Before entering the establishment it is strained and cooled down by ice or spring water for transport to the factory, its quality having been first tested by tasters, who by practice have acquired a wonderful perception of watery additions. Cleanliness is of such vital importance in the process that the company itself cleans out the farmers' cans in which the milk has been brought by means of a strong jet of steam, followed by one of water. The souring the cans after they are emptied, which is a common cause of spoiling milk next put into them, is thus effectually prevented. The milk cooled down, even in summer, to from 56° to 58°, is transported to the factory under cover of blankets and buffalo skins. A large ice-house is connected with the factory, as is also a cheese-room, so that when the demand slackens for the condensed milk cheese may be made from the milk bought by contract. The milk when strained is poured into brass pails, capable of containing fifty quarts each. Sixteen of such pails are placed in a flat tub, filled with water, which is heated by means of a coil of steam-pipe to 190° or 195°. This constitutes the great improvement upon all former processes of condensing milk by heat, the albumen of the milk in the open pails undergoing coagulation without separation from the watery part of the milk. Any portion of coagulated albumen that adheres to the pail is instantly severed by the steam jet. The coagulation only requires a few minutes, and as fast as the proper temperature is reached the pails are emptied through a fine brass-wire gauze sieve into the "steam well," which is an open egg-shaped copper vessel holding 750 quarts. A steam-jacket is fitted on to its lower end, the milk is soon brought to the boiling point, and then drawn up by suction into the condenser or vacuum pan, this being four by five feet in diameter, and holding 1000 quarts. This copper vessel is kept brilliantly clean, and the air having been exhausted by an air-pump, the milk, on turning a cock, rushes in to fill the vacuum left. Steam is next let on, heating a coil of pipe within and a steam jacket outside the condenser. The pump is kept in constant operation, and the whole process is closely watched by a girl who, like all the apparatus, is a model of cleanliness. In a few minutes she finds the thermometer indicating 190°, and the milk rapidly boiling in vacuo. The milk is allowed to flow in until 3200 quarts have been taken up, when the supply is closed, and the most diligent watching is required to keep the heat regular. The vapour drawn from the boiling milk is condensed by a stream of cold water flowing through the air-chamber, emitting the peculiar odour of milk just warm from the cow. When the 3200 quarts have been reduced to 800 quarts, the steam is shut off, and its place supplied with cold water, the heat of the milk being thus instantly raised to a very high degree, and all the remaining odour thrown off. From the time the milk is received from the farmer, only three and a-half hours are required for all the operations necessary for its complete condensation. When the milk is required to be preserved for very long and almost indefinite periods, its preservation is secured by dissolving sugar in the boiling fluid, and packing in tin cases.

REVIEWS.

A Manual of the Domestic Practice of Medicine. By W. B. Kesteven, F.R.C.S.E. Small 8vo, pp. 400. London: Longman and Co.

Medical works addressed to the public are generally viewed with considerable distrust and disfavour by the Profession; and very rightly, for too generally they are trashy and mischievous productions, written by superficially educated and inexperienced men, whose only object is to write themselves into notoriety and practice, and whose idea of a *popular* work is, not one that will truly help and instruct the non-professional public, but one that will make themselves popular. Happily, however, this is not the only way in which Medical subjects may be popularly treated of. Now and then a really accomplished and experienced Practitioner addresses a treatise on Medicine *ad usum popularem*, and produces a "guide, counsellor, and friend" of real value and great utility; and among the few existing works of this kind Mr. Kesteven's book deserves to take high rank. In an "Introductory Chapter," he gives short, but clear directions on hygiene in its various branches—as sleep, cleanliness, bathing, diet, ventilation, etc. —on nursing and nurses, leeching, blistering, fomentation, and so on. On this part of the work we will only remark that we think it a mistake to say that "the quantity of alcohol in port is, on the average, about 18 per cent.; in sherry, about 15 per cent. Other foreign light wines contain about 13 per cent." The great majority of readers will by *alcohol* understand *spirit* in the common acceptation of the term; but light foreign wines—*pure wines* —contain on the average about 20 per cent. of proof spirit, some so little as 17, a few as much as 26 per cent; while sherries in the English market average about 32, and ports 35 per cent. of proof spirit—they often contain as much as 40, and sometimes even 45 per cent.; this point is the more noticeable because when speaking of "spirits" Mr. Kesteven does not give the percentage of alcohol contained in gin, brandy, etc. In Section I. Mr. Kesteven gives a table of "the most prominent symptoms of disease, so that by reference to a symptom the reader may, if at a loss, be guided to the disease in which the symptom occurs;" he then treats, in alphabetical order, of "diseases and emergencies, their symptoms, causes, and treatment." Section II. is on "Accidents, and their treatment." Section III. on "Poisoning." Section IV. on "Medicines." As a specimen of the mode in which he handles subjects we may refer to small-pox; he gives the symptoms of the stages of incubation, invasion, eruption, and decline, noticing the differences in the discrete, semi-confluent, and confluent forms, and the benignant, modified, and malignant varieties; then come complications, causes, and treatment. The spirit in which he advises on the last may be understood from the warning which he gives, that "more harm is likely to be done by meddlesome physicking than by entirely withholding medicine." Then follows an excellent chapter on vaccination, in which he gives most valuable and instructive information, supported by statistics, on the protection afforded by vaccination. The only addition we can suggest to this is a few words of warning that vaccination may, just like any other irritation, excite an outbreak of eczema, and kindred skin diseases, in children predisposed to them. In the table of poisons, their symptoms and treatment, we do not observe any mention of Burnet's Disinfecting Fluid, which has been the cause of many cases of accidental poisoning, from having been given instead of fluid magnesia. Section IV., "On Medicines," contains an "Alphabetical list of medicines and table of prescriptions; with observations on the use and doses of medicines, a classification of medicines and prescriptions, a table of medical weights and measures, and a list of articles for a medicine-chest." Some of the electuaries are directed to be made up with "confection of senna," we observe; it would have been more useful and generally practical to make them all with treacle.

In the preface to the work Mr. Kesteven says, "It is not the intention of this manual to supersede the office of the Professional attendant; the pretence could only be a self-evident and useless imposition. Common-sense and the instincts of

self-preservation will urge the sufferer to seek for aid where skill and science inspire confidence, and afford the only rational ground of hope for a speedy and permanent restoration to health. Skill and science, however, are not at the command of all with whom the *praetiee* of Medicine may become an unavoidable and urgent obligation." Years ago there were many parts of England where Medical aid was difficult of attainment, or where the only Professional aid within reach was of the very lowest and rudest kind; and then, in numberless households, "Buchan's Domestic Medicine," and one or two other like works, were an invaluable guide and stay. In England such helps are now rarely needed, but in our colonies, and the many semi-populated and semi-civilised parts of the world where Englishmen are scattered, such a family guide as Mr. Kesteven's book must be most valuable; we have indeed, already, heard of some marked proofs of this. Families emigrating cannot do better than arm themselves with this "Manual;" with its aid, and common-sense, they may treat disease and accident with confidence and safety till Medical assistance ean be procured; and they may protect themselves from the necessity of having recourse to the services of ingenious Practitioners whom scant experience and less learning reduce to the device of "treating diseases by the circular method."(a)

On Diphtheria and Diphtheritie Diseases. By J. West Walker, M.B. Lond., etc. London: Churchill and Sons. 1864. Pp. 88.

This little work is a revised edition of a set of papers which appeared in the *British Medieal Journal.* The author's intention is to establish a theory that diphtheria is neither a distinct acute specific disease of modern origin having its own peculiar train of local and general symptoms, nor a modification of one of the previously-known diseases, such as scarlatina, eroup, or epidemic sore-throat. He finds in the leather-like pseudo-membranous formation the chief eharacteristic of the so-called diphtheria, but he finds that this may be associated with various groups of symptoms, and may be a concomitant of entirely different diseases. Diphtheritic exudation may occur on the skin or on the tongue, and be accompanied by little or no constitutional disturbance, and even in the throat it may be attended with the greatest possible variety of general symptoms. It is only when it is laryngeal that it is attended with croupal symptoms, and it then confers on the primary disease on which it is grafted a semblance to true croup. The amount of exudation, except in croupal cases, is by no means an index of the danger, for the danger may be slight whilst the exudation is abundant, and *viee versâ.* He therefore comes to the conclusion that diphtherite is a complication of disease rather than a disease *per se,* "manifesting itself, it is true, only at certain seasons, such seasons being noted for the extensive prevalence of zymotie diseases generally." He does not, however, deny that a new disease may have prevailed during a diphtheritic epidemic to which the term diphtheria has been applied; but if such a disease exist he denies that we have at present the positive means of recognising it, maintaining that the occurrence of the leather-like formation is no diagnostic sign, and is not peculiar to any one form of disease. The author's work is well written and well thought out. It is ingenious, if not convincing.

Thomson's Conspeetus of the British Pharmacopœia. Edited by Edmund Lloyd Birkett, M.D. Cantab, etc. Longmans. 1865.

Are we to understand by the title of this book that the late respected Professor of Materia Medica in University College has been summoned from his Elysian repose to take a look at the British Pharmacopœia, and that he has embodied his remarks on it in the neat little duodecimo before us? We really don't know what other construction to put on the title. The British Pharmacopœia was published in 1864, and Dr. Thomson died some fifteen years ago; so, except on the supposition of necromancy or spirit-rapping, or some other weirdly agency, we cannot conceive how any book can be Dr. Thomson's Conspectus of the British Pharmacopœia. Dr. Thomson, we know, published a Conspectus of the three Pharmacopœias of the three Colleges, giving in a short space their agreements and differences; but as the three are now represented by the British, it is evident that, even supposing ghostly supervision, the term Conspectus will not apply in the same sense as to the former work. Dr. Birkett, who is the fleshly editor of the present work, sees the difficulty, and adroitly meets it by remarking in his preface "it is as necessary as ever to hold *in conspectu* the prominent points of Pharmacy, Materia Medica, and Therapeutics." Undoubtedly; but that is not meant by a Conspectus of a Pharmacopœia. However, we will not be hypercritical. What's in a name after all? The book is a good and useful little manual of Therapeutics and Materia Medica, adapted from Thomson's Conspectus by Dr. Birkett. We suppose that the name "Conspectus" has been retained for commercial reasons; and, although it has a title suggestive of the uncanny, we are sure the book will be found a very tangible aid and a very useful companion in the brougham or the consulting-room.

PROVINCIAL CORRESPONDENCE.

IRELAND.

Dublin, May 10.

The Dublin International Exhibition of Arts and Manufactures 1865, was opened yesterday, with great *éclat,* by His Royal Highness the Prince of Wales, and although the events of the day are not, in strict propriety, subjects for record in a Medical journal, a brief notice of the proceedings, and a short account of the locality in which they took place, may be not unacceptable to your readers, as introductory to future reports, which I hope to send you, on the Surgical appliances, chemical and pharmaceutical productions, and other matters specially interesting to the Profession, to be found in this rich collection of the world's treasures.

The building through which the Exhibition is entered, presents to Earlsfort-terrace a handsome stone front, adorned with coupled columns of the Roman Doric and the Corinthian order, with Italian and Byzantine windows, and leads, through its grand hall, to a supplemental structure of glass and iron, correctly described in the "Stranger's Guide to Dublin," as exquisitely light, airy, and tasteful, the principal transept being 447 feet long by 84 feet wide, and 65 feet high, having a circular extension opening on the park, an extent of thirteen acres, laid out with admirable taste, and diversified with fountains, rockeries, shrubberies and cascades, an ornamental pond, croquet grounds, parterres, and a maze, similar in plan to that at Hampton Court.

The addition which such a park so judiciously laid out, and connected with a palace containing every facility for the study of the fine arts, the enjoyment of music, and of other means of rational recreation, and, moreover, actually in the city, makes to the sanitary and elevating resources of the inhabitants of Dublin is obvious; and it is matter of congratulation that so great and useful a work, now temporarily applied to the purposes of a vast International Exhibition, should have been inaugurated under the auspices of the Heir Apparent to the Crown of these realms.

Long before the arrival of His Royal Highness some ten thousand persons had assembled to witness the interesting proceedings of the day. In addition to the Duke of Cambridge, the Prince of Leiningen, the Lord Lieutenant and Lady Wodehouse, and others, who accompanied the Prince, there were present the Lord Mayor of Dublin, the Archbishops of Armagh and Dublin, the Lord Chancellor of Ireland, the Lord Justice of Appeal, the Duke of Leinster, the Marquises of Kildare, Drogheda, and Conyngham, the Earls of Meath, Charlemont, Rosse (Chancellor of the University), and Howth, Field-Marshal Viscount Gough, and many others of the nobility, judges, etc. The music, by a band and chorus of nearly 1000 performers, was conducted by Mr. Joseph Robinson, and included the 100th Psalm, the Coronation Anthem, "The Heavens are Telling," from the "Creation," the Grand March from "Le Prophete," Mendelssohn's Hymn of Praise, Handel's Grand Hallelujah Chorus, the National Anthem, and the Danish National Hymn. All passed off admirably, and this great undertaking was most auspiciously inaugurated.

I may have dwelt at too great length in this introductory letter upon matters not strictly Professional, but nothing calculated to advance civilisation or to promote a taste for healthy recreation and for pursuits enlarging to the mind can be considered unworthy the attention of the Physician. In my next I hope to be more special.

GENERAL CORRESPONDENCE.

ACUPRESSURE—EXPERIMENTS ON THE LOWER ANIMALS.

LETTER FROM MR. R. LAWSON TAIT.

[To the Editor of the Medical Times and Gazette.]

SIR,—I observe in the *Medical Times and Gazette* a quotation taken from Professor Weber in relation to some experiments of his with acupressure upon the blood vessels of the lower animals. As the results of these experiments, Professor Weber concludes that the compression of an artery by a needle will affect its coats more deeply and swiftly than deligation with a silk ligature, etc., etc.

During the last six months I have been engaged in a series of experiments with acupressure on the lower animals, and have come to conclusions exactly the opposite of Professor Weber's. These results will be shortly published. Let me here merely state that in the many experiments that I have performed I have never seen the ulceration or cutting of the coats which he describes as the invariable results of acupressure. There must, I believe, be some strange fallacy in his experiments. Reasoning even *a priori*, and without experiment, one can scarcely imagine the flat and gentle compression exerted by acupressure could possibly cut and divide the coats of an artery to the same degree as would a tightly-drawn ligature.

That the results of my experiments on the lower animals are correct, is proved by the same appearances having been found on several occasions in the arteries of the human subject where the acupressure needle had been used. That the effects of acupressure on the arteries, as stated by Professor Weber, are incorrect, I further think is fully proved by the success attending its employment in Surgical operations upon the human subject, an employment which Professor Weber never seems to have once witnessed. No later than last night I heard Dr. Pirrie, the eminent Professor of Surgery in the University of Aberdeen, state that during the last six months he and his colleague Dr. Keith had used acupressure alone in all their amputations, and in most minor operations in the Aberdeen Infirmary; that it had never once failed or given him trouble; that it could be more easily and rapidly applied than the ligature; that he had not seen a case of pyæmia or other evil result among all those in which it had been used, and that the wounds had generally healed very kindly and rapidly, results which could not have followed were Professor Weber's statements correct. I am, &c.

R. LAWSON TAIT.

THE ARMY MEDICAL SERVICE.

[To the Editor of the Medical Times and Gazette.]

SIR,—I am sorry to see that the students have been so foolish as to come forward and take service in the Medical Department in such numbers as to render abortive the exertions that were being made to better the department. No doubt the temptation of high pay—for to the juniors the pay in India, comparatively speaking, is high—has caused them to overlook the possibility of being employed elsewhere; and even in India, if you compare the emoluments of the Indian with other skilled labour of equal length of service, you will find the Surgeon is the worst-paid man. The consolidated pay artfully gives him when in charge of a regiment just the bare pay of his rank, but if sick and absent, instead of getting the pay of a major, as his rank entitles him to, he will only get Rs. 600 in place of Rs. 789, which a major would; no matter how intelligent or how well qualified, he can never get more than his bare pay. The circumstance of his possessing Medical knowledge, in addition to the other acquirements of a gentleman, debars him from the advantages open to every other military man who will qualify himself for staff or civil employ by passing in the languages. Formerly, in addition to his Professional work, the Surgeon of a station was generally Cantonment Magistrate and Postmaster—situations which gave him great influence and increased his emoluments. Now, practically, every Doctor is tied down in India to his bare Professional salary, which extra work and responsibility do not increase. But, though this is a matter of complaint in India, the grievance becomes a trifling one compared with the position of military Surgeons at home or in the colonies. The pittance of 15s. a day is quite unsuited to his position, and, when cut down by compulsory payments (subscriptions), is more like 13s. or 13s. 6d. The difference of pay between a Surgeon and an Assistant-Surgeon is ridiculous—only 2s. I have known a Surgeon lose money by promotion:—As Assistant-Surgeon he had 13s. a day, and, ranking as captain, he drew lodging-money—2s. 3d.—as he ranked among the seniors and had choice of quarters. On promotion as Junior Surgeon, a field officer's quarters in barracks, consisting of two rooms, were allotted to him. These he could not occupy, as they were useless to him, as a married man; but they, being vacant, debarred him from drawing lodging-money. Thus he lost 3d. a day in cash by his promotion, besides having to pay higher subscriptions to mess and band. Moreover, the pay of a Surgeon on promotion is less even than that of his comparative rank, whereas it ought to be higher, and carry, as in the Royal Engineers, a charge pay when employed in a responsible post. Indeed, the most satisfactory arrangement would be to give 10s. a day on entrance, with an increase of 6d. a day on the completion of each year for all ranks; Assistant-Surgeons to draw merely length of service pay; Surgeons, 5s. rank pay in addition; besides this, all ranks to have a charge allowance when holding separate charges; and so on for the higher grades. This would tend to give satisfaction, as the pay would increase both by length of service and by promotion, and the latter would be a certain rise of 5s. per day, and not, as in some instances, a present loss.

In the society in which a military Surgeon is placed from his position, 15s. a-day to a married man ranking as major is a bare existence, and does not leave a margin to meet travelling expenses, or provide for sickness, which involves being placed on half-pay, as we are not so liberally treated in respect to sick leave as the executive officers.

If the students would only have held out another session, the Horse Guards would have had to give in, and something would have been done to give better pay and pensions, and earlier retirements to

India, March 30. ARMY SURGEONS.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 25.

Dr. ALDERSON, President.

A PAPER, by THOMAS LAYCOCK, M.D., of Edinburgh, was read

ON THE INFLUENCE OF CERTAIN NERVE-CENTRES UPON THE PRODUCTION AND PREVENTION OF DROPSIES AND DROPSICAL EFFUSIONS.

After noticing generally the deficiencies in the theories of dropsies, and especially the absence of any consideration of the part which the nervous system plays in causation, the author arranges nervous dropsies as they are centric, or reflex, or due to local nervous disorder; or as they affect the trunk, or limbs, or viscera. He then details a case of cardiac dropsy in which the anasarca was unilateral, being limited to the left arm, left side of the thorax, and left half of the scrotum and penis, with hyperæsthesia of the right thorax. This he gives as an example of a "centric" nervous dropsy. The author then points out that the gravitating theory of dropsical effusions wholly fails to explain the caprices in the distribution of the effused serum observed in this and other cases of anasarca; and refers to numerous observations made on the order of development of the dropsy in various parts of the body, and also to an experiment made upon a corpse. He further shows by diagrams that the anatomical distribution of the capillaries, as well as the connexions of the areolar tissue, influences the seat and the distribution of the effused fluid. As an example of this he explains the origin of "præcordial œdema." The author next considers how far the obstructive theory of the anasarca in cardiac dropsy can explain the distribution of the fluid, and details a case of unilateral or hemiplegic anasarca, with hyperæsthesia of the same side, but without either cardiac or renal disease; thus proving that neither the obstructive nor humoral theory was applicable to an explanation of the distribution of the fluid. On the supposition that the

nervous system had a special influence in this respect, the author proceeds to examine how far this is supported by known data, and shows that, in accordance with the conclusions to be drawn from vivisection, the influence of the nervous system in these cases is opposite on the two sides; and that while on the œdematous side the effusion is thus promoted, on the non-œdematous side it is inhibited. As a proof of this doctrine, the author relates a history of a case of cardiac dropsy, in which, when the anasarca was very extensive, embolism of the middle cerebral artery of the right side took place. As a consequence, there was palsy and finally anæsthesia of the left side, with increase of the œdema on that side, but as to the left side entire disappearance of the œdema from the leg. This illustrates the true nature of the so-called "serous metastasis," in which, with disappearance of the œdema, head-symptoms arise or effusion takes place elsewhere. Following up the clue thus obtained, the author shows how in cases like 1 and 2 a previously unilateral morbid condition of the nervous system would render an anasarca unilateral or hemiplegic, which would otherwise have been general. In proof of this he details a fourth history, in which there were symptoms of cerebellar lesion, the right testicle wasted, a stricture of the urethra of long standing, and purulent urine; and in which, after a hemiplegic attack affecting the left arm, and left side of the face and tongue, œdema appeared in the leg and arm on that side, but not on the other. He also refers to a case of the same kind related by P. Frank. Having thus established the general principles of production and inhibition of dropsical effusion under the influence of the nervous system, the author proceeds to inquire what portions of the cerebro-spinal axis are involved in dropsies, and comes to the conclusion that in Case 2, in which the hyperæsthesia was on the same side as the œdema, the lesion was spinal; but that in Case 1, in which it was on the side opposite to the œdema, the lesion was encephalic, and in the medulla oblongata. In Cases 3 and 4 the seat was more complex and higher up. The author next considers paraplegic dropsy, and details a case of facial and paraplegic anasarca with long-standing Bright's disease, in which hæmaturia and coma came on, and therewith a disappearance of the œdema from the legs, constituting another example of so-called serous metastasis. After death, however, no serous effusion into the brain was found, but the frontal bone was perforated with holes from syphilitic disease, and the cranium generally much thickened, except the occipital bone, which was unusually thin. The theory of uræmic poisoning might explain this case, but as the theory itself is very doubtful, it is as easy to class the production and removal of the dropsy with the hemiplegic cases, which the author attributes to a probable defect in the function of the cerebellum as the great central regulator of nutrition. Under the head of "reflex dropsies," the author examines the origin and development of renal anasarca, and shows that in this, as in reflex paraplegias, the urinary and genital systems have a direct influence on the cerebro-spinal centres, and that when we know with what particular organs and tissues they have physiological sympathies, we can predicate where the effusion will be specially produced or inhibited. Hence he concludes that albuminuria without tube-casts is usually a symptom and not a cause of the nervous disorders attributed to it, such as puerperal convulsions and the like. Hence, also, in renal anasarca the œdema of the external genitals and of the loins; and finally, of the legs, as paraplegic œdema. The œdema of the eyelids in anasarca has two sources of reflex action. The upper eyelid is more in relation with the emotional centres, the lower eyelid with the genito-urinary. For this reason the lower eyelid is chiefly affected with local dropsy in women with uterine disease, but in men with disease or irritation of the bladder, prostate, and vesiculæ seminales. In women with Bright's disease effusion into the cellular tissue of the neck and thorax is sometimes so copious during menstruation as to endanger life by suffocation. The author is of opinion, however, that in many of these cases the reflex influence is not exercised directly through the spinal cord, but indirectly through the cerebellum and other centres of the nutrient nervous system. The law of production and inhibition of dropsical effusions by changes in the nerve-centres renders intelligible caprices in the distribution of the fluid otherwise incomprehensible; as when, for example, in lateral decubitus, the arm of the same side is free from anasarca when it is general elsewhere; and in particular it explains the close connexion between cardiac diseases and œdema of the thorax and upper extremities through the cilio-spinal region, and the reason why a differential œdema of the two sides occurs. He further shows how the same law applies to dropsical effusions into the pleura and lungs, and explains why in these cases there is sometimes a corresponding œdema of the thorax, and why in others there is neuralgia or hyperæsthesia of the same or the opposite side. The relation of crossed œdema to certain kinds of wasting palsy and to spasmus alternans transversus of Remak is also shown. The author finally discusses general anasarca from the points of view thus developed; but while insisting that the state of the nervous system is one great factor in the causation, the condition of the blood is equally important. The concurrence of the two great morbid states is therefore necessary. He also maintains that a particular portion of the nervous system is affected, the morbid changes of which are not necessarily manifested by disorders of voluntary motion or of consciousness, but by changes in the blood and the capillaries, and by modifications of the nutrient processes. These are out of the sphere of consciousness, and belong to the processes of vegetative life which the system in question regulates and binds into a homogeneous whole. Amongst the morbid phenomena to be classed with anasarca as to the part of the nervous system which regulates their production, the author specifies purpura hæmorrhagica, both acute and chronic; diathetic and metastatic inflammations and irritations, known chiefly as the rheumatic and gouty; nervous fluxes of serous fluid from free surfaces; effusive inflammations like herpes zoster; congestions and congestive inflammations of a symmetrical kind associated with nervous symptoms; certain plastic and fibrinous inflammations, as the syphilitic and gouty; and finally, reflex variations in the temperature of parts. As to the treatment of dropsies, the author thinks a cure almost impossible when the treatment is so directed as to depress the nervous system, as by confinement to bed, especially in the wards of a crowded Hospital; but he reserves the discussion of special remedies.

Dr. Webster said the object of the author was, he gathered, to show that disease of the nervous system was a great source of dropsy. He could not controvert the author's experience, but in his own experience dropsical symptoms had been rarely found in patients who had died of disease of the brain who, during life, had been insane. Among the 298 autopsies of insane patients, which he (Dr. Webster) had published in the Society's *Transactions* or elsewhere, only four were examples of simple anasarca; 12 had effused serum in the abdomen, 8 of whom showed also serous effusion in the chest or pericardium; while in 23 other cases serum was found effused more or less copiously in the thoracic cavity, but without any indications of anasarca externally.

Dr. Gull, whilst acknowledging the interest and importance of the paper, remarked that several difficulties had occurred to him during the reading of it. The two cases which Professor Laycock had quoted as examples of hemiplegic anasarca were of the left side. This fact diminished their value as illustrations of the theory brought forward, since the venous relations of the left side of the body to the general circulation might alone have explained the limitation of the effusion in these cases. Professor Laycock had quoted a case of anasarca limited to both upper extremities, and to the head and face, from the pressure of a tumour on the superior vena cava, and objected that, according to the common principles of gravitation, and the admitted universal permeability of the areolar tissue by fluids thrown into it, such a state of things should not have existed unless there were some hitherto-unrecognised influence in operation in the dropsical textures. On this, Dr. Gull remarked that such an assumption did not seem to him necessary. The limitation of the anasarca in these well-known cases seemed to him explicable by the most obvious fact in their history; for whilst, on the one hand, the obstructed veins could not remove the fluid from the parts from which they arose, on the other hand, the fluid gravitating into the areolar tissue of neighbouring parts, whose veins were free, would be quickly absorbed, thus accounting for the limitation of the anasarca without assuming nervous interference in the phenomena. Dr. Gull remarked also that Professor Laycock had drawn most of his illustrations of partial and limited dropsies from cases of chronic albuminuria. Now, it was notorious that in the albuminous cachexia tissue changes of an inflammatory and allied character were most common, whether from local exposure to cold or the like. He was therefore disposed to view with doubt the bearing of these cases on the theory of nervous interference now propounded by the learned Professor. It was, Dr. Gull also argued, further to be made out in such cases as those recorded by Dr. Laycock, whether the peculiar distribution and limitation of

the anasarca was not due to more local obstructions of the veins or absorbents than seemed to be generally recognised. It was remarkable that in a learned Medical Society like this, the difficulties connected with dropsies should, at the present day, be discussed without an allusion to the absorbent system—a system which, on its discovery, was no doubt over-estimated in reference to its pathological bearings in dropsies, but which, probably, was now too much forgotten.

Dr. Laycock, in reply, remarked that he concurred generally with the observation made by Dr. Webster as to the comparative immunity from dropsical disorders manifested by the insane. It was only one, however, of a class of immunities of the kind, and which gave a peculiar character to the pathology of the insane. It had attracted his attention in connexion with the conclusions he had submitted to the Society, and admitted of explanation on the principle which Dr. Webster had omitted to notice—namely, that morbid states of the nervous system inhibit or prevent dropsical diseases and other affections of the class. In reply to the objections of Dr. Gull, Dr. Laycock did not desire it to be understood that he set aside other causes of dropsy, such as exposure to cold, obstruction and distension of the veins and absorbents, and the like. All these might be causes, just as they are causes of inflammation. Hence the bandaging of dropsical limbs was an important aid to cure. Further, the anatomical distribution of the vessels had an influence upon the distribution of the fluid; and in proof Dr. Laycock directed attention to two diagrams, one of which indicated the line of effusion in a case of embolism of the inferior vena cava, which corresponded over the back to the line of the seventh or eighth rib; and the other showed the line of præcordial vascularity which bounded the œdema in a case of pressure on the superior vena cava. These facts showed that the circulation of the skin over the thorax and abdomen was distinct. Vivisections had also recently been made, which tended to prove that the venous capillary circulation was under the influence of the nervous system as well as the arterial. As to other objections brought forward by Dr. Gull, he would only remark that the facts remained the same, however they might be explained. When these were verified by other observers, they might come to a different conclusion than that which he had submitted to the Society; but carefully conducted observations with exact measurements were necessary as to the order of development and particular seat of the dropsical effusion, in order to reach correct conclusions. Hitherto the facts of the kind he had laid before the Society have been looked upon as inexplicable caprices; so far he was aware, they could only be explained on the theory he had laid down, that states of the nervous system both caused and prevented dropsical effusions. In further reference to a remark of Dr. Webster, he would observe that the portion of the nervous system involved was not that which subserved to external relations and ministered to volition and consciousness, but that which regulated internal relations and the processes of vegetative life. He had only made use of the changes in motion and sensation—the palsy, the spasms, and the hyperæsthesia—which accompanied certain dropsies to determine the centric seat of lesion. But there might be nervous dropsy without any of these.

Royal Institution of Great Britain. — General Monthly Meeting, Monday, May 8, 1865.—Sir Henry Holland, Bart., M.D., D.C.L., F.R.S., President, in the chair. The President appointed the following Vice-Presidents for the ensuing year:—The Lord Wensleydale, the Earl Percy, Sir Roderick J. Murchison, and Wm. Pole, Esq. Charles Butler, Esq.; William Henty, Esq.; Walter Morrison, Esq., M.P.; George Banks Rennie, Esq.; Arthur Charles Tanqueray, Esq.; Phillip D. Tuckett, Esq., F.G.S.; were elected Members of the Royal Institution. The following Professors were re-elected:—William Thomas Brande, Esq., D.C.L., F.R.S., Hon. Professor of Chemistry; John Tyndall, Esq., Ph.D., F.R.S., Professor of Natural Philosophy; Edward Frankland, Esq., Ph.D., F.R.S., Professor of Chemistry. The special thanks of the members were returned for the following additions to "The Donation Fund for the Promotion of Experimental Researches:"—John Carrick Moore, Esq. (second annual donation), £10; Harry Mackenzie, Esq. (second donation), £20. The presents received since the last meeting were laid on the table, and the thanks of the members returned for the same.

METROPOLITAN WATERS IN APRIL, 1865.

The following are the returns of the analyses of the metropolitan waters by the Metropolitan Association of Medical Officers of Health.

The amount of saline matter in the waters supplied to the metropolis during the month of April is, with one exception (the Kent) about two grains less than that of the preceding month, and the proportion of oxidisable organic matter has not in any case exceeded eight-tenths of a grain per gallon, the range being from 0·48 to 0·80 gr.

	Total solid matter per gallon. grains.	Loss by incineration.(a) grains.	Oxidisable organic matter.(b) grains.

MEDICAL NEWS.

Royal College of Surgeons of England.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners on the 9th inst.:—

William Greenwood Sutcliffe, Ashton-under-Lyne; James Grosvenor Mackinlay, Isleworth; Abraham Robert Verity, Bridgend, Glamorganshire; and Richd. Young Vance Packman, Ebury-street, Pimlico, students of Charing-cross Hospital. Henry Charles Hilliard, Shefford, Beds; Jas. David Rowlands, Carmarthen; Frederick Martyn Rickard, Plymouth; and John Gettins, Shrewsbury, of Guy's Hospital. William Frederick Pen Davis, Ardwick, Manchester; Thomas Nathaniel Twigge, Parwich, Derbyshire; Jas. Atkin White, Cheetham-hill, Manchester; and William Nuttall, Bury, Lancashire, of the Manchester School; Edwin Atherstone, Graham's Town, Cape of Good Hope; Thomas Howells, Kennington; Edward Charles Evans, L.S.A., Cardiff; and Charles Berrell, Camberwell, of King's College. Frederick Barton, Bradford; Josiah Leale, Jersey; and William Andrew Patrick Stuart, Barbadoes, of University College. George Paddock Bate, Stone, Staffordshire, of the Westminster Hospital: Thomas Henry Willand, Aubourn, Lincolnshire, of St. Bartholomew's Hospital; Charles Victor Helsdon, North Walsham, of the Middlesex Hospital; and Thomas Loars Johnson, Wolverhampton, of the Sheffield School.

At the same meeting of the Court Mr. Joseph Collings Grigg, of Greenwich Hospital, passed his examination for Naval Surgeon. This gentleman had previously been admitted a member of the College, his diploma bearing date April 12, 1858.

Admitted members on the 10th inst.:—

Richard Frederick Nell, Cardiff; George Frederick Pritchard, Highbury; John Burges Welsh, Taunton; and John King, Stratton, Cornwall, students of King's College. John Henry Bryant, Sussex-square; Thomas Leah, Penzance; William Le Gros Denziloe, Bridport; and George Brown Millett, Penzance, of St. Mary's Hospital. Anthony Charles Colborne, M.B. and M.C. Aberd., and L.R.C.P. Lond., Pimlico; Clarence Visick, Exeter; and Howard Barrett, Richmond, of St. George's Hospital. Frank Holmes, West Gorton, near Manchester, and James Henry Worsley, Bluepits, near Manchester, of the Manchester School; John Bradley, Liverpool, and Thomas Drake Leigh, Liverpool, of the Liverpool School; John Canning Wilkins, Pinnor, Middlesex, and Joseph Wall, London, of University College; William Joseph Marsh, New Kent-road, and Nelson Albert Hilder, Camberwell, of Guy's Hospital; William Powell Keall, Bristol, of the Bristol School; and John Neesam Stone, Dublin, of the Dublin School.

Apothecaries' Hall. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, May 4, 1865:—

Nicholas Watson Fairles, South Shields; Charles Glen Bott, Brentford; William Knight Treves, Dorchester; Charles Humphrey Weld, Rolvenden, Kent; Rees Llewellyn, Maesgwyn, Breconshire; Albert Waymouth, Middlesex Hospital; William Griffith Jones, Llanelly, Carmarthen; Wm. Heath Strange, Streatley, near Reading.

The following gentleman, also on the same day, passed his first Examination:—

George Richard Cooke, Charing-cross Hospital.

(a) This represents a variety of volatile matters as well as organic matter, as ammoniacal salts, moisture, and the volatile constituents of nitrates and nitrites.

(b) The oxidisable organic matter is determined by a standard solution of permanganate of potash, the available oxygen of which is to the organic matter as 1 to 8, and the result is controlled by the colours of the water when seen through a tube two feet long.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Barter, Clement S., M.R.C.S. Eng., has been appointed Surgeon to the Bath Institution for Idiots.

Belcher, Thomas W., F.K.Q.C.P.I., has been elected one of the Examiners in Arts at the King and Queen's College of Physicians in Ireland.

Bond, Thomas, M.R.C.S., has been appointed House-Surgeon to King's College Hospital.

Bradley, C., M.R.C.S. Eng., has been elected House-Surgeon to the General Infirmary, Leeds.

Briscoe, John, M.R.C.S. Eng., has been appointed one of the Surgeons to the Radcliffe Infirmary, Oxford.

Brodie, George B., M.D. St. And., has been appointed Medical Officer for In-patients and Physician Accoucheur to Queen Charlotte's Lying-in Hospital, Marylebone-road.

Broughton, Mr. E. T., has been elected Resident Medical Officer to the Kingston-on-Thames Provident Dispensary.

Caldwell, Samuel J. B., M.R.C.S. Eng., has been appointed Assistant Medical Officer for the Workhouse of the Parish of Liverpool.

Cook, William H., M.D. Edin., has been appointed Medical Officer for the Workhouse, Hampstead.

Cooke, Alfred S., M.R.C.S. Eng., has been appointed House-Surgeon to the Stroud General Hospital and Dispensary.

Fenn, E. L., M.R.C.S. Eng., has been appointed Physician's Accoucheur's Assistant to King's College Hospital.

Griffiths, William H., M.R.C.S. Eng., has been appointed Medical Officer to the Hinckley Workhouse.

Holyoake, Thomas, Jun., M.R.C.S. Eng., has been appointed Resident Surgeon Accoucheur to the Birmingham General Dispensary.

Kenny, P. F. J., L.R.C.P. Edin., has been appointed Second Junior Resident Surgeon to the Birmingham General Dispensary.

Mackey, Edward, L.R.C.P. Edin., has been appointed Junior Resident Surgeon to the Birmingham General Dispensary.

Ringland, John, F.K.Q.C.P.I., has been elected one of the Examiners in Arts at the King and Queen's College of Physicians in Ireland.

Simmonds, Henry M., M.R.C.S. Eng., has been appointed Medical Officer for the Workhouse of St. Mary's, Newington.

Steele, William E., F.K.Q.C.P.I., has been elected one of the Examiners in Arts at the King and Queen's College of Physicians in Ireland.

Walker, George Charles, M.D. St. And , has been appointed Honorary Medical Officer to the North Dispensary, Liverpool.

DEATHS.

Biddle, Charley H., M.D. St. And , at the Public Dispensary, Leeds, on May 1, aged 27.

Buchanan, A. B., M.D. Glasg., at Glasgow, at April 4.

Davies, Sir David, K.C.H., M.D., at Lucca, Italy, on April 2, aged 73.

Drysdale, James, L.R.C.S. Edin., at Kinross, N.B., on April 21.

Eccleston, Thomas B., M.R.C.S. Eng., at Warrington, on May 6, aged 41, formerly of Newton-in-le-Willows.

Evans, Evan T., L.R.C.P. Edin., at Rose-place, Liverpool, on April 17, aged 41.

Hamilton, Charles T., M.D. Edin., at 6, Windsor-terrace, Maida-hill, W., on May 3, aged 52.

Jones, J., M.B., at Tower House, Gloucester-road, Regent's-park, N.W., on April 12, aged 55.

Kenny, Mason S., M.D. Edin., at Ballinrobe, Co. Mayo, on April 23, aged 77, formerly of Halifax.

Kinsey, Robert B., F.R.C.S. Eng., Deputy-Inspector-General of Hospitals, Dinapore, at Calcutta, on April 1, aged 48.

Lightbody, J., Surgeon-Major on half-pay, at Danube-street, Edinburgh, on April 21, aged 78.

Pendlebury, Wm. H., M.R.C.S. Eng., at Bolton, Lancashire, on April 1.

Robertson, Charles, L.R.C.P. Edin., at Scarborough, Yorkshire, April 16, aged 36.

Sawyer, John J., M.R.C.S. Eng., at Park-street, Grosvenor-square, W., on April 14.

Smith, William H., F.R.C.S. Eng., at Southsea, Hants, on April 5, aged 54.

The College Lectures.—Professor Fergusson, F.R.S., will complete the course of lectures annually delivered in the theatre of the College of Surgeons, by delivering six lectures on the "Progress of Surgery during the Present Century." The lectures will be delivered on Mondays, Wednesdays, and Fridays, at 4 o'clock, commencing on the 5th proximo.

F.R.S.—The Council of the Royal Society recommend the following gentlemen for election:—Sir F. L. M'Clintock, Lieutenant-Colonel J. T. Walker, Dr. G. Harley, Dr. R. M'Donnell, Rev. W. R. Dawes, and Messrs. H. Christy, James Cockle, A. Geikie, G. Gore, R. Grant, G. R. Gray, W. Huggins, W. K. Parker, A. Tennyson, and G. H. K. Thwaites.

Typhus in Malta.—A severe form of typhus fever has lately been very prevalent in several of the country districts in Malta. Its virulence has now abated, and from a report made by order of the Governor it appears that it was due to overcrowding in ill-ventilated apartments.

Medical Charities.—The funds of the Dorset County Hospital, situated at Dorchester, have been augmented by a bequest of £100 under the will of the late Earl of Ilchester. This benevolent nobleman left a similar amount to the Dorset Eye Infirmary at Weymouth, and liberal bequests to other institutions not strictly Medical.

The Great Northern Hospital.—The annual festival of this charity was held on Tuesday last at the Albion Tavern, Aldersgate-street. The Right Hon. the Lord Mayor presided. In the course of the evening a legacy of £2000 from the late Cuthbert Collings, Esq., and donations and subscriptions to the amount of £1040, including a donation of £180 from the Society for the Relief of Insolvent Debtors through the treasurer, B. Bond Cabbell, Esq., were announced.

Conviction under the Medical Act.—A Justice of Peace Court at Aberdeen, on Monday afternoon, had before them a case in which Frederic Adair, who addressed himself to a certain class of cases, was accused of advertising himself as M.D., F.R.C.S., without a title to do so. A witness said he had given the accused directions as to getting a diploma from Glasgow. One was produced bearing to be from the Metropolitan College, New York, conferring the degree of M.D. on Frederic Adair. After other evidence Adair was fined £5, with costs, £2 2s., for using the letters F.R.C.S. without warrant.

A Dangerous Patient.—An attempt has been made to assassinate M. Lediberder, a Practitioner of L'Orient, in Brittany, by one Nahenec, aged 68, a retired tanner, suffering from hypochondriasis. Having called to pay the bill which his Doctor had sent him, he had entered into conversation, when suddenly he discharged a double-barrelled pistol, the balls entering M. Lediberder's chest and abdomen. "You wretch!" exclaimed the Doctor, "you have murdered me." "Well," replied the assassin, "you promised to cure me," at the same time firing another pistol at his own head, which, however, was only grazed by the ball. M. Lediberder's condition is not regarded as quite hopeless, and aid has been summoned from Paris.

Westminster Hospital.—The distribution of Prizes to the students of the Westminster Hospital took place on Wednesday, May 10, Lord Charles Russell in the chair. Summer Session, 1864: *Practical Chemistry.*—Mr. W. C. Watson, prize; Mr. Joseph Oakman, certificate; Mr. John C. F. McDonald, certificate. *Materia Medica.*—Mr. Robert Charles Brookes, prize; Mr. Arthur Hill, certificate. *Botany.*—Mr. W. C. Watson, prize; Mr. Walter Moore, prize; Mr. Thomas Joseph Quicke, certificate. *Forensic Medicine.*—Mr. G. P. Bate, prize; Mr. Arthur Hill, certificate; Mr. Richard Bugden, certificate. *Midwifery.*—Mr. Richard Bugden, prize. Winter Session, 1864-65: *Anatomy.*—Mr. J. C. F. McDonald and Mr. W. C. Watson (equal), prize; Mr. Walter Moore and Mr. Robert Charles Brookes (equal), certificate. *Prosectors' Prizes.*—Mr. G. P. Bate and Mr. Robert Charles Brookes. *Chemistry.* — Mr. Winckworth, prize; Mr. Charles Henry Furnivall, certificate. *Physiology.*—Mr. J. C. F. McDonald, prize; Mr. Walter Moore, certificate. *Medicine.*—Mr. G. P. Bate, prize; Mr. Richard Bugden, certificate. *Surgery.*—Mr. G. P. Bate, prize; Mr. Arthur Hill, certificate. *Clinical Medicine.*—Mr. G. P. Bate, prize. *Clinical Surgery.*—Mr. G. P. Bate, prize. *Dental Surgery.*—Mr. Joseph Oakman, prize; Mr. Robert Charles Brookes, certificate. *Chadwick Prize.*—Mr. G. P. Bate, prize; Mr. Arthur Hill, prize.

The Hunterian Society.—Adjourned Discussion on Syphilis.—The next meeting of this Society is to be devoted to the discussion of a paper read by Mr. Hutchinson at a former one on the "Medical Aspects of Syphilis." One adjourned meeting has already taken place; but the debate not being concluded, it has been decided to resume it next Wednesday, May 17. The President invites the attendance of all interested in the subject. No paper will be read, but the following propositions will be submitted to criticism:—"1. That syphilis ought to rank as an exanthematic fever, having its stages of incubation, efflorescence, decline, and sequelæ. 2. That the secondary rash (together with iritis, retinitis, condylomata, mucous patches, and superficial inflammations of the mucous membranes) is the exanthem stage. 3. That both primary and secondary stages will, after a certain duration, disappear spontaneously. 4. That the evolution of the exanthem cannot be prevented by internal treatment during the period of incubation. 5. That the symptoms which constitute the tertiary class are rather sequelæ

(more or less accidental) than a true stage. They are irregular as to their time of outbreak, have no tendency to spontaneous cure, and they relapse over and over again after remedial treatment. 6. That a very important distinction between the secondary and tertiary symptoms is found in the fact that secondary phenomena are, as a rule, symmetrical, and tertiary, as a rule, not so. 7. From the symmetry of secondary symptoms we infer that they depend on a poison circulating in the blood; and from the non-symmetry of the tertiary that they depend upon defective organisation of the solids rather than upon any pre-virus still existing in the blood. 8. This statement as to the non-symmetry of tertiary lesions applies only to acquired syphilis. In inherited syphilis some very remarkable differences are noticed. The distinctions between the stages are much less marked, and most of the symptoms are symmetrical. 9. Of the symptoms which should be classed as tertiary, the following are the chief: Serpiginous ulcerations of the skin and mucous membranes; syphilitic orchitis; nodes, whether of bone, periosteum, cellular tissue, tendon, bursa, or ligament; deposits in the internal viscera, and diseases of the nervous system. 10. That the investigations of recent observers have proved that very numerous and important organic diseases are remotely but directly consequent upon syphilis, and are to be cured only proceeding on that supposition.

The Russian Epidemic.—The *Journal de St. Pétersbourg* publishes the following return respecting the epidemic at St. Petersburg:—"In the first days of April the number of sick had considerably decreased, despite the period of festivities, the breaking up of the ice, and other hygienic disadvantages; though in the week after Easter the Hospitals of the capital were again crowded; but this fact must be attributed to the great affluence of workmen. The Hospital Doctors have observed that there lies the real cause of typhus, of relapsing fever, and other virulent maladies which have shown themselves among the newly-arrived workmen. Nevertheless, there is room enough in the Hospitals; and the sick, thanks to the collections that have been made in every quarter, are admirably taken care of and fed, and even given tea, sugar, and change of linen. The following is a comparison between March, 1864, and March, 1865:—

Number of Sick in all the Hospitals.

	March, 1864.	March, 1865.
Sick	5,634	11,404
Cured	2,396	5,343
Died	370	1,211
Not cured	2,868	4,850

The following is the proportion of deaths:—

	1864.	1865.
To the number of sick	1 in 15	1 in $9\frac{1}{3}$
To the number of cured	1 in $6\frac{1}{8}$	1 in $4\frac{1}{2}$

Odontological Society.—The monthly meeting of this Society was held on Monday, May 1, Thomas A. Rogers, Esq., President, in the chair. The President referred to the recent death of Mr. Parkinson, the second President of the Society, and said he only echoed the sentiments of the whole Profession in publicly recording the sorrow of their Society at the loss they had sustained. The Secretary brought forward a model taken in the practice of Mr. Walkinshaw, representing a case of torsion, in which the lateral incisor on the left side was turned half round. On turning the tooth round by means of the forceps it was found to be of an oval shape transverely, so that it projected considerably beyond the natural arch. Some discussion ensued as to the use of the forceps for turning teeth, Mr. Tomes and Mr. Catlin stating that they had frequently performed the operation with complete success. Models were also brought forward by Mr. Williams, representing cases of double cleft palate with double harelip, taken from children at the age of four, seven, and seventeen days. Mr. H. Rogers said he had been making experiments with a view to improve the quality of solders for the mouth. He tried several metals, but ultimately preferred cadmium, making the solder in the proportion of a grain and a quarter of cadmium to a pennyweight of gold. That solder flowed easily, held well, and came a good colour out of hydrochloric acid. Mr. Ramsay then read a paper on the treatment of congenital cleft palate adopted by Dr. Kingsley and himself. He proceeded to explain the method of producing the artificial velum, noticing the improvement which took place in mastication and deglutition after the fissure had been artificially closed. He also took up the subject of articulation, explaining the system he adopted in instructing the patient to articulate; and, lastly, compared Dr. Kingsley's method of mechanical treatment with the Surgical operations which hitherto had been considered the most successful method for remedying those congenital deformities. A long and interesting discussion followed, and at the close the thanks of the Society were unanimously voted to Mr. Ramsay.

University College, London.—Faculty of Medicine.—Distribution of Prizes on Monday, May 8, 1865.—Sir Rutherford Alcock, K.C.B., in the chair. The following prizes were awarded:—*Practical Physiology and Histology*, Professor Harley, M.D.—Silver medal, Mr. Richard Gowers; Certificates, George V. Poore, Thos. R. Loy, Gysbert H. Maasdorp, R. L. Roberts. *Anatomy*, Professor Ellis.—Senior Class: gold medal, G. H. Maasdorp; 1st silver medal, J. Wreford Langmore; 2nd silver medal, T. R. Loy; certificates, Richard Matthews Pryce, Louis Le Grand, Thomas Lettis. Junior Class: silver medal, W. H. Allchin; certificates, David Havard, Samuel Pidwell, William J. Scott, Tempest Anderson. *Anatomy and Physiology*, Professor Sharpey, M.D.—Gold medal, William R. Gowers; 1st silver medal, J. Davis Thomas; 2nd silver medal, George V. Poore; certificates, Louis Le Grand, Thos. Hopgood, J. W. Langmore, R. M. Pryce, Thomas B. Hay, Tempest Anderson, G. H. Maasdorp. *Chemistry*, Professor Williamson.—Gold medal, Frederick Toplis; 1st silver medal, James John Bowey; 2nd silver medal, Tempest Anderson; certificates, Temple A. Orme, Henry N. Martin, Henry James Benham, R. C. Joy, R. L. Roberts, Henry Cass, J. C. Bruce, Milward Harding, W. W. Houlder, A. Payton Hurlestone, Y. Yamaora. *Comparative Anatomy*, Professor Grant, M.D.—Gold medal, William H. Allchin; certificates, Henry Cass, R. L. Roberts, Tempest Anderson, James C. Bruce. *Principles and Practice of Medicine*, Professor Jenner, M.D.—Gold medal, J. Wickham Legg; 1st silver medal, William Hoffmeister; 2nd silver medal, Julian A. M. Evans; certificates, William A. Stuart, Charles J. Hardy Smith, W. Cunningham Cass. *Surgery*, Professor Erichsen.—Gold medal, Marcus Beek; 1st silver medal, Frederick B. Nunneley; 2nd silver medal, Henry Clothier; certificates, F. J. Grose, B. H. Allen, C. J. Hardy Smith, Joseph Thomson, jun., Stammen Morrison, J. E. Coxwell. *Special Class of Clinical Medicine*, Professor Reynolds, M.D.—1st prize, William Andrew Stuart; 2nd prize, William Hoffmeister; 3rd prize, Edward De Morgan; certificates, Henry Clothier, John Williams, John W. Legg, William C. Cass, Charles F. Leshbridge, Robert C. Beck, Thomas F. Hopgood, Charles R. Streton, Joseph Thompson. *Fellowes' Clinical Medals.*—Summer, 1864: gold medal, George Jackson. Winter term, 1864-65: gold medal, William V. Snow.

A Benevolent Proposal.—The following letter appeared in the *Times* of Thursday, May 11:—

"*To the Editor of the Times.*

"Sir,—A proposal has been made to me by Captain Erskine, Her Britannic Majesty's Consul at Funchal, in the island of Madeira, of so liberal and charitable a nature that I venture to hope you will help in its realisation by giving it the publicity of your columns.

"He offers, with the co-operation of several residents and visitors, to guarantee the maintenance and Medical treatment of twenty consumptive patients during the coming winter, if the authorities of the Brompton Hospital will undertake to provide transport to and from the place. This, with the assistance of the governors and public, the committee hope to accomplish.

"If the experiment prove successful, measures can subsequently be taken for its permanent continuance. It is suggested that the first party sent out should consist entirely of men, from the greater ease with which they can be conveyed and provided for on their arrival.

"I sincerely hope no impediment will prevent the success of this excellent scheme. During my recent visit to the island I became convinced that the climate, though not perhaps beneficial to all cases of phthisis indiscriminately, still exerts a most singular and salutary influence on them if properly selected. The proposed sanatorium would thus not only be a work of the highest charity, but would tend materially to advance Medical knowledge by enabling the effects of climate as a therapeutic agent in pulmonary disease to be studied under circumstances the most favourable.

"I remain your obedient servant,

"William H. Stone, F.R.C.P.,

"Assistant-Physician to the Hospital.

"Hospital for Consumption and Diseases of the Chest, Brompton, London, S.W., May 10."

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

H.M.S. Dreadnought.—Our present arrangements do not permit us to insert announcements of marriages.

Dr. R. Ballota Taylor.—The examinations for the degree of M.D. Erlangen take place at that University in the months of February and March, and June and July, or at any other time the examiners may think fit to appoint. They are held in the Latin or German languages.

Griffin Testimonial Fund.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The following subscription has been further received on behalf of the above fund:—J. G. Leete, Esq., Thrapstone, 10s.; amount previously announced, £123 11s. 3d.; received at *Lancet* office, £9 9s.

I am, &c.

Robert Fowler, M.D., Treasurer and Hon. Sec.

145, Bishopsgate-street Without, May 10.

The Mysterious Poison Case at Dawlish.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I have only just succeeded in obtaining samples of Simpson's rat poison from Messrs. Blackwell and Son, of Plymouth, who appear to be the only agent for this article in the West of England, as I have failed in getting it in most of the chief towns, even Exeter and Bristol, most of the druggists of whom I have inquired informing me that it is very seldom found in the trade. I have also analysed it, and find that the packets contain a very irregular quantity of material, varying from seven and a half to thirteen and a half grains; and the four packets contained forty-one and a half grains, giving an average of a little more than ten grains for each powder if all were equally well mixed and properly weighed or divided. The mixture consists of arsenious acid—potato starch—coloured by Smaltz, and flavoured or scented with some essential oil, probably oil of rhodium. I found ten grains of the well-mixed powder to contain four grains of arsenious acid. It is therefore certain that Mrs. Williams had arsenious acid in her own possession, and that she must have taken from six to eight grains, as two empty packets were found by the police in her bedroom. This is a quantity sufficient to kill, but requiring more time, probably, than she liked; and the explanation of the reason why the third packet was made use of has already been given. I greatly regret that there was no opportunity given me of examining the saliva for strychnia, as that would have determined the question whether that poison had also been taken into the mouth. Mrs. Williams had been buried during the interval of the adjournment of the inquest, and I never saw the handkerchief. It is probable, therefore, that Mrs. Williams purchased all these rat and vermin poisons at Plymouth, on her way up to Dawlish from Devonport, and the tracing of the arsenic into her own possession is satisfactory to all parties, as the matter is now fully explained; all other theories must be for ever set at rest.

I am, &c.

Old Market-street, Bristol. W. Bird Herapath.

Poor-law Medical Relief.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I shall feel obliged by your calling attention to the circular letter(a) from the Poor-law Board to the Boards of Guardians, as it is a document of very considerable importance. I should recommend the Medical officers of each Union to meet and, if possible, come to some definite decision as to what should be considered "expensive medicines." Cod-liver oil and quinine are named; and, in addition to these, I should say, leeches, castor oil, sarsaparilla, and, perhaps, a few other drugs might be added, but not too many, for fear that all may be rejected.

It may be fairly pointed out to the guardians that the recommendation of the Select Committee was made for the benefit of the poor, as it was considered that, in consequence of the expensive nature of many articles, and the very low salaries paid to the Medical officers, they could not always afford to purchase them, and, as a consequence, the poor have not had them to any very great extent; therefore, to attempt to reduce any of the salaries cannot be submitted to by the Medical officers. Should any of the Boards of Guardians be disposed to find all the medicines for the poor, I should strongly recommend the Medical officers to second the proposal, and submit to a general revision of their salaries.

I am, &c.

12, Royal-terrace, Weymouth, April 15. Richard Griffin.

Snuffism in Epilepsy.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—*Apropos* of Professor Laycock's paper on the treatment of epilepsy by snuffism, I should like to refer to the supposed efficiency of this test of malingering in doubtful cases. I suspect that Medical men not unfrequently think themselves uncommonly shrewd in detecting imposture when no imposition whatever exists, the result being that the Physician is the dupe, not of the patient, but of his own want of knowledge. Dr. Watson observes that "Dr. Hutchinson relates the case of a sailor who was suspected to be a cheat, in whom the convulsions of epilepsy were instantly removed by blowing some fine Scotch snuff up his nostrils through a quill. This brought on another kind of fit—viz., a fit of sneezing—which lasted nearly half an hour, and there was no return of the epilepsy so long as Dr. Hutchinson remained in the ship." (Lectures, vol. i., p 645.) Now, although the trial of snuff in some other cases of epilepsy did not lessen the number of attacks, is it not probable that the sailor really laboured under epilepsy? At any rate, it seems perfectly clear that the test is utterly worthless, and might lead the Practitioner to a most cruel and unjust conclusion.

In conclusion, I beg to add that Dr. Marshall Hall pointed out that the use of snuff would in some instances prevent the occurrence of the fit.

May 3. I am, &c. M.R.C.P.

Protracted Pregnancy and Large Size of Child.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—A few days ago a lady was delivered of a child weighing eleven pounds and a half; it was a male. Her pregnancy must have lasted at least forty-two weeks, even assuming that impregnation had taken place just before the expected menstruation. Quickening came on five months and a half before delivery. Eight years ago she was delivered of very large twins, and had no child since.

I am, &c.

Artillery-place, May 9. Augustus Hess, M.D., M.R.C.P.L.

Government Fees for Life Insurance.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—We shall feel obliged if you will give insertion to the enclosed correspondence, having reference to the remuneration of the Medical examiners to be appointed under the Government Insurances and Annuities Act.

We are, &c.

T. L. Walford.
Wm. Butler Young.
Francis Workman.

Reading, March 11, 1865.

"Sir,—We beg to acknowledge the receipt of your letter, dated March 8th, having reference to the appointment of Medical men to examine persons presenting themselves for examination under the 'Government Insurances and Annuities Act.'

"In reply, we beg to state that some time ago the Medical men of Reading resolved not to accept a lower fee than half a guinea for the examination of a life from any insurance office. In the present case, bearing in mind the object of the above-mentioned Act, we are disposed to relax this resolution, and are willing to accept the sum of 10s. as the fee for all examinations where the sum assured exceeds £50, and the sum of 5s. where it does not exceed that amount.

"We shall feel obliged if you will bring the subject of the remuneration of the Medical examiners again under the notice of the Postmaster-General, as we feel assured that on a further consideration his Lordship will be satisfied that the amount which he proposes to recommend to the Commissioners of Her Majesty's Treasury is too small compared with the amount of time and labour required for each examination, the questions in the form which you have enclosed being more minute than those required by insurance offices generally.

"We feel a greater confidence in asking for a more liberal remuneration as the security against risk must depend upon the care with which the Medical examination is made. Awaiting your reply,

"We are, sir, your obedient servants,

"T. L. Walford.
Wm. Butler Young.
Francis Workman.

"F. J. Scudamore, Esq., General Post-office, London."

"General Post Office, April 13, 1865.

"Sir,—In acknowledging the receipt of the letter signed by yourself and Messrs. Young and Workman, dated the 11th inst., I beg leave to inform you that the subject of the fees to be paid for the Medical examination of persons proposing to insure their lives under the Government Insurance Act was very fully considered by the Postmaster-General before the circular letter dated the 8th March last was issued, and that the replies to that letter expressing willingness to undertake the duty for the terms proposed have been so numerous as to render it unnecessary—at all events, for the present—to make any alteration in those terms.

"The subject was again brought under the notice of the Postmaster-General by a deputation from the Parliamentary Committee of the British Medical Association on March 15; but even at that early date, after the issue of the circular letter, the terms had been accepted so generally that his Lordship felt bound to inform the deputation that he could hold out no hope that the amount would be increased.

"Since that date the majority of the Medical men to whom the circular letter was addressed have accepted the terms, and applications are made daily to the Department by other members of the Profession for employment under the Act—in many cases by more Medical men than are required.

"Looking, therefore, to all these circumstances, I can only express to you the regret of the Postmaster-General that he cannot entertain the application made in your former letter of March 11.

"I am, Sir,

"Your most obedient servant,

"T. L. Walford, Esq." "Frank J. Scudamore.

On Catarrh.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Your correspondent "Alpha"(b) seems to have had considerable difficulty in stopping the bleeding from the leech-bites when he leeched the nares. Permit me to bring before his notice the simple expedient of plugging the nostrils with a small dossil of lint dipped in cold water; he will find this all that is necessary for his purpose, though perhaps not all that could be desired. About ten years ago, when leeching my nares for a severe headache, and when in the act of making an experiment of my case by collecting the blood as it dropped from my nose, I was called out to see a patient taken suddenly ill; the plugging of the nostrils with wetted lint at once arrested the bleeding, which was still dropping somewhat freely. The mucous membrane of the nose is very vascular. I collected upwards of two and a-half ounces of blood, including, of course, what came out of the two leeches; the nares is, therefore, a good surface to take blood from when our supply of leeches is small; and it might with propriety be adopted in Hospitals and other charities as a measure of economy; but, independent of these considerations, I have found leeching the nares useful in congestive headaches, in the headaches of the plethoric, and in cases of incipient apoplexy. Did space permit, I could give cases; as it is, I shall only give one.

About eight years ago, two brothers, captains of vessels, called at the same port at the same time, the one brother to wait the outfit of a new vessel; the other to get his vessel repaired. The captain of the new vessel (a stout, plethoric man) called on me complaining of giddiness, drowsiness, numbness of the feet and hands, and other symptoms of incipient apoplexy. Leeching the nares and purgatives entirely removed those symptoms in a few days. My patient had, however, scarcely recovered from his illness when I was sent for to inspect the body of his brother, who had suddenly died of apoplexy,—the third of a family of four brothers who had died of this disease. The treatment I have found most useful

(b) See *Medical Times and Gazette*, April 1, 1865.

for catarrh or coryza in the early stage is a mustard foot-bath, repeated, if necessary, two or three nights in succession, mustard applied to the nape of the neck, or the nape of the neck to be well rubbed with a stimulating liniment. The following I generally use:—R. Lin. saponis; tr. aconiti (Fleming's); tr. capsici; chloroform, āā ʒij. M. Sig. The nape of the neck to be well rubbed with this liniment night and morning.

The rest of the treatment consists in a good glass of brandy-punch or whisky-toddy immediately after the chill or on going to bed, followed in the morning by a saline draught, and, if necessary, a dose of Plummer's pill with aloes in the evening, and, if convenient (which it seldom is), two days within doors. When the catarrh is accompanied with pain in the ear, as it often is, I have found benefit from plugging the ear with wool dipped in hot olive or almond oil; the oil can be heated by merely holding the pledget of wool to the fire. This treatment in my hands has been attended with excellent results; I can, therefore, confidently recommend it to "Alpha," or to any one subject to catarrh. I am, &c.

Blantyre, May 5. THOS. DOWNIE, M.D., etc.

P.S.—In justice to "Alpha," I have to state that I have not leeched specially for catarrh, and therefore he is entitled to whatever merit is due for the information we have received.

COMMUNICATIONS have been received from—

Mr. C. S. BARTER; Dr. FOTHERBY; Mr. W. COPNEY; Dr. W. BIRD HERAPATH; Mr. F. J. WILSON; Dr. ROBERT FOWLER; Mr. HARRY G. MOORE; Mr. R. FREEMAN; Dr. JOHN WHITMORE; Dr. HARRY LEACH; Mr. T. L. WALFORD; M.R.C.P.; Dr. A. HESS; Dr. R. B. TAYLOR; Mr. W. FAIRLIE CLARKE; Mr. C. C. ATKINSON; ROYAL INSTITUTION; ODONTOLOGICAL SOCIETY; HUNTERIAN SOCIETY; Mr. R. LAWSON TAIT; THE ROYAL ALBERT VETERINARY COLLEGE; Mr. GEORGE GREWCOOK; APOTHECARIES' HALL; Dr. T. DOWNIE; HARVEIAN SOCIETY OF LONDON; Dr. ALEXANDER ROBERTSON; OBSTETRICAL SOCIETY OF LONDON.

BOOKS RECEIVED.

A Treatise on Smoky Chimneys: their Cure and Prevention. By Fredk. Edwards, jun.

*** Fifteen causes are enumerated:—1. A fire-place being too open. 2. Doors and windows of a room being fitted too closely. 3. Fires being lighted in two or three adjoining rooms which are inadequately supplied with the air required by the grates in use. 4. A chimney being very short. 5. A chimney being situated in an external wall and not being sufficiently protected against the action of the external air. 6. A chimney being exposed on two or three sides to the action of the external air, and the brickwork not being sufficiently thick. 7. A low chimney being in connexion with a room adjoining a house or building in which the air becomes rarefied. 8. A down current in a fire-place bringing smoke from an adjoining chimney. 9. The top of a chimney being situated below a pitched roof. 10. The top of a chimney being situated near to a tower or similar source of obstruction to the wind. 11. A short chimney being enclosed on three or four sides by high contiguous buildings. 12. Rooms with short chimneys being situated between the main body of a building and a contiguous eminence. 13. Chimneys of one house being lower than those of one adjoining. 14. A chimney being too small for the fire-grate used. 15. Two fire-places being used for one chimney.

The Epidemic of Fever in Lower Bengal.

*** Anonymous.—The disease is a congestive remittent fever. The writer advocates the early use of quinine in very small doses, ½—½ gr., and says that 3—4 gr. doses aggravate the symptoms. He recommends quinine also as a prophylactic. "If the Medical Profession had sufficiently urged upon Government and private individuals the necessity of this measure, instead of suggesting the doubtful necessity of clearing jungle, under the pretence of which large and valuable fruit and other harmless trees, had been cut down by the insolent and greedy subordinate officials, and if accordingly quinine had been liberally supplied to the poor villagers, the sorest calamities would certainly have been averted from millions of families in Bengal."

The Law of Lunacy as it Affects the Insane Charged with Crime. By J. G. Davey, M.D.

*** Dr. Davey maintains in this pamphlet "that the several tests which the ingenuity of the peers and judges has created, tests held to discriminate the sane from the insane, the responsible from the irresponsible, constitute a mere sham, a metaphysical chimera—in short, an idle fiction, a *delusion*." He holds that the springs of all human action are to be sought, not in the understanding or knowing faculties, but in the tone and quality of the moral feelings, the affections, and propensities.

Essai sur la Médication Isolanto ou Traitement des Inflammations en Général par les Enduits Imperméables; avec des Observations Cliniques a l'Appui Suivi de Quelques Considérations sur la Nature et la Traitement de la Fièvre Dite Puerpérale. Par le Dr. Ferdinand Benoist. Poitiers. 1864.

*** The method recommended is the covering of the surface over the inflamed part with a layer of collodion. The author is certainly enthusiastic, and we think his enthusiasm carries him rather too far. Doubtless in some cases collodion is a valuable remedy, but we should hesitate to trust in it, as the author does, in deep-seated inflammation.

Archives de Médicine Navale. Tome I. Nos. 1 and 2.

*** Published by order of the French Minister of Marine. The present number contains a report of the Hospital ship *La Caravane* in the Gaboon. The writer gives a miserable account of the dietetic resources of the station. The deficiency of fresh animal food and vegetables is such as to weaken the strongest constitution, and produce anæmia even when paludal fever is not conjoined.

A Treatise on Vaccination; being a Description of its Nature, its Origin, and Progress amongst the Population of India. By Daniel Robert Thompson, M.D. Madras: Gantz, Brothers.

*** This little book is intended apparently for the use of native students. The author lays great stress upon his doctrine that "up to the evening of the seventh day" vaccinia is only a "local disease."

Insanity and Crime: a Paper Read before the Bath and Bristol Branch of the British Medical Association, on February 18, 1864. By James George Davey, M.D.

*** Dr. Davey, in this paper, advocates the view of Townley's insanity. Like other Medical writers, he is dissatisfied with the present "plea of insanity."

The Modern Practice of Medicine: a Lecture Delivered before the Royal College of Surgeons. By D. Rutherford Haldane, M.D. Edinburgh: Oliver and Boyd.

*** The central idea which Dr. Haldane's remarks are intended to enforce is contained in the following extract:—"The Physician seldom attempts to *cure* disease; he endeavours to place and maintain his patient in the most favourable condition for recovery, and he treats symptoms, although he often does not know on what they essentially depend."

Cocoa: its Growth and Culture, and Manufacture, etc. Accompanied by easy methods of analysis whereby its purity may be ascertained. By Charles Hewett, of the firm of Dunn and Hewett, chocolate and cocoa manufacturers. 1862.

*** Does not regard the addition of starches and sugar an *adulteration*. Nor do we, unless the article is sold as *pure* cocoa. Let it be understood that manufactured cocoas are all thus "amalgamated," and we should not complain.

Inhalation the most Rational Treatment for Diseases of the Respiratory Organs. By C. T. Schmid, M.D., and C. Milner, M.D. London and Cambridge: Macmillan and Co.

*** This pamphlet contains an account of Dr. Siegle's apparatus for the inhalation of pulverised fluids, and the application of this method in the treatment of various diseases.

On the Inhalation of Gases and Medicated Vapours in the Treatment of Consumption, etc. By W. Abbotts Smith, M.D. London: R. Hardwicke.

*** Reprint from the *Medical Mirror*. It is a fair, but brief summary of the use of inhalations in orthodox practice. Appended to this is a second paper on the Treatment of Hooping-Cough, advocating the use of the bromide of potassium.

Sanitary Statistics of Cheltenham. By Edward C. Wilson, M.B. Oxon., etc. London: Longman and Co.

*** This is a paper which was read before the British Association at Bath last year.

On the Use of Alkaline Lactates in the Treatment of Functional Diseases of the Digestive Organs. By J. E. Petrequin, M.D. Paris: Grimault and Co. 1864.

*** We believe this pamphlet has been distributed pretty extensively among the Profession in this country by M. Du Buisson, the Pharmaceutical Chemist of Lyons, who prepares the lozenges and powders containing the lactates of soda and magnesia.

Census of the Island of Bombay, taken February 2, 1864.

*** It seems that the taking of this census was no easy task. The poor and ignorant natives often shrank from the inquiry, and actually hid their families, from the fear that the enumeration was made with a view to taxation. The total population of Bombay as enumerated was 816,562, the males being to the females in a ratio of 185·4 to 100.

Hints towards an Improved System of Poor-law Medical Relief. By E. T. Warry, M.D.

*** "I would wish to impress upon guardians of the poor in England that, by paying their Medical officers in a manner proportionate to their services, they will ensure to the poor prompt attention, skilful treatment, and good medicine, thus materially economising the public expenditure." It is very certain that it is only by making these appointments worth the holding that the poor will ever get the sort of attendance that should be provided for them.

Collection de Mémoires sur une Fonction Méconnue du Pancreas, la digestion des aliments azotés. Par Lucien Corvisart, Médicin Ordinaire de l'Empereur. Paris. 1857-63. Pp. 206.

*** It is scarcely necessary to review this book at length, inasmuch as the memoirs have become, we should hope, familiar to English physiologists as they have appeared. However, we think it well that they have been brought together in the present form.

Case of Degeneration and Atrophy of the Cerebrum, causing Unilateral Epilepsy. By Kenneth McLeod, A.M., M.D. 1864.

*** The history of a case admitted into the Durham County Asylum. Very interesting and important, but impossible to review. The paper must be read *in extenso*.

First Annual Report of the Self-Supporting Dispensary at Colombo. By S. de M. Aserappa, M.D., Edin.

*** The objects of the Institution are—1. To bring within easy reach of the working classes of the inhabitants of Colombo efficient Medical aid. 2. To lead the natives generally to a due appreciation of European Medical treatment.

Seventeenth Annual Report of the Chinese Hospital at Shanghai.

*** This Hospital is associated with a missionary enterprise, and there can be no doubt that the greatest successes must await those who follow the footsteps of their Master, and find their way to the hearts of men by compassionating and healing their sick.

The Painless Extinction of Life in Animals designed for Human Food. By Henry MacCormac, M.D. Longman. 1864.

*** The proposed plan consists in the use of carbonic acid gas. The author would discourage bleeding. We should like to hear something about the keeping qualities of meat that has not been bled, especially in hot weather.

A Review of the Treatment of Tropical Diseases. By Joseph Ewart, M.D., Bengal Medical Service. Part II. Tropical Dysentery. 1863.

*** The subject is discussed chronologically. A great part of this pamphlet is occupied with the subject of ipecacuanha as a remedy.

Lunatic Asylum Reports: Dorset, Sussex, Perth, Nottingham, Devon, Warwickshire, Norfolk, Northampton, Wilts, Wye House, Buxton, and Brislington House, near Bristol.

*** We shall review these as soon as possible.

Vital and Economical Statistics of the Hospitals, Infirmaries, etc., of England and Wales for the Year 1863. By F. Buckle, M.D. London: John Churchill and Sons.

*** Will be noticed shortly.

The Saline Treatment of Cholera. By J. Kellie, M.R.C.S., Deputy-Inspector-General of Hospitals, H.M. Indian Army.

*** The object of this pamphlet is to defend the practice of Dr. Stevens from misrepresentation. Dr. Kellie advocates the injection of Dr. Stevens' solution into the rectum while acetate of lead or some other astringent is given by the mouth.

The Difference between the Statutes bearing on Public Health for England and Ireland. By E D. Mapother.
*** This paper advocates the extension of our sanitary Acts (with necessary modifications) to Ireland.

Rules of the Medical Provident Society in Connexion with the British Medical Association.
*** The British Medical Association has done good service by the establishment of this Society. We look forward with interest to its working. The table of contributions has been certified by Mr. Finlaison.

Annual Report of the Bourton-on-the-Water Village Hospital. January, 1865.
*** We have more than once alluded to the Cranley Village Hospital. Here is a report of another successful attempt at a similar institution.

In Memoriam of the late William Williamson, A.M., M.D. By Alexander Harvey, M.D. Aberdeen. 1865.
*** This feeling address, inculcating a lesson of caution, was delivered in the Royal Infirmary of Aberdeen on the occasion of Dr. Williamson's death from a second attack of typhus.

Practical Suggestions as to Means of Providing Cheap and Abundant Food. London: Longman and Co. 1865.
*** The "food" chiefly had in view is milk. The writer hopes "that new systems of cropping and feeding may be found of a nature to provide milk and vegetables at much lower prices than those now demanded."

For and Against Tobacco. By B. W. Richardson, M.A., M.D. London: John Churchill and Sons.
*** In spite of all that Dr. Richardson has to say against the use of tobacco, he sums up by calling it "one of the least hurtful of luxuries."

Report of the Nottingham Dispensary. 1864.

L'Art Medical, Intérêts Sociaux, Scientifiques, and Professionnels. Brussels. 1865. No. 2.
*** A new periodical. This number contains a contribution towards the history and diagnosis of "Sterility in the Female," by M. Houzé.

Nord Americanische, Deutsch' Medicinische Zeitschrift für Practische Heilkunde. Buffalo. April, 1865. No. 1.
*** A new periodical published for the benefit of the German Practitioners in North America.

The Sewage of the Metropolis. A Letter to John Thwaites, Esq.; being a Comparative Analysis of Baron Liebig's Three Letters. By Messrs. Napier and Hope. 1865.
*** Part of an important controversy upon a subject which requires to be viewed from more points than one.

The Archives of Dentistry, No. 3. London: John Churchill and Sons.
*** It contains three original papers—one on Filling Teeth with Gold, by Mr. Bate; one on Mechanical Dentistry, by Mr. Edwin Freeman; and one by Dr. B. W. Richardson, designated Historical Notes on the Science and Practice of Dentistry in England.

Journal de Médicine Mentale. Paris. 1864. Tome iv.
*** Contains a discussion upon the partial responsibility of the insane, and a capital paper on the value to be attached to anything *written* by the insane.

Man considered Socially and Morally. By G. Sparkes. London: Longman and Co
*** This is not exactly the sort of book for us to review at any length. We need only say that our Professional brethren may spend a leisure half-hour more unprofitably than in reading it.

Observations on the Psychological Differences which Exist among the Typical Races of Man. By R. Dunn, F.R.C.S.
*** An interesting and suggestive paper.

The Spirit of Nursing. By Harry Jones, M.A., Incumbent of St. Luke's, Berwick-street. London: John Churchill and Sons.
*** A pamphlet which deserves to be extensively distributed, and to be carefully read both by Doctors and clergy.

The Philosophy of Health; or, an Exposition of the Physiological and Sanitary Conditions Conducive to Human Longevity and Happiness. By Southwood Smith, M.D. Eleventh Edition.
*** Contains much new matter.

The Sanitary Commission of the United States Army. A succinct Narrative of its Works and Purposes. New York. 1864. Pp. 318.
*** One has only to read through the index to this volume to see in how many directions this valuable organisation has been operating for the benefit of the troops. It is one of the noblest efforts of the day.

Hunt on Stammering. 6th Edition.
*** Two years only have elapsed since the fifth edition was published. The book is well known and appreciated. We have only to announce the new edition.

The Irrationale of Speech. By a Minute Philosopher. Longmans. 1864. Pp. 33.
*** Written in a pleasant and taking style.

First Help in Accidents. By Charles H. Schaible, M.D. London: R. Hardwicke. 1864.
*** We can conceive of many circumstances under which the information contained in a book of this sort would be desirable to the public.

Handbook of Dental Anatomy and Surgery. By John Smith, M.D.
*** Will be reviewed soon.

The Medical Service. [Republished from the *Bombay Gazette*, September, 1864.]
*** A good and, let us hope, an effective grumble at Sir C. Wood.

A Brief Sketch of the Past and Present Condition of the Bengal Medical Service. By a Surgeon of the Bengal Army. Calcutta. 1865.
*** Shall be kept in mind.

The Canada Lancet. Montreal. September, 1864.
*** A journal likely to be practically useful.

Observations on the Function of the Liver. By Robert M'Donnell, M.D.
*** Will be noticed shortly.

On the Structure and Formation of the Sarcolemma of Striped Muscle, etc. By Dr. Lionel Beale.
*** An abstract will be given on an early opportunity.

The Archives of Medicine. No. 15. London: John Churchill and Sons.
*** Contains some important physiological papers.

The Physician and his Work: a Sermon. By Steuart A. Pears, D.D. Derby: Bemrose and Sons. 1864.
*** A worthy tribute to a self-denying Profession.

Reports of the Inspectors of Factories for the Half-year ending October 31, 1864.
*** We shall notice this on an early opportunity.

VITAL STATISTICS OF LONDON.

Week ending Saturday, May 6, 1865.

BIRTHS.

Births of Boys, 1006; Girls, 1068; Total, 2074.
Average of 10 corresponding weeks, 1855-64, 1840·4.

DEATHS.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29·760 in.
Mean temperature	54·1
Highest point of thermometer	74·0
Lowest point of thermometer	31·4
Mean dew-point temperature	44·3
General direction of wind	S.W.
Whole amount of rain in the week	0·16 in.

APPOINTMENTS FOR THE WEEK

May 13. *Saturday (this day).*

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.
Royal Institution, 4 p.m. Prof. Bain, "On the Physical Accompaniments of Mind."

15. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

16. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.
Anthropological Society of London, 8 p.m. Meeting.
Pathological Society, 8 p.m. Meeting.
Royal Institution, 4 p.m. Professor Frankland, F.R.S., "On Organic Chemistry."

17. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.
Hunterian Society, 8 p.m. Resumed discussion on Mr. Hutchinson's paper, "The Medical Aspects of Syphilis."

18. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.
Harveian Society of London, 8 p.m. Meeting.
Royal Institution, 4 p.m. Professor Frankland, F.R.S., "On Organic Chemistry."

19. *Friday.*

Operations, Westminster Ophthalmic 1½ p.m.
Royal Institution, 8 p.m. Wm. Huggins, Esq., "On Stellar Physics and Chemistry."

EXPECTED OPERATIONS.

King's College Hospital.—The following Operations will be performed on Saturday (to-day) at two o'clock:—
By Mr. Fergusson—Pirogoff's Amputation of the Foot; Ligature of External Iliac.

ORIGINAL LECTURES.

ON

THE FOOD OF MAN IN RELATION TO HIS USEFUL WORK.

By LYON PLAYFAIR, C.B., LL.D., F.R.S.,
Professor of Chemistry in the University of Edinburgh; Vice-President of the Royal Society, Edinburgh; Vice-President, and formerly President, of the Chemical Society, London, etc.

DELIVERED AT THE ROYAL SOCIETY, EDINBURGH, APRIL 3, 1865, AND ROYAL INSTITUTION, LONDON, APRIL 28, 1865.

(Continued from page 488.)

DIVISION III.

Secretions as Measures of Work.

A. *Secretion per vesicam.*

27. WE have now to examine how far the secretions present us with measures of the work performed by the body. Commencing as we did in the first division of the lecture, it is necessary to inquire how far the urea secreted by a man living on a mere subsistence diet represents the amount of tissue which we have supposed to be wasted in internal dynamical work. Further on it will be seen that, in a man of good digestion at least, one-twelfth of the nitrogen of the food passes away in the fæces, without having been built into muscle or other tissue. Hence, of the 875 grains (2 oz) of flesh-formers required to support *opus vitale*, 73 grains will pass out *per anum*, and 802 grains will be moulded into tissue, and be transformed into urea and the other products of wasted muscle. Hence, in the urine of a man supported by the lowest diet sufficient for life, we should still find 267 grains of urea. The same amount must appear in the first days of starvation, during which life is supported by the wasting tissues; or what is the same thing, it will appear when non-nitrogenous food is taken. In Ranke's experiments upon himself, we find that, in the first case, he passed 17·02 grammes of urea, and in the second case 17·10 grammes.(a) The mean gives 263 grains of urea—a number remarkably close to our calculated quantity, and probably identical, if the undetermined uric acid be accounted for. Beigel(b) during a three weeks' "hungercur" found the urea sink to 17·83 grammes, or 275 grains. A patient in the fifth week of typhus would possibly pass even less than 267 grains of urea, because part of the subsistence food, in the low state of dynamical vital work, would go to build up tissue; and accordingly we are not surprised to find that Brattler,(c) in the fifth week, found the urea as low as 16 grammes (247 grains). But when the patient becomes convalescent, and receives the standard diet for quietude—viz., 2·5 ounce of flesh-formers, he should then pass 335 grains of urea. Turning to the researches of Vogel(d) and of S. Moos,(e) we find that the secretion gradually rises from 22 grammes (339 grains) to the normal quantity of 35 grammes. Haughton(f) also states that convalescents in Hospitals pass about 300 grains of urea.

28. The experiments of the latter observer on the amount of urea secreted by average healthy men, living on a mixed diet, give from 560 to 580 grains. The mean of the extensive table of analyses in Parkes'(g) excellent work is, however, only 512 grains. If we add to this his average for uric acid, in its equivalent of urea, we would have 521 grains. If, now, we take as a mean, for the present, the results of Barral,(h) Valentin,(i) Vierordt,(k) and E. Smith,(l) for the nitrogen in the fæces as being about one-eighth that in the urine (one-twelfth according to Ranke), then this, calculated as urea, would give $521 + 65 = 586$ grains of an equivalent of urea. We can convert this into flesh-formers:—

$$586 \times 3 = 1758.$$

Now, 4 oz., or 1750 grains, form the usual diet of non-labouring men.

It will thus be seen that numbers closely approximating to the demand are obtained from recognised averages. But in order to apply them to the special class of healthy men (soldiers) described in Table II., we must take the diet as there given. Soldiers during peace are supposed to be well exercised by a daily march of seven miles. This march represents work equal to 38,333 metre kilos. If we take Haughton's mean of 575 grains of urea for such men, then the tissue transformed to produce this would be 3·94 oz., to which, using Ranke's proportion of one-twelfth of nitrogen in fæces, as we do for reasons hereafter to be stated, 0·33 oz. have to be added; making 4·27 oz. as against 4·21 oz. in Table I. Taking, then, 3·94 oz., we have:—

Potential energy in transformed tissue, 211,822 metre kilos.
Useful external work, . . . 38,333 ,,

But as the former number includes the energy required to support *opus vitale*, we obtain the amount available for external dynamical work by subtracting it:—

$$211{,}822 - 107{,}524 = 104{,}298 \text{ metre kilos.}$$

Hence we have still nearly three times as much force available as is represented by useful work; but we need not be surprised at this when we know that the healthy soldier is capable of more exertion than he takes in peace.

29. Passing from our standard man in health to a hard-worked labourer, we can readily calculate how much urea should be produced by his plastic food. We obtain the amount which is transformed from tissue by deducting that which passes away as fæces:—

$$2406 - \frac{2406}{12} = 2205{\cdot}5 \text{ grains.}$$

Without any error worth taking into account, the urea may be obtained by dividing this number by 3 (the correct number is 3·01); hence the working man, doing really a hard day's labour, should have 735 grains of urea in his urine, including its equivalent of uric acid. There are very few estimates of the urine of hard-worked labourers, and I have found it no easy matter to induce them to be made the subject of experiment. Nevertheless, in conjunction with my friend Dr. A. Dalzell, I have estimated the amount of urea in the urine of hard-worked labourers, and we are still continuing our inquiries on this subject. Before alluding to them, it will be more convenient to consider Dr. E. Smith's (m) researches on weavers and tailors. The two weavers were engaged in "the very laborious occupation of wide-width cocoa-matting." Applying my tables to the recorded food of these men, I find that they received a daily supply of 5·33 oz., or 2333 grains of plastic nutriment, containing 366 grains of nitrogen. As an average of twenty-six days' experiment they gave:—

702·9 grains of urea, containing .	328·0	grs. nitrog.
8·52 oz. fæces, containing . . .	40·93	,,
Total nitrogen . . .	368·93	,,

As this differs by only three grains from the nitrogen of the ingesta, as determined independently of the experiment, the latter has obviously been done with great care.

The tailors, who were fully fed, received 4·63 oz. flesh-formers, according to my tables, containing 318 grains of nitrogen, and as an average of twenty-six days gave in egesta:—

608·4 grains of urea, containing .	283·7	grs. nitrog.
6·98 oz. fæces, containing .	26·43	,,
Total nitrogen . .	311·13	,,

These tailors were, however, overfed; for while the weavers slightly lost weight, the tailors gained about 16 oz. each during the experiment. The lesser quantity of urea in this case was a necessary result of diminished food and work as compared with the weavers.

A distinguished colleague in my University, Professor Christison, whose knowledge as a chemist does not require to be referred to, had long since the idea that work, with corresponding food, increased the urea. When he was twenty-eight years of age and remarkably vigorous, he worked for two days as a carpenter to try this problem, and in addition walked on each of these two days ten miles, at a pace of nearly five miles per hour. As a mean of the two days, he passed 845 grains of urea; but, as the process of analysis was not then by the mercury method, we may reduce it, to make it comparable to our present standard, to 800 grains. But perhaps this may be too large a deduction, as we find that

(m) Phil. *Trans.*, v. 151, p. 747, *et seq.*

Hammond, exercising himself in a similar hard way, passed 865 grains.

We may compare these instances with those recently determined in my laboratory, and which were generally made on two men in each occupation for at least two days:—

Hammerman	530 grains.
Quarrymen	550 ,,
Tailors	608 ,,
Weavers.	703 ,,
Blacksmiths	695 ,,
Forgemen	740 ,,
Hard-working—pedestrian .	800 ,,

The work of the two first set of workmen is fatiguing, but not laborious. The work of a hammerer (9) is 480,000 foot-pounds, which is within the capability of a fairly fed man with 4·2 oz. of plastic food. The difficulty of getting working men to understand the value of such inquiries has considerably retarded these determinations. In the case of the two blacksmiths, the difference between the urea of Sunday and labouring days is instructive:—

	Sundays.	Labour Days.
H.	1. 38·56 grammes.	1. 41·38 grammes.
	2. 34·47 ,,	2. 46·69 ,,
Mean,	36·51	44·03
M.	1. 31·42 grammes.	1. 40·61 grammes.
	2. 31·06 ,,	2. 49·08 ,,
Mean,	31·24	44·84

H. on the Saturday evening previous to the first Sunday had killed a pig and made merry with his friends—having, in fact, been drunk; hence that day's urine was probably deranged. Taking the mean, then, of the three observations, we have for

	Grammes.	Grains.
Sundays, or days of rest . .	32·32	499
Week-days, or days of labour .	44·43	686

The difference between 686 and 695, as given in the table, is for the equivalent of uric acid.

30. It will be seen that the demand of 730 grains of urea for a man doing the hard work of 790,000 foot-pounds is not beyond what is found in many cases. In fact, it follows as a necessity, if Tables III., IV., and V. are correct returns of the food of men engaged in labour. The researches of Lehmann(n) and Ranke(o) have shown, that when much nitrogenous food is taken, an increase in the amount of urea follows. If, then, the plastic food of the adult man stands to the hard-worked labourer as 4·2 : 5·5, the urea must increase in nearly like proportion. There is now no longer any question that all the nitrogen of the ingesta is to be found again in the urine and fæces. Bischchof and Voit(p) have proved this for dogs; Henneberg(q) for cows; Voit(r) for dogs and pigeons; Lehman(s) for pigs; Ranke(t) and Smith(u) for men. As this is now determined beyond doubt, it scarcely needed new experiments to prove that a labourer, eating more food than a man not working, must pass more urea than the latter. The dispute as to the effects of *luxus consumption* involved the decision of this as the common battle-field for the disputants on both sides. Thus Beigil(v) found a secretion of 711 grains of urea in the case of men, when they had lived on animal food and rested, and 806 grains, under the same conditions, when they had active work. Becher found 729 grains, Lehmann 798 grains, and Ranke 1330 grains under like conditions. We need not, therefore, discuss the *questio vexata* as to whether albumen may or may not pass directly into urea, when in excess in the blood, without being built into tissue, for this is not the normal mode of nutrition. *Luxus consumption* may be a question to discuss when considering aldermanic dinners, but it can have no meaning when applied to the hard fare of the artisan, who takes no more food than is necessary for his work. The discussion, also, as to whether exercise increases the elimination of urea has little further interest for us, when we find such men as Lehmann,(w) Hammond,(x) Beigil,(y) Speck,(z) Franque,(a) and Beneke,(b) deciding in favour of the fact that it is increased, against the varying experiments of Voit(c) and the younger Draper(d) on the other side. Dr. E. Smith has explained much of the anomalies of the latter physiologists, by showing that the period of the production of urea is not necessarily its period of elimination.(e). In most of the experiments made on this subject, the heavy exercise has been taken, not with the corresponding diet, but with the old diet, and under such circumstances the increased elimination of urea from the system is sometimes retarded two days. Hammond's experiments, even upon the same diet, were, however, very conclusive. His results are as follow:—

	Urea.	Uric acid.
With no exercise . .	487·0 grs.	24·9 grs.
Moderate ,, . .	682·1 ,,	13·7 ,,
Hard ,, . .	865·0 ,,	8·2 ,,

31. When a large amount of animal diet is the chief source of food, exercise becomes a necessity, in order to waste the tissues for the support of respiration and other vital movements. Without it the animal soon loathes the food. This is not only the experience of carnivora, but also of man. Darwin tells us that, when in the Pampas, he lived tolerably well on a meat diet, "but felt that it would only agree with me with hard exercise;" and he tells us that the Guachos, who live upon meat, eat largely of fat, probably not only for respiratory food, but also as a protection against unnecessary muscular waste, as we have explained. Sir John Richardson observed the same fact in his Arctic travels, having noticed "that when people have fed a long time solely upon lean animal food, the desire for fat becomes so insatiable that they can consume a large quantity of unmixed, and even only fat, without nausea." The hyena in confinement wastes its tissues by moving backwards and forwards incessantly in its den, and thus is able to consume its animal diet. All this shows that the normal function of nutrition is to build its plastic food into tissues, to be transformed by internal and external dynamical work into carbonic acid, water, and urea.

32. We have confined our attention chiefly to urea, because, as a representative of dynamical labour, it is not mixed up with any other kind of work, such as *opus calorificum*. Carbonic acid is a marked product of work, but then it represents the sum of two factors,—increase in dynamical and in respiratory action. Thus, a labourer, living upon our standard diet, exhales in eighteen hours' quietude, and six hours' hard work, the following quantities of carbon, in the form of carbonic acid, after deducting the carbon in urea and in fæces(f):—

In 18 hours' quietude, 2375 grs. of carbon.
,, 6 ,, labour, 3212 ,, ,,

In one hour's work, 535 grains of carbon are exhaled as carbonic acid, of which nearly one-fourth, or 135 grains, is due to the transformation of tissue, and the rest to the increased demand of the oxygen inspired for non-nitrogenous food.

B.—*Assimilative Work, as Measured by the Secretions per Anum.*

33. The measure of the digestive or assimilative work in a man of healthy digestion is, I believe, to be found in the nitrogen of the fæces.(g) Although the alvine evacuation frequently does contain undigested food, either in cases of over-eating or of indigestion, in full health, it is difficult to find with the microscope even traces of unchanged food. Bischof and Voit could not detect any muscular fibres in the fæces of the dog,

(e) The experiments of E Smith upon prisoners working on the treadmill are perhaps the most difficult to explain, for with this heavy work there was only an increase of sixteen grains daily. They worked every alternate day, but clearly under abnormal conditions, for "their muscular system was overworked and underfed." Their food, I find, contained daily 250 grains of nitrogen, while their urine and fæces contained 280 grains. Hence the working experiment was not one of health.
(f) 220 grains of carbon are allowed for fæces, and all of which is deducted from the six hours' labour.
(g) It is only as this lecture passes through the press that I observe Mareet has given the same view, without, however, working it out. Not having found any such views in his two papers on fæces, I did not think of looking at his lecture on the chemistry of digestion till the last moment. The passage to which I refer is as follows:—"The principal object of the alvine evacuation is obviously to rid the body of certain parts of the intestinal secretions which, after having served their purpose in effecting the digestion of food, are not fit to return to the blood."—*Jour. Ch. Soc.*, xv., 418.

and not even fat, when that had been purposely added to the meat. Rawitz(h) and other observers are of the same opinion. Hence the common notion that fæces represent the refuse of food is not supported by correct observation. Undoubtedly they contain various ingredients, nitrogenous as well as non-nitrogenous, mixed with mineral matter (Marcet).(i)

34. The average weight of fæces secreted in health is 4·6 oz., according to Wehsarg(k), or 5½ oz. (Liebig). In Ranke's(l) experiments, on a mixed diet, the nitrogen excreted by the fæces is to that in the urine as 1 : 12·5. We take one-twelfth as the amount in health. But although this is the case in man, it is not so with regard to the carnivora. In Pettenkoffer's experiments with a flesh-fed dog, the nitrogen in the fæces was to that in the urine as 1 : 72; and in the still more extensive experiments of Bischof and Voit, as 1 : 76. But the ratio(m) alters when fat or starch is added to the flesh; in the first case it is as 1 : 41, and in the second 1 : 40. When the dog was fed on flesh and sugar, it was as 1 : 23·3, and on starch alone the proportion became reversed, and then the nitrogen in the fæces was to that in the urine as 2 : 1. A little consideration will explain these differences. There are four fluids engaged in the promotion of digestion. All of them contain albuminous ferments, which receive special names, as pepsin when in gastric juice, ptyalin when in saliva, pancreatine in pancreatic juice, and intestinal ferment in the juice of the intestines. But we know nothing more of their chemical composition than that they are albuminous bodies, slightly oxygenised, and in the process of change. We do know that they have different actions,—pepsin acting on albuminous bodies, ptyalin and pancreatine converting starch into sugar, and the latter fat into its acids and glycerine; but in all probability the same ferments in different conditions produce their varying effects, just as we find the gastric ferment also able to act upon fats as well as on flesh-formers(n), and the intestinal ferment combining the functions of the salivary, gastric, and pancreatic ferments. In fact, experiment tells us that alkaline gastric juice acts like pancreatic juice, and the latter, when acidified, plays the part of the former.

Referring to the proportion of nitrogen in the urine to that in the fæces of the carnivora, it is now possible to explain the apparent anomaly, that the addition of non-nitrogenous aliments to the diet increased, instead of diminishing, the amount of that element in the fæces. When the animal is fed on flesh free from fat, the gastric ferment alone is brought into activity, aided partially perhaps by the intestinal ferment, and the residue of these appear in the fæces, which are found to contain but little nitrogen. When fat is now added to the diet, a large amount of pancreatic juice is brought into activity, and the used-up ferment of this juice is added to that of the gastric and intestinal juices as before. Hence we find that the proportion of nitrogen in the fæces is increased. When starch is mixed with the flesh, then the salivary ferment co-operates with the other three ferments in preparing the food for assimilation, and we find the proportion of nitrogen rather greater than before. When a carnivorous animal is placed in such an anomalous position as in feeding it on starch alone a much larger quantity of salivary, pancreatic, and intestinal ferments appear to be called into action to digest this unusual and unmixed diet, and hence the amount of nitrogen in the fæces becomes increased to an unusual amount.

35. The usual amount of nitrogen in the fæces of man is 6·5 per cent. in dry and 1·7 in fresh excrement; while the carbon is from 43 to 44 per cent. in the former. This is almost identical with the composition of normal fæces in the carnivora. The reason obviously is, that the changed albuminous ferments which form the nitrogenous constituents of fæces in health are the same in both classes of animals. Just as yeast loses some of its nitrogen by work, as emulsin becomes poorer in nitrogen and richer in oxygen when it has ceased to act on amygdalin, so do these different forms of albumen in their degradation suffer like changes. A well-known experiment of Lehmann is instructive on the subject under consideration. When emulsin (the casein of sweet almonds) is introduced with amygdalin into the stomach of an animal, the well-known fermentation by which that body is converted into oil of bitter almonds and prussic acid takes place, and the animal dies. On the other hand, when emulsin alone is introduced to the stomach, and amygdalin is injected to the blood, the animal does not suffer by the experiment. But upon reversing the mode of administration, and injecting the emulsin to the blood and putting the amygdalin into the stomach, the animal dies as before. Hence, we find that the ferment, after acting upon the substances which it met with in the intestines, could not be absorbed, for had it been it would have met with amygdalin in the blood, and would have produced fatal effects. That it had acted as a ferment upon the materials in process of digestion and had become exhausted is certain, for it altogether changed in its passage, the fæces of the animal not containing any emulsin capable of acting upon fresh portions of amygdalin. No experiment could be more conclusive for our views, because emulsin is simply changed casein, as these digestive ferments are changed albumen, each having certain peculiarities of action, according to the alkaline or acid fluids with which they act, or with other varying conditions.

36. Let us now return to the proportion of nitrogen found in the alvine dejections of man; it stands in relation to that in the urine as 1 : 12. Where it is present in larger proportions than this, then the excess is probably due to undigested flesh or to an excessive secretion of ferments necessary to overcome some digestive difficulty. In other words, one-twelfth of all the plastic food taken by a man is converted into digestive ferments, and this is excreted *per anum*.

I am not inclined to agree with those physiologists (o) who consider that these ferments secreted from the blood are the degraded products of tissue-waste in their passage to urea. On the contrary, I believe them merely to be albumen of the blood, the oxygenation of which is incipient, so as to make it ready to build up tissue, as in its passage to fibrin.(p) Hence when there is an extensive demand on the blood for tissue material, as in the case of work in excess of the food supplied (for instance, as observed by E. Smith with his overworked prisoners), then the amount of the alvine dejection diminishes. These digestive ferments secreted from the blood cannot be albuminous materials in a downward career, otherwise their surplus, beyond that required for fermentation, would not again be absorbed into the nutrient fluid. It is only a small portion of the whole that is rendered unfit for re-absorption and is reduced to a degraded condition. If the great bulk of what is generally esteemed to be the ferments were not taken back into the blood, the amount of nitrogenous matter in the alvine dejections must be much greater than we find to be the case. Let us take very moderate computations as to the quantities of digestive juices secreted in twenty-four hours by a standard man, and this re-absorption will appear to be a necessity :—

1·6 kilog.	of saliva, (q)	contains	2·4	grammes	ptyaline.
6·4 ,,	gastric juice(r)	,,	20·5	,,	pepsin.
4·0 ,,	pancreatic(s)	,,	50·8	,,	pancreatin.
0·2 ,,	intestinal(t)	,,	1·8	,,	ferment.
	Total . . .		75·5	grammes.	

Now as the whole fæces contain only 9·4 grammes of these exhausted ferments, it is obvious enough that the larger quantity represented above cannot consist of degraded matter in its descending career. When it is further borne in mind that the daily waste of tissues in a healthy man is only 112 grammes, it is impossible for us to suppose that more than half that quantity of degraded matter is preserved in the blood, to be excreted and then re-absorbed. This view would be quite inconsistent with the admirable arrangements of the excretory organs for speedily carrying off used-up matter from the nutrient fluid.

The functions of these digestive secretions must be con-

(h) Ueber die Einfach Nährung Mittel.
(i) *Phil. Trans.*, 1854 and 1857.
(k) Mikros. Und. Chem. Untersuchg. des Fæces, 1853.
(l) *Op. Cit.*, p. 311.
(m) These numbers are relative, not absolute. The fæces of flesh diet contained 6·5, of starch 4·4, of sugar 7·9 per cent. of nitrogen; but the proportions of nitrogen in urine to nitrogen in fæces are as given in the text. Thus we find, on summing up the quantities, that the nitrogen in urine and in fæces, on a diet of flesh and sugar, is, in grammes, as 85·22 : 3·65; on flesh, starch, and fat, as 101·46 : 2·57; and on starch alone as 5·68 : 10·26. I have omitted the fæces on bread diet, for they seem to have been chiefly undigested bread.—(Ernährung des Fleischfressers.)

(p) Smee, *R. S. Proc.*, xii., 399, 505.
(q) Dalton's "Human Phys.," p. 96.
(r) Katherine Kutt, the Esthonian peasant, with a gastric fistula, gave no less than 30 lbs. daily; the usual estimate, however, from researches on dogs, and applying them to man, is 14 lbs.
(s) The estimates on this subject vary enormously, some going as high as 15 lbs. for a standard man. I have therefore taken a low estimate, nearly that of Bernard, who has devoted so much study to the pancreas.
(t) I allow this for intestinal juice, from the experiments of Bidder and Schmidt.

sidered as assimilative in the largest sense of the term. Chemical affinity generally is assimilative effort. When hydrogen unites with oxygen, each element endeavours to assimilate the chemical characters of the other element to itself, and when they are equal in power neutrality results. These ferments, as they are termed, when secreted in the digestive fluids, are albuminous substances changed and fitted for assimilation in the body, and capable of preparing the ingested food to assume their own state. They meet with resistance, which their large mass enables them to overcome, but a small portion of them succumb in the conflict, and are finally excreted in the alvine dejections, along with certain non-nitrogenous materials, which have probably been used in co-operation with them to fit the calorifacient constituents of food for absorption into the blood.

ORIGINAL COMMUNICATIONS.

ON A NEW FORM OF FIXED BANDAGE FOR FRACTURES, &c.

By CAMPBELL DE MORGAN, F.R.S.,
Surgeon to the Middlesex Hospital.

In the first and several subsequent numbers of the *Gazette Médicale* de Paris for the present year are some papers by Dr. L. Hamon (de Fresnay), entitled "Essai sur la methode Amovo inamovible, ou plutôt valvaire, appliquee a la therapeutique des fractures au moyen d'un nouvel appareil (Bandage Gelatino alcoolisé lacé)." Under a very high sounding title is described, albeit at a most tedious length, a really valuable and simple mode of applying a firm apparatus.

I have tried it now very frequently in the Middlesex Hospital, and my colleagues are also using it. It certainly appears to me to be in some respects superior to any starch or gum, or plaster of Paris bandage, and is quite as easy of application. The material with which the bandage is stiffened is glue, and it should be prepared as follows:—The best French glue should be used. It should be broken up and soaked in a little cold water for some hours, and then melted in the usual way in a glue pot, as little water being used as possible. It is not necessary to soak the glue in cold water, but if this is not done it will require the longer heating. When it is to be used, about a fifth part of its bulk of alcohol must be added—methylated spirit answers quite well. At first this converts a great part of the melted glue into a whitish coagulum, but by a little stirring it all liquifies, and is then fit for use. The alcohol is added to induce the rapid drying of the glue—which would otherwise remain soft for many hours, but when mixed with the spirit begins to get firm on the surface very soon after it is applied, and in a short time becomes tolerably firm throughout. It should be applied with a moderate sized flat hogs' bristle brush. Supposing that a simple fracture of the leg is to be treated, these are the steps to be taken:—

The foot should be neatly and firmly bandaged from the toes to the ankle. Two or three streaks of glue along the sides and front will secure the bandage, so that it need not be again disturbed. The leg from the ankle to the knee should then be covered with a very thin layer of cotton wool—not the medicated wool, as it is called, but such as it procured in sheets for lining dresses. Of this a layer not more than the eighth of an inch in thickness can be easily stripped off, and smoothly applied to the leg. A cotton bandage should then be rolled very smoothly and with tolerable firmness up the leg from the ankle to the knee, and well painted over with the glue. Another bandage should then be placed over the first, and the glueing process repeated. A third may then be applied and glued, and then a bandage should be put on over all, and the leg placed in position. and retained, if necessary, by sand-bags or junks. Of course, if the Surgeon please he may apply strips of bandage, or of any linen or cotton material he may find at hand, instead of repeating the rolling process. The glue should be laid on freely, and brushed a little into the bandage. In some cases two layers of the glued bandage will be found sufficient. In others it may be desirable to give greater support; but this can always be done as an after-process. The leg should be left at rest for from twelve to twenty-four hours. The glued bandage must then be cut through its whole length. This may be done with the ordinary scissors used for the starched bandage, or a director may be insinuated beneath the bandage and cut upon with a sharp knife. If too long a time elapses before the bandage is cut through, it becomes so hard that great difficulty may be found in cutting it at all. When the bandage is thus slit up, so great is its elasticity that it may have its edges separated sufficiently to allow it to be easily slipped off the leg; and when left to itself it will resume its original shape, and this elasticity it will retain for as long as it is used. A strip not more than a quarter of an inch wide, and running the whole length of the bandage, should now be cut off from one edge, and holes punched out parallel to the edges on either side, and about half an inch from them; into these "œillets" are to be inserted, such as are commonly used in laced bandages or boots.

The punching and insertion of the œillets are rapidly done with the common instruments used for the purpose, which, with the œillets, can be had at any toolmaker's.

The bandage is now complete. If it is thought desirable to strengthen it generally, or in any particular part, this may be done by gluing on fresh strips of linen. Its appearance may be improved by gluing on an edging of tape round the top and bottom, and along the sides of the slit. It is re-applied to the leg, and laced up as firmly as may be thought necessary. The lace, if it is not furnished with a tag, is best introduced on an eyed probe, and it should always be passed from without inwards. If the tag is introduced from within it always gets entangled in the cotton wool, and the process of lacing is extremely troublesome.

Thus a case is formed which is completely moulded in the form of the limb, is very elastic, very firm, and very durable, and which can be accommodated with perfect ease to all the varying states of swelling of the limb.

In situations where the roller cannot be conveniently carried round the part, the splint can be just as well formed by laying strips of linen in any direction and glueing them. The cotton wool of course adheres to the first layer of the bandage, and comes off when it is removed. It is applied in the first instance in great measure to keep the glue from contact with the skin.

The great advantage of this splint is its union of firmness with elasticity. These qualities it retains undiminished for a great length of time. I have found no alteration in these respects during the many weeks that some patients have worn it; a patient now in the Hospital has worn one for six weeks, and I find no change in either its firmness or elasticity. At any time it could, if required, be strengthened by a few strips of linen being glued on it.

I have described it as applied to fracture of the leg, but it can be used in any situation where support is required. Thus I have used it in Pott's fracture, enclosing not only the leg, but the ankle and foot, and have found that it could be slipped on and off with the greatest ease. I have used it in fractured patella, after sprains to the knee and ankle-joints, in diseased knee-joint, and in case of diseased hip-joint encircling the pelvis and upper part of the thigh.

Altogether this "bandage gelatino alcoolisé lacé" appears to me to be one of the best as well as the most easily applied, and most convenient in its after use, of any of the modifications of Seutin's bandage which have as yet been tried, and it is well worth the notice of Surgeons. The advantage which it possesses over others is in its elasticity, which permits of its being widely opened when slit up, without cracking or losing its form. Hence it can be applied as a laced bandage, and may be worn for weeks together, while the patient is moving about, without the trouble of re-adjustment; while it can be accommodated to any change in the state of the limb, through increase of swelling or its diminution, by simply letting out the lace, or taking it in, without even removing the bandage. It is, moreover, very light, and yet strong enough for any purpose to which a splint can be applicable.

Metropolitan Association of Medical Officers of Health.—On Saturday evening, the 20th, Mr. Walton will read a paper on "Contagious Diseases of the Eyes in London Workhouses." On the Saturday following Dr. Clouston, of Carlisle, will read a paper on "Dysentery as a Consequence of Sewage Irrigation." The meetings are held at the Scottish Corporation Hall, Crane-court, Fleet-street, at 7.30 p.m.

St. Mary's Hospital.—The ceremony of laying the foundation stone of the new wing will take place on the 23rd of May. The stone will be laid by H.R.H. the Prince of Wales. The Right Rev. the Bishop of London will officiate in the religious part of the ceremony.

EPIDEMIC OF CEREBRO-SPINAL MENINGITIS AT SUNDERLAND IN 1830.

By JOHN SCOTT, M.R.C.S.

Sir,—I send an account of an epidemic which prevailed at Sunderland in the year 1830. It has some resemblance to those existing on the Continent in 1865, and I think has some interest in the history of disease. If you think so, please insert it. I am, &c.

Hanley, Staffordshire. John Scott.

The late numerous discussions and papers on the epidemic of cerebro-spinal meningitis now prevailing on some parts of the Continent of Europe have recalled vividly to my memory a disease which existed as an epidemic in Sunderland during the year 1830. I was at that time an apprentice to the late Mr. T. H. Embleton, a general Practitioner of that town; and though I knew then but little of the science of Medicine, yet the great fatality of the disease and the having watched to its fatal termination a case which occurred in a member of my own family, impressed the facts of the disease so strongly on my recollection that I have no doubt that I can recall them correctly, even at this distance of time. It is now many years since I left that part of England. I do not know who of the older Practitioners are left, or it is probable that a much better account of the disease might be got.

The disease began in the autumn of 1830. The earliest date I do not know, but I know well that a fatal case occurred on October 12 of that year, and that there had been many fatal cases before as there were many after it. I do not recollect that it was preceded by any distress among the working classes, by high price of provisions or any of those causes which usually precede epidemics, but I have a strong impression that there had been during the few preceding months a great excess of sickness, especially among paupers, though of what kind I have no recollection. The disease was at first considered to be typhus fever, and a great number of fatal cases had occurred before I ever heard any other name applied to it. The first time I heard the name meningitis used was as applied to one of the cases in which Dr. Brown, of Sunderland, had been called in, in consultation, and I well recollect the discussions to which the application of that name to the case gave rise. That case I know terminated fatally, with all the symptoms which, at that time, marked so many cases of the same disease. During the whole epidemic the disease was very fatal; but I believe it followed the usual law, that the cases were much less severe during the latter than the earlier periods, and that recoveries were much more frequent towards the end of the epidemic. In the practice to which I have referred, and which was the only one with which I was intimately acquainted, thirteen fatal cases occurred in rapid succession with hardly a case of recovery. My impression, indeed, is, without a single recovery, but I may be mistaken in that. The disease was not confined to the lower parts of the town, to the narrow lanes and alleys, which two years later were to become the first home of epidemic cholera in England, but attacked pretty equally all parts; at least, I know that cases were by no means rare in the most open and best built localities, and among families in at least comfortable circumstances. The greater number of cases with which I was acquainted did, indeed, exist among the poor, but that was probably from the character of the practice referred to. During the whole of the epidemic the cases were scattered about very much, seldom more than one being seen in a house, and the question was often asked, Why is it that it does not spread like fever, and that you have generally but one case in a house? This scattered character was rather characteristic of the disease. It prevailed chiefly among children, and though at this distance of time I can recollect the exact age of but one patient, my belief is that there were few cases above fifteen or sixteen years of age. The symptoms of the disease, as I recollect them, are chiefly gathered from one case closely observed, a few seen now and then, and what I constantly heard of the progress of cases under treatment.

The attack always began with violent headache and fever, judged by every one at first to be typhus. There was severe pain in the back and limbs, and I think, in some cases, sickness. At this, almost the outset, there was great prostration and partial coma, which, after three or four days in the cases which ran the least rapid course, was followed by some mitigation of symptoms, and the display of more intelligence. This was shortly followed by convulsions of a severe character, and in most cases, especially those most slow in progress, by well-marked opisthotonos. In all cases there was obstinate constipation, over which the remedies employed seemed to exert little influence, especially in the early stage of the disease. At an early period the cheeks were flushed, and the eyes very much suffused; but later, the look was rather that of a person suffering from pulmonic congestion. The treatment followed by all who then treated the disease was antiphlogistic in the strictest sense of the term, and calomel given freely, but I do not remember salivation ever being produced. I saw but one post-mortem during the time; it was that of a child ten or twelve years of age, and the only thing I recollect about it is that the posterior portion of the brain looked as though it had been smeared over with some thick fluid like cream, and had then had a portion of the fluid scraped off.

I do not know if at that time a disease answering to this description existed in any other place in England, but I do know during this last thirty-five years I have never seen any cases precisely resembling these, still less proofs of cases existing as an epidemic such as occurred at Sunderland in 1830. The impression made on my mind at the time was very distinct, and the recollection of the general aspect of the cases is even now most vivid. The resemblance of the epidemic to that now existing on the Continent seems in many things very marked. It is like it in its epidemic character, in its marked general resemblance to typhus fever, and especially in the convulsions, tetanic spasms, and opisthotonos which marks the later stages of both diseases. The idea of a specific eruption in typhus, or, indeed, in any continued fever, except small-pox, measles, and scarlet fevers, had not been conceived, and, consequently, was not thought of as a diagnostic sign. It is very probable that the early history of a disease is frequently overlooked from its existing during its period of genesis as a sporadic, or rather as a very local epidemic disease, until becoming more developed, it spreads over a wider range, is of more frequent occurrence, and then it is said a new disease has rapidly originated; while the fact is a new disease, like all new things of Nature's production, is a thing of slow growth.

HOLIDAY NOTES ON SOME CONTINENTAL SPAS.

(Second Series.)

CAUTERETS.

By HERMANN WEBER, M.D., F.R.C.P.,

Physician to the German Hospital.

(Continued from page 439.)

Cauterets is, after Bagnères-de-Luchon, the most frequented Spa in the Pyrenees. It is a small town of about 1400 inhabitants in the Departement "Hautes Pyrénées, arrondissement d'Argelès," about 550 miles distant from Paris, and 28 miles from the railway-station at Tarbes. It is situated in the rather narrow valley of the Gave de Cauterets, 3254 feet (992 mètres) above the level of the sea, between mountains rising to the height of from 6000 to 8000 feet. The aspect of the valley is in one direction friendly and cheerful, the mountains being covered with bright verdure and pine forests up to their summits; while in the other direction it is rather desolate and wild. The climate is said to be uncertain, exposed to sudden changes, and, through the great elevation and the near proximity of the mountains, more frequently visited by fogs than Luchon.

Like the latter place, it has been renowned for its hot springs in remote ages, and counts even Julius Cæsar among its early visitors, whose name is borne by one of the principal springs; certain it is, that it has been visited by the celebrated sister of Francis I., Marguerite, the Queen of Navarre, who wrote here part of the "Heptaméron" and left an interesting description of the journey to and from the place.

Cauterets possesses about twenty-four springs. All the more important ones are characterised by sulphuret of sodium; but they vary considerably with regard to temperature (from 75°8 to 140° F.), and also with regard to the amount of sulphurets. The Physicians at Cauterets maintain that their different sources offer specimens of all qualities of sulphuretted waters of the Pyrenees, from the mildest to the most energetic. This is of considerable value, as it is often desirable to use at first the milder waters, passing gradually to the stronger sources. A great inconvenience, however, in many respects,

is the circumstance that almost all the sources are situated out of the town, having separate establishments, some being more than two miles distant. Only two of the principal sulphuretted sources—the "*César nouveau*" and "les Espagnols"—have been conducted into the town, and supply the "thermal establishment;" the sources "Rieumizet" and "Bruzaud" are likewise near this establishment, but the former is not at all sulphurous, and the latter has lost the greater portion of its sulphurets through a faulty conduction from the origin of the spring to the place of its utilisation.

The different sources have been divided, according to the locality of their origin, into the following groups (a):—

I. *Groupe du Nord* (François), or, according to others, *groupe de l'Est.*

All the sources of this group originate on a mountain near Cauterets. "César nouveau" (120°F.) and "Espagnols" (119° F.) have been conducted in tubes to the thermal establishment in Cauterets, which contains twenty-four separate baths and several grand douches. The water of these sources loses much of its sulphurets on its passage. Thus, according to Filhol ("Eaux Minér. des Pyrénées, 1853, p. 335, and table), a litre of "César nouveau" contains at the source 0·0267 grm. of sulphuret of sodium, in the "Bassin d'Arrivée" only 0·0186 grm., and in the bath only 0·0099 grm. (Buron); a litre of "Espagnols" at the source, 0·0123 grm., and in the bath, 0·0123 grm. This loss might probably be avoided if the tubes in which the water is conducted were to be completely filled by the latter. In spite of this loss the waters of this establishment are reckoned amongst the most powerful of Cauterets. Chronic rheumatism, scrofulous affections, and diseases of the skin are generally treated here.

Pause, or *Pause vieux*, has a separate establishment at the place of its origin on the mountain. The baths, of polished marble, are provided with a douche ascendante and three jets for the water in its natural temperature (112·5° F.), for the cooled mineral, and for the common cold water. The establishment contains also some douches and a buvette (108·5° F.). The amount of sulphuret of sodium at the grand douche is 0·0245 grm. per litre (Filhol); in a bath of 93·2° F., 0·0151 grm. per litre (Buron.) Cutaneous affections are most frequently attended here, but also chronic rheumatic affections and chronic catarrhs of the respiratory organs.

Pause nouveau is composed of several springs united in the establishment of this name, which contains similar accommodation as the Pause vieux. The temperature is about 2° F. higher than that of the latter source; the amount of sulphurets differs only slightly. These baths are considered a good test for the existence or non-existence of syphilis, as in the former ease the characteristie eruptions are said to show themselves very soon.

"*César vieux*," the source which is said to have been visited by Julius Cæsar, furnishes at present only a "buvette" with a temperature of 118° 4 F., and 0·0308 grm. of sulphuret of sodium in the litre (Buron).

"*Bruzaud*" has been conducted to the town of Cauterets itself, but the water loses on its way, as already mentioned, nearly all its sulphurets, and may, therefore, be considered as an almost pure, slightly alkaline, thermal water (99° 5 F.). It is highly spoken of in uterine affections (fluor albus, superficial ulceration of the os uteri, engorgement of the womb), in gastralgia, and various conditions in which the patients are better without much sulphur! The establishment makes a rather poor impression.

"*Rieumizet*" is a weak sulphatic saline source of rather low temperature (75° to 77° F.), more sedative than exciting, employed in abdominal affections and under similar circumstances as "Bruzaud." The establishment contains eleven separate baths and some douches ascendantes.

Groupe du centre (or de l'Ouest). This groupe is formed by the "*Raillère*" alone, a source which for two centuries past has enjoyed a very high reputation for its beneficial influence on some affections of the respiratory mucous membrane, and on chronic pharyngitis. The source "vieille" at Eaux Bonnes is the only one which equals it in this reputation; but the "Raillère" is considered as less exciting, which may depend, according to Filhol's suggestion (l. c. p. 337), on its being richer in alkalines and organic substances. The establishment is situated about a mile distant from Cauterets, in a wild spot on a terrace, at the foot of a granitic mountain (Mont Péguère), and overhanging the banks of the Gave de Marcadau; its elevation above the sea is 3640 feet. It contains about thirty baths, many of which are provided with moveable douches; it has also a buvette, and adjoined to it a special building for gargling the throat. The temperature of the water at the drinking-fountain ("buvette") is, according to Buron, 102° F., and the amount of sulphuret of sodium is 0·0199 grm. per litre; the temperature in the baths is from 95° to 98° F., and the proportion of sulphurets rather lower.

In the neighbourhood of the "Raillère" are stables for the imperial horses of the stud at Tarbes, their chronic bronchial affections being much benefited by the use of these waters.

III. *Groupe du Sud.*

"*Petit St. Sauveur*," almost a mile and a-half from Cauterets, possesses a small establishment with twelve "Cabinets de bains." Its natural temperature is about 86° F., and its amount of sulphuret of sodium 0·0099 grm. per litre (Buron), which rises when heated to 0·0149 grm. Filhol ascribes this peculiarity of showing by the "sulphurometer" when warmed a higher degree of sulphuration to the richness of the water in alkalines. This source is considered as very similar to those of St. Sauveur, near Luz, and is employed in baths and douches only.

"*La source du Pré*" is near the latter. It has a temperature of 116°6 F., and contains 0·0223 grm. of sulphuret of sodium in the litre. It is likewise rarely taken internally, and is used principally for chronic and atonic rheumatism and affections of the skin. The establishment, which possesses seventeen "cabinets de bains," with a douche descendante, is the favourite resort of Spaniards, who in considerable numbers annually cross the mountains in order to undergo a curious so-called nine days' treatment, which is customary with them. As this treatment is of some therapeutical interest, I will give it in the words of Dr. Gouet ("Des eaux Mineralcs de Cauterets," Paris, 1858, p. 47):—

". . . . Aprés un bain tempéré pour se préparer ils boivent de six á huit verres de l'eau de Mahourat et prennent au Pré, avec ou sans douche, deux bains par jour á la température naturelle de l'eau qu'ils supportent pendant près d'une demiheure. En sortant du bain, où l'on conçoit difficilement que tous indistinctement puissent autant séjourner impunément, ils s'enveloppent d'une couverture de laine et, assis sur un tabouret dans le cabinet même, ils complètent l'effet du bain par une sudation si abondante, que le sol en est inondé. Ils s'habillent alors et après quelques instants de répos dans la galerie, ils s'entourent d'une autre converture en guise de manteau; ainsi drapés en vrais *hidalgos*, ils regagnent gravement leur logis. La neuvaine finie, ils retournent au pays, déjà soulagés et sans doute bientôt guéris, à en juger par les imitateurs aussi nombreux qui leur succèdent d'année en année, les mêmes ayant rarement besoin d'y revenir." This treatment certainly does not lack in energy, and it can well be imagined that it produces a revolution in the body sufficient in many instances to lead the functions back into their normal track; but in many others it must be of doubtful value.

The source "*Mahourat*" or "*Maouhourat*" (121° 122° F.) is used only internally. It contains about 0·0149 grm. of sulphuret of sodium in the litre (Buron), and a comparatively small proportion of glairine. It is considered as easily digestible, and especially suitable to cases of gastralgia and intestinal disorders; it is employed also in many cases of chronic catarrh of the respiratory organs where the "Raillère" is too exciting.

The source "*des Yeux*" is a small streamlet close to the last-named, of similar constitution as to temperature and proportion of sulphurets, reputed for its healing powers in catarrhal and scrofulous ophthalmia.

"*Les bains des Bois*," a small establishment of several baths and douches, and two piscines for four or six persons, supplied from several sources, with a rather low proportion of sulphurets. The temperature of these sources lies between 95° and 114° F. They are only employed externally, under similar circumstances as the source "Petit St. Sauveur."

There is another group of sources called "*les oeufs*," from their smell. Their temperature is high—from 121° to 140° F.—and they contain a moderate amount of sulphurets (0·0192 grm. per litre). These sources are as yet not employed. They are so abundant—yielding more than 600,000 litres in twenty-four hours—that Dr. Buron has proposed to utilise them for piscines, with a constant renewal of the water, to form, so to say, river baths of thermal sulphuretted waters—a suggestion which appears very reasonable, and the carrying out of which

(a) On this subject, as well as on others connected with the action and use of the springs of Cauterets, I owe much information to the kindness of Dr. Buron

would, no doubt, considerably increase the reputation and usefulness of Cauterets.

In taking a general survey of all the sources of Cauterets, we find them exhibiting in the *physical appearance* a great resemblance to those of Luchon, but in their process of decomposition none of them exhibit the phenomenon of "blanchiment," and they emit also a much smaller amount of hydrosulphuric acid. Filhol ascribes this to their greater richness in alkaline and earthy carbonates and silicates, and to their smaller proportion of sulphurets. The Cauterets waters contain, as a whole, a smaller amount of free silicic acid, but a larger one of organic matter than those of Luchon. They deposit very little sulphur, and their products of decomposition are peculiarly rich in hyposulphate of soda, which is quite in accordance with the limited evolution of sulphuret of hydrogen.

The *therapeutical actions* of the waters of Cauterets have been already alluded to in the sketch of the different sources and establishments.

The *affections of the respiratory organs* stand at the head of morbid conditions treated at Cauterets, and many of these are much benefited and cured there.

The simple *chronic catarrh* of the bronchi, trachea, and larynx is, in general, cured, and with it the tendency to frequent attacks of cold, if the waters are properly used. The *emphysema of the lungs* is likewise often mentioned among the diseases curable at Cauterets, but when emphysema is in any progressed stage, it is surely not cured, but only the chronic catarrh, so frequently connected with it, is removed or ameliorated, and through this the symptoms are much mitigated, often for a long space of time.

Granular pharyngitis and laryngitis, "angine glanduleuse," and similar affections, are much relieved, and more recent cases are, in general, cured. In these cases gargling with the source "Raillère" is used with great diligence.

Tubercular phthisis is often attended at Cauterets, and some of the Medical men assert that the water of the "Raillère" frequently cures the first and second stages. Even Dr. Fontan, who practises at Luchon, attributes to the source "la Raillère" at Cauterets and the source "*Vieille*" at Eaux Bonnes a curative action in pulmonary tubercles in the first stages. (Recherches sur les eaux nunée des Pyrénées, 1853.)

Dr. Buron, however, who is as intelligent as unprejudiced, has not met with any real cures of indisputable tubercular affections of the lungs, although he has in many instances of tubercles in early stages, in persons of rather torpid constitution, seen much benefit from a cautious use of the waters. Excitable constitutions, with tendency to pyrexia, are, in general, more injured than benefited. One can scarcely help thinking that many of the cases of cure in advanced tubercular phthisis were only simulating this disease, and were in reality caused by bronchial dilatation, condensation of tissue or abscess from pneumonia, and other conditions occasionally mistaken for tubercular consumption.

In *diseases of the skin* the action of the waters of Cauterets is similar to that of the waters of Luchon. Like the latter place, Cauterets has the advantage of possessing sources of varying strength, but it can scarcely be considered as superior to Luchon. The same remarks are applicable to *rheumatic*, *scrofulous*, and *syphilitic affections*.

Cauterets enjoys a considerable reputation with regard to *diseases of women*, as chlorosis, fluor albus, superficial ulceration of the os uteri, etc. In the management of chlorosis and of the oligæmia connected with the majority of chronic affections of the uterus, the exciting influence of the mountain air, of the unwonted occupation of mind and body, and of the thermal treatment, are probably of greater value than the sulphur contained in these waters; and in the chronic catarrh of the vagina and uterus, which is so often the principal cause of the fluor albus, and of the superficial ulceration of the os uteri, the douche ascendante of an almost pure warm water does probably likewise the greater portion of the healing work. At all events, the results obtained in these various complaints at some of the non-sulphuretted spas, are quite as striking as those gained at Cauterets; we may, therefore, infer that these results are due to the other influences, and not to the sulphur, the more so as the Physicians at Cauterets employ in general in these affections either the weakest sulphuretted springs, as "Petit-St.-Sauveur," and "Bruzaud," or the non-sulphuretted "Rieumizet."

With regard to the manner in which the waters of Cauterets are employed, it is similar to that at Luchon,(b) but, in addition to the entire bath, greater use is made of the half-bath(c) and foot-bath, especially in affections of the respiratory organs, in which a derivatory action is attributed to these partial baths.

The *gargling*, too, principally with the water of the "Raillère," is more frequently recommended at Cauterets than perhaps anywhere else; it is generally done in the morning, before, during, or after the bath, but may be repeated in the course of the day. The internal use of the waters is likewise, perhaps, more general than at Luchon. The quantity of water taken is about the same as at the latter place.

The bathing apparatus, it must be owned, is less complete than at Luchon. The absence of a larger central establishment, and of spacious piscines, is to be regretted. Proper arrangements for the aspiration, with the exception of some imperfect attempts, are likewise wanting.

Physicians.—Besides Dr. Buron, who during the winter resides at Pau, Drs. Dimbarre, Cardinal, Daudirac, Goucet, Darré, Broca, and others, enjoy general esteem.

The accommodation in the Hotels de France, du Lion d'Or, des Ambassadeurs, de la Paix is satisfactory, and, in addition, furnished apartments may be had in almost all the private houses. The price for rooms is rather higher than at Luchon.

The season at Cauterets extends from the middle of June to the end of September, but the months of July and August are preferable.

(To be continued.)

(b) Confer this Journal, vol. i. 1865, p. 439.

(c) In the half-bath the patient sits in the water up to the waist, while the upper part of the body is covered with flannel.

REPORT OF A CASE OF

ANEURISM OF THE BRACHIAL AND RADIAL ARTERIES, WITH A VASCULAR TUMOUR OF THE THUMB OCCURRING IN THE SAME ARM—WITH REMARKS.

By W. DUNNETT SPANTON, M.R.C.S.
House-Surgeon to the North Staffordshire Infirmary.

Mary R., aged 23 years, single, was admitted into the Sheffield General Infirmary, under the care of Mr. Barber, on November 5, 1863, for a swelling of the left thumb.

The patient was a tall, fat, large-boned woman, with very flabby muscles, florid countenance, yellowish hair, and dark-blue eyes. She had a large bronchocele, which had existed as long as she could remember. She had been a maid servant since childhood, and always enjoyed excellent health; was never under any Medical treatment.

On admission there was a swelling about as large as half a small orange over the ball of the left thumb; the skin being tense, red, shining, and hot, and evidently containing pus. There was no distinct fluctuation; no pulsation. The left thumb was much smaller than the right; the patient complained of much pain in the tumour. On close examination there was found a small pulsating tumour the size of an ordinary marble, globular in form, situated on the left radial artery in the space between the first and second metacarpal bones; the artery was distinctly to be felt, and was larger than that of the right arm. By compressing the artery the aneurism could be quite emptied, but no difference was then to be observed in the palmar tumour.

The history the patient gave was this:—As long as she could remember she had a swelling over the ball of the left thumb, which never pained her, or gave rise to any inconvenience, till about ten months before she came to the Infirmary. It then began to "gather" at times, discharging a little matter each time. Of late it increased more rapidly in size, and in consequence of this and increasing pain, caused the patient to leave her situation. The present inflamed state came on about three weeks before admission, in consequence of a blow. The aneurism of the radial was first noticed two years since by her sister; it never gave any pain, and increased very slowly in size.

I made a small puncture in the tumour of the thumb, and a few drops of pus escaped, giving relief to the patient. There was less hæmorrhage than one would have expected from an ordinary abscess in that situation.

The following day, on a further examination, there was found an aneurism of the left brachial artery, about three inches above the bend of the elbow, which the patient was quite unaware of; it was the size of a large pigeon's egg,

fusiform, pulsating strongly and expansively. By pressure on the artery above the aneurism could be nearly emptied; a loud murmur was heard over it with the stethoscope; the circumference of the left arm was eleven inches, of the right ten and a-quarter; the brachial, radial, and ulnar arteries of the left arm were much larger than those of the right, but there was no feeling of increased hardness in the vessels; the temperature of the brachial aneurism was 96° F., of the tumour of the thumb 97·5°, of the healthy arm 90°. There was audible a distinct, soft, systolic murmur at the base of the heart and along the course of the aorta; no bulging nor increased dulness. No other enlargements than those mentioned were to be found. The patient was kept quiet, and a tourniquet was applied over the brachial artery in its upper third, being kept on for a few hours at a time.

On November 9 the palmar tumour was softer and less painful, and ceased to discharge. Considerable deposit had taken place in the radial aneurism; in the brachial pulsation was less violent, and it could not be so completely emptied on pressure.

November 13.—Tumour of palm quite soft and flabby, painless, without pulsation. Radial aneurism hard and firm, with very slight pulsation to be felt. Brachial much the same.

24th.—During the last few days pulsation had become more marked in the radial, somewhat less in the brachial aneurism.

For some time pressure was applied over the artery at intervals, but the aneurism remained in much the same state. It was not considered advisable to attempt to ligature the vessel; a firm bandage was therefore kept applied over the brachial aneurism, and the patient left the Infirmary in much the same condition as on admission.

Remarks.—Spontaneous aneurism of the arteries of the arm and forearm appears to be a very rare affection, and more especially so in women. There are but few cases recorded in Surgical works, and many Surgeons of large experience state that they never saw one. Some have even expressed a belief that such a disease never occurs; that when aneurism is met with in the arm, it has invariably arisen from violence, not from disease of the vessels simply. Hodgson says that "those morbid alterations in the coats of arteries which predispose to the formation of aneurisms are rarely met with in the brachial artery or its branches. . . I have never seen an aneurism in the arm which was not produced by accidental violence." ("Diseases of Arteries," p. 388.)

I have found three recorded cases of aneurism of the brachial, and four of the arteries of the forearm.

Pelletan mentions one case in which the brachial was tied. Hæmorrhage occurred on the tenth day, and the patient died on the fourteenth. There was found calcareous degeneration of the artery, and a fissure extended through the coats of the vessel as far as the disease of the artery existed. (*Clinique Chirurg.*, tome ii., p. 4.)

Liston, speaking of spontaneous aneurism at the bend of the elbow, says he treated but one such case, in which the brachial was tied, and the patient recovered.—("Practical Surgery," p. 18.)

Scarpa relates three cases of aneurism of the brachial, but I have excluded them from the list, as each one seems distinctly traceable to injury.—("On Aneurism," second edition Wishart's *Trans.*, p. 188-194.)

Guattain mentions a case of aneurism of the palmar arch, which appears to have been of spontaneous origin. The tumour was the size of an apple, did not pulsate, but was tense and fluctuating. It was cured by being laid open, and afterwards firmly bandaged; the wound being healed in twenty-six days.—("Observations on Aneurism," by Erichsen, Syd. Soc., p. 316, case 21.)

Sir Astley Cooper says, "I do not recollect to have seen a case of aneurism from disease in the brachial artery," and "only one case of aneurism of the ulnar artery from disease." In the latter case the ulnar was tied, and "the patient died from the constitutional irritation resulting from the operation."—("Lectures on Surgery," p. 78-81.)

John Hunter does not mention any instance of the disease in his writings.

Mr. Birkett has recorded a case of spontaneous aneurism of the brachial, which occurred in a Surgeon who was subject to rheumatism. The tumour was small, situated at the bend of the elbow, and was discovered accidentally. Venesection had never been performed in either arm. After compression, employed for about four months, the aneurism was cured. Mr. Birkett remarks that he has been unable to find a similar case recorded, and that Sir B. Brodie had never met with one.—(Guy's Hospital Reports, 1862, p. 310.)

Dr. Gulston Wollaston has lately informed me that Mr. Birkett's patient has continued well since the report was written, and that the disease has not shown any tendency to return.

A very interesting case of aneurism of the ulnar artery has been recorded by Mr. Campbell De Morgan (*Med. Times and Gaz.*, Nov. 22, 1862). It occurred in a man, 47 years of age, spontaneously; was about the size of a duck's egg, fusiform, and could be quite emptied by pressure. There was no pulsation in the ulnar artery below; the radial beat freely. The patient had albuminuria and disease of the heart. Pressure was tried in various ways, but without producing any permanent benefit; and the tumour remained much the same up to the time of the patient's death; which occurred six months after admission into Hospital. When the aneurism was examined, there was found to be a free opening into the ulnar artery above; but below the vessel appeared to be closed. There was found, however, a very small opening at the upper part of the aneurism, which communicated with the ulnar artery below. There was but a very thin deposit of fibrine, which was quite smooth.

Mr. De Morgan remarks that this case is important, as showing "that closure of an artery below an aneurismal sac does not tend of itself, even after a considerable time, to cure or diminish it;" and, moreover, "how entirely insufficient is the mere closure of the artery below the sac to arrest or diminish pulsation."

Erichsen says:—"Spontaneous aneurism in the forearm is of extremely rare occurrence. I am only acquainted with one—that recorded by Mr. Todd as occurring in a woman 28 years of age, which had existed several years before the brachial was ligatured, when pulsation in the tumour ceased, though it continued solid and hard for some months after the operation."—("Treatise on Surgery," p. 553.)

In order to collect any cases which might not have been mentioned in any of the Medical periodicals or standard works, I wrote to forty-one of the principal provincial and London Hospitals to inquire if any instances of aneurism below the axilla were known to have occurred. To my inquiry I had thirty replies; twenty-six of which were to the effect that no cases of the kind were recorded in the Hospital books, nor were known to have occurred. In many instances the Surgeons to whom the question was put had been attached to the Hospital for a half a century or more.

I am indebted to Mr. Thomas Jones for the following account of a case of aneurism of the ulnar artery, under the care of Mr. Pollock, at St. George's Hospital:—

"It was in a boy about 16 years of age, admitted under the Physician for extensive disease of the heart. A tumour the size of one's fist was found in the upper part of the right forearm, over the ulnar artery. A very slight brûit could be heard, but there was a certain amount of pulsation. From the extreme emaciation of the boy and the absence of the characteristic brûit of aneurism, the tumour was considered by the majority of the Surgeons to be malignant. Mr. Pollock, under whose care the boy was now placed, thought it was an aneurism, and accordingly applied pressure. The boy, however, rapidly sank, and died about a month after admission. On post-mortem examination, disease of the valves of the heart was found, and plugging of the ulnar artery. Immediately above the plug the artery was enormously dilated—forming, in fact, the tumour, which contained coagulated (imperfectly-formed) blood. The artery has not been very carefully dissected as yet, to see whether any of its coats has given way."

For the next case I am indebted to Mr. Williams, of Norwich. It occurred in a man who was admitted into the Norwich Hospital for rheumatism in the year 1859. "It was a well marked case," Mr. Williams says, "and not produced by any injury or wound: it was indeed a true aneurism. He was 43 years of age, a labourer. The aneurism was situated at the bend of the right elbow, and was the size of a flattened hen's egg when first noticed by me. In three weeks it had attained the size of a small orange, pulsated visibly, and gave a very distinct bruit. He strictly refused to have any operation performed, and urgently desired to go home. This, of course, could not be denied, and he went home, and I have never heard what became of him. I should not think he could have lived long, for he had the symptoms and signs of aneurism at the base of the heart."

At the Newcastle Infirmary an instance occurred of aneu-

rism of the palmar arch, for an account of which I have to thank Dr. Bolton. "An elderly woman was brought by her husband as a casual to the Hospital from a country district. A large pulsating tumour possessing a well-marked aneurismal thrill, occupied the palm of the left hand, the pulsation of which ceased entirely on compressing the vessels of the forearm. Observing the serious nature of the case (there being besides distinct evidence of atheromatous degeneration of the aorta, and the radial and ulnar arteries of both arms), I recommended her admission into the Hospital. The husband, however, would not leave her, being firmly of opinion that the tumour contained 'matter or humour which should be let out with a lance.' Being pressed by him to use my 'lance,' in order to satisfy him, and at the same time secure her as a patient, I put a small pointed bistoury into the centre of the tumour—presto! a jet of florid blood shot upwards, blinding the old man, and besprinkling those around. A compress and bandage restrained further hæmorrhage, and the husband, now alarmed, permitted the removal of the patient to the wards. On the second day the compress was removed, the puncture had healed, and the tumour appeared consolidated and less in size. Mr. Armandale, her Surgeon, declined operative procedure in consequence of the diseased condition of the arterial system, and the tumour having become smaller and more solid from compression, the patient left shortly afterwards. How the case progressed or terminated we did not learn."

Among the eleven cases I have mentioned, disease of the heart is stated to have been present in five, and probably in a sixth. It seems quite probable that it may have also existed in the remaining ones, but was not recorded. Three of the cases in which compression was tried as a means of cure resemble each other very strongly in the absence of any tendency to heal by this method. Why this should be so does not seem very clear, for in Mr. De Morgan's case firm clots were found after death in the head and in the heart and large vessels, though the aneurism was almost empty.

An interesting feature in the case of Mr. Barber's patient, Mary R., is the occurrence of more than one aneurism in the same arm. There is clearly in this girl an unusual tendency to disease throughout the vascular system. We find disease about the aorta, and a large bronchocele in addition to the aneurisms of the arm and forearm. No cause was discoverable. The patient had led a healthy country life: her family history was good. It seems probable that a fatty condition of the vessels may have existed, and this view is strengthened by the patient's general appearance. It is very improbable that atheroma existed at such an early age.

The palmar vascular tumour was remarkable for the absence of any pulsation or murmur; but this may be accounted for on the supposition that it consisted chiefly of veins, or that the vessels had become occluded from the suppuration which had occurred. I heard a short time since that the patient has not presented herself again at the Infirmary, and it is not known how the case has progressed since the report was written.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

KING'S COLLEGE HOSPITAL.

CASES FROM THE OUT-PATIENTS' DEPARTMENT —CLINICAL REMARKS.

(Under the care of Mr. SPENCER WATSON.)

The following clinical remarks were made by Mr. Watson on the cases:—

Cases 1 and 2 were each typical of a class. The sores in these two patients might by a superficial observer have been regarded as very similar; but, apart from the history and circumstances of each, there were certain peculiarities of form and appearance which marked the one as a chronic epithelioma and the other as a primary syphilitic sore. The outline of the epithelioma, though approaching somewhat to an oval, was irregular; its edges were rounded and callous, and at one or two points were continuous, with white lines of cicatrix extending a short distance into the mucous membrane. This character is noticeable, as it shows that the processes going on in the tissues had been a long time at work. The surface of the ulcer had a very indolent, half-dried appearance, with no attempt at granulation. Contrasted with these, the syphilitic sore was rounded and of a regular outline, the edges somewhat raised, but evidently the result of a recent deposit, and the ulcerated surface, though not distinctly granulating at first, had a somewhat florid tint, which became brighter as soon as the mercury began to affect the gums. The history in each case only confirmed the inferences drawn from these appearances. Case 3, though from the first of a somewhat doubtful nature, was scarcely one in which any serious error of diagnosis could occur. In the first place, the age of the patient was such that it was extremely unlikely that aneurism would be found. Then, 2nd, he was of an age and of a class of patients in whom strumous abscesses are very common; and 3rd, the progress of the case confirmed the opinion of its belonging to the latter and not to the former disease. Nevertheless, it presented such a remarkable resemblance to a case of subclavian aneurism at first, that if the same series of symptoms had occurred in an elderly person, and under different circumstances, it would have been a case in which the diagnosis must have been very different. A somewhat similar case has been recently under Mr. Watson's care of an enlarged lymphatic gland in the axilla simulating axillary aneurism.

Case 1.—*A Case of Epithelioma of the Lip—Removal by the Knife.*

H. R., aged 57 years, a chaff-cutter, has had very good health up to the time of admission, on November 4, 1864. He is pallid and of spare habit, but has no appearance of cachexia. Seven years ago he was scalded on the lower lip by some hot wax, and since then he has had a sore which has lately rather increased in size. It is situated near the right angle of the mouth on the lower lip, is about the size of half-a-crown, has raised edges, an ash-grey ungranulating surface, and is surrounded by a slight amount of induration. Beneath the jaw of the same side is an enlarged lymphatic gland. He has been a smoker of tobacco, and has generally smoked a short clay pipe.

November 5.—Mr. Watson, considering the sore to be of the character of epithelioma, removed it by a V-shaped incision, and brought the edges of the wound together by means of hare-lip pins.

21st.—The lower part of the wound has healed, but the upper part is still granulating.

30th.—The wound has entirely healed, leaving a scarcely perceptible scar. The slight enlargement of one of the lymphatic glands remains.

Case 2.—*Chancre on the Lip.*

V. F., aged 19, an unmarried woman, came to the Hospital on October 10, 1864, with a sore on the lower lip, having an indurated base and associated with enlarged glands under the jaw. She was also suffering from œdema of the labia majora, and a discharge probably of a leucorrhœal nature. The appearance of the sore was from the first suspicious, and in the course of a week or ten days an eruption of a scaly character, and having a slight brownish tint, made its appearance.

Mr. Watson now put her under a course of mercurial fumigations, and subsequently prescribed mercurial ointment for inunction.

October 31.—The gums are slightly spongy, but not tender. The hardness around the base of the sore on the lip has disappeared, and the eruption is fading. The mercurial fumigation to be continued.

November 7.—The eruption has faded and the sore healed, leaving a slight hardness.

14th.—There are slight remains of an ulcer on the right tonsil, but in all other respects she has quite recovered.

Case 3.—*Pulsating Swelling below the Right Clavicle simulating Aneurism, but terminating in Abscess.*

H. F., aged 17 years, a tolerably healthy lad, who works as a shoemaker at the Refuge in Great Queen-street. He first noticed a swelling in the right sub-clavicular region on March 26, 1864, and can recollect no injury to account for it. He has never had any swellings in the neck or other parts of the body.

March 30.—*Present Condition.*—Occupying the middle of the subclavicular region, on the right side, is a swelling slightly raised above the surface, in which there is distinct pulsation synchronous with the heart's action. It is tender on pressure, and has a faint purplish tint on the surface. He suffers a good deal of pain at night from it. The pulsation of the axillary and radial arteries are not interfered with. With stethoscope a single whirring bruit is heard over the swelling.

April 1.—The pulsation has almost disappeared, and can only be felt when firm pressure is made on to the artery.

There is more pain, and the redness of the skin has extended. He was now admitted into the Hospital, and after a week or ten days an abscess was evidently pointing, and was opened by the House-Surgeon. The cavity very soon closed satisfactorily, and he left the Hospital very much improved in health.

Case 4.—Foreign Body in the Cheek—Attempted Removal by Operation—Subsequent Formation of Sinus and Removal.

W. H., aged 13 years, applied to the Hospital in the early part of the year 1864 with a sinus in the right cheek, immediately in front of the masseter and at about the level of the molar teeth. He had been playing with another boy some weeks previously, and had been stabbed in the cheek by his playmate with a wooden sword or lath. He thought that a piece of wood remained in the wound. Mr. Watson, on probing the wound, thought he could feel a foreign body, and therefore recommended that chloroform should be given in order to facilitate its removal. This was accordingly done, the wound enlarged, and search made with forceps; but, though the object was seized on one occasion, it was found impossible to withdraw it, and the operation was therefore desisted from. It then appeared to Mr. Watson, and to Mr. Henry Smith, who saw the patient at the same time, that it was possible the bone had become necrosed, and the sinus was kept open by this cause.

In the course of months a second exploratory operation was performed, but with no better success; and on December 7, 1864, nine months after the injury (a sinus having made its appearance at the posterior border of the jaw opposite its angle), a hard body was found presenting itself at this new opening. Mr. Watson seized it with forceps and easily removed it. This turned out to be the pointed edge of the wooden sword, which had worked its way beneath the masseter, and had at length formed for itself a means of exit. The difficulty of removing it was at once seen on inspecting the piece of wood, the end of it nearest the original wound being broad and jagged, and the other end being cut to a sharp point. The sinuses rapidly healed, and the boy has had no further trouble.

COMPLETE OCCLUSION OF THE VAGINA IN A PATIENT AGED 21—RETENTION OF MENSES FOR NINE MONTHS — OPERATION — SPEEDY RECOVERY.

(Under the care of Mr. JOHN WOOD.)

This case is possessed of some interest as illustrating that the ill consequences sometimes ensuing from the puncturing of a tumour containing retained menses may be obviated by taking the precaution of syringing the cavity after the operation with some antiseptic fluid, and keeping it thoroughly clean.

Agnes H., aged 21, an anæmic-looking girl, was admitted, under Mr. Wood's care, into King's College Hospital March 10, 1865. She had not had any symptoms of the menstrual period until about nine months before she applied for relief.

On admission, there was a large tumour in the vagina, covered in by a tough villous membrane, which completely occluded its orifice. By passing the finger into the rectum, and a sound into the bladder, the tumour was found to occupy the space between the two, extending backward as as far as the uterus, which was enlarged. Fluctuation was distinctly perceived. Chloroform having been administered, an exploratory puncture was made with a fine trocar, revealing the menstrual nature of the contents. The contents were evacuated by puncture with an abdominal trocar and canula, and about a quart of dark grumous fluid, having a slightly offensive odour, escaped. The opening made by the trocar was then enlarged with a pair of curved scissors, an elliptical piece being entirely removed, and the mucous membrane stitched to the skin with silver-wire sutures. The cavity was then thoroughly syringed out with a solution of Condy's fluid, and a double-action catheter introduced into the uterus (which had become greatly distended by the pressure of the fluid), and this was syringed out in like manner. A large piece of false membrane (something like a deciduous membrane) came away from the inner surface of the uterus which, when examined with the microscope, appeared in be inspissated mucus and epithelium. This syringing was repeated for several days, and another large piece of false membrane came away, being the fellow piece to the former, the two fragments formed a complete cast of the inner surface of the uterus.

She left the Hospital, April 22, completely cured and much improved in health, having had no bad symptoms.

THREE CASES OF REMOVAL OF A LOOSE CARTILAGE FROM THE KNEE-JOINT.

It is still an open question which operation should be adopted for the removal of loose cartilages from joints: the direct, in which the body is extracted at once through an incision made directly into the joint; or the indirect, in which the synovial membrane is divided subcutaneously, and the cartilage is forced out of the joint into the surrounding cellular tissue, where it is allowed to remain, either to undergo absorption, or to be subsequently removed by a fresh incision through the skin, when it is supposed that the wound in the synovial membrane has healed.

The following statistics referred to in Holmes's "System of Surgery" (vol. iii., p. 739) show that both operations are attended in many instances with very unsatisfactory, often very serious, results. Of 131 direct operations, 98 were successful, 5 were doubtful, and 28 ended fatally; while of 39 indirect operations, 19 were successful, 15 failed, that is, the cartilage could not be extracted, and 5 were fatal. From these figures it would appear that the direct method is followed by death in more than 20 per cent. of the cases in which it is employed, while the indirect, although attended with a much lower mortality than the direct, can claim but little superiority, since only 19 cases out of a total of 39 were successful. It may be thought that the numbers here given place the indirect method in too unfavourable a light; it is, however, certain that the operation is in many cases a difficult and troublesome one, and that it occasionally fails in the hands of the most skilful Surgeons. Indeed, it is sometimes impracticable, from the want of sufficient depth of cellular tissue outside the joint in which to lodge a cartilage of large size; granting the body can be displaced into the subcutaneous tissue, it will under these circumstances be impossible to leave it there, on account of the disturbance it would produce; hence an operation commenced as the indirect is not infrequently, of necessity, converted into the direct.

It would, of course, be improper to conclude that the direct is the better proceeding from the evidence afforded by the following cases. They were, however, so entirely successful that they must be allowed some weight; at least, they are important as showing under what circumstances a favourable result may be expected after the operation.

It will be noticed that the patients were confined to bed before anything was done, in order that all tendency to inflammatory disturbance, so commonly present in these cases, might subside. Precautions were taken at the time of the operation to protect the joint from the entrance of air; the wound was closed carefully; and subsequently a splint was employed for maintaining the joint in a state of perfect quiet till the opening into its capsule had completely healed.

The case for which we are indebted to the kindness of Mr. Holmes is particularly valuable, affording as it does an example of how difficult, or even impossible, it may be to make use of the subcutaneous method of operating where the cartilage is of large size. It goes, also, with Mr. Coote's case in showing how little disturbance, either constitutional or local, may result from a large wound made directly into the knee-joint, provided sufficient care is taken in the management of the patient before and after the operation, and at the time of its performance. This is indeed strictly in harmony with clinical experience, which teaches that the mischief which follows a wound of a joint is, in the majority of cases, regulated to a great extent by collateral circumstances, such as the previous condition of the joint, the management of the wound, and above all the admission or non-admission of air into the articulation.

The operation for radical cure in these cases should not generally be undertaken until palliative treatment has failed after a fair trial. In many instances a well-adjusted knee-cap will keep the cartilage fixed so that no inconvenience is felt from it; and Mr. Wormald has relieved patients of all symptoms by fixing the body by the side of the "ligamentum patellæ," and retaining it there by a shield of gutta-percha carefully moulded to its shape and kept constantly applied.

ST. BARTHOLOMEW'S HOSPITAL.

1. *Loose Cartilage Removed from the Knee-Joint by Direct Incision—Recovery.*

(Under the care of Mr. COOTE.)

J. M., aged 15, became an in-patient on February 14. His mother stated that four months previously he had fallen down and bruised the right knee. This accident was immediately followed by a sharp attack of inflammation, and the boy had

since frequently complained of pain coming on suddenly as he was walking, or if he attempted to run. The joint was often swollen and tender, especially at night, if he had taken during the day any unusual exercise. On examining the articulation, Mr. Coote at once felt a loose cartilage, apparently of large size, lying on the outer side of the ligamentum patellæ. The boy was ordered to be kept in bed, and at the end of a week Mr. Coote, having first fixed the cartilage by two needles passed down upon it, removed it through an incision about an inch and a-half long. The wound was immediately closed with strapping and a compress, and all disturbance to the joint prevented by bandaging the limb to a back splint. No bad symptom occurred; no effusion into, or heat about, the joint took place; and the patient was discharged cured about five weeks after the operation.

2. *Loose Cartilage in the Knee-joint—Removal by Direct Incision—Recovery.*

(Under the care of Mr. SAVORY.)

D. M., aged 17, was admitted into the Hospital a few months ago suffering from the usual symptoms of loose cartilage in the knee, to which he had been subject for about two years. He was placed in bed, and a long splint was applied to the back of the limb. After the joint had been thus kept at rest for ten days, Mr. Savory extracted the cartilage by direct incision. Care was taken that no air entered the joint, and the edges of the wound were immediately adjusted with strapping and a bandage. No unpleasant symptom of any kind followed the operation. The use of the splint was continued till the wound was quite healed, and the lad left the Hospital in about three weeks. The cartilage was as big as a large almond.

Mr. Holmes has kindly furnished us with the notes of the following case, in which he operated about a year ago at St. George's Hospital:—

T. McP., aged 56, a labourer, had been conscious of the existence of a loose body in his knee for many years, but of late it had become much larger as he supposed, and led to frequent attacks of pain, followed by swelling of the joint, preventing him from following his employment. The loose body was easily found, and could be driven up into the pouch of synovial membrane, above and external to the patella. The operation was performed at this part of the joint on May 4, 1864. The incision was meant to be subcutaneous, and it was proposed to have driven the loose body out of the joint into the surrounding cellular tissue, but from its large size this was found impossible; so the puncture was enlarged, and the cartilage extracted. About a teaspoonful of synovial fluid escaped; the limb was carefully bandaged from the foot upwards, and kept on a splint. The man was discharged on June 4, with a laced bandage to support the knee. The cartilage was almost as large as the end of the first finger, and contained a great deal of earthy deposit.

Belfast Branch of the Royal Medical Benevolent Fund Society of Ireland.—The usual quarterly meeting of the Committee of this branch of the above society was held on the 3rd instant in No. 33, High-street, Dr. Patterson presiding, in the absence of the permanent President, Dr. T. H. Purdon. Amongst the other members present were—Dr. Browne, R.N., Dr. Cumming, Dr. Moore, Dr. Drennan, and Dr. Stewart, Hon. Sec. This being the period of the year for applications to be sent in for grants at the ensuing annual distribution of funds by the parent Society, a larger number than usual was submitted for consideration, which occupied the attention of the meeting for some time in carefully weighing the merits of each party. Ultimately, all were disposed of to the best of the Committee's judgment, the greater number being recommended for assistance. The Committee having discussed the best means of adding to the list of subscribers by inducing members of the Profession not yet on the roll thereof, as well in Belfast as in the country districts, to join it, the Chairman, with Dr. Browne, the local treasurer, was requested to call upon the members generally in town; and Dr. Moore having kindly volunteered to visit several of the neighbouring towns—viz., Holywood, Bangor, Banbridge, Carrickfergus, Ballymena, etc.—in furtherance of the objects of the Society, he was appointed a deputation accordingly, on the part of the Committee, on this mission, and also Dr. Browne, to attend the annual meeting in Dublin next month. Some further routine business having been disposed of, the meeting separated.

SATURDAY, MAY 20.

CEREBRO-SPINAL MENINGITIS.

The public have lately heard a great deal about the "Russian epidemic," and have been watching with anxiety the progress of the disease which has been making such ravages in the valley of the lower Vistula and in the neighbourhood of Dantzic. To Medical men, however, it was very soon apparent that this was no new disease, but one which had long been known to the Profession. It is an old acquaintance, which has suddenly made its appearance in a new locality,—an acquaintance who has often "cropped up" in the course of Medical history. From a communication which we publish in another column, it appears to have flourished at Sunderland in 1830. M. Boudin, and other French military Surgeons, met with it abundantly nearly twenty years ago, and recognised its alliance with typhus.(a) An extensive epidemic of it prevailed at Montgomery, Alabama, U.S., in 1848, and there is now an eminent American Physician in London, who not only witnessed very many of the cases, but suffered the disease in his own person. Most of the American writers describe it as having prevailed extensively of late years. There are traces of it so early as 1816. We know an army Surgeon who met with it in the Mediterranean five or six years ago. But, at any rate, during the years 1862-1864, the cerebro-spinal meningitis, or "spotted fever,"—a petechial typhus with peculiar cerebro-spinal complications—has been very prevalent in America. Many cases have occurred in the civil as well as in the military and naval Hospitals; it has shown itself in many widely-scattered places over the vast area of the United States, and everywhere with the same fatality; it has been discussed at every Medical Society; it holds a prominent place in the American Professional literature of the last three years, and yet, strange to say, it has excited no apprehension in this country. But when an epidemic of a similar kind has appeared in Prussia all eyes are turned to the spot, although, when we consider the constant intercourse which is kept up between this country and the New World, there seems almost as much ground to fear lest an epidemic disease should be brought to our shores from America as from the Baltic.

We propose here to give, in a few bold touches, a rough outline of the "spotted fever," or cerebro-spinal meningitis, as it has occurred of late in America, to furnish our readers with a sketch of the symptoms and progress of the disease, to mention the principal morbid appearances which have been met with after death, and to indicate the treatment which has generally been adopted. We shall then, in conclusion, give a brief abstract of a few cases which we have gathered from

(a) *Arch. Generales de Méd.*, September and October, 1849. Quoted in Ranking's Abstract, vol. x.

American sources, and which may be taken as types of the disease. It will be seen that these cases occurred in persons of both sexes, of all ages, of various employments, under the most different conditions, and in places far distant from one another.

The disease is ushered in with rigors, pains in the limbs and joints, distressing nausea and vomiting, and there is almost always pain in the head. Sometimes this begins in the forehead, sometimes at the occiput or in the neck. It is generally extremely severe and persistent. From the head it gradually extends along the spine, and it is often associated with tetanic convulsions. The muscles of the back and jaws are affected with tonic spasms, and opisthotonos is sometimes very marked. Contractions and rigidity of the limbs, especially of the upper, are occasionally noticed. Delirium is generally an early symptom; sometimes active and violent, accompanied with great restlessness and agitation; at other times it is low and muttering. In most cases it is intermittent, and alternates with somnolence or stupor, the exacerbations growing less frequent, and the somnolence deepening into coma as the disease approaches its termination. The breathing is sighing and irregular. The pupils are commonly dilated, vision is indistinct, and the conjunctiva injected. There is rapid and extreme prostration. The face is pallid. The surface cold and shrunken. The pulse quick, feeble, and sometimes imperceptible. The tongue is generally covered with a whitish fur, though sometimes it is brown. The appetite may be natural or completely lost. This is not generally a marked symptom. As a rule the bowels are inactive. The urine presents no special modification, though in rare cases there is hæmaturia, and in others albuminuria. The eruption—which is not, however, a constant accompaniment of the disease—consists of spots which vary in size from that of a pin's head to that of a "ten cent piece." They are either rose coloured and slightly papular, or truly petechial. They never entirely disappear on pressure, and they remain after death. In fatal cases patients generally die comatose.

The mortality of this disease is said to be not much less than 50 or 60 per cent. Whether or not it is contagious is a question which is still undecided.

We now come to the morbid appearances. As might be expected from the symptoms, they are found in the membranes of the brain and spinal cord. In rapidly fatal cases, there is simply great engorgement of the sinuses and veins, with more or less effusion of serum into the arachnoid and ventricular spaces. But in more protracted cases indications of acute inflammatory action are found. There are plastic exudations (which sometimes become purulent) into the sub-arachnoid space and into the meshes of the *pia mater*. Purulent effusion has been noticed in the ventricles, and occasionally superficial softening of the brain substance. Similar changes are also found in the coverings of the cord where the case has shown spinal symptoms. The serous and synovial membranes throughout the body are often more or less inflamed. The blood is usually dark and fluid; the spleen enlarged and softened; and the lungs in a state of hypostatic congestion.

The treatment which has been adopted in cases of cerebro-spinal meningitis is of a supporting and stimulating kind. Antiphlogistic measures have been tried, and abandoned as worse than useless. The patients have been allowed beef-tea and milk *ad libitum*, with a moderate quantity of alcoholic stimulants. Frictions, sinapisms, and other means of counteracting the tendency to collapse have been constantly employed. Strychnia has been tried, but without apparent benefit. The drugs which have been found the most useful are quinine, the preparations of iron, and, above all, opium. Some speak highly of the advantage of profuse diaphoresis, while others have seen good results from the application of ice to the head and along the spine.

Case 1.—F. J. S., midshipman, at Newport, Rhode Island, aged 16, was placed on sick-list January 15, 1863, complaining of sore throat with slight headache. Later in the day the headache became more severe, with fever and delirium. There were jactitations and restlessness; tongue brownish. During the night these symptoms increased.

January 16.—An eruption has appeared on the legs and arms, in some places of the bright blush of erythema; in others there are livid spots, as large as a pea; there are also some dark-coloured pimples. Tongue brown and covered with sordes. Ordered, cold water to be applied to the head, stimulants, diaphoretics.

17th.—Patient drowsy; livid spots disappearing; no fever; tongue white in the middle and red at the tip and edges; three small pustules on the right leg.

18th.—The delirium continues, though he can be aroused to answer questions; spots fading; no excitement of pulse; complains of much pain in the joints; tongue covered with a thick brown fur and the teeth with sordes; tenderness in the right iliac fossa, with tympanitis. Ordered a blister to the back of the neck, ice to the head; Dover's powder, 10 grains, at bedtime.

19th.—Delirium continues; passes urine involuntarily; pulse 145; extreme tenderness of epigastric and iliac regions, with tympanitis; tongue brown and dry; face flushed; debility extreme. Ordered carbonate of ammonia, 4 grains every hour. The symptoms increased gradually. The pulse rose to 163 beats in a minute; and at 11.20 p.m. he expired.

No post-mortem examination.(b)

Case 2.—E. F., aged 19, a young woman living in Philadelphia, employed in "a manufactory of postage-currency notes," retired to bed in her usual health, at 11 p.m., February 19, 1863. Next morning, at 7 o'clock, she complained of headache, chilliness, and pains in her back and limbs. At 3 p.m. she was seen by Dr. Packard, and presented the symptoms of a severe cold. Ordered an anodyne febrifuge mixture, a hot foot-bath, and warm drinks. At 10 p.m. her pulse was 160, her tongue white and furred, and her throat sore, though presenting no abnormal appearance. Her hands and arms and her body were pungently hot, while her legs and feet were cold. She lay in a semi-stupor, unless when asked a question. Active stimulation and support were ordered, and counter-irritants applied externally.

All night she was unconscious, and when seen on the morning of the 21st she was evidently dying. Her pulse was gone, and the surface was growing cold. Dark, bluish-purple spots, of varying size, generally very small, were scattered over the face, arms, and body. The lower extremities were covered with irregular pale bluish patches and streaks, as if from bruises. At 11 a.m. she died.

At the post-mortem examination, made twenty-one hours after death, the only morbid appearances which were found were the following:—The pericardium contained about ʒi. of turbid serum; the peritoneal coat of the stomach and also of the small intestines was spotted here and there with purplish-blue maculæ; the mesenteric glands were much enlarged; Peyer's patches were thickened and decidedly injected; both kidneys were intensely congested. The brain and spinal cord were not examined.(c)

Case 3.—W. K. B., midshipman, aged 17, admitted on sick-list at Newport, Rhode Island, March 16, 1863. Feverish, delirious, and very restless. Small red spots on his face, wrists, and lower extremities. Ordered sulphate of quinine and strychnia in pills every four hours.

17th.—Delirious and in constant motion. Cold applied to head. Quinine omitted; strychnia continued.

18th.—Rather easier; pulse soft; tongue natural. Ordered a blister to the back of the neck. Other treatment continued.

19th.—Had a paroxysm of fever towards evening; delirium almost constant; coughs a good deal; expectorates bloody mucus; fauces inflamed; chest sounds normal; pain in right hypochondriac region; bowels not open. Ordered castor oil, f ʒij., and a blister to the right hypochondrium. Milk punch; Dover's powder, 8 grs., at bedtime. Continue the strychnia.

20th.—More comfortable; pulse softer and less frequent; tongue cleaner. Ordered Dover's powder, 5 grs., thrice a-day. Continue the other treatment.

On the 21st the strychnia was discontinued. The patient progressed favourably on a tonic and nutritious treatment

(b) Dr. Wales in the *American Journal of the Medical Sciences*, January, 1864, p. 27.

(c) Dr. Packard in the *American Journal of the Medical Sciences*, Oct., 1863, p. 403.

until the 27th, when he had an accession of fever with restlessness and opisthotonic convulsions.

On the 28th he was better, and the improvement was sustained until April 3, when he had two consecutive and long-continued paroxysms of convulsions, which left him very weak and insensible.

On the morning of the 4th he was tranquil and partly conscious; but at 6 p.m. he was seized with *black vomit*, which lasted until 8.30 p.m., when he expired.

No post-mortem examination.(d)

Case 4.—D., midshipman, aged 16, admitted into Hospital, at Newport, Rhode Island, March 29, 1863, was seized suddenly with headache, vertigo, and stupor; pulse thready; ecchymotic spots upon lower limbs. Ordered strychnia $\frac{1}{32}$ thrice daily; blister to neck; wine.

March 30.—Stupor and vertigo less; pulse improved; tongue moist; headache continuous; distressing nausea. Ordered brandy and beef-tea; strychnia as before.

31st.—Continues to improve; cephalic symptoms gone. Treatment continued.

April 1.—Partial opisthotonos occurred last evening. Strychnia suspended; pulse irregular and feeble.

2nd.—Opisthotonos relaxed during the night, but he was very restless until tranquillised by an opiate enema; slept until morning; when he awoke he spoke but once, "It hurts," and was turned over upon his back. Brandy and stimulants were freely used, but without avail. He expired at 9.10 a.m.

No post-mortem examination made.(e)

Case 5.—G., midshipman, aged 14, admitted on sick list at Newport, Rhode Island, April 8, 1863.

Last night was seized with sore throat, fever, and headache. This morning he has stupor, from which it is difficult to arouse him; headache; pulse almost imperceptible; death-like pallor; extreme debility; arms and legs dotted with minute ecchymoses; passed his urine and fæces involuntarily. Stimulants were ordered immediately; and sinapisms applied to the abdomen and extremities. No apparent improvement. In the evening, mixtures containing strychnia and quinine were prescribed. Friction with tinct. of camphor and chloroform to the spine and surface. Later in the evening, some signs of reaction; pulse perceptible; pallor less—even a tinge of redness on the cheeks; great jactitations. Frictions kept up.

April 9.—At 2 a.m. this morning, the patient became furiously delirious, and died at 7.48 a.m.(f).

Case 6.—D., aged 46, farmer, living in Sicking County, Ohio. Habits somewhat intemperate. Had been taken with a severe chill on November 27, 1863, succeeded by high fever and delirium. He had milder remittent chills, followed with free perspiration. Cathartics and diaphoretics administered.

November 30.—Expression calm; face flushed; skin moist; tongue moist and clean; intense thirst; mind rational; pulse 142. Complains of soreness throughout the whole body as if he had been beaten, with darting pains along the extremities. Sees spectra and wanders occasionally.

December 1.—No improvement; feels cold, and did not sleep. Ordered morphia, chlorate of potash, and ipecac.

2nd.—No better. Perspiration excessive during the night. Great thirst. There is great soreness amounting to tenderness over the limbs; and on the inside of the left knee, a little above the joint, a diffuse swelling has appeared, with a faint blush of red. There is a similar one just above the wrist joint of the right arm. The pain in these spots is extreme, and the slightest pressure cannot be borne. Bowels torpid. Ordered a cathartic of Rochelle salts, followed by morphia, quinine, and iodide of potass.

3rd.—Perspiration continues; pulse more feeble; is quicter and less disposed to talk; eats nothing. The swelling on each limb is extending.

4th.—Head drawn back; not quite rational; pulse almost imperceptible at the wrist; evidently sinking rapidly. The swellings gradually increasing. Died at 12 a.m.(g)

Case 7.—Leonard S., aged 9, living at Philadelphia, was seized with stiffness in his lower jaw and in the muscles of the throat on the 11th of February, 1864. During the night he was restless, continually throwing off the bed-clothes.

12th.—In the morning his speech was thick, mumbling his words as if his tongue or throat was swollen. During the morning he complained of being cold, and had a severe chill, his skin assuming a purplish hue. In the afternoon he became very sick, and began to vomit, his skin retaining its bluish and collapsed appearance. Complained of violent pain across the forehead, with extreme restlessness and apparent suffering. Sinapisms were applied to the surface, and cordials administered.

During the night he continued restless, vomited frequently, cried out with pains in his head, and, when touched or moved, complained of extreme muscular soreness.

13th.—Had convulsions, and was unconscious; his body covered with an eruption like purpura; muscles at the back of the neck retracted, and his head thrown backwards; pupils dilated, and insensible to light; pulse slow, but scarcely perceptible, surface below its natural temperature; lips and hands congested, and of a dark purplish colour. Scattered over the face, body, and extremities, were numerous spots, resembling petechiæ of a dull red colour, not elevated nor affected by pressure. The boy was restless, in constant motion, with considerable jactitation of the muscles, and making frequent spasmodic efforts to vomit. Ordered dry cups to the nucha and spine, mustard to the lower extremities, and a turpentine enema. Subsequently, he passed into another severe and protracted spasm, and died at 5 p.m., after an illness of forty-eight hours.

Post-mortem Examination.—Head: On cutting through the scalp, the blood flowed away more freely than usual, and was found abnormally fluid within the veins. The vessels of the dura mater were distinctly congested with fluid blood—a yellow effusion existed in the sub-arachnoid space; it proved to be of a serous character, and to exist in the spinal canal also. The substance of the brain was firm, but slightly congested. In the lateral ventricles there was a somewhat abundant reddish serum, and on cutting into any part of the brain substance, the gap was soon filled up with serum exuding from the cut surfaces; about two fluid ounces of serum were found in the pericardium; the mesenteric glands were enlarged and congested; some purpura spots existed here and there on the mesentery; the mucous membrane of the stomach was very deeply congested at the central part of the organ; Peyer's patches were normal; the kidneys were much congested.(h)

Case 8.—H. S., aged 3, residing in Philadelphia, had been quite well until the night of March 15, 1864, when he complained of severe headache, with nausea and vomited freely.

At 4 p.m. next day the pulse was 146, and the surface pale; there was also slight injection of the conjunctiva, and severe pain in the calf of the left leg. Ordered flying sinapisms to the surface, a turpentine enema, and five drops of ol. terebinth. every hour.

17th.—There were several vibices about the knees, and numerous petechiæ on the left side of the face and a few on the leg; the tongue moist and creamy; slight strabismus; the head retracted; great soreness of the muscles; pulse 120; skin warmer; pupils not affected. Ordered grain doses of quinine every hour with brandy.

18th.—Very restless; grinds his teeth; head strongly retracted; muscles of the neck rigid.

19th.—Spots fading; eyes much injected; pulse 120, stronger. The quinine, brandy, and turpentine continued; had also one-eighth of a grain of morphia at bed time.

20th.—Pulse 84, but very weak, the brandy being omitted. Resume brandy.

28th.—Pulse 96; no retraction of head; spots nearly gone. From this time convalescence could be dated, and though there were one or two partial relapses, the little patient recovered entirely.(i)

Case 9.—Private J. M., 90th Pennsylvania Volunteers, residing in Washington, aged 40, and of sound constitution. On the morning of July 28, 1864, he arose, dressed himself, and went out to the pump for a drink of fresh water, as was his daily practice, and then returned to the ward, apparently in his usual health. *About 6 o'clock* he was suddenly seized with a great pain in his back between the shoulder-blades. He said it felt as if a bar of hot iron was being pressed into his spine. He had no chill. A mustard plaster speedily relieved the pain. *At 7 o'clock* the paroxysm of burning pain

(d) Dr. Wales in the *American Journal of the Medical Sciences*, January, 1864, p. 29.

returned, which was again relieved by a sinapism. He felt sick and tried to vomit. He declined food, and had no thirst. His strength appeared to be good. After it was over, he fell into a profuse perspiration and slept an hour. *About* 10 *o'clock* he was seized again with the same intense burning pain in the dorsal region. This paroxysm was much severer and more prolonged than the others. There were no convulsive movements. Cupping was ordered; and at 11 *o'clock*, on raising him up in bed for the cups to be applied, he had a fourth paroxysm. He fell over on the shoulder of an attendant, exclaiming, "Oh, such pain!" and immediately became unconscious as if in syncope. Face deathly pale; eyes fixed; muscles relaxed; pulse weak; respiration interrupted. The face and lips soon became livid; right pupil larger than left; radial pulse imperceptible. He then took three or four long, sighing inspirations, and died at 11.30 a.m., despite the application of ammonia to the nostrils and the use of Marshall Hall's method of artificial respiration. He did not exhibit petechiæ or any other spots.

Post-mortem Examination Six Hours after Death.—No rigor mortis. Upon removing the calvarium, about four ounces of blood and serum flowed out. The veins over the brain were congested with fluid blood. There was a moderate amount of sub-arachnoid effusion, and the ventricles contained about an ounce of serum. The spinal cord and its membranes appeared healthy and not congested. Thorax: The lungs were intensely congested; otherwise healthy. About eight ounces of serum in both pleuræ; the pericardium contained two ounces. Heart slightly hypertrophied; no insufficiency of the valves; but the mitral and tricuspid valves were thickened. Abdomen: All the abdominal viscera healthy, except the kidneys, which were in a state of acute congestion. The urine contained albumen. Blood was everywhere fluid and dark.(k)

ROUGH NOTES ON SYPHILIS.—No. I.

The general impressions which we have formed, from personal observation, of the ordinary course of syphilitic disease are these:—

That there is an interval—a period of incubation—of from one to three or four weeks first of all; that this is followed by a lesion at the point of implantation of the virus; that a hardening process is *commonly*, although not *invariably*, set up at this part, and in the neighbouring glands, with generally, although not by any means necessarily, some disintegration of tissue, more or less ulcerative in character; that this induration is a twofold product—viz., of constitutional infection with some local changes—a perverted nutrition—induced by the retention of the virus in, and its action upon, the part. This comprehends the primary stage. Then follows another interval of four to eight weeks on the average (a kind of secondary incubation), during which the morbid principle appears to become multiplied; the lymphatic glands and system are being slowly affected, and then an exanthem occurs, with or without congestion of the throat, and sometimes catarrhal symptoms; that, just prior to the period of this outbreak, and contemporaneously with it, there is general malaise, often attended with a slight rise in the temperature in the evening. This is the secondary stage. Beyond this it becomes a question of a recurrence of the secondary manifestations in mild cases, and of the occurrence of other forms, or of tertiaries, in the severe.

From three or four years' continuous observation of the disease in the same subject, we have become more and more impressed with the cyclical character of the evolution of syphilitic manifestations. The so-called relapses belong to the nature of the disease, and our own observations here are strongly corroborative of those of M. Diday. In the mild forms the tendency is for the disease to disappear—wear itself out—in one, two, or three years, during which time there are occasional manifestations of the syphilitic phenomena, and then the patient's health—apparently—becomes re-established. This tendency to self-limitation we believe to be irrespective of treatment; but then we have been unable to test the *permanency* of the natural or artificial cures by a very prolonged observation of the patients, or by their marrying and begetting healthy offspring.

It follows from this description that we regard true syphilis as having a close connection and alliance with the contagious exanthemata. Constitutional syphilis depends upon an animal poison; it is contagious; one attack gives immunity from another, quite as much as one attack of small-pox or scarlatina is protective against a second. The evolution of the manifestations conform to the type of the contagious exanthemata group, in being characterised—by a period of incubation after exposure to contagion—a multiplication of the poison—a general outbreak or manifestation, frequently preceded by febrile commotion—a more or less definite course—the disease capable of being grouped into varieties, according to its degrees of intensity—the severity of the manifestations liable to be influenced by individual peculiarities—and the disease itself often inducing such modifications of nutrition, ill-health, and cachexia as to induce various morbid changes and actions, which are as much the offspring of a lowered health and depressed power as of the direct action of a virus, conforming to the sequelæ stage of the contagious exanthemata, in which the "dregs of a fever" poison, and the depression and debility engendered by its action, cause various kinds of morbid processes.(l)

The exact interval between the date of contagion and the first appearance of a lesion is most difficult to determine. There are so many disturbing causes—the false statements and erroneous impressions of the patients—the probability of multiple sources of infection from different exposures within short periods—the occasional commixture of the local with the true syphilitic ulcers, or the appearance of induration at late dates in any kind of lesion;—these are disturbing causes which offer almost insuperable difficulties. If we assume the earliest manifestation of induration in the chancre or glands as the epoch at which the true character of any given sore becomes stamped upon it, then, we must undoubtedly hold that Ricord's dogma as to the appearance of the chancre within a *few days after contagion* is erroneous, for the interval between exposure to contagion and the manifestation of induration is occasionally very long, and it is, we believe, invariably much longer than Ricord states. Even where the exact source and date of contagion is pretty positive, it is not by any means improbable that some local lesion—excoriation or ulceration—may have been contracted, which was not the product of the syphilitic virus *per se*, although such virus may have subsequently manifested itself at that seat. If a man inoculates the most trivial crack or abrasion with the acrid, purulent, or catamenial discharges of a prostitute, he may contract an inflamed ulcer, which shall have healed up perhaps, before any sign of a syphilitic infection be manifested. A great many trifling ulcers, inflamed erosions, and pus-discharging sores, present themselves in actual practice which do not conform to the descriptions given of the characters of the soft or hard sore,

(k) Dr. Liddell in the *American Journal of the Medical Sciences*, January, 1863, p. 21.

(l) These rough notes were written many months ago, and we scarcely need call the reader's attention to the similarity between these views and those entertained by Mr. Hutchinson. We are disposed to give more prominence to the action and effects of a syphilitic virus in the "tertiaries" than he has done.

and which seem to us to be simple venereal ulcers—the product of illicit intercourse certainly, but not at all necessarily the result of a specific poison, any more than a purulent urethritis is the result always of a direct gonorrhous contagion. The genital organs are liable to various diseases and local lesions just as other parts are, and promiscuous intercourse exposes these organs to such accidents. Many of these minor venereal affections cannot be exactly classified: you cannot tell what they are, or how they have arisen. One thing is quite certain, that, although very many are local affections merely, you cannot *tell what any one of them may become*, nor how often the syphilitic poison obtains an entrance through such portals, to manifest its action there, on the inguinal glands or system of the patient afterwards. These trifling lesions may be innocent enough in their nature, or fraught with bad consequences to the patient's subsequent health. What we desire to say, however, is this—that an explanation may be found, in these occurrences, of the appearance of local lesions without any of those intervals mentioned by authors; the syphilitic disease being engrafted on a simple lesion, and manifesting itself at a later date. Many cases of true chancre present themselves in practice in which one fails to trace the long intervals laid down by authors.

THE WEEK.

THE UNION CHARGEABILITY BILL.

The debates in Parliament on the proposed alteration in the area of rating for the support of the poor have been largely charged with references to Medical authorities and appeals to Medical science. The principle of the new Bill is, as the *Times* succinctly describes it, to make the area of rating the same as the area of management. The anomaly of relief administered according to one fixed standard in an aggregate of parishes called a Union, the whole extent of which is equally dependent for manual labour on the relieved class, whilst the necessary funds are provided in a different proportion by each parish in that Union, is so great that we can only wonder that reform has been postponed so long. The evils that the system has led to, need not the evidence of Dr. Hunter's or Mr. Simon's report to prove their reality. It is clear that, according to the parochial system of rating, labourers working but not living in a parish exact from the parishioners no poor's-rates for their support, whilst the contrary is true of labourers who live in another parish whether they work there or not. It must follow that ratepayers will naturally endeavour to obtain the former state of things and to avoid the latter. Thus it is in many parishes cottages are quietly got rid of. When they fall down they are not rebuilt, and any excuse that presents itself for demolishing a labourer's cottage is welcomed. The results, as the Profession well know, are overcrowding, the aggregation and consequent deterioration of the population in towns, immorality, and epidemic disease. Papers before Parliament state that, whilst the number of inmates per house has decreased throughout England, there are 800 parishes in which the people have increased, whilst their dwellings have become fewer. A system by which, in the same Union, one parish may be rated at ¼d. in the pound whilst the neighbouring parish is rated at 5s. 9¼d. must necessarily produce such effects. Mr. Simon's and Dr. Hunter's figures, we see, are called in question by Mr. Henley. We have no doubt that Mr. Simon will be able to give that gentleman a most satisfactory reply, and we are therefore content to leave the defence of their report to its authors. But we may say that facts which thoroughly confirm its main conclusions have come to our knowledge from various sources, and we have not the least doubt that it is substantially true. The pertinacity with which the progress of the Bill has been opposed is not to be wondered at. People who have hitherto supported their labourers at the expense of their neighbours find the arrangement inexpensive and agreeable, and are not anxious to change it. We believe that the new measure, by equalising the poor's-rates over considerable areas, would remove from the ratepayers of each smaller area all selfish inducements to restrict the number of the poor who live on it, would stem the tide of population which has long set into the towns, would, by equalising and scattering the labouring class, promote their well-being and diminish the force and frequency of epidemic visitations, and would, by the better health of the poor so obtained, diminish the aggregate of poor's-rates throughout the land.

THE ST. GILES'S WORKHOUSE INQUIRY—THE CASE OF GIBSON.

The following is the most important portion of the letter from the Poor-law Board to the Guardians of the St. Giles's Union on Mr. Farnell's report in reference to the case of Richard Gibson:—

"The Board have very carefully considered the depositions of the several witnesses who gave evidence at the investigation, and they consider that it has been clearly established that the deceased was left in a disgraceful state of neglect as regards his personal cleanliness for some time before his death. It appears that in addition to being neglected in this respect, he was kept in a ward intended for convalescents, which is not provided with the conveniences necessary for bed-ridden patients; and it is further to be inferred that he was not supplied with suitable and sufficient nourishment and stimulants.

"For the neglect of the deceased's personal condition, the Board consider that the paid nurse, Mrs. Elson, who is responsible for the conduct of the pauper nurses acting under her directions, is principally to blame, and that Dr. Craig, being responsible for the Medical treatment of the deceased, is properly chargeable with the neglect to obtain for him the stimulants and extra diet which his state rendered necessary.

"The Board find that it is alleged in extenuation of the neglect of duty on the part both of Dr. Craig and Mrs. Elson, that no complaint was made to them or the master of the workhouse, either by the deceased himself or by any other inmate on his behalf. It also appears that Dr. Craig, a week before the death of Richard Gibson, was himself suffering under premonitory symptoms of typhus fever, by which he was laid up two or three days after Gibson's death.

"Dr. Craig alleges that he visits every patient daily; that he went to the bed of Richard Gibson every day, but did not speak to or examine him so often; that he examined his leg once a week, and ordered dressings for it, but did not see that the dressings were applied. Dr. Craig further states that he thinks that the diet allowed to the deceased was sufficient, but it appears that he was not allowed meat every day until about a fortnight, nor any beer until four days, before his death; and that no food was supplied to him between four in the afternoon and eight o'clock the following morning. The Board have not failed to observe that in the evidence given before the coroner by Mr. Beale, who made the post-mortem examination of the deceased, he states that 'the cause of his death was independent of the filth on his body;' and that death was owing to 'the effusion of serum on the brain.' It appears, moreover, that the ulcer on his leg, for which the deceased had been principally under Medical treatment, was better, and had been reduced to a small size.

"Although the Board think that in justice to the Medical officer and the nurse this statement of Mr. Beale should be borne in mind, they still are of opinion that Dr. Craig, by failing to ascertain the personal condition of the deceased, and neglecting to order for him such articles of nourishment as he required; and that Mrs. Elson, by omitting to insure proper attention to his personal comforts and cleanliness, have so gravely neglected their duties that the Board would not be justified in permitting either of them to continue in the offices which they at present hold. The Board, therefore, request that the directors will communicate this decision to Dr. Craig and Mrs. Elson, and require them at once to resign their respective offices as Assistant-Medical Officer and nurse at the workhouse.

"On perusing the deposition of Mr. Rankley, the master of the workhouse, the Board observe that he states as follows:—'The infirmary has always been considered to be under the special care of the Medical officer of the workhouse and the

nurses.' The Board consider it necessary that it should be distinctly pointed out to Mr. Rankley that, as the chief officer of the workhouse, the infirmary, as well as all other parts of the establishment, are under his general superintendence, and that he is responsible for the good management of the sick wards equally with the other portions of the workhouse.

"The Board, therefore, cannot absolve him from blame for the neglect which has occurred in this case, and will in future hold him strictly responsible for the state and management of the infirmary.

"I am, Sir, your obedient servant,

"ENFIELD, Secretary.

"To Mr. T. D. Robinson, Vestry Clerk,
Broad-street, St. Giles, W.C."

PARLIAMENTARY. — THE FULHAM GAS WORKS — THE UNION CHARGEABILITY BILL—CATTLE DISEASES—SEWAGE UTILISATION.

On Thursday, May 11, in the House of Lords, the Bishop of London called attention to the proposed additions to the Imperial Gas Company's works in the neighbourhood of Fulham and Chelsea. The extension of these works was likely to prove seriously detrimental to the health of the neighbourhood, and, therefore, to the value of all the property within reach of the unhealthy influences which the extension of the gas works would entail. He trusted that their Lordships would not allow this Bill to pass, and hoped if it had passed through committee a motion would be made to throw out the Bill on the third reading, and thus prevent a great public evil from being inflicted on the metropolis.

After a few words from Lord Ravensworth to a similar effect, the subject was dropped.

In the House of Commons,

On the order for going into Committee on the Union Chargeability Bill,

Mr. Bentinck moved that it be an instruction to the Committee, "with a view to rendering the working of the system of Union chargeability more just and equal, to facilitate in certain cases the alteration of the limits of existing Unions." He argued that the Bill would inflict great injustice, by transferring a great burden from the towns to the country districts. He called on the House not to sanction a measure based on such a principle.

Mr. Packe seconded the motion.

After a debate in which the principles of the measure rather than Mr. Bentinck's motion were discussed, the House divided. The numbers were:—

For the motion	118
Against	193
Majority against the motion . .	—75

On the question that the Speaker leave the chair, the debate was continued by Mr. Thompson moving that the Bill be referred to a Select Committee. This was seconded by Mr. Ferrand. The discussion of this motion was finally adjourned by Sir G. Grey until Monday.

In the House of Commons on Monday,

Sir J. C. Jervoise asked the Vice-President of the Committee of Council on Education whether Her Majesty's Government intended to institute any measure with a view to obviate the loss, inconvenience, and alarm attendant on conclusions, unsupported by demonstration, as to the so-called dangerous communicable disorders in man and beast.

Mr. Bruce said that as the Government did not admit the accuracy of the statements in question, nor that the conclusions contained in the report were unsupported by evidence, but, on the contrary, were based on the most ample evidence, they were not prepared to institute any such measure as the hon. baronet had indicated.

The adjourned debate on the Union Chargeability Bill was resumed by

Mr. Henley, who recapitulated all the circumstances connected with the introduction of the Bill, and complained that the report of Mr. Simon and Dr. Hunter, on which it was founded, was published at such a time that the House had no opportunity of considering it, though it was used by the newspapers as the subject of "sensation" articles, which excited a prejudice against the proprietors of the land. The report itself read as if it had been "done to order," and he thought some of the assertions it contained were both painful and monstrous. He cited a mass of statistics to show the condition of the midland counties, and to prove that the statements of the report were unfounded, and the descriptions of the destruction of cottages exaggerated. The House had no certain information on the subject, and such assertions as those in the report demanded further inquiry; he, therefore, cordially supported the amendment referring the bill to a Select Committee.

Mr. Bruce reminded the House the object the bill was intended to effect had been advocated by the best writers of the last half-century, and it could not be denied that the demolition of cottages had been going on for thirty or forty years. He could not follow Mr. Henley through the statistics he had quoted, but he contended that if the report had never been made the measure would not the less have been necessary.

After a number of speakers had been heard, Mr. C. Villiers said the Bill had been introduced on the recommendation of the Committee which sat for three years to inquire into the general administration of the Poor-law. The original promoters of the reform of the old Poor-law always believed that the substitution of the union for the parish rating was essential to the success of the new system. On these grounds the Bill had been introduced. The demand for inquiry was only made as a means of delaying the measure. But this course would not be approved by the farmers, who were distinctly in favour of the Bill. They did not consider the law of parochial settlement an advantage to them. The report that had been so much condemned he believed to be a valuable document. But the Bill was not founded on it. He had never seen the report till after the Bill was brought in, but he had received many assurances that the statements of Dr. Hunter were quite accurate. He read several communications confirming those statements as to the evils caused by insufficient cottage accommodation. He described how much had already been done in the same direction as the change now proposed. He trusted the House would accept the measure, and concluded by asking Mr. Thompson to withdraw his amendment.

Mr. Thompson, as the dissolution had been announced for the second week in July, and to refer the Bill to a Select Committee would therefore be useless, hoped the House would permit him to withdraw his amendment.

The House, however, insisted on dividing, when the following numbers appeared:—

Ayes	266
Noes	93
Majority against the amendment .	—173

In the House of Lords on Tuesday,

Lord Ravensworth moved the second reading of the Sewage Utilisation Bill, briefly explaining its chief provisions and the powers sought to be granted by it. The Bill was entirely permissive in character, merely enabling the local authorities of towns and parishes to take such steps as they might deem expedient for distributing over their land the sewage of their respective districts, which had hitherto found its way into and poisoned streams and watercourses.

The Bill was read a second time.

FROM ABROAD.—THE OPHTHALMOSCOPE IN THE DIAGNOSIS OF HYDROCEPHALUS—MORTALITY OF FRENCH TROOPS IN ROME—PRODUCTION OF SEX—WET-NURSING IN FRANCE.

M. BOUCHUT has recently read a paper at the Academy of Sciences in which he gives an account of the application of the ophthalmoscope to the diagnosis of chronic hydrocephalus in young children. How difficult this often is prior to the head having attained a size capable of removing all doubts, is familiar to all; while even enlargement of the head itself may arise from another affection accompanied with convulsions, and often confounded with commencing hydrocephalus,—viz., rickets confined to the cranium. Cephalic auscultation having proved insufficient for diagnosis, M. Bouchut resolved to have recourse to the ophthalmoscope, as in chronic hydrocephalus the circulation and nutrition of the eye undergo notable modifications in consequence of the compression produced by the presence of fluid. In proportion as the fluid increases in quantity, the following changes are observable:—1, greater vascularity of the papilla and retina, together with dilatation of the veins, which retain their habitual colour; 2, an increase in the number of the veins of the retina; 3, partial or complete serous infiltration of the papilla; 4, atrophy of the retina and its vessels; 5, more or less considerable, and sometimes complete, atrophy of the optic nerve. These lesions vary with the

duration of the disease and the amount of effusion, and are the consequence either of compression of the sinuses preventing the blood returning into the cavernous sinus, giving rise to the œdema of the retina, or of compression of the optic nerves within the cranium. These lesions, with the exception of œdema of the papilla, do not prevent the child from distinguishing objects. The most important fact, however, is that these changes are not observable in rickets. In 22 children, from 3 to 5 years of age, examined by M. Bouchat, and in whom little deformity of the body existed, while there was increased size of the head with persistence of the anterior fontenelle (some of them having suffered from convulsions, and others not having exhibited any symptom referable to disorder of the nervous system), no change in the papilla, or disorder of the venous circulation of the retina, could be detected.

The French Emperor may draw an additional argument for the removal of his troops from Rome from the fact that the climate is ill suited for them. From the Statistical Report on the French Army for 1863, just published, it appears that, while the mortality is only 9·22 per 1000 for the troops stationed in France and 12·29 in Algeria, it rises to the high figure of 17·92 in the Roman States. The general mean mortality is 10 per 1000. The deaths from disease are 8·30 per 1000 in France, 10·99 in Algeria, and 16·98 in Italy, the general mean being 9·03. The general mean of deaths from accident is 0·52, and from suicide 0·45 per 1000. Passing the various important affections in review, as typhoid and pernicious fevers, pneumonia, phthisis, dysentery, etc., the Roman States maintain their unfortunate predominance, the mortality being from twice to five times as great as in France and Algeria. In typhoid fever the deaths rose to 54 per cent., and in pernicious fever to 67 per cent.!

M. Thury's ingenious hypothesis on the production of sex has been for some time before the world, and has, we believe, from practical men engaged in breeding, received some confirmation. According to the Genevese Professor, every ovum passes through two phases or degrees of maturation, and accordingly as fecundation takes place at the commencement or towards the termination of such period females or males are produced. M. Coste described to the Academy of Sciences some experiments he has made in the matter with regard to multiparous animals—viz., fowls and rabbits—and the results are in no wise confirmatory of the doctrine laid down by M. Thury, the sexes being sometimes intermingled and at others the reverse of what might have been anticipated.

There is certainly one circumstance in which they do *not* "manage these things better in France"—viz., the nursing of young infants. With ourselves the employment of wet nurses is almost a mere sign of fine-ladyism, except in cases in which the mother's health forbids her suckling; but in France the middle and shopkeeping classes make it a rule to divest themselves of the trouble, duty, and pleasure of bringing up their own infants, and consign them to hireling nurses living at a distance. Such infants are in some respects worse off than those brought up at the public expense, as the nurses to whom these latter are consigned are submitted to a system of vigilant inspection. M. Alexander Mayer, shocked by the evils of the system, and evidently seeing no hope of obtaining its radical abolition by inducing mothers to take upon themselves the duties they thus consign to ignorant peasants, proposes that a Society for the Protection of Infants should be organised, one of whose chief objects would be the formation of "maternal colonies" in the vicinity of large towns, in which suitable nurses, together with healthy cows, should be maintained under efficient supervision. Prizes are also to be given to nurses who best fulfil their duties. We need not more fully describe the project, which is painted in all the glowing colours in which most French projects are depicted, and promises so many advantages that it is doubtful whether one half of them could be realised. A far simpler plan would be the organising a plan of supervision of existing nurses through the agency of the provincial Practitioners who reside in their vicinity. Whatever we may think of the remedy, there can be no doubt of the magnitude of the evil, thousands upon thousands of new-born infants being sent from Paris and the large towns under the charge of ignorant and often designing women, the parents having no security for their good treatment or even their identity.

NOTES ON CONTINENTAL MEDICAL SCHOOLS.—BOLOGNA, PADUA, AND VENICE.

(From a Correspondent.)

The following are some rather desultory notes of a tour in the North of Italy, in which some of the most celebrated of her Medical Schools were visited. The gifted country which in the seventeenth century took the lead in the *renaissance* of anatomy and rational Medicine, as decidedly as in the two previous centuries she had in the revival of classical literature and art, has long been outstripped by her younger competitors, and almost entirely neglected by them. But, under the impulse of liberal and national institutions, great improvements are now taking place; and those of our Profession who may be travelling in Italy will not regret it should they pay at least a passing visit to the Universities and Hospitals. English Doctors are always sure of a kind and courteous reception.

The University of Bologna, the oldest in Italy, was crowded by students of civil law from all parts of Europe long before the Faculty of Medicine was founded in the fourteenth century; but it speedily acquired fame as a school of anatomy, and there dissection of the human body was first practised in the Middle Ages. Madonna Manzolina was one of the lady professors of Bologna, and lectured on anatomy; and the celebrated Malpighi was one of her successors. At present, the Medical faculty is the most flourishing, and to it more than half of the 700 students of the University belong. Professor Tommasini, who so much raised its character for clinical Medicine, is now removed to Pavia. The great Hospital was founded in the middle of the seventeenth century, and there is a smaller one appropriated to clinical cases. The anatomical lectures at the University are well attended, and illustrated from the very fine collection of wax models in the Natural History Museum. This is not so extensive as that at Florence, and none of the models are equal to some of the best at Guy's Hospital; but it is large and well arranged, and the pathological department is particularly good. The elegant attitudes, elaborate headdresses, and even necklaces, of some of the figures are, to an English eye, amusing enough. There is a very poor collection of wet preparations.

Ferrara, formerly the second town of the Romagna, is now one of the most deserted in Northern Italy. Celebrated for the brilliant court of the Este dynasty, and for the residence of Tasso and of Aristo, its Medical school never rivalled the neighbouring ones of Padua and Bologna. The Hospital now contains only 150 beds. It is, however, remarkably clean and well ventilated, and within its walls is the dungeon in which Tasso is said to have been ten years confined as a madman. In the University library is a series of anatomical drawings from dissections by Cavani, in the sixteenth century.

Padua, though still under Austrian rule, is a busy city, and its Medical school perhaps the most distinguished in Italy. Vesalius, Fallopius, Fabricius ab Aquapendent, Spigelius, Sanctorius, and Morgagni, all were Professors at Padua. The University is a noble building, and the broad stairways and open loggia are covered with the shields of students from all parts of Europe, who have studied there for more than three centuries, the illustrious Harvey among them. The great hall is a very fine room, and there the Senate hold their annual admission to degrees as in ancient times. A still more interesting place is the Anatomical Theatre, the oldest in Europe, built by Fabricius in 1594. This venerable building was altered during the present century to admit more light, but still retains its original form and the actual benches used in the sixteenth century. The seats rise very steeply in almost a complete circle around the professor's chair. In an adjoining room are preserved the chair of Fabricius, the skull of Signoroin, a former Professor of Surgery, and portraits of

most of the distinguished men of the University. The museum is not remarkable from a Medical point of view, but contains one of the finest collections of fossil fishes in the world, and also the astronomical instruments of Galileo, who was Professor at Padua for sixteen years. The Spidale Civile is a large building, containing 500 beds. There are smaller schools for Ophthalmic Surgery and Midwifery in other parts of the city, and a Foundling Hospital which dates from the end of the eleventh century, and is consequently the oldest in Europe. Professor Vauzetti is a great admirer of British Surgery, and has introduced Mr. Syme's amputation at the ankle with great success. When the writer visited the Hospital he was shown a case of fibrous tumour of the uterus, accompanied with great and continued hæmorrhage, in which the Professor had incised the neck of the uterus as recommended by Mr. Baker Brown, and the result was remarkably good. He has also performed ovariotomy more than once, but not yet successfully; as too often happens on the Continent, the operation is not undertaken until the case is almost hopeless. Excision of joints has also been introduced at Padua, and, as with us, has proved most valuable in the case of the elbow. Dr. Pinali is now trying hypodermic injection of quinine in cases of sciatica and facial neuralgia believed to depend on marsh poison, and generally with good effect. The internal arrangements of the Hospital, beds, and diet are good, and the ventilation much better than in the great Hospitals of Paris and Vienna. Professor Vauzetti's clinical lectures are especially admirable, and the students are numerous and zealous.

The Medical School of Venice has never attained great celebrity, but the great Civil Hospital there is well worthy of a visit. It occupies a magnificent building close to the great church of SS. John and Paul, which was formerly one of the "Scuola" which in ancient Venice were such useful and admirable benevolent institutions. The façade is a good specimen of the richest *renaissance* architecture. The entrance is through a noble columned hall, beyond which lies a great court with the wards around it. There are 1200 beds, with separate departments for the various Medical divisions, and also one for Jews. The wards have, many of them, most beautiful carved and painted ceilings. One, a magnificent hall, contains no less than 130 beds, with ample space between them, and the richly-carved wood ceiling is without any central supports. The chapel is also sumptuously adorned with marbles, and contains a very fine picture by Tintoretto. The students are principally those who have taken their degree at Padua. M. Asson, who belongs to the Hebrew community, M. Naunás, and Dr. Minich, are among the officers of the Hospital. The last-named gentleman especially, is particularly courteous to English visitors, and, like Professor Vauzetti, speaks French fluently. As in most of the Italian Hospitals, the cleanliness and abundance of light and air contrast very favourably with those of France and Germany. There is every indication that under the present wise and liberal Government Medical science will revive in Italy. One characteristic is remarkable in all the Hospital officers—a readiness to learn from all quarters, and what to an Englishman is very gratifying, a high appreciation of our own teaching and practice.

REVIEWS.

The Philosophy of Health; or, an Exposition of the Physiological and Sanitary Conditions conducive to Human Longevity and Happiness. By Southwood Smith, M.D. Eleventh Edition, Revised and Enlarged. London: Longmans. 1865. Pp. 396.

Dr. Southwood Smith was one of the pioneers of sanitary reform in this country, and his book was designed not to teach technical hygiene, but, by enlightening the popular mind respecting the structure and functions of the human body, to warn them as to their dealings with so delicate and intricate an organisation. The present edition, published under the direction of a grandson of the author, has undergone considerable improvement, and several chapters relating to the nervous system have been added.

The book is so well known that it is unnecessary for us to review it at length. We shall, however, make a short extract containing Dr. S. Smith's definition of health; and we do so because in these statistical days we are very apt to lose sight of its true nature while busying ourselves about its measure:—

"As long as the actions of the organic organs are sound—that is, as long as their processes are duly performed—the impression communicated to the sentient nerves is in its nature agreeable; is, in fact, *the pleasurable consciousness which constitutes the feeling of health.* The state of health is nothing but the result of the due performance of the organic organs."

Handbook of Dental Anatomy and Surgery, for the use of Students and Practitioners. By John Smith, M.D., F.R.C.S., Surgeon-Dentist to the Royal Infirmary, Edinburgh, etc. London: John Churchill and Sons. 1864. Pp. 136.

Concise and practical, we can recommend this little book to the students in Hospitals, and to young Practitioners who are making their earliest essays in dentistry. To such one of the most useful chapters is that upon extraction, and the use and appropriate selection of the forceps, key, or elevator. We warn them, however, against the final chapter, upon the use of anæsthetics. The less they are employed in dentistry the better; and when chloroform is administered we would say, "Do *not* administer it in the manner Dr. Smith advises you." If you give it at all, take your time over it.

Vital and Economical Statistics of the Hospitals, Infirmaries, etc., of England and Wales for the Year 1863. By Fleetwood Buckle, M.D., L.R.C.P., Lond., House Surgeon and Secretary of the West Norfolk and Lynn Hospital, etc. London: John Churchill and Sons. 1865. Pp. 78.

Dr. Buckle, in this pamphlet, gives us the statistics for one year of 117 Hospitals and Infirmaries in England and Wales, distributed over four extensive tables. In the first he gives the number of cases treated, the rate of mortality, the average cost of in and out patients and per bed, with the total expenditure, the cost of the various articles of diet, medicine, etc. The number of persons on the staff of each establishment is added. Table 2 shows the operations performed during the year, with the results and rate of mortality. Table 3 is a list of diseases for which a large number of patients were treated. Table 4 shows the operations performed and their results. The diversity of arrangements in the several institutions is very striking. Thus at Lynn the cubic space allowed to each inmate is 350 cubic feet, while in some London Hospitals 2000 cubic feet is not regarded as excessive. So, too, with the diet and the cost per head. We have no doubt that these tables will be frequently referred to as a ready source of information upon a variety of interesting matters relating to Hospital economics.

Observations on the Functions of the Liver, more especially with Reference to the Formation of the Material known as Amyloid Substance or Animal Dextrine, and the Ultimate Destruction of this Substance in the Animal Economy. By Robert McDonnell, M.D., M.R.I.A., Surgeon to Jervis-street Hospital, etc. Dublin: Fannin and Co. 1865. Pp. 39.

Taking into consideration the circumstances connected with diet, etc., under which the amyloid formation in the liver varies, and the long determined difference in composition between the portal and hepatic venous blood, the author considers that this material is transformed into an azotised protoplasma (fibrine being in his view a result of disintegration of tissue and not a nutritive material). The following extract expresses his views:—"May it not be that the liver does for the adult what divers tissues do during the development of the fœtus? May not this great organ form, with the help of the amyloid substance secreted in it, also a nitrogenous compound, just as the muscles of the fœtus convert the amyloid substance contained in them into the highly nitrogenous materials of muscular tissue? May not, in fact, the amyloid substance of the liver be the basis of an azotised protoplasma, forming a constituent of the blood of the adult animal, as the amyloid substance of muscle is the basis of the material from which the evolution of muscular tissue is accomplished? A general consideration of the functions performed by the liver leads one to answer these questions in the affirmative. For if it be true that the blood which enters the liver is rich in fibrine and albumen, and that these materials are so completely changed within this organ that little or none of them leave it by the hepatic vessels, what becomes of them? It is true their hydro-carbonous constituents may be thrown off as bile; but what of the nitrogen contained in them? If it does not escape by the bile ducts it has no other mode of exit save by the hepatic vessels.

The author conceives it to be re-united with the hydro-carbonaceous amyloid substance, and to leave the liver as a newly-formed proteic compound, partly, perhaps, as globuline, and partly as a material in its reactions resembling casein or albuminose."—P. 25.

First Help in Accidents; being a Surgical Guide in the Absence or Before the Arrival of Medical Assistance. For the use of the Public, especially for the Members of both the Military and Naval Services, Volunteers, and Travellers, etc. By Charles H. Schaible, M.D., Ph.D., Royal Military Academy, Woolwich. Hardwicke, London. 1864. Pp. 226.

Such a little book as this, by diffusing some common knowledge of Surgery, is calculated to be of considerable service, not only where Medical aid is difficult to obtain, but in those cases where prompt action alone will save life in certain accidents. Everybody, for example, should know what to do to check hæmorrhage; and if every one need not know how to put up a fracture, all ought to be sufficiently informed to avoid doing mischief. Dr. Schaible has, we think, succeeded very well in the task he set himself. The following titles of his fifteen chapters will give an idea of what the book contains:—Dressing of Wounds—Bleeding, Source and Arresting of—Wounds: their Varieties and Treatment—Bruises and Contusions—Burns and Scalds—Effects of Cold and Heat, Frozen Limbs, Sunstroke, etc.—Sprains, Dislocations—Fractures or Broken Bones—Of the Lodgment of Foreign Bodies in the Throat, in the Gullet, or in the Air Passages—Of Poisoning—Of Suffocation—Of the Signs of Real Death—Of Transport of Injured Persons and of Invalids—Hygienic Rules for Walking and for Marches; Accidents which may Happen to Soldiers on March—Resumé.

Reports of the Inspectors of Factories, for the Half-year ending 30th October, 1864. Presented to both Houses of Parliament. 1865.

The most important portion of the Report is that which relates to those trades newly brought under sanitary supervision by the Factory Acts Extension Act of last year. The Act applies to the manufacture of earthenware, lucifer matches, percussion caps and cartridges, and the employments of paper staining and fustian cutting. The last of these seems one of the most wretched trades it is possible to conceive, and Mr. Baker's account of it will show that Government had not taken up the subject too soon. Under this Act masters have the power of making rules for the preservation of cleanliness, ventilation, etc., in their own establishments; but both Mr. Redgrave and Mr. Baker say that this part of the enactment is, for various reasons, inoperative.

Lunatic Asylum Reports for 1864.

Dr. W. P. Stiff, the Superintendent of the Nottingham Asylum, reminds parochial officers of the necessity of complying with the requirements of the law in the removal to an Asylum of a dangerous lunatic, who, being not a pauper, has no relation or friend to take care of him. In this case the order for admission to an Asylum must be given by *two* justices. He mentions an instance where an action being brought, in consequence of irregularity in this matter, damages and costs to the extent of £900 were inflicted upon a relieving-officer. Mr. G. S. Saunders, of the Devon Asylum, has some observations in his report upon the subject of the use of thermometry in diagnosis, prognosis, and treatment—especially where patients in the Asylum wilfully throw obstacles in the way of stethoscopic investigations. At the Northampton Asylum, Dr. Edwin Wing has been using the bromide of potassium in the epileptic cases, and he belives with some good results. He says, "The number of epileptics in this establishment has averaged about 140, being nearly equally divided between each sex; and as proof that I have not exaggerated the beneficial results of the use of the medicine, I may add that, during the last five months of 1863, 1012 fits were recorded as having happened on the male side, whereas during the first five months of 1864, when they were under treatment, the number of fits was 706, thus giving a decrease of 306 in five months. On the female side the beneficial results were not so marked, but still the decrease was 157—viz., from 1127 to 970. The mere diminution in the number of fits, however, is not the only happy effect of the drug, as it undoubtedly exercises a most powerful influence on the nervous system, and often soothes the irritability of epilepsy when no other medicine will take any effect, and has thus tended to lessen materially the number of minor accidents, such as black eyes, bruises, etc., which so often disfigure the pages of Asylum registers." Dr. Thurnam (Wilts Asylum) deplores the want of uniformity in the statistical tables drawn up by the superintendents of Asylums. We are pretty nearly tired of repeating the same complaint. The Association of Medical Officers of Asylums for the Insane ought to take this subject up. It is really sad to see the uselessness of the tables in the annual reports when one cannot but feel that a vast amount of labour has been expended upon them. The following observations on the "cottage system" and the "associated" system we take from Dr. Fox's report on Burlington House:—

"In many respects there is a striking analogy between the treatment which is applicable to the insane and that which is adapted to the education of the young, and in no instance is this more evident than in the benefit which an insane person derives from attrition with those who are similarly affected. Here by force of example, there by ironical remarks—at one time animated by *esprit de corps*, at another by active benevolence—patients act upon each other, assert their privileges, and even enforce such regulations for the welfare of the community as are equally beneficial to the individual. For these reasons we don't hesitate to express our preference of the plan of association over that which is called the "cottage system;" but just as a public school is not found to be applicable to every boy, so the mixed society of an asylum is not fit for every description of mental derangement. To prevent the weakly from being oppressed, the shy and effeminate from becoming a mope, or the patient, whose first faint symptoms of insanity consist in acoustic or visual illusion, from acquiring too much familiarity with more painful phenomena, it is desirable that a separate method of treating such persons shall be provided, and yet that they shall be within reach of the larger community and able to participate in some of the social resources of an asylum."

PROVINCIAL CORRESPONDENCE.

IRELAND.

Dublin, May 13.

In my last letter I gave a short account of the opening, by His Royal Highness the Prince of Wales, of our International Exhibition of Arts and Manufacture, 1865; I shall now proceed, according to promise, briefly to describe some of the objects in the same most likely to interest your readers.

Resisting, if possible, the attractions of the sculpture hall and picture galleries, we find, in the North-East Gallery of the Winter Garden portion of the Exhibition, Section II. of the British Department, devoted to Chemical and Pharmaceutical Processes, and Products generally. One of the most striking collections in this department is that of Messrs. Johnson, Matthey, and Co., Hatton-garden, London, who exhibit a rich display of the precious metals and their preparations. Conspicuous among these is a large platinum boiler for the concentration or rectification of sulphuric acid. This boiler, of the value of £1500, is stated to be capable of rectifying to the full strength three tons of sulphuric acid per diem; it is soldered by the patent autogenous process—that is, with platinum,—whereby the extra expense of gold is avoided, and is stronger and more durable than vessels soldered in the old fashion. There are also a platinum alembic, value £350, for the separation and refining of gold and silver; a platinum syphon, value £120, for sulphuric acid apparatus; a platinum pyrometer, platinum tubes, crucibles, etc.

In the same case is a model of an ingot of pure platinum, which was melted for, and exhibited in, the Exhibition of 1862. The weight of the ingot was 3200 ounces, its value £3840. A note is added that no heat that can be obtained by the use of fuel will melt platinum, even the heat of smelting or glasshouse furnaces has no effect upon it—hence its great value for chemical purposes. But by the new process perfected by Mr. St. Clair Deville, consisting in the use of the heat of combined gases, under particular conditions, it can be melted with facility. The model is considered worthy of preservation, as it is not likely that such a mass of fused platinum will ever again be produced.

Some very beautiful specimens of magnesium, produced under Mr. Sonstadt's patents, are exhibited in the same case,

for the "Magnesium Metal Company." These are a mass of pure distilled magnesium, weighing 134 ounces; an obelisk of pure magnesium metal (a solid casting), weighing 162 ounces; turnings of the same metal, weight 13 ounces; steam valve of the same metal, weighing 27 ounces; a coil of pure magnesium wire, one mile and six yards in length, weighing 47 ounces; and a coil of ribbon of the same, 4800 feet long, weighing 40 ounces.

The manufacture of magnesium, as now conducted in Manchester, may be divided into three stages—1. The preparation of anhydrous chloride of magnesium from the native carbonate of magnesia; 2. the decomposition of the resulting chloride of magnesium, by heating to redness in a crucible five parts of the chloride with one of sodium; 3. The purification of the magnesium so produced by distillation. The principal application which has as yet been made of the new metal, as it may be called, is in the production of a brilliant light, displaying colour as in sunshine, and admirably adapted for photographic purposes. In Surgery the magnesium light is now freely used in examinations with the speculum, and it has recently received a new application in connexion with the laryngoscope. The metal itself is white, of a silvery lustre, which it preserves in dry air; in a moist atmosphere it oxidises and becomes dull, like zinc. Its specific gravity is 1·350.

In a pamphlet left in the Exhibition, and from which I have drawn the foregoing particulars, it is calculated that whenever magnesium shall be demanded in large quantities it will be cheaply produced. Even already the price of the wire has been reduced to one penny per foot.

In an adjoining case are exhibited some very beautiful crystals of nitrate of silver, nitrate of silver in sticks and points, the new fused sulphate of zinc point, in ebony holder. etc., etc.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 9.

Dr. ALDERSON, President.

A PAPER, by Mr. HENRY LEE, F.R.C.S., was read on

THE SURGICAL TREATMENT OF CERTAIN CASES OF ACUTE INFLAMMATION OF THE VEINS.

The author stated that in Mr. Arnott's admirable paper on "Inflammation of the Veins," published in the fifteenth volume of the Medico-Chirurgical *Transactions*, he had drawn the inference that the dangerous consequences of phlebitis bear no direct relation to the extent of the vein which is inflamed. He had there proved, by an excellent collection of cases, and by his observations on those cases, that death in cases of phlebitis does not take place from the inflammation extending to the heart, but from the entrance of some morbid product into the general circulation (pp. 44 and 61). In a paper by Mr. Lee, published in the thirty-fifth volume of the Society's *Transactions*, he had endeavoured to show that the material which obstructs the cavities of veins in cases of phlebitis is derived from the blood itself, and is not, in the early stages of the disease a secretion from the lining membrane of the vessels; that the veins become extensively inflamed only in cases where coagula have previously formed; and that the purulent-looking fluid often found in the cavities of inflamed veins is derived from the changes which under the circumstances take place in the fibrin of the blood. The distinction which he wished to establish between the process by means of which fibrin is deposited from the blood, and that by which lymph is secreted from the lining membrane of a vein, was of primary importance, not only with regard to the pathology of this class of diseases, but also with regard to their Surgical treatment; for it must be obvious that if the material which occupies the cavities of the vessels in cases of phlebitis were secreted by the inner coats of the veins, it would adhere firmly to that membrane, and would be found lining equally the whole circumference. It would not be displaced by the force of the circulation, nor by any other mechanical means likely to be employed. Moreover, the morbid process would extend by continuity of action, and would not be arrested by any Surgical interference. If, on the other hand, the material found in the veins were derived from the blood, it might be expected to adhere slightly only to the walls of the vessels, to be attached to one part only of those walls, and to be removed easily by any mechanical force. It would be deposited in uncertain quantity, and at irregular intervals, leaving portions of the lining membrane between those intervals free from deposit, and of its natural appearance. The deposit would often, as had actually occurred in some of the cases related by Mr. Arnott, terminate abruptly at the entrance of a fresh vessel; the reason of this abrupt termination being, as it appeared to Mr. Lee, the greater velocity and force of the circulation in the common trunk than in that which is partially obstructed. Now, the appearances actually observed on post-mortem examinations in cases of phlebitis all belonged to the latter and not to the former class, and the conclusion necessarily followed that the disease extends, as far as its severer symptoms are concerned, not by continuity of action in the lining membrane of the vessels, but by means of their contents, often in a more or less perfectly coagulated state. If that were the true course of the fatal symptoms in phlebitis, it appeared surprising that more attempts had not been made to arrest the progress of the disease by Surgical treatment. Such attempts, however, had not been entirely wanting. Hunter remarked that when inflammation takes place beyond the orifice (of a vein) so as to alarm the Surgeon, he should immediately make a compress upon the vein at the inflamed part, to make the two sides adhere together; or, if suppuration has taken place, then the compress must be put upon that part of the vein just above the suppuration.(a) Now, as lymph was not effused in the early stages of phlebitis from the lining membrane as a secretion from its inner surface, the adhesion produced by Hunter's method of treatment could be formed by coagulum of blood only. This would not, under ordinary circumstances, become organised; it would adhere to one side only of the vessel, and it would constantly be liable to become displaced. Such a bond of union, although it might for a time prevent the morbid contents of a vein from entering the general circulation, could scarcely be looked upon as affording a permanent bond of union between the sides of the vessel. In cases where the affected vein is seated superficially, a much more certain and effectual way of closing its canal and of barring the entrance of its contents from the general circulation might be adopted. This method, which when properly performed Mr. H. Lee believed to be free from danger, was adopted in three out of four of the following cases. The fourth case was given as an illustration of Mr. Hunter's method of treatment. It would, the author thought, be obvious that, although Mr. Hunter's method might perhaps have been successfully adopted in the first case, it could not have been used with any reasonable chance of success in the second and third. Four cases were then read in which, in severe cases of phlebitis, the current of blood was artificially arrested between the inflamed vein and the centre of the circulation. In one instance a pad was placed over the upper extremity of the basilic vein, and retained in its position by a bandage. In two cases a needle was passed under a healthy and unaffected portion of the vein, and pressure was made by means of a figure-of-8 ligature; and in one case the vein above the seat of the inflammation was divided subcutaneously, the two divided extremities being secured by acupressure. Of these different plans of effecting the same object, Mr. Lee preferred decidedly the latter. In any future similar case it was that to which he should have recourse. By the operation of subcutaneous section a permanent union was effected, because that union took place between the opposed portions of cellular tissue on the outside of the vessel. Such a union was vascular, and, therefore, not liable to be broken down. By it no suppuration need be excited, and the needles used for the purpose of acupressure might be removed at the expiration of two, three, or four days, when the union would be complete. Union could not be ensured within the same period by the pressure of a needle placed under the vein. If the needle be removed at that time, the current of blood would be liable to be re-established through the vein; if it be left, suppuration might be excited on the outside of the vessel: this might lead to the coagulation of the blood both above and below the part where the vessel was compressed, and the coagula thus formed might undergo the very changes which produced the serious symptoms for which the operation was undertaken. In one of the recorded cases this appeared in some measure actually to have happened, for although the current of blood through the vein was arrested, yet suppuration took place both above and below

(a) Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge p. 29.

the needle last introduced. In another case, on the contrary, where the vein was divided, no trace of inflammation extended beyond the divided part. In both these cases the products of the diseased actions were expelled from the interior of the veins by the process of suppuration; but had the flow of blood through the vessels been allowed to continue, some of these same morbid products would have been carried in the course of the circulation, and would have produced their effects in other and distant organs.

Mr. Moore had been so much impressed with the danger of applying ligatures to varicose veins that he always denuded the vein by cutting down upon it to avoid the danger of transfixing it.

Mr. Savory bore testimony to the interest of the paper; but objected to the point of view from which Mr. Lee regarded the subject. He was startled to find that while Mr. Lee, at the commencement, referred to the admirable paper of Mr. Arnott, he was altogether silent on subsequent researches. Are these to be ignored? Is Virchow's masterly work, for example, to be set aside? With the present paper before them, he thought he was entitled to ask Mr. Lee what he meant by phlebitis? Upon what evidence does he assume the existence of phlebitis? In his view, what are the characters presented by phlebitis upon dissection? Does he regard the formation of clots in a vein as evidence of phlebitis? Indeed, what effect has phlebitis upon the interior of a vein? Is no distinction to be drawn between phlebitis and thrombosis? To what changes may these conditions ultimately lead? These questions have supreme interest in reference to the great subject of pyæmia. Will Virchow's views stand the test of a scrutiny as severe as that to which he has subjected the doctrine he has laboured to overthrow? Evidence appears to be yet wanting to show not merely the coexistence of disintegrated fibrin and abscesses scattered in distant parts, but that these bear to each other the relation of cause and effect. A great question still awaits an answer—and, by the way, must be answered before a satisfactory opinion can be formed of the plan of treatment adopted by Mr. Lee—What relation, if any, does phlebitis hold to thrombosis on the one hand, and to pyæmia on the other?

Mr. Curling said the paper presented some points of much interest, but he thought Mr. Lee had taken too mechanical a view of the mode of treatment which he advocated. There was no evidence, moreover, that the cases detailed were of so serious a nature as Mr. Lee supposed. He (Mr. Curling) had seen cases of a similar kind in which no such treatment was employed, and no bad effects followed. In these cases of phlebitis, when pyæmia resulted, it arose from causes not mentioned by Mr. Lee, such as a bad atmosphere, contagion, &c. Mr. Curling thought that too much fear was entertained of dealing with veins in a state of disease when the patient was in circumstances favourable to health.

Mr. Henry Lee, in reply, said his paper was upon the surgical treatment of acute inflammation of the veins after that disease had already been produced. He had purposely abstained on the present occasion from considering the best mode of operating for varicose veins, or from dwelling on the pathology of phlebitis. Those subjects had been fully discussed on former occasions, and some of the conclusions arrived at were recorded in the *Transactions* of this Society. As, however, the two subjects mentioned had been introduced to the notice of the Society, he might be allowed to say that in the operation for varicose veins it was, in his opinion, a dangerous practice to lay bare the coats of the vein. It was an operation that had been adopted by some of the older Surgeons, and had often led to dangerous and even fatal consequences. The question which Mr. Savory had been good enough to ask—namely, whether the lining membrane of veins was liable to ordinary inflammation, and whether lymph could be thrown out upon its surface, was one of primary importance with regard to the pathology of this disease. All recognised the results of inflammation of a vein. After it had existed some time the coats of the vein became thickened; they could be felt as a hard unyielding cord below the skin; and if removed from the body and cut transversely, they would remain open like the coats of an artery; at the same time the cavity of the vein was filled with coagula, or with the fibrin of the blood more or less decolorised. Now, the great question at issue was, Does the inflammation of the vein produce this coagulation of the blood? or does the coagulation of the blood produce the inflammation of the vein? Is the lining membrane of the veins subject to spontaneous inflammation like the serous membranes of the body, and does it, like them, when inflamed, secrete lymph? Now he (Mr. Lee) ever since he had given his attention to this subject, had held that the lining membrane of veins was not at all analogous in its pathological relations to the serous membranes. Being non-vascular, it was not, like them, liable to attacks of spontaneous inflammation, and especially it was not capable, like them, of secreting coagulable lymph. When a serous membrane was inflamed, the lymph secreted united with the lymph on the opposed surface, and the cavity was closed where such a union took place. If the veins were liable to such mode of action, the circulation in our bodies would be constantly and permanently obstructed. But Nature had wisely ordained otherwise. The lining membrane of the veins, even under great irritation, would not secrete lymph; and the obstruction in veins was derived entirely from the materials of the blood. These observations applied to the disease in its earlier stages. During the later stages, when the parts had become altered by long-continued diseased action, the lining membrane of the veins might secrete lymph or pus like other parts. It was so with regard to the cartilages of joints, which might be taken as a rough illustration of the present subject: naturally they contained no vessels, and they could not secrete lymph; but after having undergone changes produced by long-continued disease, they might become permeated by vessels, and then they would secrete lymph and pus like other inflamed parts. In the early stage of the disease, he (Mr. Lee) had never seen a case in which lymph was effused on the lining membrane of a vein, and he held that in all cases of acute phlebitis the severe symptoms depended upon some morbid matter which had entered the cavity of the vein. If a portion of a vein were isolated from the rest of the circulation, and closed at two points by acupressure, the part of the vessel thus isolated might be cut or irritated in any way, and no symptoms of general irritation would be induced; whereas it was well known, from the writings of Sir B. Brodie and some of the older Surgeons, what serious and fatal consequences would occasionally follow operations on the veins when such a precaution was not taken. When Ambrose Paré suggested the ligature of divided arteries as a safe and comparatively painless mode of preventing hæmorrhage, it was long before his doctrine was generally received; and it will not be, therefore, surprising if a considerable interval should elapse before the simple mode of preventing hæmorrhage on the one hand or absorption on the other, from divided veins by acupressure, comes into general practice. But he (Mr. Lee) could say now, from a very considerable experience in operating upon varicose veins, that it was a plan perfectly effective and free from danger. When properly performed, it not only prevented any symptoms of general irritation from the usual operation of varicose veins, but when from any accidental circumstance inflammation of a vein had arisen, it would (as had been proved by the cases now read to the Society) prevent the extension of the inflammation along the inflamed vessel. This it did, of course, by preventing the transmission of the irritating contents of the vessels, upon which alone he (Mr. Lee) believed the symptoms to depend. With regard to the cases related being instances of genuine acute phlebitis, such as, without some preventive treatment, generally led to a fatal termination, he had only to appeal to the symptoms observed. When a severe rigor occurred in these cases, followed by a profuse perspiration, and the pulse continued from 120 to 140, he need not say that the gravest consequences were to be apprehended.

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, March 8.

Dr. Barnes, President, in the Chair.

Dr. Tyler Smith exhibited a portion of a Dermoid Cyst, with teeth attached, passed per rectum from a lady who had for a year and a half previously evacuated by the same canal a quantity of hair.

A paper from Mr. Rouse, of New Zealand, was read, describing peculiar Marks on the Neck of an Infant born before his arrival, and which had not been touched. There was much difficulty in getting the child to respire; and the marks were so similar to those made for the purpose of infanticide that, had not the mother been very anxious for a live child, and it was certain it had not been touched, and had not the thick coating of vernix caseosa been perfect, he should have put these marks down to attempts at strangling.

Mr. Harris exhibited a Deciduous Bag, with a small opening at one end, expelled some days before delivery at full term. There was nothing in or after the labour to explain its nature. As there was considerable difference of opinion as to its origin, Dr. Meadows and Dr. Graily Hewitt were asked to examine it and report.

Mr. Roper read a short paper on Labour in Primiparous Women late in Life, in which he questioned the commonly received opinion that labour after forty-five years of age was necessarily or commonly difficult; and quoted Dr. R. Lee's cases in support. He believed that the soft parts which oppose the head were rather lax and wasted after the age mentioned, besides which the uterus acted with more vigour than in multiparæ at that age.

The President said he had recently read a paper by Dr. Matthews Duncan, in which it was shown that the weight of the child diminished in women who had passed the age of thirty. This circumstance would help to account for the comparative facility of primiparous labour at a late period of life.

The President showed a number of Outlines of Children's Heads, illustrating the changes of form imparted by various modes of delivery. They were made by running a pencil around the head laid on a sheet of paper; and, in some instances, correction was made by measurements of the diameters of the head by means of the callipers. In this way the forms the head assumed in difficult labour, terminated by forceps, craniotomy, and by turning in contracted pelvis, were strikingly manifested.

Dr. J. Braxton Hicks, F.R.S., read a paper on

TWO CASES OF FACE PRESENTATION IN THE MENTO-POSTERIOR POSITION; WITH REMARKS.

The author began by pointing out that *à priori* there was no anatomical reason which rendered it absolutely impossible that spontaneous delivery should be effected with the chin posterior in face presentation, even within the range of normal pelvis and head, as represented by some authors. Quotations from the works of nearly all the English authors were given to show the variety of opinions upon the subject. Smellie's case delivered by the forceps was recited, with his opinions and advice upon the treatment of such cases. Two cases given by Prof. Braun were quoted, in one of which the fœtus was delivered by the natural powers, and in the other by the forceps, the chin coming over the perineum first. The author supplied another case in which, after ineffectual efforts to alter the position, he delivered the child alive by the forceps, without any detriment to the mother. The chin appeared first, coming over the perinæum. The child was large and the pelvis normal. He also gave another case, where the face descended partly exterior to vulva so readily that, although the chin made the anterior rotation at the last moment, it seemed highly probable that it could have been born by natural powers had rotation been difficult. The state of our knowledge of face-presentation was then summed up as follows:—That although in the majority of cases the chin rotates forward during the descent in face-presentation, whatever was the position it occupied originally, yet in some rare cases the chin passes through the outlet obliquely; while in others the rotation cannot be accomplished at all, either by nature or art. Under these circumstances, in some very rare instances delivery takes place spontaneously, though the greater number of this rare class require the use of the forceps, by means of which either the chin over the perineum, or the vertex beneath the arch of the pubis, might appear first. The author thought, from a consideration of the foregoing cases of Smellie, Braun, and his own, in all of which the children were born alive, that provided the chin could not be brought anteriorly, then the head should be brought down in the most practicable mode, chin or occiput first, and not necessarily with the occiput first, as recommended by Smellie.

The President signalised the value of this memoir as tending to give precision to, and extend our knowledge of, labour with face-presentation. His own experience had proved to him that such labours were not so uniformly favourable as was commonly taught. Difficulty might occur at two stages: 1st, at the brim; in this case he deprecated the forceps and craniotomy, and recommended turning as giving the child the best chance. 2ndly, in the pelvis; difficulty might arise here in the way indicated in the paper—viz., from the head retaining the position in which it entered the cavity. The proper rotation depended upon a due relation between the head of a live child, or one recently dead, and the pelvis. In Dr. Hicks's case the child was alive; it was, therefore, probable that the pelvis was large in proportion. In such a case he should not despair of turning if art or nature failed to rotate the chin. In cases of due relation of pelvis and child, birth with the chin posteriorly was almost impossible; for in proportion as the face descended, there was a rapidly widening base of a wedge, formed by the occiput bent back upon the child's trunk, which could not pass the pelvis.

Dr. Meadows exhibited a specimen of Imperforate Bowel, in which the colon ended at about an inch from the anal orifice, to which it was connected by means of an impervious cord, the anus being itself perfect. Attempts were unsuccessfully made during life to reach the bowel by the anal orifice, and the child died on the twenty-second day after birth.

Dr. Bathurst Woodman read a description of a fœtus, delivered by Dr. Gayton, in which the anterior parietes of the abdomen were absent, the viscera being covered only by peritoneum; the anus and rectum were absent; the imperfect penis was divided. The bladder had no outlet except the urachus, which was still pervious. The rest of the organs were as usual, except that the foramen ovale was closed by a membranous septum. The fœtus lived a few seconds after birth.

THE PATHOLOGICAL SOCIETY.

Tuesday, April 18.

Dr. Peacock, President.

Dr. Playfair brought forward a case of

INVAGINATION OF THE INTESTINES IN AN INFANT FOUR MONTHS OLD.

The child was constantly vomiting and passing blood per rectum. There was an elongated tumour in the left hypochondrium. Opium was given and insufflation was attempted, but without benefit. The child died next day. There was a large mass of small intestine prolapsed through the ileocæcal valve, and occupying the whole of the large intestine as far as the entrance of the rectum. Dr. Playfair observed that the failure of the insufflation was no argument against the treatment, as the prolapsus was so great that no treatment could have succeeded.

Dr. Cayley produced a specimen of

CANCER (MEDULLARY) FROM THE SUPRA-RENAL BODY.

There was cancer of many other organs. The cancer was only a tubercle occupying but part of one capsule, yet a good deal of sallowness of complexion had been noticed.

Dr. Ogle brought forward a specimen, which he believed to be unique of its kind, of

CANCER OF ONE SUPRA-RENAL CAPSULE IN AN INFANT AGED 3.

The tumour was as large as a cocoa-nut. The patient was brought to the out-patient room at St. George's Hospital. She had an enormous development of hair on the organs of generation and other parts of the body, and from birth had been of a dark gipsy colour, as indicated by a water-coloured drawing which was exhibited. There was a tumour in the left hypochondrium, which appeared during life to be the spleen. Persistent vomiting set in, and continued for a day or two before death. After death it seemed that the cancer had been confined to the supra-renal capsule and to the liver. The symptoms of the case have been already published in the *Lancet*.

Mr. Callender doubted whether the tumour had really originated in the supra-renal capsule; but

Dr. Ogle stated that, on anatomical examination, it appeared that the supra-renal capsule was not found elsewhere, and that the deposit really did occupy this organ.

Dr. Greenhow remarked that in none of the cases of cancer of the supra-renal body elsewhere published, had there been the discoloration of the skin and the constitutional symptoms of Addison's disease. In Dr. Cayley's case he remarked that the discoloration was not the same as that seen in the true Addison's disease.

The specimen was referred to Mr. Callender and Mr. Partridge, in combination with Dr. Dickinson and Dr. Ogle.

Dr. Cayley showed a

TUMOUR OF THE BRAIN FROM A CHILD AGED 2.

The child was observed to droop her head, and to have rigidity of the right arm and leg. This was followed by rigidity of the other arm and leg, convulsions, and soon deafness, and the lower half of the right cornea ulcerated. After death a large

tumour was found near the crura cerebelli—consisting of fine fibres and granular nuclei—much resembling the cerebral substance to the naked eye, and of the kind which has recently been called glioma.

Dr. R. Bennett exhibited a specimen of

GASTRO-COLIC FISTULA.

There was a large ulcer in the transverse colon, from which the ulceration had extended to the great curvature of the stomach. There were two or three smaller ulcers in the neighbourhood, in some of which perforation had nearly taken place. There was no evidence of cancer. It seemed quite evident that the ulceration began in the intestine and spread to the stomach. The disease began with vomiting and constipation, rendering it probable that there was intestinal obstruction. There was a little pain, referred to the course of the colon, but none in the stomach. She suffered most from vomiting, which did not come on immediately after food. The vomiting was always of the same kind—viz., spumous, sour, yeasty fluid, of a light yellow colour, with no fœcal odour. It was somewhat relieved by creosote. There were no sarcinæ. The motions soon became almost natural in form, colour, etc. She eventually died from asthenia.

Dr. Murchison referred to the rarity of ulceration extending from the colon into the stomach, and stated that in all recorded cases hitherto this ulceration had been found to be cancerous. He mentioned that in most cases the communication is indicated by fœcal vomiting and the passing of undigested food by the motions.

Dr. R. Bennett stated that the edges of the ulcer were examined by the microscope, but that no elements of cancer were found.

Dr. Gibb exhibited

DRAWINGS OF THE LARYNGOSCOPIC APPEARANCES OF A CASE OF PRIMARY CANCER OF THE LARYNX,

affecting the epiglottis and parts above the vocal cords. The symptoms were hacking cough, dysphagia, especially with fluids, but no alteration of voice. There was an enlarged gland under the jaw. Dr. Gibb showed drawings of the parts at an earlier and later stage of the disease, showing the progress of the cancer to the destruction of the epiglottis and one of the vocal cords, producing aphonia. A post-mortem examination verified the results of laryngoscopic investigation; but the permission to remove the parts was refused. Dr. Gibb remarked that he knew of eight or nine cases in which cancer had begun in the larynx, two of which had been published in the *Transactions* of this Society.

Dr. Ogle showed a drawing of a

PECULIAR CONDITION OF THE FINGER-NAIL,

from a woman, a patient of his, who had laboured under neuralgia of the arm after a blow, which had caused abscess at this part; and who suffered from pain and numbness in the affected finger. The epidermis of the finger grew thickened and hardened, and the nail increased in size and become nodulated on its surface, jagged at its edges, and irregular in figure. He referred to the large growths of the hoof observed in horses in whom the nerve has been divided as probably indicating a pathological condition analogous to that which obtained in the case of his patient; also to the remarkable condition of the skin (excessive development of epidermis, and roughness and dryness of the surface) often noticed in paralysed limbs. Dr. Ogle also adverted to the remarkable and quick growth of nails in paralysed limbs.

Dr. Ogle also showed two specimens of

SOFTENING OF THE SPINAL CORD, IN ONE OF WHICH THERE WAS SUPPURATION WITHIN THE THECA VERTEBRALIS,

in insane patients who had suffered from general paralysis, attended in one case by epilepsy. For the opportunity of exhibiting these specimens, Dr. Ogle had to thank Dr. Boyd, of Wells.

Dr. Murchison showed a specimen of

EMBOLISM FROM A CASE OF TYPHUS FEVER,

in which rapid gangrene had attacked the whole limb, from the higher part of the thigh downwards. He noted that there were two states of the leg seen after typhus—viz., the ordinary "white leg," from obstruction of the veins, and gangrene of the feet, from embolism in the arteries. In the present case both conditions seemed to be combined. On post-mortem examination the aorta was found plugged just above the bifurcation, and the plug extended down the left common and external iliac down to the middle of the femoral artery, the clot being in some places discoloured and adherent. The femoral vein was also plugged. There were two large blocks in the spleen, and extensive blocks in the kidneys, and the right renal artery was obstructed.

Dr. Murchison also showed a

SPECIMEN FROM A PATIENT WHO DIED OF PERFORATION OF THE BOWEL AFTER TYPHOID FEVER ON THE FORTY-SIXTH DAY.

The patient had recovered on the twenty-fourth day, but had had a relapse followed by the symptoms of perforation—viz., peritonitis and rapid sinking.

Dr. Lichtenberg exhibited

AN ANEURISM OF THE AORTA WITH RUPTURE INTO THE RIGHT AURICLE,

in a man who had suffered primary amputation of the arm at the German Hospital. He was convalescent from this when the symptoms of the fatal cardiac disease showed themselves.

Dr. J. Pollock showed

AN ANEURISM OF THE AORTA, IN WHICH RUPTURE WAS THOUGHT TO HAVE OCCURRED INTO THE PULMONARY ARTERY.

It was somewhat doubtful whether the rupture had not been produced in the post-mortem examination, but during life the aneurism had made so much pressure on the pulmonary artery as to have obliterated two of the valve-flaps.

Dr. Pollock also showed

A KIDNEY COMPLETELY WASTED, SO THAT NO TRACE OF THE NORMAL TISSUE WAS LEFT.

The only cause seemed to be an abnormal condition of the opening of the ureter from the pelvis of the kidney, which was replaced by a slit-like or valvular opening. The other kidney was much diseased, and the patient had suffered from epileptic fits.

HARVEIAN SOCIETY OF LONDON.

Thursday, March 16.

Dr. J. C. Langmore, President.

Mr. William Adams mentioned that he had frequently had to treat cases of

INFANTILE PARALYSIS,

and that in some instances he had been able to restore the power of locomotion where it had been supposed to have been irretrevably lost. Infantile paralysis came on frequently during teething, at the age of 1 or 2 years. Both legs or both arms are paralysed suddenly or in the course of a few hours, or only one limb may be affected. Sir B. Brodie used to say that unless this paralysis is naturally recovered from in six months, it is hopeless. In three to six months there is usually the greatest amount of recovery, the rectus muscle of the thigh often being the last to recover. As to the pathology of the disease, Mr. Adams confessed that he knew nothing of it. The most recent German writers on the subject attribute it entirely to the muscles; and Rilliet and Barthez recorded only two post-mortem examinations. In these, as well as in the one made by Mr. Adams, no appearance could be made out to account for the disease, and children do not die of it. Consequently, the cause of it is not investigated. If Practitioners were but aware of this fact, they would probably make the necessary examinations. It must be remarked that natural recovery of the muscular powers may progress from six months up to three or four years, during which time a series of events takes place—namely, contraction of all the joints. Mr. Wilkinson had lately brought him a child with great contraction of the knee joints. The muscles around the hip joints are usually the first to recover. A child was sent him from Clifton, of the age of from 6 to 7, which had never stood. It had contraction of the joints, arms, legs, and trunk, and Mr. Adams was able to promise the parents of the child that it should walk in three months. Dr. Brown-Séquard had requested Mr. Adams to see a young lady, aged seven years, in consequence of paralysis of both legs, and in three months this child was able to walk with steel supports. If a child could use the psoas and iliacus muscles, it could be made to walk, and this was the practical test. It should be laid down on the floor, and if it can draw up its knees success is certain. With regard to treatment in the early stages, he had known counter-irritation down the spine used, but the chances were that no treatment would do much good. When the child has paralysis with flaccid muscles, rubbing and warm clothing are of use. Galvanism of both legs under water is also useful, notwithstanding that many Physicians and Surgeons disparaged this remedy, and said it had been tried and found to be valueless. He (Mr. Adams) used two tin boots, filled with warm water, in each of

which the little patient's foot is placed, and galvanism is applied. Dr. Gull had written some valuable papers on galvanism in the "Guy's Hospital Reports." The nutrition of the limb must, if possible, be maintained. Dr. Junod's boot for exhausting the air was once in much repute, and is now, perhaps, too much neglected. A paralytic patient of his could always warm the leg in ten minutes by this apparatus; the boot has no bad effects, but is liable to get out of order. It is, doubtless, a most useful remedy in many cases of paralysis. In some cases of infantile paralysis, the rectus muscle remains paralysed for life and the leg swings; but this can be compensated for by mechanical means, so as to enable the child to walk.

OBITUARY.

DEATH OF DR. VALENTINE MOTT, OF NEW YORK.

At the age of eighty, a great American Surgeon whose name is as well known here as that of almost any of our renowned Surgical worthies, the man who first tied the innominata—Valentine Mott—has gone to the world of shadows. His name will ever be a prominent one in the history of Surgery. The remark of his biographer in the *New York Herald*, "*He never made a mistake in his life*," will excite a smile—a mournful one—among our readers, who know so well that the only men who never mistakes are they who never have anything to do, and that the truth of the old proverb, *humanum est errare*, must be occasionally illustrated in the lives of men who practise a conjectural art. But all will acknowledge that few men in any country have successfully performed so many capital operations. Seven successful ligatures of the subclavian, sixteen amputations of the lower jaw, extirpation of the entire clavicle, forty-six ligatures of the common carotid, seven of the external iliac, and fifty-two of the femoral, with one hundred and sixty-five lithotomies, and nearly a thousand amputations, constitute a Surgical career of almost unequalled magnificence.

This venerable Surgeon, who died on the 26th of last April, was born at Glen Cove, Long Island, on the 20th of August, 1785. The family in America sprang from the parentage of a wealthy English gentleman, who established his residence on Long Island as early as 1667, and was mentioned in the old record of the island as a rentier.

Young Mott received a good classical education at Newtown, Long Island. Before attaining the age of eighteen he commenced the study of Medicine under Dr. Valentine Seaman, a kinsman. He graduated at Columbia College, after which, in November, 1806, he visited London, and entered Guy's Hospital as a pupil to Sir Astley Cooper, who soon kindled in young Mott a desire to emulate his tutor. His genius and inclinations soon attracted the special attention of his master, and between the matured greatness of Sir Astley and the expanding abilities of young Mott there was thus established a reciprocation of admiration which terminated only in death. Mott remained at Guy's about two years. Having there laid the foundation of his subsequent success, he visited Edinburgh, where he attended a course of lectures, after which he returned to London and resumed his attendance at Guy's and St. Thomas's Hospitals. It was his original design to complete his curriculum at Paris, but the interdiction of intercourse between the two countries, despite all necessary passports and private letters in his possession, compelled him to abandon the project, and he returned to America in the autumn of 1809. Upon his arrival he immediately commenced the practice of his Profession in the city of New York. In 1810 he was made Demonstrator of Anatomy to the late distinguished Dr. Wright Post, who was Professor of Anatomy and Surgery in Columbia College, and in the spring of 1811 he was elected Professor of Surgery. When entrusted with this important position he was not quite 26 years old. In 1814 Columbia College (Medical Department) was merged into the College of Physicians and Surgeons, and Dr. Mott was retained in the Surgical chair. In that year he was appointed Surgeon to the New York Hospital—a position which he held for some years. In 1826 he was Professor of Surgery in Rutgers College. Subsequently we find him again Professor in the College of Physicians and Surgeons. During this extended career Dr. Mott performed some of the most remarkable operations known in the history of Surgery. His first great achievement was in 1816, when he successfully performed an amputation at the hip joint. In 1818 he performed the difficult and delicate operation of placing a ligature around the brachiocephalic trunk or arteria innominata, only two inches from the heart, for aneurism of the right subclavian artery. This was the first operation of the kind in history, and the patient lived twenty-six days after. The New York papers say that when Sir Astley Cooper heard of this wonderful achievement of his pupil, he remarked, "I would rather be the author of that one operation than of all I have ever originated."

Besides these operations, and the numerous capital operations to which we have already alluded, in 1827 he tied the common iliac artery. It was the first time this operation was performed in any country, and was perfectly successful. The subject of it, in 1856, was still living, his life then having been extended nearly thirty years. On the 17th of June, 1827, he extirpated the entire clavicle for osteo-sarcoma. This operation originated with him, and has been performed but twice since—once by Warren, of Boston, and once by our own Travers. The subject, a distinguished clergyman of the South, was still living a few years before the Civil War broke out which is now so near its close.

In 1834 Dr. Mott visited Europe for relief from his arduous labours, remaining seven years. In 1841, immediately after his return to this country, he associated himself with Professors Pattison and Revere, then of Philadelphia, and Paine, Draper, and Bedford, in founding the University Medical College of New York. The first winter it opened with 300 students, by far the largest class ever inaugurating any Medical College in any country. To the great name of Dr. Mott, more than to any other influence, was this extraordinary success mainly due. The College was the idol of his heart, and he held its Presidency and Professorship of Surgery till 1849, when he retired from both. The effect of his retirement was so severely felt that in 1851 he resumed his connexion with the College, and filled the honourable post of Emeritus Professor of Surgery. So important was the name of Mott to the vitality of this institution, that, out of the city of New York, it was by the Profession, oftener than otherwise, designated as "Mott's School," in contradistinction to the two other Medical Colleges. Dr. Mott (with Drs. Stevens and Isaac Wood) was one of the projectors of the New York Academy of Medicine, in which he held the position of President. In 1856 he was Senior Consulting Surgeon to the City, to Bellevue, to St. Vincent's, to the Jews', and to the Woman's Hospitals. He had conferred upon him more honorary distinctions than any other Medical man in America. He received the degree of LL.D. from the Regents of the University of the States of New York in 1849. Besides being an Honorary Fellow of the Medical societies of the States of New York, Rhode Island, Massachusetts, New Jersey, Louisiana, etc., he was Foreign Associate of the Imperial Academy of Medicine of Paris, a distinction held at the time by but one man in Great Britain (Marshall Hall), and one in America (Mott). He was also Honorary Fellow of the King and Queen's College of Physicians of Ireland, Fellow of the Royal Medico-Chirurgical Society of London, of the Royal Medical Society of Brussels, and of Athens, of the Chirurgical Society of Paris, and he was Knight of the Fourth Order of the Mejidid of Constantinople, etc., etc. The King and Queen's College of Physicians of Ireland was founded in 1646, and during the last two centuries it has conferred Honorary Fellowships but about twenty times, and one of these was upon Mott. Dr. Mott's "Velpeau's Operative Surgery," his "Travels in the East," and his various Surgical papers contributed to American periodical Medical literature during the last forty years, are enduring monuments of his capacity as a writer; but his greatest merits were in Operative Surgery.

The loss of Dr. Mott to Medical and Surgical science will be severely felt. At the time of his death he unquestionably stood in America at the head of his Profession, and the richest legacy he has left are the hundreds of well-educated pupils throughout the country, alleviating the sufferings of humanity by disease, accident, or the casualties of war.

Up to the day of his death he maintained a close intimacy with Mr. Hammond, the late Director of the Medical Department of the Army, who was so infamously ill-used by the present Secretary-at-War, Stanton, and whose cause was supported in these columns in a manner which, we are proud to hear, was heartily commended by Mott and highly valued by Hammond and the Medical Profession generally in the Northern States. Neither President, Ministers, Senate, nor

Congress, are in these States representatives of the wealth, refinement, or education of the people. Universal suffrage has raised to political power a class of men with whom the *gentlemen* of America will not associate. If a man of education does enter Congress, his former associates look upon him as losing caste, partly by joining a lower order of men, and partly because he can only do this by courting the popularity of the mob. In such a state of things, it is no wonder that an independent man of science and the Profession which he represents must be beaten by any official who uses his power without scruple; nor is it surprising that Hammond and the Medical Department had to yield to the vulgar bully, Stanton. But Mott stood by him and the Department to the last, and the papers contributed by members of the Sanitary Commission, edited by Hammond, form an addition of great value to the literature of Military Surgery. The contributions of Dr. Mott to this volume are on "Pain and Anæsthetics," and on "Hæmorrhage from Wounds, and the Best Means of Arresting it." Both are popular rather than scientific essays, but extremely well adapted for their intended purpose. Of other work done by the United States' Sanitary Commission, and of the manner in which its great purposes were accomplished, it will be our duty and pleasure to write on some less melancholy occasion.

We have only to add a copy of the resolutions which were unanimously agreed to at a meeting of the New York Academy of Medicine called after the death of its late President:—

"Resolved, That this Academy, in assembling to do honour to the memory of Dr. Valentine Mott, who has just passed away in a ripe old age, recognise the fact that since its first organisation no member has been taken from among them who has filled a larger space in public estimation as a Physician and Surgeon than their deceased associate and late honoured President.

"Resolved, That our common country has reason to cherish the memory of Dr. Mott, not only as the greatest Surgeon ever produced in America, but as one who has taken rank with the first of this century in any part of the world; as one whose reputation was, indeed, world-wide, and whose name is known and revered wherever our Profession are found.

"Resolved, That this Academy are deeply sensible of the debt of gratitude our Profession owes to our late associate, from the legacy he has left us, of great improvements in Surgical science and art—improvements by which we are now enabled to save many valuable lives, which, without them, must have been lost, and which, in all future time, will be recognised as among the greatest achievements performed by any of its members.

"Resolved, That as it is not possible in this manner to testify our sense of the high character of Dr. Mott, as a citizen as well as a Surgeon, we will appoint one of our members to pronounce an eulogy on the deceased, and make a more fitting and enduring memorial of his character and virtues, and that at the meeting of the Academy held for the purpose citizens generally be invited to attend.

"Resolved, That we tender to the family of the deceased our warmest sympathies for the bereavement they have suffered, but hope and trust that, conscious as they must be, that although the head of the family has been taken from them, he has filled up the full measure of an useful and well-spent life, they have all the consolation possible in their affliction.

"Resolved, That we will attend his funeral in a body, and that we invite the Surgeons of the army and navy, and the members of our Profession generally in this city and its vicinity, to unite with us in paying this last tribute of respect to the memory of our lamented colleague.

"Resolved, That a copy of these resolutions be communicated to the family of the deceased, and that they be published in the daily papers."

MEDICAL NEWS.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.—DOUBLE QUALIFICATION.—The following gentlemen passed their First Professional Examinations during the recent sittings of the Examiners:—

John Brooke, Unwin, Sussex; Tom Bates, March, Cambridge; William John Naismith, Sultanpore, India; James Robinson, Lancashire; Richard Green, Boston, U.S.; William Cunninghame Stirling Hunter, Dundee; John Alexander, Caithness; Christopher Allcock, Nottingham; William Henry Clarke, Birmingham; Wolfred Nelson Cote, Plattsburgh, N.Y.; Edwin Shelton Jones, Carnarvonshire; James Affleck, Ayr; John Affleck, Dumfriesshire; Alexander Hamilton, Dundee; W. K. Farrelle, Longford; H. S. Cribbes, Killin; John M'Rae, Ross-shire; G. R. Gilruth, Edinburgh; W. E. Wyllys, Somersetshire; John G. Braytun, Cumberland; Donald Campbell, Perthshire; Robert Pattie, Dumfriesshire; W. E. Stainton Stanley, Cumberland; Henry M'Laurence, County Londonderry; James W. Cox, Annan; Thomas F. Martin, County Louth; Thomas James Kane, Galway; Emerson J. Reynolds, Dublin; George M. Sinclair, Haddington; Richard W. Waring, Cavendish; James L. H. H. Porteous, Haddingtonshire.

And the following gentlemen passed their Final Examinations, and were admitted L.R.C.P., Edinburgh, and L.R.C.S., Edinburgh:—

Joseph Leman, Buckingham, Canada; Frank Godfrey, Salisbury; Thorburn Paterson, Mid-Lothian; James Hickinbotham, Birmingham; James Simpson, Cumberland; William Scobie Mackenzie, Sutherlandshire; John Fothergill, Westmoreland; John Burton, Walsall; Charles O'Hara, County Fermanagh; William Smyth, County Tyrone; Henry Robert Smith, Berwick-on-Tweed; John Johnstone, Liverpool; Henry Patchett, Lancashire; William George Washington Thompson, Ballymoney; John Raby, Cornwall; George Bell Murray, Annan; John Thompson Richardson Wotherspoon, Dumfriesshire; David Abercromby Burt, Fifeshire; Robert Shiels, Edinburgh; James Benson, County Roscommon; James Lindsay Mason, Montreal.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary Examinations for the Diploma, were admitted Members of the College, at a meeting of the Court of Examiners on the 11th inst.:—

Benjamin Lamb Powne, L.S.A., Billingboro', Lincolnshire; Wm. Lively Shepard, Gray's-inn-road; and Robert David Broughton, Ruyton, near Shrewsbury, students of St. Bartholomew's Hospital. Thos. Gray Pratt, March, Cambridgeshire; Thomas Hamilton Spilsbury, Sierra Leone; and Henry Edward Harrison, Great Ormond-street, of King's College. Thos. Joseph Faweitt, and Anthony Bell, Newcastle-on-Tyne, of the Newcastle School; Richard Bugden, Tenterden, Kent, of the Westminster Hospital; David Shoolbraid, Duff Town, Banffshire, of the Aberdeen School; John Cremonini, Bilston, Staffordshire, of the Birmingham School; Edward Butler Rutledge, Ingatestone, Essex, of the London Hospital; and Oliver Dillon Thomas, Pontypool, of the Middlesex Hospital.

It appears that six candidates out of the sixty-two who offered themselves for examination were referred back to their studies for six months.

The following gentlemen passed their Primary Examinations in Anatomy and Physiology on the 16th inst., and when eligible will be admitted to the Pass Examinations:—

Michael Perry, William Square, Julius Lawrence Levy, and William Overston, Students of St. Bartholomew's Hospital; Nicholas Hall and Arthur Tudor Humphreys Trevor, of King's College; Frederick Sydney Coombe and Frederick Adams Dawson, of St. George's Hospital; Thomas Charles Croose Wheateraft and Joseph Randle Buck, of Birmingham; Sydney Griesbach and Lionel Hirst, of Leeds; Matthew Wilson Kennedy and Joseph Stanislaus Meagher, of Dublin; Henry Leigh Mallory and John Heyes Anderton, of Manchester; George Yeats, of Aberdeen; Richard Harris, of Guy's Hospital; and William Jones Williams, of Edinburgh.

It is stated that no less than seventeen candidates out of the thirty-seven who presented themselves for examination were referred back to their studies for three months, having failed to acquit themselves to the satisfaction of the Court, and that another candidate was referred for six months, having been detected copying from a book. At a meeting of the Council on the 15th inst., Mr. Thomas Seccombe, of the Royal Navy, was admitted a Fellow of the College by election, his Diploma of Membership bearing date May 12, 1843. On this occasion Messrs. Adams, Annandale, and Agnis attended, and received from the hands of the President the respective Jacksonian Prizes and Special Honorarium recently awarded to them for the excellence of their essays.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentlemen passed their Final Examinations and were admitted Licentiates of the College during the recent sittings of the Examiners:—

Henry Sydney, Kent; David James Brakenridge, Perthshire; James Taylor, County Antrim; John George Thornley, Londonderry; Thomas John Denton, Yorkshire; John Burns Gibson, Ayrshire; Robert Jameson, Ayrshire; Bernard Doyle, County Down; Alexander Angus Halley Knight, Berwickshire; John Chiene, Edinburgh; Roderick M'Laren, Dumfries; Robert Main Mackelvie, Wigtownshire; James Keith Anderson, Arbroath; Andrew James Duncan, Bengal; Douglas Glendinning, Dumfriesshire; Frederick William Adolphus Skae, Edinburgh.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, May 11, 1865:—

Henry Whiting, Southend, Essex; George Fortescue Webb, Dawlish, Devon; William Nuttall, Bury, Lancashire; Morden Wright, St. Bartholomew's Hospital; Jarvas Wright, Knutsford, Cheshire; Herbert Wood, Ashton-under-Lyne; Edward Ingram Bostock, Horsham, Surrey; John Tasker Evans, Fore-street, Hertford; Josiah Allen, Ripley, near Derby; David Howell Thomas, Swansea; Ernest Last Fyson, Exning, near Newmarket; John Thomas Langley, Ganarew, Monmouth; Charles Edward Covey, Basingstoke; James Burdwood Watson, Havant.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ANDREWS, CHARLES, M.D., has been elected Medical Officer for the Fulham Union Workhouse.

BROWN, COLVILLE, M.D. Edin., has been elected Medical Officer for the Berwick-upon-Tweed Union Workhouse.

CHURCH, W. S., M.R.C.P. Lond., has been elected Physician to the Royal General Dispensary, Bartholomew-close.

COGAN, CECIL C., M.D. St. And., has been elected one of the House-Surgeons to the Royal Kent Dispensary, Greenwich.

CREED, THOMAS, M.D. St. And., has been elected one of the Surgeons for the District of Greenwich, Royal Kent Dispensary.

EDWARDS, HENRY, M.R.C.S. Eng., has been appointed Medical Officer for the Llandaff District of the Cardiff Union, and for the Workhouse and Industrial Schools.

EVE, RICHARD W., M.D. Aberd., has been elected one of the Surgeons for the District of Deptford, Royal Kent Dispensary.

FREEMAN, R. T., M.R.C.S. Eng., has been elected one of the Surgeons for the District of Deptford, Royal Kent Dispensary.

EE, SAMUEL J., M.B. Lond., has been appointed Assistant-Physician to the Hospital for Sick Children, Great Ormond-street.

ACQUES, J. T., M.R.C.S. Eng., has been appointed House-Surgeon and Apothecary to the Leicester Infirmary and Fever House.

MILLER, JOHN N., M.B. Lond., has been elected one of the House-Surgeons to the Royal Kent Dispensary.

MOON, FREDERICK, M.B. Lond., has been elected one of the Surgeons for the District of Greenwich, Royal Kent Dispensary.

MOORE, WILLIAM W., M.D. Edin., has been elected Assistant-Physician to the Sussex County Hospital, Brighton.

ALMER, HENRY R., M.R.C.S. Eng., has been elected one of the Surgeons for the District of Greenwich, Royal Kent Dispensary.

ROBERTS, R., M.R.C.S. Eng., has been elected one of the Surgeons for the District of Deptford, Royal Kent Dispensary.

ROGERS, C. E. H., M.R.C.S. Eng., has been appointed House-Surgeon to the Retford Dispensary, Notts.

COTT, WILLIAM, M.D. St. And., has been elected one of the Surgeons for the District of Greenwich, Royal Kent Dispensary.

AYLER, CALEB, M.D. St. And., has been elected one of the Surgeons for the District of Deptford, Royal Kent Dispensary.

AYLOR, Dr. JAMES, has been appointed Assistant Medical Officer to Barnhill Poorhouse.

WALSH, RICHARD, L.R.C.P. Edin., has been elected Medical Officer to the Clogheen Union Workhouse, Co. Tipperary.

DEATHS.

BRYCE, THOMAS, L.F.P.S. Glasg., at St. Andrew-square, Glasgow, on May 7.

CONSIDINE, Dr. WILLIAM, at Mobile, Alabama, on February 8, formerly of Rathmines, Dublin.

ALLOGLY, THOMAS, F.R.C.S.I., at Clogheen, Co. Tipperary, on April 2, aged 73.

KIRKWOOD, ALEXANDER, M.D. Edin., of Berwick-on-Tweed, on April 2.

LYONS, F., M.D., at South-terrace, Cork, on May 6.

ROBINSON, D., Surgeon, at Milu's-bridge, near Huddersfield, on March 29, aged 74, formerly of Longwood.

SADLER, THOMAS, L.S.A., at Bath-parade, Cheltenham, on March 20, aged 55.

ECCOMBE, WILLIAM, M.R.C.S. Eng., Staff-Surgeon, at Hobart Town, in February.

LOAN, CHARLES F., M.D. Edin., at Sandgate-street, Ayr, N.B., on May 1.

UTLEFFE, ROBERT B., Surgeon-Major H.M. M.N.I., at 27, Chepstow-place, Bayswater, on May 10, aged 53.

WILKINS, WILLIAM W., Surgeon, at Icknield-street West, Birmingham, on April 1, formerly of Madras.

WILMOT, J. H., M.D., Staff-Surgeon, at Ahmedabad, Bombay, on April 7.

ST. BARTHOLOMEW'S MEDICAL COLLEGE, 1864-5.—The following scholarships and foundation prizes have been awarded as follows:—*Senior Scholarship in Medicine, Surgery, and Materia Medica*—1. W. L. Shepard; 2. T. Cuddeford; 3. J. O. Adams. *Senior Scholarship in Anatomy, Physiology, and Chemistry*—1. W. J. Garrett; 2. W. Square; 3. F. H. Haynes. *Wix Prize*—H. Rundle. *Hichens Prize*—E. W. Berridge. *Practical Anatomy, Sen.*—Foster Prize: H. C. Upton; F. H. Haynes and R. B. Moore (equal); J. A. J. Timmins and J. Quick (equal); W. B. Burn, F. H. Lovell, and W. Square (equal); 9. W. H. Tattersall. *Practical Anatomy, Jun.*—Treasurer's Prize: L. Newton; 2nd prize. C. Wade; 3. J. Kirkman; E. B. Crowfoot and W. Thurston (equal); 6. E. Angove; 7. H. J. Butlin; 8. L. Clapham.

MESSRS. THOS. HAWKINS AND J. J. MOREWOOD have addressed the ratepayers of London, stating that twenty years ago they offered to drain the metropolis "on a plan which the Board of Works is carrying out;" that they proposed to do it for an annual charge of £30,000 for twenty-five years, whereas the present cost is £200,000 a-year, which will have to be paid for forty years or more; and that Government "again and again approved their plan," but, after "an incessant intrigue," the Board of Works "usurped their plan and their place." They also protest against the proposal to give the engineers of the drainage works a gratuity of £10,000, and "have petitioned Parliament for an inquiry into their own rights and the ratepayers' wrongs."

PATHOLOGICAL AND OBSTETRICAL SOCIETIES OF DUBLIN.—Dr. Churchill, who happens this year to be President of both the above Societies, received the members and other guests at a *conversazione* at his house in St. Stephen's-green, on the evening of Thursday, the 11th instant. Among those present on the occasion were some of the many visitors from Great Britain and the Continent, who were attracted to Dublin by the opening of the International Exhibition. The President successfully followed the example of one of his predecessors in dispensing with those microscopic and other objects of interest usually exhibited on such occasions, for which, indeed, in so crowded an assembly, there would scarcely have been room, while conversation was the more animated and not the less interesting from being left to take its own course. After an adjournment to the refreshment-room the guests separated, having had a most agreeable opportunity for Professional and social intercourse.

COLLEGIATE ELECTIONS.—The Fellows and Members of the College will no doubt be surprised to hear that Mr. James Moncrieff Arnott, F.R.S., twice President of the College of Surgeons, a member of the Council and Court of Examiners, and representative of the College at the General Council of Medical Education and Registration, and the most indefatigable and painstaking worker in the College, with which he has been so long and so honourably connected, is about to resign not only all these lucrative appointments, but also all others he holds in this metropolis, and to retire into the country. A large accession of property and the state of health of an attached daughter is the reason assigned for this step. As an examiner he will no doubt be succeeded by Professor Hilton, F.R.S., an appointment which will give general satisfaction. For his seat in the Council there will of course be a contest; already the names of Messrs. Turner and Ransom, of Manchester, and McWhinnie, of London, are mentioned. Mr. Ransom, it is expected, will retire in favour of the superior claims of his distinguished townsman. The retiring members of the Council are, as far as at present known, Messrs. Quain, of University College, and Shaw, of the Middlesex Hospital, who, it is stated, will offer themselves for re-election. The resignation of Mr. Arnott saves Mr. Wormald, who would otherwise have had to offer himself for re-election. He will therefore deservedly succeed to the President's chair, and his friends will wish him a continuance of robust health to enjoy the dignity he has so well earned by his independence and sterling honesty of principles. At the Westminster Life Office, it is stated, Mr. Campbell De Morgan will succeed Mr. Arnott, unless a Physician should be considered more desirable. The members will be glad to hear that it is proposed to invite them to another *soirée* at the College before the annual election in July next.

ROYAL MEDICAL BENEVOLENT COLLEGE.—The thirteenth annual festival in connexion with this College was held on Saturday last at the Freemasons' Tavern, the Right Hon. Earl Granville, K.G., in the chair. There are at the present time resident in the College, at Epsom, twenty-four pensioners, aged Medical men or their widows, each of whom is provided with three comfortably furnished rooms, an annual allowance of three and a-half tons of coals, and a pension of £21 a year. There are also resident in the College 200 boys, the sons of Medical men. The foundation scholars, numbering forty, are educated and maintained gratuitously, while the remainder are charged £40 a year each for an education of the highest class, board, washing, use of books, etc. There are also some day scholars, not necessarily the sons of Medical men. The accounts for the past year exhibit a balance of only £310, the total receipts having been £11,892 18s. 10d. After the usual loyal toasts had been honoured, Dr. Babington proposed "the Army, Navy, and Volunteers." Admiral Burney responded for the Navy, and Mr. J. L. Propert for the Army and Volunteers. The toast of "the Church," proposed by Mr. Scourfield, M.P., was acknowledged by the Rev. G. Pocock. In proposing the toast of the evening, the noble chairman dwelt upon the merits which the institution possessed, and the claims which it had upon all who desired to see suffering and affliction alleviated. The institution had been founded by those whose work was exceedingly laborious, and its success might be attributed to the earnestness and zeal which the friends of

this excellent charity had displayed. There was, probably, no Profession in which accident and chance exercised so large an influence as that of Medicine; for, while some of its members soon attained distinction and wealth, others, through no fault of their own, would remain in obscurity, still working for the good of their fellow-creatures. No Profession, therefore, had more claims for sympathy upon every class of the community. The noble lord concluded by appealing to the company for that support which the institution so eminently deserves. In acknowledging the toast of "the Chairman," proposed by Sir Charles Locock, Earl Granville expressed the satisfaction which he experienced at occupying the position of president of an institution which was calculated to confer so many benefits upon the distressed and suffering. Several other toasts followed. The subscriptions amounted in the course of the evening to nearly £1000.

British Museum.—The annual accounts of the British Museum have been issued. The expenditure for the past year has been £97,533, and the estimate for the current year is £100,164. Year by year additions are made in all the departments, and 1864 has been no exception from the rule. An extensive collection was obtained of the remains of human industry of a very early period, discovered in a cave on the banks of the Aveyron, in France. The Bishop of Newfoundland has presented to the zoological department a mummy specimen of the great auk, which was found in a deposit of frozen guano in Newfoundland, pressed flat, with the flesh converted into adipocere. With the exception of the extremities of the toes this example is perfect in every respect, even to the pen feathers on the wing; the beak is as perfect as on the day when the bird died. It is especially of interest on account of the belief that the bird has lately become extinct. Professor Owen has to acknowledge nearly 13,000 additions to the department of natural history. The Rev. H. B. Tristram has presented a large number of specimens of animals collected in Syria and Judæa, among which may be identified the "hare," the "coney," the "chamois," and other animals of Scripture. Among the additions to the department of geology, the most interesting, in relation to questions as to the antiquity of man and the cranial and dental characters of primitive races, are the partly petrified remains of the men who inhabited the limestone caverns of the south of France at the period when chamois, boquetin, wild horse, reindeer, the great extinct ox, etc., existed, and especially the reindeer, abounded in that part of Europe, and when, the use of metals being unknown, the primitive implements were chipped flints, by means of which diverse weapons and instruments, including needles, were manufactured from the bones and antlers of the beasts captured and killed for food. On some of those bone instruments the reindeer and horse had been delineated in outline with much truth and spirit, and these are probably among the earliest examples of the graphic art. While these evidences expand our knowledge of the relations of the human species with quadrupeds locally or absolutely extinct, others have been received indicative of the continuance of species now extinct to a more recent period than we had previously evidence of. Among such specimens are the valuable donations by the Hon. W. O. Stanley. The jaws and teeth of the northern elephant (*elephas primigenius*) were discovered with remains of red deer, stumps of large trees, hazelnuts, and alderberries, in a bed of compact peat, about three feet thick, covered by a deposit of blue clay of varying thickness, overlaid by a sandy deposit with shells of existing and neighbouring marine species, all cut through in excavating the harbour at Holyhead. But, among the evidences of a past animal existence, perhaps the oldest, geologically, are of highest interest. The Museum has been enriched, by a donation from the directors of the Geological Survey of Canada, with fossils of crustaceous and testaceous rank from the Cambrian or Lower Silurian shales, and more especially with a beautifully etched section of the still Lower Laurentian marble, exhibiting evidences of the protozoal foraminiferous organism called "Eozoon Canadense," which, at the present phase of geological science, is the most ancient fossil organism known. These are, indeed, valuable donations; but the one great gift for which Professor Owen cries out is the gift of space for the proper exhibition of the treasures that are thus accumulating in Bloomsbury. At present all that can be done with valuable acquisitions that flow in is to stow them where they may be safely kept, in hope of a time when they may be exhibited under proper conditions of light and access, or else to displace other articles to make room for the new arrivals to be seen.

Testimonial to Sir John Liddell, K.C.B., late Director-General of the Naval Medical Department.—On Tuesday a deputation of the following Medical officers waited upon Sir John Liddell, at his residence in Chester-square, and presented, on the part of a large proportion of their brother officers, a handsome service of plate:—Dr. Bryson, Medical Director-General; Inspectors-General of Hospitals and Fleets Wilson, Nisbet, Hilditch, Sir James Prior, Salmon, Kinnear, Smart; Walter Dickson, Medical Inspector H.M. Customs; Staff-Surgeons Baynes, Bernard, Grigor, Donnet, and Domville, hon. secretary. The testimonial (consisting of a handsome candelabrum and four richly chased fruit stands) was consequent upon his retirement from office, a fact which was no sooner known than a simultaneous desire was manifested on the part of naval Medical officers to convey to Sir John Liddell some signal mark of sympathy and regard, and of the high estimation in which he was held by those over whom he long and honourably presided. "Actuated by these feelings, local meetings spontaneously assembled at the several ports, and on the 4th of March, in union therewith, a general meeting was held in London, under the presidency of Dr. Wilson, Inspector-General, which was numerously attended by every class of the naval Medical service. It was there resolved to give effect to the desire so generally shown of recording their admiration of the great Professional and administrative qualities evinced by the late Director-General throughout a long and distinguished career, and their grateful sense of his strenuous and successful efforts to elevate the status of naval Medical officers, and to maintain the honour and efficiency of the department." The candelabrum (manufactured by Hancock, of Bond-street,) is in the form of an oak tree, with six spreading branches, the extremity of each so formed as to hold a light, and the centre supports a richly cut dish. The base is triangular, artistically representing rocks covered with moss. On each side is left a space for inscriptions, arms, orders, etc.; and surrounding the tree are three draped female dancers, holding wreaths, garlands, etc. The whole rests upon a plateau, the border of which corresponds with the base of the centrepiece. The inscription is as follows:—"To Sir John Liddell, Knight Bachelor of the United Kingdom, Knight Commander of the Most Honourable Order of the Bath, Knight of St. Anne of Russia, Knight of the Redeemer of Greece, late Director-General of the Medical Department of the Navy, and an honorary Physician to the Queen. In token of esteem from Medical Officers of Her Majesty's fleet, 1865." The four fruit stands are of the tazza shape, with richly chased border. The act of presentation was confided to Dr. Wilson, as an old and esteemed officer, and in doing so he gave expression to a terse address:—"Sir John Liddell,—We are here to present you this testimonial to the value of your services (as a Medical officer, especially as chief Medical Officer of the Navy), on your relinquishing the toil and trammels of office, and retiring to the calmer engagements and amenities of private life. We are rather a small party, but we represent a large body of our brother officers, who have co-operated with us cordially and successfully in bringing about this good work—and a good work it assuredly is, in every sense, since the material is good, the workmanship exquisite, *opus superabat materiam*, and the object excellent—namely, that of showing the estimation in which you are held by the Medical Officers of the Navy. It is not well to praise a man to his face, and I am not here to praise you; but I affirm that your conduct throughout, whether toiling in the ranks as an ordinary member of the corps, or conducting its concerns as Director-General, has been such—being discriminative, faithful, and fearless—as to deserve, nay demand, some such demonstrative recognition as this. And now let me express the hope, the hope of us all, that you may have health and long life to contemplate, with the satisfaction which it must excite, this beautiful product of artistic skill, considering it, as it is, a permanent proof of regard, an abiding and eloquent certificate of merit." The late Medical Director-General replied:—"Dr. Wilson and Gentlemen,—I accept with pleasure the splendid testimonial that you have generously conferred upon me, which is very gratifying, as it will be an enduring testimony not only of your approbation of my conduct while at the head of the Medical Department of the Navy, but as a proof of the goodwill and kindly feeling of the corps, whose interest and honour I have striven to uphold. I assure you that I appreciate cordially the value of this beautiful specimen of art, which is creditable to your taste, not so much for its intrinsic worth,

which is great, but far more for your good feeling of regard on my retirement from the public service. It is true that my shortcomings, of which I am very sensible, have been great, and that I have not succeeded in attaining all the good I tried to accomplish; but I trust that the corps will feel that I used every honest endeavour to render the best services to all that circumstances enabled me to make."—*Army and Navy Gazette.*

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Will "A Naval Medical Officer" send us his name and address in confidence?

Dr. Collis's excellent work on Tumours shall be reviewed next week.

Zeta.—We cannot recommend any particular Practitioner. Consult any respectable Medical man in your own neighbourhood. Your case is thoroughly understood.

New Articles of Diet for the Sick.—We have received samples of *Extractum Carnis, Liebig*, from Van Abbott's Dietetic Depôt, No. 5, Princes-street, Cavendish-square.—Also, a packet of *Cerealina*, a new material for puddings, gruels, etc, from Richmond Keith, Ingram-court, Fenchurch-street.—Also, a sample of *Oxygen Water* from the Oxygenated Water Company, Limited, 39, Long Acre.—All these shall be noticed immediately.

Lisbon Wine.—In reply to a correspondent who asks about this wine, the author of the *Report on Cheap Wine* says:—

"It is virtually extinct as an article of commerce under its own name, because, such is the hypocrisy of the age, no one would venture to offer a friend a glass of Lisbon unless he called it sherry. Lisbon wine, as I recollect it, was a sweetish, pleasant wine, of no high character; but it is years since I tasted it." The other day, being at my own wine merchant's, I was told that they lately had rummaged out an old stock of obsolete wines, as Lisbon, Calcavella, etc., and I eagerly asked for some. "Oh, no," was the reply, "they were not saleable, so they were medicated, and made into sherry."

A new set of Classes for the instruction of Medical students in the subjects of the Preliminary Classical and Mathematical Examinations, and the Matriculation Examinations of the University of London, is opened at the St. John's College, St. John's-wood, London, N.W., of which the Rev. Dr. Alston is Principal.

Chemists and Druggists Bill.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—This Bill is, as you observe, likely to injuriously affect the practice of most Medical men. Being suggested by the General Medical Council, and eagerly supported by the trade, there is every prospect of its becoming law. The Parliamentary Committee of the British Medical Association have endeavoured to mitigate its effect on the Profession by suggesting the insertion of the following clauses:—

"To Clause 17, which saves the rights of Medical Practitioners, it is proposed to add—'And it shall not be lawful for any person registered under this Act to prescribe for any patient, or undertake the treatment of disease, or in any way assume to act as a Medical Practitioner, and every chemist and druggist so offending shall, upon a summary conviction, forfeit or pay a sum not exceeding £10.'

"As Clause 19 insert the following:—'No patent, quack, or other medicine shall be sold, unless a sworn certificate of its composition be lodged with the Registrar appointed under this Act, and a copy thereof be open for inspection in the shop or place in which such medicine is sold, and any person or proprietor of a shop, selling any secret remedy, shall, on summary conviction for each such offence, be liable to a penalty not exceeding £20.'"

A petition in support of these clauses was presented by Sir Fitzroy Kelly, M.P., to the House of Commons on Monday, the 15th inst., a copy of which I send you. I am, &c.

13, Finsbury-square, E.C., May 16. Septimus Gibbon, M.B.

"Chemists and Druggists Bill.

"To the Honourable Commons of the United Kingdom of Great Britain and Ireland, in Parliament assembled.

"The humble petition of the Metropolitan Counties Branch of the British Medical Association

"Sheweth,—That two Bills, entitled 'Bills to Regulate the Qualifications of Chemists and Druggists,' are now depending in your honourable House.

"That chemists and druggists are neither qualified by law nor competent by education to practise Medicine.

"That injury to health, and not unfrequently loss of life, result from chemists and druggists undertaking the duties of Medical Practitioners.

"That the sale of patent, quack, and other secret medicines has an injurious influence on the health of the community, more especially on the infantile portion of it.

"That the traffic in secret remedies, which is repudiated by the qualified Practitioner, enables the unqualified pretender and the uneducated quack to victimise Her Majesty's subjects to an incredible extent, as well in person as in purse.

"Your petitioners therefore humbly pray that in the said Bill adequate provision may be made:—

"1st. For preventing the registered chemists and druggists from practising Medicine and Surgery.

"For preventing the sale of any patent, quack, or other medicine, unless a sworn certificate of its composition be lodged with the registrar appointed under the Bill, or be otherwise made accessible to the public.

"And your petitioners will ever pray, etc.

"Signed on behalf of the Branch Association,

"Charles F. J. Lord, President.
A. P. Stewart, M.D.,
Alexander Henry, M.D.,
Septimus Gibbon, A.B. and M.B.,
} Hon. Secretaries."

Lecture V.

DISEASES OF SUBOXIDATION.—ON GOUT.

(Continued from page 434.)

On the Treatment of Gout.

In the present state of our knowledge the treatment of gout may be divided into two parts: first, the specific; and second, the expectant treatment. Each method has its own advantages and disadvantages, and by the right use of both proceedings the greatest good with the least harm may be attained.

The specific treatment aims to get rid of the attack as soon as possible; that is, to put an end to the pain at once; to stop the fibrinous and crystalline thickening of the joints, and to allow the patient to return to his usual mode of life in the shortest possible time.

The disadvantages of this treatment are, first, that the specific sometimes acts more violently than is intended; and secondly, that cutting short an attack leads more quickly to a return of the disease, because the usual mode of life is that which has caused, and therefore will again cause, the gout; and thirdly, that the urate of soda existing in excess in the serum and diffusing into all the textures, where it is oxidised, if stopped in its active oxidation in any part, is more liable to set up a process of active oxidation in the fibrous textures of some internal organ, as the stomach, the brain, or the heart.

The expectant treatment aims to keep the gout fixed in the extremities until the textures and blood are freed as much as possible from the urates by oxidation, and to effect a long-continued change for the better in the usual mode of life, at least during the illness; and from both these causes a long interval is likely to intervene between the fits of gout.

The disadvantages of this treatment are, first, that the patient may get very feeble from the long-continued inflammation and confinement, and that out of this other ailments may thus arise; secondly, that the joints, in consequence of the duration of the inflammation, may become much more thickened by fibrin and urates than they otherwise might be, and that thus also the general health may give way from the loss of exercise.

The value of the specific treatment is seen when some more important organ than a joint is attacked by violent gouty or rheumatic inflammation. Then, to avoid irreparable injury to the organ, the specific inflammation must be stopped as quickly as possible. Acute inflammation of the eye furnishes by far the most striking example of the use of colchicum. By the specific treatment the eye may be saved; by the expectant treatment it will be lost; and the activity of the specific treatment must bear a direct proportion to the intensity of the inflammation. In a slight attack the expectant treatment alone may be required, but in a violent outburst the most energetic specific treatment, even with the help of local or general bleeding, will scarcely be able to preserve the sight of the inflamed eye.

The specific treatment consists in giving colchicum, veratria, sabadilla, and different quack medicines the composition of which is unknown, but which probably contain one or other of these remedies.

By far the most popular specific is colchicum; and if the action of this substance was fully known the action of all the other gout specifics would be understood.

There is no question that the alkaloid colchicine is the active substance in colchicum; and, though this substance is not yet isolated and analysed, there are good grounds for belief that it closely resembles veratrine, perhaps as closely as quinine does cinchonine.

Colchicine $= CxHyN_2Oz.$
Veratrine $= C_{64}H_{52}N_2O_{16}.$
Strychnine $= C_{42}H_{22}N_2O_4.$
Quinine $= C_{40}H_{24}N_2O_4.$
Cinchonine $= C_{40}H_{24}N_2O_2.$
Morphine $= C_{31}H_{19}NO_6.$

It is very evident that the analyses of these different alkaloids gives no clue whatever to their Medical properties; and so the analysis of colchicine will give no explanation of the mode of its action. But, however much these alkaloids differ in their action, they all have this in common, that they act energetically on the nervous system.

The problem to be solved is, how does colchicum stop the excessive oxidation set up in the parts where the urates are most liable to accumulate, partly, perhaps, in consequence of the non-vascular nature of the textures?

That colchicine acts as a diuretic, and throws the uric acid out of the blood, is not capable of proof, and if it were would not give any explanation of its action on the joint. That colchicine promotes the oxidation of the uric acid by directly furnishing oxygen, as peroxide of lead might do, is contrary to all chemical probability. There remains the unproved assumption that colchicine, like these other alkaloids, acts on Dr. Liebreich's protagon that the alkaloid has a chemical action, by actual contact with the nerve substance of the blood vessels, where the gouty inflammation is going on, causing such an action on the vessels that the inflammation ceases.

This assumption makes the action of colchicine comparable with the action of veratrine, strychnine, and morphine, all of which act with intensity on the nervous substance; and this assumption leads to a conjecture as to the action of quinine, that it also may act on the nerves of the blood-vessels, stopping the internal congestion, on which the external rigor of ague depends. The deafening and prostrating effects of large doses of quinine can arise only from an action on the auditory and cardiac nerves, and the arrest or prevention of an ague fit can best be comprehended by the assumption that quinine acts on the nerves of the capillaries, stopping congestion; whilst colchicine acts on the same system of nerves, stopping inflammation.

M. Roudanowski has stated to the Académie des Sciences that, after poisoning animals by strychnine, nicotine, opium, and chloroform, he has detected by the microscope changes in the nerve cells or in the myeline; but his observations cannot yet be received as conclusive.

In M. Laville's specific, veratrine is probably the active alkaloid; most probably a small amount of morphine is also dissolved in the wine with which it is prepared. It is said to be made from sabadilla seed, but whatever the source or nature of the alkaloid, it must have an action corresponding to colchicine, and the good and the harm from this specific cannot be much more nor less than the good and the harm of colchicum. It cuts short the attack, and thus saves the injury to the joints from the continuance or severity of the inflammation; but it does this by stopping the oxidation of the urates in the textures, and hence a relapse or renewal of the inflammation more quickly and easily takes place.

Moreover, like all other specifics, it gradually loses its effect when it has been used in many attacks, and one at the least of those who have been its most public supporters have abandoned it for some fresh, though far less potent, remedy.

Used in half-drachm doses every four hours, or one drachm doses twice or thrice daily, it acts often most decidedly. If anything, it causes less action on the stomach, and more action on the bowels than colchicum, and from the disposition to drowsiness which it frequently occasions, probably the irritative action is moderated by some opiate.

There can be little question that colchicine used by subcutaneous injection into the neighbourhood of the inflamed part would put an end to the attack; but the danger of an overdose would, perhaps, be greater than when taken in by the stomach, and the benefit derived from its use would not compensate for the fear of its abuse. It would probably act more quickly and more strongly than when taken into the stomach, but this rapid relief would be gained at much greater risk to life from the alkaloid acting on the nerves of the heart and causing dangerous syncope. Moreover, relief from pain and time for the full action of the colchicine when taken by the mouth may be obtained by the subcutaneous injection of one-fourth or one-third of a grain of acetate of morphine in ten or twelve minims of water into the neighbourhood of the inflamed joint.

Late one evening I was sent for to a gentleman suffering with a most violent attack of gout in the knee; the heat and the pain were excessive. There was some swelling and some redness. The attack had begun in the previous night, and had increased in intensity all day. I injected the third of a grain of morphine into the inside of the thigh near the knee, and gave a drachm of Laville, ordering another drachm to be taken when he awoke. He slept for upwards of six hours without waking, and he seemed very certain that but for the injection

the night would have been passed in even more agony than the day. After four drachms of Laville the attack subsided, and the following night no morphine was required.

In sciatica the use of the subcutaneous injection is most beneficial; sometimes almost whilst giving the morphia the pain subsides, and in eight or ten minutes drowsiness comes on, and sound and continuous sleep follows; but the alkaloid acts more strongly than when taken into the stomach, and an overdose may easily be given, and the poison is beyond the reach of an antidote.

The expectant treatment consists in preventing the accumulation of the urates in the serum and textures, and in promoting its elimination and oxidation.

The accumulation of urates is greatly to be prevented by a strict diet, chiefly as regards the quantity of animal and vegetable albuminous food that is eaten.

The elimination of urates is best effected by washing the serum and textures—that is, by increasing the flow of urine by means of water or diuretics. When the serum is comparatively free from urates, then the urates in the textures diffuse back into the blood and may be thrown out.

The oxidation of the uric acid in the textures and blood can be effected directly or indirectly by air, diet, and medicine.

So that the expectant treatment consists of diet, to prevent accumulation of urates, and to promote its oxidation; diuretics to promote its elimination; and air and medicine to promote its oxidation.

During and after an attack of gout, when thickening of the joints exists, medicines that promote the absorption of the effused fibrin and serum are very useful. Of these iodine externally and iodide of potassium with alkalies internally are the most efficacious. Iodine, perhaps, acts indirectly as an oxidiser.

But first of the diet:—

Let us suppose that the minimum diet of health may be represented by 10·5 grammes (162 grains) of soluble nitrogen, and 240 grammes (3696 grains = 8 ounces nearly) of soluble carbon—

If 1 ounce of meat when dry contains 108 grains of nitrogen and 33 grains of carbon; or,

If 1 egg contains 118 grains of nitrogen and 62 grains of carbon,

And 1 ounce of butter contains 355 grains of carbon,

And 5 ounces of dry bread contain 232 grains of nitrogen and 464 grains of carbon,

And 21 ounces of arrowroot contain 3633 grains of carbon,

Then it is easy to see that 2 ounces of dry meat, or 2 eggs, or 5 ounces of bread will give more nitrogen than the system requires to repair ordinary losses, and the excess may have to be thrown out, partly in the form of urates, when the oxidation is insufficient to produce urea.

If 2 ounces of dry meat or 2 eggs only are taken, about 10 ounces of butter would be necessary to furnish the fuel and power for the system, or an equivalent quantity of fat must be absorbed from the stores deposited in the cellular tissue. Or, if 5 ounces of dry bread only were eaten, then above 9 ounces of fat must be taken up in twenty-four hours; but 2 ounces of dry meat, or 2 eggs, or 5 ounces of bread, requiring the wasting of the body by 9 or 10 ounces of fat daily, could not long be endured. Moreover, these quantities of nitrogenous food produce more uric acid than a less nitrogenous diet would do.

If a little more than 21 ounces of dry arrowroot were taken daily, this would supply more carbon than is lost in the daily oxidation. The excess of carbon must either be deposited as fat, or must take away the oxygen, so as to leave none free to act on the nitrogenous substance that is passing out from the albuminous textures. Hence, with carbonaceous diet in excess, the whole of the uric acid from the tissues might pass off through the blood unoxidised.

It follows, then, that in gout a minimum of albuminous food should be taken in order to produce the least uric acid; and a minimum of carbonaceous food in order to allow the uric acid to be oxidised as much as possible.

If a pint of ordinary beef-tea, free from fat, contains 46 grains of nitrogen and 160 grains of carbon, and if an ounce of dry arrowroot contains 363 grains of carbon, then $3\frac{1}{2}$ pints of beef tea and 9 ounces of arrowroot will contain the full amount of elements that are required even in health for the system, and far less than this would be desirable when the minimum production of urates is required.

Secondly, as to air.

In oxygen the energy exists without which all our heat and all our power, and, indirectly, if not directly, all our growth would stop. The nitrogen of the air probably only dilutes the oxygen to the strength we can bear. Some experiments of M. Regnault's show that in less dilute oxygen more of this gas is not inhaled than in our atmosphere. M. Pettenkoffer will probably give us more accurate knowledge of this subject, and enable us to see the amount of intermediate oxidations going on within the body by comparing under natural conditions the total amount of oxygen that goes in with the amount that comes out in the carbonic acid and water that are the products of the ultimate oxidation only.

The use or uselessness, in the treatment of gout, of the inhalation of oxygen and of ozone can be determined only by the most careful experiments. At present, voluntarily increased rapidity of respiration by exercise (blowing the fire, in other words) is likely to add more oxygen to the blood than strengthening the mixture of oxygen in the air.

The oppressive and debilitating effect produced by the respiration of air heated to the temperature of the blood proves that diluting the oxygen by expansion produces a very decided effect on the oxidising action in the body. The hotter the air, the less will be the amount of oxygen in a given space; and the colder the air, the more oxygen will the lungs obtain. Moreover, the diffusion of the gases in the vesicles and the bronchial tubes must be greatly influenced by the different temperatures of the different parts of the column of air. The purer the air, the less carbonic acid, and the less mineral, vegetable, and animal impurities will it contain in the form of dust. Any increase in the amount of carbonic acid in the inspired air produces a chemical impediment to the escape of carbonic acid from the blood, and the passage of smoke and dust into the air vesicles themselves mechanically interferes with the actions of solution and diffusion on which respiration depends.

When there is reaction, cold air (or cold water) promotes oxidation; but continued external cold directly or indirectly causes contraction of the vessels of the surface, and drives the blood within; and hence the greatest oxidation takes place by keeping the circulation free on the skin and extremities by the warmest possible clothing by enveloping the inflamed part in cotton and oil-silk, or in flannel.

Thirdly, on the action of medicines in promoting oxidation, elimination, and absorption. For indirectly promoting oxidation the two most potent medicines we possess are alkalies and iron.

Alkalies assist in the oxidation of organic substances, not by giving oxygen, but by promoting the formation of vegetable and animal acids, and ultimately forming carbonates out of the burning matter. Familiar instances are the saponification of fats, the use of caustic potash in Trommer's test for sugar, the use of lime in Moore's test; the use of potass in Liebig's method of determining the amount of oxygen gas by pyrogallic acid.

Hence caustic alkalies, potass, soda, magnesia, are more efficacious as oxidisers than carbonates, and carbonates more potent than bicarbonates. But even bicarbonates, when heated with organic substances, lead to the formation of organic acids, which displace the carbonic acid, and thus promote the oxidising action. Thus diabetic sugar with sulphate of copper and carbonate or bicarbonate of potash in the cold gives no reduction, but when heated to 212° the reduction is evident. Ammonia is at least partly oxidised in passing through the system, and therefore it is of no avail in the treatment of gout as an oxidiser, though it may be used to neutralise acid in the stomach, or to act as a temporary stimulant.

Iron indirectly is an oxidiser, by its power of drawing oxygen into the blood. The great object of giving iron as medicine is the formation of blood-globules. For this hæmatoglobulin itself would probably be the best preparation, as being nearest in composition to the substance ultimately formed; but hitherto all attempts to prepare even hæmatin in quantity as a medicine have failed, and dried colouring matter of the blood is the simplest substitute. The reduced metal, the oxide, the carbonate, or some vegetable salts, are usually given, and all with good effect. The large amount of iron that passes off in the fæces and urine shows how little metal attains the intended object. In ten minutes I have found a solution of sulphate of iron passing out in the urine, and in twenty-four hours in the fæces. Hence very small doses of hæmatoglobulin would probably be equivalent to the large doses of other iron medicines which are given. In the active state of gout iron of any kind is inadmissible; in the passive state it becomes a most efficacious remedy.

All the salts of the organic acids that pass through the

stomach into the blood, as, for example, the acetates, tartrates, citrates, are oxidised and pass into the urine and textures as carbonates; and hence all effervescing saline draughts may be considered as acting in the tissues as the carbonates of the alkalics act; that is, they promote the formation of organic acids in the textures; and these acids pass by the absorbents, and by the veins back into the blood, to be oxidised and thrown out by the urine and by the skin.

The mineral waters, reputed good for gout, are mostly dilute solutions of alkali—*e.g.*, Vichy water. Generally the stronger the water the more efficaciously it acts, but the action of the water itself must not be disregarded—*e.g.* Buxton; the water diffuses not only into the urine, making that more dilute, but it dilutes the serum of the blood, and diffuses into the textures, dissolving deposited urates, and hindering fresh deposition of crystals. Thus water alone in sufficient quantity acts not only as a diuretic, but as a dialytic remedy, and in gout the action of the water of mineral waters might be still more exactly defined as urilytic. The water takes the uric acid as urates from the textures and carries it to the blood to be oxidised, and thrown out as urea and carbonic acid.

In the gouty deposits, however, there is another deposit—namely, fibrin, which is by no means soluble like the urates, for water and alkaline carbonates have but little action on deposited fibrin. How far iodine, bromine, and mercury possess the power of indirectly or directly oxidising fibrin has yet to be determined. In the present state of our knowledge, nitrate of potass is of all remedies the one which can pass most readily into the joints, and can exert a solvent action on the fibrin that may be deposited there.

On the Secondary Mechanical Diseases that arise from the Wrong Chemistry of Gout.

The accumulation of urates from the want of oxidation in the textures, and the deposition of fibrin in and around the joints, gradually produce more or less complete loss of motion. In extreme cases after each attack of gout, a lower degree of locomotion is reached by the patient. The stiff fingers and toes are followed by stiff ankles and wrists, and these by stiff elbows and knees, which generally fix the patient in the sitting position. Then the hips and shoulders become affected, and the jaws will scarcely open to allow solid food to pass. Ultimately, even the neck loses much of its mobility.

These different stages may be reached gradually and successively; or many stages may be passed through in a single attack. When once a joint has become fixed, very little liberty of motion is afterwards regained, but by persevering endeavours to extend and to flex the joint, in spite of the pain which the attempted motion causes, more use of the limb may be got than at first sight might be thought possible. As soon, however, as a fresh attack of gout comes on, far more motion usually is lost than had been regained.

The consequences that result from the more or less complete loss of motion may be divided into two classes. The first are mechanical, and the second chemical, and these are so connected the one with the other, that it might perhaps better be said that the effects are mechanico-chemical and chemico-mechanical.

The mechanico-chemical effects may be seen in almost every texture of the body.

In the skin the inability to relieve the pressure of one part on the other or of any part on the surrounding matter causes fresh irritation, and then ulceration; so that sores will form wherever the pressure is greatest.

In the cellular tissue the uniform position causes the veins to become distended, increased effusion into the cellular tissue occurs, and the absorption of fluid is diminished, and œdema in the legs and sometimes in the arms may be observed.

In the glandular organs the loss of exercise causes diminished flow of blood through the textures, and hence diminished secretion of bile, urine, saliva, occurs.

The chemico-mechanical effects of complete loss of motion are seen in increased loss of oxidation and nutrition in all the vascular and non-vascular structures of the body.

In the skin dry or moist eczema very frequently occurs.

In the muscles the muscular fibre so wastes and fatty matter so takes the place of contractile texture, that even if the joints were free to move, the muscles themselves are so changed in chemical composition that they become ultimately unfit for work.

Then the tendons contract, and the shortened muscles drag the limbs and extremities into outrageous distortions.

In the blood vessels and cornea, atheroma and the arcus senilis, even in comparative youth, give evidence of the low degree of nutrition and oxidation that is taking place in the textures.

In the glandular blood vessels—as, for example, in those of the kidney—the same alteration occurs. Some of the components of the urine remain in the blood, while the albumen of the blood passes into the urine. Thus one of the consequences of the gout tends to reproduce the cause of the gout.

The very bones undergo changes of nutrition from the ossicles (a) of the ear to the thigh bones, at first thickening in parts, with increased vascularity, whilst elsewhere increased earthy deposit gives an ivory hardness; afterwards absorption may occur in places, so that the trochlea of the humerus or the neck of the thigh-bone may be more or less completely absorbed, and the form of the bones may thus be entirely changed.

At first the nerves and the brain seem the only parts of the body unaltered, but increased sensibility aggravates the sufferings of the patient. Then comes great irritability, with want of decision; then loss of perception or false perceptions amounting to hallucinations, of which the patient himself may be perfectly conscious. If the strength of nutrition returns, all these symptoms may entirely disappear, showing that no permanent alteration of the nervous centres has occurred.

Thus the original chemical disease of suboxidation of the urates may cause such an entire loss of mechanical power that not even a crumb of food can be raised to the mouth or a fly can be driven away from the skin, and death would soon result from the debility of starvation, if external force was not made to compensate for that which cannot be produced within.

But gradually the textures deteriorate and the fluids stagnate, and debility or dropsy mechanically put a stop to the sufferings which the wrong chemistry had originally produced.

ORIGINAL COMMUNICATIONS.

SURGICAL INQUIRIES.—No. III.

THE SURGICAL BEARINGS OF THE TISSUE, OR CELLULAR PATHOLOGY.

By FURNEAUX JORDAN,

Surgeon to the Queen's Hospital, Lecturer on Anatomy at Sydenham College, Birmingham.

I USE the word tissue or tissue-element pathology in preference to the term "cellular" pathology, because of the important modification which is being made in our views of the structure and origin of the tissue, and by no one more than by Professor Beale. At the same time, the word "cell" (without here implying the necessary existence of a cell-wall) still remains as the most convenient to apply to certain morphological elements which everywhere prevail in the tissues, in the glands, and in the embryo, and which are allowed to be the chief centres of action in normal nutrition, secretion, and development.

My object in this inquiry is to show the better adaptation and the more universal applicability of the tissue-germ pathology to the phenomena of Surgical disease and injury. To do this with advantage, I must first review the main evidences in its favour, and glance, at the same time, at the defects of the exudation theory.

To the genius of Goodsir is due the increasing recognition of the inherent activity of the cell, but to Virchow belongs the merit of showing that all specific action in pathology belongs to the tissue elements, and that no specific action is exercised by the vessels or nerves.

The only action which vessels possess shows itself in a diminished supply of blood. It is also impossible that nerve influence can be essential to inflammation, because, now that we recognise the division of the axis cylinder of nerves, the assumed pathological influence must necessarily be transmitted to the whole area to which the given nerve is distributed. But, in fact, pathological activity is always most marked where the cause (acting on the tissue elements) operates most intensely. Indeed, there is proof of overwhelming completeness that vascular and nervous influence are not necessary to pathological action. The cornea, cartilage, certain papillæ of the skin, and the abundant substance of the umbilical cord, are all seats of typical forms of inflammation, and yet are

(a) Pathological *Transactions*, vol. ii., p. 321.

totally devoid of vessels and nerves. Again, inflammation constantly occurs in parts, the nerve supply to which is suspended either by disease or injury. The argument which Mr. Paget (a name I shall never mention without unqualified regard) advances in favour of the nerve theory admits of another, and, I think, a more probable explanation. In working for some hours with the microscope, Mr. Paget found the closed eye congested; this he attributes to the irritation of the retina of the used eye. But if any one will close firmly both eyes for a short time, both will become congested as in sleep; and, on the contrary, any microscopist who keeps both eyes open will find, after several hours' work (I know this from experience), that if there be any irritation at all it is in the eye most used.

Mr. Paget, with his rare honesty, recognises the cellular pathology in the so-called non-vascular structures. Is it not an anomaly, however, to suppose that the tissue elements determine pathological action, which they are equally capable of determining everywhere, in the cornea and cartilage, etc., only, and that in other localities the vessels and nerves are the determining agents? It is difficult to see why a pathology which interprets all active processes in all organs (and which is based on and progresses with the most modern histological research) should be rejected for a theory which is confessedly inadequate to explain inflammation in certain localities.

The tissue pathology teaches that all specific action lies in the tissue elements. One specific action is the production of new tissue elements; hence the dictum that every cell (tissue element, endoplast, germinal, and formed matter, etc.) is the product of a previous cell. There is no shadow of evidence to show that cells can be originated in a structureless fluid exuded from the blood. But, as in the plant, all cells are produced from cells—(and surely the plant with its physiology and pathology, its tumours, possibly its inflammation, scrofula, and cancer is, notwithstanding the absence of a controlling nervous system, of more interest to the pathologist than the crystallising and physical processes of inorganic bodies)—so in the diseased tissues of the animal, cells divide and multiply, and the result will be in accordance with the subsequent changes which the young products undergo. This production of young cells can be seen. It is possible for every one to see in an abscess the gradual production of pus cells from the tissue (mostly the several forms of connective tissue) cells. At one spot may be seen the nucleus dividing. At another the cell also may be seen actually dividing with portions of the already divided nucleus in each segment. Close to a cluster of young cells mark the site of a former cell. At a point midway between the healthy tissue and the central true pus the cell is half a connective tissue cell and half a pus cell. The transitions are gradual, and can be easily traced.

Before closing these general remarks on the scope and characters of the tissue pathology, I would briefly observe that the existence of dyscrasiæ is in opposition to the idea of a blood pathology. The blood in its normal and in all its abnormal states is utterly dependent on the states and actions of the solid organs and on the characters of the ingesta. The blood is the very reverse of an independent, permanent, self-making, self-renewing, and self-regenerating fluid. Local disease or persistently injurious food can alone give rise to diathetic taint.

The symmetry of disease, which Mr. Paget regards as a bulwark of the "humoral" pathology is to me one of the strongest evidences of a tissue-controlling pathology. The tissue elements in corresponding or symmetrical sites may be fairly regarded as absolutely similar, while arterial blood is everywhere the same. Just as physiological nutrition is symmetrical, and is determined by the tissue elements and not by the blood, so pathological activity is also symmetrical, and is also determined by the tissue elements. I do not deny that the blood may be the means of carrying a contagious fluid which shall stimulate identically similar cells to similar action, because I do not deny the existence of dyscrasiæ or noxious agents in the blood, but it must not be forgotten that such such agents are (as is the blood itself) derived from sources external to the blood. Cancer does not originate in the blood, but when a local cancer has arisen by a direct descent from tissue cells, the blood may carry an infectious fluid from it which will stimulate tissue cells elsewhere (often symmetrically, as I have several times seen) to take on cancerous action. The blood may be a medium of conveyance, but nothing more. It can do or originate nothing.

Inflammation is the key to all pathology. In consequence of some cause acting on, or in, the tissue elements, they (the cells, or corpuscles of germinal and formed matter) absorb an increased quantity of material, and become larger and opaque. An excellent illustration of this stage is seen in the interstitial keratitis of hereditary syphilis, which disease, curiously enough, rarely proceeds further. I have seen the opaque contents of the corneal cells (there is an excellent microscopic delineation of this disease in Dr. Chance's admirable translation of Virchow), of several years' duration, absorbed in a few weeks under the influence of mercury. This enlargement, as will be inferred, is not necessarily permanent, as the absorbed material may disappear. On the other hand, if enlargement proceeds beyond a certain limit, especially if rapidly induced, local death is the result. Should the inflammatory action proceed, formative or divisional activity of the cell-structures ensues. The nuclei enlarge and become elongated, the centre is next constricted, and soon two nuclei are seen. If nucleoli are present, similar changes will first occur in them. Lastly, the cell-wall also divides. Virchow observed that as early as the second day, in the vicinity of a thread seton, two or more cells may be found with straight partitions between them, each cell having a nucleus. Mr. Turner, a most able observer (see *Edin. Med. Journal*, 1864, and numerous notes in his edition of Paget's Pathology), considers, as a result of his careful examination of pleuritic adhesions, that the young cells he saw were formed within the old cell-wall, and that, by the liquefaction of the latter, the former were released. The progress of histology will, doubtless, throw great light on this question. The accelerated or retarded division, as well as the varying quantity, of formed material (adopting for the moment Dr. Beale's views), would, I think, easily explain the apparent discrepancies of different observers.

At this stage also the inflammatory process may cease. The clusters of young cells (granulations superficial or deep) simply become young connective tissue. In this way arise most of the enlargements which in this country have been called hypertrophies. Typical Surgical illustrations of this formative inflammation are seen in the thickening of the synovial membrane, which Brodie described as gelatinous degeneration, in the slow enlargement of bones, and in the formation of most polypi.

Should the inflammatory action proceed, the proliferation of the cells continues more or less rapidly, and the intercellular substance diminishes in corresponding degree. When pus is formed, the multiplying tissue elements become round, with a bi-partite or tri-partite nucleus, and the intercellular substance is completely liquefied. A more rapid and severe inflammation chokes the sources of nutritive supply by the precipitate crowding of its young products, and death occurs either of molecules (ulceration, phagedena) or of the mass (sloughing, gangrene).

The hyperæmia which attends upon inflammation is a purely secondary phenomenon, and is called into existence by the increased nutritive requirements of the active cell changes.

Exudation is not found; indeed, there is no room for it in many inflammations. In inflammation of certain surfaces, however, there is undoubtedly an exudation of fibrine or mucus, according to the surface affected, but the exudation is a local product—a product of the tissue elements. It is washed to the surface by means of the serum, which exudes from the vessels as a result of obstruction, and the exudation carries with it the loosened young germs of the proliferating process which are present in large numbers in the inflamed tissue of the surface. Mr. Turner has fully traced the steps of the production of these from the connective-tissue corpuscles at the inflamed and denuded surfaces. The lymph which is found on inflamed serous surfaces is simply the surplus quantity which the lymphatics have been unable to remove. The absorption of this local product into the blood gives rise to hyperinosis.

I must turn now from this Medical aspect of the question to the more express objects of this inquiry. *Pus* has already been seen to be a young tissue. Its direct origin from the tissue cells has been traced by observers so competent and numerous that I should have some hesitation in dwelling on the fact, were it not that every student's Manual of Surgery still teaches the spontaneous origin of pus-cells from an imaginary homogenous lymph. Every one can repeat the simple experiment of Virchow; if an ulcer be wiped clean, pus-cells quickly appear, but not a trace of lymph, chemically or microscopically.

The reparative process has always excited the interest of Surgeons. The mere number of the processes of repair, as at present widely taught ought naturally to create a suspicion

that the simplicity and uniformity of Nature have escaped the detection of past schools of pathology. The cellular pathology offers not a theory merely, but demonstrates beyond cavil the fact of proliferation of the tissue-cells adjacent to every wound and ulcer. Every wound, on the surface or not, whether cut, or torn, or crushed, or punctured, every broken bone, simple or compound, heals by one uniform simple process. New cells are produced from the old tissue cells in the vicinity of the injury and become cicatricial tissue; it may be in a few hours, without pain, or tenderness, or suppuration, or it may be after months or years with pain, suppuration, and all the accidents which are apt to thwart the beneficence of repair. It appears to me to be a strong confirmation of Virchow's view as to the seat of inflammation being in the connective tissues that the structures produced by reparative action are invariably connective tissues. Besides connective tissue epithelium only (in open wounds) is formed in repair, and here is another significant circumstance—namely, that the young epithelium is never formed except at the margins, that is, where the old epithelium is present. Virchow believes that epithelium may be formed from connective tissue cells, but I cannot avoid the conclusion that in ordinary repair the new epithelium is entirely descended from the old marginal epithelium; and hence arises, I consider, the difficulty which occurs in the central healing of large surface wounds. This difficulty is less explicable on Virchow's theory, and is perfectly unintelligible on the exudation view, seeing that the fibrine-yielding (?) vessels lie under as well as at the margins of the granulating surface. The young connective tissue I need scarcely say forms from the granulations which spring from the connective tissue which everywhere is present in every possible wound.

The process of granulation has been already referred to; it appears to me that Virchow's experiment of wiping an ulcer is as conclusive against the development of cicatricial tissue as it is conclusive against the formation of pus from lymph. No lymph is ever to be found; what, then, is the origin of cicatricial connective tissue and epithelium? It has been said that the intercellular substance of the cellular pathologists is the lymph in which the cells arise. This supposition is signally refuted by the fact that a granulation, as depicted by the exudation pathologists themselves, consists of cells only at the very time, moreover, when the supposed lymph is just exuded and most abundant. The intercellular substance appears at a later period when the necessity for lymph has passed away. Another consideration touching granulations has often occurred to me: if repair is effected by a fluid exuded from the blood in which cell-forms spontaneously arise, why should granulations exist at all? That clusters of cells (granulations) should occur from the proliferation of previous cells is inevitable, but what is the necessity for the grouping of the free-formed cells in a stratum of lymph?

There is one mode of union commonly taught, chiefly because it has received the sanction of the justly great authority Paget. It is called immediate union—union without time, material, or process. I must not at present dwell on this topic, because it is not necessarily linked to any particular pathology. But, merely remarking here that the little masses of induration in Mr. Paget's best illustration could have been produced by no other means than inflammation, I would ask if the histological difficulties are not insuperable. Suppose the breast to have been removed, as in Mr. Paget's case, does a nerve tube become instantaneously continuous with a capillary, or does a globule of fat stick on the end of a muscular fibre in an equally short period of time, or, rather, in no time at all? No doubt two wet surfaces may stick together so intimately that the process of repair is effected in the most favourable manner possible, but the very fluid (whether derived from the blood or the tissues, or both) which wets the surfaces must itself prevent instantaneous repair. The painless and rapid union of two surfaces of young tissue-germs will explain all facts and contradict none.

The possibility of the organisation of blood-clot could never have obtained credence had it not been for the existence of an exudation pathology—the exudation pathology itself being based on a now exploded exudation physiology. If an exudation which comes from the blood can be organised, why can it not be organised while still in the blood? The question is a fair one. But if no exudation can ever be found undergoing organisation, and if, also, wherever organisation is going on cell multiplication is indisputably active (it is for the exudationists to explain this, on their hypothesis, unnecessary, surplus, and purposeless phenomenon) the organisation of blood-clot becomes as doubtful in theory as it will be found to be unsupported by fact. The supposed illustrations, seeing that blood-clot in the living body is of every-day occurrence, are remarkably few in number and indefinite in character. To students it is not a living fact, but a tradition resting on one or two esteemed names. The simple explanation of every supposed case is this, and I do not hesitate to say that a re-examination of every specimen extant will give it confirmation; the blood-clot has excited cell action in the adjacent structures to which it is adherent, the resulting young tissue has extended into the clot and temporarily incorporated its elements. Thus all the organised elements are continuous with and outgrowths from the adjacent attached surface.

The tissue pathology, embracing, as it does, the well-ascertained facts of modern histology, the tubular communications of cells, for instance, and especially the continuity of the connective tissues (Reichert), teaches in theory what really best comports with the facts of practice—namely, the continuity of disease in apparently different tissues, and also the common origin of apparently different diseases when occurring in the same tissue. Taking the latter point first, it is common for circumscribed abscess, diffused abscess, cellulitis, ulceration, and gangrene to be regarded as distinct and well-defined conditions. Instances no doubt occur with well-marked physical differences, but even in these there are no abrupt lines of demarcation, and the great majority of cases in practice are intermediate conditions. In both circumscribed abscess and diffused abscess there are the same gradations from healthy tissue to pus. In one the gradations are marked and rapid, the pus is in a single and larger collection: in the other the gradations are less marked, the collections of pus small and multiple—hence the term diffused. Death of tissue (sloughing) is limited in abscess, especially in the circumscribed; in cellulitis it becomes a marked feature. Here again, however, there is every intermediate stage between pus and slough, as there is between granulation tissue and pus. I have made incisions into tissue which was yellow, but solid and succulent, and I have watched such tissue become partly slough, partly granulation substance, and partly pus. In short, the same little piece of tissue presented every result of the inflammatory process, and each result was inseparably blended with the others. Ulceration, again, is merely cell action going on from tissue elements to granulations, from granulations to pus and slough or *débris*. The action may be slow and slight, as in indolent ulcer, or it may be rapid and severe, as in sloughing phagedæna. The difference between ulceration and abscess, or cellulitis, is thus merely contingent and physical. The induration which constitutes an early phenomenon in cellulitis, abscess, and ulceration is due to the rapid and abundant proliferation of the cells of the connective tissue. On the exudation view of these diseases the earlier stages should be soft, because at such times the exudation is most fluid and most abundant. The absence of all lines of demarcation in pathology, which cannot but have an important bearing on treatment, is a subject to which I can now merely allude. On another occasion I shall again consider this eminently practical question in Surgery, and adduce evidence of, I believe, unexpected intermediate pathological conditions.

I turn now to the other and allied proposition, the continuity of disease in the several forms of connective tissue. In abscess of the connective tissue over a bone there is no doubt that the periosteum and bone are also more or less implicated. I have seen marked osteitis in two instances recently after a few weeks of suppurative synovitis, which osteitis would no doubt have speedily recovered had the synovitis been capable of recovery. Seeing that bone, periosteum, and cartilage are directly continuous structures (the differences being chiefly chemical) it is impossible that inflammation should arise and proceed in one without implicating the others. If inflammation is apparently most active in the periosteum, the bone and medullary tissue on the one side, and the connective tissue on the other are invariably affected. The connective tissue inflammation is chronic, showing itself in increased tissue in chronic osteitis; it is acute and suppurative in acute osteitis; in the latter instance the suppuration occurs before the bone or periosteum slough—that is, before they become foreign bodies.

Inflammation of bone does not differ from inflammation of the softer varieties of connective tissue. The inflammatory products are direct conversions of the bone cells. With increased growth of cell contents and division of nuclei there is absorption of the intercellular calcareous substance which

permits of greater freedom of cell proliferation. The young cells may secrete fresh intercellular substance and throw out tubular branches, giving rise to condensation or sclerosis. Or the cell action may proceed to the formation of granulation substance, and later of pus, mixed with dead particles of old basis substance, and then caries is said to be present. Or if the granulation process be more localised, and proceed more completely to pus-cell formation, the circumscribed caries is called abscess of bone. If these processes occur on the surface we speak of them as ulceration of bone. Lastly, if cell action be rapidly induced, we get earlier and larger sloughing and the expression necrosis is used. Death is slower and implicates only small fragments in inflammation of the well-nourished cancellous tissue (caries), and more rapid and extensive in the lowly nourished compact tissue (necrosis); yet it must not be forgotten that all these processes merge into each other, and are always more or less combined—indeed, the so-called caries and necrosis are absolutely identical, and differ only in degree. I recently exhibited a femur at the Midland Medical Society which illustrated continuously with each other every result of bone inflammation, new bone, sclerosis, caries, abscess, necrosis, and ulceration.

It would be easy to take every branch of Surgery, and show how much better all pathological phenomena are explained by the tissue-element theory. How, for instance, in retinitis the changes occur in the connective tissue of the retina, and hence the appearance of extensive disease to the ophthalmoscope, as pointed out by Libreich, with comparatively little functional impairment; how that in the Hunterian chancre the induration is due entirely to cell growth; how the atheromatous patch which precedes aneurism is an inflammatory cell growth, clearly traceable, by the microscope, at the inner aspect of the middle and outer aspect of the inner arterial tunics which degenerates fattily, and which eventually, with the covering epithelium, is washed away, leaving a weakened spot which may be gradually dilated into an aneurismal sac; but at present I must be satisfied with pointing out some of the principal Surgical bearings of the tissue pathology, and conclude with one or two further remarks.

Microscopic observation leaves little doubt that tumours in their origin and growth are allied to inflammation in its earlier stage. No necessary or constant constituent can be pointed to in cancer. Practically the mere variety of cell forms and appearances is the most valuable diagnostic feature, and this probably depends upon varying but rapid rates of growth. Virchow considers that the cancer cell is mostly analogous to the epithelial cell, and Buckhardt and Turner have depicted epithelial cells from the ureters precisely similar to the supposed cancer cell. When a cancer forms there is first a rapid proliferation of connective tissue cells, the resulting young cells present the "indifferent stage" of Virchow, then they grow to the cancer elements in obedience to some principle at present quite unknown. Cancer, like pus and tubercle and tumours generally grows by the addition of the granulations of peripheral cells to the exterior. The life of cancer cells, although not so short as the life of pus cells, is of brief duration, hence the more or less early disintegration of the central or first formed cells of the cancerous mass.

Of tubercle I need say little here, except that it is of inflammatory and cellular origin. It begins as a granulating process, the young cells are early arrested in their growth, become dwarfed and shrivelled up, and speedily become subject to fatty degeneration, which occurs in the portions which are oldest, central, and furthest removed from the sources of nutrition. In the meninges the granular and cellular characters of tubercle are alike unmistakably evident. In bone the so-called tubercle is invariably inspissated dried pus, as Reinhardt has shown it to be in the lungs.

Treatment.—Whenever an advance takes place in pathology we must be content to wait patiently for its effect on treatment. Advances in pathology do not necessarily effect advances in treatment, because treatment at present rests on empirical more than on pathological grounds. No doubt activity of cell action can be to some extent controlled by lessening the quantity of the ministering fluid. Drugs, too, have marked influences on local tissue change.

The cellular pathology which attaches greater importance to local disease (every possible disease having primarily a local origin) necessarily teaches the great importance of local remedies. It also teaches, on grounds which have been already referred to, the desirability of greater uniformity of treatment.

Both experience and pathology teach, it appears to me, that all wounds of bone and soft parts alike should be treated alike. The treatment of wounds of soft parts should also be uniform. Neglecting, say in contused wounds, to bring the parts together as in incised wounds, because of the fallacy of different modes of union, has protracted many a weary convalescence and aggravated many a hideous deformity. In Surgical treatment, it is happily possible to call into exercise the most powerful agents known in therapeutics—rest and pressure. The influence of pressure in Surgical affections has yet to be appreciated; there are few cases, however, in which it may not be applied with advantage. Even in acute inflammations (abscess, cellulitis, erysipelas, ulceration, sloughing phagedæna) the beneficial effects of poultices and other applications are more than trebled by the outside application of a bandage or a layer of shot (in a bag) as position and locality may require. In chronic inflammation, as in all active cell formation (as distinguished from passive cell action or degeneration), pressure is invariably useful. Pressure, more than any known agent, will control or arrest cell or tissue-element action. To devise the best modes and degrees of pressure will be no inconsiderable part of the great work of future Surgery.

The previous observations have been based on the results of the numerous workers in the tissue pathology and in recent histology (especially of connective tissue), Virchow, Goodsir, Donders, Von Wittich, Kölliker, Lockhart Clarke, Redfern, Simon, Haldane, Turner, Stirling, Weber, His, Billroth, Böttcher, Rindfleish, and others. It is, however, even more just to them than to myself to say that for many facts, illustrations, and deductions I alone must be responsible.

CASES OF REFLEX PARALYSIS, WITH OBSERVATIONS.

By ALEX. ROBERTSON, M.D.

Physician to the Town's Hospital and City Parochial Lunatic Asylum Glasgow.

In no class of diseases have the investigations of late years been attended by more satisfactory results than those pertaining to the great nerve centres. More especially does this hold true in regard to the morbid conditions of the spinal cord and its intra-cranial prolongation. Our knowledge of the functions of the several constituents of these parts, through the combined labours of physiologists and pathologists, has been steadily advancing; and step by step with this advancement have we been enabled to distinguish between their respective disorders, and, in many cases, to localise with much precision the exact seat of the morbid changes.

An important group of so-called functional derangements, comprehending the reflex forms of paralysis, has been separated from the others by general consent, inasmuch as they are believed to have their origin in some peripheral excitation, and to be unaccompanied by any decided alteration in the central organ, though there may be, as suggested by Dr. Brown-Séquard, an anæmic condition of the segment or zone of the cord over which the morbid influence conveyed by the afferent nerves extends. I have said that they are separated from the others by general consent advisedly, for there are not wanting pathologists who maintain that they should be classified with the organic forms, and that structural changes have not been observed in those cases where post-mortem examinations have been made, simply because they have not been properly looked for. It is certainly difficult, if not impossible, to prove that morbid conditions of the microscopical elements of the tissues may not have been present; but the burden of proof should rest with those who hold the affirmative. Besides, a strong reason for believing that the central change, if any, is slight, rests in the fact of the speedy recovery from the palsy when the irritating cause is removed. Nor, though a decided central alteration were found in every case, would it invalidate the doctrine that it was due to the irritation in the course, or at the distribution of the nerve, which was transmitted to the centre, and induced there, by reflex action on the vaso-motor nerves, an abnormal contraction of the bloodvessels, with its necessary consequences, impaired nutrition and functions of the part affected. And should such defective nutrition be to a great extent or of long standing, serious organic changes could scarcely fail to be produced.

The first of the two cases that I have to submit illustrates one of the rarest forms of derangement of the central nervous

system – reflex hemiplegia. I shall shortly narrate the history and leading symptoms.

On the 16th of last November, about 8 a.m., I was called hurriedly to see J. C., an Hospital sick nurse, who was reported to have been seized with a shock of palsy. I was rather surprised at this message, as the woman was not old, 41, and, although delicate looking, had certainly not the aspect of one disposed to apoplexy. Besides she had been attending to her duty the day before, and made no complaint. I found her in bed, quite calm, and intelligent as usual, ready to answer all my questions, which she did with promptitude, and manifested not the least mental confusion or excitement. She told me that when a child of about seven or eight years of age she took "nervous fits" three or four times a-day for three years; that afterwards she got quite well, but since then has been of a nervous disposition. About ten months since became affected with giddiness and ringing in the ears, and one morning was seized with numbness of the left side, which troubled her for about two months, when she recovered completely; but the latter symptom returned for a few days in the month of May, again leaving her in her ordinary health. For several years has occasionally suffered from severe pain in the left hip, extending down as far as the knee, which was aggravated on both of the occasions referred to. Believes that this pain is connected with constipation of the bowels, as she always experiences relief when they are free. About eight days ago, and she thinks owing to anxiety about her family, she had a return of the symptoms, especially of the numbness of the side; but they were not so severe as to unfit her for her work. However, at 1 o'clock this morning the pain in her left haunch, which had been annoying her a good deal for some days, became excruciating, and, as before, extended down the back of the thigh as far as the knee. At the same time she felt that she had partially lost the power of the left arm and leg. Suffered severely all night; but, about an hour since, at her own request, another nurse gave her a soap and water injection, clearing out a quantity of impacted fæcal matter; and in three minutes she was almost free from the pain in the thigh. Says that now the numbness continues, and affects also the same side of the face. Cannot hold small articles, such as a needle, in her hand; the sense of touch, however, when tested by compasses, is not much impaired as contrasted with the opposite side. Feels the left side colder than the right, though no difference is observable. Has no other abnormal sensation. Retains some power of grasping with the left hand, but it is decidedly weaker; can move the leg in bed in all directions, though not so freely as usual; and when she tries to walk she drags it after her. Has full power of bladder, and has been passing a moderate quantity of healthy urine. Sight of both eyes, particularly the left, is impaired; but this is not recent, as it has been failing for some years. Considers it is due to constant sewing, by which she earned her livelihood before she became nurse; pupils are natural. The other special senses are in their normal condition, and so also is the power of swallowing. There is no distortion of face nor impairment of speech; protrudes tongue correctly. Menstrual discharge is not now flowing, but has been seldom free from it during the last three months. Heart sounds natural; pulse 100, small and soft. Tongue is clean, but is troubled with flatulence, and has a poor appetite. Is of a nervous temperament, but possesses considerable vigour of mind, and is not easily excited. The bowels were acted on freely, and afterwards had a draught of tr. assafœtida and tr. valerian ammon., of each ʒss., in mist. camphor ʒj., every four hours.

On the 18th, the third day after the seizure, the report bears that she had greatly improved, and was attending to her duty, being able to walk nearly quite well, though not free from numbness of the left side. Prescribed tr. ferri. muriat., gtt. xv.; quinæ. sulphat, gr. j., thrice daily, with full diet. From this time her recovery continued, and she acted as nurse till she left the establishment about six weeks afterwards.

She called at the Hospital in the beginning of April, when she told me that she had been working regularly at her employment as a seamstress since she left, and had continued free from paralytic symptoms, except on several occasions after an unusually hard day's work, when the numbness and loss of power returned in a slight degree, but passed away after a few hours' rest. She incidentally mentioned that when she had the serious attacks above described, an intensely itching eruption had broken out on her head, which lasted about a week, and produced an unusual quantity of scabs during its continuance; she also remarked that the left side of her face had often been swelled a little without any cause that she knew of, and was quite sure that the right had never been affected in the same way.

Remarks.—Here, then, we have severe sciatica arising at intervals from a recognised cause,—impaction of the lower bowel; but on the last occasion the morbid impression produced on the lower part of the spinal cord had been very severe, and the woman's system, naturally a susceptible one, was more than ordinarily so, owing to her mental anxiety, and the drain on her vital powers from the prolonged menstrual flux; hence, probably, the reason why the impression was transmitted upwards along the cord to the medulla oblongata, producing a partial hemiplegia, which like the sciatica, was confined to the left side. The effects of the treatment pursued support this view of the case; for instant relief from the pain was experienced, and the paralysis quickly passed away after the removal of the apparent exciting cause of both—the impaction of the bowel. It may be suggested that some of the symptoms indicated hysteria; and that the case might be classed under the hysterical hemiplegia described by the late Dr. Todd in his lectures on paralysis. But the leading features of that disease were wanting; and besides, some cases of palsy which have been held to be of this nature would probably have been more correctly viewed as reflex in their origin. The eruption on the scalp, attended by increased exudation, and the fulness of the left side of the face, are very interesting, as they indicate that the paralysing influence had produced a decided impression on the trunk of the cervical sympathetic. It is also worthy of notice that the anæsthesia was more pronounced than is usual in this kind of paralysis, as not infrequently sensation is unimpaired.

I have now to record a case of paraplegia arising from an eccentric cause.

J. R., aged 30, clerk, admitted May 22, 1864. Nearly two years ago was convicted of embezzlement, and was sentenced to eighteen months' imprisonment. When he had completed about ten months of his term, his health began to give way, —he got nervous, slept indifferently at night, his appetite became weak, and he began to pass small worms in his stools, which have troubled him ever since. Though he was ordered a generous diet, with metallic tonics, cod liver oil, etc., and had local treatment for the worms, he did not improve in any respect. About three or four months since felt his legs becoming very weak, much more so than his arms; and when his period of confinement had expired, a fortnight ago, this weakness had increased so much that he was unable to walk above a few steps at a time. About a month after he began to lose the power of his legs he noticed that he could not pass his urine with the same freedom as before. Since then this difficulty has varied much in degree, being sometimes much less than at others; but latterly it has increased so much that at present he has completely lost the power of his bladder, and has passed no water since yesterday. Is an intelligent, well-informed man; and gave a clear statement of his symptoms. Has a pale, nervous, depressed aspect; complains of dull headache, and says he has been subject to it during his confinement. Special senses are correct; and pupils, though rather open, contract readily under light. Motor and sensory power of the upper extremities and body generally are and have been unaffected. Has no pain in back. Sensation is perfect in lower extremities; and can also walk some steps, but very soon gait becomes tottering. Is not subject to starting of his legs, nor can reflex movements be produced by tickling. Complains of great itching about anus and scrotum. Pulse only 52; skin rather cold. Urine had to be drawn off for several days by the catheter; but then he became able to pass it himself, though slowly and with difficulty. Was ordered full diet; to take twice daily a pill containing strychniæ, gr. $\frac{1}{20}$; ferri sulphat., quinæ sulphat., āā gr. j.; extr. aloes, aq., gr. $1\frac{1}{2}$. To have an enema twice a-week of tr. ferri muriat, ʒij.; aq. calcis, ʒviii. Cold douche to spine, and surface afterwards to be thoroughly rubbed. The continuous galvanic current was also passed repeatedly between the lower part of spine and the hypogastrium. Under this treatment he improved; but there was great variation in his progress to recovery. Thus, on June 8, I find recorded in my note-book, "That his urine had again to be drawn off by the catheter, though he had been passing it himself for some days previously. Itching at anus is very troublesome." Again, on the 24th of the same month, the entry is:—"Bladder and legs have recovered their power to a great extent; but the stools are not yet free from thread-worms, though they are fewer, and the itching is much less." From this date he progressed

favourably; and on August 2 he was dismissed cured. His condition on dismissal is reported as follows:—"Worms are now quite away. Has been walking about for some weeks, and feels strong on his legs. Bladder has recovered its tone; but has a feeling of heat in urethra when he passes urine. Is returning to his occupation as a clerk."

Remarks.—This is a characteristic case of reflex paralysis. 1st. There is the obvious cause, the ascarides in the rectum, existing for some months before the paralytic symptoms set in. 2nd. The incomplete loss of power, and the variation in its degree, corresponding very much with the varying intensity of the local irritation. 3rd. There was no anæsthesia; and there was an absence of abnormal sensations in his legs. 4th. There was no pain in the course of the spine. 5th. It passed away entirely as soon as the disease upon which it depended was cured. 6th. One peculiarity is to be noticed:—The bladder was more than usually affected; but the paralysis differed materially in its character from that arising from ordinary organic causes; as, though complete on several occasions, it was not continuous, but recurrent; and generally it was only partial.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

SAMARITAN HOSPITAL.

CASES OF OVARIOTOMY.

(Under the care of Mr. SPENCER WELLS.)

(Continued from page 493.)

Case 5.—Solid Ovarian Tumour—Ascites—Prolapsus of Uterus and Vagina—Ovariotomy—Death Twenty-seven Hours After.

On March 23, 1864, a married woman, 29 years of age, called on Mr. Wells with a letter from Dr. Woodhouse, of Hertford. She was the mother of three children. The two youngest were twins, and three years old. She had a flushed, hectic aspect, and was considerably emaciated. There were some varicose veins in the right thigh, but no œdema of the legs. The digestive system was out of order. Sleep was troubled. There was a good deal of cough, especially at night, and some mucous expectoration. Respiration was prolonged, and the right side of the chest was somewhat duller than the left. The second sound of the heart was feeble; but there was no abnormal bruit. The heart itself was somewhat displaced. The girth at the umbilical level was 40½ inches; the distance from the umbilicus to the ensiform cartilage, 12½ inches; to the symphisis pubis, 8 inches; and to either ilium, 11 inches. All the abdomen below a line seven inches above the umbilicus was dull on percussion, and was occupied by a lobulated tumour, whose lobules were hard, resistant, and freely moveable on each other, the interspaces being filled with ascitic fluid. The integuments of the abdomen were œdematous, and marked with lineæ albicantes. There was no tenderness on pressure. Crepitus was heard on the right side. The ensiform cartilage was tilted forward by the pressure of the tumour. The catamenia were absent. They had first appeared when the patient was 12 years of age, and had always been very abundant until October, 1862, when they suddenly disappeared. They came on again in scanty quantity in the summer of 1863, and since then they had been absent. Leucorrhœa was constant. The uterus was dragged upwards, so that its vaginal portion was almost effaced. It was moveable, and its cavity was three and a-half inches in length. There was no history of hereditary disease. The patient had been brought up in the country, and had done ordinary household work. She occasionally had suffered from oppression in the chest. The first sign of the present illness was the sudden amenorrhœa in October, 1862. Very shortly after this, an abdominal tumour was discovered, and it rapidly enlarged.

The patient was admitted into the Samaritan Hospital on the 18th of April, 1864. She was suffering from dyspnœa, and the urine was very scanty—only eleven ounces in twenty-four hours—specific gravity 1035, and free from albumen. It was evident that a very large abdominal tumour was surrounded by fluid which was free in the peritoneal cavity; and it was arranged that an exploratory incision should be made as soon as the state of the chest permitted. But as the dyspnœa increased, and there were physical signs of increasing accumulation of fluid in the left pleural cavity and more displacement of the heart to the right side, Mr. Wells evacuated four pints of ascitic fluid by a fine trochar on the 18th of May. Some slight relief was afforded, but there was little alteration in the state of the chest, and increasing dulness on the right side down to the third rib, with crepitation from the third to the fifth, pointed to consolidation or condensation of the upper part of the right lung. It was agreed to tap again, watch the state of the chest, and hope that any relief obtained by removal of the ascitic fluid would be a favourable indication for the removal of the tumour.

On the 10th of June Mr. Wells accordingly tapped, and again removed four pints of ascitic fluid. Considerable relief followed; the signs of pleural effusion, displacement of heart, and condensation of right lung gradually diminished. But on considering the question of ovariotomy with her husband, they decided to wait, as Mr. Wells could not assure them that the case was a favourable one. She was discharged June, 1864, and returned to the country, where Dr. Woodhouse kindly watched her. He wrote in October to say that her general health had improved, and that the state of the chest was more satisfactory, but that she was unwilling to submit to operation. She went on pretty well during the winter, but increase in the size of the abdomen, and greater suffering in the early part of this year, made her again anxious for relief, and on the 29th of March, 1865, she was re-admitted to the Hospital. Respiration was now tolerably free in both lungs; there were no signs of effusion of fluid into the chest; the heart's sounds were normal, and the pulse much stronger than formerly. The girth at the umbilical level was 47 inches, the distance from the umbilicus to the ensiform cartilage 17 inches, to the pubic symphisis 9 inches, to the right ilium 16½ inches, and to the left ilium 15 inches. The ensiform cartilage was much pushed forward by the tumour, which appeared to move freely under the abdominal parietes; the umbilicus protruded; there were dilated veins in the walls of the abdomen; the right loin was dull on percussion, the left tympanitic; there was prolapsus both of the anterior and of the posterior walls of the vagina, and part of the mucous membrane was ulcerated. A very thin layer of ascitic fluid covered the tumour, which filled the entire abdomen. Limited fluctuation was to be felt to the right of the epigastrium. The uterus, when replaced, appeared small and moveable.

Mr. Wells performed ovariotomy on the 3rd of April, with the able assistance of Mr. Fergusson and Dr. Wright. Drs. Kœpl, of Brussels, Prieger (Kreuznach), Marion Sims, Woodhouse, and others were present. Mr. Clover gave chloroform. The incision extended from two inches below the ensiform cartilage to four inches above the pubes. It was twenty inches long in the distended parietes, but after the tumour was removed it was only thirteen inches long. There were no adhesions, except to the omentum, a piece of which of about the size of the palm of the hand adhered to the upper and front part of the tumour. It was easily separated. There were two or three pints of reddish serum in the peritoneal cavity, which also contained a good deal of yellowish lymph, which appeared to have been originally contained in some of the cysts of which the tumour was composed. The removal of the tumour was first prevented by a sort of pedicle formed of a thick, cord-like process of fibrous tissue (hypertrophied ovarian ligament). This was secured in a clamp and cut. The true pedicle was a close, broad attachment to the left side of the uterus. Holding the Fallopian tube with a vulsellum, Mr. Wells cut away the tumour, shaving it off, as it were, from the angle of the fundus uteri. There was very free hæmorrhage, which was first checked by a hæmorrhoidal clamp; two vessels close to the Fallopian tube were then tied with silk, the ends being cut short, and as oozing still continued, the whole bleeding surface was transfixed and tied in two portions with a common ligature, whose ends were fixed to the clamp. A good deal of bloody serum and some clots were sponged out of the abdominal cavity. The wound was closed by one hare-lip pin at the umbilicus, and another half-way between the umbilicus and the ensiform cartilage, and then by a number of deep and some superficial sutures of silk.

The tumour weighed thirty-seven pounds after four pounds of blood and fluid had drained away from it. It thus originally weighed forty-one pounds, and besides this there were four pounds of ascitic fluid, making a total removal of forty-five pounds. Mr. Wells showed the tumour to the Pathological Society on the 4th of April, and it was afterwards examined by Dr. Harley, of University College, and by Dr. Ritchie, who reported it to be "an immense ovarian tumour,

characterised by the number and comparative minuteness of ts loculi and by the diversity of their contents. No two loculi agreed in size or in the kind of contained fluid. The largest loculi were no larger than two closed fists, and were not near the surface of the tumour, but, on the contrary, deep in its substance. Very few of the cysts contained clear serum; several were filled with gruelly ovarian fluid; but the great majority of them contained a fluid in which were suspended flakes of fibrine in various stages of fatty degeneration. The lining membrane of some of the smaller cysts was puckered in folds. Many cysts were flattened in such a way that they could contain little or no fluid, and their agglomeration gave a solid consistence to that part of the tumour where they abounded."

The patient rallied well. An hour after the operation her pulse was 116. In the evening the pulse was 128. Four ounces of urine were passed. At midnight she was in a profuse perspiration, or rather transudation, but quite cheerful and free from pain. Next morning the pulse was 140; there was considerable tympanites; a fair quantity of high coloured urine had been passed. Mr. Wells gave five grains of quinine by the mouth, and double that quantity by the rectum, and fixed a tight bandage round the false ribs. Champagne was given freely, and beef tea was injected into the rectum, but the patient sank and died twenty-seven hours after the operation.

At the examination made eighteen hours after death, it was found that the wound was accurately united and contracted to thirteen inches in length, four below and nine above the umbilicus. The clamp was quite secure on the pedicle, and the tied omentum was well fixed to the abdominal wall by the harelip pin. Stomach very much distended, pushing up the diaphragm to the nipple. Intestines not much distended. Scarcely any marks of peritonitis, except some recent lymph over anterior surface of liver. Peritoneal surface of the wound thoroughly united, so that none of the stitches were seen. Four to six ounces of red serum in pelvic cavity, together with a few small clots. Ligatures passing from left side of uterus, and a round cord-like elongation from the left broad ligament, passed between the lips of the wound, and were fixed to the clamp. Uterus healthy, four inches long; right ovary healthy; bladder and vagina healthy. A mass of fatty fibrine as large as an apple in left broad ligament. Liver large and fatty; gall-bladder filled with gall-stones, 55 in number; heart healthy, some red coagulum in it, but no fibrinous deposits; lungs emphysematous, otherwise healthy; old adhesions at right apex; tissues not at all ex-sanguine.

Case 6.—*Adherent Multilocular Cyst—Polypus Uteri—Stricture of Rectum—Four Tappings—Ovariotomy—Recovery.*

Mrs. B., aged 42, had been a cook for sixteen years. She married when she was 27, but never became pregnant. Twenty years ago she had an attack of rheumatic fever; seven years ago went to live at Durham, and a year later she began to complain of pain all over the bowels, and of a swelling and hardness, which commenced in the right iliac region, and gradually extended over the abdomen to the left side. No notice was taken of the increasing enlargement for a period of three years. In June, 1861, she became an out-patient at the Durham Hospital, and was treated medicinally without deriving much benefit. In December, 1863, finding her tumour steadily increasing, she consulted Dr. Watkin, of Durham, who recommended her as an in-patient to the Durham Hospital. She was received under the care of Mr. Stoker, who tapped her (February 3, 1864), evacuating nine gallons of clear, thin fluid. The tapping was repeated with similar results on June 28 and on October 26. On January 31, 1865, she was again tapped, but the fluid was somewhat thicker, and not so copious.

About this time the patient was recommended to come to London by Dr. Watkin, to consult Mr. Spencer Wells, and she was admitted into the Samaritan Hospital under his care on March 30, 1865. She was of a quiet, cheerful disposition, and her constitution did not seem much broken down. Both legs were œdematous. She vomited after eating, this being evidently due to mechanical pressure of the tumour on the stomach. Her lungs were healthy, and there was no trace of disease of the heart. The urine was rather scanty, but contained no albumen.

The girth at the umbilical level was 39 inches, the distance from the umbilicus to the ensiform cartilage was 10 inches, to the pubes 9 inches, and to either ilium 11 inches. The abdomen was occupied by a fluctuating tumour, which reached upwards nearly to the ensiform cartilage. The right loin was tympanitic, the left dull. The abdominal parietes were thin, but could not be seen to move on the tumour. The catamenia for the last twelve months had lasted over a fortnight or three weeks, and had been rather abundant. On examination, Mr. Wells detected a small mucous polypus in the cervix. This he removed on April 6. The uterus was four and a-half inches long; its situation was normal. No tumour could be felt per vaginam. Mr. Wells wrote down as his diagnosis,—"Large ovarian cyst, principally simple; probably of left side, though history points to right; some attachment to abdominal wall. Large uterus, which is not very intimately connected with cyst." Ovariotomy was performed on April 11, 1865, in the presence of Drs. Reinhardt (Munich), Seidener (Crimea), Marion Sims, etc. Dr. Parson gave chloroform. The incision, five inches long, was made midway between the umbilicus and the pubes. Adhesions were rather extensive, but were easily broken up. The sac was evacuated and withdrawn. The pedicle rose from the right side of the uterus; it was three inches long, and as broad as two fingers. It was secured in a middle-sized clamp, and kept outside without traction. The left ovary was of the natural size, perhaps rather harder than usual. The wound was closed with deep and superficial sutures of silk. The weight of the tumour was five pounds. Twenty-two pints of fluid were also removed at the operation. The patient rallied very well. For the first two days there was some pain, but there was no sickness nor tympanites, and the urine was clear and abundant. The clamp was removed on the eleventh day along with the last of the deep stitches. On the thirteenth day constipation and pain were complained of, and on examination Mr. Wells detected a fibrous stricture, hardly admitting the point of the finger, in the rectum about an inch from the anus. This, on inquiry, was found to have existed long before the ovarian disease began, as she had not been able to pass a solid motion for many years. This stricture was dilated by laminaria tents, and she left the Hospital in good health on May 15, passing solid fæces more freely than she had done for several years. She called on the 23rd, looking perfectly well, and said that the obstruction in the rectum had quite disappeared.

(To be continued.)

KING'S COLLEGE HOSPITAL.

OVARIAN TUMOUR, TAPPED THREE TIMES PREVIOUSLY—OVARIOTOMY—RAPID RECOVERY.

(Under the care of Mr. FERGUSSON.)

The following points of interest are attached to this case—viz., the returning of the stump of the pedicle into the abdominal cavity, instead of its being held by a clamp and kept out of the wound, the remarkably little discharge from the wound, and the very rapid recovery which the patient made without a single bad symptom.

Esther A., aged 26, single, admitted February 28, 1865. Very delicate from a child; when 13 years of age she noticed some abnormal swelling in the abdomen; about five years ago she had a severe attack of pain, accompanied by sickness and cough; after this she remained very weak, and has since had pain (though not constantly) of a dull aching character in the right side of the abdomen; she has had no pains in the thigh.

Since this attack the swelling in the abdomen, which has not been on one side more than on the other, has been gradually increasing. She commenced to menstruate at 17 years of age, and has always been irregular, no pain accompanying the discharge; for the last two years she has not menstruated till seven weeks ago, since which time, without any intermission, there has been a bloody discharge from the vagina.

She has been tapped three times, the first time two years ago; on this occasion twelve quarts were drawn off. The second time was a year ago, when the same quantity of fluid was drawn off, and the cyst injected with tr. iodinii. This was followed by a good deal of pain and fever; it enlarged again rapidly, and in seven months was re-tapped, and a large quantity of fluid drawn off. After this a large, apparently solid, tumour was left, which she wished to have removed. It has increased very slowly latterly, and has increased uniformly.

On admission there was dulness over the whole surface, except in the left hypochondriac, lumbar, and iliac regions. Fluctuation distinct, especially over the left side; on the right side fluctuation is less distinct, and it is not communicated

from the other side. It is harder on the right side. There is no tenderness. She is a moderately healthy-looking woman. Tongue clean and moist; bowels regular; pulse 80; respiration 20, easy. She has lately suffered from pain in the right hypochondriac region.

On March 10 Mr. Fergusson operated as follows. He first made an incision of about five inches in the median line below the umbilicus. It was then found that no adhesions existed in front, and that there were two cysts. A large trocar was thrust into the larger cyst (left), and about six quarts of a dark brown liquid were drawn off. From the smaller one on the right side two quarts of a lighter coloured and very viscid fluid were withdrawn. The cyst was then withdrawn easily, it being attached by a very long narrow pedicle. The pedicle was transfixed with a needle and double ligature, the ligature divided and the needle withdrawn, and each half of the pedicle securely tied. The cyst was then cut off, the pedicle returned into the cavity of the abdomen, and the ligatures left hanging out of the wound. The edges of the wound were brought together with sutures, and a pad and bandage applied. The cysts proved to be simple, and did not communicate.

13th.—Had a good deal of retching after the operation, but this soon ceased. Slept pretty well last night. Pulse 126. No headache; tongue clean. Has very little pain.

14th.—Pulse 104; going on well; appetite good; slept well.

15th.—Pulse 100; has very little pain, and no tenderness in abdomen. Dressings removed; very little matter came out. The wound strapped. Was sick this morning; tongue clean; good appetite. Is ordered a little fish.

16th.—Pulse 96; feels much better; has no sickness, and very little pain; bowels not open since 11th.

18th.—Pulse 86; feels very well.

24th.—Ligature from pedicle came away to-day; wound nearly healed.

April 6th.—Convalescent; gets up every day; wound not quite healed.

12th.—Discharged well.

For the notes of this case we are indebted to Mr. Miles A. Wood, the dresser at the time.

THE LONDON HOSPITAL.

CLINICAL LECTURE ON A CASE OF COMPOUND DEPRESSED FRACTURE OF THE SKULL, WITH A WOUND OF THE SUPERIOR LONGITUDINAL SINUS.

By Mr. JOHN ADAMS, Surgeon to the Hospital.

Donacio L., a Malay, aged 24, a sailor, was brought into the Hospital on April 19, having fallen from the main-top-gallant mast, a height of about thirty feet, by which he sustained a compound fracture of the skull. A large wound of the scalp across the vertex of the skull revealed an extensive fracture, the bone being depressed to a great extent, but not deeply. He was sensible, and gave his name when asked, but he was labouring under severe shock, for his skin was cold and clammy, and his pulse was feeble and slow. A small quantity of stimulant was given, and he was placed in bed and kept warm. On further examination, after enlarging the wound, the fracture was found extending about three inches and a half in length, in a semi-circular direction, within two inches of the edge of the squamous portion of the left temporal bone across the vertex of the skull, and along the mesial line for ome distance in the track of the sagittal suture.

Mr. Adams determined to raised the depressed bone if possible, and he inserted an elevator in the fissure between the edges of the fracture; but on prising up the bone a quantity of dark blood flowed out, which apparently came from the surface of the dura mater. On a further attempt to elevate the bone, an immense gush of dark blood occurred, at once indicative of a laceration of the superior longitudinal sinus. All further attempts at the raising of the fracture were now discontinued, as the hæmorrhage was so copious as to compromise the patient's safety. The bleeding was checked by the introduction of a piece of lint between the edges of the fracture, but was only completely arrested by the raising of the head. To prevent the risk of any further loss of blood, a sponge was confined by the aid of a bandage carried beneath the chin, and the bleeding did not recur. A pint of venous blood had escaped, and the patient was of necessity exceedingly weak; it was, therefore, requisite to give him brandy, which raised his pulse, which was beginning to sink rapidly. His head was ordered to be kept raised, and a nurse was ordered to watch him and to apply further pressure in case of necessity.

April 20.—He was restless and weak, moaning continually during the night. He was nourished with beef-tea and a small quantity of brandy, and some saline medicine and ammonia were ordered. The wound was not touched.

21st.—He had passed a better night. As his bowels had not been opened, three grains of calomel were given him.

22nd.—He is not quite so well this morning; his pulse is hard and very slow, about 50 per minute, and his tongue is white, furred, and indented by the teeth at its edge. As the calomel had not acted, a dose of salts and senna was given. The wound looked healthy, and the plugs of lint were removed.

23rd.—His bowels were much purged during the night, and he got no sleep; the surface of his body was cold, and his pulse continued weak and slow. He was troubled much with cough, and his general sensibility was apparently unimpaired.

From the 24th to the 27th he progressed very favourably, the wound was granulating healthily, his consciousness was perfect, and he amused himself by reading.

28th.—He was seized with a violent shivering early this morning, and this recurred in the evening, but not to the same extent, but his pulse rose first to 80 per minute, and after the second fit of shivering to 120 per minute.

29th.—Much worse; pulse low and feeble, and general debility and listlessness are very apparent. He was ordered ammonia, æther, and camphor, a mutton chop, and ten ounces of wine.

May 1.—Obviously worse: his fæces and urine are passed involuntarily. He afterwards became very low—refused all food; his pulse was 150 per minute. He had no signs of hemiplegia, and becoming from day to day gradually weaker he died apparently from exhaustion on the 5th of May.

Sectio Cadaveris.—On raising the scalp the fracture was found to have extended in an oblique direction from the left temple to beyond the right parietal eminence, and thence it passed irregularly along the sagittal and lambdoidal sutures, leaving a triangular piece of bone inclosed between these three lines. The dura mater on the left side under this piece of bone, was covered with a layer of dark, fœtid, semi-fluid lymph, bearing every appearance of the residue of effused blood partially absorbed and putrid. The superior longitudinal sinus had been opened, and was now blocked up beneath the fracture with dense fibrinous coagulum. The pia mater and the arachnoid in the neighbourhood were of a dark greenish hue, and the underlying brain substance presented a dirty grey appearance. The fracture extended across the middle fossa of the skull on both sides, and the back part of the ethnoid bone was fractured.

This case, Gentlemen, is rather unusual in some respects, and deserves our attention because it involves some questions of a practical nature. We may first consider it as one of compound depressed fracture, with very slight symptoms of cerebral compression. Surgeons of deservedly great authority have laid it down as a rule that in all cases of compound depressed fracture of the skull, whether symptoms of compression exist or not, it is desirable to raise the depressed bone to its proper level; to this I by no means demur, as it is obviously the Surgeon's duty to place the fractured bone in as nearly a natural position as possible, provided this can be done without violence. But I would not advise you to follow this plan implicitly, for I have seen many cases where the bone has been found depressed extensively—I do not mean deeply—in which success has attended a strictly anti-inflammatory treatment, the bone being left *in situ*. I therefore advise you to follow Brodie's advice in such matters, to this effect—where you can raise the bone without much force, do so by all means; but do not employ the trephine or any description of saw, and thus tear away the bone from its bed of dura mater, unless the bone is deeply depressed or indented into the brain-substance. If symptoms of pressure exist, the rule to raise the bone is peremptory. Were there any symptoms of pressure in this case? I thought so, or I should have left the case alone. You will remember that when I saw the patient he was becoming insensible, and his pulse was very slow; and, although I could not detect any hemiplegia or dilated pupil, I nevertheless thought these signs quite sufficient to justify me in using the elevator. For, in cases of depression, or wherever there is a force compressing the brain, you must not expect to find all the stereotyped symptoms of compression existing together; as

unconsciousness, slow pulse, dilated pupil, hemiplegia, stertorous breathing, incontinence of fæces, and retention of urine, and think that you can by the trephine or any other means relieve your patient. No; such a combination of unfortunate conditions indicates an absolutely irremediable state of things, from which no patient can recover; and you had almost better let him alone rather than hasten his death by your trephining.

Still, do not allow me to discourage you in any attempt to prolong life. I only want to guard you against unwarranted expectations in severe cases of this description. The cases which are amenable to treatment are infinitely more simple, and if hemiplegia is clearly perceptible, even in the absence of all other symptoms, if the seat of pressure can be detected, "lay on the trephine," as the old Surgeons say, and remove the source of the mischief. During my attempt to raise the bone a small quantity of dark blood escaped, and I thought I had got in hand a case of hæmorrhage upon the surface of the dura mater; and so I had, unquestionably; but on a further attempt to elevate the bone an enormous quantity of blood escaped, and I concluded that the superior longitudinal sinus was wounded. No doubt this had been lacerated by the fracture along the sagittal suture; but I dare say I increased the rent by my attempts to raise the bone. There is, however, nothing that need disconcert you in an opening into a sinus. It is certainly not a pleasant circumstance; but the bleeding, if it takes place on the outside of the dura mater, may always be controlled by suitable position and topical pressure, as in the case before us. There are numerous cases on record of wounded sinuses which have completely recovered. When fatal, their fatality depends in some cases on the loss of blood, and in others on pyæmia and its concomitant results. When the blood is poured into the arachnoid cavity it is almost invariably fatal. I do not know that I can say more on this case to guide you in the general management of cases of such severity as the one before us. Every case must be treated according to existing symptoms, and I cannot advise you to obey any rule implicitly. It seems to me that we shall come to as correct an understanding of cases as it is possible to do if, in forming an opinion of the true pathological condition in all cases, we regard well the physiology of the parts implicated in Surgical accidents or in diseases; and the inference I would have you draw from this instance is, that, although the brain had undoubtedly suffered from general concussion, yet no amount of compression existed sufficient to obscure its functions altogether. I need scarcely direct your attention to the shivering fits, which clearly indicated some pyæmia, although no further examination of any other organ was made to verify the opinion.

There is, however, one other remark to be made, that, notwithstanding the enormous amount of injury the skull had sustained, the brain discharged its functions tolerably well, and the true spinal system of nerves were not at any time seriously compromised.

MIDDLESEX HOSPITAL.

CASE OF SCRIVENERS' CRAMP—RECOVERY BY REST TO THE HAND AND TONICS.

(Under the care of Mr. HULKE.)

A TALL, fair, copyist, aged 26, apparently in perfect health, came to the out-patient room May 16, 1864, with spasm of the flexor muscles of the thumb and forefinger when she tried to write. She said that for five years she had been in the habit of writing continuously from 10 till 5 o'clock, and sometimes as late as 11 p.m. A year ago she found a difficulty in holding her pen, and this difficulty had increased so much, that now on taking her pen it was jerked irregularly over the paper by an involuntary, irregular, spasmodic contraction of the thumb and fore and second fingers. She could, however, use her hand without trouble in dressing, and manage her knife and fork.

Writing was entirely forbidden, and she was directed to douche the hand, and take cinchona. Already, on the 23rd, there was some improvement. A trial to write was less spasmodic. In June the improvement had become decided. By the following September she could write a short letter fairly and evenly, her thumb and fingers were under almost complete control, and there was scarcely any irregularity in their movements, even when sustained.

In the following January she wrote a clear, regular hand, and took a situation as governess.

At the same time that this patient was under Mr. Hulke's care, a tailor came to the Hospital affected with a similar cramp; when he tried to sew his thumb and forefinger were involuntarily flexed on the palm. The sequel of this case is unknown, as he neglected to return.

SATURDAY, MAY 27.

THE COLLEGE OF SURGEONS' ELECTION.

THE approaching election of the Council of the College of Surgeons will now shortly take place, and the Fellows of the College, on whom the choice of representatives depends, will do well to be careful that the trust imposed upon them is well fulfilled, in order that the duties of the College to the Profession at large shall be faithfully, and at the same time liberally, carried out.

Mr. Arnott, on his retirement from his seat in the Council, as well as from the Board of Examiners, carries, we believe, with him the good wishes and the respect of the Profession generally; although occasionally having to differ from this gentleman's political views, yet we hold him to be an honest representative of a conservative system, which doubtless has done good service in its way. He retires from active life with the just honours due to an upright, straightforward man.

The Council, therefore, will have another duty to perform in choosing from their own body a representative for the General Council of Medical Education and Registration. The filling up Mr. Arnott's place in the Court of Examiners will cause the vacancy in the Council of the College for which the contest, to be decided by the Fellows, is shortly to take place. It appears, up to the present time, but two principal candidates come forward; the one, Mr. MeWhinnie, a London Surgeon, the other, Mr. Turner, of provincial celebrity; the energy, therefore, with which the Provincial gentlemen will urge their claims will be a very good test of the interest they take in the management of the College affairs. The want of unanimity of action displayed by country practitioners in their support of a provincial candidate has often been a matter of surprise to us, and we have often called attention to it in these columns. If they are content that the College of Surgeons of England is to be almost entirely controlled by elections from the various London Hospitals, well and good; we then have no more to say on the matter; but surely it cannot but be a reflection upon our provincial schools that we get no representative from our large and justly celebrated schools of the northern and midland counties. A little more union among the Fellows must necessarily lead to a more just representation of their claims; and in these days of rapid communication and travel, both by telegraph and rail, it is unfair to suggest that absence from a town residence would be assigned as a reason for neglect of the business of the College. We fear that the privilege to which we consider

all Fellows equally entitled is greatly negatived by the fact that personal attendance is necessary on the day of election; and this circumstance alone forms a most important reason why the whole system of voting should be thoroughly altered, and that the privilege of voting by proxy should be as soon as possible conceded to all the Fellows of the College. This is obviously a point for the provincial men to insist upon, and, doubtless, if they will return any country councillor who will pledge himself to carry out these views, the thin edge of the wedge will be driven further home. The newer members of the Council display a greater liberality to their fellow Professionals, and it is most certain that from the new infusion of younger blood the alterations proposed must take their origin. Let the provincial Fellows insist well on this point. Mr. Turner, of Manchester, has, at the last dinner, announced himself as a reformer, in the "virtuous and legitimate meaning of the appellation," and we feel sure that this gentleman's expressed sentiments are a genuine interpretation of his intended mode of action. We heartily wish his perseverance success. Messrs. Quain and Shaw retire, but offer themselves for re-election. We shall see whether they have come up to the mark in the estimation of the Fellows. We should like to have seen a little more of the scientific element infused into the composition of the College Council, and we confess to some regret in observing the names of Bishop and Gulliver absent. The mention of the name of the latter gentleman recalls to our mind the complete absence of any representative of the interests of our public services. This should not be.

Fellows should remember that if they have not signed the bye-laws of the College they are not entitled to vote. They will be able to comply with that condition at the next meeting of the Council.

We have suggested these points to our readers for their consideration during the next month. A number of provincial gentlemen are expected to support the chair at the annual dinner, when Mr. De la Garde, of Exeter, will preside; and on these occasions of general meeting surely some plan might be arranged with a view to carry out reforms which must originate with the great body of the Fellows.

MODERN DERMATOLOGY.—No. V.

Mr. Milton(a), whose work on diseases of the skin has only just come into our hands, treats very fully of eczema, more than a third of his whole book being devoted to its consideration. He altogether denies the vesicular nature of the complaint, and reminds us that he was at least one of the earliest to do so, having put forward his views on the subject in a paper read at the Medico-Chirurgical Society four years ago. He defines eczema as "a non-contagious inflammation of the papillæ of the skin, attended with increased nervous sensation in these parts, augmented and abnormal action of the perspiratory ducts, the contents of which often exhibit pus globules and plastic lymph, and increased secretion of very imperfectly formed epidermis, standing nearer to erythema and pityriasis than to herpes or impetigo, though capable of being complicated by both; divisible in its natural state into two great forms, the acute and chronic, between which it is not always easy to draw a clear and positive line of separation, instances out of both divisions of cure, under the same form of treatment being numerous enough." The affected surface is "weeping," not covered by vesicles; in true eczema, he says, "a portion of the skin becomes red, inflamed, and uneasy, stiff, and itching, but rarely swollen, except when the complaint attacks the ear. The cuticle rapidly dies, and is cast off, or torn by scratching. To this succeeds a discharge of serum, which, judging from the appearance of the orifices whence it exudes, is poured out by the sudoriferous ducts. When the process is more slow, the falling of the cuticle is succeeded by a cuticle thicker and coarser in its texture, and gradually assuming the look of a soft scale." In mode of treatment Mr. Milton agrees very closely with Mr. Wilson. Lowering means he rejects altogether. "Antiphlogistic treatment failed in every case of severe eczema, so far as any curative power, or any power of preventing relapses, was concerned." "It is rarely necessary to prescribe more than a gentle aperient and febrifuge." Iodide of potassium he has found useless, "except when there was rheumatism;" then it is of great service, especially if combined with colchicum. Cod-liver oil "is one of the most valuable remedies in eczema, as in so many other skin diseases. . . . and if the patient is to derive lasting benefit from its use, it should be given quite three to six months." Arsenic he gives only in the last stage of the disorder: "when the skin remains red and tender, with a quick reproduction of unhealthy cuticle or scabs, great itching, and a strong tendency in the disorder to stand still, this, and this only, is the stage for which I would recommend it, and here I think arsenic is invaluable." But his favourite remedy is iron, which he gives in large doses—"during the first year or two of life, one or two drachms of steel wine two or three times daily;" in older children, the saccharine carbonate, "or the tincture of the muriate, in doses of five to fifteen minims;" and in adults of middle age or in the decline of life, "a drachm or more may be given at a time." If pure and carefully prepared, and when "properly aided by food, exercise, baths, and aperients, it may be safely said that few, if any, cases of eczema will, in the long run, resist its influence." Mr. Wilson also, as we have seen, gives iron, but combines it with arsenic. If, after a full trial of steel, the disease persists, Mr. Milton would give cod-liver oil and arsenic; these failing to cure, he recommends the biniodide or bichloride of mercury—"from an eighth to a sixth of a grain once, twice, or three times a day." Mr. Startin also, we believe, relies greatly on the bichloride of mercury for the cure of eczema. Whatever course of treatment be adopted, says Mr. Milton, it must be steadily persevered with, and success will follow; but if the "guiding principles of treatment are every now and then to be abandoned for the sake of meeting some complication, or in deference to some theory, or out of dread of some imaginary danger, then good-bye to all chance of a cure."

For external treatment Mr. Milton adopts very nearly the same means as Mr. Wilson. Of tar and creosote he speaks in terms more graphic than elegant—"nearly every writer recommends them, and I believe few use them. In creosote I confess at once I have very little faith; I never saw any particular benefit from it in any skin disease. Tar makes such a filthy mess that I doubt if it will ever come into general use, and how Hebra can get his private patients to rub in a mixture of tar and cod liver oil quite passes my comprehension."

Mr. Milton devotes considerable space to the consideration of the question, "Is it ever dangerous to cure eczema?" and answers it with a decided negative. "I always," he says, "do my best to cure eczema at once, under whatever circumstances I meet with it, and in no instance have I ever seen any ill effects from checking the discharge."

Mr. Wilson differs from most modern dermatologists in the sense in which he uses the term psoriasis. MM. Bazin and Hardy and Dr. Hillier employ it as synonymous with lepra, and indeed almost discard the latter term, and describe lepra vulgaris, etc., as varieties of psoriasis. Dr. Hillier says, "Psoriasis is a convenient term to employ for a distinct and well-defined disease, including what Willan intended by lepra, or lepra of the Greeks, and all other varieties of skin disease, in which the cutis is reddened, thickened, and covered with an increased formation of epidermic cells, adherent to each other and to the skin, but rubbed off without much difficulty, and not characterised at any stage by vesicles, pustules, or ulceration."

(a) On the Modern Treatment of some Diseases of the Skin. By J. L. Milton, Surgeon to St. John's Hospital for Skin Diseases. Pp. 116. London: R. Hardwicke.

Hebra and other German dermatologists employ the term in the same way. Mr. Wilson, on the contrary, confines the use of it to signifying a form of chronic eczema, "squamous eczema of the trunk and limbs," as pityriasis is squamous eczema of the scalp; "that state of skin in which the integument is red, coarse, thickened, wrinkled or smooth, brittle, dry, itchy, and desquamating;" while to designate lepra and its varieties, vulgaris, guttata, etc., he revives the old term *Alphos*, which he makes do duty for the lepra and the psoriasis of the other dermatologists; and while the French dermatologists regard lepra or psoriasis as "*the dartre* of persons of a sanguine temperament," Mr. Wilson separates it from the "eczematous affections," and forms a distinct class of "Alphous affections." His class of "Leprous affections" embraces the "consideration of the true or ancient lepra, the elephantiasis of the Greeks, and all the varieties of this grave disease—the principal forms being included under the heads of lepra and vitigo."

Much inkshed and some confusion will probably be excited by this proceeding of Mr. Wilson's; but such a multiplication of synonyms has obtained in the nomenclature of squamous diseases of the skin, with such consequent confusion, that one cannot wonder at Mr. Wilson's going back to Celsus and other ancient writers and attempting to restore the limited nomenclature of their days. As the part at present published of his "Handbook of Cutaneous Medicine" does not include the class of "alphous affections," we cannot give any exact account of his differential diagnosis between psoriasis and alphos, but in the last edition of his larger work it stands thus. In alphos "the hypertrophy of the skin is the greatest; the patches are circular in form, elevated above the level of the surrounding parts markedly, healing from the centre, never attaining a large size; the scales are thick, regular in structure, and the disease is more amenable to treatment than *psoriasis*, in which the hypertrophy is less, the patches irregular in form, less elevated, healing irregularly, always attaining a large size, the scales being thinner, irregular in structure, the disease being less amenable to treatment." Dr. Tilbury Fox observes, "Regarding these differences as those of degree, not kind, I shall describe lepra and psoriasis under the term lepra, recommending, with Mr. Wilson, the adoption of alphos." Mr. Wilson would probably in the diagnosis between the two diseases give considerable weight to the history of the disease, especially as regards its outbreak and the parts of the body it most affects, lepra, or his alphos, notoriously attacking by preference, and most persistently lingering in, the parts of the skin where the epithelium is thick, especially the elbows and knees. All the dermatologists allow that alphos is non-contagious, and that its hereditary tendency is well established. But very little is known as to its etiology. Mr. Wilson says, "The cause is a special poison, the nature of which is obscure. I have stated my belief, and I see no reason to change that opinion, that the leprous poison is in its essence and origin *syphilitic*—that it is, in fact, a manifestation of the syphilitic poison after transmission through at least one, and probably through several generations;" and in support of this opinion he adds, "I have published one example, and seen several, of a real lepra (alphos) vulgaris in the children of a man who was under my care for the remote effects of syphilis, and who appeared besides to have had congenital syphilis." Dr. Tilbury Fox agrees with Mr. Wilson in this opinion as to the cause of the disease. The French dermatologists, we have already said, consider it to be the *dartre* of the sanguine temperament. Devergie states that of 200 cases, 162 were of this temperament; but this really amounts to very little more than a statement of an universally admitted fact—viz., that the disease, in the vast majority of cases, appears in strong, apparently healthy persons. All classes are liable to it, and it has been attributed to an immense variety of influences—climate, humidity, changes of temperature, mode of life, gastro-intestinal irritation, chlorosis, arthritis, drinking cold water when heated, cessation of established discharges, diet, mental states, certain occupations, etc., etc.—into the effect of all of which Hebra has very carefully examined, and has arrived at the conclusion that none of them can be truly counted as causes. Dr. Hillier says, "It is usually stated that psoriasis is caused by a great variety of conditions; but there is little evidence of the truth of these statements. It would rather appear that it may occur under very varying conditions, and that the cause is not known." In this journal, vol. ii., 1864, p. 93, will be found a statement of the views of Dr. Wertheim, of Vienna, on the production of the disease. "Having observed that the arms of such patients (with psoriasis) become, after a few days, the seat of a fungous growth, mostly of the species known as the penicilium glaucum, while that of other patients did not," he injected an emulsion of the fungus into the crural veins of some dogs. Twenty-four hours after the injection isolated red spots, slightly elevated, appeared upon the extremities, and a repetition of the injection rendered the spots more active. Similar results resulted from injecting an emulsion of yeast from beer. "On examining the eruption, which, in its seat, symmetry, shape, and progress, presented many analogies with psoriasis, microscopically he found it to be the result of obstruction of the cutaneous capillaries by the vegetable elements injected. Applying this observation to psoriasis in man, he regards the entrance of parasitic vegetable elements into the circulating system as the cause of the cutaneous lesion, and explains the greater prevalence of the disease in man (245 males to 25 females, according to Devergie) to their consuming more of alcoholic beverages than women do." We are not aware that any other dermatologist has accepted this hastily-formed theory; and certainly it seems to have very little claim to serious consideration. The presence of the penicilium is accidental in, and by no means peculiar to, psoriasis; it, like other substances, only mechanically obstructs the capillaries; and "anatomically, psoriasis is hyperæmia and exudation into the upper layers of the cutis, with an increased production of epidermic cells" (Hillier). Can a mechanical obstruction of the capillaries cause this in twenty-four hours?

In the treatment of alphos, most dermatologists recommend some form of arsenic as *the* remedy. In his lately-delivered address on skin diseases, Mr. Wilson says:—"There is one disease—namely, alphos—in which arsenic is the only known remedy. In this disease there is no disorder of the general health, and the medicine may be commenced without previous preparation of the patient;" but this rule must not be indiscriminately applied; there are many exceptions to it. As Mr. Wilson states in his larger work, "the leprous patient may suffer from other diseases, these are apt to constitute so many complications of lepra, and may require to be relieved before the special treatment is commenced, or, at any rate, consentaneously with it." In a person predisposed to the disease, any disturbance or lowering of the general health, as excess in wine or food, overwork, hyperlactation, disorder of the stomach from any cause, etc., will bring on an outbreak of the eruption; in such cases the first indication is "the removal of complications, together with the regulation of the assimilative organs," and the treatment must consist of "gentle aperients, salines, bitters with alkalies, bitters with mineral acids, colchicum, etc." By these means the patient may be restored to health without the use of arsenic or any other remedy specially directed against the skin affection. Mr. Wilson's remarks on this point are well worth attention, and will apply to the treatment of many other diseases besides that in question. "Occasionally," he observes, "the effects of this treatment are very remarkable. With the improvement in the general health, the lepra is always improved, and sometimes will get entirely well without specific remedies. The Practitioner must not, however, in this event rush to the conclusion that the remedies have cured the lepra, and will, therefore, cure it again. . . . . The Medical man allays the constitutional disturbance, and the lepra gets well—not by the virtues of his medicine, but spontaneously. It is the

failure to see this fact in its true light that imports so many remedies and suggestions into the treatment of lepra—remedies which flourish for a week in the periodical in which they first appear, then probably languish for a year in some annual abstract of delusive cures, and then are forgotten for ever, and deservedly so, not even leaving behind them the appreciation of that small, thin streak of truth upon which they were founded."

The general health being restored or undisturbed, there is, as we have remarked, according to most authorities, "but one reliable remedy"—arsenic. But here again we will quote a caution given by Mr. Wilson:—"Arsenic will cure lepra with certainty; but neither arsenic nor any other known medicine will prevent it from returning again. Sometimes, after a thorough dispersion by arsenic, the eruption never reappears; but more frequently it recurs the following year, or after a lapse of several years."

English dermatologists most generally prefer Fowler's solution; some few employ the liquor arsenici chloridi (P.L.); it is of rather less than half the strength of the liquor arsenicalis, and does not seem to possess any decided advantage, though it may, perhaps, be sometimes useful to be able to give it in combination with the nitro-muriatic acid. Bazin gives arseniate of ammonia or of iron; Hardy the arseniate of soda; he also very strongly recommends the tincture of cantharides and the balsam of copaiba; but Dr. Hillier observes: "I have had so little occasion to be dissatisfied with arsenic that I have not given cantharides a good trial;" and Mr. Wilson also says: "In the presence of so excellent and certain a remedy as arsenic, it is difficult to find an opportunity for making trial of these other medicines." Dr. H. Bennett, Biett, and some others, have recommended the combination of arsenic and cantharides.

As to local treatment, Mr. Wilson is of opinion that "for the cure of lepra it is useless; but various indications present themselves which render local treatment for the relief of irritation of the skin advantageous and necessary;" while with Hebra it is a very different thing. Dr. Tilbury Fox says, "Hebra believes it (local treatment) to be the *sine quâ non*, the *alpha* and *omega* of treatment. The French Physicians hold the medium view. I confess that local means serve to advance the recovery very much." Tar, in some form or another, is the most general favourite of local applications, and after that the oil of juniper, or *huile de cade*. "Tar may be used alone, or in the form of an ointment, with equal parts of lard. Hebra advises its employment in the form of a soap, or equal parts of soft soap, spirits, and tar may be used." The scales must be first removed, by water dressing or other means, and then the stimulating remedies rubbed firmly and freely into the skin. Dr. Tilbury Fox advises, for local treatment, "baths—hot vapour, sulphur, and alkaline; the former and the latter are useful in detaching the scales and allowing the proper action of other remedies, and also induce the skin to return to its natural action. When the patches have been denuded of their scales by maceration or bathing, the best application is tar, either with glycerine or alcohol; generally about equal parts make a proper application. The tar should be applied at night, or night and morning, for some time. The oil of juniper, or *huile de cade*, is efficacious." Sometimes soothing measures are necessary, as glycerine, oxide of zinc, and aq. calcis as a lotion, or alkaline baths and lotions. Hebra has also found the hydropathic treatment decidedly beneficial in some cases. Most dermatologists, however, appear to agree more nearly with Mr. Wilson than with Hebra, and to hold that "the local treatment of lepra is not to be regarded as curative; it is simply palliative; the cure must come from within, from that improved and altered state of the blood which results from the proper administration of arsenic."

Her Majesty has been pleased to appoint Horace Watts, Esq., M.D., to be Colonial Surgeon for the Falkland Islands. —*London Gazette*, May 23.

HOSPITAL FOR LADIES.—INSULT TO THE MEDICAL PROFESSION.

There are two ways of rising above one's fellows in Medicine. One is the exceedingly troublesome, laborious, and expensive method of abandoning the small fees of general practice, and devoting the earlier and better years of life to a prolonged studentship. Such is the fate of men who "keep about the Hospital" when their usual term of study is past, who are found doing all sorts of work in museums, laboratories, Hospital wards, and dissecting-rooms; and if such men succeed to Hospital appointments, and if thereby the Hospital appointment seems to be the mark of a scientific worker, it must be recollected that such men have fairly raised themselves to begin with, and that the appointment acquires half its prestige from the character of the men who have heretofore filled it. But it is possible to conceive of another set of men, who try to make themselves famous, not by rising above, but by endeavours to depress and vilify their brethren.

We do not know the names of the gentlemen who are attached to a new "Hospital for Ladies" in Soho-square; but we are sure that they will thank us for giving them the opportunity of repudiating all connexion with the latter set of "distinguished specialists," and of disclaiming all complicity with a foolish and offensive paragraph in *The Times* of Monday. This paragraph claims for the new Institution the credit of being the first to throw open comfortable wards for ladies of limited incomes; whereas a highly respectable Home for invalid ladies has been in existence in Harley-street for many years. The ground upon which the new ward for ladies claims public support, is—not merely charity to necessitous gentlewomen—but the ignorance of the Medical Profession!

"The misfortune is," we are assured, "with regard to most of the maladies of women, running, as they do, through every degree, from simple headache to palpable wasting away, that so little is known of them by the Profession generally"!

Not content with this insolent libel on the Medical Profession, the writer goes on to invent an ideal state of society; he *finges* (if we may coin a word) a set of men in respectable positions eager to send their wives out of doors, and destitute of female relations and nurses, to perform the commonest ministrations to the sick!

"In the ideal state of society it would, of course, be the duty of the husband, when failing health arrives, to take his place by the wife's pillow and to tend her lovingly, as he himself was tended. But is this possible? Not to descend to the case of the working classes, with whom such a cessation of labour would involve a stoppage of wages, and consequent withdrawal of the very supplies of which the wife, or sister, or daughter stands most in need, there are thousands of men in respectable, even influential positions, who would find themselves as much incapacited from regular attendance by the sick bed as they would be out of place if they actually were there."

Then follows that absurdest of views, that people are better off, and better attended to, in Hospitals than in their own homes; just as if the "eminent Doctors" who hold Hospital appointments lived within the walls, and were always within beck and call.

"For the most part, heads of families can and do pay heavy Doctors' bills, but they never can insure that those for whom they would gladly coin their blood receive that attention which their case requires. The remark has a good deal of truth in it that poor people if they could only stay long enough in Hospital, have a better chance of recovery than the rich, because they are surrounded with every Medical appliance, are under the supervision of an experienced staff, must submit to the rules of the establishment, and, should a crisis arise *there is no time lost in sending for a Doctor—he is at the bedside in an instant*. What an ease it would be to many a father's, brother's, husband's thoughts if he could feel that one of his flock,—it may be his only female companion,—instead of pining in solitude and ill-health at home, half-cared for by the servants, and *visited by the Medical man at hours suiting his own con-*

venience, was in a private ward, comfortably fitted-up, and rendered by payment as much her own for the time being as any furnished apartment, with the advantages of the *best Medical advice* and the attendance of skilled nurses! There is another view of the subject. At present one of the most untoward events that can happen in a household is for the governess to fall sick. In the first place, illness, with its concomitants of Professional visits, is never agreeable; and servants continually refuse to wait upon invalids who are not strictly members of the family."

The tone of the entire article entitled "Hospital for Ladies," in Monday's *Times*, is unjust towards the general Medical Practitioner, whom it charges with ignorance of a very common class of female maladies. It looks like a puff of the gentlemen attached to the new Hospital, whose merits, be they great or little, cannot be enhanced by any attempt to depreciate their brethren. It tends to depreciate English home habits, and to promote the custom of sending away the sick amongst strangers. It promotes still further the prevalent curse of gratuitous Medical attendance; and it fosters the unchristian habit of not regarding governesses, and other persons occupying a similar position, as part of a family, but as mere tools or drudges, to be worked whilst well, and turned out when sick to the tender mercies of an advertising "charitable" institution.

THE WEEK.

THE NAVAL MEDICAL SERVICE.

In our last issue we noticed the fact that a distinguished body of Naval Medical Officers had waited on Sir John Liddell, late Director-General of the department, and presented him, in the name of a large number of the corps over which he had lately presided, with a handsome testimonial of their esteem. Such spontaneous offering to a chief on withdrawal from public life is as honourable to the donors as to the recipient, and we doubt not that to the former it will afford a pleasing recollection through life. The sense of disappointment which Sir John Liddell so freely expressed, in returning thanks, at his want of success in carrying out his reforms of the Medical establishment of the Royal Navy, must be cordially accepted by the corps as the assurance of there having been no "want of will" on his part to efface those inequalities which depreciate the Navy Medical officers. Nor should the corps be depressed that an officer of his standing and distinguished services admits his inability to counteract the opposing influences of a Board composed of officers of the so-called executive class, who, with a petty jealousy, conceive their prerogative invaded by the just progress of the non-combatant element of the Service. Rising, as the Medical Profession is, in general society, it will not calmly look on while a portion of its body—hitherto as much distinguished by Professional acquirements as by the high social position some of its members have attained—is withered by the neglect of the naval authorities and deteriorated by the admission into the rank of junior officers, of a large proportion of men whose chances of success in private life may be judged as very small, after the ingenuous report of their practical qualifications rendered by the examiners appointed by the Admiralty. We do not hesitate to state our belief that not merely the naval service, but the entire Profession has had a benefit conferred by that Report, and we should regret to find that on the score of expediency this faithful guardianship of the portal of admission to the navy had been set aside or weakened by the substitution of any less severe scrutiny. The disadvantages the united services of navy and army suffer have been thoroughly investigated by a Committee of the Royal College of Physicians, who being thus introduced fully to a knowledge of the real state of things, have expressed opinions thereon that have seemed too strong to the minds of the Fellows of the College who have not assisted in the inquiry. We have already expressed our opinion of the conduct of the College in this matter. We do not concur in the desirability of the leading body of the Profession, which holds most direct relations with the Government offices, avoiding a Collegiate expression of opinion on the ground that it may, in the slightest degree, involve their relationship, and we regret that for reasons of policy the report of their Committee, which cannot be controverted, should be retarded in its effect. We are constantly receiving letters of complaint from Naval Surgeons concerning the manner in which the Naval Warrant of 1859 has been frustrated; and if any corroboration was necessary of the literal correctness of the Committee's Report, as far as the navy is concerned, our portfolios could amply afford the same. We believe, however, that the words of Sir John Liddell—"I have not succeeded in attaining all the good I tried to accomplish"—will sink deeply into the mind of the service, and will suffice to show the timid and uninformed sections of the Royal College of Physicians that the Naval Medical Department requires reforms which its late worthy chief was unable to establish, and that, therefore, the case stands in need of the helping hand from the Profession which they are supposed to represent.

DEATH IN A BOX.

We have received an account of a coroner's inquest lately held at Liverpool, which, as a tale of marvel and mystery, might have challenged the powers of the late Edgar Poe to surpass it. To say that the solution of the mystery, which appears to have been accepted on very scanty evidence by the coroner's jury, was an impossible one would, perhaps, not be justifiable; but on the face of the tale it must strike any Professional reader as most improbable and unsatisfactory. The facts are shortly these:—The deceased was a married woman, and an inveterate drunkard. She was short of stature, five feet high, and very thin. Her husband stated that he last saw her alive on Friday afternoon. She was then drunk. He had put her out of the house, but she got a ladder and effected an entrance into her husband's premises by climbing over the wall of an adjoining yard. In getting over the wall, she was seen by her husband's brother to fall "head first" upon a barrel of ginger-beer bottles, and then upon the flags. He saw her roll about, and when she got up she seemed hardly to know the way into the house. The brother, however, heard her go upstairs, and he saw her soon after asleep in his bed. The brother and husband slept together that night, and they heard her snoring. Nothing more was seen of her, according to the evidence of the husband, until between three and four o'clock on Saturday. He states that he then found her dead in a clothes box in his bedroom.

"He went to the box and tried the 'hasp,' and found that it was broken. He then caught hold of the lid, and found that it was loose. On opening the box he found the deceased there. He could not see her flesh; he could only see her back. She had a cloth jacket on. Witness put his fingers on her back, and found it was quite stiff. Her face was down at the end of the box. She was doubled up."

The box measured 2 feet 1½ inches in length, 1 foot 6 inches wide, and 1 foot 5 inches deep. The deceased woman is said to have been wedged in the box, with her head and knees underneath her body.

These are the main facts of this most curious case. The inquiry into the mode of death seems to have been conducted by the police in the loosest possible manner. Although warned by the Surgeon, Mr. E. Taylor Gibson, who was called in, they took the body out of the box, had it straightened, and washed. They then directed Mr. Gibson to make a post-mortem examination, and he, without receiving the Coroner's order, incautiously complied. For this he was reprimanded and mulcted of his fee by the Deputy Coroner. Mr. Gibson seems not to have formed a very clear idea of the cause of death:

"He found on each temple a bruise—the only external marks of violence. On opening the skull he found ecchy-

mosis under each of these bruises. The brain was greatly congested. Falling from the wall as described would account for the ecchymosis, and in his opinion 'the cause of death was from falling,' combined with the congested state of the brain."

On being cross-examined by the Deputy-Coroner, he said that he could not say whether the congestion of the brain was produced by the fall or by suffocation from confinement in so small a space. His theory was that she had got into the box herself, although neither he nor any other witness explained how a person under such circumstances, with the head and limbs bent under the body, and the back uppermost, could have replaced the lid of the box. Mr. Gibson afterwards, in cross-examination, allowed that suffocation was the cause of death, and the jury returned a verdict of "Found suffocated." The jury, it will be observed, appended to their verdict no word of doubt as to the mode in which the woman got into the box, although to us it seems almost incredible that a woman with her clothes on could have coiled herself into a space scarcely more than two feet long, a foot and a half broad, and a foot and five inches deep, have replaced the lid, and then placed herself in the position in which she was found. This theory seems to have satisfied the Coroner's jury and the Deputy-Coroner, for the only doubt the latter expressed was as to the worth of the Medical evidence. To us the Medical evidence only seems to have shared the unsatisfactory and inconclusive character of the whole inquiry.

THE MERCHANT SEAMEN AND GREENWICH HOSPITAL.

(From a Correspondent.)

The Seamen's Hospital Society have, by the advice of their Medical officers, elected to abandon the *Dreadnought*, and to find a home on shore. It is well known that the Lords of the Admiralty have decided to empty Greenwich Hospital, and to create a system of out-pensioners' allowance. In a very short space of time that immense mass of buildings, with the exception of the Hospital proper, will be unoccupied. The claims of merchant seamen to the benefits of Greenwich Hospital have been always superlatively great, for the mercantile marine of Great Britain has, directly and indirectly, subscribed many thousands of pounds to the institution in question, and has received no kind of equivalent help therefrom. We hear, nevertheless, from unquestionable authority that the Seamen's Hospital Society have purchased a site for their building close to the walls of Greenwich Hospital, and from the Greenwich Hospital Commissioners, and we cannot refrain from commenting on the manifest injustice that has necessitated such a proceeding. The funds of the *Dreadnought* were, from 1845 to 1854, assisted by a grant from Government of a percentage from the Merchant Seamen's Fund, and afterwards by a certain proportion of the unclaimed wages and effects of deceased merchant seamen, which aid amounted to an annual income of £1500. But in 1854 this sum was withdrawn from the Society, since which time no Government help has been given to the support of the *Dreadnought* Hospital, though an annual sum of not less than £9000 is paid into the Exchequer from unclaimed wages and effects of deceased merchant sailors. A Hospital established for the exclusive benefit of the mercantile marine of this country ought, surely to have some claim upon such a source of revenue. The *Dreadnought* is burdened with an expenditure not incidental to other Hospitals, having to bury, at the expense of the institution, the large majority of those who die within its walls. It is, therefore, a paramount duty on the part of the Admiralty either to grant to the Seaman's Hospital Society a liberal annual payment from the unclaimed wages' fund, or (and which seems the natural course) to offer to them a part of Greenwich Hospital. That noble pile would then be restored to its original and intended uses, and we should then have a home for sick sailors worthy of the nation and its commercial prosperity.

PARLIAMENTARY.—THE BRITISH MUSEUM—THE UNION CHARGEABILITY BILL—IRISH LUNATICS—MR. SIMON'S AND DR. HUNTER'S REPORTS—THE SALARY OF THE MEDICAL OFFICER OF THE PRIVY COUNCIL—THE NOXIOUS VAPOUR ACT.

On Thursday, May 18, in the House of Commons,

The Chancellor of the Exchequer, in reply to Mr. Augustus Smith, said no Bill for the removal of any part of the collections in the British Museum would be introduced till the House had had an opportunity of discussing its main principle; no plans or estimates could be prepared till the questions pending between the Board of Works and the trustees had been settled.

The House went into committee on the Union Chargeability Bill.

On Clause 2, Mr. Henley moved amendments which would have the effect of repealing the Acts authorising the removal of the chargeable poor "to any other union or parish, or to Scotland and Ireland." The abolition of this system, he said, would be a great boon to the poor. No inconvenience had arisen from the successive limitations that had been enacted of the power of removal. They had been gradually approaching the point of abolition, and might now as well do away with the system altogether.

Mr. Ayrton spoke in favour of Mr. Henley's amendments. The present system had demoralised the poor to such an extent that on any given day there were in England, though so rich a country, more than a million of paupers on the relief books. He hoped the Government would consent to the proposal, or, if there were any practical objections to including it in the present Bill, would undertake to accomplish it by a separate measure.

Mr. C. Villiers acknowledged that the proposal of Mr. Henley had taken him by surprise; he had not expected to hear such views from him. Considering that Mr. Henley had always opposed such changes, he had a right to doubt the character of the proposition. The public would also require some explanation of it. He believed it was intended to create alarm in the country as to the extent to which this Bill would go, and, by an amendment, get rid of the measure altogether.

Mr. Henley wished the House to take notice that the Government admitted his proposal to be a sound and good one, but that it was rejected because it came from the Opposition side of the House. He certainly had always advocated the parochial system, and still thought it the best; but, the House having decided by a very large majority to abolish it, was there any inconsistency in his proposing that the Law of Settlement should go with it? He denied that he had taken the House by surprise, as he had placed his notice on the paper before the recess.

After a few words from Sir R. Knightley and Mr. Gilpin, The Committee divided. The numbers were—

For the amendments	110
Against	184
Majority against the amendments . .	74

Mr. Kekewich then proposed an addition to Clause 2, enacting that after the 25th day of March, 1866, no persons shall be removable from any parish or union in which "they shall have resided for one year," next before the application for the warrant for such removal.

Mr. Locke said such a provision would inflict great injury on the poor parishes of the metropolis.

Mr. Villiers admitted that one year's residence was sufficient to entitle a man to a settlement, and would not oppose the amendment of Mr. Kekewich. As to the inequality of the rating in the London parishes, it was an evil generally acknowledged. The remedy, of course, was a readjustment and better distribution of the rate, on a principle similar to that of the present Bill. He should be glad to introduce such a measure for the metropolis if it had any chance of success.

The words proposed by Mr. Kekewich were added to the clause, which was then agreed to.

The remaining clauses were passed, and the Bill, with amendments, was ordered to be reported.

On Friday,

Mr. McEvoy, in calling attention to the number and treatment of lunatics in Ireland, said of 16,600 lunatics 8000 were confined in gaols, workhouses, and lunatic asylums. The management and treatment of lunatics, therefore, became an important question. There were at present in the gaols 669 who had been committed as dangerous lunatics; and a very large proportion of these had remained in prison for a con-

siderable period. The retention of lunatics in gaols had been condemned by the inspectors of both lunatic asylums and prisons. In the first place, the health of the lunatics was not sufficiently looked after, and the discipline of the gaol was very much impaired. The last report of the inspectors of lunatics recommended that the Irish system should be assimilated to that of England. It was a most improper practice to commit lunatics to gaols or to confine them in workhouses—they should be sent to proper lunatic asylums, where there would be a prospect of a large number recovering their reason.

Sir R. Peel said the hon. member was doubtless aware that Government were doing their best to remedy the want of proper lunatic asylums in Ireland. When the six new asylums they were building, in addition to the sixteen already in existence, were completed there would be no want of accommodation for lunatics, and, except in the metropolitan districts of Dublin, there would no longer be any necessity for confining them in gaols or in workhouses. Even under the present arrangement, whenever a lunatic was certified by the proper Medical officers of the gaols to be dangerous, he was, if possible, at once removed to a lunatic asylum. The Government were devoting the most anxious attention to that subject, and in the course of less than three years every one of the district asylums, with the single exception he had mentioned, would be completed, and there would be every accommodation for all the dangerous lunatics who either now or who might hereafter be committed to gaols.

Mr. Blake thought that, considering the importance of placing dangerous lunatics under proper treatment in the earliest stages of their malady, the magistrates in Ireland should have the power of sending them in the first instance to the asylum instead of the gaol.

Sir C. O'Loghlen concurred in thinking it would be desirable, when the district asylums were completed, that magistrates should be empowered to commit dangerous lunatics direct to those institutions.

In Committee of Supply, on the vote of £13,824 for the department of the Privy Council,

Sir J. Jervoise observed that he did not think the country got value for the £1500 paid to the Medical officer of the Privy Council. Considerable sums had been spent on experiments connected with vaccination. He thought that the experiments and reports of the Medical branch of the Department were superficial, and the conclusions come to not very satisfactory.

Colonel Dunne wished to know was this Medical officer the gentleman who had made the very elaborate report which had been used by the Government in the recent debates on the Poor-laws, and who seemed to have a very slight acquaintance with truth. If so, the salary ought to be stopped. In referring to that report, his observation was founded on the statements made by hon. members in the course of the debate.

Mr. Bruce said that the document referred to by the hon. and gallant member had not been prepared by the Medical officer of the Privy Council, but by a gentleman specially employed for the purpose. He was not, however, prepared to admit the justness of the criticism passed on that report. On the contrary, after a conference which he should have with Dr. Hunter on Monday, he expected to be able to state that gentleman's reason for those statements which had elicited the accusations made against him. He alluded more particularly to those of the noble lord the member for North Leicestershire. With respect to Dr. Simon, he must say that he did not know a more able or a more hardworking man. Year after year increased attention was paid to sanitary matters, and valuable reports were made by the Medical branch of the Privy Council Department.

Sir W. Jolliffe thought that the Medical branch was a useful one; but at the same time he was of opinion that the department would do well to exercise a little more vigilance with respect to the reports, in order that those documents might not excite the criticism, not to say ridicule, of the House.

Mr. F. Powell wished to know how the special report was to be paid for. How did it appear in the Estimates? He was not prepared to join in the remarks which had been made adverse to it, because the more clear and bold the colouring of pictures relating to the domiciliary arrangements of the poor the better. He felt sure that a state of things far more disgraceful to our civilisation would be found in our manufacturing districts than that reported in the agricultural neighbourhoods. As an owner of property in the former districts, he had found himself continually foiled in his efforts to provide for the manufacturing classes dwellings more favourable to decency and comfort by the ignorance of the very people for whose welfare he had expended his money. It was of no use to furnish their rooms with the means of ventilation if the people would never open the windows; when he had made arrangements for ample and separate sleeping accommodation a large portion of the space so provided would be used for the purposes of lumber and storage, and the whole family would crowd into one room. Instead, therefore, of reporting adversely upon the condition of the agricultural districts, he hoped that the Medical officer would give an impartial description of the existing state of things in both agricultural and manufacturing districts.

Mr. Bruce said the scheme alluded to by his hon. friend was included in the contingent expenses under the Public Health Act, 21st and 22nd Victoria, cap. 97, which amounted to £7000, including £2000 for the National Vaccine Establishment, and £2000 for vaccination inspection. He might also mention that the Report alluded to contained a great many particulars with reference to an outbreak of fever at Manchester, and that all the reports which had hitherto appeared had treated the subject of our large towns at considerable length. He believed that Dr. Hunter had been most unjustly charged with presenting a report in which his adverse criticism was the result of animus.

Mr. Hunt believed that Dr. Hunter's inquiries would lead to more accurate reports if some notification of his intended visit to any part of the country were made by that gentleman, so that persons in the neighbourhood might have an opportunity of furnishing him with correct information and of rebutting charges made by interested parties.

Colonel Dunne was unable himself to judge of the accuracy of Dr. Hunter's Report, but a distinguished Member of the House had said that it was incorrect, and that statement was echoed on both sides of the House.

The vote was then agreed to.

In the House of Lords on Monday, May 22, on the motion of Lord Kinnaird, the order for the second reading of the Metalliferous Mines Bill was discharged.

At the suggestion of Lord Granville, the Sewage Utilisation Bill was referred to a Select Committee.

Lord Derby called the attention of the House to the Report of Dr. Angus Smith on the results of the Noxious Vapours Act. The facts stated in the Report were, he said, very remarkable. They proved that though the Bill had been in operation less than a year, it had been very successful. He read several of the scientific details of the Report, showing the quantities of deleterious gases that, by the provisions of the Act, had been prevented from passing into the atmosphere, into which they were before allowed to escape. These results, he argued, were very encouraging, as proving what could be done by applying the discoveries of modern science to the processes of manufacture. No subject better deserved the consideration of a Government, or the efforts of statesmen, than how to effect these changes by means of legislation, as it was possible, without injury to manufacturers, to improve agriculture and benefit the health of the people.

Lord Stanley of Alderley admitted the good results of the measure, but feared there were difficulties in the way of extending similar legislation to other kinds of manufactures.

In the House of Commons,

On the order for considering the report of the Union Chargeability Bill, as amended,

Mr. A. Bruce justified the statistical facts referred to, and replied to the objections which had been urged by Mr. Henley to the Report of Dr. Hunter on the subject of the demolition of cottages, the correctness of which he defended, though not all the expressions in the Report.

Mr. Henley explained the remarks he had made upon the Reports of Mr. Simon and Dr. Hunter. The latter, he said, had brought a broad charge against the rural landlords of driving out people by the demolition of cottages. That was the charge he (Mr. Henley) had endeavoured to meet, and he did not think that Mr. Bruce's explanation had altered the case. He referred to other matters in the Report of Dr. Hunter, which he thought evidence of unfairness. The view he took of the motion before the House was that it was a protest against the exemption of certain species of property from a fair share of the burden of the poor.

Mr. Portman pointed out instances of inaccuracies in Dr. Hunter's Report.

The discussion, which had wandered a good deal from the

subject of the motion, was continued by Lord Henniker, Sir H. Verney, and Mr. Scourfield.

Mr. Villiers, after noticing the erratic character of the debate, and replying to criticisms upon the Report of Dr. Hunter, who, he believed, had understated the case, said he had not depended upon that Report; there were authorities without number in favour of the Bill.

FROM ABROAD.—FRENCH OPINIONS ON JENNER—PROCESS OF DEGLUTITION—THE FRENCH SCIENTIFIC CONGRESS.

One of the most attractive discourses upon the History of Medicine, now weekly delivering at the Paris Faculty of Medicine under the name of "Conferences," was that of M. Lorain on the life of Jenner. It was immensely applauded by the crowded audience, but the Medical critics are not quite agreed in their appreciation of it. M. Tartivel, in the *Union Médicale*, believes that M. Lorain only did justice to his subject in the eulogium he passed:—

"Jenner bears no resemblance to the discoverers of our time. His was the glory to close the last century with the greatest and most useful discovery that has been made in Medicine; and yet he never dreamed of assuming the air of a demigod or of procuring statues to be raised to himself while living, and it is doubtful whether he would have willingly seen his photograph in the print-sellers' windows. He was truly a great man, and, had Diogenes met him, he would have extinguished his lantern. He was simple and modest, and when his name had become celebrated all over the world he had the good sense to remain a country doctor. He traversed fields, plains, mountains, and valleys, whether on foot or on horseback, going from village to village, hamlet to hamlet, farm to farm, visiting his patients, whether farmers, peasants, or shepherds, mingling with the practice of Physic the cultivation of natural history, and enriching the museum of Hunter, his illustrious master, with numerous specimens met with during these excursions. Thus went on his way this wise and happy man in perpetual and intimate communion with the soul of nature, observing, meditating, and dreaming, incessantly spelling the mysterious letters of that great book which is always open, and in which so few know how to read. One day he perused in it the discovery of vaccination, and that day he saved from death thousands more than ever fell before a Cæsar or a Napoleon. And yet the name of Jenner is well nigh entirely unknown to that great swarm of mankind which seems to have far more regard for those who crush than for those who save it. Tardily statues have been raised to him, but the mother who is so anxious to have her child vaccinated is ignorant of the very name of the man to whom she owes the benefit."

M. Guardia, speaking of this lecture in the *Gazette Médicale*, holds somewhat different language:—

"Louis Valentin, an enthusiastic admirer of Jenner, does not hesitate to place the discovery of vaccination above that of the circulation; but it is only a panegyrist who would not be staggered by so bold an approximation. For my part, I cannot see any possible comparison between Harvey and Jenner. The former furnished an unanswerable demonstration of an extremely complex fact, of which only a portion had been made out before his time, while the latter substituted only one virus for another, being advertised of this long before by the experience of the country people, by frequently repeated reflections, and by popular tradition. . . . Jenner has recounted in his own fashion, not to say arranged and somewhat travestied, the history of his discovery. M. Bousquet, one of his panegyrists, has had the courage to blame him for the compromises, and concealments more worthy of a casuist than of a man who ingenuously recognises what he owes to others. Not having the habitude of academical euphuisms, I may say that I believe that Jenner was too jealous of his glory, and too frightened of losing by dividing it. There is a littleness in his obstinacy in vindicating the priority of, and the exclusive property in, his discovery. After reading all that he has written on vaccination, and well reflecting upon this, I must regard him as somewhat vain-glorious and boasting. He never ceases to speak of the benefits of vaccination, and finds little difficulty in chanting his own praises in every variety of tone. Jenner, whose simplicity and *bonhomie* have been so much spoken of, certainly did not err from excess of modesty. He was much bent on his own ideas, sustaining and defending them with obstinacy, and, like the authors of systems, he willingly believed that after him there would remain nothing else to be done. . . . M. Lorain has somewhat too much lamented the lot of Jenner, whose merits do not seem to him to have been sufficiently recognised and recompensed. Is this not pushing sympathy a little too far for a man who was spoiled by fortune? Nothing was wanting to Jenner's ambition, and the most insatiable self-love could not desire greater recognitions than he received. The British Parliament decreed honours to him, which in free countries are only accorded to the great. Europe and America voted him considerable subscriptions, while from his grateful fellow-countrymen he received in money about a million francs. Numerous medals were struck in his honour during his life, and since his death three or four statues have been raised, one of which stands by the side of that of Wellington in one of the principal squares of London. What more could be desired? And was it well of Jenner, thus loaded with fortune's favours, to complain to the Emperor Alexander of the ingratitude of men?"

With respect to Jenner's statues, we may observe that the only one we know of, first erected in Trafalgar-square, was, on the remonstrance of the members of the clubs in its neighbourhood, removed some time since to what we suppose was considered the more congenial vicinity of the children and nurserymaids in Kensington-gardens.

M. Guinier, of Montpellier, has been making some auto-laryngoscopic demonstrations in Paris, with the view of proving that the generally received views of the process of deglutition require some modification. He says that it can be easily seen that the alimentary bolus passes directly, without any preliminary falling back of the epiglottis, on to the flooring formed by the contraction of the glottis. In the same way, liquids employed as gargles penetrate beneath the epiglottis, and come in direct contact with the intra-laryngean mucous folds and the cordæ vocales. It follows that the simple contraction of the cordæ vocales suffices to prevent the pasaage of foreign bodies into the trachea. This contraction is automatic, and brought by reflex action into relation to the sensation produced by the contact of a foreign body with the mucous membrane of the supra-glottal regions, and especially the epiglottis, which thus becomes an organ endowed with special sensation.

If any of our readers would like a pleasant summer's visit to Normandy, we would recommend them to bear in mind that the thirty-second meeting of the French Scientific Congress will commence at Rouen on the 31st July. There is a special section for Medicine, at which the following subjects are proposed to be discussed:—1. The influence of manufacturing crises on the public health. 2. The causes and remedies of the mortality of children in manufacturing towns. 3. Does crossing of races give rise to sterility or degeneration of species? 4. The effects of the abuse of alcoholic drinks upon the product of conception, and the frequency of nervous diseases in the children of persons given to such abuse. 5. The diagnosis of apparent death. 6. The preservative power and regeneration of the vaccine virus. 7. The hygienic questions arising from the passage of a course of water through a large city. 8. Twin births, their causes, and the vitality of the infants which result. 9. The diseases to which the weavers other occupations of Rouen are more especially liable. 10. Is it possible to educate the deaf-dumb by any other methods than those employed in the special establishments devoted to their instruction? 11. The reforms and ameliorations required in the public provision for the poor. 12. The increase of insanity; is the present number of asylums sufficient, and what changes are required in their organisation? 13. What are the causes of the epidemics which prevail at Rouen, and why is it that the plague, which was of such frequent occurrence in the middle ages, has not reappeared during two centuries?

Académie de Médécine.—M. Gubler has just been elected into the Section of Therapeutics and Materia Medica by 55 out of 77 members present. By this election the full number of the Academy of 100 members is made up, there being no vacancy in any of the eleven sections of which it is composed.

REVIEWS.

Guy's Hospital Reports. Edited by Samuel Wilks, M.D. Third series, Vol. x. London: John Churchill and Sons. 1864.

It would be absurd to praise Guy's Hospital Reports. Every one turns to them with the assurance that he will there find the results of laborious work given in the most convenient form and expressed in the truest language.

The present volume well supports the credit of its predecessors. It opens with the "Fourth Decennial Report of the Guy's Hospital Lying-in Charity," collated from the Records by Dr. Braxton Hicks, and presented by the Obstetric Physicians. The Report is very carefully drawn up, and to those who interest themselves in obstetric science must be very valuable, were it only for the statistics given of the comparative frequency of the various accidents and complications to which labour and the puerperal state are liable.

The Report has, however, a more general value, for it throws light upon a question which has more than once given rise to prolonged discussion and even to angry dispute; the question whether lying-in Hospitals are or are not a public benefit.

From October, 1854, to the end of September, 1863, 14,871 women were delivered at their own homes. Of these 44 died, giving a maternal mortality of 0·29 per cent. If we compare this with the returns of lying-in Hospitals, we may form some idea of the mortality induced by the crowding together of puerperal women.

	Were Delivered.	Died.	Mortality per cent.
In the Lying-in Hospital at Vienna from 1851 to 1859 inclusive .	73,600	2527	3·4
In Queen Charlotte's Lying-in Hospital from 1828 to 1863 inclusive	7,736	202	2·6
In the Dublin Rotundo from 1828 to 1861 inclusive . . .	63,621	924	1·45
Guy's Hospital Charity, at patients' own homes, from Oct., 1854, to Sept., 1863 . .	14,871	44	0·29

The excessive mortality in the Lying-in Hospitals must be due entirely to Hospital complications, for it is evident that patients under the constant supervision of the Medical attendant must be better treated than those who too often delay sending for Medical assistance until it is too late. A sufficient illustration of this is given in the Report before us. Out of 18 cases of eclampsia, some of which were evidently hysterical, 5 mothers died, 2 of them being undelivered. In Vienna, out of 23 cases of uræmic convulsions which occurred in 1859, 6 died. Again, taking the mortality of the children, we have an example of the same evil consequence of delay, or of the inexperience of the students, for out of 43 cases in which the funis presented or was prolapsed, 30 children were born dead, or nearly 70 per cent. In Vienna, out of 58 cases, only 14 children were born dead, or about 24 per cent.

Following Dr. Hicks's Report is a paper by Mr. Bader, recommending the treatment of granular conjunctivitis by the inoculation of pus. Mr. Bader uses various kinds of pus—sometimes pure gonorrhœal matter—and has evidently taken some pains to devise means of having this desirable matter always at hand when wanted.

Dr. Habershon contributes two papers. In the first he lays down some general rules for the administration of arsenic in the three forms of disease in which arsenic is of service; viz., (1) miasmatic poisoning, (2) diseases of the skin, and (3) some diseases of the nervous system. Dr. Habershon's second paper is an interesting report of two cases of Addison's disease.

Mr. Bryant offers us "A Clinical Report on Inflammation and Tumours on the Breast," in which he enters at length into the question of diagnosis of the nature of mammary tumour. Mr. Bryant's section "On Innocent Tumours of the Breast" forms a capital sequel to the paper which Mr. Birkett published in the first volume of the Reports, "On Adenocele of the Breast." Mr. Bryant shows that adenocele of the breast is most frequently met with during the period of greatest functional activity of the mamma, while cancer is met with after the functional activity has commenced to decline. Adenocele is more frequent in the unmarried; cancer more frequent in the married. Accurate rules are laid down for the clinical examination of the diseased mamma, and the value of various diagnostic symptoms, such as retraction of the nipple, discharge from the nipple, enlargement of the lymphatic glands, etc., is descanted upon. Mr. Bryant's paper is very complete.

Mr. Towne continues his papers upon the stereoscope. Mr. Cooper Foster reports a case of intestinal obstruction, which seems again to open up the question of exploratory incisions into the abdomen in cases of internal strangulation. Dr. Hilton Fagge gives the details of a case of aneurism of an artery which, arising from the internal iliac, ran down the back of the thigh and terminated in the popliteal, and was the main artery of the thigh and leg. Mr. Birkett contributes two papers; the first is a report of a remarkable case of disease affecting the shaft of the tibia, the second is a detailed report of cases of inguinal hernia depending upon abnormal conditions of the vaginal process of the peritoneum. Both of these papers are worthy of their distinguished author. Dr. Taylor presents us with three papers on those subjects of Medico-legal interest in which he delights, and in which he stands unrivalled as an authority. Mr. Cock selects some interesting aneurisms from among the cases which have come under his care during the last twenty years. Dr. Owen Rees makes some valuable clinical remarks on calculous disease. Dr. Braxton Hicks contributes a paper upon the glandular nature of the proliferous disease of the ovary. He agrees with Mr. Spencer Wells that many cases of multilocular ovarian tumour are to be looked upon as cases of adenoma of the ovary. He differs in some details from Dr. Wilson Fox as to the progress of growth of ovarian disease, and he corroborates an opinion which was first advanced by Dr. Charles G. Ritchie in the pages of this journal, that some forms of ovarian disease are probably produced by parthenogenetic development of an ovum while still contained in its Graafian follicle.

Dr. Pavy contributes a most valuable paper on "The So-called Amyloid Degeneration,"—a subject which is closely allied to physiological inquiries, in which it is well known that Dr. Pavy is deeply interested. Dr. Pavy's paper gives the result of the work of others as well as of his own, and will be read with profit even by those who have not hitherto paid any great attention to the subject.

Two cases of "Chronic Impairment of Hearing Improved after Scarlet Fever," by Mr. Hinton, and a paper on "Certain Abnormal Conditions of the Bones," by Mr. Durham, complete a volume which is profusely illustrated, and whose arrangement does credit to its able editor, Dr. Wilks. Mr. Durham's paper is particularly good, and affords the best account we know of that obscure disease, *Mollities ossium*, and of the chemical and microscopical characters of the altered bones. A General Index to the ten volumes of the Third Series of Reports completes the work.

GENERAL CORRESPONDENCE.

THE JAMAICA INQUEST.

Letter from Mr. Alex. Fiddes.

[To the Editor of the Medical Times and Gazette.]

Sir,—In an article in your journal of the 25th March, headed "Colonial Medical Ethics," you have been pleased to make some comments on the proceedings at a coroner's inquest held in this city on the body of Richard Bailey, who died in the Public Hospital after an operation for the removal of a broken catheter from the urethra, and in reference to the evidence given by the Medical witnesses at this inquiry, you express an opinion that the antiquated "code of Dr. Sangrado and Cuchillo still regulate Professional relations in this quarter of the world."

Admitting that Professional relations here are not so pacific as they might be, I can assure you, nevertheless, that these are not so bad as you have been led to suppose; but be that as it may, I have to remark that neither myself nor any of the eight Medical Practitioners who were examined at the inquest are in any way responsible for the Professional disagreements which have lately occurred. These have arisen entirely from the extraordinary conduct of one individual, who, in relation to the Public Hospital, has for the last five or six years set aside the civilities and courtesies of Professional life, and if you will take the trouble to refer to the published documentary testimony which I herewith transmit, you will not fail to perceive that it was my determination to uphold the etiquette of the Profession against the assaults that were being made

against it, which lately compelled me to throw up my appointment of Surgeon to the Hospital, and that it was the same feeling which actuated my colleague, Dr. Dunn, in obliging him to refuse the continuation of his services as a Medical officer of the institution.

With regard to the conduct of myself and of the other Practitioners in the City who gave evidence at the inquest on Richard Bailey, I have only to observe that neither I nor any of them are blameable for the unfortunate result of that inquiry. The inquest was demanded by the inspector of the Hospital, and I, with all the members of the Profession in the city, was summoned by the Coroner to give evidence thereat. The testimony which was there adduced was no doubt damaging to Drs. Bowerbank and Anderson, the principal Medical officers, but it was impossible for any Medical witness who had due regard for his own Professional reputation, and the sanctity of his oath, to help them out of their difficulty.

What are the facts of Richard Bailey's case? The patient, without any stricture or prostatic disease, but with a urethra sufficiently capacious to admit a No. 14 bougie, had a No. 2 catheter introduced into the bladder, and secured therein by tapes; there appears to have been considerable uneasiness thereafter, and in some way or other the instrument was broken; about four inches of it fell out, the remaining six and a-half inches remained in the urethra and bladder; this foreign body could be felt by external examination,, and a No. 12 sound was readily passed alongside of it into the bladder, yet no attempt was made to remove the broken instrument until after the lapse of nine days; and when a message had come down from Government making inquiry about the case, the patient was then subjected to a cutting operation in the perinæum, from the effect of which he died —at any rate, he sank a few days after the operation, the wound, on dissection, being found black and sloughy, and the coverings of the testes verging on gangrene.

Was it possible for any Medical man conversant with urethral Surgery to endorse the propriety of the practice which was adopted in this case? Was the introduction and retention of a No. 2 catheter in a morbidly wide and roomy urethra a justifiable measure? Was it proper to permit six and a-half inches of catheter to remain nine days in the urinary canal without making any attempt to effect the extraction of it? Was it in accordance with sound Surgical principles to open the urethra in the perinæum when the broken catheter might have been readily seized and extracted in a few seconds by means of an ordinary urethral forceps, or by one or other of the extracting instruments found in all well-appointed lithotrity cases? You state that the accident which occurred to the patient of Drs. Bowerbank and Anderson was one of no ordinary difficulty; but I would be glad to learn where the difficulty lay. Is it a matter of extraordinary difficulty to manipulate the blades of a urethral forceps in a canal of sufficient calibre to permit the passage of a No. 14 sound, and to seize the shank of a broken catheter lying a few inches distant from the urethral orifice? If so simple an operation cannot be readily executed, the art of Surgery must have reached a very low ebb; but neither I nor any of the eight Medical witnesses who were examined at Bailey's inquest ventured to endorse or confirm such a view, nor did any of the twelve jurors entertain it. These gentlemen, after a patient inquiry of seven days' duration, unanimously returned a verdict to the effect that Richard Bailey died from improper Surgical treatment. Such a verdict is, no doubt, a painful one to those more immediately affected by it, but it was impossible that the jurors could have arrived at any other decision. Nor will Dr. Bowerbank himself be much surprised at it, if he reflects that for the last five or six years he has openly and avowedly ignored the Professional qualifications of every Medical man who has been connected with the public Hospital during the last twenty years. It is curious that in the first month of his Hospital incumbency he should have encountered the untoward occurrences which Richard Bailey's death has entailed, and if the verdict which has been recorded upon it have no other good effect, it will at all events afford another illustration of the non-perfectibility of human nature, and prove a sufficient exemplification of the operation of retributive justice in the moral government of our planet.

I am, &c.,

Alex. Fiddes, Fellow of the Royal College of Surgeons of Edinburgh.

Kingston, Jamaica, April 24.

[*** The article to which Mr. Fiddes refers was an expression of our unbiassed opinion, formed after a careful examination of the evidence given at the coroner's inquest. Believing a great principle of Medical ethics to be at stake, we abstained from sitting in judgment on the Surgical treatment pursued in the management of the case. We considered this a question entirely apart from the main one suggested by the whole story. We are quite ready to acknowledge that the treatment of the patient does not receive our entire approval; but any Surgical deficiency displayed was only forced into general notice by the fact that it became a party weapon in one of those miserable feuds which more than anything else injure the Profession in the eyes of a keen-sighted public.—Ed.]

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, May 9.

Dr. Alderson, President.

Professor Harley read some notes of

TWO CASES OF INTERMITTENT HÆMATURIA; WITH REMARKS UPON THEIR PATHOLOGY AND TREATMENT.

The chief peculiarity presented in the cases described in this communication was that the urine passed at one period of the day varied from a dark chocolate colour to an almost purple blackness, whereas at all other times the secretion was, to all intents and purposes, normal. One of the patients was a Medical gentleman who had for many years been resident in a warm climate, where he had contracted malarial fever; the other was a Londoner who had never suffered from any true aguish attack, but in whose case the bloody urine was passed whenever he was exposed to cold. Indeed, according to the patient's own statement, during the last two winters his urine invariably became bloody about an hour after his suffering from cold hands or feet. Both patients appeared to suffer from hepatic derangement, the one whose attack could be traced to malaria being slightly jaundiced at the time the urinary symptom manifested itself. The other, although not suffering from true jaundice, had an exceedingly sallow, bilious appearance. As regards the pathology of these specimens of urine, the author remarked that had the morning's urine only been brought under the notice of the Physician, he could never have dreamt of the existence of any urinary affection; whereas had the midday specimen alone been subjected to his inspection, he could not have failed to suspect the existence of grave organic changes in the renal organs. Neither of these opinions could possibly be correct; the varying condition of the renal secretion clearly pointing to intense congestion of the chylopoietic viscera of a transient and periodic character. Professor Harley further pointed out the difference between the affection here described and the other form of disease with which it is apt to be confounded—namely, ordinary hæmaturia. The easiest way of establishing a correct differential diagnosis was, he said, that in ordinary hæmaturia the urine is not only coagulable by heat and nitric acid, but contains blood-corpuscles, which gradually become deposited on standing, and leave a clear, pale-coloured supernatant liquid. In this form of intermitting hæmaturia, as also in some cases of the non-intermittent variety, the urine, although coagulable by heat and nitric acid, contains few or no blood-corpuscles, and the colouring matter is not deposited on standing, but remains uniformly distributed throughout the liquid. Besides this, the urine contains numerous granular tube casts, and has an increased percentage of urea. Lastly, as regards treatment, it was shown that while the usual remedies employed in the treatment of hæmaturia failed to make the slightest impression on this form of disease, the employment of mercurials and quinine caused it rapidly to disappear.

A paper, by Dr. Wm. H. Dickinson, was read, entitled

NOTES OF FOUR CASES OF INTERMITTENT HÆMATURIA.

The case most fully reported was that of a man who had frequently been in St. George's Hospital. In the autumn of 1859 he was first attacked with his present complaint. One morning he was seized with shivering, nausea, and pain in the loins, and when he passed urine he found it was black and apparently bloody. From that time to the present he had

often been under observation at St. George's Hospital, and he had been in the hands of all the Physicians of that establishment, latterly under the care of Dr. Fuller. He had no constant ailment, but his health was broken by short attacks of hæmaturia. From the beginning of the disorder these had always been of the same character. They owned no other cause but exposure to cold. He usually got up and went to his work apparently well. In cold weather he was liable to be attacked with shivering, retching, and dull pain in the loins, at the same time yawning and feeling disposed to stretch himself. The testicles were retracted, and he had pain passing down the thighs. When he passed urine it was black and turbid, and was found to be highly albuminous, of great specific gravity, and containing an excess of urea; the microscope showed numbers of dark granular casts and a dark molecular deposit; no blood globules had ever been found. The urine retained these characters for two or three urinations. When he got warm it recovered its natural characters; and next day he was well, excepting that he was somewhat reduced by the attack. In continuous cold weather these attacks had come on for several successive days, but they had never lasted through the night. He had never had an attack in the summer, though once, in comparatively warm weather, it was brought on by his washing windows with cold water. Movement had no tendency to produce it; he was always better when taking exercise, as it kept him warm. The man had an anæmic and cachectic appearance. No organic disease could be discovered. While in the Hospital many plans of treatment had been tried, but none had appeared to prevent the recurrence of the complaint. Quinine proved inefficacious; mercurials were apparently injurious. While taking blue-pill, he had, for the first time in his life, an attack while in-doors. During the time he was under this treatment he had an attack of pneumonia, which was followed by peculiar symptoms of prostration, which it was thought must have proved fatal, but from which he eventually recovered. Three similar cases were briefly reported, two of which had occurred in the practice of Dr. George Johnson, and one in that of Dr. F. Cock, which gentlemen had communicated the facts to the author. In conclusion, Dr. Dickinson maintained that the disorder was essentially due to an alteration in the blood, a similar state of urine having been found during typhus, and also in man and animals after the inhalation of arseniuretted hydrogen. The points which the disorder has in common with ague were adverted to, but the absence of any periodical tendency and the inefficacy of quinine as a remedy were cited as essential differences. As to treatment, it was considered that as yet the disorder was beyond our reach; the most we could do was to palliate the effects of the loss of blood. Quinine was believed to be useless except in this respect; while the administration of mercurials, both on general principles and on the experience afforded by the above case, was believed to be detrimental.

Dr. Greenhow believed that the second case mentioned in the paper had been under his care in the Middlesex Hospital, and had been treated in every possible way, and with mercury and quinine amongst other remedies. He could not understand how the remedies employed by Dr. Harley of a similar kind had been so successful as to effect a cure in forty-eight hours. The boy who was the subject of this case was affected with hæmaturia at irregular intervals, cold being the chief exciting cause. The attacks were less frequent in summer than winter.

Dr. Fuller said that in his case he could not attribute any effects to the drugs or the modes of treatment employed. The patient did as well when no means of cure were resorted to; simply lying in bed was sufficient. The complaint recurred at irregular intervals, no cause, except cold, appearing to influence their occurrence.

Dr. C. J. B. Williams said that we could only arrive at the cause of these attacks from post-mortem evidence. The peculiarity of these cases was the severity of the attacks and their total cessation without apparent cause. In cases of intermittent fever, blood and albumen were occasionally found in the urine, arising from congestion of the internal organs during the paroxysms. It was interesting thus to see symptoms of Bright's disease in an early stage, and then pass off. It was also remarkable that the symptoms recurred sometimes with cold, sometimes without. It would seem as if there were some structural change of the kidneys which was unable to resist the influence of an influx of blood upon them, and their secretion became thus modified. Hæmorrhage from the nose it was known occurred from cold. In aguish countries the cold stage of intermittent fever sometimes produced epistaxis. Remedies did not seem to be of much avail in recurrent hæmaturia, as patients appeared to get well without treatment.

Dr. Harley explained that in the case alluded to by Dr. Greenhow the treatment consisted in the administration of a good dose of calomel, followed by a large dose of quinine.

Dr. Dickinson having replied, the Society adjourned.

METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

At the monthly evening meeting, May 20, at the Scottish Corporation Hall, Fleet-street, Dr. Druitt, President, in the chair,

Professor Mapother, of Dublin, was received as honorary member.

Mr. Haynes Walton then read a paper entitled

REMARKS ON THE CONTAGIOUS AFFECTIONS OF THE EYE.

After some introductory remarks, he said:—The word contagious is used by the Profession for the most part as synonymous with infection, but some among them employ the latter in a sense that the former does not admit of—namely, that of contamination by anything injurious to the human frame from any source. I wish to express by it the communication of ocular disease from one individual to another. The direct effect of contagious influence on the eye appears only in conjunctival affections—*i.e.*, inflammation of the conjunctival membrane and of the meibomian glands, attended with puro-mucous and purulent discharge; but from this surface and single tissue implication, the organ of sight suffers more distress from permanent injury and from complete spoiling, than from all the other diseases which invade it. Yet only some of the forms of the contagious inflammations are recognised, and with scarcely any of them are rules for preservation sufficiently applied, by which I mean those that are really of practical application, for, as in everything of the kind, such treatment can never keep pace with our knowledge for the necessity of it. Nor are the morbific causes which originate them sufficiently taught. I regard all the puro-mucous and purulent diseases as contagious. In some instances the milder forms of some of them, together with the absence of severe ulterior consequences, have been perhaps the cause of this fact being overlooked, or but very partially recognised. If my friends should detect any discrepancy between my former statements and these, they must receive in explanation a wider field for observation and more accuracy in reading disease. Catarrhal ophthalmia, rightly so called, is too well known to require any careful description. It is enough for me to speak of it as conjunctivitis with a puro-mucous discharge, the eyeball proper being unimplicated. The general tendency of the affection is not to invade other ocular tissues. To trace it to an atmospheric origin is generally easy, but that it is contagious can unequivocally be shown. The commonest instances of the contagion are to be found among the poor, not only because of the close proximity of individuals, but of the auxiliaries to be found among their home dwellings that favour its conveyance, and the kindred disadvantages arising out of the communities which legislative enactments provide for them. These vital and physical causes greatly increase the extent of contaminating force. According, then, to the opportunity for this leavening influence, so, most assuredly, will be the propagation of the ophthalmia, and in recognising which we shall be the better prepared with our treatment. I have witnessed the contagion of catarrhal ophthalmia on a grand scale, I have personally inspected the individual suffering it has occasioned, and I can tell of the obstinacy of its duration. In the year 1861 I was sent for by the guardians of the Central London District Schools, which receives the pauper children of five unions, in consequence of an ophthalmic affection that existed, requested to examine the diseased inmates, and to make a Medical report. I may mention, in parenthesis, that the disease had existed prior to the year 1858, although I was not aware of it, and I get my information from this paragraph, which I take from a report made after my visit by a Committee appointed to examine into the state of this and other pauper schools:—"On a careful consideration of the information gained by their visits to these schools, the Committee regret that it is their duty to report that the children at the Central London District Schools present the least satisfactory general appearance, and that this arises principally, though by no

means entirely, from the prevalence of an ophthalmic affection. The Committee find that a very large proportion of the children are so affected, and have been so, both before, and continuously since, a similar Committee visited the school in 1858." There were many hundred children there; I believe some twelve or fourteen. I examined with care, taking notes as I went, two hundred of them affected with ophthalmia, and I well remember the long and tiresome job. I beg to draw attention specially to the fact, significant as I shall show, that there was catarrhal ophthalmia, and nothing more—mild in form, yet definite in symptoms. It had not in a single instance passed into the form of purulent ophthalmia,—the most fatal malady to which the eye is subject, and the cause of the greater proportion of blindness in the world. No part of the eye besides that immediately attacked suffered. In not a single instance was the cornea implicated,—no ulceration, no sloughing, no opacity. The conjunctiva alone and the meibomian apparatus were diseased. In a few instances I detected the remains of former eye complaints. It would be scarcely possible to find this number of pauper children under one roof without some marks of strumous ophthalmia. I was struck with the miserable appearance and stunted growth of the children in general; and the answer to my remarks respecting these was, that they could not be otherwise, as they were all bred and born on gin and sprats. I found the clothing very scanty, the diet meagre and badly cooked, and the supply of warmth insufficient. So excessive was the ventilation in the dormitories that, during the previous winter, sometimes the temperature fell to 32°, and with the fires and gaslights it was usually at 45°. I believe it has long been a prevalent opinion, and which has even been taught by some of our authorities, that this ophthalmia, as excited by atmospheric causes, is scarcely, if at all, contagious, as contagion is ordinarily conveyed without palpable inoculation, and other means cognisable to our senses, except it assume an aggravated or virulent form. I find, too, that this opinion was entertained by a Surgeon in London of the highest ophthalmic eminence, who visited the school in 1858 with reference to the ophthalmia. He says, in the Report of the Committee already quoted:—"Such a complaint is liable to assume more or less of an epidemic character, and may even become contagious." It has not, however, changed its type; it could never have been less than catarrhal ophthalmia; it could never have been more, and I do not think that any one will doubt the contagion; there could be no question about it. The fullest opportunity was afforded for it, because there was no precaution taken against the occurrence; the diseased and the healthy intermingled. The virus must have been frequently carried by direct inoculation of the recent secretion, as well as by the more general, but subtle, and less cognisable ways of the transfer of particles of poison through the atmosphere. If, therefore, it is proved that catarrhal ophthalmia can be a great curse in a large establishment, without actually spoiling eyes, should there not be much care bestowed in checking it and much supervision exercised? Besides, very trustworthy observers assert that slight circumstances may convert catarrhal into another and severer ophthalmia; and hence has arisen the scourges of this kind in past years in our fleets and armies. That the ophthalmia had not passed into a severe form after so long a time may be considered unusual, although not unaccountable, when the surrounding circumstances are examined. There were absent the conditions for such development. The children were not in the least crowded. There was not any foulness of atmosphere; on the contrary, the entire building was overventilated. The utmost cleanliness was observed in the whole detail of management, and the best Surgical measures were applied. It was very different, however, with the memorable ophthalmia of the workhouse schools of the Tipperary and Athlone Unions in 1851. I learn from the Report of Sir W. Wilde that in the Tipperary establishment the ophthalmia was introduced into the schools in a mild form, and, as I believe, of the catarrhal type, in the spring of the year, and in October it assumed a more violent and decided character. It there met with a hot-bed for growth and contagion. But it was to be yet further intensified in the workhouse. After Sir William had described the state of those who were seeking admission to this overcrowded and degraded place, as being worn out by previous want and privations of every kind, exhausted indeed to the last degree, he said—"The general health of the workhouse was very bad indeed. We had cholera, dysentery, fever, and small-pox, as well as several cases of gangrene and dropsy. There was no proper sewerage, neither was there sufficient water to cleanse the entire house or purify the privies, except what a horse brought daily from town." Being anxious to know what is the present state of the Central London District Schools, I wrote a few days ago to the gentlemen who was Surgeon there at the time of my visit, requesting certain information. These are his answers:—"1st. The ophthalmia no doubt originated through the admission of three or four hundred children from another school where there had been an outbreak. Secondly. I believe it has not disappeared. I resigned three years ago, as it made too great claim upon my time. A Surgeon now resides upon the premises. While I held the Surgeoney, my own Assistant, and two others specially engaged for the eye cases, devoted their whole time to the treatment of the children. About four or five hundred cases were at one time under treatment, most of them mild, some chiefly discoverable through the condition of the inner surface of the eyelid. I believe one or both of the ophthalmic assistants remained for a year or two after my resignation. 3rdly. The disease yielded to rigid separation of the diseased from the healthy, and mild astringents occasionally. These applications were injected thoroughly under the eyelids, and the utmost cleanliness was at the same time observed, carried out by a largely increased staff of nurses. 4thly. I regard the disease as only kept under, and circumstances might reproduce it at any time. It is the bane of these large pauper schools, and unmanageable when it once breaks out." It is now time to say something about treatment; and have I not been anticipated in this? Has not each of my hearers determined for himself, on his own conviction, the one, and the only one, remedy to be depended on? Who will not say, Remove contaminating influence? How this should be done effectually can only be determined when a multitude of other circumstances are examined and considered. It may happen that the separation of the sound from the unsound to the greatest extent afforded by any vast building might be inadequate; but migration of the one or the other to new premises absolutely required. I understand that all the hints which were given by other Medical men and myself as to the hygienic deficiencies were attended to, and all the ophthalmic treatment was carried out; but yet you hear the disease is not eradicated. It is, then, the question of prevention which is to be worked out; and fortunate will it be for the public if there should be enough vitality in the meeting of this evening from which shall spring some sources of investigation and observation to discover knowledge to be applied whenever such disease, or a still more severe one, rages, which shall stay the pestilence. I shall not waste our time in talking about ophthalmic treatment; that is almost beyond the question. Then there is scope for difference of opinion, and who is to arbitrate? But on the grand radical matter of isolation I suppose common-sense forces us to agree. I hope, Sir, that we shall have expressed presently the individual experience of many of the members on this point. For my own part I venture in all such epidemics these suggestions:—Absolute separation of the diseased persons from the healthy. Among the diseased also I should extend the classification, if severer cases occurred, for obvious reasons; and it may be wise to have several of these draughtings. The institution of a rigid convalescent system of probation, to prevent relapsing cases from doing mischief. A morning and evening inspection of the whole establishment, so that there may be the most timely removal of diseased individuals. The strictest attention to the withdrawal of any known or supposed exciting cause of the disease. The adoption of the highest hygienic measures among those who are under Surgical treatment, so that there may be the prevention of those circumstances and conditions that are likely to intensify the disease. I propose next to make some remarks about purulent ophthalmia in infants. This dangerous complaint is generally supposed to be almost entirely confined to the lowest ranks of life; a very erroneous impression, although among the poor its ravages are much greater from want of early recognition and proper treatment. I need not take any notice of its contagious nature, as it is seldom so propagated, except in Foundling Hospitals on the Continent, and in a few other uncommon ways, because of the isolation in general of the child, and the fact that the mother and the nurse exercise care about their own eyes from the notoriousness of the danger of the disease, and, in addition, the caution usually enjoined by the Medical attendant. It is to the origin—the infection, I suppose, I must call it here—that I wish to direct attention. It has been my impression for many years that the laws of preservation might be extensively and effectually applied, and,

besides, that the disease, when taken, might be divested of its severity, and its frightful ravages thereby averted. Let me inquire how infant purulent ophthalmia originates. Very, very often, by inoculation with leucorrhœal matter from the mother, by gonorrhœal inoculation from the same source, and sometimes we cannot tell how. Some supposed cases of it called mild are nothing of the sort, but merely catarrhal inflammation. I ought to tell you that the chief difference between these is, that in the purulent ophthalmia the palpebral conjunctiva is more quickly and intensely diseased, its papillary structure getting changed into the state we call granular; hence the mattery discharge and the amount of it. If any one takes the trouble to make inquiries about the state of the mothers of these diseased children, he will be astonished to find how often the leucorrhœal infection prevails. He must not always expect to get the truth by direct inquiries. I should like to ask this question of the Accoucheurs,—In any well-marked case of leucorrhœa is it practicable to wash out the vagina in the commencement of parturition, so as to prevent the transmission of the disease, and can the object be the better secured by the use of chemical agents? Although I lack information on this point, I can give valuable suggestions on another. Cleanse the eyes of children born under such circumstances at once and most carefully. Daily inspect them, and apply treatment when requisite without delay. I never saw an eye lost that I treated early—that is, before the cornea was affected. Hundreds of eyes would annually be saved if this watchfulness were adopted. What hints for those who have the charge of parish midwifery! Why not tell the mothers of the contingency, and get their watchfulness too? I have found that a premature child seldom escapes maternal infection. The last four cases of purulent ophthalmia that I have had in private practice have been from leucorrhœal matter. Two of the children were premature. Of course infection is not inevitable when leucorrhœa is present. It is here as in other things, infectious and contagious: the escapes cannot be accounted for. Infantile purulent ophthalmia, from the infection of gonorrhœa, is very much less common, and is almost entirely confined to the children of prostitutes. The remarks that I have made about prevention in the last-named form of the disease are equally applicable here, and it should be remembered that the gonorrhœal form is the more severe. I shall conclude by making some few and short remarks on the contagion of granular conjunctivitis. Granulation of the eyelid is the term generally used. This is the sequel for the most part of the purulent ophthalmia. The under eyelid is generally the more affected. Strictly pathologically speaking, it is chronic hypertrophy of the conjunctival villi, and I need not say any more on this head, nor describe the appearances, for everybody must be familiar with what I allude to. There is, too, an accompanying characteristic inflammatory state of the cornea, with more or less of haze or opacity, and redness of the tunics immediately around. This state of the eye is an unexpected source of frequent contagion. It is a deceptive state. I will explain. A true granular eyelid is seldom seen, except as a chronic disease, and it may be a very chronic one. Should there be still any purulent secretion, it is generally scanty and thin. Now the duration and the absence of well-marked pus generally prevent, in the minds of the Medical attendant and others, the idea of contagion. But there is a still more disarming state. The granular conjunctiva may exist along with the vascular state of the front of the eyeball, and without any purulent secretion. No one not versed in ophthalmic disease would suspect any contaminating danger. But the danger is merely masked. Apparently slight causes, atmospheric changes, fatigue, irritation from dust, or the application of irritating drugs, drunkenness, seem to reproduce the discharge, sometimes with all the former severity, and a patient supposed to be harmless may then inoculate many of those around him with purulent ophthalmia. This granular eyelid clings closely to the poor Irish. At our Ophthalmic Hospital we call it the Irish eye. It is always among the abodes of them in all countries, and I do not think that it is due, as some say, to peculiarities of Irish constitution, but to mere contagion. The Irish take it into our workhouses, schools, and prisons. Yesterday I saw a fine-looking girl in the street, about 14 years' old, selling flowers, with a pair of well-marked Irish eyelids. I alighted, and went to learn her history. She was born in England, of Irish parents, and lived in an Irish community. I offered to have her eyes attended to, but she thanked me with "No;" adding, "I have some eye-water, Sir." Here is a great scope for the application of preventive measures, and the special field for it is in those establishments which receive the poor, and in which there can be proper supervision and separation. I would subject the unfortunate possessor of granular conjunctiva to the same rules and regulations as if he were in an acute stage of purulent ophthalmia.

Remarks were then made by the PRESIDENT on the wide scope of the pathology of mucous inflammations, ranging, as they do, from the most trivial catarrh in man to gonorrhœa, with its subsequent rheumatic ophthalmia and articular rheumatism, and to glanders in the horse. He expressed his belief in the possibility of transplantation of most diseases of the class.

Dr. MAPOTHER spoke of the valuable observations of Mr. Walton on the contagiousness of granular lids.

Mr. LIDDELL adverted to general causes which make catarrhal ophthalmia epidemic; and

Mr. RENDLE gave a vivid and interesting account, which deserves separate publication, of his visits to the children at some pauper establishments, and of the extreme *coldness*, and other signs of low vitality exhibited by the children, and of the happy adaptation of means to end for the generation and propagation of contagious ophthalmia.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners on the 23rd inst.:—

James Milward, Bristol; William Hawett, Wigan, Lancashire; and Henry Bowden Lyle, Ashburton, students of Guy's Hospital. William Cunningham Cass, Cowes, Isle of Wight, and John Pearson Hughes, Llandovery, S. Wales, of University College. Thomas Conry and George Percy, of Dublin; Charles Taylor Aveling, Shacklewell; and Charles Henry Spooner, L.S.A., Newington, of St. Thomas's Hospital. Theodore Fennell, Rain Hill, Lancashire, and Robert Gear Roper, City-road, of St. Bartholomew's Hospital. James Copland Worthington, Lowestoft, and John Roberts Dunn, Warbleton, Sussex, of the Middlesex Hospital. George Yeats, M.D. and C.M. Aberdeen, of Aberdeen. James David Charles Whiting, Upper Ebury-street, of St. George's Hospital. William Baines Dawson, Brentwood, and Thomas Albert Neame, Hungerford, Berks, of the London Hospital. David Charles Lloyd Owen, L.S.A., Smethwick, Birmingham; Edward Farrington Boult, L.S.A., Bath, of King's College; and William Young Martin, Little Hulton, Lancashire, of the Manchester School.

The following gentlemen were admitted members on the 24th inst:—

Charles Frederick Lethbridge, Torquay, Devon, and Albert William Walls, Bayswater, of University College Hospital. Vincent Edmund Noel, Devonport, and Henry Albert Reeves, Newbury, Berkshire, of the Middlesex Hospital. John Powell, L.S.A., Chichester, of St. Bartholomews; and John Edward Tilton, Stonehouse, Gloucester.

At the same meeting of the Court, Mr. John Frederick Mitchell, of H.M.S. *Lizard*, Sheerness, passed his examination as Naval Surgeon, his diploma of membership bearing date March 14, 1856. It is stated that out of the twenty-nine candidates who offered themselves for examination for the diploma, five were referred back to their studies for six months.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, May 18, 1865:—

John Hogan Quin, North-street, Leeds; John Lowe Price, Cheltenham; John King, Stratton, Cornwall; John Oakley, Shrewsbury; William Lively Shepard, Gray's-inn-road; Thomas Joseph Faweitt, Newcastle-on-Tyne.

The following gentleman, also on the same day, passed his first Examination:—

John Cremonini, General Hospital, Birmingham.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ARMSTRONG, J. F., L.R.C.P. Lond., has been elected Medical Officer for the Workhouse of Reeth, Yorkshire.

BRODRIBB, URIAH P., M.B. Lond., has been elected Physician and Surgeon to the Royal Portland Dispensary, Dorsetshire.

CAIRD, T. W., M.R.C.S. Eng., has been appointed Surgeon to the County Prison, Exeter.

FIDDES, DAVID, M.D. Aberd., has been appointed Examiner in Medicine in the University of Aberdeen.

Fletcher, James O., M.D. St. And., has been appointed Surgeon to the City Gaol, Manchester.

Gaye, Robert E., M.R.C.S. Eng., has been elected Medical Officer to the Paddington Workhouse.

Jones, J. T., M.B., has been elected House-Surgeon to the Brecknock County and Borough General Infirmary.

Leigh, George F., L.S.A., has been appointed Medical Officer for the Penistone Union Workhouse, Yorkshire.

Smith, James W. F., M.D., Aberd., has been appointed joint Lecturer on Clinical Medicine at the Royal Infirmary, Aberdeen.

Tweedale, Thomas, M.R.C.S. Eng., has been elected Medical Officer and Public Vaccinator for the Stainland District of the Halifax Union.

DEATHS.

Brook, William, L.S.A., at Stainland, Halifax, Yorkshire, on April 28.

Butt, William B., Surgeon H.M. Bengal Army, on board the *St. Lawrence*, on his voyage from India, on April 14, aged 38.

Dunlap, James, M.D. Edin., at Queen's-terrace, Windsor, on April 21, aged 63.

Graham, James M., L.R.C.S.I., at Cupar, Fife, N.B., on May 19, aged 80.

Kearns, John, L.R.C.P. Edin., at High-street, Kilkenny, on May 8, aged 46.

Williams, Thomas, M.D. Lond., F.R.S., at Swansea, on April 23, aged 47.

Walker, Ebenezer, M.R.C.S. Eng,, at Drury-lane, Wakefield, on May 6, aged 43.

Wood, James, M.D., F.R.C.P. Edin., at 19, Royal-circus, Edinburgh, on May 10, aged 80.

The Case of Richard Gibson.—In consequence of the letter from the Poor-law Board, conveying their decision in this case, Dr. Craig, the Assistant Medical Officer, and Mrs. Elson, the paid nurse, have tendered their resignations, which the Directors of the Poor have accepted; and Mr. Rankley, the master of the workhouse, has been duly admonished as to his future conduct in the discharge of his duties.

The Trial of Dr. Pritchard.—We learn that the trial of Dr. Pritchard, on the charge of murdering his wife and mother-in-law by means of poison, will take place at Edinburgh, for certain, between the 15th and 20th of June next—that is, if it does not commence on Thursday, the 15th, it will on Monday, the 19th, or Tuesday, the 20th. The Lord Justice Clerk will judge the case and take notes of the evidence, although two other Justiciary Judges, who have not yet been fixed upon, will also be on the bench. The Lord Advocate will conduct the prosecution.—*Glasgow Morning Journal.*

Herpes Zona.—If treated early, the pain and inflammation may be relieved in twenty-four hours by means of the following application:—Collodion, rendered elastic by the addition of castor-oil, 120 drachms; deutochloride of mercury, one grain. If the affection is more advanced, the mixture should be applied several days in succession by means of a pencil. It is useful also in preventing the fall of eschars, followed by sores, which are so painful in the aged.—*Rev. Méd.*, April 15.

Deaths from Trichiniasis.—By a letter dated Lubeck, May 9, we learn that the Senator Dittmers and all his family, consisting of seven persons, have been poisoned by smoked and uncooked ham, which was found to be loaded with trichinæ. Four persons have already succumbed. While on this subject, we wish to direct our readers' attention to a valuable and exhaustive report on trichiniasis, by Dr. Thudichum, contained in the last Report of the Medical Officer of the Privy Council.

The Hospital for Sick Children.—The thirteenth annual meeting of the governors of the Hospital for Sick Children was held on Wednesday at the Hospital in the large room used as a play-room for the convalescent children. The chair was taken by the Hon. A. Kinnaird, M.P. Among the friends present were Major the Hon. S. P. Vereker, Mr. F. H. Dickinson, Dr. Charles West, Mr. H. A. Bathurst, and others. The annual Report, which was read and unanimously adopted by the meeting, referred to the encouraging progress made by the charity during the past year, an increase of ten beds having been made. The annual subscriptions received during the year amounted to £1937 13s., which, with donations and legacies, including a munificent gift of £500 from Mr. R. W. Crawford, M.P., and of moneys placed at his disposal by the Hon. Rustomjee Jamsetjee Jejheebhoy, of Bombay, made the total income of the charity £6206 18s. 2d. The expenditure having been £4281 13s. 1d., the Committee were enabled to invest nearly £2000 towards the re-building of the Hospital. It was also stated by the Chairman that a further enlargement of the present wards is in progress, and fifteen additional beds will soon be opened, making a total of seventy-five beds for in-patients. A vote of thanks to the Chairman terminated the business of the meeting.

Excision of the Tongue.—A correspondent, an intelligent English student, in Edinburgh states that the woman upon whom Mr. Syme operated about eight or ten days ago did well until the evening of the 23rd, when at about 11 o'clock she died. Her death was most sudden and unexpected, Mr. Syme having considered her so far recovered as to request that she should try and leave her bed. It is the fourth case he has had, three of which have proved fatal. On the 24th Mr. Syme operated for axillary aneurism; he first made a small incision above the clavicle so as to admit the finger of an assistant, and thus press the artery against the rib, he then cut into the sac, turned out the clots, and tied the artery above and below the rupture. Mr. Syme is certainly a fearless operator, and a good Surgeon.

Medical Colonisation.—The gas-lighting, the water supply, the pavement, the houses and shops, etc,, being in tolerable order, the tenants were not long in taking possession; but the time of their stay, except in very few instances, was of very short duration. And it is to be remarked here, as we have noticed it in other localities, the publicans and those who are connected with medicine were the first to commence business; for in the metropolis, except under peculiar circumstances, business comes slowly to the newly-established Medical Practitioner, and it is often found to his advantage to begin in a recently built and improving neighbourhood. In the Caledonian-road, without taking into account the streets which lead into it, there are now either nine or ten Medical Practitioners and chemists. Public-houses are also a matter of much speculation; persons who have capital and a fair character purchase or take a lease of one of those large buildings which are reared in what seems to be a desert region, for the purpose of a public-house; for this a beer licence is easily got, and a trustworthy person is put in to manage, and in due course of time the proprietor applies for a spirit licence, and this, if the position is well chosen, is worth five or six hundred pounds, and often a very much larger sum. In some cases the speculator is satisfied with this amount of profit, and he disposes of it to some one who intends either to try to make a living out of the business, or to improve it, so that, as the locality improves, the sale of the goodwill, etc., would produce a larger sum in the market, and in this way, in the course of a few years, premises of this kind change hands with profit several times. In connexion with business of this kind, the sums advanced by the great London brewers, so that they may ensure the opportunity of supplying houses with ale, porter, etc., are enormous.—From an article entitled "How Metropolitan Neighbourhoods Grow," in the *Builder*.

St. Mary's Hospital, Paddington.—On Tuesday afternoon the ceremony of laying the foundation stone of the new wing about to be erected to this building was performed by his Royal Highness the Prince of Wales, in the presence of a large number of ladies and gentlemen. His Royal Highness was received on his arrival, shortly after 3 o'clock, in the board-room of the Hospital by the Vice-Presidents, Treasurer, Medical staff, etc., connected with the administration of the charity, and almost at once the Reception Committee passed in procession before his Royal Highness to the spot where the ceremony was to take place. Here the Prince was received with the utmost enthusiasm. An address was then read to his Royal Highness, which, after referring to the fact that the original foundation stone of St. Mary's Hospital was laid by the Prince's lamented father, the late Prince Consort, proceeded to observe that although St. Mary's was the youngest of the general Hospitals and Medical schools of London, it having been founded in a new and fast growing suburb, the requirements of the neighbourhood had already rendered increased accommodation absolutely necessary. Indeed, the applications for admission grew in number from day to day; the frequency with which urgent cases had to be refused the benefits of the charity afforded the strongest arguments in favour of the extension of the present accommodation. The new wing was to include a chapel, not now possessed, and the Governors ventured to hope that it would be agreeable to the feelings of his Royal Highness if the new wing should be called after himself—the Albert Edward wing, and the two wards receive the names of the Alexandra and Albert Victor wards, the latter to be exclusively devoted to the reception of children under the age of five years. Prayers having been offered up, Mr. Catherwood, the architect, presented the

Prince with a massive silver trowel. The bottle containing the coins and documents having been deposited in the cavity, the foundation stone, which was of polished granite weighing upwards of two tons, was duly laid by his Royal Highness amid loud cheers, the guard presenting arms. Prayers having been again offered up, and the Hundredth Psalm sung by the children, the presentation to his Royal Highness of purses collected by ladies and children in behalf of the Hospital funds having take place, the ceremony concluded with the National and Danish Anthems.

EXCESSIVE SLEEPINESS OF NEW-BORN INFANTS.—Dr. Bieraum observes that the normal condition of young infants is to sleep much, and that in the inverse proportion of their age. But sleep is sometimes observed in an excessive degree, not as the result of any material affection of the brain, but consisting in a mere functional exaggeration of the natural conditions. From these it is distinguished by its excessive duration and the little desire for sucking which the child manifests; and after the sleep has continued for some days after birth, so far from the child thriving, it falls away. He cites the case of a delicate, new-born, full-timed infant, which slept almost continuously during the first ten days after birth, and could only be awaked with difficulty, sucking only rarely and very inertly. Stools and urine were voided in a regular manner, but in small quantity. On the eleventh day the sleepiness began to diminish, and the desire for the breast increased; and the infant grew up to be a child of good mental and corporal powers. Dr. Bieraum feels surprised that this excessive sleepiness of young infants, which is now and then met with in practice, is not noticed in the books on children.—*Journal für Kinderk.*, 1864. No. 3, p. 242.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

THE ALKALINE TREATMENT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Permit me, through the medium of your valuable journal, to ask whether the carbonate of lithia taken in five-grain doses twice a-day, in combination with eighteen grains of bicarbonate of potass, if taken continuously for three months, can be injurious to the system generally in cases of chronic gout. Some of your Medical correspondents will doubtless be able to answer this question satisfactorily.

I am, &c. A CONSTANT READER.

Leamington, May 26.

GRIFFIN TESTIMONIAL FUND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The following subscription has been further received on behalf of the above fund:—Dr. W. W. Miller, Eye, 10s.; amount previously announced, £124 1s. 3d.; received at *Lancet* office, £9 9s.

I am, &c.

ROBERT FOWLER, M.D., Treasurer and Hon. Sec.

145, Bishopsgate-street Without, May 25, 1865.

THE NURSING INSTITUTE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In a recent number of your journal I read a very favourable notice of the above-named Institution. I see by the daily advertisements in the *Times* and other papers that the Committee undertake to supply "wet nurses." I should be glad to know the precise nature of that arrangement,—whether the wet nurses recommended through the Institute are married or single women, and whether any restrictions are attached to the recommendation;—such, for instance, as those which are judiciously incorporated into the rules of some lying-in institutions (that in Endell-street is one of them), requiring a certificate from the Medical attendant as to the urgent need of a wet nurse, as a means of saving infantile life, before authorising the employment of one from the Hospital. Viewing this subject in its moral and physical aspects, I need say no more to show the great importance of such inquiries as those which I have suggested.

I am, &c. M. A. B.

*** We must refer to the Secretary for information. We dare say that the common-sense theory is acted on, that a woman who offers herself as wet nurse cannot support her own baby; and that, by letting her receive good wages as a wet nurse, she may be able to provide for her own child while saving the life of that which she undertakes to feed.—ED.

CHLOROFORM APNŒA—USE OF ELECTRICITY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As chloroform begins to be used in the cure of aneurism by the compression plan, where the pain of the clamp has always been such a hindrance,—as chloroform is now almost universal in its applicability in Hospitals, in midwifery, in dentistry, etc.—and it is advisable to publish the best form of artificial respiration in accidents, I think you would be doing good if you stated that in such cases of apnœa, as well as in drowning cases, where the diaphragm and respiratory muscles are perfectly still, most excellent action may be at once instituted by the use of electricity in form of primary induced current (not the secondary current), and that it is in the "break" of the current the muscles contract,—not as usually believed, when the circuit is complete. It is also very important that the current should not be directed to the heart, as in a case in the *British and Foreign Review* this quarter, where it failed, but directed in the track of the phrenic, where, in animals, it never, or very seldom, fails to set up artificial respiration in chloroform apnœa. I believe I am right in saying the Faradisation "break" is the same exactly as the ancient electric jar discharge, of which elder Physicians and Physicists have wise old experiences; it is all-important the poles of the Faradisation apparatus should be moist, as the dry poles do not act on the muscles, but on the skin. The dry pole is valuable in curing specks on the cornea, bad ulcers of legs, etc.; but the moist pole acts well in aphonia, chorea, etc., by influencing, as in chloroform accidents, the muscles. I am, &c.

Sackville-street, April 18. CHARLES KIDD, M.D.

P.S.—It would not be worth while to insist so often on these points, but that in one or two discussions at Medical societies of late the widest and wildest errors and guesses were put forward, by instrument makers and others, as to other varieties of new-fangled galvanic action that might be useful by theory; whereas all readers of French and German literature well know that galvanism does not answer at all, as proved by the Duchennes (father and son), Du Bois Raymond, Matteucci, and, above all, by Lallemand and Duroy; but the Faradisation current has been well tested in hundreds of cases. It would be infinitely more important, in fine, to test electricity in the Hospitals than to rely on the supposed safety, where safety there is none, of specific inhalers for chloroform, by which the best French and German authorities on chloroform—Langenbeck and Giraldes—say it is an idle dream to think we can measure 3½ per cent., and insure safety with efficiency.

A GOOD EXAMPLE.

(*From a Correspondent.*)

The late Mr. W. W. James, of Exeter, has, we believe, left by will a legacy of £2000, which will ultimately, after certain members of his family have had a life interest in it, be handed over to the trustees of the Devon and Exeter Hospital, the interest to be divided annually among the Surgeons to that institution. This appears to us to be a wise as well as a generous bequest, and it will probably form the nucleus of a fund from which the Medical officers to the Hospital will receive, if not an equivalent for their services, at least an acknowledgment of them. We have often had occasion to speak of the excessive amount of unpaid labour which the members of our Profession are expected to perform at Hospitals and Dispensaries. There can, we think, be no doubt that the work would be better done, more heartily and zealously, if it were not altogether honorary, and that in this way the poor would be gainers if the Medical officers of our public charities received some remuneration. We hope, therefore, that the good example which has been set by Mr. W. W. James will not be forgotten, and that his far-seeing benevolence will find many imitators.

*** We fully agree with our respected correspondent that the principle that men should be paid for work done is a good one; but we do not think that the example of a member of the Profession who leaves a portion of his fortune to a Hospital, which he has served gratuitously during life, for the payment of his successors is one which will or ought to be imitated. Many a man leaves a legacy to a Hospital which had been much better left to his poor relations.—ED.

ON THE CHEMICAL EXAMINATION OF WINE.

By M. SCHLUMBERGER.

Wine, when it leaves the wine press, as must, is composed of the following parts:—

1. Water.	70	to 90	per cent.
2. Sugar.	15	,, 30	,,
3. Acid	0½	,, 1	,,
4. Other substances, gum, albumen, extractive, ashes	1	,, 2	,,

After fermentation, the must, as wine, contains still the same parts, with the exception of the greater part of sugar, which, during the period of fermentation, has become transmuted, one half into alcohol, and the other half into carbonic acid. The composition of wine is consequently as follows:—

1. Water.	80	to 90	per cent.
2. Sugar or Glycose	1	,, 2	,,
3. Alcohol	5	,, 15	,,
4. Acid	0½	,, 1	,,
5. Other substances, as gum, ashes, extractive, and different kinds of ether	1	,, 2	,,

A complete analysis of wine, embracing its finest component parts, is difficult, as the best chemists differ in opinion, especially with regard to the amount of sugar contained in wine.

To determine the amount of alcohol, different modes may be employed, but the most reliable will always be found to be distillation; to determine the amount of acid, potass, ammonia, soda, are now used, and, for greater convenience, the volumetric method is usually employed. For this purpose, solutions of soda are preferred to ammonia, on account of their immutability in preservation, and the facility of producing them in a pure state in the requisite standard. This may likewise be said of solutions of potass.

We are obliged to make, by a chemical analysis of wine, another distinction of substances, namely into those which form the greater quantity, or rather the real body of the wine, and those which, though they are, with regard to quantity, only slightly represented, give to wine its fine taste, smell, and real value, and are, figuratively speaking, the soul of the wine.

Body of the Wine.

Water. | Alcohol. | Sugar or Glycose. | Acid.

Aromatic Substances.

Extractive. | Ætherial oils.

The principal difference between the many thousand kinds of wine will be found chiefly in the taste, but not in the taste of the water, or alcohol, or sugar, or acid, but in that taste which emanates from the aromatic substances contained in wine. The taste of water, alcohol, sugar, and acid is the same in all kinds of wine; there is no difference in the taste of alcohol in Hock and Sauterne; the taste of the sugar in French and Spanish wines is the same as in Austrian wines; and lastly, no one will be able to distinguish a difference of taste in wine, acid, or water. But the aromatic taste in a hundred kinds of wine will differ as often. This taste emanates, is formed, and depends on the different kinds of grapes, the climate, the position, the condition of the ground, and a great many more or less important causes

Professor Mulder, in his celebrated "Chemistry of Wine," has placed together the wine-examinations of all known analytical chemists of wine; most of them only determine accurately the quantity of acid and alcohol contained in wine; and though these examinations differ widely from each other, yet curiously enough they all (with the exception of one) agree in the statement that the greatest amount of alcohol is found in port wine, where its quantum always varies between 17 and 21 per cent. Only Gingal, of Portugal, states most distinctly that genuine port wine contains never more than 12 per cent. ·75 (12¾ per cent.) of absolute alcohol, and that all those port wines are adulterated wherein more than the just-mentioned quantity of alcohol is found; consequently, how seldom is genuine and unadulterated port wine obtained!

With regard to the amount of alcohol, Madeira follows port wine, and differs very little from it. Liqueur wines are, as a rule, stronger than red wines; Turançon, Lachrymæ-Christi, Benicarlo, Malaga, Frontignan contain all from 12 to 15 per cent. alcohol.

The genuine French and Austro-Hungarian wines contain less alcohol—generally 9 to 17 per cent.: a good Bordeaux contains 10, 11, 12 per cent.; Burgundy, 9, 10, 11 per cent.; Voeslau, 11, 12, 13 per cent.; Champagne, 10, 11 per cent.; Hock, 7 to 12 per cent., but mostly 9 to 10 per cent., etc.

As it is easy to add alcohol to wine, the value of the wine cannot depend on the quantity of alcohol found; likewise, its value does not depend on the small quantity of acid, because acid may be neutralised by different means. (In the previously mentioned examinations the amount of acid varies between 4 and 7 per cent. per mill., but may on an average be accepted at 6 per cent. per mill.)

The extractive substances—the aromatic and volatile parts—are stated to be generally 1 to 2 per cent; but are exceptionally more. On their quantity, or, more correctly, on their quality, and the right proportion of their composition, depends alone the value of the wine; and all alcoholometers, hydrometers, and instruments to determine the amount of acid can therefore be considered only as auxiliary means to determine the value of wine.

I am, &c.

Voeslau, May, 1865. R. Schlumberger.

P.S.—With regard to the natural inherent amount of alcohol in port wine, I am disposed to doubt the correctness of Gingal's statement, and am of opinion that port wine, in proportion to other wines, may in good wine years contain about 15 to 16 per cent. of alcohol; but any amount beyond that I consider likewise an adulteration.

BOOKS RECEIVED.

The Fortnightly Review. No. 1. London: Chapman and Hall.

*** Edited by Lewes, and numbering George Eliot amongst its contributors. Very clever and very liberal; but not altogether "orthodox." The article on "Heart and Brain," by the editor, deserves perusal, as it is practical and suggestive: and it is a good thing for us when our terms and theories are overhauled by an acute thinker, in the Profession or out of it. We see, by the bye, that even so exact a writer as the editor uses the word "stimulus," which we thought almost peculiar to the Scots.

The "Flint Implements" from Drift Not Authentic. By Nicholas Whitley. London: Longman and Co. 1865.

*** A very acute criticism of the evidence on which the genuineness of flint implements rests.

The Book of Prescriptions, containing more than 3000 Prescriptions. By Henry Beasley. Third Edition. London: John Churchill and Sons.

*** Some new matter, in accordance with the P.B.

Introductory Lecture given at the Leeds School of Medicine, October, 1864. By Mr. Nunneley.

*** Well worth reading.

The Ophthalmic Review. No. 5.

*** Contains some interesting papers.

Notes on Cases of Tumour in the Mediastinum. By E. Symes Thompson, M.D.

APPOINTMENTS FOR THE WEEK

May 27. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m.; Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

Metropolitan Association of Medical Officers of Health, 7½ p.m. Dr. Clouston (of Carlisle), "On the Production of Dysentery by Sewage Irrigation."

Royal Institution, 4 p.m. Alex. S. Herschell, Esq., "On Meteorology."

29. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

30. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.

Royal Institution, 4 p.m. Professor Frankland, F.R.S., "On Organic Chemistry."

31. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

Hunterian Society, 8 p.m. Dr. Sutton, "On the Influence of Alcohol on the Development and the Prevention of Phthisis."

June 1. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Linnean Society, 8 p.m. Dr. Cobbold, "Remarks on the Best Methods of Displaying Entozoa in Museums;" also, "On the Question of Animal Individuality as Applied to the Helminths."

Royal Institution, 4 p.m. Professor Frankland, F.R.S., "On Organic Chemistry."

2. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m. Professor Huxley, "On the Methods and Results of Ethnology."

Western Medical and Surgical Society, 8 p.m. Annual Meeting. Secretaries' and Financial Reports to be Read; Officers for next Session to be Elected; Practical Evening for Cases, etc.

ORIGINAL LECTURES.

ON THE ASSIMILATION OF SUGAR BY THE LIVER.

FROM

THE LECTURES ON PHYSIOLOGY.

DELIVERED AT

Guy's Hospital.

By F. W. PAVY, M.D., F.R.S.,
Assistant-Physician to the Hospital.

Part III.

I have now furnished you, gentlemen, with an exposition of my own results and the objections that have been raised to them.

From Brücke's analyses, which have been confirmed by Dr. Bence Jones, it seems that healthy urine contains a trace of sugar. I had premised that this should be so without knowing anything of Brücke's experiments and before Dr. Bence Jones' were made known. Looking at the diffusibility of sugar, and the fact that a minute quantity of it exists always in the circulation, I expressed myself thus in one of my Lettsomian Lectures which appeared in the *Lancet* for December 22, 1860:—"I should say, even, that the trace of sugar, which is natural to the blood throughout the body, is constantly being drawn upon by the kidney; but that the amount for removal is so small that it is not susceptible of detection in the urine. Did we possess more perfect means of detection than we do, I imagine a minute trace of sugar would be reckoned as a normal constituent of the urine."

It is a curious coincidence that Dr. Bence Jones' communication was read at the Chemical Society the very evening the number of the *Lancet* containing the above was passing through the press. Dr. Bence Jones, writing quite recently (*Medical Times and Gazette*, January 21, 1865), again states that he has satisfied himself by the most careful investigation that Professor Brücke is right in saying that healthy urine contains sugar.

Now, accepting it as proved that healthy urine contains a trace of sugar, I look upon such a fact as affording one of the strongest arguments that could be brought forward against the validity of the glycogenic theory. It is admitted that no appreciable destruction of sugar takes place in the lungs: therefore, whatever sugar is poured into the circulation from the liver and reaches the right side of the heart will also be found in the arterial system. It must hence be conveyed in due proportion to the kidney, and, on account of its diffusibility, must be in part eliminated with the urine in compliance with the laws of osmosis. Now, if from the minute quantity of sugar naturally existing in the blood, sugar can be shown to exist to a minute extent in the urine, what, it may be asked, would be the condition of the urine if the blood of the right side of the heart were strongly impregnated with sugar as was formerly supposed? I confidently assert that, under such a state of things, we must all have been diabetics. The state of the urine forms an index of the amount of sugar existing in the circulation; and let sugar to any considerable extent reach the general circulation, and it will be sure to determine a correspondingly saccharine condition of the urine.

Dr. Bence Jones, in his recent lectures in the *Medical Times and Gazette*, treats of diabetes as a disease of suboxidation. He seems to have carefully avoided saying anything about the subject of glycogenesis either one way or the other. After enumerating the different kinds of saccharine substances, and stating that they are not all able to pass as glucose into the urine, he says, "but they are all capable of being oxidised in the blood and textures into carbonic acid and water, whilst giving heat or motion or other energy to the body." Now, if from this we are to infer that Dr. Bence Jones is of opinion that the sugar we consume reaches as such the general circulation and undergoes oxidation as it is contained in the blood and is passing through the textures, I think his corroboration of Brücke's analysis stands directly opposed to him. I maintain that the trace of sugar encountered in healthy urine comes by the simple law of diffusion from the minute quantity of sugar always encountered, no matter what the diet, in healthy blood. The presence of this trace of sugar in healthy urine proves that the capacity for the destruction of sugar in the blood cannot be very great. Now, suppose saccharine food to be ingested, and that the sugar reached the general circulation; it would be carried to the kidneys as well as elsewhere, and what would be the condition of the urine under these circumstances? The ingestion of sugar, unless in very large quantity, does not give rise to the presence of sugar, such as is capable of being recognised by ordinary testing, in the urine; but I contend it would do so if the sugar reached the general circulation. Dr. Bence Jones treats of diabetes as a disease of suboxidation, and speaks about the oxidation of sugar in the system as though such a process had been actually proved to occur. He, however, adduces no evidence, and I must confess I am aware of none, that can be taken as showing that the sugar we consume is disposed of by undergoing direct oxidation in the body.

Indeed, my experiments, to which I will now refer, show that sugar is transformed by, or undergoes its first step of, assimilation in, the liver. I have found that from sugar amyloid substance is produced in the liver. This, I think, you will admit to be sufficiently proved by the tabulated results before us, to which I will proceed to call your attention.

Here, first, we have the condition of the liver under a purely animal diet. Eleven dogs were kept for some days prior to death upon a strictly animal diet, and the table shows that their total weight amounted to 158 lbs. 11½ oz., and the total weight of their livers to 85¼ oz. This gives to the liver the relative weight of the $\frac{1}{30}$th part of that of the animal. In other words, we have just over *half-an-ounce* of liver to every pound of dog. In the case of seven out of the eleven dogs an analysis was made for the determination of the amount of amyloid substance present, and the average given was 7·19 per cent.

Next, we come to five dogs kept for several days previous to death upon a vegetable diet. The food consisted of barley-meal and potatoes, or, where this was refused, of bread and potatoes. The weight of the five dogs amounted to 80 lbs. 7 oz., and that of their livers to 83¾ oz. This gives to the liver the relative weight of the 1-15th part of that of the animal. Or, in other words, we have over *one ounce* of liver to each pound of dog. It was ascertained that the amount of amyloid substance present in all the livers was large. A quantitative analysis, however, was made of only three, and the average given by these was 17.23 per cent.

Lastly, we have the table referring to four dogs under a diet of animal food with an admixture of sugar. About a quarter of a pound was the quantity of sugar that was administered daily. The weight of the four dogs amounted to 51 lbs., 12 oz., and the weight of their livers to 49 oz. This gives to the liver the relative weight of the 1-16½th part of that of the animal; or, in other words, we get just under an ounce of liver to each pound of dog. In the case of all four livers an analysis was made, and 14.5 per cent. forms the average of the amounts of crude amyloid substance obtained.

According to these three sets of results, therefore, the livers of the vegetable-feeding dogs were just double; and those of the animal feeders with the allowance of sugar, nearly double in relative weight the livers derived from the dogs under a purely animal diet. The amount of amyloid substance present varied correspondingly, the average per centage under the diets of vegetable food and the animal food with sugar being more than the double of that given by the strictly animal diet.

Let me now direct your attention to the results I have obtained upon the rabbit. The conditions of the experiments to be referred to were so simple and the effects so remarked, that I think but one interpretation can be drawn from them. The results, as you will perceive, are corroborative of those obtained upon the dog.

For the first experiment a couple of full-grown rabbits, as nearly as possible resembling each other, were taken. One of them was kept fasting, whilst the other was fed daily, through a gum-elastic tube passed down the œsophagus into the stomach, for three days, upon one ounce of starch and three-quarters of an ounce of grape sugar mixed with water, so as to be rendered sufficiently fluid for injection. On the fourth day both rabbits were killed, and here are the results that were obtained:—

	Weight of rabbit.	Weight of liver.	Amount of crude amyloid substance yielded by liver.
	lbs. oz.	oz.	
Rabbit fasting . . .	3 1	1⅗	1·3 per cent.
Rabbit on starch and grape sugar	3 4	2⅘	15·4 ,,

For the next experiment, two half-grown rabbits, likewise as nearly as possible of the same size and condition, were

taken. One of them was kept fasting, and the other, upon one ounce of starch and one ounce of cane sugar, administered daily for three days. The examination on the fourth day displayed these results:—

	Weight of rabbit.	Weight of liver.	Amount of crude amyloid substance yielded by liver.
	lb. oz.	oz.	
Rabbit fasting . . .	1 14	1	1·4 per cent.
Rabbit on starch and cane sugar	1 14¾	2⅜	16·9 ,,

With such results I think it may be looked upon as established that sugar derived from without is transformed by the liver into amyloid substance. It may be considered that we have here the first step in the assimilative process to which sugar is subjected in the animal economy; and should this step fail to be accomplished, the sugar would pass through the liver; and, reaching the general circulation, would occasion diabetes. But I do not say that sugar is the only source of the amyloid substance. It is quite certain that it is not so. There is still amyloid substance in the liver, notwithstanding saccharine and amylaceous materials may have been altogether excluded from the diet. I believe that the liver is capable of forming amyloid substance from the products of the retrograde metamorphosis of assimilated animal food and worn-out tissue. By this, materials would be brought into a condition for being turned to account in the system, instead of being discharged as useless.

I must not omit to refer to a property enjoyed by the amyloid substance which enables it to be retained in the liver cells, so that the gradual assimilative influence of the organ may be exerted upon it. Sugar, as I have already stated, is a substance enjoying great diffusibility. With its diffusibility, we may say it would be physically impossible that it could exist stored up in the liver cells whilst a current of blood was flowing through the capillaries around. In the amyloid substance, however, we have a body directly opposed to sugar in respect of diffusibility. It refuses altogether to pass through vegetable parchment or thick animal membranes. Hence it has no disposition to escape from the liver cells, and the circulation can take place around without carrying it away. Should it reach the circulation and be mingled with the blood it would be immediately transformed into sugar and occasion saccharine urine.

Having thus shown that sugar is transformed by the liver into amyloid substance, the next step is to determine into what the amyloid substance is converted. Upon this point, I will simply tell you that Dr. McDonnell has recently enunciated the opinion that it is united with nitrogen, and leaves the liver through the hepatic veins as a newly-formed proteic compound, partly, perhaps, he says, as globuline, and partly as a material in its reactions resembling cascine or albuminose. From the philosophical reasoning adopted, Dr. McDonnell's opinion is entitled to consideration, although I must confess my own investigations have led me to look in another direction for the product of the metamorphosis of the hepatic amyloid substance. It is due to Dr. McDonnell, however, to admit that as yet I have obtained no data sufficiently precise to justify me in entertaining anything more than a surmise upon the matter.

Diabetes I look upon as the result of a defective assimilating action of the liver. If the cases that fall under observation be attentively examined, they will be found to present considerable variation. In some a perfect exclusion of saccharine and amylaceous materials from the diet may be made, and still the diabetic shall pass a considerable quantity of sugar. I should say here that the saccharine principle comes from the unnatural transformation into sugar of the amyloid substance formed by the liver from products derived from animal food, and from the wear and tear, or disintegration of the tissues. In others —and this is the kind of case that is especially met with amongst elderly people—sugar disappears from the urine when restriction from saccharine and amylaceous articles of food is practised. Here there seems to be simply a want of power to assimilate the sugar and starch ingested. In a healthy person, when sugar and starch are taken, they are lost sight of in the system, because there is the power to transform them, so that they may be to the service of the economy. In such a diabetic, however, as I am now picturing to you, whatever sugar and starch may happen to be ingested will pass through the system and be eliminated with the urine, because there is the want of power to assimilate or transform them so that they may be turned to account in the economy. In other cases, again—and these are not so rare as perhaps may be thought for—there is the power to utilise a certain amount of sugar and starch, and this may be taken without occasioning the presence of sugar in the urine, whilst if the certain amount be exceeded sugar is immediately to be recognised in the urine.

I have met with several cases of the last form of diabetes that I have described to you. Such patients have come to me as ordinary diabetics. The diet has been restricted so as to exclude sugar and starch from the articles ingested. The sugar has disappeared from the urine, and after a time it has been found that a certain amount of ordinary bread and potatoes may be taken without rendering the urine saccharine. An excess, however, immediately affords evidence that the complaint has not completely disappeared. In one case—an exceedingly instructive one—the patient regarded himself as completely cured. He was able to take a mixed diet without passing sugar with his urine. All that was required to be attended to was, moderation in the consumption of bread and such-like articles of vegetable food. At an evil moment he was tempted to drink some cyder. Being thirsty, he drank off a pint; and within two hours, from the sweet taste experienced in his mouth, he felt sure his complaint had returned. His urine he soon afterwards brought to me to be examined, and the result showed that his suspicions were well founded. This patient, although several weeks have now elapsed, has never since been in so favourable a state as before. At first, notwithstanding that he fell back upon the restricted diet, sugar was present in the urine; and now, although there is no sugar under it, yet he cannot deviate from it without passing saccharine urine. It is hence evident how easily a relapse may be brought about by indiscretion in what is taken, where it may be even imagined that a complete cure has been effected.

The point remaining to be attained in the pathology of diabetes is to go one step further than we have done and ascertain the cause of the sugar failing to undergo assimilation as it ought to do. It has been for a long time known that puncture of the fourth ventricle produces a temporary diabetes. This has not, however, helped us to unravel the nature of diabetes, because it cannot be definitely stated in what way the effect is produced. Some years ago I discovered that injuring certain portions of the sympathetic system will likewise produce diabetes. A paper upon this subject appeared in the "Guy's Hospital Reports" for 1859. I found that injuring, amongst other parts, the superior cervical ganglion of the sympathetic rapidly produced a strongly saccharine state of the urine. At first, each time I experimented upon this ganglion I obtained the diabetic result. Somewhile afterwards, on several times repeating the experiment, I was surprised to find that if I obtained any effect it was but a very slight one: nothing to be compared to what I had obtained before. I have been at a loss to account for this difference until recently, when it occurred to me to use the fumes of puff-ball as an anæsthetic, instead of chloroform, whilst performing the operation.

I was in no doubt about a strongly-marked diabetic effect having been produced in my early experiments. In one case, indeed, I observed as much as 20½ grains of sugar to the fluid ounce in the urine within half an hour after the operation; and in another 34 grains to the ounce in less than two hours. I was not conscious that I operated differently to what I had done before; but yet there was the difference in the result. Reflecting upon the alteration which the administration of chloroform produces upon the calorific effect resulting from the division of the carotid portion of the sympathetic in the neck, it occurred to me as possible that the administration of chloroform might exercise an influence upon the result of my experiment. I cannot say whether I used chloroform in a manner to produce so full an anæsthetic effect in my early experiments as I do now. At all events, I have recently substituted for chloroform the smoke of puff-ball as an anæsthetic agent, and have found in several experiments that injuring the superior cervical ganglion has been followed, without exception, by the rapid production of strongly saccharine urine.

The inference first natural to be drawn was that the artificial diabetes was occasioned by an alteration in the state of the blood-vessels connected with the liver. I therefore resolved to ascertain how such an inference would stand when submitted to the test of experiment. I tied the hepatic artery, and still found that saccharine urine resulted after operating on the sympathetic. In one hour's time the urine contained 8½ grains, and in two hours' time 12 grains of sugar to the ounce. After ligature of the cæliac axis, also, sugar has appeared to nearly the same extent in the urine. One hour

afterwards there were 7·38 grains, and three hours afterwards 6·66 grains to the ounce. After ligaturing the portal vein as well as the hepatic artery, as was to be expected, there is no appearance of sugar in the urine.

With these experiments I do not see how it is reconcileable that the effect of the operation on the sympathetic can be in a direct manner attributable to an action upon the blood-vessels. It is only upon the coats of the arteries that we can conceive the sympathetic to exert any material direct influence, it being through the muscular element that it influences the circulation. Possibly the operation on the sympathetic may lead to an alteration in the quality of the blood that is passing to the liver, and so occasion the result. This is the most likely supposition that I can offer at present. Tying the portal vein so as to allow a stream of arterial blood only to pass through the liver occasions a saccharine condition of the urine; and injecting carbonate of soda into the circulation previous to operating on the sympathetic prevents the production of saccharine urine. Hence some justification is afforded for looking to the state of blood to supply the explanation required. The effect of the carbonate of soda thus ascertained by experiment in checking the production of saccharine urine after operating on the sympathetic tallies with the known therapeutic influence of the Vichy waters in diabetes.

ORIGINAL COMMUNICATIONS.

SEWAGE EXHALATIONS THE CAUSE OF DYSENTERY.

AN ACCOUNT OF AN OUTBREAK OF DYSENTERY IN THE CUMBERLAND AND WESTMORELAND ASYLUM, WHICH WAS CAUSED BY THE EFFLUVIA FROM A FIELD IRRIGATED BY SEWAGE.(a)

By T. S. CLOUSTON, M.D.,
Medical Superintendent.

The Cumberland and Westmoreland Asylum is built on a dry, sandy hill, about three miles from Carlisle. There are no manufactories or polluted streams near it. The subsoil of the land lying at the base of the hill on which it is built is a stiff brick clay. The water supply is derived from a small stream which arises from the drainage of neighbouring fields, and from several springs in those fields. The water was analysed before the site was determined on, and found to be very pure. The building is well ventilated, and the water-closets and drains were constructed on the most approved principles. Two of the soil drains, however, have frequently had to be taken up since the opening of the institution on account of being choked up when rags, etc., were thrown down the water-closets by the patients. The water from the baths and lavatories is not thrown into the sewage drains, it having been thought that the sewage would be too much diluted if mixed with it. The main drain conveys the sewage to a large vaulted close tank, 40 feet by 40 feet, and 6 feet 6 inches in height, situated about 150 yards from the nearest inhabited part of the Asylum,—a small detached block—and 200 yards from the main building. It was intended that the sewage should be pumped out of this tank into carts, and so distributed over the land. The solid part was to be allowed to accumulate in the bottom of the tank, and to be cleared out through a man-hole at the top at periodic intervals.

The Asylum was opened in the beginning of 1862, and has since generally contained over 200 patients. Many of those, as in all Asylums, are paralytics, weak epileptics, and maniacal patients, whose nervous energy has been greatly exhausted by previous excitement. Many of the patients are old and weak when sent from workhouses to the Asylum. There are about thirty sane people connected with it as officials, attendants, and workmen. The regular diet of each male patient consists of 24 ounces of animal food, 14 pints of milk, 16 ounces suet dumpling, 7 pints of oatmeal porridge, 78 ounces of bread, and 7 pints of tea per week. The females have somewhat less solid food, and coffee as well as tea every day. Extra diet of all kinds is given to the sick and weak. Stimulants are only given by Medical order, not even beer being a part of the regular dietary of the patients or their attendants. Each patient has from 500 to 900 cubic feet of air in the dormitories and single bedrooms, and more than this amount in their day-rooms.

(a) Paper read before a special meeting of the Metropolitan Association of Medical Officers of Health on May 27, 1865.

During the first two years after its opening, the mortality in the Asylum was not half the average mortality in all the other county Asylums. No epidemic appeared in the Asylum till the end of 1863, when there were two cases of typhoid fever, one of which proved fatal. A source of contamination of the water supply was at that time discovered and remedied. It consisted of the contents of a drain which received the slops of half a dozen cottages and the washings of a few hundred yards of a public road. No water-closets emptied themselves into this drain. The cases of fever were of the ordinary type in all respects, and the post-mortem appearances in the one that died were such as are ordinarily found in such cases. I attributed them at the time to the impure water. During the first two years after the opening of the Asylum, diarrhœa was not unusually common among the patients, not more than a dozen cases having been treated for it each year.

Towards the end of February, 1864, a patient who suffered from chronic pleurisy, and whose mental state was that of the most extreme dementia, was attacked by severe and prolonged diarrhœa, with some dysenteric symptoms. The dysenteric symptoms passed off, but the diarrhœa continued till he died, in June. This case attracted no unusual attention, until, in the beginning of April, three men were attacked with very severe dysentery within five days of each other. One of them was a general paralytic, in the last stage of the disease; the second had paralysis agitans in a severe form, and they both died within a week; the third was aged 81, and laboured under chronic mania, and he died in three weeks.

I shall describe the dysentery more particularly afterwards, however. It presented sufficiently marked and novel features to warrant a very full description of its symptoms and pathology. In the meantime I shall confine myself to the history and etiology of the epidemic as an epidemic.

On May 8 two men were attacked by the disease, one of them being an attendant, a young man in robust health, who had only been three days in the Asylum, and both ultimately died. No cases then occurred until June 3, when a woman was attacked by the disease, and, as she was previously phthisical, she very soon died. In the same month four other female patients were attacked, two of whom died. One of those who died was a deaf and dumb epileptic, of feeble nervous power; the other, an old woman of 65. Of the two who recovered, one was a woman who had been for a long time subject to severe dyspeptic attacks, accompanied by a tendency to diarrhœa, and the other was a previously healthy congenital imbecile. On July 2 a man was attacked and died. On July 6 two women were attacked by the disease, one of whom, aged 66, previously exhausted by chronic mania, died, and the other, a congenital imbecile, recovered. On the 13th, a man and a woman were attacked by the disease, both of whom died. They were aged 73 and 66 respectively, and the man was partially paralysed. Between the 17th and the 22nd four men were attacked, none of whom died; but one of them was attacked again on August 2 and died. The disease was apparently checked at first by astringents and opiates in this case. On August 2, and on the 4th, two cases were attacked and both recovered. On the 7th a woman was attacked and died. This woman had been previously in good bodily health. From the 18th to the 23rd of August three cases were attacked, one woman and two men. The woman (a general paralytic) died; the two men, one of whom laboured under phthisis, recovered. These were the last cases that occurred in 1864.

Of the twenty-six persons attacked nineteen had been inmates of the wards on the ground floor of the Asylum. Eleven of them had slept in bedrooms on the ground floor. All the women attacked had been inmates of this ward, except one who lived in the detached block near the sewage tank. I may mention, however, that in the wards on the ground floor the majority of the weaker, older, and paralysed patients reside, in order that they may have freer access to the airing courts.

On March 12, 1865, a woman was attacked by diarrhœa, which gradually passed into dysentery, with slight bloody and purulent evacuations; and on the 19th and 28th, within forty-eight hours four women were attacked with dysentery. All those five cases were in the ward on the ground floor. The four who were last attacked all died, although two of them had been previously in average health.

Altogether, therefore, thirty-one persons were attacked by dysentery, of whom twenty died.

During all this long-continued prevalence of the disease in the Asylum, I find from my prescription-book that diarrhœa

was much more common than in the two previous years, but this is, no doubt, partly accounted for by the extreme vigilance of the attendants in watching for and reporting at once all cases that had the smallest symptom approaching a bowel complaint, and its immediate treatment by me. No doubt I treated many slight cases of diarrhœa that but for the prevalence of the epidemic I should never have heard of. But making ample allowance for these, ordinary diarrhœa was much more prevalent than usual. There were no cases of very severe and continued diarrhœa, however, that would not yield to treatment by astringents and opiates. We shall see, when we come to describe the dysentery more particularly, that it seldom was preceded by long-continued diarrhœa, but in by far the majority of the cases appeared as dysentery almost from the beginning.

Cases of erysipelas were not more common than usual, and there was no other epidemic disease prevalent in the Asylum.

From the time when the first case of dysentery occurred, I endeavoured to discover the cause of the disease, well knowing that there must be a cause either in the unfavourable hygienic condition of the Asylum or in the food or water. The drainage was the first thing looked to. That, with the exception of the one drain that was frequently being obstructed to which I referred, was found apparently in a satisfactory condition. And the period when the patients were attacked with dysentery I found to bear no relation to the periods when the drain was obstructed and the ground opened to clear it out. The whole Asylum was thoroughly and specially cleaned, and the water-closets kept sweet. McDougall's disinfecting powder was used largely whenever it could be applied. The bread, water, and milk were analysed by Dr. Macadam, of Edinburgh, and found to be free from any obviously deleterious matter. The water was made to pass through a charcoal filter, and boiled before being used for drinking by the patients. All the feeble patients were sent up to the upper wards; they were all made to wear flannel shirts and drawers, and the ventilation was increased by opening the upper sashes of the windows during the night. All those prophylactic means proved unavailing. Still fresh cases occurred, and I confess that I was almost hopeless as to discovering the cause of the epidemic. The soup which the patients had as part of their dietary was discontinued. All the patients in the lower wards had twenty minims of dilute sulphuric acid administered to them three times a-day, because during the cholera epidemic it had been recommended as a prophylactic for bowel complaints generally, but one or two of them were attacked while taking the medicine. The dietary did not seem to be at fault, for many of the weakly patients had been on quite a different diet from the ordinary patients, and yet had the disease. The want of stimulants did not seem to be the cause, for many of those same patients had been getting stimulants of all kinds in considerable quantity.

Although in the asylum there had been no other epidemic disease while the dysentery prevailed, yet in March and April three of the inmates of a cottage a few yards from the asylum had typhoid fever. The first of the three attacked had not been staying at home except on the Saturday and Sunday nights previously, and he was never brought home, but taken to the next village. A month after he was attacked the two inmates of the cottage who had always been living there took the disease. They had frequently been to see their brother while he was ill, and at the time I resolved that for the future I should always adopt the same precautions in the case of typhoid fever as in diseases usually supposed to be infectious.

It had often occurred to me whether the dysentery might not be connected with the distribution of the sewage of the asylum. I mentioned that this was thrown into a large tank, and that it had been intended to pump it up into carts to be distributed over the land. But this was found to be impracticable from the large quantity of sewage. An opening was therefore made in the upper part of the tank, and the liquid part of the sewage which overflowed at this opening was conducted by open cuts to irrigate about three acres of grass land immediately below it. The opening through which the sewage escaped from the tank was only about six inches square. The irrigated field was about 300 yards from the female ward in which the greater number of cases occurred, and 350 yards from the corresponding male ward. The land had been drained shortly before the asylum was opened. The upper part of it had a sandy subsoil, and the lower and greater part of it had stiff brick clay under the soil. The direction of the cuts was often changed to make the sewage run on different parts of the field, but this was not done very scientifically.

The reasons which at first made me think the application of the sewage had nothing to do with the dysentery were these:—1st. The sewage had been so applied for two years previously, during which there had been no epidemic diseases of any kind. 2nd. Sewage had been applied in much the same way in many other places, and I had not heard of any epidemic diseases being produced. Jock's Lodge Cavalry Barracks are situated by the side of an immense extent of land which is always being flooded by all the sewage of Edinburgh, and they are said to be the most healthy barracks in the kingdom. How could the sewage from a building with 250 people do any harm, therefore? And at many asylums I knew the sewage to be used in the same way quite close to the building. 3rd. I had never heard of dysentery being connected in this country with sewage exhalations as a cause at all. 4th. I had never perceived any offensive smell at the house; and 5th. Although a very offensive odour was perceived near the irrigated field, yet I was inclined to hold the views of Professors Christison and Bennett, of Edinburgh, as to the general harmlessness of stinks.

In the month of August, however, an offensive odour from the sewage was clearly perceived at the asylum during several hot sultry evenings, and I considered it advisable to convey the sewage away from the tank in a covered drain to the boundary of the asylum farm, where it is thrown into a deep ditch and largely diluted with water. After that time no more cases of dysentery occurred in the asylum during the year 1864, and those at time labouring under the disease recovered.

The sudden termination of the epidemic coincidently with the removal of the sewage exhalations at a time of the year when dysentery is beginning to be most prevalent, afforded a very strong presumption that the effluvia and the epidemic of dysentery were cause and effect. The fact that the tank had not been thoroughly cleaned out for two years, and that the land was a stiff clay through which the sewage would not readily percolate, was strongly confirmatory in my mind of this view. But in order to apply what I considered to be a sure test, I made out a list of the days when the patients were attacked by this disease, and sent them to a meteorologist well known in the neighbourhood for the accuracy of his observations—the Rev. F. Redford—asking him to tell me the direction in which the wind was blowing on those days. The irrigated field was to the north of the asylum, and I expected to find that the wind had been blowing from that direction each day. I then thought that such a poison must be in operation up to the time when the disease begins. But the list was returned to me with only one day marked with a north wind. I then asked him to give me the number of times the wind had blown from the north during the fortnight previous to each outbreak of the disease. It had been from that direction in fifteen out of the twenty-two periods of attacks, and in almost all the cases it had blown for more than one day from that direction. But the seven remaining periods, which were all in July and August, when there had been no north wind, still puzzled me, until I remembered that it was during a sultry evening with no wind that the sewage smell had been perceived at the asylum. On a more careful examination of the meteorological record, I found that such evenings had preceded the outbreaks of the disease, not only in the seven cases unaccounted for, but also in many of the other cases when the wind had been blowing from the north during the day. A further examination showed that within a week of each outbreak of the disease there had been either north winds or hot sultry evenings, with no wind during the night. I also found that in the spring and early part of the summer when the outbreaks had occurred at one time on the male side of the house, and at another on the female side, and there were no calm evenings preceding, that the wind had blown from a point west of north before the male patients were attacked, and due north before the females were attacked. This was precisely what might have been expected, for the building stands east and west, and being a long building the wind would require to blow somewhat from the west to bring the effluvia to the male side. Indeed, it would seem that the number of cases attacked were in the ratio of the number of times the wind had blown from the north or the number of sultry evenings previously. Between April 5 and 14 three males were attacked, and the wind had blown from the north and north north west at least twelve times from March 26 till April 14; and from the beginning of March up to the 9th there had been several evenings quite calm, with a high barometrical pressure. This last condition I found to be very common during the fortnight preceding the attacks. It would

obviously tend to prevent the diffusion of the effluvia through the atmosphere, thus keeping it near the ground, and accounting for the great number of patients in the wards on the ground floor being attacked. Then on May 8 a male patient and the male attendant were attacked by the disease. I found that there had been four calm nights immediately preceding this date, and that the wind had blown twice from the north north west. Again, on June 3, a woman was attacked, and another on the 9th. I find that the wind had several times blown from the north previous to those dates, and that there had been several warm, calm nights. Certainly no conditions could be more favourable for such a poisen to produce its effects than when a warm night with a high barometrical pressure caused strong exhalations, while a gentle wind from the proper direction wafted them in through the windows I had caused to be opened to let in fresh air, to be breathed by my patients when they were asleep and most liable to their deleterious influence.

From the first of the season, up till July, when the direction of the effluvia would be determined chiefly by the wind, males and females were attacked at different times, according as the wind blew towards the male or female side of the Asylum; in July and August, when, through the sultry calm nights, with a high barometrical pressure, the effluvia would spread in all directions along the ground, males and females were attacked promiscuously.

Although I could no longer doubt that the sewage effluvia had caused the dysentery, yet I attributed this to the state of the sewage chiefly, and secondarily to the kind of soil to which it had been applied. As those who had houses further down along the stream into which the sewage was emptied objected to its being allowed to run there permanently, and as I believed, if it were properly applied, it would be harmless to the health of the inmates of the Asylum, I had the tank emptied and thoroughly cleansed, I was to have had the field better drained and levelled, and deeply trenched, so that the sewage might be spread over a larger surface, and applied more scientifically, and that the extra liquid might drain away. All this could not be done at once, and in the course of the operations the drain had to be taken up which conveyed the sewage from the tank. While this was up the sewage had to be accumulated in the tank when the wind was blowing from the north, and allowed to run off by a pipe from the bottom of it when the wind was blowing from other directions. But for one night this had been allowed to run on the land when, as I ascertained in the morning, the wind had been blowing towards the house. It had been nearly calm during the night, too, as I afterwards ascertained. In a week from that time those five cases of dysentery occurred. But another cause must have been in operation, for an obstructed drain was found near the ward in which the cases occurred, which had formed a little cesspool under the soil immediately below the windows of the ward. This can only have existed for a few days, until the soil was saturated and the water rose, as it did at last, into the water-closets. The drain was, of course, at once repaired, the soil removed, McDougall's powder thrown in, and fresh soil was substituted.

This outbreak of the dysentery was, therefore, in all points confirmatory of my previous conclusions as to the bad effects of sewage effluvia; but it showed that it was not necessary for that sewage to have been pent up in large quantity for a long time to become prejudicial to health. The sewage that was run over the land immediately before the dysentery broke out this time was fresh from the drains, the tank having been thoroughly cleansed out. The land to which it was applied had had no sewage applied to it for some time, but, in afterwards trenching this land, it was found that the sand from the upper part of the field had completely obstructed the drains through the clay, so that it had been, latterly at least, as if it had never been drained.

Shortly before this time one of the men employed by the asylum had involuntarily made himself the subject of an experiment showing the poisonous effects of sewage gases. He was putting a new tile in a drain, and happened to put his head close to its mouth, breathing a quantity of the foul air that emanated from it. For the next four days he felt languid, had no appetite, felt very cold at times, had a sensation of something in his throat which made him swallow, and often had the sensation of smelling the drain again. He then was seized with severe pain in the abdomen, as if his "inside were being twisted out." This was shortly followed by vomiting and severe diarrhœa. He says the matters vomited smelt of the drain, and the dejections were very fœtid and of the same odour. He then had a pinched look, his tongue was coated with a thick, dirty, yellowish fur, his breath was offensive, his pulse was quick and feeble, and he could take no food. The diarrhœa continued and became worse, till he could scarcely leave the water-closet, and the evacuations were slimy and mucous, and were slightly tinged with blood, while he had great straining at stool. During all this time the pain was very intense in the abdomen. He said he felt as if his inside were all going away. He had been taking Dover's powder from the time the diarrhœa became very severe, and he seemed to think that on the second day, when the blood appeared in his stools, the powders relieved the pain and lessened the diarrhœa; which continued in a less severe form, however, for two days longer, with no blood in the dejections. It then ceased, leaving the patient weak for another fortnight. The day after the diarrhœa ceased he had very great difficulty in micturition.

This man had not slept in the asylum, but three miles away from it; he had been in every respect a strong, healthy man previously, and there had been no cases of severe diarrhœa or dysentery in the asylum for four months previously. It therefore seems certain that the foul air he breathed from the drain was the cause of his illness; and we shall see, when I describe more fully the dysentery which occurred among the patients, how much his symptoms resembled theirs. This is, therefore, a most instructive case.

As to the extent to which diarrhœa prevailed among the attendants, and servants, and officials in the Asylum during the period when dysentery was prevalent, I find that at least a dozen of them had it in a more or less severe form. In some cases it was coincident with the outbreaks of dysentery among the patients. Many of them had never had such attacks in their lives before. It seems reasonable to infer that the poisonous effluvia which in the case of the patients and the one attendant caused dysentery, was got rid of more easily in the other cases, and merely caused diarrhœa, just as it did in the workman's case who breathed a whiff or two of the undiluted air from the drain. Another curious fact, that may have reference to the action of the poison, is, that at the time when the last five patients were attacked by dysentery this year two other women in the same ward in which they resided (that on the ground floor), who had had dysentery last year and recovered, were observed to lose their appetite, to become listless, and to cease to occupy themselves. They were both imbeciles, and could not describe their sensations; but this state continued a fortnight, when they again resumed their usual condition. All this time they had been getting quinine and iron. They had no diarrhœa. Does not this point to the influence of the same poison on persons who had become somewhat inured to its influence, and on whom, therefore, it had lost its full effect?

As the sewage effluvia had evidently produced the dysentery, I began to think that it might have had something to do with the typhoid fever too. The first inmate of the cottage attacked was only at home on the Saturday nights and Sundays. On the Saturday and Sunday nights, March 19 and 20 (he had been attacked on the 22nd), the wind blew from the east and north chiefly, and the nights were calm. This direction of wind would not bring the effluvia to the cottage, and it is unlikely that the calm would be so complete at that time of the year that the effluvia would spread in all directions; but on the previous Saturday and Sunday nights the wind had blown from the N.W. veering to the W.S.W., which would be the precise direction to bring it to the cottage. He would breathe the effluvia for two nights, nine days before he was attacked by typhoid fever. The other two inmates of the cottage were attacked on April 17, and up to April 9 from the 5th there had been calm nights with a high barometrical pressure, and the wind blowing from the N.N.W. They, too, had certainly been breathing the effluvia for four days and four nights eight days before they were attacked; and I also find that though there were no north winds in the fortnight preceding the time when the two patients were attacked with typhoid fever in the asylum on October 29 and December 1, 1863, yet in the fortnight preceding the former period there were seven perfectly calm nights, with very high barometrical pressure and five such nights in the fortnight before the latter date, which is certainly an unusual circumstance at that season.

I have endeavoured to find out the period of incubation of the poison, during which it was in the system before it produced the dysentery. If north winds and calm evenings had occurred singly, this might have been done accurately, but in most cases the effluvia was breathed for two or three days at a

time, and taking the period of fourteen days before each case was attacked, I find that in that time the cause had been in operation more than once. That the poison produced the disease in three days from the time of its first inhalation, I have positive evidence in the case of the attendant who had only been in the house for that time when he was seized with it. The sewage exhalations had been breathed by him during all that time. Then there were four days of incubation in the case of the workman who breathed the gas contained in the drain. One of the patients was attacked on June 18, and for three days before that the wind had been blowing briskly from the south west, so that in this case there must have been at least three days of incubation. Another case was attacked on July 13, and there had been no north winds, or periods of absolute calm, for five days.

In regard to the five cases attacked this year, it was six days from the time when the sewage had been running over the land during the night, with a north wind blowing, until the cases were attacked, but during the four succeeding nights there had been an absolute calm, so that any effluvia still rising from the ground would be breathed by the patients. And then there was the obstructed drain, which was obstructed up to the time when the patients were attacked. It would seem that the sewage poison took from three to six days to produce the dysentery after it had been inhaled. It is quite impossible to say that in some cases it may not have produced it in less time. My experience does not determine that point.

In one case the action of the poison seemed to be hastened by a dose of castor oil, which had been given to overcome constipation; for the ordinary purgative effects of the medicine passed into a severe and fatal attack of dysentery.

My friend the meteorologist informs me that the occasions during which the wind blew from the north before the outbreaks of dysentery were almost the only occasions on which the wind had been from the north.

(To be continued.)

RUPTURE OF THE EYE THROUGH THE SCLEROTIC.

By GEORGE LAWSON, F.R.C S.,
Assistant-Surgeon to the Royal London Ophthalmic and the Middlesex Hospitals.

Rupture of the Globe.—This is the most severe injury which can happen to the eye. It either destroys the eye at once, or else so impairs it that it seldom sufficiently recovers to be of much service. It is usually caused by blows on the eye with the fist, or with some blunt or semi-blunt instrument, or by the patient falling and striking his eye against some projecting object. The exact part at which the eye bursts will depend partly on the situation of the point which receives the force of the blow; still the locality in which the rupture takes place is so frequently the same that it must depend on more than mere accidental circumstances.

The split in the sclerotic is almost invariably near the margin of the cornea, following somewhat the direction of its curvature, about from one-sixteenth to one-eighth of an inch distant from it, and immediately anterior to the insertion of the recti muscles. The rent most commonly occurs in the horizontal diameter and upper region of the eye, in a line extending inwards from between the margin of the cornea and the superior rectus. The next most frequent site is towards the inner side, between the cornea and the internal rectus. It is comparatively seldom that it occurs to the lower or outer side of the cornea. If the rent is either to the inner or the outer side of the cornea, the split is more or less vertical, thus following the curve of the cornea.

In endeavouring to ascertain the reason why the rupture should so invariably take place between the insertion of the recti and the margin of the cornea, we must for a moment refer to the anatomy of the eye, and at the same time notice the support which the neighbouring parts afford it.

On looking at the sclerotic we shall find that this coat is thickest posteriorly, and that it gradually becomes thinner as it advances forwards, until it is thinnest immediately behind the insertion of the recti, but that between the insertion of the recti and the cornea it increases again in thickness. Now, the whole of the posterior, the strongest part of the sclerotic, derives a material support from the soft cushion of fat on which it rests, whilst its weakest portion is strengthened by the tendons of the recti muscles, so that the only part which may be regarded as completely exposed to the direct impulse of blows is between the insertion of the recti and the cornea.

There is, however, another reason which seems to account for rupture taking place so commonly in this situation.

In blows on the eye, the prominent cornea, the segment of a smaller sphere than that which forms the rest of the eye, is usually sufficiently strong to maintain its own integrity, but driven with force against the sclerotic, on which it is implanted, it acts almost like a wedge, and the part of that coat which is unsupported by the orbital fat, and unprotected by other tissues being superimposed, yields before its impulse and splits. When, however, the sclerotic is ruptured, as in Case 6, by a large piece of metal, or indeed by any foreign body, striking it with great force in its rapid flight past the eye, the seat of the rupture will be the part struck, and the line of the rent will indicate the direction of the course the body was driven.

The cornea itself may be, and is frequently, ruptured by blows on the eye, but the injury is usually less severe and the result less disastrous than in the cases we are now considering of rupture of the eye through the sclerotic. A blow to rupture the sclerotic must be direct or nearly so, and inflicted with great force—whereas a side or glancing one will split the cornea.

In rupture of the sclerotic, the injury is unfortunately not confined to the laceration only of this coat. The force which is required to produce it is so great that all the tissues within the eye suffer more or less. A detachment of the iris to a greater or less extent commonly occurs, and hæmorrhage takes place into the anterior chamber. A portion of the iris may be prolapsed through the wound, or, in some cases, even the whole iris may be detached from its great circumference and be shot out with the lens. The lens is usually dislocated. Most frequently it is jerked out through the wound, and escapes unnoticed; or it sometimes happens that it is seen lying beneath the conjunctiva, that membrane remaining entire over the rent in the sclerotic. Occasionally the lens is dislocated backwards into the vitreous, and perhaps, partially supported by a few filmy shreds of the suspensory ligament which still remain attached to it, it does not sink to the fundus, but floats backwards and forwards with the movements of the eye, and gives rise to as much irritation as the presence of a foreign body. The ciliary processes are usually more or less injured, and blood is effused from them into the vitreous.

The choroid is very frequently involved in the injury, and some of the vessels being ruptured, hæmorrhage, generally from its anterior surface, ensues, the clot, according to its size, producing a displacement of a portion or the whole of the retina, and a corresponding bulging into the vitreous. Occasionally, either from a rent in the retina produced by the injury or from a breaking through of its substance by the hæmorrhage from behind, blood clots are seen lying on its surface; or if in such a case the hæmorrhage continues, the blood is extravasated into the vitreous, breaking down its substance, and ultimately causing its complete disorganisation. But in addition to this, small filmy clots of blood will be often found between the choroid and the sclerotic, causing here and there small detachments of the one from the other. Vitreous humour may escape from the wound at the time of the injury, but unless the loss of it is very great the detachment of the retina and the hæmorrhage between it and the choroid cannot be considered as consequent on it. The displacement of the retina is in the very large majority of cases secondary to the choroidal hæmorrhage, and occasioned by it.

The primary hæmorrhage which a loss of vitreous occasions is almost invariably between the choroid and sclerotic, and is dependent on the giving way of the choroidal vessels from over distension, owing to the sudden withdrawal of the support which the vitreous had afforded. It is sometimes seen to follow the extraction of cataract in unhealthy eyes. The extravasations of blood between the choroid and sclerotic which are often found in cases of ruptured globe are generally limited in extent, and produced either by a direct laceration of the vessels from the blow which inflicted the injury or else by the blood from the anterior choroidal vessels forcing its way posteriorly through the thin tissue of the choroid and forming small clots between it and the sclerotic. Lastly, hæmorrhage may take place from a ruptured retinal vessel, but this is very rare. Such is frequently the condition of an eye after it has been ruptured by a violent blow. All the different textures may not be implicated to the extent described, though it is very usual to find them all more or less involved after such

a serious injury. Certain it is, that in the very large majority of cases the eye is irreparably lost.

(To be continued.)

ON TWO NEW SPECIFIC REMEDIES FOR GONORRHŒA.(a)

By THOMAS B. HENDERSON, M.D., F.F.P. and S. Glasg.

A CONTRIBUTION to the practice of medicine such as we have before us for the title of this paper needs little or no introduction. The paucity of remedies for gonorrhœa has been regretted, I believe, by almost every General Practitioner.

This complaint, from its occasionally intractable character, has sometimes proved, or threatened to prove, an *opprobrium chirurgorum*. Without doubt, ingenuity in prescribing the two specifics known to the Profession has been attended with great success. But even with the greatest skill and ingenuity they occasionally fail. Too often they sicken or nauseate the patient, and in delicate constitutions, if given in doses large enough to have a curative action, they always produce inconvenience and disorder. I believe, in consequence of these effects, many Practitioners dispense, or endeavour to dispense, with the use of specific remedies, treating their cases principally by local measures. The variety of these applications surely indicates a general want of proper remedies, each of the agents used being useful in a few instances only. Does it not seem strange that no addition has been made to the specific remedies known to the Profession since the re-introduction of Cubeb pepper by the late Sir Astley Cooper, now probably forty years ago, so graphically described in his "Lectures on Surgery," 3rd edit., p. 467-8.

The first of the medicines I have to introduce to Professional notice is the oil of yellow sandal wood. It is obtained by distillation from the wood of the tree Sirium myrtifolium, of the genus *Santalum*. It grows in the East Indies. One pound of the wood yields two drachms of the oil. Lindley writes: "This oil is said to be used to adulterate the oil of roses." Professor Redwood, in his supplement to the Pharmacopœia, on the authority of Dr. O'Shaughnessy, writes, "Sandal wood in powder is given by the native Physicians in ardent remitting fevers. With milk it is also prescribed in gonorrhœa." I have ransacked many works on Materia Medica and have not found even the name of yellow sandal wood.

In my experiments with this drug I have found it perfectly innocuous even in large doses. From twenty to forty minims three times a-day, diluted with three parts of rectified spirit, and flavoured with Ol. cassiæ or Ol. cinnam., is the ordinary formula I employ; water and a confection after. In cases of the disease at the first, second, or third stage, in susceptible persons, I have often seen the most marked suppression of the discharge within forty-eight hours. It has the great advantage of being a pleasant medicine, not liable to cause sickness, agreeable to the taste, and grateful to the stomach. It is a medicine as to efficacy, in my opinion, equal, and frequently superior, to Bals. Copaib. or Cubeb pepper. I have often succeeded with it when both had been fairly tried and failed. Besides, it is convenient and portable; and if the patient is delicate, or in bad health, or the system disordered, the possession of a remedy which will act as a stomachic medicine and cure the disease is, I think, to be highly valued. I have used it in many cases during the past five years. I have no theory to offer as to its mode of acting. My experiments have been numerous, but entirely of a practical character. The odour of the drug is slightly perceptible in the urine. Its action on the urethra is observed, in susceptible cases, within a few days after beginning its use. Almost every druggist keeps it for perfumery purposes.

The other remedy I have experimented on is the gurjun or gurgina balsam, or wood oil. It is the product of the *dipterocarpus turbinatus*, an immense tree growing in different parts of India. Incisions are made and heat by fire is applied to the root. One tree yields about 40 gallons in a season; distilled with water it yields 35 per cent. of volatile oil. Wood oil is a liquid of the consistence of olive oil, of a dark reddish colour and slight odour. Pereira gives a good account of this medicine when speaking of the adulterations of Bals. Copaib. In the new edition of Royle's Materia Medica, p. 319, it has the honour of occupying one line. Referring to the products of the dipterocarpæ, it is written, "There is a wood oil which contains a principle analogous to copaiba." In the other works of Materia Medica it is either not mentioned or only slightly noticed. The description of this medicine which caused me to try it for myself is contained in the valuable "Manual of Practical Therapeutics," by Edward John Waring, of the East India Company's Service, first edition, 1854, pp. 200, from which I beg to make the following extract:—

"Gurjun or wood oil tree is found at Chitagong, Pegu, the Tenasserim Provinces, etc. It is found abundantly in all the bazaars of India. By distillation it yields an essential oil, which in all its medicinal properties and actions closely resembles copaiba. Dr. O'Shaughnessy employed it in numerous cases of gonorrhœa and gleet; and the results seem perfectly conclusive, that in the treatment of these and other affections of the genito-urinary system the essential oil of gurjun is nearly equal in efficacy to copaiba. It generally causes a sensation of warmth in the epigastrium, eructations, and sometimes slight purging. It greatly increases the quantity of the urine, which has a terebinthinate odour. Dr. O'S. found that some obstinate cases of gonorrhœa and gleet, which had long resisted copaiba and cubebs, were cured by this remedy. E. J. Waring writes: 'In the few cases I have had an opportunity of trying it, the results have been uniformly satisfactory. It might be advantageously introduced into English practice as a cheap and efficient substitute for copaiba. The dose is 10 to 15 drops thrice daily.'"

It is now several years since I commenced to experiment with wood oil. I have only used it in cases where copaiba had been fully tried and failed. In every case it was successful within a week. No symptoms of inconvenience in any of the cases were produced. I gave it in what may be called large doses—a tea-spoonful two or three times a-day, uncombined. I have not been able to investigate its action further, as my supply became exhausted, and it is not easily procured in this country. I am thoroughly convinced it is an excellent medicine. I think it is probable this oil was introduced into England without there being a demand for it, and those holding it tried to get quit of it by mixing it with copaiba. Being detected, the cry has gone against its use in that way, and very properly so, fulfilling the old saying, "Give a dog a bad name," etc. That it can be procured abundantly at a moderate price I have no doubt; for at the International Exhibition, London, 1862, I observed several specimens, such as the following:—

INDIA—CLASS IV.

Sub-class Vegetable Substances used in Manufactures.

Gurjun Oil.	Wood Oil.	Wood Oil.
Chitagong.	Mangolore.	Capave.
	P. P. Coelho.	Moulmain.
5702 . . .	10,750 . .	. 5692.

It is not necessary for me to lengthen this paper by giving cases in which there was nothing remarkable further than the favourable result I have described. And I hope enough has been said to induce the Profession to make these two medicines the subject of their observation on fitting opportunities presenting themselves.

(a) Read before the Glasgow Medical Society, March 7, 1865.

ROYAL COLLEGE OF SURGEONS.—The Council of this institution has just approved of the following subjects for the prizes offered by the College for competition amongst its members:—For the Collegial triennial anatomical prize, to be awarded in 1868, the subject is "the anatomical structure of those parts of the eyeball which are contained within the sclerotic and cornea, with illustrations drawn from each of the five great divisions of the vertebrata." There are two subjects for the Jacksonian prize of the present year, the essays for which must be sent in on or before Christmas-day next,—viz., "the diseased conditions of the knee-joint which require amputation of the limb, and of those conditions which are favourable for excision of the joint; with an explanation of the relative advantages of both operations, as far as can be ascertained by cases properly authenticated." The second subject is "the relative value of the various modes of treatment of popliteal aneurism, illustrated by cases." There are also two subjects for prizes for the ensuing year 1866—viz., "Ovariotomy: Pathology and diagnosis of cases suitable for this operation, with the best method of performing it, and the results of recorded cases;" and "Fractures into joints: their modes of union, with the treatment and result; the dissertation to be illustrated by cases, preparations, and drawings." The terms and conditions may be known to intending competitors on application to the secretary of the College.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

GUY'S HOSPITAL.

CASE OF ASIATIC CHOLERA—RECOVERY.

(Under the care of Dr. WILKS.)

In calling this a case of Asiatic cholera, we simply imply that it was such a case as would have been so called during the prevailing epidemic of that disease. Dr. Wilks said that every year he saw one or two such cases, but seldom so early in the year as this, and he remarked that the patients, however ill they might seem, recovered. As regards treatment, Dr. Wilks did not speak confidently of any particular plan. Indeed, he said that he felt convinced that those Medical men who got the most credit for treating cholera really treated it worst. They did many things, but not much for the patient. They had many little expedients, but no general principle of action.

For the notes of the case we are indebted to A. B. Shepherd, M.A., Dr. Wilks' clinical clerk.

Samuel W., aged 33, admitted, under Dr. Wilks, into Clinical Ward, soon after noon on May 25. Was at his usual work at 7 a.m. this morning—hammerer to a blacksmith—when he was suddenly seized with profuse vomiting and purging. Says he had been quite well up to that time; had eaten nothing since his supper, consisting of bread and cheese and onions, at 10 p.m. the evening before. Soon after his admission he was attacked with cramps in his flanks and legs. On admission he was pale; his countenance anxious; his eyes sunken; his skin cold to the touch; tongue white, and it and breath cold; coldness of forehead, followed every now and then by heat and sweats; articulation abrupt; vomiting, purging, and cramps continuous; no urine passed; stools, consisting of white flocculi floating in watery fluid, alkaline when passed; vomit of the same "ricewater" character. Throughout the day his pulse and the thermometer indicated nothing abnormal. Ordered, acid sulph. dil., ♏xx.; tinct. cardam., ʒj.; æth. chlor., ♏xx.; aquæ ad., ʒss. Unâquâque horâ. Ice; arrowroot.

Very thirsty. Ordered to have as much water as he wished. About 6 p.m. his vomit became green; stools as before, and still alkaline; both and the cramp still continued; extremities colder; breath and tongue decidedly cold. Said the pressure of the clothes caused cramp, and threw them off. In this state he continued till 2 a.m. Between that time and 4 a.m. he passed no motions, and only three between 4.0 a.m. and 7.20 a.m., the time of the third. They were now acid, and he passed his urine with them; the two last slimy, of a mixed colour of black and green. He was sick only once during this time. Slept moderately well.

26th.—10 a.m.—More comfortable; no cramp, but pain from flank to flank. Still lies with his arms by his sides outside the bedclothes. Temperature 98° 4′; respiration 27; pulse 88. Has taken two cups of arrowroot. No sickness; no stools.

It is unnecessary to prolong this report in detail. The patient steadily improved. His skin was so sore that he feared to be touched.

KING'S COLLEGE HOSPITAL.

RIGHT HEMIPLEGIA, WITH COMPLETE LOSS OF SPEECH—PARTIAL IMPROVEMENT—ATTACKS OF EPILEPTIFORM CONVULSION—INCREASE OF PARALYSIS—FATAL RESULT—BRAIN HEALTHY—GRANULAR DEGENERATION OF SPINAL CORD.

(Under the care of Dr. LIONEL BEALE.)

When a patient loses speech and is paralysed on one side of his body, there must, one would think *à priori*, be some lesion of the higher part of his nervous system. The following case shows, however, that these two symptoms may exist without any discoverable alteration. The brain was quite healthy. This statement is not open to the objection which is often urged in similar cases, that the examination was not carefully and properly made. It is enough to say that the examination was made by Dr. Beale.

Although the patient could not put out his tongue when told, we must not infer that it was paralysed—*i.e.*, paralysed from disease of the lingual nerves or their nuclei. Patients who have what Trousseau calls aphasia and Broca aphemia frequently cannot put out the tongue when told. Indeed, these patients have, it would seem, a difficulty in executing any movement they may be told to perform, even with the muscles which are not paralysed.

For the notes of the case we are indebted to Dr. Morris Tonge, Medical Registrar to the Hospital:—

W. R., aged 44, married, silver polisher, was admitted into King's College Hospital, under Dr. Beale, on November 10, 1864, for chronic rheumatism. He had well-marked arcus senilis in both eyes. A few hours after admission he had sudden right hemiplegia, with almost complete unconsciousness, for several hours. The next day he was quite sensible, but unable to speak or put out his tongue, and the right arm and leg were almost completely paralysed. Reflex action was increased in the paralysed leg, but became normal after a few days. Face drawn to the left; pupils unequal. On the eighth day he had an epileptic fit, the right side being most convulsed, and the right pupil dilated and insensible to light. The palsy of the limbs and speech gradually improved. On the twenty-first day he put out the tongue, and on the twenty-sixth day he could move the right arm freely, and articulate pretty well. On the thirty-ninth day he had a fit affecting the left side. The next day he was sensible, but again unable to put out his tongue, and had much less power over the right arm. On the forty-second day he had two more fits, one affecting the right side. On the forty-sixth day he was quite unable to articulate, and the paralysis of the right arm and leg was all but complete. He passed his motions and urine under him throughout. Bedsores gradually formed about the hips and sacrum, and he lost flesh very much. He became gradually weaker, remaining quite sensible, and died on January 14, 1865, having been sixty-five days in Hospital.

Autopsy. — Sub-arachnoid fluid very abundant; slight opacity of the arachnoid. Brain and medulla oblongata very firm, and perfectly healthy. Several portions of the cord were found to be in a condition resembling that termed by Mr. Lockhart Clarke "transparent granular degeneration." They were of moderately firm consistence, and distinguishable from the healthy portions of cord by their translucence and reddish grey colour. Their position, was, roughly, as follows:—One in the left lateral tract at the commencement of the dorsal region; two in the middle dorsal region, one of them being in the right lateral tract; and the other lower down, involving the central part of the cord; and two in the lower dorsal region, both involving the antero-lateral tract, one of them on the right side. On microscopical examination, no healthy nerve-structure was seen in the diseased parts, which consisted of finely-granular fibres, granular matter, and numerous corpora amylacea. The minute vessels were in a state of fatty degeneration.

NORTH STAFFORDSHIRE INFIRMARY.

CASE OF PARALYSIS OF RIGHT SIDE OF BODY AND FACE, WITH LOSS OF SPEECH—FATAL RESULT—LARGE CLOT FOUND IN LEFT CORPUS STRIATUM AND THALAMUS OPTICUS.

The following case is worthy of record, as showing what happens as regards a patient's power of talking when he has extensive damage to his brain by a large clot. But as this patient only lived a few days, it would not be safe to use the case as a fact in the argument as to whether the faculty of language resides on the left or on both sides of the brain. Such cases should of course be recorded, in order to help to complete our knowledge of the pathology of language, but Physicians differ far too widely in their opinion as to the causes of inability to talk in recent cases to make it safe to use the case in an argument for or against M. Broca's views. What one would call a defect of speech, another would ascribe to partial insensibility. In the meantime, a faithful record of facts will have value when further investigation has cleared away the obscurity which at present renders it difficult even to differ in opinion with precision as to speech, language, etc. A fact well observed will have a proper value in time, although it may at first be misintepreted.

For the report of this case we are indebted to Mr. Dunnett Spanton.

John T., aged 40, widower, a carter, living at Longton, was

admitted into the North Staffordshire Infirmary on December 7, 1864, at 7 p.m. It was stated that the patient had always been a strong, healthy man, never having "had a day's illness in his life." He had been accustomed to moderate, but not excessive, drinking. There was no history of syphilis. He had been out, as usual, in the morning to cart sand, and, at about 2 p m., was found lying in the road insensible. After some delay he was conveyed to the Infirmary, a distance of about four miles.

On admission he appeared a strong, muscular man, of middle height. He was insensible, unable to stand or speak; there was complete motor paralysis of the right arm and leg, and right side of the face; no reflex action on tickling the right sole; there was no paralysis of the left side. Pupils dilated, left larger than the right; acting but little to light. Breathing loud and stertorous. Ordered to take two calomel and colocynth pills; the head to be shaved, and cold applied.

At 10 p.m. the patient was conscious and able to reply, in indistinct monosyllables, to questions. When pinched hard moved all his limbs, but the right arm and leg very slightly. Slight reflex action in right leg; pupils as before; respiration stertorous, 20; pulse full, soft, 80. Protruded tongue when desired, which deviated to the right. Urine dribbled away, was drawn off by catheter.

December 8.—Restless during the night. Now more conscious; still replying to questions by signs and indistinct monosyllables. Towards evening became very restless, with flushed face and hot skin. Less conscious, though he appeared to understand what was said, and would attempt to put out his tongue. When I pointed to his brow, and asked if he had pain there, said "Yes." Was ordered to be cupped at the nape.

9th.—Better; dozed a little after the cupping; more intelligent. Quite unable to move right arm or leg, which felt colder than left. Some sensation on pinching them. Paralysis of face as before. Pupils equal, large, act to light. Face flushed, with vacant expression. Bowels freely moved yesterday after an enema. Urine drawn off, containing a large amount of albumen; scanty. Ordered an effervescing mixture, with five grains iodide of potassium, every four hours; milk, beef-tea, and arrowroot.

10th.—To add half-a-drachm of nitric ether to the draught, and a blister applied to the head.

13th.—Conscious; unable to articulate, though sometimes making an attempt. Very restless. Right pupil larger than left; both sluggish. Breathing stertorous, rapid, heaving. Pulse small, 95. From this time he became weaker, and died comatose the following morning.

Post-mortem Examination made Four Hours after Death.—Rigor mortis moderate. Body well nourished. Head: Dura mater firmly adherent to the skull; natural in appearance. No thickening of arachnoid. Brain substance of natural colour; bloody points numerous. About six drachms of reddish serum in left lateral ventricle; less in right. On cutting into the left corpus striatum, there oozed out a semi-solid clot of dark blood, which was found to extend into the substance of the left thalamus opticus for three-quarters of an inch, being altogether the size of a Brazil nut. The surrounding brain tissue was very soft. The clot was about two lines beneath the surface of the corpus striatum and thalamus. The lining membrane of the ventricles presented a minutely granular appearance. The granules, under the microscope, appeared to consist of lymph. There was no plugging found in the middle cerebral artery. The vertebral and basilar arteries and the cerebral, in a few places, were atheromatous. Other parts of the brain healthy. Examined under the microscope, the clot was found to consist of blood, compound granular cells, and small branches of vessels. These were granular, and in some places appeared to be almost covered with rows of minute fat globules, which here and there were aggregated so as to form irregular, but distinct masses without any apparent investing membrane. No blood crystals were observed. In the healthy-looking brain tissue adjacent to the clot, the capillaries, chiefly about the $\frac{1}{1000}$th inch in diameter, presented the appearance already described; and surrounding them were minute extravasations of blood, though in some of them no blood corpuscles could be clearly distinguished. Chest: a small quantity of serum in pericardium. All the cavities of the heart and the pulmonary artery contained firm fibrinous clots, except the right auricle, in which was dark blood. Valves healthy. Left ventricle much hypertrophied concentrically, the walls being nearly an inch and a-half thick; the columnæ carneæ very large; the musculi papillares at least twice the ordinary thickness. The cavity was large enough only to contain one finger easily. Aorta atheromatous, the patches being large and thick. Lungs healthy. Other organs not examined.

BIRMINGHAM GENERAL HOSPITAL.

PARAPLEGIA FROM MORBID GROWTHS WITHIN THE VERTEBRAL COLUMN.

(Communicated by JAS. RUSSELL, M.D.)

Case 1.—*Syphilis—Paraplegia—Death—Node on Spinal Dura Mater—Nodes in the Liver.*

I am indebted to the kindness of my colleague, Mr. Crompton, for the opportunity of publishing the following case, as well as of examining the spinal cord:—

John B., aged 28, draper.

Sectio Cadaveris Sixty Hours after Death.—On the posterior aspect of the spinal cord, about the middle of the cervical enlargement, was a firm growth of regular ovoid shape, an inch and a quarter in length, by half an inch in breadth. It was closely connected with the dura mater on one aspect, and with the substance of the cord on the other, a distinct line of demarcation, however, subsisting between the growth and the nervous tissue. It had hardly indented the cord, although it had somewhat flattened its natural curved outline. The substance of the growth was homogenous, of a grey colour, and of the consistence of fibro-cartilage. The tissue of the cord was uniformly soft, beyond what would be explained by the interval between death and the post-mortem examination; but there was no morbid change perceptible by the naked eye in any particular part. By the microscope the growth was found to consist almost entirely of cell-like bodies without nuclei, of irregular shape, with some fibrous bands scattered among them. Many of the cells were nearly filled with oil globules, and a considerable number of similar globules and granular matter were scattered through different specimens. The entire cord, excepting the part beneath the adventitious structure, was perfectly healthy; the tubules were well formed, and did not manifest any tendency to break up. But in the portion corresponding to the morbid growth a very striking difference was observable; here the tissue presented a large abundance of granule cells, thickly dotting every specimen, and the tubules were, without exception, remarkably small. They were not broken, but were nearly empty of their natural contents. The minute vessels of the cord were healthy, though they were generally empty. Mr. Bracy informs me that the brain was firm and quite healthy. There was no unusual amount of subarachnoid or ventricular fluid; the vessels at the were also healthy. The only other organ in the body which exhibited evidence of disease was the liver; its surface was puckered, its capsule thickened in places, and it contained numerous masses scattered through its substance, chiefly towards the surface of what, from the description, I have no doubt were syphilitic nodes. The largest of them attained the size of a horse-bean. The bladder was surrounded by a large abscess, resulting from a false passage made through the urethra in unsuccessful attempts to pass a catheter before the patient was brought to the Hospital.

Mr. Bracy gave me the following history of the case:—The patient had lived in Ceylon, and there had contracted "a black chancre." When he entered the Hospital he had a circular ulcer, having the appearance of a secondary sore, on the outer part of the right thigh. Eleven months ago he returned to England, and, having come into possession of a considerable amount of ready money, abandoned himself to dissipation, and contracted gonorrhœa, of which he was cured, but renewed the disease, which had not subsided when he came into the Hospital. A few days before admission he lost the use of his legs very rapidly, the power of motion leaving them in the course of twenty-four hours, the limb at the same time becoming numbed. With these symptoms he experienced difficulty in expelling his urine, and the immediate cause of his being brought to the Hospital was the inability of his Surgeon to introduce a catheter. The sphincter ani was so completely relaxed that the anus formed a large opening, whence flatus and fæces continually escaped. He was pale, emaciated, and weak; was unable to move his lower limbs, though he retained some power over the toes of his right foot. In the course of a few days his urine flowed involuntarily. He regained some control over his right leg, and could just move his knee from the bed. He could move his arms quite well, and his ribs acted

freely in respiration. Sensation was unimpaired in the lower limbs. He died suddenly of apnœa eleven days after admission.

I add a few particulars of the following case as a companion to the preceding, though it appears probable that its place is among those cases, some of which have been narrated by Dr. Gull in the 39th vol. of the *Med.-Chir. Trans.*, wherein paraplegia is caused by inflammatory action propagated to the cord during the course of an attack of gonorrhœa along the veins or by means of the blood.

Mr. P., aged about 36. He has been of very dissipated habits. My friend and colleague in the case has known him ten years; he has never had to treat him for any venereal affection prior to the present occasion; he, however, tells me that about four months before the present illness the patient complained to him of some difficulty in "forcing out his water," a No. 8 catheter passed easily, and the symptom speedily subsided. Six weeks before I saw the patient he contracted gonorrhœa. four weeks afterwards, as the discharge was subsiding, he experienced slowly-increasing weakness in his lower extremities, together with numbness and a dulled sensation in the tips of his fingers. At the end of the second week he was almost helpless. He had also indefinite pains, which he called rheumatic, along the inner side and front of each leg, passing, as he specially stated, behind each inner ankle. This pain was usually so much aggravated about 5 a.m. that he was obliged to get out of bed. Some numbness was complained of in the soles of the feet, and at my visit there was present a feeling of tightness round the epigastrium. There had not been any cramps nor startings. Micturition and defecation were unaffected, but the bowels were costive. His spirits were depressed. I found the patient barely able to raise his feet from the bed, but without any increase of reflex sensibility; sensation was unimpaired, neither exalted nor depressed. The upper extremities were healthy. The muscles were firm. No pain was produced by pressure upon the vertebræ. The pupils were of medium size. The urine was free from albumen, free also from exudation cells; it deposited phosphates on boiling, and after standing presented a sediment of crystals of triple phosphate and of oxalate of lime. I have omitted to state that there was slight tenderness in the perineum. As I could not see the patient apart from his wife, who was ill in the same room, I was unable to prosecute my examination farther. A blister was placed over the lumbar region of the spine, and ten grains of iodide of potassium were directed to be taken three times in the day. In four days he had lost the pains in his legs, but motor power had further diminished, and he had some difficulty in expelling his urine. He was without pain. Pulse 84. Appetite good. Bowels continued costive. His chief complaint was of awakening in the night, very restless and uneasy. To continue the iodide of potassium. To take with each dose of the mixture, calomel, gr.j.; pulv. Doveri, gr. iij. I did not see the patient again, but five days afterwards my friend told me that slight salivation had commenced, and that motor power was returning in the patient's legs. From that time he slowly recovered.

Although I was unable to obtain a post-mortem examination in the following case, its nature was so evident from the external manifestations that it is worthy of mention in the present relation.

Case 2.—*Rapid Paraplegia—Speedily Fatal—External Tumours of a Malignant Character.*

Mr. H., aged 54. He has been out of health twelve months, and has been emaciating for some time past. Five months since he began to complain of pain in the right shoulder and arm, subsequently along the course of the right sciatic nerve, and afterwards along the course of the nerve on the left side also. Five weeks before I saw him he consulted his Medical attendant, when some enlargement at the outer end of the right clavicle was discovered; some weeks after similar enlargements were noticed in connexion with certain ribs of the right side. These enlargements, firm when first noticed, soon became soft, and increased with surprising rapidity. About a fortnight ago the patient lost sensation in his rectum, and the stools were passed unconsciously; his bowels also became obstinately costive. The urine then dribbled, and the bladder was distended. About the same time numbness was experienced in the lower extremities, with impairment of motor power. I found the patient quite unable to stand, though retaining power to kick his legs freely when on the bed; their muscles had wasted considerably. The arms were not affected, and the ribs moved in breathing. Sensation was greatly dulled in all parts of the body below the level of the thorax—dulled to an extent, apparently, disproportioned to the motor paralysis. I found the outer half of the right clavicle occupied by a soft, elastic growth of considerable size; a ridge of similar outgrowths from the second, third, and fourth ribs, at the point of junction with the cartilages, ran along the chest on the right side of the sternum. The skin was unattached to the tumours, and was free from vascular turgescence. In ten days paraplegia was complete; reflex sensibility was extinguished in the right and almost in the left leg; the bowels were greatly distended, and required severe purgatives; anæsthesia involved the base of the thorax; but the movement of the ribs continued free. The patient had no pain except in the lower part of the cervical spine; but when moved he complained of great pain in the hips. Nothing was apparent to examination in the vertebral column. The costal tumours had considerably increased in size; one of them extended across the sternum; the skin over them had become tense. He died four days afterwards, apparently from apnœa. Permission to examine the body was refused.

SATURDAY, JUNE 3.

THE PROFESSION A POLITICAL POWER.

The near approach of a general election affords an opportunity to the Profession which we shall be sadly wanting in our duty to ourselves and to our calling if we let slip. The past history of the now moribund Parliament ought to have taught us a lesson. The Profession has seen its interests treated on every occasion with either unmistakeable hostility or, at the best, with civil indifference in the councils of the nation. We utterly disclaim all party feeling. In this journal we know neither Whigs nor Tories. But we should be wanting in our duty did we not state our mature conviction that the present Administration have omitted no opportunities of casting a slight on the status, the interests, and the influence of the body to whom the lives and health of her Majesty's subjects and servants are by law committed. It matters not to which department of Government we look, the same fact presents itself in unmistakeable colours. In the Indian Department Sir Charles Wood, had his design not been frustrated by the firmness and pertinacity of Mr. Hennessy, would have inflicted a fatal injury on the Indian Medical service. The faithless conduct of the Horse Guards in tampering with the Queen's Warrant has been smilingly acquiesced in by the Ministers at the War Office. The Greenwich Hospital Bill now before Parliament is an apt illustratiou of the mode in which the Naval Medical service is treate by the Lords of the Admiralty. The most impeccable and unimpeachable of Lord Chancellors lightens the labours of law reform and provision for his family by cultivating his forensic wit and amusing the House of Lords at the expense of the Doctors; and at the Poor-law Board the toils and responsibilities of Medical attendance on the poor are still appraised at fractions of farthings per head. We cannot say whether any other Government would show a more just appreciation of the value of our science or of the pretensions of its professors. But this we do affirm, that if the Profession of Medicine will but recognise the true value of their own political power, they may at once make it dangerous for any Government to treat them with either contumely or neglect.

If the Profession, however, wish to assert their political force, they must pledge themselves to no political section. With a common object before them, and laying aside all lay-political bias, they will immediately become themselves a powerful party. They should learn to look on the next Parliament as simply an arena where a battle is to be fought, which may result in placing their art in the position which it is entitled to occupy—in the vanguard of liberal callings, or in sinking it beneath the level of a respectable trade. No Minister in the present balanced state of political power could venture to set at defiance a body of highly-cultivated gentlemen so numerous as the Profession of Medicine if they once make themselves heard in Parliament. Let Medical men not only refuse their vote, but actively oppose the return of every candidate—be he Liberal, Conservative, or Radical—who will not pledge himself to Poor-law Medical reform; to the removal of the causes of just dissatisfaction in the Army and Naval Medical Departments; and to the proper recognition and remuneration of Medical services whenever they are rendered to the State; and we have no fear for the result. We need only remind our readers of the clerical organisation which has converted the overwhelming majority on Church-rates into an actual minority.

It is also most necessary that the Profession should have their special representatives in the House of Commons—men who have occupied positions in their own body, who are influenced by Professional feeling and are well qualified to judge on Professional questions. We are not forgetful of what was done by the late Mr. Wakley, nor ignorant of the services of Dr. Brady; but we do no injustice to the latter gentleman or to the memory of the former when we assert that the Medical Profession is not, and has not been, adequately represented in Parliament by members of its own body qualified to pronounce authoritatively on topics in which its honour, interests, or usefulness are concerned. We hail with pleasure the prospect of a change in this respect.

Sir Charles Locock is offering himself in the Conservative interest to the electors of the Isle of Wight; Mr. Mitchell Henry on the Liberal side is opposing the Blenheim interest at Woodstock, and Mr. Alfred Smee is soliciting the Conservative electors at Rochester. We heartily wish all these gentlemen success. Although they differ in politics, we know that they will each have at heart the interests of the body with which their names have been long honourably connected and in which their reputation has been made. It would be especially valuable to the Profession to possess such an advocate in the House as Sir Charles Locock, a man of such large influence, such excellent abilities, such unflagging energy, and such high personal character. Each of the three candidates would, if elected, worthily represent the Medical feeling of the day, and we hope that those of our readers, whatever their political creed, who have it in their power will vote for them.

Yet it must be remembered that three votes would make but a small show in the division list, but votes in the House are to be had in payment for votes on the hustings, and we believe that no body of men, with the exception, perhaps, of landowners, could return more votes to the hustings than the registered Practitioners of Medicine, Surgery, and Midwifery.

THE CHEMISTS AND DRUGGISTS BILLS.

It is sufficiently manifest that a chemist and druggist stands already on different footing from other persons as regards his facilities for carrying on an unauthorised Medical practice. He is known to be acquainted with the names of drugs, and is supposed to have some knowledge of their properties, and the uneducated portion of the public have but a very hazy notion of the distinction between the qualifications of a druggist and of an apothecary. They are quite unable to recognise the fact that an acquaintance with the British Pharmacopœia does not necessarily bring with it a knowledge of pathology and an aptitude for diagnosis.

Should either of the Chemists and Druggists Bills now before Parliament become law as originally drawn, the temptations and facilities to illegal practice will be greatly increased. The public will be impressed with the idea—erroneous, of course—that the examination and registration of druggists will guarantee the possession by them of a certain knowledge of the art of prescribing, and, indeed, it would almost seem that the establishment of such a guarantee is one of the objects of the promoters of the measures. It is, therefore, important that neither of the Bills should pass without provision being made against the extension of the illegal "counter practice."

The legitimate business of a druggist is two-fold—consisting first of the compounding of the prescriptions of qualified Medical Practitioners, and secondly, of the simple retailing over the counter, by the pound or ounce, of such drugs as his customers *may ask for by name*. Any departure from these two branches of trade—as, for instance, where the customer states the ailment for which a remedy is needed, leaving the selection of the drug and the magnitude of the dose to the chemist, is irregular, and at once converts the druggist into an unauthorised Medical Practitioner. To prevent these practices entirely would be impossible, for the public would never submit to a law which would compel uneducated persons, in the case of a trifling ailment, to provide themselves with the prescription of a qualified Practitioner, or else to indicate by name the medicine they require, instead of asking for "stuff good for a cough." Such a law would, we believe, be on the whole beneficial, but would be too un-English for that public which insists on its right to go if it pleases to the village schoolmaster for its law, or to the blacksmith for the extraction of its teeth. The suggestion of the Committee of the Medical Council is to add a clause to the effect that nothing in the Act contained shall entitle any person registered thereunder to practise Medicine or Surgery. It is not pretended by the Committee that this clause would in any manner modify the effect of the Bill, but it is said that "the members of the pharmaceutic body would thus have constantly before them the sentiments of the Legislature as to the principles on which the Pharmacy Act was founded." We would remind the members of the Committee that ordinary individuals care nothing for the "sentiments of the Legislature" unless backed up by a penalty attached to particular offences.

Perhaps no better method can be suggested of counteracting this mischievous tendency of an otherwise useful Act than that of giving to the Council of the Pharmaceutical Society a power of removing from the Register, either temporarily or permanently, the name of any druggist who shall, after due inquiry, be judged by such Council to have been guilty of illegally practising Medicine. The discretion thus given would get over the vast difficulty of drawing the line in the right place. We have sufficient confidence in the Council to believe that the power would be properly exercised; and if not, it would of course be still open to the Apothecaries' Company to proceed under their Act. It would be well, however, that the establishment of a Register should be accompanied by a simultaneous check upon any attempts to make an undue use of the *prestige* which registration will confer.

WORKHOUSE HOSPITALS.

We most cordially support the proposition of the deputation to the Hon. Mr. Villiers, a report of which will be found in another column. At the present time, the Poor-law Board is assisted by twelve inspectors, and as one of their most important duties is the supervision of Medical relief and administration of Workhouse Hospitals, it is strange indeed that none of them are themselves of the Medical Profession. It can be no reflection on a barrister to say that he is unable to form a correct judgment as to the dietary necessary in a Workhouse Hospital, or that he is

unqualified to express an opinion as to the arrangements provided for the performance of Surgical operations or the treatment of the sick; and we cannot but believe that the proposed addition of Medical men to the staff of inspectors will be received by the Poor-law Board as the most important help they can obtain in the difficult task they have before them of removing the shameful evils which have been shown to exist in the metropolitan workhouses.

The need of Medical assistance has indeed been frequently recognised by the Poor-law Board. Physicians of eminence have from time to time been employed to report upon the condition of certain workhouses, and the value of their reports forms the strongest argument that such inspection should be permanent and systematic. No other department of the public Medical Service is left exclusively to lay-supervision. The Hospitals of the Army and Navy are subject to the visits of Medical officers qualified by their rank and experience to supervise not only the nurses, wards, beds, and other details of Hospital management, but the manner in which the Surgeons' duties are performed. So, again, the Hospitals for insane are not left to the supervision of the laity alone, but are inspected by Professional Commissioners, who examine the practice of the Medical officers in charge, and require reports and other evidence that their duties are well performed.

In the Workhouse Hospitals no supervision of this kind is now carried on. The Medical officer may have exclusive and uncontrolled charge of 200 patients without responsibility to any Professional authority; and as they are in many cases most shamefully paid, it would be to look for superhuman excellence to expect that the machinery employed should always be perfect and require no supervision. The unpopularity of Workhouse Hospitals is sufficiently notorious, and there exists a wide-spread belief that neglect is to be found elsewhere than in the wards of St. Giles's.

A remedy is, therefore, urgently called for, and it appears to us that none can be more obvious than persistent inspection by competent Medical men. This can be accomplished by the Poor-law Board without any new legislation and without any violation of municipal principles. Boards of guardians would probably object to interference with their privileges; but they cannot be supposed to understand the administration of Hospitals. It is charitable to believe that it is ignorance, not inhumanity, on the part of parochial authorities, which fails to afford the sick pauper the comforts and advantages which are to be found in the institutions supported by voluntary contributions; and only let what is strictly necessary be laid before the guardians, on less impeachable authority than that of their own officer, and public opinion will support them in carrying out all that is required to make the wards sufficient, the beds comfortable, and the nursing as good as possible, considering the great difficulties which exist in obtaining qualified persons to act in that capacity. The Medical officers of workhouses would, we are certain, receive the visits of Medical inspectors to their Hospitals as a great benefit. They would no longer feel the burthen of undivided responsibility; they would have the opportunity of consultation in all matters of Professional difficulty; and they would at once have a powerful machinery for representing their wants and wishes at the Poor-law Board.

But the importance of a Medical element in the administration of the Poor-law cannot stop at a reform of the Workhouse Hospitals. The mode of providing medicines, the salaries of the Medical officers, and other important matters would necessarily be submitted to their judgment and control, and it is impossible to conceive that a greater boon could be conferred upon the Medical officers of the Poor-law than the appointment of some one at head quarters to represent the grievances under which they too often labour. Nor would the public fail to find the advantage of the valuable reports which an organised Medical staff would be enabled to present from time to time to the Poor-law Board. The statistics of disease amongst the extreme poor are altogether unknown, and the results of treatment in Workhouse Hospitals are not at present recorded in any tangible form, whilst no means exist for watching the progress of epidemics at all comparable to that which it is in the power of the Poor-law Board to institute, and which would be most properly confided to the Medical inspectors.

HOMES FOR GENTLEWOMEN DURING ILLNESS.

The promoters of the new ward for ladies at the Hospital in Soho-square certainly have no claim to a monopoly of doing good, so far as relates to the necessities of sick gentlewomen. Not only the Home for Invalid Ladies in Harley-street, but the Samaritan Hospital and Mr. I. B. Brown's Surgical Home for Women, admit ladies at a trifling weekly rate of payment. All of these Hospitals, however, keep up a monopoly of Medical attendance. Every patient who is admitted is compelled to place herself under the hands of the Physicians and Surgeons of the respective institutions, and to forego the services of every other Practitioner. Now, if it be really the welfare and comfort of the invalid ladies that is aimed at, and not the Professional advancement of the Medical officers, let these gentlemen say,—"We do not want a monopoly of benevolence, we do not want to ventilate our own names exclusively; we are willing to tender our services, but not to force them; ladies, though necessitous, may be indulged in their predilections for their own attendant; let any respectable Practitioner be at liberty to treat any patient, subject to certain rules, whilst the charity provides bed, diet, drugs, nursing, and all the comforts of a home." We are glad to tell our readers that such a Hospital is about to be opened in connexion with the Church Home for Ladies, 28, Delamere-terrace, Upper Westbourne-terrace, an institution under the guidance of Miss Hales, and approved by Drs. Walshe, Arthur Farre, William Fergusson, Greenhalgh, Gream, and other well-known names. We find in the prospectus,—

"The above Home is now open to receive ladies who wish to assist in parochial work. When funds are sufficient, this Home will also receive ladies in delicate health, or who require nursing, kind care, and attention in some illness. Many whose means are limited, and who may be lonely in the world, and are often sent up to London for advice, seriously ill, might be glad for the sum of a guinea a week to know of such a Home. Any lady may have her own Medical attendant, provided she pays the expense, etc."

We cordially wish every success to the new institution, and congratulate the founders on the liberality of their regulations.

As a proof that such an institution is needed,—that is to say, in which the sufferers may have the comforts of a home at small fixed cost, without the attendance of Medical gentlemen for whom, notwithstanding their eminence, they may chance to have no predilection,—a well-known Physician and contributor to these pages gives us the following anecdote:—

"About four years ago," he says, "I was sent for to see a single lady, a namesake and distant relative of my own, whom I had not seen for years. She was nearly 70 years old, but marvellously youthful looking, and proud of her good looks, and, as she did not get on very well with her family, had long lived a sort of wandering kind of life in lodgings at the West-end. She told me that she wanted to confide a frightful secret to me, as she soon did, by showing me an ulcerated cancer of the right breast, into which one could have put a hen's egg. She had carefully concealed this mortal sore from every living creature, and yet, as I learned, had been twice an inmate in a well-known home for invalid gentlewomen. On my asking how this could be, she said that she chose not to confess her hidden malady to the Medical officers of the institution, and described with the glee of female maliciousness what shifts she had been put to to hide it, and how she was obliged to destroy the rags, etc., which she applied to it. She spoke in high terms of the kindness received from the Physician, and from every other officer of the house, but often felt amused at

wondering what alteration the learned and amiable Doctor would have made in his prescriptions had he known what his patient really ailed."

THE GOVERNMENT AND THE NAVAL MEDICAL DEPARTMENT.

The recent debate on the Greenwich Hospital Bill has brought to light one of the most striking instances of injustice toward Medical officers in the public service, which even the history of the present Administration can furnish. We need only remind our readers that it is the intention of the Government by this Bill to make Greenwich Hospital less an almshouse and more a Hospital, in the modern sense of the term, than it has hitherto been. It has been found that under the present system the pensioners, shut out from all amusement and occupation, leading a life of enforced idleness, fall into vicious habits. Separated to a great extent from their homes and families, and bereft of the healthy interests and enjoyments of life, the veterans sink either into helpless vacuity or betake themselves to the alehouse or to worse places. The number of pensioners has hitherto been about 1600, but Greenwich Hospital is so little popular that there are at present above 50 vacancies. It is proposed to remedy this state of things by introducing a wide system of out-door pensions, which will allow the men to live with their wives and children and to contribute to the support of their families. Greenwich Hospital for the future is to be an infirmary for sick, infirm, and helpless seamen. Under the old system the number of cases in the infirmary has been about 300. It is proposed to raise the number of sick and infirm to 600. Such is a sketch of the general intention of the Bill, which we think is a good and wise one. Now, however, let us examine some of its details. By the contemplated changes a large yearly surplus will be left in the hands of Government, and it is proposed by the Admiralty to bestow this in the shape of good service pensions on various grades of officers. The Executive, of course, come in for the lion's share. Six post-captains, nine commanders, and thirty lieutenants are to be pensioned at the rate of £80, £65, and £50 a-year; in fact, the good-service pensions granted to lieutenants will be so numerous that 10 per cent. of that rank of officers on the active list must obtain them. The same bounty is to be extended to other grades of officers; nine masters are to have pensions of £50 a-year; fifteen paymasters are to receive £50 a-year; and nine warrant officers £25 a-year each. Even the chaplains are not forgotten, for certain livings belonging to the Greenwich Hospital estates are to be sold, and the proceeds are to furnish good-service pensions for naval clergymen. *Only to the Medical officers is no good-service pension to be granted.* This piece of glaring injustice speaks for itself. It is really unnecessary to prove its iniquity. One of the main features of the proposed reform, as stated in the minute of the Admiralty Board, dated November 28, 1864, is:—"To apply the consequent saving for the increase of out-pensions, and also, in part, to additional pensions *to the classes of officers who have hitherto been employed at Greenwich.* Not only have Medical officers been employed at Greenwich, but they have done their work so well there that the Royal Commissioners have reported that in the infirmary department "the dietary, the dormitories, the dress of the patients, the attention bestowed on their comforts, leave nothing to be reformed." "This establishment," they state, "is conducted in a manner which is worthy of a great national institution." Yet the class of officers to whose exertions the only perfect portion of the administration of Greenwich Hospital is owing are to have no participation in the bounty which is to be scattered broadcast to all other ranks. Paymasters have never, *as a class*, been employed at Greenwich Hospital, although a few have had clerks' offices given them in preference to civilians. The Government, therefore, has gone out of its way to give fifteen of these officers pensions, whilst the just claims of the Medical officers have been contemptuously passed over. Mr. Childers' reply to Mr. Hennessy's question in the debate of Monday last, was as remarkable for its sneering tone as for its want of honesty. No doubt the same staff of Medical officers will be still employed at Greenwich; but will not the same numbers of some other grades of officers who are to receive pensions be still employed there? It is true that the higher executive ranks will lose some posts, which, however, will be doubly recompensed by the pensions allotted to them. But with regard to the paymasters, for instance, there is a special clause in the letter of the Lords of the Admiralty to the Treasury providing that one or more of them shall be retained at the Hospital for performing the duties of clerks. The same is true with regard to the chaplains. There are at present two chaplains to Greenwich Hospital; the same number will be required under the new scheme.

There are at present but three good service pensions of £100 a year each for the whole Medical Department of the Navy, whilst it is proposed to give eighty pensions of £50 a year each to the lieutenants' rank. But we think we have said enough to expose the gross injustice which the Government have meted out to the Medical Department of the Navy on this matter. Our best thanks are due to Mr. Hennessy for his watchful care of the interests of our Profession on this as on former occasions, and we hope that our Medical brethren in King's County will remember, at the coming election, that he has proved himself a firm friend of the Profession. Lastly, we are not sorry to announce one fact which forms a suitable comment on the Government policy to the Naval Medical Department, and which, if it continue, must compel the attention not only of the Duke of Somerset and his coadjutors, but of Parliament itself. It is this: at the present time there is not a single candidate for an appointment as Assistant-Surgeon in her Majesty's Royal Navy on the Director-General's list.

SEWAGE DIFFICULTIES.

Dr. Clouston, Medical Superintendent of the County Lunatic Asylum, near Carlisle, has given to the Metropolitan Association of Medical Officers of Health the history of a series of cases of dysentery, typhoid fever, and diarrhœa, so clearly due to the irrigation of an adjoining field with the sewage of the institution, that all who are concerned in promoting schemes for a similar application of liquid sewage may well pause and ask whether it is so universally safe as is now commonly taken for granted. Thirty-one cases of dysentery and twenty deaths occurring in little more than thirteen months amongst about 250 persons is certainly a startling fact. Nothing, too, can be more clear than every link in the chain of evidence brought together by Dr. Clouston. The chief victims were, of course, the old and crazy and paralytic; so that fifteen of the twenty deaths might be put down to the conjoint agency of old age and infirmity; but at least one young and robust man was cut off. But this history, while it shows that sewage irrigation may be a most formidable poison, also shows the reason why. Sewage to be harmless must be absorbed by the earth. It requires a deeply porous soil, like that mentioned by Mr. Rawlinson in Lombardy, where beds of sand and gravel alternate, so that the water when it has lost its manure elements may find its way steadily downwards. But the land at Carlisle was not porous; it did not absorb; the drains which had been laid down became blocked, and the water instead of passing deep through porous beds, stagnated in the hollows of a clay surface thinly overlaid with sand, and returned in pestiferous streams to the Asylum. We fully accept Dr. Clouston's *dictum*, that it is unsafe to apply sewage to land with a stiff clay subsoil within 300 yards of human habitations, without the most deep and thorough tillage, and every other precaution, both with the land and the sewage, to ensure absorp-

tion by the soil, and uninterrupted drainage of superfluous moisture.

Now for a few words on sewage difficulties generally; because in this, as in many other cases, now that the general principle is accepted, people think there is no need of further thought, as if the details, the means of doing a very ticklish thing in such a way that it shall not be a nuisance, would come of themselves. It is not a very delicate subject, though a necessary one, so we may as well hold our noses, and plunge *in medias res*.

Assuming that the *water*-closet is a necessary evil in towns —though for villages, and for all cases where there is not a perfect water-supply, the *earth*-closets of the Rev. Mr. Moule seem preferable—the first question is, what shall be the immediate destination of the sewage, a river or a tank? If a river, it is of the utmost consequence that the sewage arrive quickly and before decomposition. As Mr. Rawlinson and Mr. Chadwick have shown, at Salisbury and elsewhere, *putrid* sewage, which has been festering in cesspits, badly-constructed sewers, etc., kills fish and befouls rivers. Fresh sewage feeds fish; the trout haunt the outfall of the sewer and become — so we are credibly informed—so fat as to fry without butter.(a) Yet to send sewage into rivers is a nasty and wasteful process, and very unsafe if water be taken for drinking purposes. True, as Dr. Letheby and Mr. Rawlinson affirm, water in motion becomes purified, by the growth of animals and vegetables, the action of the air, and the absorption of the banks and bottoms of rivers; but the principle of turning even fresh sewage into rivers is bad, and that of foul sewage worse.

Leaving the rivers, then, how is sewage to be applied to land? and here we have to notice that distressing habit of jumping to conclusions, of dogmatising on general principles, and ignoring details, that want of a practical way of dealing with subjects which makes sanitarians and abstract sanitary science, though founded on truth, so much the laughing-stock of men who have to put science into practice.

Now, we blush to say it, but some sanitarians really talk as if all that was required was to let the soil pipe of the house empty itself on the nearest lawn, or field, or garden. It is said, for instance, that during a sewage squabble at the watering place of Bournemouth, it was coolly proposed that the sewage of houses a very few yards distant should be emptied on a small field or pleasure-ground right in the middle of the town.

On this point we are glad to find that two of the ablest writers on the subject—Dr. Spencer T. Cobbold (b), the well-known helminthologist; the other, not a philosopher, nor natural historian, but one who is actually in the habit of applying sewage—Mr. William Menzies, Deputy-Surveyor of Windsor Forest and Parks(c), speak out and give us some wholesome truths.

It must be recollected that the *stercus humanum* is greedily explored by numbers of animals, pigs, ducks, κυνέσσιν οἰωνοῖσί τε πᾶσι. Dr. Cobbold shows with great force the dangers of a wide-spread invasion of disease due to parasites —from the old, familiar tapeworm, in its various forms, to the new Bilhazia, which invades the kidneys, and which has been detected here in the bodies of men and monkeys by the acuteness of Dr. John Harley. And Mr. Menzies, like a practical man, shows the danger of putting on the surface of land any sewage containing solids capable of lodging, festering on the surface, instead of soaking into the earth. The subject is so important, and our space this week so limited, that we must return to it in our next.

By Wm. Menzies. Illustrated with numerous Drawings. London: Longmans. 1865. 4to. Pp. 84.

THE WEEK.

THE WESTMINSTER ELECTION.

Sir John Shelley and Sir De Lacy Evans have intimated their intention of resigning their seats for Westminster. Mr. John Stuart Mill appears to unite the suffrages of both Liberals and Conservatives. The latter willingly do homage to the profoundest thinker of the day, who, whilst advocating progress, seems the most determined enemy to mob law. It is generally understood that Mr. Edwin Chadwick intends to offer himself, in order to give his services in the discussion of those measures of reform in sanitary matters, in political economy, and educational questions which have occupied so large a share of his life. What electors require is not merely a man who agrees with their own special views, but one who has thought out and mastered the details of any given subject, so that, at all events, it shall be thoroughly sifted and ventilated before a conclusion is arrived at.

"THE EVILS OF ENGLAND."(d)

It is with the greatest pleasure that we call our readers' attention to the issue of a shilling edition of the little work which bears this title. It lays bare the very secret root of one-half of the social evils of our time—viz., misplaced philanthropy; that system of patches which consists in palliating evils instead of preventing them; which prefers building Hospitals for the sick to providing wholesome houses for the healthy; which allows every sort of evil from filth and idleness to flourish, and then provides "institutions" to remedy the mischief. The author's doctrine is this, that if a man will not work neither should he eat; that starvation is the natural penalty of idleness; and that they who step in and try to avert the penalty, without removing the crime, do but starve the honest labourer whilst trying to keep the idle one. Every penny given in idle charity, so miscalled, to the idle is so much robbed from the wage we might give to the honest worker. There are, however, hosts of people who fail in life, not through idleness or improvidence, but through *weakness*, bodily or mental—especially mental. Many of the small tradesmen in the metropolis end their days in the workhouse, neither through idleness nor dishonesty, but for want of enterprise and want of judgment or insight into probabilities. Their ordinary course of life is such that, what with rent, families, etc., they just pay their way and put by nothing. Many investments, also, are treacherous; they who venture nothing get nothing, and they who venture everything too often lose all. Hence public as well as private provision should be made for the cripples of our social system, but in such a way as to be no premium to the idle, nor yet to encourage jobs for officers and *employès*.

There are twenty subjects at the least—such as druggists' practice, quack medicines, waste of time, of manure, of life, of health—on which we should be glad to quote the author's opinions; we will only mention his dicta on Foundling Hospitals, because, spite of the repeated exposure of the folly and mischief and immorality of such institutions, there are sentimental philanthropists who from time to time revive the idea of setting them up in the vain hope of preventing infanticide:— "The proportion of child murders is greatest in the cities cursed with these establishments." It is in vain to try and set aside the order of nature. Infants "ought to be lying upon mothers' laps; they ought to be pressed to mothers' breasts;" and there is absolutely no substitute. The Mendicity Society, the soup kitchens, poor laws, and all other means of doing away with the penalty

(d) "The Evils of England, Social and Economical: being a Series of Short Essays on Beggars and Thieves; Charities and their Abuses; Paupers and Poor Laws; the Waste of Resource in Men, Money, Time, and Material, but specially the Mean, Disloyal, and Pernicious Vice of Indiscriminate Almsgiving." By a London Physician. London: Renshaw. 1865.

of idleness, are discussed with inimitable causticity and acuteness. So admirably is this little work written, so telling and pungent the phraseology, and the logic so clear, that it would be worth studying for its manner, even though its matter were less valuable than it is; and we hold the writer responsible for a most reprehensible waste if he hide his talent in a napkin, and do not take every available opportunity for giving his neighbours the instruction he can so well impart. (b)

PARLIAMENTARY. — UNION CHARGEABILITY BILL — SEWAGE UTILISATION BILL.

In the House of Commons, on Thursday, May 25, on the order for the third reading of the Union Chargeability Bill,

Mr. Henley entered into a variety of explanatory details with reference to the wholesale charge which, he said, had been made against rural landlords of demolishing cottages, appealing to specific cases in the county of Oxford in refutation of the charge, observing that, as regarded that county, a more unfounded charge never was made. After a critical examination of the Bill, he expressed his conviction that it would be of no benefit to the poor in the rural unions.

Mr. Bentinck likewise complained of unfounded charges made in support of the Bill, which, he said, was of a hypocritical character, in professing to be for the benefit of the poor.

Mr. Knight insisted upon the absence of evidence on the subject of close parishes and the pulling down of houses, and the Bill was a measure for mulcting counties for the advantage of boroughs.

After a few remarks by Mr. Mitford, the Bill was read the third time and passed.

On Friday, in the House of Lords,

Lord Ravensworth, in moving that the following peers—Earl Derby, Earl Romney, Viscount Strathallan, Viscount Torrington, Viscount Eversley, Lord Polwarth, Lord Boyle, Lord Redesdale, Lord Silchester, Lord Ravensworth, Lord Portman, and Lord Ebury—should form a Select Committee upon the Sewage Utilisation Bill, also gave notice that on Monday next he should move the addition of the name of the Earl of Essex to the list of the Committee.

The motion was then agreed to.

On Monday, in the House of Commons, during the debate on the Greenwich Hospital Bill,

Mr. Hennessy asked the Senior Lord of the Admiralty (Mr. Childers) a question with reference to the Medical officers. The Commissioners in their report stated that there was one branch of the establishment in which no reformation was required—the Medical branch. He would ask, therefore, how it was that Medical officers in the navy were excluded from participation in the good service pensions.

In the course of his speech in reply to various questions and objections to the Bill, Mr. Childers said the hon. Member for King's County had truly stated that "the Doctors" had been favourably reported upon by the Commissioners, and the Admiralty were not going to take away any part of their employment. On the contrary, they would probably be more fully occupied than at present.

On Tuesday, in the House of Commons,

Lord R. Montagu asked the Under Secretary of State for the Home Department whether a Commission was to be appointed to inquire into the state of the rivers of England, and the best means of remedying the pollution of rivers by mines and factories; and, if so, whether he would lay upon the table a copy of the instructions given to that Commission; and how soon it was expected the Commission would have completed the inquiry?

Sir G. Grey said a Commission, consisting of three persons possessing engineering and chemical knowledge, had been appointed to make inquiries in certain districts in which the principal manufactures were carried on upon the subject intimated by the noble lord. He had no objection to produce the Commission, and also a copy of the letter of instruction addressed to the Commissioners, indicating the basis upon which their inquiry should be carried on. It was impossible to say how soon these inquiries would be concluded.

Mr. Neate called attention to defects in the law relating to lunatics; and was proceeding in his speech when the House was counted out, at twenty minutes past seven o'clock.

FROM ABROAD.—ACTION FOR RECOVERY OF FEES IN FRANCE—LAENNEC'S STATUE—INFANTILE SYPHILIS—THE CALL OF CZERMAK TO JENA.

Another example of the wider and more beneficial operation of the French Medical Association, as contrasted with the British Medical Association, is supplied in a communication in the *Union Médicale* from M. Tassier, Vice-President of the Branch Association for the Department of the Saone et Loire. Dr. Brenet, it seems, being called to one Bonnardin, who had met with an accident while unloading a cask of wine, found that he had fractured the lower end of the femur, a small fragment lying loose in the popliteal space. The great swelling which was present prevented any exact adjustment being made, and the serious inflammation which followed compelled M. Brenet to content himself with securing the immoveability of the limb. When, at the end of two months, this inflammation had subsided, the patient determined upon being taken to his home, which was at some distance from the place where the accident occurred. There he was seen by other Medical men, who, finding that union had not taken place, put the patient under the influence of anæsthetics and adjusted the fracture without difficulty. It would have been well had they limited themselves to this; but, pursuing a line of conduct which has been only too frequently met with among ourselves, they criticised the treatment that had already been adopted, and, without making allowance for the difficulties which surrounded the case at first, even supplied the patient with a certificate of its faultiness. Fortified with this, when M. Brenet, at the end of two years, sent in an account of six pounds for twelve visits at a distance of five miles, the patient not only refused to discharge it, but made a demand of 500 francs for the damage he had received from the delay in his recovery due to malpraxis. At this stage the beneficial operation of the Association comes into play, M. Brenet having laid all the facts before it and demanded its support. After due examination at a general meeting, this was accorded, the standing counsel of the Association was directed to maintain the claim, while a memorial was forwarded to the tribunal which tried the case, signed by every member of the Association, declaring that the only fault they could find attaching to M. Brenet was the moderateness of the charge which he had made. If this is not furnishing fraternal and effectual support, both material and moral, we know not the meaning of the term. The Tribunal condemned Bonnardin to the payment of the sum claimed, with interest, and dismissed the charge of malpraxis; and we may quote a passage of the judgment, as showing that sound views concerning Medical responsibility prevail among the French judicial body:—

"Providing a Surgeon acts according to the rules of his art, he incurs no responsibility, whatever may be the result of his operation; and that even if it may be asserted that such operation executed more skilfully might prove more advantageous or less mischievous to the patient. Pushing Medical responsibility beyond certain limits would be only to deprive patients of the succour of art precisely at the moment when they have the most urgent need of it. For, when a serious accident, calling for immediate aid, occurred, no Surgeon would venture to operate upon the patient, in the fear that if, in spite of his efforts, the results proved unfortunate, he might be himself

(b) We hope it may not be out of place to say three words to get rid of a bugbear. The author is speaking of the arguments used for keeping up the prevalent vicious and wasteful kind of indiscriminate charity. "First and foremost," he says, "there is that great stumbling-block in the nation's way, the 11th verse of the 15th chapter of Deuteronomy. I speak from experience. Whenever I have expressed my hope that the day will come when destitution shall be unknown, and poverty be reduced to those narrow limits within which spontaneous charity will be amply sufficient for all our necessities, my mouth has been closed by the passage 'The poor shall never cease out of the land.'" It will comfort the author to turn to that most authorised translation and exposition of the Jewish Scriptures, the Septuagint, where he will find that the true sense of the passage is, "The poor must not be let starve." The preface to a Cambridge Septuagint which we possess clears up the meaning of the word ἐκλίπῃ (translated *cease*) by showing that it really means *die*. The verb is a future tense with the force of imperative—οὐ γαρ μὴ ἐκλίπῃ ἐνδεὴς—*i.e.*, "for the poor man shall (or must) not perish." It is a command to relieve distress, but not a prophecy of perpetual pauperism. Of course, we do not dogmatise on such a point; we only offer a conjectural but probable explanation of an unintelligible text. We accept the command, but act on the spirit, and not in the letter. We eschew almsgiving when it tends to pauperise.—Ed.

accused of having occasioned them, and no one would act without a consultation, giving rise to the loss of precious time and the production of irreparable misehief."

Speaking of the French Medical Assoeiation, we may advert to the project which it has taken under its auspices of raising a statue to Laennec. It is true that it does not contribute from its own funds—which have been subseribed for other purposes—the money neeessary for this purpose; but there can be no doubt that a powerful impulse has been given to the subscription by its agency; and it is highly important that projects of this character should be under the patronage of influential associations. Before closing the subscription lists, however, an appeal is also made to those members of the Profession who are unconnected with the Association, whether at home or abroad, and we can have no doubt that many of our own countrymen on being apprised of the desire of the Committee to comprise also the names of foreigners in its list will feel pleasure in contributing. In no country are the advantages and importance of auscultation more appreciated than in our own; and the more international our recognitions of the benefits conferred on science become the better. Subscriptions are received at the offices of all the Paris Medical journals.

The period of incubation of infantile syphilis was much disputed in the recent discussion upon the propagation of the disease through vaccination; and the question becomes still more complicated by some figures communicated by Dr. Simas, Physician to the Misericordia Hospital, Lisbon, to the Medical Society of that city. He has had under his own personal observation 216 cases of hereditary syphilis during 1858-65, and among these the symptoms were observed in the first year in 27 cases; in the second year, in 49; in the third, in 56; in the fourth, in 30; in the fifth, in 14; in the sixth, in 16; in the seventh, in 7; in the eighth, in 2; in the ninth in 7; in the eleventh, in 4; in the thirteenth and fourteenth, one each; and in the eighteenth, in 2. This is a very different statement to that of M. Depaul, who fixes the limit of the appearance of syphilis to seven weeks, or of MM. Diday and Roger, who fix it at three months.

The *Wien Med Wochenschrift* deplores that by some mismanagement of the authorities so distinguished a physiologist as Czermak has been allowed to remain unemployed in Austria, and has just accepted the offer of the chair of Physiology at Jena. By endeavouring to enforce conditions upon him he would not submit to, Ludwig had already been driven from the Joseph Academy to Leipzig, and Czermak is not to be his successor, while local prejudices seem to have militated against his appointment at Prague in place of the aged veteran Purkinje. That Czermak has deserved well of all anxious for the advance of physiology is seen from the fact that it was he who founded the physiological institutes at Craeow and Pesth, and created among the students there a zealous fervour for physiological pursuits. In 1860, various considerations induced him to give up his Professorship in the latter University, and repair to Prague, his native city, where he expended a large sum of money in founding a private Physiological institute, with every appliance for study and teaching. This does not seem to have answered very well, for in the session of 1864-5 he had only thirty students there. While his institute was in the course of erection in 1861-63, he visited France and England, and popularised the employment of the laryngoscope, as our readers well know.

The State of the Fever Epidemic in St. Petersburg.—The *Russian Correspondence* of May 9 says:—"The number of sick, which had considerably diminished in April, has again increased during the second Easter week. This arises principally from the affluence of the workmen in the building trade, who begin to arrive about this period. Notwithstanding the recrudescence there is no want of room in the Hospitals.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF OXFORD.

The ancient history of Oxford is in some degree connected with the history that was last before us, the history of Bath. Extreme believers in the antiquarian school are given to follow the teachings of a strange—I had almost said unearthly—scholar named Wood—Anthony Wood—who, in 1631, was born opposite to Merton College, who became a student there, and looked up the antiquities of his native city with a zeal that knew no weariness, until death stopped it sixty-five years after it began. Wood, who lived alone all day, kept no company in the evening, but, as the sun went down, did softly escape from the study, and, all by himself, in some quiet nook of some old inn, do his pipe and his pot—Wood, haply over his pipe and pot, and haply in the morning early—for, by the way, he was an early riser—discovered and elaborated the story, or the fact, that Oxford dates from the same Brutus and his Trojan band whom we once followed in legend from Greece into Britain, who built new Troy, and who laid the foundation of that line of kings from whom came Hudibras, the immortal Bladud, and next unto him King Lear.

Brutus, who, it will be remembered, landed at Totnes (his landing is computed as 1108 before Christ), brought with him certain Greek philosophers, who, after they had arrived and had seen the Court properly arranged, and learned that they were rather out of place there, looked out for a spot where they might retire and study as became them. After due search they determined upon settling in a quiet retired spot near to modern Oxford, where they built, or had built for them, the requisite accommodation, and where they endeavoured to allure pupils to attend their discourses. The place where they taught thus gained the name of Greekdale, from the founders of the school, but no one can tell precisely where Greekdale was situated. The story goes on to say that the successors of the first Greeks, becoming dissatisfied with the locality where their fathers taught, sought out a more pleasant site, where they had trees overhead, shady walks for contemplation, rivers for fresh waters and it may be for commeree and fishing, and easy roads for entrance and for exit; so they moved, or, as the term is, they translated themselves to an adjoining spot, which, beeause it was very beautiful, they called Bellositum or Bellosite, where they lived, disputed, learned, taught, fashioned their lives, left their bones for the earth, and their works for their monuments.

Regarding Greekdale, however, we must not sit down content and contented to hear no more of it than hath been told in the above. We Esculapian people must perforce look into the matter a little more deeply, when we shall find, perchance, something vastly to our own advantage. For the sake of being sure that nothing is lost, I have taken down old John Leland, often quoted in these pages as antiquary royal to fat Harry, and forsooth he—Leland, I mean, certainly not Harry—putteth out a faint story to the effect that the original of Oxford was, in truth, a school of Physic. There were, quoth the antiquary royal, in the flourishing times of the Britons, two schools (though the history that giveth the story is not altogether to be approved)—two schools very rich in learning and in eloquence, on the banks of the Isis. One of these schools was called, in the first instance, Græcedale, because certain men professed the Greek tongue, and the other Latinedale, because men skilled in the Latine tongue dwelt there. But, he adds,—and this is what concerns us—there be not wanting some who call this Latindale, Leechdale or Lechdale, and affirm it to have been a school of Physieians, vulgarly "Leeches." "Now," continues Leland, "who was

the first author who first appointed the said two schools I cannot as yet, though I have sought after it diligently, learn of any. In the meantime, it hardly appears, so slight is the record, when the school did exist; yet, notwithstanding, John Rouse of Warwick, in his book of the Universities or Academies of Britaine, who followeth the authority of David Tavanus, writeth that Sampson, who was elected Archbishop of York by Ambrosius, the invincible King of the Britains, studied at Greekdale, but afterwards, as the vicissitudes of all things are, the glory of both schools was transferred to Bellosite, which they now call Oxford."

Bellosite, in French *Beaumont*, in Latin *Bellus mons*, was believed to be situated in the parishes of Oxford, called in a later day the parishes of St. Giles and Mary Magdalen. The town itself, called Bellosite or Bellesite, was founded, according to Rouse, by Ebrank, son of Memprick, king of the Britons, who made it a noble city, called first Caer-Memprick, next Bellesite, and afterwards Oxford. Thenceforward, when the school or university of Greekdale was transferred to it, Bellesite became a great seat of learning and where the church of St. Giles was in due time erected; there was originally another church or temple where graduates were made, and from whence they passed forth with their academic spoil. In the Saxon time the place had and held the name of Oxenford or Ouseford, from which comes the modern name Oxford. So say some, Oxenford means that near the place was a ford over which oxen crossed; so say others, near the place was a river called the Ouse, now called the Isis. On an island in this river, add the latter argumentatists, in time there was built an Abbey called Osney or Ouseney.

We may take what we please of these early histories or traditions, and the most we can say is, that in the legendary stage of young England there were schools at Oxford, and we must wait until we come to the reign of Alfred the Great before we arrive at the reliable; then there is something to be said which is of interest and of some trust, which, in justice not less to the king than to the subject, we may for a minute or two dwell upon.

Oxford came under the protection of King Alfred near upon the year 886. About that time it had become an important school, and it appears that one Grimbald, a "vast scholar," with certain great clerks, who attended him and followed him as their leader, settled in Oxford, and began to teach there. They found, however, on their arrival and settlement certain other great clerks and teachers who had long been resident, and who followed their own rules and ordinances. Grimbald, it is said, had some kind of authority from the King to lay out a course of study and discipline, and, it would seem, ventured to make innovations on the old system. He ventured too much, and with the result that might have been expected—*i.e.*, the old schoolmen rebelled, and for three years carried on a grievous contention. At last matters became so serious that the good King must needs come down to see what he could do towards pacification. According to chronicler Wood, who quotes from Asser Menevensis, the complaint made to the King by the old schoolmen was, that learning, once so progressive in Oxford, had, since the advent of Grimbald, been on the decline. The King heard both sides, offered words of wisdom and peace, and, hoping he had succeeded in bringing together the discordants, went his way. But Grimbald, who evidently had looked for direct support from majesty, was displeased, and soon afterwards left for Winchester. Tradition sets forth arguments in favour of the proceedings of the old schoolmen in this affray. It claims for them that amongst their predecessors there had been men of illustrious name, amongst others the venerable Bede, Gildas, and of John of Beverley, whose ordinances were almost sacred, and could not be cast aside at the mere word of a stranger.

The reader will have observed that in what has yet been said no mention has been made of Oxford during the Roman occupation of Britain. In truth, but little can be said, for little is known. That the city existed during the Roman period is certain, for it is mentioned at least twice by Roman authorities; but it was clearly then an insignificant town, little known as connected with letters, and valueless as a military centre or depôt. After the Roman occupation it fell again into the hands of the Britons, and Vortigern, the British king, restored it in or about the year 474, and made it his own royal residence, under the name of Caer Vortigern. Within 200 years from this time the whole kingdom was under the domain of the Saxons, and Oxford became, as we have seen it already, a Saxon town, known as Oxonaford.

We may return now to Alfred the Great. Alfred not merely endeavoured to pacify the turbulent spirits of learned Oxford, but he himself took up his residence there with his three sons, Edward, Athelward, and Alsward; he even governed here for a time, and had a mint from which money was coined in his name. He also has the credit of making the city a more distinguished seat of learning, for he encouraged his nobles to flock to it for education, and founded three schools, or colleges,—one for grammarians, called the "Parva Aula Universitatis;" the second for logicians or philosophers, called the "Aula Minor Universitatis; and the third for theologians, called the "Aula Magna Universitatis." In the early part of this reform introduced by the King, the University was confirmed by the Pope. The Papal grant was derived from Martin the Fourth, and the event has been chronicled as follows:—

> "And in the yere eght hundred foure score and tweyne,
> The Pope Martyne graunte to Kyng Alverede
> To founde and make a studye than ageyne;
> And in an Universitie for clerks to rede,
> The whiche he made at Oxonford in dede
> To that intent, that clerkes by sapience
> Agayne heritieks shulde make resistence."

Historian Wood takes occasion, in referring to Alfred as the new founder of learned Oxford, to define what was meant primitively by the word University. He says that an University such as Oxford was made was a joining together and incorporation of many public schools in one town or city; a place for the reception of all people who desire to learn, representing the whole kingdom wherein it is,—nay, the whole world, inasmuch as any person thereof may come to it to acquire knowledge and wisdom. In the time of Alfred, Oxford was called a school; and he is believed to have appointed to each of the institutions one professor, and to have provided for the maintenance of twenty-six students.

I referred a moment ago to Grimbald, the scholar, whom Alfred brought to Oxford, and who afterwards was moved to Winchester, of the monastery of which city he became abbot. Grimbald, or Grimbaldus, was first known to the King when the latter was on his travel to Rome. He was a man of great learning, cultivated music with much assiduity and skill, and was a most fascinating and accomplished teacher of eloquent discourse. Nor was Grimbaldus alone in his work as Professor at the revival of the University; he had by his side, also, through the labour and grace of the great king, another wonderful scholar of the time, who, born of Scottish parents in Ireland, claimed both countries as his own, and who boasted in the possession of the name of Johannes Scotus Erigena. Scotus was a man of many travels; Greece, Italy, and Gaul were countries he knew well, and it is surmised that he had penetrated far eastward into parts of the world then almost unknown, or at best known only by mysterious traditional connection with the origin of the sciences and the arts. What he taught in the new University is not very definite; that he excited much jealousy in the hearts of the old schoolmen is rendered pretty obvious by the fact that he retired ultimately and set up as a teacher in the monastery of Malmesbury. In this position a cruel fate—a worse fate, perchance, than any that Oxford would have brought—befel him; he was stabbed by certain of his students and died from his wounds. I have noted the career of this scholar with some interest, because he was one of the earliest of the reformers of the Church, and because he laid in the University of Oxford the first seed of that opposition to one particular tenet of the Church of Rome which afterwards became so strong in that city, and for which Ridley and Latimer, in after years, lighted, from that spot, a fire that shone all England through. To be brief, Johannes Scotus Erigena denied the doctrine of transubstantiation, by which denial, in the opinion of his contemporaries, he was largely reduced in favour. There are some men who only live to die, and other men who only die to live. Scotus belonged to the second class; he died to live.

One more great man deserves mention as belonging to the University during the reign of Alfred: I mean Neotus, better known as St. Neot, after whom St. Neots is derived. Neotus was the master of Alfred while yet the wild oats of that famous Prince were in the hand of the sower, and were in danger of being cast over a wider area than might have been profitable to this nation in its Saxon days. Neotus was himself of royal descent, and partly by his learning, but mainly by his assumed sanctity, was held in such estimation that he was canonised, and, being buried in Cornwall, in the Church of St. Guerer (also once an Oxford scholar), first displaced poor Guerer from his saintship there; afterwards, as

a box of dry bones, he travelled into Huntingdonshire, and finally, some centuries later still, took another journey to the Abbey of Croyland, where perchance, if the earth has not translated him into more active matter, he may still be a crumbling remnant and tatter of sainted humanity.

Such were some of the Oxford celebrities in the time of Alfred; such was the city—a city of schools, we may suppose, that as yet had no citizens proper. There would be hostels and so much trade as was called into existence by the wants of the masters, and pupils, and strangers who flocked there; but these would be the servants of the schools, after all, followers of the camp of learning, obeying in all things the behest of the superior power, and having no rights of a municipal character. At the same time, the schools did not monopolise all the glory: the religious houses had a small share in that; and there was a shrine there which lasted until Wolsey, the second founder of Oxford University, pulled it down, and put to good or bad service for himself or his master the riches by which it was surrounded. This famous shrine was dedicated to a woman named Saint Frideswide. She was the daughter of a petty prince of the Heptarchy who built at Oxford a nunnery to the glory of the Virgin and the saints, and made Frideswide abbess, with twelve virgins of noble blood as her inferiors. Frideswide did not enjoy her supremacy many years. Invested with her authority in 730, she died in 740, and was at once canonised, the nunnery remaining as dedicated to her. In process of time the shrine was included in a chapel of a priory. There it stood long, and at it, in the thirteenth and fourteenth centuries, many miracles were believed to be wrought. At length Wolsey got chapel, shrine, and, according to many, saintly bones, too—the first of which he pocketed, the second of which he levelled, and the third of which he let some faithful man enclose by stealth in a silk bag, and bury ultimately with so much secresy that no one knows whither the bones are gone. The present cathedral of Oxford belonged in the twelfth century to the Priory of St. Frideswide.

We cannot dwell at any length on the progress of the schools of Oxford previously to the Norman conquest. The city evidently retained its importance, and indeed began to assume position politically; here the brave Edmund Ironside, after his encounter and conference with Canute the Great, was assassinated; here Canute, following the example of Alfred, held his right royal courts and parliaments; here Harold the First, sometimes called Harold Harefoot, was crowned after the death of Canute; here during his short reign this Harefoot lived and died, here he was buried, and from his grave was dragged by Hardicanute to be disgraced by decapitation and cast into the Thames. Over Oxford and its shire, in the reign of Edward the Confessor, the eldest son of that king was set as governor; and when in the next reign Harold the Second had seized the crown, Edgar Atheling, the rightful heir of sovereignty was raised by the usurper to a very high position by being made Earl of Oxford.

When Harold the Second gave way to the Conqueror, Oxford remained true to its Saxon rulers, and held out against the Norman as long as its resources would permit. But what was an unfortified town, a town of students and philosophers, whose whole mission was peace, to do against the long bows of Normandy? It was attacked, stormed, carried, and, as was the manner of William, given away afterwards to one of his nobility, Robert de Ouilli, who soon fortified it, and left his seal upon it in form of a strong castle and rampart. So soon, however, as the shock of subjection was over, Oxford gradually resumed its place, in the history of the world, as a school or university, and again became a favourite resort of royalty. William the Second resided in the place, and built a keep to the castle, which remains, in part, to this day.

In the stormy reign of Stephen, Oxford was for a time the refuge of the Empress Maud, and her escape, in 1142, from the besieged castle with four knights clothed in white that they might not be distinguished from the snow which lay thickly on the earth, is an incident that would form, for the historical painter, a noble subject. In the latter part of this reign, also, there was a great ceremony at Oxford, a gathering of the nobles to negotiate the virtual transference of the crown of England from Stephen to Henry the Second.

We must pass over the reigns of Richard the First and John to enter that of Henry the Third. The reign of this last-named King is most remarkable in relation to Oxford. Here in 1258 the famous "Statutes of Oxford" were read and confirmed by the king, who promised, through them, to abide by the great charter of rights, to place an honest man at the head of the High Court of Judicature, and to summon a parliament triennially to make and unmake the laws. The king promised, I say, to abide by these statutes—nay, he swore to abide by them in a most solemn oath; but he did not find the oath convenient, so he broke it, and in 1260 was absolved for his offence by his Holiness, Urban the Fourth, in a manner as complaisant as it was handsome.

But the name of Henry is more intimately and worthily connected with Oxford from the circumstance that in the 28th year of his reign the University was incorporated by Royal charter. By the terms of this document the schools passed under the title of the "Chancellor, Masters, and Scholars of the University of Oxford," and a constitution differing little in essentials from that which exists at the present hour was granted. Thus the last grand step in the consolidation of this fabric of learning was taken, and our history may be allowed to find in that event a convenient and natural resting place, for a week at least.

PROVINCIAL CORRESPONDENCE.

IRELAND.

Dublin, May 26, 1865.

In the North Transept of the International Exhibition a compartment is devoted to "Surgical Instruments." Messrs. Thompson and O'Neill, of Henry-street, exhibit a very beautiful assortment of their own manufacture, comprising sets of pocket instruments in cases, amputating instruments, obstetrical instruments, instruments for ovariotomy, polypus and spring forceps, aneurism compresses, instrument for morbus coxæ, appliance for contracted knee, &c. They have also a registered air funnel vapour bath, the superiority of which consists in the introduction of the hot-air funnel through the centre of the boiler, the result of this construction being that immediately on lighting the spirit lamp a rapid current of hot air is generated, which mixing with the steam raises the temperature in half a minute to the requisite degree, and maintains it at the same. The use of the mixture of hot air and steam is said to make the bath more agreeable and less relaxing than the ordinary vapour bath, and to diminish the cost of its production. Another advantage of this bath is its great portability; it can, in fact, be carried in a portmanteau, and by means of it the traveller may, on reaching his destination, in a few minutes, and without the aid of other fire than that of his spirit-lamp enjoy the refreshment of a bath.

In the adjoining case Mr. Grossmith, of Fleet-street, London, exhibits an extensive assortment of his admirable artificial eyes, which were awarded prize medals in the London Great Exhibitions. They are certainly most beautiful and perfect imitations of natural eyes. They are said to be so easy of adaptation that they can be fitted in a few minutes, movements being obtained precisely in accordance with those of the natural eye. The same case contains specimens of Mr. Grossmith's artificial legs with patent action knee and ankle-joints, which enable the patient to walk, sit, or ride with ease and comfort. They are stated to be lighter, less expensive, and more durable than any self-acting leg hitherto manufactured, and are undoubtedly very beautiful specimens of workmanship. They will be found more fully described by Mr. Traer, and illustrated in the number of your journal for September 6, 1862, pp. 260-261.

Suspended over Mr. Grossmith's is a small case containing an assortment of Mr. Tufnell's tubular gutta-percha bougies for the treatment of stricture of the rectum. A description and representation of these instruments will be found in Mr. Tufnell's "Practical Remarks upon Stricture of the Rectum," published in the 30th volume of the *Dublin Quarterly Journal of Medical Science*.

Mr. Salt, of Birmingham, exhibits his abdominal belt for obesity, dropsy, umbilical hernia, etc., described and represented in your impression of February 25, 1865 (page 215). He has also a great variety of his patent "orthonemic" trusses, umbilical belts, and truss pads.

Mr. Heather Bigg, of Wimpole-street and Leicester-square, London, has an illustrative series of "appliances invented for the mechanical treatment of deformities, deficiencies, and debilities of the human frame." Each instrument is adapted for a child of four years of age, and the collection is divided into appliances intended for the head and trunk, for the upper, and for the lower extremities. These appliances have been

fully described and represented in the *Medical Times and Gazette* for 1862, vol. ii., p. 233.

Mr. Pratt, of Oxford-street, exhibits an extensive variety of very beautiful instruments, including Her Majesty's army new regulation case for a full Surgeon, price fifty guineas; Pratt's artificial leg, exhibited for lightness and durability; his support for the knee-joint; his spinal measurer for registering the amount of lateral curvature, etc., etc., as well as Surgical instruments used for various purposes by Messrs. Fergusson, Henry Thompson, Baker Brown, Drs. Simpson, Marion Sims, etc.; I may also mention an arm compress for arresting epileptic fits in some cases where there is the "aura epileptica," invented for a patient of Dr. Brown-Séquard. Several of Mr. Pratt's instruments have likewise been described and illustrated in your second volume for 1862, page 335.

The last collection I shall notice in this compartment is that of Mr. S. Ash, of Great Brunswick-street, Dublin, containing a large assortment of artificial teeth and dental instruments, together with specimens of the several materials and apparatus employed in Dental Surgery.

For the information of those of your readers who may be inclined to take their holiday in this direction—and I trust they will be many—I may mention that very liberal arrangements have been entered into between the several railway and steam-packet companies and the managers of the Exhibition, with the view of affording to tourists unusual facilities for visiting not only the Exhibition, but also the celebrated scenery and antiquities of Ireland. The arrangements, which will be in force before this letter can be published, are as follow:—"On and after the 1st June return tickets, available for one month, will be issued between London, and the principal railway stations in England and Scotland, and Dublin, at an abatement of 15 per cent. below the ordinary return ticket rate; tickets of admission will also be issued at the principal stations, which will entitle the holder to six admissions to the Exhibition for 4s. 6d., being 50 per cent. under the average rate. Excursion trains will be organised to run fortnightly, or oftener if necessary, at very moderate fares. The excursion ticket will be good for a fortnight, and will entitle the holder to a ticket giving him two admissions to the Exhibition for 1s. To tourists from the Continent *coupon* tickets to Dublin will be issued at 25 per cent. under the ordinary return ticket fares. The journey may be broken at London, Birmingham, Manchester, Chester, and Liverpool. For a small additional fee, Continental tourists may travel by the Irish mail trains and steamers. On the Irish railways, also, excursion tickets will be issued at greatly reduced fares."

GENERAL CORRESPONDENCE.

NAVAL MEDICAL OFFICERS AND GREENWICH HOSPITAL.

[To the Editor of the Medical Times and Gazette.]

Sir,—With your permission, I would invite the attention of the Profession generally to a fresh display of animosity on the part of the present Board of Admiralty towards Naval Medical officers. In a Bill now before Parliament for the better Government of Greenwich Hospital, and which received a second reading on Monday night, it is proposed to give out of the funds of that institution good service pensions to various classes of officers, but specially excluding the Medical branch from any participation in the same. The excuse for this exclusion was given in a flippant and no very respectful manner by the junior Lord of the Admiralty on Monday night, in answer to a question from Mr. Hennessy. The excuse, strange as it may appear, is this: "Medical officers must still be employed at Greenwich in staff appointments, terminable every five years, and, therefore, they are not entitled to good service pensions." Admirals, captains, commanders, and lieutenants are liberally provided for; masters are not forgotten; chaplains are taken care of; and paymasters are to have more than justice meted out to them; but Medical officers are utterly ignored as unworthy of the slightest consideration. So that the only class of officers hitherto connected with Greenwich, whose services received the unqualified approbation of the Commissioners who inquired into the working of that Institution, are the only officers whom my Lords deem unworthy of any participation in the proposed good service pensions.

The favoured class already enjoys upwards of £7000 from the country and upwards of £5000 from Greenwich Hospital annually in the shape of good service pensions. It is now proposed to increase those pensions very largely, and when we recollect that an admiral's commission may be viewed in the light of a good service pension—as there are many more of them than the service requires—it must be acknowledged that the Lords of the Admiralty take very good care of their own class.

I will not trouble you with any more detailed information on this subject at the present time, but on a future occasion I may do so. It is just possible that Mr. Hennessy, supported by Sir John Pakington, may bring the Government to a sense of justice when the House goes into committee on the Bill. And I am only anxious now that you may be pleased to give this communication a prominent place in your next issue, for the twofold purpose of cautioning young Surgeons from placing any confidence in the present Board of Admiralty and of bringing the admirable conduct of Mr. Hennessy under the favourable notice of the Physicians and Surgeons of King's County. I am, &c.

London, May 31. A Physician.

THE DUTIES OF MEDICAL MEN AT THE COMING ELECTION.

[To the Editor of the Medical Times and Gazette.]

Sir,—We are on the eve of a general election, and I appeal to you and your numerous readers whether this is not the time for concerted action amongst ourselves as a body.

I am a constant reader of your paper, and I bear in recollection that from time to time, prompted by circumstances, you are in the habit of making practical suggestions for use upon occasions such as the present, when, if ever, the voice of our Profession has a chance of a hearing from those who are, or aspire to be, members of our Legislature.

I have not personally the privilege and advantage of Government employment, yet I cannot but entertain a conviction of the suitableness of this occasion to a reconsideration of the position and requirements of that oft-censured, over-worked, and underpaid section of our community holding office under the Poor-law Board. I am, &c.

Birkenhead, May 30. F.R.C.S.

MR. J. Z. LAURENCE'S HEAD REST.

Letter from Dr. Charles Taylor.

[To the Editor of the Medical Times and Gazette.]

Sir,—I noticed in a recent number of the *Medical Times and Gazette* a description of a head rest introduced by Mr. J. Z. Laurence, of the Surrey County Eye Infirmary, for use in ophthalmic operations. I have since obtained the same for the Nottingham Eye Dispensary, and trust you will allow me sufficient space to bear testimony to its great utility. I have used it in a great number of cases, and find that both with and without chloroform it is of the greatest assistance in all operations, and accomplishes all that can be desired. The head is comfortably fixed, and that sudden involuntary start which is so frequent just as the knife penetrates the cornea, so apt to occasion wounding of the lens, and in other ways to mar the result of the most careful operation, is entirely prevented.

I understand it has been adopted in Berlin, and have no doubt that when its merits have been sufficiently tested its use will become general. I am, &c.

Charles Taylor, M.D.,
Surgeon to the Nottingham Eye Dispensary.

Nottingham, May 25.

Professor Boeck, of Christiana, is now in Ireland. He is staying in the County Wicklow, having been brought over there from Norway to syphilise a patient.

Ovariotomy in France.—The progress of the question of ovariotomy would seem to be great in France, if we contrast the Academical denunciations of a not distant period with the most recent communication made to the Academy of Medicine by M. Berrut, in which, after detailing a successful case, he comes to the conclusion that while Surgeons are well authorised to proceed to the operation at an earlier stage, it becomes imperative upon them to resort to it as an ultimate resource.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 23.

Dr. ALDERSON, President.

A PAPER, by Mr. HENRY LEE, was read on

AMPUTATION OF THE LEG BY A LONG RECTANGULAR FLAP FROM THE CALF.

The author called attention to Mr. Hey's mode of operating by means of a long flap from the back of the leg, and to Mr. Teale's plan by a long rectangular flap from the front. The advantages of both these plans might be combined by making a rectangular flap from the back instead of from the front of the leg; a thick soft cushion might thus be provided for the ends of the bones, and no large nerve need be left in the flap. The operation described was performed according to Mr. Teale's plan as far as the external incisions were concerned, but the long flap was made from the back instead of from the front of the limb. Two parallel incisions were made along the sides of the leg; these were met by a third transverse incision behind, which joined the lower extremities of the first two. These incisions, which formed the three sides of a square, extended through the skin and cellular tissue only. A fourth incision was made transversely through the skin in front of the leg, so as to form a flap in this situation, one-fourth only of the length of the posterior flap. When the skin had somewhat retracted by its natural elasticity, an incision was made through the parts situated in front of the bones, which were reflected upward to a level with the upper extremities of the first longitudinal incisions. The deeper structures at the back of the leg were then freely divided in the situation of the lower transverse incision. The conjoined gastrocnemius and soleus muscles were separated from the subjacent parts, and reflected as high as the anterior flap. This part of the operation was performed with the greatest facility on account of the loose attachments of these muscles, especially at the lower parts of the leg. The deeper layer of muscles, together with the large vessels and nerves, were divided as high as the incisions would permit, and the bones sawn through in the usual way. The flaps were then adjusted in the manner recommended by Mr. Teale. The long flap thus formed was much thicker than when taken from the front of the leg. It was consequently less liable to slough. It afforded a much more efficient protection to the ends of the bones, and a thicker and softer pad upon which to rest a part of the weight of the body when an artificial limb was applied. Three cases were detailed in which this mode of operating had been adopted, and drawings given of the stumps after they had healed. Two other cases were mentioned. In one of these, which was performed after great loss of blood from ulceration of the anterior tibial artery, in a case of very severe compound fracture, the patient died. In the other case the patient made a rapid and good recovery. These were, the author believed, all the instances in which this particular operaion had been performed.

Mr. HOLMES COOTE said that the cases were few indeed in which the patient was able to bear the weight of the body on the end of the stump. An artificial limb was so constructed that the support was afforded by pressure on the circumference of the limb. He had oftener performed the operation recommended by Mr. Teale, and with very good results; and had taken the flap of integument, in cases where he had no choice, from the front, the back, or, indeed, from the sides of the limb. One objection to the "long flap" consisted in its "shrinking," so that the operation finally resembled that of the common double flap. But he had had cases in which, after Mr. Teale's operation, the structures covering the ends of the bone were more free and normal than in other forms of amputation.

Mr. BIRKETT had hoped that the subject of amputation of the limbs would have brought more Hospital Surgeons together. He conceived that the great object in amputation was to get a perfectly transverse division of muscles, nerves, etc., therefore he had a predilection for the operation which was most frequently performed by the late Mr. Key—viz., elliptical division of skin, circular of muscle, and complete transverse division of vessels and nerves. He could not quite agree with Mr. Lee that it was an advantage of his operation that the patient could bear on the end of the stump. There was a strong feeling in the minds of mechanicians that weight should never be borne on the end of the stump, but on the part above the cicatrix. With the operation he had just spoken of, the scar was very small. Mr. Birkett then referred to stumps which he had seen after amputation, in which the flap was taken from the gastrocnemius. The flap was hanging loose, and looked often as if it never would cicatrise. He thought, however, that Mr. Lee's modification was acceptable, if that plan of operation was to be performed at all.

Mr. HENRY LEE said it was well known that the object of Surgeons generally was to prevent pressure on the extremity of a stump by resting the weight on the limb above the cicatrix. So engrafted with this idea are the minds of the mechanicians also that he had the greatest difficulty in persuading them to make an artificial limb which would press on the end of the stump. But an essential part of Teale's operation was that with a stump thus formed the patient should rest on it. This was the great object of Mr. Teale's operation. The cases he (Mr. Lee) had just read were the only cases in which the operation described in the paper had been performed. Mr. Teale had, by letter, informed him that he (Mr. Teale) had not performed that particular operation. One of the patients operated on, and whose case was related in the paper, had just written to the nurse challenging her to walk three miles with her. In this case particular care had been taken to see that the patient did bear on the end of the stump, and that it was not more sensitive than any other part. Mr. Lee then showed a preparation of a stump, and drawings illustrating the points of his paper.

A paper by Mr. CHARLES HUNTER was read on the

HYPODERMIC ADMINISTRATION OF CERTAIN MEDICINES.

In this paper the author brought forward the results of his investigations into the effects of medicines when subcutaneously injected. It is now six years since Mr. Hunter proposed the injection of medicines into the cellular tissue with their general therapeutic object in view. In the case of medicines thus injected for general effects, he called the method the "hypodermic," to distinguish it from the endermic, and from the local injection of Wood. From the endermic method, which term is often and erroneously applied to the hypodermic, it differs much; the endermic is a superficial application, which must be uncertain in its action, which may act powerfully and dangerously, or prove wholly useless. The hypodermic differs from the "method of Wood." The latter plan has for its object the local treatment of a local affection. The injection was supposed by Dr. Wood to be efficacious simply through the localisation. Theoretically this method must be limited in its sphere of action to neuralgia or sciatica: to those cases alone accessible to the point of the injecting syringe. Mr. Hunter, in advancing the hypodermic method, maintained that localisation of the injection in neuralgic cases was theoretically wrong and practically unnecessary. In 1858 and 1859 he brought forward these propositions in the *Medical Times and Gazette:*—1. That equal effect followed distant and local injections in neuralgic cases. 2. That by distant injections the ill-effects of repeated localisation were avoided, such as local irritation, thickening of the skin, abscess, etc. 3. That diseases can be treated with benefit and curatively by this plan, which are neither local nor neuralgic, and which have failed to receive benefit from other modes of medicinal administration. Mr. Hunter is inclined to think that the sickness which used rather frequently to follow the localisation of the injection, and which is dreaded as an evil attending subcutaneous puncture, is in part due to the localisation of the painful part, as he has hardly found sickness occur at all in his experience of the last few years. In 1859 the first cases were published in the *British Medical Journal* January 8, 1859, *Medical Times and Gazette*, vol. i., 1859, in which Mr. Hunter proved that diseases affecting the nervous system generally could be treated with benefit by the subcutaneous injection; the cases were serious ones, which had resisted other treatment, and were chiefly cases of insomnia and exhaustion from mania, delirium tremens, tetanus, etc. They exemplified the proposition that, "by the introduction of narcotics into the cellular membrane of the body, we have a mode of attacking and subduing cerebral excitability more rapid, more certain, and more sure in action than by the stomachic doses of narcotics."(a) Cases of spinal irritability and excitement were then treated, and with benefit, in cases in which stomachic doses had failed to relieve. Instances were

(a) *Medical Times and Gazette*, March 26, 1859.

given of tetanus, chorea, epilepsy, etc.(b) The hypodermic method is considered by the author superior to the stomachic, rectal, and endermic modes of medicinal administration, in emergent cases, in which the indications are for anodynes, antispasmodics, hypnotics, and nerve-tonics. And he has found greater and more permanent benefit to accrue from this mode of treatment than from the stomachic use of morphia, atropia, codeia, and other alkaloids. In many diseases there can be no certainty about the stomachic dose. In delirium tremens, for instance, the pill, the draught, or powder, may lie in the stomach undigested; it may be vomited; it may be absorbed, partly or wholly, and, if the latter, so slowly as to do no real good. In the mean while the life of the patient is at stake, and death from exhaustion may occur before that sleep which would save the patient can be procured. The investigations of the author led him to believe the hypodermic administration of any alkaloid for the above-mentioned purposes to be more beneficial than the stomachic as regards rapidity of action, certainty of effect, purity of effect, greater permanence of effect, avoidance of exhaustion. 1. Rapidity of effect.—With morphia sleep can be procured, or delirium quieted, in a few minutes. Atropine will affect the mouth in two or three minutes, and ease the pain of sciatica when injected into the tissue of the arm in five or ten minutes—in less time, in fact, than is usually occupied for absorption into the blood of the remedy from the stomach. 2. Certainty of effect.—This, as a rule, ought to follow, for the whole amount (when properly and carefully) injected must be all absorbed and circulated. But by the stomach one can only guess at the amount absorbed, and consequently one has often to repeat the dose to approach a certainty of effect. Enormous doses and quantities of opium may lie in the stomach doing no good in maniacal and other cases, but rather doing harm through the delay their inertness causes, and the uncertainty as to its absorption. In such cases the hypodermic injection of a small dose will often answer at once, while the opium still lies unabsorbed in the stomach. 3. Purity of effect. As injected into the cellular tissue, so is the agent absorbed, and its direct and sure effects manifest themselves upon the system. The same agent, *e.g.* morphia, given by the mouth will often cause headache, sickness, giddiness, hepatic and bowel constipation, etc. These ill effects, as they do not, as a rule, follow the hypodermic injection, must be due to the different mode of administration; nor need we wonder that a digesting membrane ever being filled with all kinds of pabulum should modify the vegetable alkaloids whilst chemically acting upon other compounds. 4. Greater permanence of effect.—The author has had various cases of neuralgia and sciatica which for years resisted the internal administration of opium, morphia, belladonna, strychnia, etc., which cases he has cured with the injection of morphia, atropia, strychnia, or some other alkaloid. The cure has no necessary dependance upon the number of injections. One lady who had suffered much from sciatica had no pain for one year after one injection. Another patient has remained free from neuralgia since 1859 after a single injection. In two cases of sciatica, one a hatter, the other a driver to a florist, three or four years have elapsed since they were treated; there has been no relapse in either; both had walked lame and suffered pain for four or five years. The author attributes the greater benefits thus derived, partly to the three first advantages that he believes the hypodermic method to possess, and partly also to the slight shock that the diseased nerves sustain through the rapid way in which the alkaloid is brought into contact with them. 5. Avoidance of exhaustion.—This is an important advantage of the hypodermic method, chiefly due to the rapidity of its action. In the violent spasms of lockjaw, of colic, or even of retention, life may be lost by delay; but even in minor cases, the longer the time that elapses before relief of the spasm or pain is obtained, the greater the subsequent exhaustion. Many hours often elapse before any benefit follows the use of stomachic medication, but by the injection of the cellular tissue the desired relief can be obtained in from five to thirty minutes, instead of after many hours. In the case of delirium tremens the continuous muscular excitement—exhausting in proportion to its activity—is often stopped in a very few minutes, and then sleep follows. The tonic effects of certain medicines are more strikingly manifested by the hypodermic than by other modes of administration. So-called tonics may be thus administered with benefit, when they cannot be borne by the mouth. Quinine may, for instance, cause sickness and headache and fail to do good by the mouth, but greatly benefits by the cellular administration.(c) Agents not called tonics may act as such when thus employed, and when of the class usually called anodynes, may act more tonically than when given by the mouth. In this paper space must limit me to a brief notice of morphia, thus used for its tonic effects. Morphia may be used subcutaneously, not to relieve pain, nor stop spasm, nor as a narcotic; but as a nerve tonic in cases of great nervous exhaustion, or of irritability or great mental depression. In cases, in fact, in which the brain has been overtaxed, and the mental equilibrium lost—as in some cases of melancholia, accompanied by great and unnecessary anxiety, with insomnia. In mania *à potu* and in delirium tremens I have even used the puncture, with morphia, so to steady and quiet the mind and nerves of the patient, as to enable him in a few minutes to walk to his office and go through his duties. In the drunkard, as in the overtaxed and melancholic case, there is great mental excitement, and worry, and anxiety, and insomnia. The stomachic anodyne will constantly fail to produce any effects; but the hypodermic dose, even where it fails to give sleep, will almost invariably remove the anxiety, the restlessness, and the nervous irritability which are the states leading to exhaustion, and unfitting him for application to work. Thus administered, morphia has nerve-tonic effects, without the disadvantages that so often attend its use when given by the mouth, for it does not interfere with the liver or the bowels, it does not cloud the brain, occasion loss of appetite, nor cause sickness, with the well regulated dose. In the mentally overtaxed, or the melancholic patient, the night administration will not always cause sleep; it sometimes rather arouses the brain—it may even keep the patient awake, in "a calm state of dreamy doziness," which has the equivalent effect of good sleep the next day; the patient will arise refreshed, mentally stronger, and fit for his day's work. Upon the spinal marrow and its nerves the tonic effects of morphia are more marked when thus administered. The greater permanence of effect when cases have been cured by this plan, and by a comparatively small number of doses, seems to indicate that something more than the mere anodyne influence has been at work. A lady, Mrs. R., was subject to neuralgia in 1859. She had been at times relieved by morphia and opium; she was treated once by the morphia puncture, and has not since had neuralgia. Another patient, Mrs. W. W., was subject to repeated attacks of tic doloreux. The morphia injection cured it last year; she has had no return, notwithstanding a trip to St. Petersburg in bad weather. Sciatica is more than simple pain of the nerve; although of long standing, a single puncture with morphia may relieve all the pain, but the stiffness, the lameness, the deficient nutrition, remain for some time. The repetition of the injection will restore power or tone, and if three or four injections are used where these symptoms remain, in long-standing cases, the patients will often say they feel more power return with each injection. Stomachic doses do not produce these tonic effects so strikingly.

The PRESIDENT said the object was one of very great interest, so great that the Council had appointed a committee to investigate it.

Mr. C. H. MOORE said no plan had been more deservedly put forward than this, and nowhere had its use been better shown than in the cancer wards of the Middlesex Hospital. The experience in these wards enabled him to confirm what the author had stated as to the advantage of this plan of giving morphia. In but few instances did the appetite fail, and then probably from giving too much. He (Mr. Moore) had tried several plans of giving morphia. For instance, he had blistered the shoulders and had then sprinkled morphia on it. This was in a case in which cancer had invaded the brachial plexus, and in this case he tried the hypodermic injection of morphia, and had found it infinitely more successful. He had also convinced himself that the action of the morphia he thus injected was not local only, nor even chiefly local, but general. For instance, in one case of disease in the axilla, causing severe pain by pressure on the nerves and œdema of the arm by pressure on the veins, he had tried local injection of the œdematous limb and injection elsewhere. In the first the action of the remedy was much delayed; but he had ascertained its most important use to be that of prolonging chloroform sleep. And here there were two advantages: one that the patient slept through the pain after the operation—especially in such cases as the destruction of cancer by chloride of zinc—and another that the sickness following chloroform, although perhaps not prevented, was postponed.

(b) *Op. cit.*, p. 389, etc.

(c) Paper by M. Desvignes, Med. Chir. Soc. Reports.

Dr. Wynn Williams, whilst agreeing with the author in his chief conclusions, wished to state that he had adopted the subcutaneous injection of morphia since it was first recommended by Alexander Wood, and in his experience local pain was more speedily relieved by injection locally. For instance, when the pain was neuralgic or of the nature of tic, and the source of irritation eccentric, the injection had better be made as near as possible to the seat of pain, or, at any rate, in the track of nerves having a similar origin. Where the source of irritation was eccentric, the pain depending on disease of the brain or spinal cord, it would answer as well to inject in any other part. In the first class of cases the injection relieved the local pain before it induced sleep by its general action. As regards permanency of action, he did not feel sure that he had caught the author's meaning, *i.e.*, whether he meant the sleep was more continuous, or that the cure was more permanent. He (Dr. Williams) had observed that the effects of morphia given by subcutaneous injection were much more speedy and passed more rapidly off than when administered by the mouth. When thus given, the dose would be larger and the action more continuous, the absorption of it into the system being more gradual. Another good effect was that, given by injection, opium did not constipate the bowels. It would always induce sleep when given in a sufficiently large dose. In a case of cancer of the rectum, which he had attended with Mr. Curling, four grains of morphia had been injected, and this would produce sleep for six hours, with slight intermissions. When the injection was made over the sacrum, the pain was relieved before sleep was induced; if elsewhere, not until the patient went to sleep.

Mr. Savory said all would agree that the hypodermic method was a valuable means of administering medicines, but he thought that some would hardly be prepared to accept all the conclusions at which the author had arrived. In comparing the introduction of drugs by this means with that by the stomach, it would need accurate and extended research before any general results could be obtained, so much must be allowed to the different action of different substances. For example, with regard to rapidity of effect, prussic acid seemed to pass from the stomach at a rate which could scarcely be exceeded, whereas woorara was hardly absorbed at all through the mucous membrane, and between these came a host of substances exhibiting every variety in this respect. Nor was this due to the previous action of the gastric juice, for some substances, such as strychnia, might be kept in it for a long period without any sensible alteration. But then there is another means of administering medicines and other substances —by the rectum. It was, perhaps, not generally known that absorption is, under some conditions, more active from the rectum than from the stomach. Not of solids, for these will remain a long while in the rectum without being dissolved; but when substances are in a state of complete solution, they may pass from the rectum far more quickly than from the stomach. Strychnia, for example, when in solution, will kill more rapidly, and in smaller doses, when introduced by the rectum than when taken by the mouth. A fourth of a grain, or even less, for instance, when passed into the rectum, will act with greater energy than a grain or more when given by the stomach. No doubt each of these several means is, in its turn, the best, —no one can be said to possess a constant or uniform advantage over the others. We have yet to learn under what circumstances and for which remedies this or that method should be chosen; and the subject requires immediate investigation.

Dr. Fuller could bear witness to what the author had stated as to the general effect of injection of morphia. It was quite true that if the injection were made near the seat of pain the relief might be a little more speedy, but we owe to Mr. Hunter the observation that the injection of morphia in any part acted in the same way and to nearly the same extent. This was an important practical point, as the continued introduction at one part might lead to abscesses.

Mr. Hulke said he should not like the meeting to break up with the idea that four grains of morphia might be safely injected. He had known patients nearly lost by the injection of two-thirds of a grain.

Dr. Wynn Williams explained that in his patient's case the large dose of four grains had been gradually arrived at after two years' treatment. He did not mean in any way to imply that this was a safe dose. Indeed, the dose he generally commenced with was only a quarter of a grain.

Dr. A. P. Stewart could not admit Mr. Moore's experiment on the anasarcous compared with the healthy limb, as conclusive regarding the local and general action of morphia; for in the anasarcous limb there was a total arrest of absorption, without which there could be no therapeutical action. As to the inconvenience of hypodermic injections, he could not speak so lightly of them as others did. He had repeatedly seen nausea, vomiting, vertigo, and even mild delirium, following the subcutaneous injection of morphia. As regards the use of quinine, he had on a former occasion made some inquiry as to the effects, both local and general, of its hypodermic use, the author of the paper (M. Desvignes) having been silent as to the existence of any inconvenience, and he (Dr. Stewart) had hoped that Mr. Moore would have given the Society the results of his recent and very interesting experiments. He (Dr. Stewart) had often administered remedies by the rectum. His favourite method of treating intestinal obstructions (ileus) had long been the injection of extract of belladonna in doses of two or three grains. In one case, seven or eight grains had been given by mistake. The absence of any serious symptoms was probably attributable to the great abdominal distension, which prevented absorption taking place to any extent; but in other cases, after repeated smaller doses, the wild and extravagant delirium of poisoning by belladonna had been fully developed. He was not aware of the facts stated by Mr. Savory, that strychnia acted more powerfully when given by the rectum. But such a conclusion was not warranted by the fact of the prompt and powerful action of one-sixteenth of a grain so administered, for he (Dr. Stewart) never gave by the mouth a larger dose than the fiftieth of a grain to begin with, and never increased it beyond the twenty-fifth, and from these doses he obtained very decided results. As regards the general subject of the hypodermic injection of remedies, he thought the Society should suspend judgment until the Committee had reported on it.

The President asked if the author's patients were treated in public or in private practice, and if in private practice the patient objected to the injection.

Mr. Hunter, in reply to the President, said that since the cases first treated at St. George's Hospital, he had drawn the conclusions from his observations on the patients of a public charity (the Royal Pimlico Dispensary), as well as from the results of the treatment in private practice. For the most part he had found no objection to the use of the plan on the part of his patients. A nervous patient might occasionally have objected to it, having heard it described as an operation. It is an operation of the simplest kind, giving hardly any or no pain, and causing no irritation if the operator attends to simple rules.(d) The puncture is almost painless if made in the outer part of the arm; it is more painful if localised to the tender neuralgic site. To Dr. W. Williams, the Author said he had used it in neuralgia of centric and excentric origin. He had not found, taking the cases collectively, that the result of the puncture was more successful if localised. In incurable neuralgia of centric origin the relief is the same in most cases, wherever injected. Sleep is by no means a necessary result of the puncture with morphia; many patients do not sleep from it. The alkaloid injected seems often to be first engaged in removing the pain or the mental excitement existing at the time. Sleep may then follow or not, according to the dose. To Dr. Stewart, Mr. Hunter replied that sickness and giddiness may certainly occur from this use of morphia. Such cases are quite the exception; they may be caused by the injection of a dose too large for the nature of the case, or to some idiosyncrasy of the constitution. The Author has very rarely found sickness follow the injection the last few years (though using the plan daily) since he has injected smaller quantities of the alkaloids, and has for the most part ceased to localise. Mr. Hunter thought four grains a fatal quantity to inject beneath the human skin, except under a well-established fact of the patient being accustomed to a much larger dose by the mouth. He had himself injected more than four grains at a time, but the patient had for many years taken by the mouth thirty grains of morphia daily. One grain of morphia is quite the maximum for a first injection, and then only in cases of very great cerebral excitement. Half-a-grain of morphia is a full injecting dose for the treatment of most cases; much less a quantity is often quite sufficient. Mr. Hunter quite believed in greater permanence of effect by this plan than by the mouth; atropine, for instance, has often failed, when given daily by the mouth, to do more than palliate, but the same dose (a thirtieth of a grain), by the cellular tissue, will perhaps succeed, once or twice repeated.

(d) *Medical Times and Gazette*, 1859.

To Mr. Savory the Author replied that the treatment as proposed by him was only for emergent cases, as for those requiring speedy relief from pain, or for those cases in which medicines failed in their effect as usually given. The author could cite one or more instances of each class of disease mentioned in the diagram in which stomachic treatment had previously failed to relieve the patient; in most cases the same alkaloid was used hypodermically and succeeded. Mr. Hunter readily allowed most speedy action to follow the rectal administration of some medicines; it might act even quicker than by the hypodermic method; but he considered it a less certain and less reliable mode of introducing the medicine. It is, moreover, one which it would hardly be advisable to use in many forms of disease, for which the hypodermic plan seems to be well adapted.

THE PATHOLOGICAL SOCIETY.

TUESDAY, MAY 3.

Dr. PEACOCK, President.

MR. HENRY LEE exhibited a drawing of a specimen of

OSTEO-MYELITIS.

The patient had had a compound comminuted fracture of the leg, and in three or four weeks he began to suffer pain in the bone. Then followed low nervous excitement and muttering delirium. As the patient was sinking, amputation was performed, and he did well. It was very rare, Mr. Lee said, that we were able to get a specimen of osteo-myelitis in the stage of its fullest development, although not unfrequently we met with suppuration or necrosis. The whole of the cancellous structure was injected, and the most of the injection was near the cortex.

Mr. HOLMES then showed a specimen of

OVARIAN CYST REMOVED BY OVARIOTOMY.

His chief object in bringing the specimen before the Society was that all cases operated on at St. George's might be published. The operator in this case was Mr. Tatum. The patient, a young woman, aged 25, had had ovarian dropsy four years. She had been tapped fifteen or sixteen times, and as the periods of relief afforded gradually narrowed, ovariotomy was advised. Her general health, however, was so good, that she was unwilling at first to assent. Excepting on account of some firm adhesions to the anterior abdominal wall, the operation was easy. The pedicle was secured by a twisted silver wire, and was then put into the abdomen. Except tympanitis, no symptoms followed. She was well in about six weeks after operation.

Mr. HENRY LEE said that the method of securing the pedicle was a very satisfactory one. He wished to say that the plan had been suggested to him by Dr. Marion Sims, and that he (Mr. Lee) had then suggested it to Mr. Tatum, who adopted it. It was the first time this plan had been adopted in this country.

Mr. HOLMES remarked, that as Dr. Marion Sims was present he would, perhaps, speak on the subject. The plan had been adopted in America.

Dr. MARION SIMS said the plan of transfixing the pedicle with silver wire, and then returning it into the abdomen, had originated with himself. In 1849 he had tried to strangulate an epithelioma of the cheek by a silver wire. The wire, however, cut its way through the skin, and the skin then healed over it. He then thought of ligaturing the pedicle in this way. In a case of ovariotomy, by M. Nélaton, he (Dr. Sims) secured the pedicle by transfixing it by silver wire, twisting the wire, and then cutting it close off. The patient died in five days. It was seen that the wire had sunk into the pedicle, and that it had been healed over.

In reply to Mr. Partridge, Dr. SIMS said the wire cut its way to a certain depth. The cut surface then healed, and thus there was a circulation in the parts within and outside the wire.

Mr. HULKE believed the action of the ligature depended on its tightness rather than on its nature.

Dr. C. J. B. WILLIAMS said the thread would be permeable for animal matter, and by the decomposition and the suppuration and sloughing might occur. The wire simply cut its way like a knife.

Dr. MARKHAM said that Dr. Tyler Smith used the silk ligature in just the same way as Dr. Sims used the silver wire. He also cut it off closely and returned the pedicle in the abdomen. It was a fact that Dr. Tyler Smith's results were quite as satisfactory as in those cases in which the silver wire had been used.

Mr. TEEVAN had made experiments in order to ascertain what substance was best suited for ligatures. He found that catgut was the best material.

Mr. HULKE said that experiments seemed to prove that silkworm gut was a very valuable material for ligatures.

Mr. PARTRIDGE said that some years ago Mr. Laurence proposed catgut for ligaturing arteries. At first it was thought to answer; but afterwards it was found to produce abscesses.

Dr. GRAILY HEWITT said the success of the plan of securing the pedicle mentioned by Dr. Sims was confirmatory of the value of the practice recently adopted by Dr. Tyler Smith. Dr. Smith was the first to cut off the pedicle short, and to exclude air from the abdominal cavity by at once returning it. He considered that Dr. Smith's success was in a great measure due to this plan of dealing with the pedicle. Whether the silver wire was better than the silk ligature he was not prepared to say. *A priori* he should think the wire better; but the chief element in success was the returning the pedicle into the abdomen.

Mr. NUNN related a case of ovariotomy in which the Fallopian tube had been split down three or four inches. The rent was closed by wire, and the patient did well. He considered that Dr. Sims' plan was a most valuable one, and that if after ligature the stump preserved its vitality we were provided with everything to make ovariotomy a certainty.

Mr. PARTRIDGE showed specimens from a case of

EPISPADIAS.

The bladder was small, and the symphisis pubis was not united by fibro-cartilage, but by ligament. The patient had walked with his legs widely apart.

Mr. HULKE said a case had been recorded in Schmidt's "Jahrbucher" in which a woman who denied having ever had any sexual intercourse was found to be pregnant. She had, however, she said, had intercourse with a fellow-servant whom she had supposed a female. The supposed female was found on examination to be an epispadias.

Mr. NUNN then exhibited

NUMEROUS CALCULI WHICH HAD BEEN PASSED BY THE URETHRA.

The patient was a gentleman seventy-five years of age. The passage of the calculi was preceded by pain in his loins and by irritation in his bladder. The calculi were very numerous and very spherical.

The PRESIDENT exhibited

SPECIMENS TO ILLUSTRATE THE FORMS OF CARCINOMATOUS DEPOSIT IN THE HEART.

The first set of specimens were removed from the body of a man, aged 19, a patient of Dr. Peacock's at the Victoria Park Hospital for Diseases of the Chest. He was first taken with symptoms of disorder of the liver and digestive organs, to which succeeded dyspnœa, cough, and expectoration, and signs of consolidation on the left side of the chest. The heart was slightly displaced to the right side, the pulse was quick and feeble, and there was œdema of the trunk and extremities. He survived for about nine months. The lungs contained minute masses of deposit, which to the naked eye closely resembled tubercle, but proved on microscopic examination to be carcinomatous. The bronchial glands also were extensively cancerous, and the heart was entirely enveloped in a thick medullary deposit, which pressed upon the large vessels at the base and on the auricles. There were also deposits in the liver, spleen, and mesenteric glands, and the aggregate plates in the lower part of the small intestines displayed small masses of cancer and were in places ulcerated, resembling very closely tuberculous deposits and ulcers. The whole displayed the usual characters of encephaloid. The second specimen was a heart removed from a female, 19 years of age, a patient of Dr. Ward's at the Victoria Park Hospital. The symptoms were similar to those in the former cases, and the patient lived six months. There was a large medullary sarcomatous mass at the root of the lung, with interspersed deposits in other parts of the left lung, which had in places ulcerated, forming numerous small cavities. The mass at the root of the lung had pressed upon the pericardium, and within that membrane there were tumours surrounding and involving the vena cava descendens and right auricle and the pulmonary veins and left auricle. The glands near the stomach and duodenum were also affected, but the other organs in the body were free from disease. The President remarked that carci-

nomatous deposits were generally regarded as of very rare occurrence in the substance of the heart, and the opinion was certainly correct so far as primary deposits are concerned. There were, however, a considerable number of cases on record in which the heart was found to be cancerous in connexion with similar disease in other parts of the system. He found fourteen or fifteen such instances recorded in the *Transactions* of the Society; four cases had occurred at the Victoria Park Hospital within the last two or three years, and altogether he had had little difficulty in collecting upwadrs of forty cases of the kind from different sources. Of these cases, however, it appeared very doubtful whether more than one or two could be regarded as instances of primary cancer of the heart, though in the reports of several no mention was made of the existence of similar disease in any other part of the system. The other cases might be classed into three sets:—1st. Those in which the disease arose, probably nearly simultaneously, in the heart and in the lungs or adjacent parts of the body. 2ndly. Those in which the disease originated in the bronchial or mediastinal glands, and involved, more or less extensively, the heart; and, 3rdly. Those in which the disease first appeared in some distant part of the system—the eye, axilla, mamma, abdominal organs, or testicle, etc.—and deposits subsequently occurred in some part of the heart. Of these the case which he first named was an example of the first form, and the other afforded an instance of the second. Of the third form a considerable number of the recorded cases were examples. Of the kinds of cancerous disease which affected the heart, by far the most common was encephaloid; melanosis occurred in a few instances, and four or five were stated to have been examples of scirrhus; but in reference to some of the last cases the information was very imperfect. It does not appear that there are generally any symptoms which specially characterise the occurrence of carcinomatous deposits in the heart. If the disease is so situated as to interfere with the vessels entering or proceeding from the heart, or with the action of the valves, they, of course, produce decided symptoms. In some instances, by pressure on the pericardium, they give rise to pericarditis, of which the signs may be recognised during life; but in other cases there are no indications of cardiac disease, and the deposits are only detected in post-mortem examination.

The PRESIDENT also exhibited a specimen of

CORNISH MINER'S LUNG.

The specimen was removed from the body of a man, 55 years age, who had been of somewhat irregular habits, and had worked in different tin and copper mines in Cornwall for about thirty-eight years. He had begun to work underground when he was 13 or 14 years of age, and had been compelled to give up working two years before his death. He had been ailing for about five years, and had complained of pain in the right side of the chest, which prevented his lying on that side, of difficulty of breathing, and of cough and expectoration. He had spat some blood, and was considerably emaciated. The left lung was firmly adherent to the parietes by old and thick false membranes, and the substance of the lung was sparingly crepitant, emphysematous at the edges, and of a deep blue or black colour. The bronchial tubes contained a brown-coloured, muco-purulent fluid. The right lung was also firmly attached by thick, fibro-cartilaginous adhesions. It was throughout considerably solidified, especially at the upper part, and at the apex there were several irregularly-shaped cavities, which, together with the bronchial tubes, contained a brown-coloured fluid, similar to that in the bronchial tubes of the other lung. The larynx and trachea were enlarged, and the mucous membrane of the trachea and larger tubes were studded with small yellowish-coloured specks of lymph. No tubercle was found in any part of either lung. The third rib was carious, and near it there existed an abscess under the integument. The heart was flaccid and apparently atrophied. It weighed from ten to ten and a-half ounces avoirdupois. The pulmonary artery and aorta were much dilated. The kidneys were natural, except that the cortical portions were somewhat narrow. One supra renal body consisted of scarcely anything but loose cellular tissue; the other was converted into a cyst containing a dirty brown-coloured grumous fluid. Dr. Peacock stated that the body of the miner from which this specimen was removed was the only one which he had had the opportunity of examining after death, but he thought it probable that the lung afforded a characteristic example of the form of disease which proved so fatal to miners, and which is commonly called in the mining districts "miners' asthma" or "miners' consumption." When not otherwise predisposed to consumption, the miners become subject to chronic bronchitis and emphysema when they have scarcely attained middle age, and shortly after that period many of them die with signs of consolidation and breaking down of portions of the lung tissue. When, however, they are predisposed to consumption, they die at a much earlier period, and apparently of true tubercular phthisis. The chief predisposing cause of the pulmonary affections was probably the impure air which the miners breathe when underground; the disease being called into active operation from the occurrence of inflammation, caused by cold taken in the shafts or at the surface, after the men had been working in warm and ill-ventilated places. It has been thought that the miners are injured by the inhalation of gritty particles, like the French millstone makers or builders, but such does not seem to be the case with the Cornish miners; though the dust of the mines may in some degree be influential in causing disease among the lead miners of the North of England. Portions of the lung exhibited to the Society had been carefully analysed by Dr. Bernays, but no siliceous material was detected in them. The dark material was found to be carbon. Dr. Peacock thought that the injurious effect of the occupation of mining was considerably aggravated by the very early age at which the men go to work in the mines in Cornwall, many of them beginning before the age of 13 or 14, that at which this man commenced working underground. The condition of the supra-renal bodies was noticeable in connexion with the peculiarly sallow, dingy complexion about all old metal miners.

Mr. THOMAS SMITH showed a specimen of

MEDULLARY CANCER FROM THE CALF OF AN INFANT.

The child, now seventeen months old, was four months old when he first saw it. At the age of three months it had had a fall, and then a swelling formed, which was supposed at first to be formed of blood. The child, however, was in good general health, and learned to crawl about as well as other children. At the age of ten months the tumour was still, although larger and harder, thought to be a blood swelling, and in this opinion Mr. Lawrence and Mr. Paget concurred. A puncture was made, and altered blood clots, etc., were evacuated. The limb was restored to nearly its natural size. Six months later the child was again seen, and then it had failed much in health, and it was clear that there was medullary cancer of the leg. Amputation was performed, and the child recovered in three weeks, but in another fortnight died. There was no return of the disease locally, but the child had a short cough and became emaciated, and small tubercles were scattered over the body. Mr. Smith thought the medullary disease might have arisen from degeneration of blood or lymph.

TUMOUR OF THE TYMPANUM—PARTIAL ULCERATION OF THE MEMBRANA TYMPANUM.

Mr. HINTON, at a previous meeting, exhibited the petrous bones of a man, aged 30, who died from disease of the heart. He was somewhat deaf, requiring the voice to be slightly raised, and hearing a low-ticking watch six inches right and one inch left. He could only remember that he had been deaf in the left ear, with a humming noise, but without pain or discharge, for about two months. On the right side the membrana tympani presented a small orifice about the centre, two lines in length by one in height, and the membrane around it was soft and flabby; the edges of the surface were rounded; a few cretaceous deposits also existed, and some fine adhesions around the malleus and incus; the stapes was only slightly moveable; above the short process of the malleus the membrane was wanting to a small extent. On the left side, in the position occupied by the perforation on the right, there was a thinned and depressed portion of the membrane. On narrowly examining this part the outer layers, dermoid, and fibrous were seen to be wanting and the mucous membrane alone remained; above the short process of the malleus the membrane was deficient on this side also, but to a greater extent, the aperture measuring transversely two and a-half lines; within the tympanum in the corresponding position, and embracing the heads of the malleus and incus, was a soft but firm fleshy mass, attached to the bone and communicating with the aperture in the membrane; it was not surrounding any special membrane, and consisted of a pale, finely-fibrillated stroma, with numerous small, dark-coloured, and shrivelled cells; the mastoid cells and upper portion of the tympanum contained a thin dirty-grey fluid. The lower part of the tympanic cavity was free from fluid, and its lining membrane normal. Malleus, incus, and stapes bound

together by bands, but the stapes moved with tolerable freedom. The Eustachian tube on each side was free from obstruction; the labyrinth on the left side showed very large crystals of otoconic, and these collected here and there into large masses. The blood-vessels also were, in comparison with what is found in normal conditions, very large and full.

METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

At a meeting held on Saturday evening, May 27th, Dr. Druitt, President, in the chair, Dr. Clouston, of Carlisle, read a paper upon

THE PRODUCTION OF DYSENTERY BY SEWAGE IRRIGATION.

It consisted in an account of an outbreak of dysentery in the Cumberland and Westmoreland Lunatic Asylum, which was caused by the effluvia from a field irrigated by sewage. We publish this paper at length in another part of our columns.

The reading of the paper was followed by an interesting discussion in which the President, Dr. Ballard, Dr. Sanderson, Dr. Spencer Cobbold, Dr. Hillier, Mr. Lord, Dr. Mapother of Dublin, Mr. Burge, and Dr. Iliff took part.

MEDICAL INSPECTION OF WORKHOUSE HOSPITALS.

On Tuesday last a deputation of the Workhouse Visiting Society waited upon the Hon. C. P. Villiers, M.P., President of the Poor-law Board, in reference to the present condition of workhouse Hospitals, and the importance of persistent inspection by competent Medical men. The deputation was introduced by the Earl of Devon, and supported by E. Buxton, Esq., M.P., E. Warner, Esq., M.P., G. Lyall, Esq., M.P., Sir J. Kay Shuttleworth, Bart., A. Smith, Esq., M.P., Dr. Watson, Dr. Burrows, Dr. Sieveking, Dr. Markham, Dr. Goodfellow, and Dr. Stallard.

The Earl of Devon, whilst not wishing to commit himself to all the proposals of the deputation, nevertheless believed that the object was one which required ventilation, and he had no doubt that the Poor-law Board would listen to any suggestions which were thought useful. There were three points upon which the deputation would express their views—the condition of the Hospitals, the nursing, and the necessity for Medical supervision.

E. Buxton, Esq., M.P., said that he would take it as established that there was great room for improvement in the condition of workhouse Hospitals, and the deputation believed that the first and most important step towards a better state would be the appointment of Medical inspectors, who would secure for the poor proper advice, medicines, Hospital accommodation, and other comforts. The many evils of the present system would gradually disappear, and the nursing would improve under the influence of inspectors experienced in the treatment of the sick. The expense would not be great.

The President of the Poor-law Board inquired as to the particular defects in the present system which, in the opinion of the Society, rendered necessary the appointment of Medical inspectors.

Dr. Stallard said that the following defects had been observed:—

1st. That, compared with other Hospitals, the Medical staff was insufficient. In no public Hospitals are so many as 200 patients committed to the sole care of one Surgeon.

2nd. That the united service of advice and medicines is not calculated to secure the best of either. That the drugs ought in all cases to be supplied by the guardians, and the advice by a staff of Physicians and Surgeons, who should not have individual charge of more than 100 beds.

3rd. That the Medical officers are subject to no Medical supervision or control. The public have, therefore, no guarantee that the duties are faithfully performed. In all other public Hospitals there is inspection,—in the lunatic asylums by the Commissioners of Lunacy, and in the army and navy by Surgeons of rank and experience. The salaries of many of the Workhouse Surgeons were such as to raise a fear that the duties could not be performed without personal loss, and the remuneration certainly justified the necessity for careful and systematic inspection. The knowledge must be special to supervise a special organisation, and none but Medical men could exercise any real influence over the duties of the Surgeon and the administration of Hospital details.

4th. The general construction of the Hospitals is defective,—the wards small, over-crowded, ill-ventilated, and unprovided with the furniture and comforts supplied at other Hospitals.

5th. The nursing is most inefficient, the paupers too often employed being morally and physically unfit for the duties imposed upon them.

The Society believe that the only efficient remedy for these defects would be the appointment of two Physicians and one Surgeon, as additional Commissioners, to organise and inspect the administration of the Workhouse Hospitals, and advise the Poor-Law Board in the many sanitary and Medical questions which must constantly come before them.

G. Lyall, Esq., M.P., stated that a new infirmary had been built at Reigate some years ago, and had been approved by the Poor-law Board; but the plans not having been submitted to any Medical inspection, the building had proved most inefficient in several respects. He therefore thought that Medical inspectors ought to be employed to supervise the construction of new Hospitals, and organise the details of their fitting and management.

Dr. Goodfellow said that no one acquainted with the workhouse Hospitals could be satisfied with their present state. He regretted that there was so great a difference between the criminal and the poor. The qualification for the office of Surgeon to a gaol was generally much higher than that of the parish Surgeon, and the name itself was too often associated with inferiority. The salaries were often such as to prevent respectable men from holding the appointment. If the election could not be taken out of the hands of the guardians, the Medical officers should be paid, *pro rata*, according to a scale to be fixed by the Poor-law Board.

E. Warner, Esq., M.P. (Norwich), stated that it was clear there were many subjects upon which Medical inspectors could alone decide,—as, for instance, the dietary of the sick, which ought to be regulated by superior Medical authority. Moreover, they were alone judges of the adequacy of the Hospital accommodation, the character of the nursing, the quality of the drugs, and many other subjects equally important. He believed the inspection should be persistent, and carried out at short intervals.

Dr. Sieveking stated that at least in one particular the Poor-law Board had signally failed—viz., the introduction of skilled nurses. Guardians had entirely disregarded the circular of the Board issued some years ago. He believed that the power of the Board would be greatly strengthened by the appointment of eminent Medical men as additional commissioners. They would act as *amici curiæ*, and would assist in carrying out all the improvements needed. They should not be required to render their services in an occasional or desultory way, but must give their whole time and energy to the work. Mere Medical and Surgical knowledge would be insufficient without special acquaintance with workhouse Hospitals.

Mr. Villiers observed that the Poor-law Board had undoubtedly effected great improvements in workhouse Hospitals. Their main difficulty was the existence of local acts which enabled the guardians to resist the authority of the Board. He hoped to introduce a bill to remedy this defect. He agreed as to the propriety of occasional inspection by Physicians of eminence, and would take the recommendations of the deputation into his serious consideration.

The Earl of Devon having thanked Mr. Villiers for his courtesy and attention, the deputation withdrew.

MEDICAL CHARITIES.—Mr. Cuthbert Collings, of Palmergreen, Southgate, Middlesex, lately deceased, has bequeathed no less than £24,000 to charitable institutions, including the following, viz:—The London Hospital, £4000; the Small-Pox Hospital, £2000; the Royal Free Hospital, £2000; the Great Northern Hospital, £2000; the City of London Hospital for Diseases of the Chest, Victoria-park, £2000; the London Fever Hospital, £1000; the Royal Hospital for Incurables, Putney, £1000; the Metropolitan Free Hospital, Devonshire-square, £1000; the National Hospital for Paralysed and Epileptics, £1000; and the Newcastle Infirmary, £1000, making a total of £17,000 bequeathed by this benevolent and wealthy retired currier to Medical charities alone. Truly "there is nothing like leather."

MEDICAL NEWS.

UNIVERSITY OF ST. ANDREWS.—The following gentlemen passed their examinations for and obtained the degree of M.D. on April 27 :—

Braithwaite, Robert, M.R.C.S., L.S.A., F.L.S, Vauxhall-walk, London; Cay, Charles V., M.R.C.S., Windsor Barracks; Collins, John C., M.R.C.S., L.S.A., Priory-street, Cheltenham; Dyer, Thomas, M.R.C.S., L.S.A., Forest Hill, Kent; Neale, Melville, M.R.C.P., M.R.C.S., Raby-street, Bath; Waring, Edward I., F.R.C.S., F.L.S., Talbot-villas, London.

APOTHECARIES' HALL. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, May 25, 1865 :—

Frederic Henry Ward, Finchley-road, Walworth; John Burdett Willey, Leicester; David Elliott, Newcastle-on-Tyne; Richard Murhall Hickman, Seaton, near Shrewsbury.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ANDERSON, T. MCCALL, M.D. Glasg., has been appointed Government Medical Inspector of Emigrants from the Clyde.

ATKINSON, FREDERICK P., M.B. Aberd., has been elected House-Surgeon to St. Bartholomew's Hospital, Chatham.

BERRELL, C., M.R.C.S. Eng., has been appointed Assistant Medical Officer to the Warwick County Lunatic Asylum.

BOTT, C. G., M.R.C.S. Eng., has been appointed House-Surgeon and Secretary to the Leeds Public Dispensary.

EARLE, EDWARD E., M.R.C.S. Eng., has been elected Resident Surgeon to the Dispensary, Weston-super-Mare.

GUNTHER, THEODORE, M.D., has been appointed Medical Officer for the Parish of Hampton Wick.

JAMIESON, JOHN, L.R.C.P. Edin., has been appointed Surgeon to the Constabulary, Kilkelly, Co. Mayo.

KING, EDWARD P., M.R.C.S. Eng., has been appointed Coroner for the Manor of Chepstow.

MARTIN, PAULIN, M.R.C.S. Eng., has been appointed Surgeon to the Oxford Diocesan Training College, Culham, near Abingdon.

RABY, J., L.R.C.P., has been elected Assistant House-Surgeon to St. Bartholomew's Hospital, Chatham.

DEATHS.

CANWOOD, ROBERT, M.R.C.S. Eng., at Barnsley, Yorkshire, on May 5, aged 56.

ESSERY, THOMAS A., F.R.C.S. Eng., at Heathfield-street, Swansea, on May 13, aged 47.

HUNT, JOSEPH, L.S.A., at Farnworth, on May 19, aged 50, formerly of Ashton-under-Lyne.

KEITH, JOHN, late Surgeon H.E.I.Co.'s Service, at South College-street, Elgin, N.B., on May 11.

MERRYWEATHER, Dr. H. COLLINS, at Wilmington, North Carolina, on April 10.

MILLER, WILLIAM E, M.R.C.S. Eng., at Castle Cary, Somersetshire, on May 12, aged 58.

REID, DUNCAN, M.D. Aberd., at Crown-court, Union-street, Aberdeen, on May 16, aged 60.

ROGERS, WILLIAM G., M.R.C.S. Eng., at 2, Verulam-terrace, Hammersmith, on May 27, aged 25.

ROULSTON, JOHN, M.R.C.S. Eng., at Helperby, Boroughbridge, Yorkshire, on May 8.

SKINNER, Dr., at Orford-road, Manchester, on May 27, aged 37.

WILSON, GEORGE C., L.F.P.S. Glasg., at Lockerbie, Dumfriesshire, on May 15, aged 45.

WAR OFFICE, MAY 30.—The Queen has been graciously pleased to give orders for the appointment of Surgeon-Major William Munro, M.D., 93rd Regiment, and Surgeon-Major Henry Bruges Buckle, 1st Punjab Regiment of Infantry, to be Ordinary Members of the Military Division of the Third Class, or Companions of the most Hon. Order of the Bath.—From the *London Gazette*, Tuesday, May 30.

THE Profession will be glad to learn that there is a probability that the Queen will grant a pension to the widow of the late distinguished Physician and chemist, Dr. R. Dundas Thomson, F.R.S., in consideration of her husband's services in the cause of science.

UNIVERSITY INTELLIGENCE.—OXFORD, MAY 26.—The nomination of George Rolleston, M.D., of Pembroke College, and of Edward Benjamin Gray, M.D., of Exeter College, to the office of Public Examiners in the Faculty of Medicine, under the statute of 1833, was submitted to the House and approved.

SOCIAL SCIENCE ASSOCIATION.—The ninth annual meeting of the National Association for the Promotion of Social Science will be held at Sheffield, under the presidency of Lord Brougham, from the 4th to the 11th of October.

THE COLLEGE FELLOWSHIP. — An unusually large number of Members of the College have been undergoing their examinations for the above distinction during this week; no less than six senior candidates of twelve years and upwards, and nine juniors offered themselves for the Fellowship, when the following papers on Anatomy and Physiology were submitted to them—viz., 1. Give an account of the structure of skin, hair, and nails in man. Describe the sebaceous, sudoriparous, and ceruminous glands, and the nature and uses of their secretions. State the mode in which the cutaneous nerves terminate, and mention the functions that they perform. 2. Describe the origin, course, distribution, and functions of the spinal accessory nerve and its branches. 3. Describe the intimate composition of the ganglions of nerves. Give the general and minute structure of nervous plexuses; state the supposed functions of these, and of the ganglionic system of nerves. Mention also the position of the ganglia and plexuses of the greatest interest and importance in the human body. 4. Enumerate the muscles attached to the thyroid, cricoid, and arytenoid cartilages. Mention those which act upon the vocal cords, whether in separating or closing them, and also in tightening and relaxing them. Describe the true and false vocal cords, and the ventricles of the larynx; and give a brief account of the mechanism of the voice. 5. What are the sources and modes of production of animal heat? By what means is it maintained and regulated? and what are the circumstances by which it is influenced, so as to render the blood of some animals warmer than that of others. 6. Give a full description of the relative position of the parts seen in a lateral section of the male pelvis. The juniors were required to undergo an examination on Dissections and Demonstrations on Wednesday, and on the following morning both seniors and juniors had the following questions on Surgery and Pathology submitted to them—viz., 1. What is meant by glaucoma? Describe the symptoms, progress, consequences, and treatment of the acute form of this disease. 2. What cases may require the operation of tying the subclavian artery? Which part of that vessel should be selected for the ligature? Give your reasons for this selection; describe the several steps of the operation; specify the difficulties and dangers which may be found in its performance, and the proceedings by which you would endeavour to obviate them. State also the collateral channels through which, after this operation, the circulation will be maintained. 3. Give the pathology of the different forms of pyæmia. Describe the appearances found in various organs of persons who have died of this disease, of which state the symptoms and treatment. 4. Describe the changes of structure which occur in bursæ mucosæ, or ganglions; mention the most frequent seats of these diseases, and give the treatment of them. 5. What are the conditions that would induce you to recommend excision of the knee-joint? Give a full description of that operation, and of the after-treatment of the patient under favourable and unfavourable circumstances. 6. Mention the principal morbid changes that are met with in the ovaries. Enumerate the different forms of abdominal enlargement that are liable to be mistaken for ovarian tumours; and state the means by which you would endeavour to discriminate these diseases from each other. After answering the above, the candidates, both seniors and juniors, were required to perform certain operations on the dead body, and later in the day the successful candidates were introduced to the President, by whom they were courteously informed that a satisfactory report of their proficiency would be made to the next meeting of the Council for its approval, and in conclusion the venerable and learned gentleman congratulated the candidates on their well deserved success, and expressed a hope that the same success would attend them through their Professional career.

BLOODY SWEAT IN HYSTERIA.—Dr. Franque puts on record the particulars of one of those cases which are every now and then met with in women the subjects of nervous affections. In the present instance, the woman, 45 years of age, had suffered for several years from hysterical convulsions, although menstruating regularly. She had already had three attacks of bloody sweating, which had been preceded by more than ordinary severe paroxysms of hysteria, when Dr. von Franque saw her during the occurrence of a fourth. On this occasion, most violent pains in various parts of the body had preceded

the hysteric convulsion ; and when this last had continued for an hour an abundant sweat broke out over the entire surface of the body, and this in the parts of the body which had been the seat of the severe pains was coloured red in consequence of the presence of true red blood corpuscules. As the sweat appeared, the convulsions and pains gradually subsided. The skin was entirely intact, and the sudoriferous glands must have been the source of the blood.—*Schmidt's Jahrbucher*, 1864, No. 7.

Diminishing the Contagion of Small-pox by Fatty Inunction. — Dr. Warnatz, in a communication to the Dresden Medical Society, states that several years since he had demonstrated the great therapeutical importance of fatty inunction in the various exanthemata, and especially scarlatina; but in the present paper he has not so much the treatment of variola in view as the diminution of its contagious power. From the commencement of the eruption to its ending he keeps the parts well saturated with fatty substances, the object being never to allow them to get dry, and thereby prevent the diffusion of the pustular detritus in the air. The patients are well content to pursue the practice, for it much relieves the irritation and hastens desquamation. The worse the cases the more desirable the process, which should also be continued even when a fatal issue is expected. Dr. Warnatz prefers simple hog's lard as the agent to be employed.—*Küchenmeister's Zeitschrift*, 1864, No. 2.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

An Inquirer should read Dr. Richardson's work on Tobacco.

Mr. Samuel Cutter should read Dr. Copland's works on Apoplexy, Paralysis, etc.

*** *Thomas.*—Green on Baths ; Burgess's Cazenave ; and a little book by Dr. Lory Marsh, on Special Therapeutics ; Waring's Therapeutics.

Nemo.—We would recommend our correspondent to write to, or have an interview with, his brother-Practitioner, and call his attention to the cases he mentions. In case of no improvement, we would advise him to direct the attention of some influential person to the matter, and leave it in his hands.

A Student.—There will be a Preliminary Examination in General Knowledge of candidates for the diploma of Members of the College on the 20th, 21st, and 22nd inst. Write to the Secretary.

A Fellow.—The only candidates at present known as likely to offer themselves at the ensuing election are—Messrs. Turner, Holt, McWhinnie, and Erasmus Wilson. There is a talk of bringing forward at the latest moment a former member of the Council, whose loss is much felt by his colleagues.

A Provincial Fellow.—You cannot record your vote in favour of the gentleman named without personal attendance at the College. Neither can you do so until you have been admitted to the Fellowship. There will be a meeting of the Council for this purpose on the 8th inst.

A Candidate.—The result of the examinations now going on for the Fellowship of the College cannot be made known until next week. On Tuesday last both senior and junior candidates were admitted to the written examinations in Anatomy and Physiology ; on Wednesday, the juniors only, to Dissections and Demonstrations ; and on Thursday both seniors and juniors underwent the written examination in Surgery and Pathology, and performed operations on the dead body.

G.—1. Buchner on "Force and Matter," who takes the contrary view ; the nine Bridgewater treatises, which take the affirmative view. There are also several very interesting little works by Lionel John Beale, Medical Officer of Health for St. Martin's Parish. 2. Pritchard, Waitz, Knox, Nott, and Gliddon, the publications of the Anthropological Society. The shortest compendium on the first subject is Sir Charles Bell on "Animal Mechanics," published by the Society for the Propagation of Useful Knowledge ; and on the second a little work by Dr. Steven H. Ward, published by the Society for the Propagation of Christian Knowledge.

The following is the address issued by Sir Charles Locock to the electors of the Isle of Wight :—

"Gentlemen,—Having some days since announced to you that, in compliance with a requisition, I had ventured to offer myself as a candidate to represent you in Parliament, and that requisition having been subsequently strengthened by the letters that I have received from so many of the large landowners of the island, it becomes my duty to declare the principles on which I seek your support. The occasion is peculiar, my opponent possessing so many powerful personal claims to your support, from his well-deserved popularity as an extensive landowner and as a tried public man ; but the strong feeling existing throughout the island, that this important constituency should not be represented by a member of the Church of Rome, induces me to cherish the hope that the disadvantages of my being a stranger to you will be overlooked in comparison with the support of the great principles I came forward to maintain. In politics I am a Conservative, but ready to support every measure which may be brought forward for the progressive improvement of our institutions, and the prosperity of the nation. I believe the Conservative party to be as true friends to the working-classes, and as much disposed to improve and reform any defects in the Constitution, as the party calling themselves Liberals. With the increase of wealth and intelligence, I consider that the Parliamentary franchise should be extended, and I would support any measure to extend and widen the qualification to those who, from property and intellectual acquirements, would preserve our Constitution from the perils to which it would be exposed if the franchise was lowered to the extent supported by my opponent. I would reduce the present high standard of the occupation qualification in counties to an amount more nearly approaching that required in boroughs ; but I consider that any lowering of the latter would give such an undue preponderance to men unqualified to exercise the franchise, that the votes of the more educated and wealthy would be neutralised. The question of church-rates is one of great interest, but of greater difficulty. As long as we have a national Church, the law should provide the means for the maintenance of the fabric, more especially in poor and scantily-inhabited parishes where voluntary aid could not be obtained ; but I would vote for any plan which would relieve the Dissenter from personal liability to contribute towards the maintenance of the Established Church, and trust that, although the many schemes to effect that object have hitherto failed, some other may before long be devised which may effect a satisfactory settlement of this much-discussed question. The flourishing state of the public revenue arising from the great prosperity which, by the Divine blessing, has attended our commercial and manufacturing enterprises has enabled Parliament during the last few years to remit a large amount of taxation ; and I cannot but consider that in the apportionment of that remission the agriculturists have not received that consideration to which they are entitled. All restrictions on the importation of foreign grain having been removed, no taxes should be imposed on home produce, and on any further remission of taxes the farmers have the first claim for the immediate and total abolition of the malt-tax. On the great question of national education I am, and always have been, a warm supporter of every institution which shall diffuse knowledge, coupled with religion, among the poorer classes, and would most readily vote for all measures having that object. I am of opinion that it will be always our true interest to keep peace with foreign nations, and not to interfere in their domestic affairs ; but I would oppose any mistaken economy in the public expenditure which should prevent the maintenance of our fleet and army in the highest state of efficiency, believing that a preparedness for war is at all times the surest guarantee of peace. In affording to the electors the opportunity of choosing a Protestant instead of a Roman Catholic representative, I by no means wish to interfere with the Englishman's birthright, liberty of conscience, feeling that a man's creed should not subject him to the loss of any civil or political privileges. I am a sincere member of the Church of England, and in principle and practice opposed to the return to those obsolete forms and ceremonials, the objection to which formed so strong a feature in the constitution of our Church, whose separation from Rome has been the foundation whence the libertics we now enjoy have arisen. Although I should highly prize the honour of being your chosen representative, the proud position I have attained in the exercise of my former profession will assure you that I have not any personal interest to serve in entering Parliament, and should your choice devolve upon me my best energies will be devoted to the discharge of my duties as your representative, and, whether elected or defeated, the approaching contest will give me the opportunity of becoming personally acquainted with your beautiful island and its inhabitants, and I trust I shall be welcomed as a resident, desirous at all times to lend his aid in furtherance of everything that will tend to promote the interest of all classes in the island.

"I have the honour to remain, gentlemen, your faithful servant,

"Binstead, May 27." "Charles Locock.

Dangerous Nuisances.

To the Editor of the Medical Times and Gazette.

Sir,—Sanitary and Medical science has just achieved a most useful success in the rejection by the House of Lords on Friday evening, of a Bill for the extension of large gasworks in a populous metropolitan suburb, which Bill had passed, I must suppose *per incuriam*, through the Commons.

The Lords rejected the Bill on the second reading—that is to say, on principle. I trust that the principle thus judiciously asserted will in all cases be maintained where it is proposed to extend, in town neighbourhoods, noxious manufactures of any kind which could be carried on at some distance in the country, where they would inflict, at least comparatively, little injury on health and property. The manufacture of gas is emphatically one of these. After interminable experiments, it is found substantially impossible to disengage it from dangerous and deleterious effects ; but it is quite practicable to carry it on many miles from the place where it is consumed.

It would be the climax of inconsistency to spend millions in sanitary purification of all kinds for the benefit of London, and at the same time sanction any avoidable enlargement of dangerous nuisances.

I am, &c. A Valetudinarian.

Calabar Bean.

To the Editor of the Medical Times and Gazette.

Sir,—We are sadly in want of a plain, pronounceable name for the extract of this plant, now so much used in ophthalmic practice. We have been fortunate in the name of its antagonist, for "belladonna" and "atropine" can hardly be much perverted, even by the most ingenious Malaprop ; but unless we resign ourselves to the barbarism of "Calabarine," we are driven to use some periphrasis to express the active principle of the *Physostigma*. Of this botanical name it is altogether a hopeless matter to contrive any pronounceable modification, and one is almost tempted to adopt some such short cut in nomenclature as was used the other day by a Yorkshire patient of mine, to whom I had been giving for mydriasis some disks of the gelatine containing extract of the *Physostigma*. "Would you be kind enough, Sir," said he, "to order me half-a-dozen more o' them beans?"

It matters little what new word we use, so that it is in some way derived from the name of the plant itself ; and, therefore, I would inquire of botanists whether the *Physostigma* has not some *alias* which might be taken advantage of in designating its active principle. I am, &c.

May 26. Nominis Umbra.

Poor-law Medical Relief.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I shall feel obliged by your giving insertion to the accompanying resolutions of the Southampton Board of Guardians, as they may be useful to the Poor-law Medical officers and act as a guide for other Unions. If the Medical officers of these Unions, where the guardians have come to a decision on the question of "cod-liver oil and expensive medicines," will communicate the result, either publicly through the medium of your journal, or privately to me, it will enable us to shape our proceedings accordingly. I am, &c.

12, Royal-terrace, Weymouth, May 27. Richard Griffin.

"SOUTHAMPTON BOARD OF GUARDIANS.

"At a meeting of this Board, held May 17, 1865, the following report was made:—

"A Dispensary for the Poorhouse.

"The General Purposes Committee, who were requested to confer with the Medical officers, reported that they met on Friday, when there were present Messrs. Aldridge, D.P., Payne, Ellis, Walden, Barling, and Mosely, and Messrs. Cheesman, Beneraft, and Griffin, Medical officers. Having duly conferred with the three Medical officers on the subject, and ascertained their views with regard to the supply of the whole of the medicines to the sick poor, they resolved unanimously to report to the guardians:—

"1. That a Dispensary be opened at Gower House, part of the workhouse premises, for the supply of the whole of the medicines required for the sick poor, attended by their Medical officers as parish patients.

"2. That a Dispenser be employed and paid by the guardians, whose whole time shall be devoted to the duties of dispensing such prescriptions as shall be sent to him by the Medical officers.

"3. That the Dispensary be fitted up with the requisite shelves, fixtures, and appurtenances at the expense of the guardians.

"4. That the Medical officers shall contribute towards the expenses of carrying on the Dispensary the sum of £100 per annum, in such proportions as they may arrange among themselves, which proportions should be deducted from the present amount of their salaries.(a)

"5. The committee strongly recommend the establishment of a Dispensary as, in their opinion, certain to prove most beneficial in its operations to the poor sick persons who are compelled to apply for Medical relief.

"They believe that the additional expenditure which it will necessarily occasion will be in a great measure lessened by the more rapid cure of patients, which will be occasioned by the administration of cod-liver oil, quinine, and other expensive medicines, which cannot be given at present by the Medical officers as often as is desirable.

"On the motion of Mr. White, seconded by Mr. Walden, the report was adopted *nem. con.*"

In the *Lancet* of May 20, a Dispensary Medical officer says:—"I use here some very good Norwegian cod-liver oil at 8s. 6d. per gallon, which I have tested and found to be a good fish oil, and I have not had a single complaint from any patient about its taste, etc.; but they say it is as nice an oil as they have ever had. At the Brompton Consumption Hospital they only pay 6s. 6d. per gallon for this oil, and the class of patients treated there have tender enough stomachs."

The Effects of Heat on French Wines.

It has for some time been discussed with considerable warmth whether the wines of Burgundy are improved, or even whether they would bear without deterioration long sea voyages and the temperature of high latitudes. The *Compagnie des Grands Vins de Borgogne*, represented in Paris by Messrs. Forrest, Amé, and Cie, have made an attempt to set the question at rest by sending out two hundred cases, containing samples of twelve of the finest growths of Burgundy, to San Francisco. The Chancellor of the French Consulate undertook with some friends to taste each case on arrival, and he declares that the wine arrived in perfect condition, bright, and full of flavour and *bouquet*. This lot of wine was at sea six months, passed the line twice, and rounded Cape Horn, where the vessel remained for twenty days—a pretty fair taste of the briny, as Dick Swiveller would have said.

The effect of heat alone on the condition and maturity of wines is deservedly attracting much attention. It is before the Academy of Sciences of Paris, and many theoretical and practical minds are at work upon it. For those who hold large stocks of French wines, which, under favourable circumstances, repay with good interest the outlay of capital, the question is of great commercial importance. A communication from M. Vergnette Lamotte to the Academy supports what we have stated above concerning the effect of tropical voyages on French wines, and relates experiments made by that gentleman at home. He says that he has kept wine in bottle for three months in a room heated to 104°, and even 120° Fahrenheit, with excellent results. In support of this, M. Pasteur said that he also had experimented on the maladies of various wines, and had proved that they all arose from the presence of microscopic vegetation. The vegetation takes place very slowly for a certain number of years, and it is only when the development has become considerable that the malady is recognised, although, in reality, it existed long before. M. Pasteur says that all the chemical agents he has tried have failed to supply him with a means of preserving wine good for an indefinite period. "I then thought," said M. Pasteur, "of destroying the germs of vegetation by the application of heat, and I succeeded beyond my expectations. It is only necessary to heat the wine for an hour or two to the temperature of from 140° to nearly 160° Fahr. to render it almost incapable of change. So far from the wine being injured by the process, M. Pasteur says that, in all his experience, good judges have always found the heated wine improved, both as regards flavour and *bouquet*. One of the most effective causes of the deterioration of wine, he adds, is the leaving a considerable empty space in the bottles; for the oxygen in the air and light are the acting causes of vegetation. Vegetation has the property of producing volatile acids in considerable quantities, which may be ascertained by the distillation of the wine, which, if free from fermentation, only yields from one to two-tenths of a gramme of acid per litre—that is to say, not more than one or two grains per pint, English. Practice bears out the theory of the chemists; in Burgundy, as in other wine countries, it has long been the custom to apply heat for the purpose of ripening wines. Forty years ago, M. Dubief published an account of his experiments in that way, and he has since produced a work on the subject entitled "L'immense Tresor des Vignerons et des Marchands de Vin." His deductions may be condensed in a few words—Six months in a stone room heated as mentioned above will give to wine all the effect of one or two years of age, and will arrest the vegetation in those which have already begun to ferment.—*The Wine Trade Review.*

(a) Their present salaries amount to £570.

APPOINTMENTS FOR THE WEEK

June 3. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

Royal Institution, 4 p.m. Alex. S. Herschell, Esq., "On Meteorology."

5. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

Epidemiological Society, 8 p.m. Deputy-Inspector-General Smart, M.D., R.N., "On the Dengue (Break-bono Fever) of Hot Climates—the Scarlatina Rheumaxia of Dr. Copland."

Royal Institution, 2 p.m. General Monthly Meeting.

6. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.

Anthropological Society of London, 8 p.m. Meeting.

Royal Institution, 4 p.m. Mr. Edwin Chadwick, "On the Physical and Moral Condition of the English Wage Classes."

7. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

Obstetrical Society of London (Council Meeting, 7 p.m.), 8 p.m. Adjourned discussion on Dr. Barnes' paper "On Dysmenorrhœa, etc., from a Peculiar Form of Cervix;" also, a Supplement to the same, by Dr. Barnes. Dr. J. Braxton Hicks, "Case of Extra-uterine Fœtation." Dr. B. Woodman, "Cases of Hydatiniform Degeneration of Placenta with Albuminuria."

8. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Royal Institution, 4 p.m. Mr. Edwin Chadwick, "On the Physical and Moral Condition of the English Wage Classes."

9. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m. Professor Frankland, "Latest Researches in Organic Chemistry."

ORIGINAL LECTURES.

AN INQUIRY INTO THE NATURE OF THE PHENOMENA WHICH CONSTITUTE "INFLAMMATION."

TWO LECTURES DELIVERED AT

The Royal College of Physicians.

By LIONEL S. BEALE, M.B., F.R.S.,

Fellow of the College; Professor of Physiology and of General and Morbid Anatomy in King's College, London; Physician to King's College Hospital.

Of truly Vital Actions as distinguished from the Physical and Chemical Actions of Living Beings—Vital Phenomena of Inflammation—Of Vital Stimuli: Nutritive Irritability—Excitation and Irritation—The Nature of Irritation—Alleged Resemblance of Inflammation to Combustion—Oxidation not Increased in Inflammation—Of "Excess" or "Deficiency" of Vital Action—Of Living Matter and Formed Matter, and of the so-called Force-Conditioning Machinery of the Cell—No Analogy between Living Matter and a Lifeless Machine—On Inflammation—Changes in Living Matter—Of the "Cell" of different Tissues—Quickly Growing Structures Contrasted with Slowly Growing Structures—Changes in the Formed Material—Of Germinal Matter, and of its Origin—"Omne vivum e vivo."

In the two lectures which I have asked the permission of the President to deliver to the College, I propose to discuss the nature of certain changes which seem essential to the process called "inflammation" as it occurs in man and the higher animals. The short time at my disposal will only enable me to refer to some of the most important questions comprised in the inquiry in a very general manner; and I shall adduce only some of the most important of the facts which seem to me most strongly to support the general conclusions at which I have arrived.

Of the Nature of the Changes Peculiar to Living Matter.

And in the first place I shall have to consider the nature of the general changes which I regard as peculiar to living beings, because similar changes occur in the inflammatory process. In fact, the explanation of the inflammatory process which I am about to offer involves the admission upon my part of the influence of some force or power totally distinct from any form or mode of ordinary force; for I do indeed maintain that the phenomena which distinguish all things living from things which are not alive, have not been, and, in the present state of science, cannot be, accounted for by the action of ordinary force. Inflammation is a process peculiar to living beings, and is dependent upon vital, as distinguished from physical and chemical, actions. I would venture to remark that not one of the advocates of the doctrines now so widely taught, upon the nature of vital actions, has considered the real question at issue. The actions which are called *vital*, and which are undoubtedly explained by physical laws, are not vital actions at all, but the true vital actions have been entirely ignored by many physicists and chemists.

I have endeavoured to prove that the phenomena usually termed *vital* really comprise two distinct classes of actions,—*actions purely physical and chemical, and actions purely vital.*

The purely vital actions which have been alluded to can only be accounted for by attributing them to the influence of some peculiar force or agency totally distinct in its nature from any form of ordinary force. This is not a power which exists, as it were, in a concentrated state in the germ and gradually expends itself as the tissues are evolved, or as the development of the race proceeds, but it is a power which is only temporarily associated with, and influences for a brief period of time, every particle of matter which becomes living. It is not a principle, nor an entity, nor a material. It is a power which may be transmitted infinitely, and without any increase or diminution in its intensity; and that it may not be said I am speaking indefinitely, I distinctly ask for information upon the following points, which ought to be easily explained by physicists and chemists, if their recent general inferences are correct:—How is it that the living matter, say of a simple microscopic fungus, continues to take up certain constituents dissolved in the surrounding medium? How do these constituents become decomposed, and their elements re-arranged so as to form compounds differing in composition and properties, both from the living matter and also from the constituents of the pabulum before they were absorbed? Why does matter in this peculiar living state, after apparently attracting matter towards it and increasing in size, at length undergo division into smaller portions, which separate from one another? Why do different parts of a mass of germinal matter move amongst one another, some parts advancing before other parts; and how is it that some portions of the mass take up a position *above* other portions, in spite of the force of gravitation? These are simple points upon which no information is afforded us by those who unhesitatingly assert that vital actions are in fact made up of physical and chemical actions only.

Of Vital Stimuli, Nutritive Irritability, Excitation, and Irritation.

Next, then, is the very important question of the influence of the so-called vital stimuli upon normal and morbid changes in living beings. Many suppose that organised bodies, being acted upon by certain vital stimuli, develope vital actions. Thus heat is supposed to be the vital stimulus which excites the changes resulting in the development of the chick; light is supposed to excite or stimulate certain changes going on in the vegetable organism—nay, lifeless inorganic matter is regarded as an excitant to increased vital action in certain cases. A particle of sand falling upon the conjunctiva is followed by increased action, as shown by the more rapid growth of cells and the increased vascularity. It is said the particle of sand has *excited* these changes; it is an *irritant*. But, perhaps, the heat, light, and particle of inorganic matter have been all perfectly passive. The conditions under which life was carried on before may have been physically altered, and the alteration may be due to changes, not in the living matter itself, but in the formed lifeless matter by which it is surrounded. In consequence of these *physical changes*, pabulum may flow towards the living matter more readily than before. If this be so, the living matter is not *excited* to live faster, but in consequence of more pabulum having access to it, more matter becomes living within the same period of time. The influence of the so-called *excitant* is after all of a passive character. It does not excite dormant energies or evoke vital actions, but by it some of the restrictions under which the matter lived previously are partially removed.

It is remarkable in these days, when the explanation of phenomena by hypothetical agencies, forces, or powers is assailed on all hands, some of those observers even who have been specially distinguished for their opposition to any doctrine which admits the influence of vital as distinct from physical force, should pertinaciously insist, and without attempting to explain by what mysterious means, that a living cell can exert a modifying influence upon the action of cells around it. A cell undergoing increased action is supposed to *excite* increased action in cells in its immediate neighbourhood.

Virchow asserts that cells may be *incited*, by a *stimulus* directly applied to them, to take up an increased quantity of material. He maintains that "the irritability of a part is the criterion by which we judge whether it is alive or not;" that every vital action presupposes an excitation or iritation, and says, that "we cannot imagine inflammation to take place without an irritating stimulus." The illustration he gives for the purpose of explaining, what he means by *irritation*, and in what manner he supposes the cells in the neighbourhood of the injured cells are affected, will perhaps enable us to form a clearer notion of the views now generally entertained than a long exposition of the various opinions:—"Suppose three people were sitting quietly on a bench, and suddenly a stone came and injured one of them; the *others* would be *excited*, not only by the sudden appearance of the stone, but also by the injury done to their companion, to whose help they would feel bound to hasten. Here the stone would be the '*irritant*' the injury the *irritament*, the help an expression of the *irritation* called forth in the bystanders." So that, according to this doctrine of irritation, not only have the uninjured cells a power of sympathising with their less fortunate companions, but they desire to hasten to afford them active assistance in their difficulty!

I think that the doctrine of "nutritive irritability," so far from enabling us to explain the facts, only complicates the question still further. It seems to me that the so-called "*irritant*" merely produces some physical or chemical alteration which permits the pabulum to pass more freely to the germinal matter.

No Analogy between Inflammation and Combustion.

Chemical authorities taking a somewhat different standpoint have ascribed the changes occurring in living beings to various chemical actions, and especially to oxidation. Dr. Bence Jones agrees with the statement that there is a resemblance between the process of inflammation and ordinary combustion, and has gone so far as to include "inflammation" under the head of "general and local chemical disorders arising from *peroxidation*."

Now, so far from inflammation depending upon increased oxidation, it would seem that the oxidising process is greatly diminished in intensity, or altogether stopped. In a vascular tissue in a state of inflammation, as is well known, the circulation is very slow, or is actually suspended. How, then, can there be increased oxidation? Inflammation, as is well known, occurs in tissues altogether devoid of vessels, where oxidation must be slow indeed. What, I would ask, is the evidence of increased oxidation in pneumonia, or pleurisy, or pericarditis? Bright's disease, tubular nephritis, cystitis, and other affections are considered by the same authority to depend upon peroxidation; while there is strong evidence that these morbid changes are accompanied by, if not due to, deficient oxidation; and, as is well known, the way to treat such chronic disorders is not to attempt to diminish oxidation, but to increase this process in every possible way. If we could increase oxidation at the seat of inflammation, I believe that we should diminish the activity of the inflammatory process. So that there seems to be no real resemblance between the chemical combustion of lifeless matter and the *vital process* of inflammation which occurs in living things only. Combustion is an intense chemical action, inflammation an intense vital action. Oxidation is opposed to vital action, and where truly vital actions exhibit increased intensity, the activity of the process of oxidation is not great.

Even if we regard it as conclusively proved that an increased development of heat invariably takes place at the seat of inflammation, I think a careful consideration of the facts render it more probable that the rise in temperature is due to the increased multiplication and rapid germination of the masses of germinal matter than to oxidation. The process of germination generally seems to be intimately associated with the setting free of heat, but it is very doubtful if it depends upon oxidation, since it is proved by observation that the conditions favourable to free oxidation are not present. Generally, the process of oxidation is far more active in the fully-developed tissue than in the actively growing, living germinal matter. Compare the high degree of development of the respiratory apparatus of the imago or perfect insect with that which exists in the germ. Oxidation seems to be connected rather with the disintegration or removal of *fully developed and worn-out tissue* than with the growth and multiplication of masses of germinal matter, which attains its maximum at an early period of development, and in certain morbid processes. Oxidation is clearly necessary to the breaking down and removal of tissue; but it is doubtful if it has much to do with the appropriation of pabulum by living matter, or even with the process of formation of tissue.

Of Quick and Slow Vital Changes, and of Excess and Deficiency of Vitality.

Living fast is invariably associated with brief duration. If the lasting character and slow change of a healthy as compared with an inflamed tissue is to be regarded as evidence of the manifestation of the highest possible degree of vital activity, then by this we mean the slightest possible change.

If we are to regard these characters, which exist in many healthy tissues, as evidence of an increased or high degree of vitality, as compared with pus, cancer, and other active and rapidly growing cells, then an old dry cell of cuticle is in a more highly vital state than a young and actively growing one; a dry hair more so than the soft cells of its bulb; the hard dry cells of a cocoanut shell, or a walnut shell, or a peach stone, which have ceased to change, exhibit "vitality" in a more remarkable degree than the rapidly growing cells of a young leaf, than the rapidly multiplying cells of many fungi, and the soft moist cells of all growing and changing vegetable tissues. If this view be true, an old tissue is in a higher state of vitality than a young one. Still following out the same line of argument, we should be forced to admit that that which has ceased to grow and has ceased to change—that which cannot form, or change, or modify—that which has no inherent power of motion, conversion, or formation—that which is, in short, *dead* — exhibits a higher degree of "vital activity" than the soft, ever-changing matter which possesses all these wonderful powers—which, in short, lives.

If, on the other hand, rapid growth—the appropriation of a large quantity of nutrient matter—rapid change—rapid increase of bulk—are evidences of a *a high degree of vitality*, then a pus cell and a cancer cell, so far from manifesting a *deficiency* of vital power, exhibit unmistakeable evidence of vital activity, and agree in this with all young tissues, and with the rapidly growing "cells" of the adult organism. If "increased vital activity" means anything, it means that, in a given time, a greater quantity of inanimate pabulum becomes living matter; and it follows that pus and cancer and the granular cells, growing so fast in many morbid conditions, manifest *increased*, not *deficient vitality* as compared with epithelium. But is it not more correct to say that, in the former, "the restrictions under which growth occurs are greatly diminished, as compared with the latter," than to speak of *varying degrees*, or *excess*, or *deficiency* of vital power?

In health, there are tissues exhibiting every degree of slow and rapid change (vital activity), from the scarcely altering enamel and dentine to the so-called cells (masses of germinal matter) which are found in such numbers in every villus, many of which pass through perhaps every phase of existence during the absorption of a single meal.

We very often find that tissues which grow very slowly in the normal state, in disease exhibit remarkably increased activity; and in this *more rapid growth* and change alone does the morbid condition oftentimes differ from the normal state.

(To be continued.)

---

upon the

HISTORY, THEORY, AND PRACTICE OF SYPHILISATION.

By Professor W. BOECK, of Christiania.

Delivered in the Theatre of the Meath Hospital and County of Dublin Infirmary on Friday, June 2, 1865.

Gentlemen,—I have been requested to deliver a lecture upon syphilisation: I willingly comply with this request, as Dr. Moore has had the goodness to translate my lecture, but I must apologise for my imperfect pronunciation of your language.

By syphilisation I understand the mode of treatment by which, by repeated inoculations of syphilitic matter, taken from primary sores, I bring the body into the condition that it is no longer susceptible of the action of the syphilitic virus.

It will, perhaps, be agreeable to you, Gentlemen, before I proceed further, that I should lay before you a short *résumé* of the history of this mode of treatment. Auzias-Turenne, of Paris, performed inoculations of syphilitic matter upon animals in order to see whether this virus could be transferred to them, which up to that time had been denied. In this he was at length successful, and it was chiefly apes which could with the greatest facility be inoculated. After chancres had been repeatedly produced in the same ape, a great many sceptical physicians wished to see his inoculation, and a meeting was appointed in the *Jardin des Plantes*; the old ape was inoculated, and a still greater crowd assembled a few days later to see the result. But when the ape was brought in nothing was to be seen. It may easily be imagined how this result was received, and that Auzias-Turenne was ridiculed, but he did not on that account give up the method: he continued his inoculations, found that the old ape was not susceptible of fresh inoculations, but that a second ape after inoculations got chancres, though this ape also after a series of inoculations became unsusceptible.

Auzias-Turenne now saw clearly that he had here a natural law, in itself resembling that which your immortal Jenner had discovered in the inoculation of vaccine matter, and we shall not upbraid him that his French blood now carried him away, and that his first idea was to employ the inoculation of syphilitic matter like that of vaccine matter—as a prophylactic. We cannot gainsay him that his train of ideas is logically correct, but it is not practically correct, for the great rule is, that he only gets syphilis who himself will have it.

As the result of this idea of employing syphilisation as a prophylactic, my friend Auzias wished at the time to syphilise all public girls, seamen, and soldiers, and he would

willingly have syphilised us all. No wonder, then, that such an idea met with all the opposition it deserved; but it was not long until Auzias renounced his error, and at the same time there appeared an Italian, Sperino, of Turin, who showed, by a series of experiments, that the syphilitic disease was cured during these inoculations, which Auzias, too, at the same time, demonstrated. Still, this failed to reconcile Physicians to the new method; such a prejudice had been raised against it that both the Académie de Médecine of Paris and the Academy of Turin condemned it without having the necessary materials before them for passing any judgment; the paradox involved in this method appeared to all so enormous as to render proofs of its absurdity unnecessary.

Lecturing in the University of Christiania upon syphilis, and having a section of the Hospital devoted to this disease, I carefully investigated all that was advanced upon this subject, and ascertained that there must be some truth in it. I had, through a period of very many years, found that our treatment with mercury is highly unsatisfactory; I therefore considered that, from my position, it was my duty to give a trial to this new method, although it appeared to me as paradoxical as it did to all the world, and notwithstanding that it had been condemned by two Academies. But before I began, I laid down for myself certain limits, to which I still adhere. It will be at once observed that I will not speak of the method as a prophylactic: this would be immoral; but neither am I at liberty to employ it in every case of syphilis; it is only when syphilis has become constitutional—when the syphilitic virus flows with every drop of blood through the system—that I allow myself also to inoculate it upon the skin.

The next question is, whether I shall employ syphilisation in every case of constitutional syphilis?

By a fortunate coincidence it happened that of the two individuals whom I first took under treatment by syphilisation, the one had not been treated for syphilis, while the other had been the subject of all the resources of our art. In the first the inoculations proceeded without difficulty, the symptoms gradually disappeared—in a word, I found myself upon the beaten path. In the other case all was irregular, I could effect no order at all, and when my first patient was well, the phenomena in the second were still in full bloom. I immediately began to suspect that it was to the medicines previously given that this result was attributable, and on subsequently investigating this opinion, its truth has been most completely confirmed; so that I have made it a general rule to syphilise only those who have not previously been treated with mercury, whether this has been employed for primary or constitutional symptoms. But if I be asked whether syphilisation has not some effect in these cases, I can answer decidedly in the affirmative—it often acts incredibly. Dr. Simpson, of Edinburgh, has recently described two such cases, which were sent over to me by Professor Simpson; what is there stated corresponds precisely to what I have myself noted, and of which any one may satisfy himself. But the reason why I do not undertake the treatment of such individuals is to avoid having relapses, which in these cases are apt to occur.

Now, in order to make my usual mode of proceeding as plain as possible, I shall suppose that a person labouring under primary syphilis consults me. In this case I treat the primary sore as a simple ulcer—I prescribe a weak solution of sulphate of zinc or such like, and occasionally employ a slight cauterisation with nitrate of silver; I give no internal medicine, but make the patient come to me once or twice a-week, that I may observe when the constitutional symptoms break out, for the earlier syphilisation can be commenced the better. So soon as I perceive the first constitutional signs, I commence the treatment by taking matter from an indurated chancre or from an artificial pustule in a patient under treatment by syphilisation. I inoculate first on both sides of the chest, and make three punctures with a lancet, precisely in the mode adopted in vaccinating. After three days pustules are developed, and then I inoculate again in the sides, taking the matter from the pustules produced by the first inoculation, observing carefully to make the second inoculation at a distance from the first, so that the sores may not become confluent. At the end of three days I make the third inoculation, taking the matter from the pustules of the second inoculation; and I now continue to inoculate on both sides every third day, always taking the matter for the fresh inoculation from the pustules last formed, so long as this matter continues to afford a positive result. When it no longer takes I procure new matter in the same mode as for the first inoculation, and continue with this as with the first. This second matter will yield smaller sores and a shorter series than the first, and when it no longer takes I procure a third and proceed in the same manner. This third matter will produce very little effect, and I therefore pass to the upper arm, where I proceed in precisely the same mode as in the sides; and when no effect is any longer visible in the upper arm I remove to the thighs, and continue there in the same way as in the two preceding places. By the time the inoculations are here brought to an end, from three to three and a-half or four months have probably elapsed, the symptoms which manifested themselves from the commencement have disappeared, or if some slight symptom has remained this disappears spontaneously. It often happens that during the treatment a fresh outbreak takes place, and he who is not acquainted with the method believes that some other plan must now be adopted; another infers that syphilisation is of no avail. But, let them not be deterred by any symptom, not even by the most severe iritis, which never requires anything but the instillation of a little atropia. But, happen what may, let them shut their eyes to it and continue the inoculations. The patient who, during the whole treatment, can attend to his business, feels, after it is completed, perfectly well, and may immediately expose himself to any hardships. He can endure wet, cold—in a word, everything which after mercurial treatment would render him liable to life-long illness. It is probable that I may now be asked as to the result at a later period for these individuals, and I shall speak first of the relapses. On the whole, I have treated 429 individuals, and of these 45 have come back, making about $10\frac{1}{2}$ per cent.; but, as we may calculate that some of those treated during the last year will return, I will assume that the relapses will amount to 12 or 13 per cent. But, let us now examine more closely what is called a relapse after syphilisation. In many instances a single mucous tubercle, a small white spot on the tongue or in the throat—symptoms for which nothing more than external means is employed, and for which the patients are treated only for a few days in Hospital. So far as I at this moment remember, thirteen were taken again under treatment with syphilisation, and two with iodide of potassium.

You will next ask whether tertiary symptoms have been developed in any of them. This has been the case, I believe, with three; but at the same time these individuals have been perfectly well—their general health has not, as so often happens after mercurial treatment, been broken down, and in those who have had relapses it has been good, as it is evident that in those who have had no relapse it has been particularly good.

We come now to the children of those who have been syphilised. Here we are not much better off than after the mercurial treatment; we see the same rule to prevail as after this last method, namely—that when the mother has been syphilitic, the first child or children is or are syphilitic; that they are healthy is the exception. If the father has been syphilitic, the children are, in general, healthy; that they are syphilitic is the exception.

You will next propose to me the question how I treat syphilitic children. I treat them precisely as I do adults; and it is interesting to see that the sores in these little ones bear in size a proportion to that of the child, and that the patients suffer less, and not more, than adults. The results of syphilisation in children with hereditary syphilis have not been brilliant; of forty-two children, twenty-two died, but I have taken under treatment every case that I have met with, and every one knows that in such children there are very often affections of the internal organs which lie beyond our power to cure. I cannot at this moment say how many little children with acquired syphilis I have syphilised, but they are not few, and of these only one died, the cause of death in that instance being croup after I had performed tracheotomy. Of adults, two died,—an old woman of dysentery, and a young woman of puerperal fever. This last case I forgot to include in the *résumé* I have given in the *British Medical Journal*.

Now, in order to give you a definite idea of the confidence I have in this method after having practised it daily for thirteen years, I shall say only that if I myself, or any of mine, were so unfortunate as to get syphilis, I should employ no other means than syphilisation.

Still, a few words in conclusion, gentlemen. Vaccination has for many years stood alone; syphilisation now comes to join it. Shall we stop here? I believe not. Vaccine and the syphilitic matter are both animal viruses; we see them contained under a similar law. May not also the other animal poisons be referred to a similar law? We see that Nature is simple in her diversity: should this not also here be the case?

—should not glanders, hydrophobia, etc., some time be curable? Let us all seek to clear up this dark point in our science, and let us not, as hitherto, with respect to syphilisation, seek only to extinguish the rising gleam.

[Among the crowded auditory present during the delivery of the foregoing address were:—The President of the King and Queen's College of Physicians in Ireland, the Regius Professor of Physic in the University of Dublin, Sir Wm. R. Wilde, the Professors of Surgery and of Materia Medica in the Royal College of Surgeons, the Rev. Professor Haughton, M.D., F.R.S., Professor Banks, Mr. Tufnell, Mr. Morgan, Drs. Smyly, Bennett, Banon, Martin (of Portlaw), Fleming, Head, Hardy, Hayden, Byrne, Moore, etc., etc. On the conclusion of the lecture, the President of the College of Physicians proposed, and Mr. MacNamara seconded, a vote of thanks to the learned Professor for his very lucid and interesting exposition, which, notwithstanding the disadvantage of speaking in a foreign tongue, he had so admirably delivered. The vote of thanks, which passed unanimously amid great applause, was conveyed to the Professor in suitable terms, on the part of himself and of the students, by Dr. Stokes.]

ORIGINAL COMMUNICATIONS.

RUPTURE OF THE EYE THROUGH THE SCLEROTIC.

By GEORGE LAWSON, F.R.C.S.,
Assistant-Surgeon to the Royal London Ophthalmic and the Middlesex Hospitals.

(Continued from page 571.)

Prognosis.—Our prognosis in cases of rupture of the eye through the sclerotic must always be very unfavourable; for if we regard the injury only with reference to the rent in the sclerotic, without anticipating any deeper destruction of parts, we must notice that the wound is a contused and lacerated one—the most unfavourable for primary union—and that it is in the ciliary region, the part of the eye worst suited for the reception of injuries. These facts alone would lead us to anticipate the loss of the eye; but when we further consider the force required to produce such an injury, we are led to predict a bad result.

Treatment.—When a patient who has met with this injury first presents himself for treatment, the eye is generally somewhat in the following condition:—A rent is seen in the sclerotic in the locality already indicated. A portion of iris may or may not be prolapsed through the wound. The cornea is probably entire, and the tension of the eye is—T 2 or 3. On looking into the eye, we see the anterior chamber occupied by a coagulum of blood. We can only surmise the extent of damage the deeper tissues have undergone, and treat the patient accordingly. Two or three leeches should be applied to the temple of the injured side, and repeated in twelve or twenty-four hours if the eye is very painful. Soothing applications afford the greatest relief, and a double fold of linen may be laid over the eye and kept wet with a belladonna lotion. The room in which the patient resides should be darkened. If the eye progresses favourably, towards the end of the week the blood in the anterior chamber will have been sufficiently absorbed to allow of a more accurate examination being made. The patient, though unable to discern objects, ought now to have a fair perception of light; failing to possess this, a very unfavourable prognosis must be formed. If the blood in the anterior chamber at the end of the week remains unabsorbed, and no correct diagnosis of the injury can be made, let the patient continue the treatment, and examine the eye from day to day. If, however, after ten days or a fortnight's treatment, or perhaps even longer, the eye is found to be irreparably destroyed for all purposes of vision, what is the best course to pursue? In such a case, even supposing the eye to progress favourably and to give rise to no untoward symptoms, but to proceed steadily on to recovery, the best we can hope for is, that when all active inflammation has subsided the globe will shrink, and shrink sufficiently to allow of the use of an artificial eye. This process, however, takes time, and at least from six weeks to three months' constant attention will be required, during which it will be a source of continued anxiety and very often of pain.

But eyes lost from rupture of the sclerotic do not always progress in this quiet manner; they frequently go on to suppuration, and a long, painful, and tedious process is entailed, occupying not less than six or eight weeks, and a still further period is necessary before the remnant of the globe has cicatrised, and the contraction of the stump is completed. The great danger, however, of a severe injury to one eye is the chance of the other becoming involved in a sympathetic ophthalmia, a danger always to be apprehended as long as it continues in a state capable of acting as a source of irritation. My own feeling is, that when, after a careful examination, it has been accurately decided that the eye is lost, it is far the safest and wisest plan to remove it. A long period of certain anxiety is saved, for a man must be anxious who has lost one eye, and knows that the other is, as it were, in the balance; all further suffering is put an end to, and the safety of the other eye is insured. Surely these three considerations must weigh well with a sensible man against the simple fact that the stump of a lost eye is a good button upon which to hang an artificial one, for though the deception in such cases is more complete than when the globe has been excised, it is in truth nothing more than balancing the worth of the seemly appearance of an artificial eye against the chance of losing a sound and a living one.

The following cases are illustrations of the remarks I have just made. In the first three cases recorded, the rupture of the sclerotic occurred in the upper region of the eye, its most usual situation. In Case 4 the rent was on the inner side, between the internal rectus and inner margin of the cornea. Case 5 is illustrative of what often occurs when the eye is allowed to remain after rupture of its external coats from an injury accompanied with extensive intraocular hæmorrhage.

Case 6 is an example of rupture of the sclerotic in an unusual position, occasioned by the direct impact of a large foreign body driven with force against it.

Case 1.—*Rupture of the Globe in the Upper and Inner Region of the Eye—Complete Loss of Sight—Excision.*

John C., aged 45, applied to the Hospital on February 28 of this year on account of an injury he had received to the left eye. Eighteen days previously he was walking through his back yard, the ground being at the time covered with ice, when his foot slipped and he fell, striking in his fall his left eye against the bolt of a gate. He was at once admitted into the Hospital.

State on Admission.—Along the upper and inner border of the eye, a short distance from the margin of the cornea, but anterior to the insertion of the superior rectus muscle, is a jagged wound about five-eighths of an inch in length. The anterior chamber is now clear, but blood can be seen in the vitreous. The lens appears to have escaped through the wound at the time of the injury. He has no perception of light, and it has been since the accident a constant source of pain. I therefore advised the man to have it removed, as the eye was a lost one, and would probably continue to give him much trouble and anxiety. He at once assented, and I removed it for him. The following was revealed by the examination of the eye after its excision:—On making a section of the eye it was found that the vitreous space was occupied by a thin yellow serous fluid, excepting in the immediate neighbourhood of the ciliary processes, where a small quantity of vitreous, of normal consistency, mixed with blood, was adherent to them. There had evidently been extensive hæmorrhage from the ciliary processes into the vitreous, and an escape of the lens, and the loss of a considerable portion of vitreous at the time of the accident. The choroid, retina, and sclerotic were *in situ*, but here and there were small patches of blood between the choroid and retina.

Case 2.—*Rupture of the Eye through the Sclerotic in a Line Extending Inwards from between the Margin of the Cornea and the Superior Rectus.*

Joseph F. came to the Ophthalmic Hospital on April 15, 1860, on account of an injury he had received to the left eye seven days previously. He was employed unloading ballast from railway trucks into a barge, and in striking a large piece of wood which he had laid across the rails, it flew up and struck the eye with great force.

State on Admission.—There was a rupture of the sclerotic in a line corresponding to the horizontal diameter of the cornea, between its upper margin and the superior rectus muscle. Through this wound the iris, a portion of the choroid, and some lens matter was still bulging. The whole eye was softened and somewhat shrunk, acutely inflamed, and intensely painful. The interior, as far as could be seen, was filled with blood and inflammatory effusions. He had no perception.

The eye was quite destroyed, and to relieve his sufferings and place the sound eye in safety, the injured one was excised.

The man made a quick recovery.

Case 3.—*Rupture of the Globe through the Sclerotic in a line between the Cornea and the Superior Rectus from a Blow.*

Chas. D., aged 30, came to the Hospital on December 26, 1859, on account of an injury he had received to the right eye. On the previous evening, whilst drunk, he was violently struck on the right eye, but he has no remembrance of how or by whom the injury was inflicted. There was a large transverse rupture of the sclerotic extending in a line between the superior rectus and the upper edge of the cornea. The anterior chamber was full of blood, and the eye irreparably destroyed.

Case 4.—*Rupture of the Eye through the Sclerotic from a Blow with a Piece of Iron—Escape of the Lens and Entire Iris through the Wound—Excision.*

James L. was admitted as an in-patient of the Ophthalmic Hospital on October 21, 1859, on account of an injury he had received to the left eye a fortnight previously from a blow on it with a large piece of iron. He says that immediately after the accident he lost all sight.

State on Admission.—There is a rent in the selerotic on the inner side of the cornea, between it and the internal rectus, in a line somewhat vertical, but corresponding to the curvature of the cornea. There was evidently posterior hæmorrhage, and the eye was quite blind. He complained that the sight of the right eye was dim, and that surrounding objects appeared indistinct. Under these circumstances Mr. Bowman excised the eye, and the man made a good recovery. On making an examination of the eye afterwards it was ascertained that the lens and the entire iris had escaped through the wound. The vitreous was infiltrated with blood, and hæmorrhage had taken place between the choroid and retina, and also portions of the choroid were detached by blood-clots from the sclerotic.

Case 5.—*Rupture of the Eye through the Sclerotic—Subsequent Shrinking of the Globe.*

Eliza W., aged 33, applied to the Ophthalmic Hospital on April 22, 1862, on account of an injury to the right eye four days previously. She accidentally slipped off a chair, and in her fall struck her right eye against the projecting end of the bedpost.

State on Admission.—There was a rupture of the sclerotic at the upper and inner region of the eye about one-eighth of an inch from the margin of the cornea. The anterior chamber was full of blood; the whole eye acutely inflamed, and great chemosis of the conjunctiva. The eye was quite blind, and irreparably destroyed for all purposes of vision. She was strongly urged to have it removed, as it was now useless, a source of much suffering, and might involve the other eye in sympathetic inflammation. She, however, refused, and for a time continued under treatment; but after a few visits ceased her attendance at the Hospital.

June 23.—The patient again applied to the Hospital. The injured eye was now quite shrunk. The other eye (a previously damaged one) was in a very unhealthy state. The cornea was hazy, and the ciliary vessels large.

Case 6.—*Rupture of the Globe in a Line with the Lower Margin of the Cornea—Protrusion of the whole Iris—Posterior Hæmorrhage—Excision.*

Fred. F., aged 34, a boiler maker, was brought to the Hospital on March 28, 1865, having one hour previously met with a severe injury to the left eye. He says he was driving a steel cotter through a pin to fasten together two iron plates, when the cotter flew out, and struck the left eye.

State on Admission.—The globe collapsed more than one-third. There was a wound nearly three-quarters of an inch in length in the horizontal diameter of the eye, running along the lower margin of the cornea, which it had entirely detached from the sclerotic, and extending inwards towards the caruncle for nearly a quarter of an inch through the ciliary region. Protruding from this wound, and hanging loosely, was the entire iris. The collapsed eye indicated that there had been great loss of vitreous. The anterior chamber was filled with blood. The eye was irreparably lost. This being the case, I strongly urged the man to have it removed, and having gained his consent, I at once excised it. On examining it afterwards, the following was the condition:—There was a large wound, as indicated above. The whole iris was prolapsed, having been torn from its ciliary attachment. The lens was also gone, and at least two-thirds of the vitreous had escaped. The anterior chamber was filled with blood. The retina was detached entirely, except at the optic nerve and ora serrata, and bulged forward by a large clot of blood between it and the choroid, which latter was *in situ* with the sclerotic.

5, Harley-street, Cavendish-square.

SEWAGE EXHALATIONS THE CAUSE OF DYSENTERY.

AN ACCOUNT OF AN OUTBREAK OF DYSENTERY IN THE CUMBERLAND AND WESTMORELAND ASYLUM, WHICH WAS CAUSED BY THE EFFLUVIA FROM A FIELD IRRIGATED BY SEWAGE.(a)

By T. S. CLOUSTON, M.D.,
Medical Superintendent.

(Continued from page 570.)

The Dysentery.—The type of dysentery which occurred here was so different in many respects from any of the accounts of dysentery with which I have met, that I think it demands a full description. In many of its symptoms, in the treatment most successful for it, and in its pathology, it differed widely from tropical dysentery.

All the cases did not commence in precisely the same way. Some of the patients had ordinary diarrhœa from periods varying from two to three hours up to twenty-four hours before blood appeared in the stools. In some cases there was great pain in the abdomen for twenty-four hours before the diarrhœa set in; in other cases there was scarcely any pain at any period of the disease. In some cases there were febrile symptoms at the beginning; in others these were absent till the disease had advanced considerably.

There were two classes of cases. In the first, the patient had two or three loose stools, or perhaps had no ordinary stools at all, but at once began to pass glairy mucus mixed with blood, in small quantities at a time, from the bowel. He had no pain, no fever, no want of appetite, and he refused to believe he was ill. This would continue for a day or two, and then the blood would increase in quantity, and the stools become more frequent. Pain would begin to be felt in the region of the rectum, and the pulse would mount up ten or twelve beats. For days the patient would be at stool every hour or two, and of course would become weaker. His tongue was then seen to be coated with a dirty yellowish white fur, but the appetite for such forms of nourishment as milk, strong beef-tea, calves-foot jelly made with wine was good. Solid food was not relished. The stools would then be seen to be coated with a semi-fibrinous semi-purulent looking membrane. The tongue would then become clean and glazed and beef-steaky; the evacuations become fæculent, mixed with pus, the latter element becoming gradually less as the patient advanced in his slow convalescence.

In the second class of cases, the patient had from the first great pain in the abdomen of a griping kind, a hot skin, and a pulse over 100; the dejections were copious and frequent and watery, while they were largely mixed with blood. In many cases there was sickness; in all loss of appetite. After some days the tongue and mouth would become dry and parched and black; the features pinched; the pulse small and quick; and death soon ensued. In some cases the stools would, after a time, become membranous and shreddy, and then purulent, till the patient was more gradually weakened and exhausted. One such case lived six weeks, and the attendant lived two months. Of course, this greatly depended on the previous strength. In only one of the seventeen cases of this class did the patient recover.

All the cases had the following features in common: bloody stools at first, tending to become purulent, intense fœtor of the evacuations during the whole of the disease, no scybala, and great thirst. The laundress could not wash the soiled linen without vomiting, until it had been deodorised by chloride of zinc.

As regards the previous bodily health and condition of the cases attacked by the disease, it may be best judged of when I mention that, of the thirty-one cases, only eleven had been in really good health. All the patients first attacked were very weak or very old. The attendant was the only exception to this. The disease did not confine itself to patients labouring under any one form of mental disorder; but it is remark-

(a) Paper read before a special meeting of the Metropolitan Association of Medical Officers of Health on May 27, 1865.

able that, though there are only, on an average, about eight patients in the asylum labouring under general paralysis, three of these should have died of dysentery, and out of about the same number of congenital imbeciles and idiots, four should have had the disease. It would seem, therefore, that the chief predisposing cause of the disease was diminished nervous energy rather than impaired nutritive power, for several of the patients, especially those congenital cases, were fat and well nourished.

The high rate of mortality must be looked upon as owing quite as much to the state of the patient attacked as to the fatal character of the disease. But then the attendant, who had been strong and vigorous in every respect, was carried off by it, although he was removed away from the asylum, showing that its fatal effects were not owing to weakness or impaired nutrition entirely; and one old man of 65 recovered, showing that the disease might assume a very mild form indeed.

I have no evidence whatever that the disease was infectious. The outbreak of the disease at first, the outbreaks in wards the patients of which had had no communication with the wards in which the dysenteric patients had been, the long intervals when there were no cases in the house, and the fact that the attendant who took the disease did so after three days' residence, when there were no cases in the house, and the entire immunity of the nurses who specially attended the sick, changed their linen, bathed them, etc.—all those facts go to prove nearly conclusively that the disease was not infectious.

Treatment.—In treating the first cases of the disease I naturally used opiates and astringents. I found them to be of no service whatever in the first stages of the disease. The opiates decidedly did harm in any form given by the mouth, except Dover's powder, as they caused sickness. The astringents were useful in the latter stages of the disease, and I should be at a loss to say which of the numerous vegetable and mineral astringents I found most useful, for I found each of them useful, when first given, for a day or two, but they then lost their effect. During the stage when the evacuations were purulent and the blood in them disappearing, I found it of much service to give tannin, gallic acid, acetate of lead, sulphate of copper, sulphate of zinc, nitrate of silver, alum, logwood, and powdered cinchona in this way. Decoction of pomegranate root I found of no service. The famous ipecacuanha treatment, so universally practised and so implicitly relied on in the treatment of tropical dysentery, I tried in every possible way. So far as I could judge, the results were, that in a few cases it caused vomiting that could not be stopped, and prostration that was never rallied from; in a few cases it caused no sickness even when given in large doses, and then it diminished the quantity of blood in the evacuations, while, in the majority of cases, it caused temporary nausea, without doing any more harm or any good. I gave it in the very first stages of the disease, often both by the mouth and by the rectum. I gave it in all doses, from a drachm down to ten grains. I gave it alone and in combination with opium, and after opium. I gave it once a day, and I repeated it every two hours in different cases, and the above is the unsatisfactory conclusion I must come to. Purgatives I found to aggravate the disease most unmistakably. Enemata of astringent substances I found useful in the latter stages of the disease in the cases that were going to recover, and a little opium with these increased their good effects. Enemata given by the long flexible tube, recommended by Mr. Hare, aggravated the symptoms, or rather the flexible tube in being passed up the inflamed and irritable rectum caused intense and unbearable pain. I tried iron in the form of the tincture of the muriate and of the solution of the persesquioxide with as little good effect in the first stage of the disease as the other remedies. Creosote given by the mouth diminished the sickness in many cases, and also diminished the fœtor of the evacuations Tincture of iodine was also ineffectual. Large doses of quinine were tried, but ineffectually. Chlorate of potash was also tried unsuccessfully. Diuretics were also tried in the cases where the urine was scanty and deposited urates, but they seemed of no service. Blisters over the abdomen were useless. The only plan of treatment that I was quite sure did the patients good was to remove them to the third story, to give them as much nourishment in a liquid form as they could possibly be got to take, and to give them wine and water *ad libitum*. Large vessels of milk, boiled with a little flour, and allowed to cool, were always kept by the patients day and night, and the nurses were ordered to give them some of this as often as they could be got to take it. Small pieces of ice were always grateful to them, and when there was nausea or vomiting helped to allay it. Strong beef-tea was given *ad libitum* to those who could be got to take it. Calves'-foot jelly made with wine was given to those who would take it. Soft boiled eggs in some cases were taken and did not increase the purging or cause pain after they were taken. But of all the forms of nourishment the boiled milk was taken most readily by the greater number of patients, and kept up the strength best. This was Sydenham's most trusted form of nourishment in the dysentery of his day, and certainly I found it by far the best. Patients would take it when they would take nothing else, and it never caused griping or an increase of the dejections, as any kind of solid food was so apt to do. During convalescence I did not find solid animal food in the least objectionable.

In three of the cases the patients got out of bed too soon, and had relapses of the dysentery, and then astringents were decidedly beneficial. They seemed to subdue the symptoms at once.

The cases varied extremely in the time they took to recover completely. One man recovered in a week, another was two months ill. The average duration of the disease was about five weeks. This includes the time during which the preceding and succeeding diarrhœa lasted. None of the patients who recovered had bloody stools more than a month.

Of the patients who died one lived four months, but in his case the cause of death was a sequela of the disease, and the ulceration of the gut was found cicatrising after death. Another case (the attendant) lived two months from the commencement of the disease. Several of them lived a month. A week was about the average length of time, and one case died in two days. All the patients who died in the short periods had been in weak health, or laboured under some other disease previously.

If I had now a case of the first type to treat, I should give Dover's powder in ten-grain doses three times a-day, and a large enema every morning containing a drachm of ipecacuanha and two drachms of compound kino powder, till the blood in the evacuations became very small in quantity, and pus had made its appearance. I should then give astringents in the ordinary medicinal doses, continuing each for two days only, till the patient was well. If I had a case of the second type of the disease, I should give ipecacuanha in small doses tentatively; and if it caused sickness, I should try quinine and astringents, to satisfy my conscience; I should give all the liquid nourishment and stimulants I could get the patient to take, believing that if he had any chance of recovery they would enable him to have it; but I should give the patient up as incurable from the first.

Pathology.—The morbid appearances found after death are the most distinctive and interesting features of the disease. Of the twenty cases who died, I performed post-mortem examinations in sixteen. Some of the cases were in the very first stage, while others were in all the intermediate stages, and in one case I saw the state of the intestine after it had healed; but perhaps I had better describe a typical case first, and afterwards mention the varieties. In such a case all the abdominal organs would be found healthy until the small intestine was examined. This, too, would be normal up to within five or six feet of the cæcum. The mucous membrane would then begin to appear reddened in small spots or rings round the gut. Six inches further down, the redness would be universal, and the membrane would begin to be thickened and corrugated into folds like small valvulæ conniventes. A few inches further down, a yellowish, dirty-looking deposit would be seen over the mucous membrane in rings, very thin where it began, but gradually becoming thicker and more continuous till, near the cæcum, it would be one-eighth of an inch in thickness. The swelling of the mucous membrane would also increase downwards, and the artificial folds running across the gut become more prominent. These, with their coating of deposit, made the inside of the bowel look like a series of thick transverse ridges covering its entire surface. This deposit when examined would be found to be soft on the surface, but getting more firm towards the mucous membrane, with which it incorporated itself, so that it could not be scraped off without leaving the fibrous covering of the muscular coat exposed, as a highly vascular, raw-looking surface. This deposit though on the surface a soft lymphy-looking substance, yet towards the mucous membrane it assumed quite the consistency and appearance of a soft fibrous membrane. The cæcum when examined in such a case would be found in the same state as the lower part of the small intestines, with two or three ragged ulcerations the size of beans; in the ascending

colon the ulcerations became deeper and larger, while the lymphy deposit on the surface of the mucous membrane became thicker and more fæculent in colour. Towards the transverse colon the inside of the gut was one mass of large irregular ulcers, with patches of the deposit between them. The colour of the whole surface was almost black, and this continued down to the very lower part of the rectum.

The mesenteric glands opposite the affected parts of the small and large intestine were enlarged and dark coloured, and on section were soft, and pulpy in consistency.

Such were the external appearances in a case that had lasted for about a month. On examination of the fibrinous layer by the microscope, in the fresh state, it was found to consist of nucleated cells like pus cells, fusiform cells with nucleus, and a fibrinous material between. When a small portion of the gut was hardened in absolute alcohol or dilute chromic acid, and thin sections made of the gut transversely, showing all the coats, the peritoneal coat was seen to be normal, the muscular coat also normal, except that part of it in proximity to the mucous membrane, which was more than usually vascular. In the fibrous and mucous coat the bloodvessels were enlarged and very tortuous, and on the free surface of the mucous membrane between the villi they could be seen torn and open-mouthed. The villi were enlarged, stripped of their epithelium, and lying in contact with them and dipping in between them were the fusiform and round nucleated cells. The fusiform cells predominated near the villi. Minute fibres radiated from the villi through the layer of lymphy substance, branching out and losing themselves at the free surface. Those fibres seemed to bind together the cells, and when a section through the deposit was made on the same plane as the surface of the mucous membrane, an areolar appearance was seen, the meshes being filled up with cells.

One woman died after two days' illness, and after death the solitary glands in the last part of the small intestine were found enlarged. Peyer's patches were quite unaffected; in the cæcum the mucous membrane was reddened and thickened in small patches running into each other, like the eruption on the skin in measles. In the transverse colon the whole mucous membrane was mottled and thickened. In the descending colon and rectum the mucous membrane was less diseased. In the rectum the mottling was mixed with small red points like pins' heads. There was no trace of ulceration anywhere. In this case there had been copious bloody evacuations. The torn capillaries, even where there was no actual ulceration, would of course account for the bleeding. There was no membranous deposit.

In a case which had died in five days from the commencement of the disease the mucous membrane of the small intestine was for six feet above the cæcum reddened, thickened, and thrown up like valvulæ conniventes, with a little deposit on them. The mucous membrane of the large intestine was completely covered with a thick layer of the yellowish lymphy matter described.

In another case that died a week after the commencement of the disease, the small and large intestines were affected as in the last case, but the rectum was more affected, and looked as if the small blood-vessels were hanging loose in the fibrinous deposit. In a case that died eight days after the commencement of the disease, ulceration was commencing in the cæcum and sloughing in the colon. The description of the typical case may be taken as the next stage of the disease. In a very severe case which had lasted six weeks the whole of the large intestine was of a dark colour externally, but not rough, and no effusion on the peritoneum. The interior was a raw, irregular, black surface; the walls were very much thickened, the muscular coat being thickened too, with inflammatory products, and the gut was so friable that almost the least current of water tore it up. In the rectum, blood clots projected from the open mouths of arteries.

Then the healing process was seen in the case of a man who was recovering slowly from the dysentery when he was carried off by pleurisy. In this case the small intestine was normal; but in the cæcum there were small dark-coloured depressed patches, with puckered margins. In the rectum there were healthy granulating ulcerations of a dark colour.

This series of dissections taken along with the symptoms during life enable us to follow the course of the disease as well as if the inside of the gut had been visible. First, we have inflammation of the mucous membrane of the intestine, commencing in the solitary glands of the ileum, and immediately spreading all over it. In the large intestine it commences all over the surface, not selecting any special element of the membrane. Had it not been for one or two cases, in which the solitary glands of the small intestine were affected first, I should not in any of the other cases have been able to say which element of the membrane was first affected. Then we have the inflammation, immediately followed by a lymphy deposit on the membrane. Then we have the ulceration commencing in the small intestines in the solitary glands, not as pustules at first, as some writers affirm always happens in dysentery. In the large intestines the ulceration tends to commence by portions of the membrane sloughing. The capillary vessels all over the inflamed surface from the beginning seem to lose their tone, and many of them to rupture. The contact of the poison as it is being eliminated seems to paralyse them, while it stimulates the nervous ganglia contained in the intestinal walls, causing continuous action of the bowel of a very severe kind. In the cases which recovered we have the fibrinous membrane thrown off in large shreds, as seen in the evacuations, and then we have a granulating healthy sore, which discharges pus till it heals. I cannot account for the tendency to blackening of the surface of the membrane in all the cases.

In some cases the progress of the disease was much more rapid than those I have mentioned. In one case I found the whole of the mucous membrane of the large intestine in a sloughy state after five days' illness. In two cases the small intestines were affected as far up as the junction of the jejunum and the ileum. In two cases there were ecchymosed spots on the mucous membrane of the stomach, and two other cases in which the membrane of the stomach was inflamed and thickened like that of the small intestine. In three cases the small intestine was healthy in appearance, but one of those was the case that was recovering, and died of pleurisy. Another was a case that died of abscess of the liver, after the disease of the bowel had showed signs of improvement, and the third died in a few days from the commencement of the disease. In the first two cases I have no doubt it had passed off, and in the third, contrary to the usual state of things, the larger intestine had become affected first, and the patient being weak, died before the ileum was affected by the disease. The case I have just mentioned, in which there was abscess of the liver, was the only one with this lesion, and it may have been the result either of the dysentery or of the total obstruction of the common bile duct by a large gall-stone which existed.

The pathological appearances I have here recorded are very rarely to be met with, and I have only been able to discover three recorded outbreaks of dysentery, in which they were at all similar. The one was the epidemic of dysentery that was so fatal to the British troops in the famous Walcheren expedition. Some of the cases recorded by Dr. Davis bear a close resemblance to the cases I have described. In an epidemic of dysentery which occurred at Prague, Dr. Finger records somewhat similar pathological appearances. In two of his 231 cases the jejunum and ileum were affected, and not the large intestine, and these he calls intestinal catarrh. He examined the exudation in his cases by the microscope, and found its structure to be somewhat the same as I have described in my cases. Dr. Mayne found in an epidemic which occurred at Dublin that the most rapidly fatal cases had an exudation on the surface of the mucous membrane, which could be easily scraped off. I had met with three similar cases previously, one in the Edinburgh Infirmary and two in the Royal Edinburgh Asylum.

In no case did I notice the pustular appearance of the glands noticed by so many writers, and I think the record of the pathological appearances and causes of the disease prove that Dr. Baly came to a conclusion from too limited experience when he said that all the forms of dysentery described by systematic writers are merely different stages of the same disease, and that the specific virus which he considered was always the cause of it was always derived from the soil. In its pathological appearances the dysentery I have described bears a much greater resemblance to that form of the disease caused by or connected with malaria than to tropical dysentery. The small intestine is sometimes affected in dysentery that has a malarious origin; but never in dysentery from other causes. But in no epidemic of dysentery of which I have ever read was there a tendency in all the cases to disease of the small intestine. The poison did not cause its effects at once, while it seemed to have no regular period of incubation, like the continued fevers, and unlike most of them it was unaccompanied by a skin eruption. In these respects it resembled malaria. The dysentery resembled ague, too, in

having no fixed period of termination; but then it resembled typhoid fever in being accompanied by a specific lesion of the lower part of the intestinal mucous membrane.

The whole of the facts I have stated, and the inferences from these facts, may be thus briefly summed up:—

1. An epidemic of dysentery of a very fatal character occurred in the Cumberland and Westmoreland Asylum in the years 1864-65.

2. All the positive evidence that can usually be produced to determine the cause of any disease can be produced to connect this epidemic of dysentery with exhalations from a field irrigated by sewage, as effect and cause. Ample negative evidence can be produced to show that no other probable cause of such an epidemic was in operation.

3. The old, weak, paralysed, and diseased patients were chiefly attacked, but it was not confined to them.

4. The majority of the patients attacked were inmates of the wards on the ground floor of the asylum, showing that the sewage effluvia is most concentrated near the ground. Little or no wind and a high barometrical pressure would seem to be the most favourable conditions for the injurious effects of the poison to manifest themselves.

5. It would seem to be unsafe to apply sewage in any form to land with a stiff clay subsoil within 350 yards of human habitations.

6. Diarrhœa in its ordinary form may also be caused by sewage exhalations.

7. There are strong reasons for believing that the sewage effluvia which caused dysentery and diarrhœa in some persons may have caused typhoid fever in others.

8. The sewage poison had a period of incubation in most cases before the dysentery appeared. The length of this period was probably from three to five days.

9. The dysentery was of a very fatal character, and the ipecacuanha treatment, so successful in tropical dysentery, was not so in this epidemic.

10. The two morbid appearances most characteristic of this epidemic were, 1st, a soft membranous deposit on the mucous membrane of the intestines; and 2nd, the diseased condition of the lower part of the small as well as the large intestine in all the cases.

11. The poison which caused the dysentery seemed to occupy an intermediate position between the poison which causes the continued fevers, and that which produces ague and its concomitants.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

KING'S COLLEGE HOSPITAL.

REMOVAL OF A PORTION OF THE SUPERIOR MAXILLA FOR A FIBROUS TUMOUR OF THE ANTRUM—RECOVERY—CLINICAL REMARKS.

(Under the care of Mr. FERGUSSON.)

Mr. Fergusson in some clinical remarks made after the operation, called attention to the peculiar modification of the ordinary procedure in such cases which he had adopted in the present instance. Instead of dealing so largely with the side of the face as is sometimes done, he left the principal part of the superior maxilla, and said that in the generality of instances there was no need for the removal of the whole of it, but to get at once to the circumference of the disease, and then to clip it away piecemeal, and thus make room for the introduction of the necessary instruments. By dividing the integuments in the mesial line, along the ala of the nose and below the eye—the appearance of the face is less interfered with; also by this method the vessels are divided in their narrowest part; again, the roof of the mouth is preserved entire, the upper diseased part of the antrum only being removed, leaving its floor intact.

Emily M., aged 38, single, healthy. Admitted May 11th into King's College Hospital with a tumour of fibrous character in the antrum. Stated that she had suffered from nasal polypus on two occasions, affecting the left nostril. These were removed by Mr. Fergusson, one twelve and the other two months ago. A few weeks before the removal of the last polypus she noticed a swelling in her cheek, about the size of a pea, and situated about half an inch below the inner canthus of the left eyelid, and of bony hardness. The swelling increased slowly at first, but after the removal of the polypus its growth was rapid; much pain of a severe gnawing character was felt, and much tenderness on pressure of the tumour. The left nostril has become almost completely obstructed since the rapid growth of the tumour. On admission, no cachectic appearance; on the left side of the face there was a swelling immediately below the inner half of the lower eyelid filling up the groove between the base of the nose and the contiguous part of the face, and extending downwards for an inch and a-half. The skin over the swelling was of a deeper red than elsewhere, and the superficial veins of the eyelids congested. The swelling was not of uniform hardness, being firm near the angle of the eye, but softer at its outer part. The skin was not freely moveable over the tumour. The left eyeball considerably pushed up above the level of that on the opposite side. The left nasal fossa appeared blocked up by the protrusion of its outer wall, but no swelling could be detected within the mouth, nor was there any irregularity of the alveolar ridge of the jaw, and the finger passed above the soft palate detected nothing abnormal.

10th.—The removal of the diseased portion of the superior maxilla was performed (under chloroform) as follows:—The upper lip was transfixed by a small scalpel in the mesial line from above downwards; the incision was then extended upwards and outwards into the left nostril, the superior coronary arteries being compressed by an assistant. The knife was then carried vertically downwards from the side of the root of the nose to join the first incision, passing in the groove behind the ala. A third incision was then made transversely from the upper extremity of the vertical wound, along the lower margin of the orbit. The flap thus marked out was raised and reflected outwards. The hæmorrhage was considerable at first, but speedily ceased. By the use of Hey's saw and the cutting forceps, the tumour was detached from its connexions, the upper, inner, and front part of the superior maxilla being removed with portions of the malar and superior turbinated bones, some careful dissection being necessary in detaching the bony margin and part of the floor of the orbit from the soft parts, the diseased bone being wrenched away with the "lion forceps." The cut margins of the soft parts were brought together, two harelip-pins were passed through the upper lip and one at the side of the nose, another opposite the inner canthus, and the last below and external to the lower margin of the orbit. Water dressings applied, and the patient removed to bed.

15th.—Slept well; suffered but little pain; wound looking very healthy. The whole length of the incisions united by first intention.

17th.—Severe pain in orbit last night: slight delirium; an opiate draught administered. The patient comparatively free from pain this morning. Much discharge escapes into the mouth by the left posterior opening of the nose. Pulse good; bowels open; skin moist.

18th.—Hare-lip pins removed.

19th.—Much pain in left temple. Eyelids swollen, and some chemosis.

22nd.—Scab separated from upper lip, showing margin of wound perfectly united. Chemosis quite subsided. The eyeball can be freely moved in any direction without pain. Complains of double vision.

25th.—The wound was completely united; very little discharge; the cheek has sunk very little, and there is very little deformity. Can masticate fairly well.

June 2.—Patient is still in the Hospital, and is convalescent.

For the notes of this case we are indebted to Mr. Paris Bradshawe, the dresser of the patient.

WINDSOR ROYAL INFIRMARY.

CASE OF TRISMUS—DEATH—AUTOPSY.

(Under the care of Dr. ELLISON.)

This case is one which shows how purely empirical our treatment of tetanus is. And so it must remain until we know more of the physiology of the disease. It must be kept in mind that a superficial examination of the cord or medulla is frequently not enough to enable us to discover changes in the cord. To detect the position of slight changes, Mr. Lockhart Clarke's plan should be adopted. The examination of nerve-structure in this elaborate way, however, requires more time than most Medical men in practice can give to it. Mr. Lock-

hart Clarke is now working at the pathology of this disease, and will be glad to examine the spinal cord and medulla oblongata from any case of tetanus. The cyst found in the spinal canal in the first case was probably the cause of the paraplegia, which the man had had many years. Yet it may be well to raise the question, whether a diseased condition of the cord may not render a patient liable to suffer from a slighter exciting cause than would affect a healthy man?

For the notes of these two interesting cases we are indebted to Mr. Brickwell.

Samuel L., aged 59, a gardener, was brought to the Infirmary on January 12, and admitted an in-patient, suffering from locked jaw. On Monday, December 26, he was driving along the road, and was pitched out of the cart in which he was riding, and received a slight cut on the forehead between the eyebrows, and having his left arm and leg contused. He was conveyed to a public-house in a somewhat fainting condition, and had some brandy-and-water given to him. He recovered sufficiently from his syncope to be brought to Windsor in the evening in a close fly, and, being seen by the House-Surgeon, had simple dressing applied to a small cut on his forehead, and was sent home to his lodgings, his injuries appearing to be of an unimportant character. He complained a good deal of headache and pain in his back, chiefly referred to the lumbar region.

On Saturday, December 31, he was very much better, and apparently recovering.

On Sunday, January 1, after eating a good dinner, he complained of stiffness in his jaws, and thought he was going to have the mumps. He had hot poultices applied to relieve the pain, without producing that effect, and found himself unable to take any supper on account of the stiffness of his jaw.

2nd, Monday.—He was worse. Has slept badly in the night; has more pain and stiffness in the muscles of mastication.

He was visited by the House-Surgeon on the 3rd, and at that time his jaws were found to be closed so much that the handle of a spoon could with difficulty be passed between his toothless gums. He has great difficulty in swallowing, much pain attending the act, breathing with difficulty. Opium one grain, calomel three grains, directly; blister to the nape of neck. Tr. Cannabis Indicæ, ʒiij.; Sp. Æth. S.C. ʒiij.; mist. camph., ʒviij. One ounce every four hours. In the evening he was ordered a drop of croton oil to be made into a pill with some soap, and if this did not act he was to have an enema administered. As the pill acted freely the enema was not administered. He was not seen again by the House-Surgeon till his admission on January 12, having preferred to be attended as a private patient.

12th.—Has been paralysed in his lower limbs for fourteen years, but has been able to get about and follow his occupation; had severe eczema of the legs last summer. Lips tightly compressed; keeps the fore and middle fingers of his right hand between them, in order to clear his mouth of viscid mucus which accumulates freely in the bronchi and trachea, causing a fearful sense of suffocation. Is obliged to be propped up in bed in an almost upright position; masseter muscles very hard and rigid; muscles of the submaxillary region also tense and hard; there is the smallest possible opening between the gums of the upper and lower jaws, through which he introduces the nozzle of a feeding-basin, and takes with the utmost difficulty about half a teaspoonful of liquid at a time. His power of suction appears to be abolished, and, after taking two or three gulps at the fluid, he has a severe attack of spasmodic breathing, accompanied by a violent expulsive cough, with an apparently spasmodic closure of the glottis. 3 p.m.—Commenced the administration of chloroform vapour, which was continued till one ounce had been consumed. This was done for the purpose of relaxing the muscles of the lower jaw, and to introduce an œsophagus-tube, but the slightest touch of the lower jaw caused him intense pain, brought him to a state of consciousness, and produced violent contraction of the muscles of the neck and lower jaw. An attempt to introduce a gag entirely failed. An enema of oatmeal was administered, which returned almost immediately, bringing away a small quantity of fæces. 5 p.m.—Tinct. opii, ʒj.; wine, ʒj. every hour, if he can swallow it; tinct. aconiti (Fleming's), miij. every two hours.

13th.—Slept a little in the night, but has been very restless, and had repeated suffocative attacks towards morning; still keeps his fingers between his lips, to allow the air to pass more freely; is unable to articulate, and writes down all communications. 3 p.m.—Eighteen drachms of chloroform vapour on lint were administered, commencing with twenty minims, at the end of which time he was sufficiently sensible to request the continued administration of it, as it produced a feeling of comparative ease, and caused a slight relaxation of the muscles. An endeavour was again made to fix his jaw open with a gag without success. Dr. Ellison saw him this evening, and recommended the subcutaneous injection of one grain of acetate of morphia over the masseter muscle of the right side. This was done without any apparent effect. To take tinct. opii, ʒj. at bed-time. The galvanic battery was applied without any result either for good or harm. The attempt to apply a hot flannel to his throat produced the most violent spasmodic action of the muscles. There is no hardness or tension of the muscles of the abdomen or thighs.

14th.—Writes that he feels no better, that he must die, that it is so much exertion and trouble to swallow, that he will not attempt anything more, and implores to be let alone. An attempt was made to get him to swallow beef-tea through straws, but the attempt to swallow was followed by violent convulsive action of the muscles of the throat. Vespere.—Sweating profusely; face livid; breathing hurried, spasmodic, and accompanied by much noisy rhonchus. He died struggling at 4 a.m. on the 15th.

A post-mortem examination revealed no important disease of the brain, but in the lumbar region of the spinal cord was found a cyst about as large as a hazel nut, and the cord appeared softened in consistence about the middle of the dorsal region.

WOUND OF FOREARM (LEFT) BY DISCHARGE OF POWDER IN A PISTOL—TETANUS—DEATH.

(Under the care of Dr. ELLISON.)

Ernest M., aged 14, page boy. This boy was brought to the Infirmary on May 3, 1865, at 7.30 p.m., with the symptoms of tetanus well marked. On Easter Monday, April 17, he was amusing himself with discharging powder from a pistol, when, by some accidental means, it exploded suddenly, producing a severe wound in the middle of the left forearm, on its inner aspect. Being servant to a Medical man, the wound was dressed, and appeared to be going on favourably (a large slough having separated from it, leaving a healthy granulating wound) till the morning of May 2, when he complained of feeling a stiffness about his lower jaw, preventing him from eating his breakfast; at the same time he said that his arm twitched very much, and the fingers were drawn up.

He is a light-haired, fair-complexioned lad, of nervous temperament; his face is flushed and covered with beads of perspiration; skin generally sweating; angles of mouth retracted; the skin round the wound of a peculiar white pearly colour. Passed a very restless night, on account of spasmodic action, which he terms "twitching of the skin." Has vomited frequently during the day. Has no headache or pain in his body, but complains very much of his arm aching. Has no appetite. Bowels have acted freely twice this evening, the effect of aperient medicine given him before he arrived at the Infirmary. The index and middle fingers of the left hand are firmly contracted and bent in towards the palm. The jaw is rigid, and open only to the extent of half-an-inch. He articulates clearly when free from spasms. The muscles of the neck are not continually rigid, but thrown out in bold relief when he has a spasm; the masseter appears firm and hard, the muscles of abdomen and thighs are thrown into violent action, and his body becomes so universally rigid that he may be lifted up like a piece of board. 11 p.m.—Tr. aconiti, P.L., miv., every two hours; port wine, one ounce, every three hours; beef-tea, one pint. He was allowed to inhale chloroform vapour, three drachms being administered, in quantities of half-a-drachm at a time, on lint, to the great alleviation of his distress. 12 p.m.—Tr. opii, ʒj.; sp. eth. S.C., mxv.; aqua, ʒj., statim.

May 4, 6 a.m.—Has passed a very restless night; slept somewhat between 4 and 6 a.m., but has had frequent and violent spasms. Has taken his wine and beef-tea, and has passed urine. To continue the aconite every two hours. 12 midday.—Administered chloroform till anæsthesia was produced. 2 p.m.—Tr. opii, ʒij.; aqua, ʒjss. Chloroform again administered. 10 p.m.—Has slept a good deal, and is evidently under the influence of opium; the pupils are contracted; the breathing deep and slow; the spasmodic action of the muscles continues, rousing him up and causing him to scream with agony. Pulse small, regular, feeble; skin sweating. To intermit the aconite. Has passed a good dea of flatus from the bowels, but no fæces. Has had a great deal

of borborygmus. Has passed urine. Has taken beef-tea a pint and a-half, and two and a-half pints of milk, half-an-ounce of brandy, and three ounces of wine. Chloroform vapour was again administered.

5th.—6 a.m.—Has passed a terribly restless night; has been in constant agitation, wanting to get up and dress himself, and to go home. The spasmodic action of the muscular system has been constant, exceedingly violent, and universal, producing opisthotonos; facies Hippocratica painfully marked; teeth clenched, and any attempt at swallowing liquids appears to choke him, and brings on convulsions; face and body covered with a profuse perspiration of a very unpleasant odour; has passed urine and a good deal of flatus. The inhalation of chloroform vapour was commenced and continued till complete anæsthesia was produced; the breathing became regular and natural; this condition was kept up till 11 a.m.—a period of five hours—by the careful administration of chloroform whenever he appeared to be returning to consciousness, and with this to convulsions. From 11 a.m. ceased to administer the chloroform, and at 12.10 he died rather suddenly, being conscious to the last, and asking for more chloroform, which was withheld on account of the feebleness of the pulse.

6th.—*Post-mortem Examination Twenty-four hours after Death.*—Muscular rigidity well marked; a healthy-looking wound about the junction of middle with lower third of left forearm, of an exact crucial form, extending deeply down into the muscles; surface of skin around the wound slightly ulcerated as from a burn. The scalp was first removed, and an incision made down the whole length of the vertebral column; the scalp was not unusually adherent; there was no great escape of blood on incision; there was considerable congestion of the skin of the back, and a great deal of fluid blood escaped from the line of incision afterwards. Dura mater was very adherent to the calvarium, and on removing it a considerable quantity of fluid blood escaped. The substance of the brain was firm, and a great number of bloody points appeared on section; no unusual smell, and, with the exception of this evidence of congestion, no morbid appearance was discoverable to the eye or touch in any part of the brain or spinal cord.

Medical Times and Gazette.

SATURDAY, JUNE 10.

METROPOLITAN WORKHOUSE HOSPITALS.

A most important and interesting return has just been presented to Parliament by the President of the Poor-law Board, describing the present condition of these Hospitals, and giving special details as to the quantity and quality of the accommodation provided for the sick, the cubic contents of the wards, the number of beds they contain, the nature of the disorders admitted, the proportion of aged and infirm persons in the body of the workhouses, the particulars of the nursing, and various other sanitary details of the highest import to the efficiency of the treatment. It appears that there are in the metropolitan district 41 workhouses, in which are 515 sick wards, containing 6519 beds. On the night of January 28, 1865, accurate returns were made from 35 workhouses of the persons sleeping in the Hospitals, and we observe that in 10 of these the male wards were quite full; in 3, 10 more patients were accommodated than there were beds, and in 13 others less than 10 beds were vacant in each Hospital. Twenty-six Hospitals for males may therefore be described as quite full. For females, the general accommodation is much greater; nevertheless, 7 Hospitals were full, and in one 5 persons must have slept on the floor,—a practice, we have reason to believe, which is not unfrequently adopted in order to provide the accommodation required. In 16 female Hospitals there were less than 10 vacant beds in each, so that 24 of these also may be regarded as fully occupied.

Taking the male and female Hospitals together, we find that an average of 25 out of 35 were quite full. The remainder had 553 vacant beds, but of these the majority were to be found at two or three workhouses, as at St. Leonard's, Shoreditch, where 154 beds were unoccupied.

Now, considering that the returns show as many as 6549 aged and infirm inmates who reside out of Hospital, but require occasional Medical care, and that, besides these, a considerable number of sick are now treated out of Hospital for want of room, it must certainly be concluded that the Hospital accommodation is less than what is required. There must necessarily be great fluctuations in the demand for Hospital space; every one ought, therefore, to be provided with at least 20 per cent. of vacant beds to meet those fluctuations, and the occurrence of epidemics, to which such communities are especially liable.

The character of the accommodation is next alluded to. The cubic space of 461 wards is accurately given, and we find that 4 have less than 300 cubic feet allotted to each bed; 29 have less than 400 cubic feet; 152 less than 500 c. feet; 165 less than 600 c. ft.; 67 less than 700 c. ft.; 33 less than 800 c. ft.; and only 11 more than that quantity; some of these last being only partly furnished. Now, the regulation of the Poor-law Board provides that every Hospital bed shall have allotted to it not less than 500 c. ft. of space; so that in 185 wards this rule is violated, which fact alone should show the necessity of Medical supervision. But it is simply impossible to cure disease in Hospitals thus crowded. The army regulations insist that at least 1200 c. ft. be allotted to each bed. In the public charities it is found impossible to preserve the purity of the wards with a less space than 1300 to 1500 c. ft. At King's College and several other Hospitals 1700 c. ft. is allowed to each bed, and 2000 c. ft. are considered essential for the successful treatment of zymotic disease. If Medical science possesses one established fact, it is that the first condition and most important remedy in the treatment of disease is abundant space and an unlimited supply of wholesome air. What, then, shall we say of Hospitals which have a less average space per bed than barrack sleeping rooms, which besides being thoroughly ventilated are occupied only by healthy persons during the night. The emanations of the sick are most poisonous and depressing, and in addition to a sufficient space there ought to be a change of air equal to at least 3000 cubic feet per hour for each patient. In several Hospitals under notice the ventilation is reported as imperfect; it may be doubted if it can ever be otherwise where the wards are so confined for room, and so fully occupied. Without space and ventilation, food nursing and Medical skill will be employed in vain, and we sincerely hope that steps will be immediately taken to remedy this gigantic evil.

The character of the diseases admitted into the workhouse Hospitals is essentially chronic. There is, however, a certain proportion of acute disease. Fever is in many cases sent away to the Fever Hospital, but we have 224 cases reported as under treatment, and it would be interesting to know the proportion of space allotted to each case. There were 1514 cases of acute disease, or more probably of cases which present probability of eventual cure, whilst 4655 are reported as chronic; and we have, in addition, the 6549 aged and infirm before alluded to, very many of whom would be proper occupants of the Hospital wards. We shall form some conception as to the

mass of sickness and infirmity concentrated in our metropolitan workhouses by consulting a report ordered by G. Lyall, Esq., M.P., in February last. In this we find that in the forty-one metropolitan workhouses there were 520 able-bodied men and 1673 able-bodied women, many of the latter being accompanied by illegitimate children. This number forms only 13 per cent. of the workhouse inmates, the remainder being made up of sick, aged, incurable, insane, and children; so that the able-bodied, who are, for the most part, idle, vicious, and good-for-nothing, are scarcely sufficient to wash the linen, clean the wards, watch the children, and perform the household duties, of which the rest are incapable.

Now, with these facts before us, let us observe the nature and character of the nursing provided for the sick. In the first place, we find that in thirteen workhouses there is not a single paid nurse. The sick are committed to the exclusive care of paupers, with only such supervision as the matron and Surgeon can most imperfectly exercise. In sixteen workhouses there is one paid nurse in each, and, deducting St. Pancras and Marylebone, which together employ thirty paid nurses, we find only forty-one such persons in thirty-nine workhouses. There are 859 paupers employed as nurses, and they receive only extra diet or clothing as the reward of their service. From what has been already stated, it is not difficult to surmise that they are for the most part aged and infirm themselves, or otherwise physically unfit for the arduous duties imposed upon them. To give an example: at St. Margaret's, Westminster, the Hospitals contain 280 beds, and the number of sick in March last was 245. There are three paid nurses and eleven paupers, six of whom are over 70 years of age, and only one under 50. We have here, therefore, one paid nurse to take charge of ninety-three beds, or, including the paupers, we have one attendant on twenty beds. Contrast this with any public charity, and we shall find that a staff of at least forty strong and able nurses would be employed to perform the same duty. These, moreover, would be assisted by scourers, who attend to the cleanliness of the floors and the state of the firegrates.

We cannot conclude our observations on this subject without noticing the evident desire on the part of the workhouse officials to present the most favourable aspect of things in the report before us. Persons are returned as paid nurses who are, in fact, assistant-matrons, having but little, if anything, to do with the management of the sick. At the Strand Union the Hospital contains but forty beds, to which are assigned, according to the Report, twenty-two nurses and twenty-two assistants; yet when we discover that this amount of Hospital room is all that is provided for 196 sick and 417 aged and infirm, to say nothing of the children, and that none of the nurses are paid, we may justly infer that the accommodation is insufficient and the administration bad.

Our necessary limits will not permit us to extend our observations further. More than enough has been gathered to show the urgent need of the inspection we have advocated; and we trust that no time will be lost by the Poor-law Board in providing a remedy for so great a blot in our social system.

SEWAGE DIFFICULTIES.

Until the Main Drainage of London upon the present wasteful and unscientific plan was accomplished, and until the engineers and contractors received the reward and honours due to the completion of their gigantic brickwork tunnels and reservoirs, the personages who pull the strings of the daily press sneered at all ideas of applying sewage to the land. It was pooh-poohed as a visionary and chimerical scheme, and the sewage was said to be of no value. Now that the engineering interests are safe, the public are allowed to believe that sewage has some value; and the next thing they will be enlightened upon will be the fact that the greatest obstacle to the utilisation of the London sewage will be the too costly and unscientific character of the Metropolitan Main Drainage Works.

The first essential for the safe utilisation of sewage is that the land shall be capable of absorbing it, and of allowing surplus water to filter steadily away. It does not suffice that the sewage run over the surface—it must run through a certain depth, and soak clean away; it must not form pools on an impervious surface, nor yet, if it soak through sand, must it find hollows in a clay substratum, where it can lodge and form subterranean quagmires. The best land is a rich black mould; the next, sand or gravel; the worst, clay, unless thoroughly well prepared. Some eminent authorities distrust sand, at least unless covered with an actively growing crop. In fact, there would seem to be considerable danger in allowing the sands on a barren seacoast to become impregnated with sewage.

The next point is, the preparation of the sewage itself. Common decency, as well as the danger of parasitic disease, point to the fact that liquid sewage should be filtered, so as to deprive it of solid matter likely to lodge and fester on the surface. Mr. Menzies, whose work on Sewage deserves attention because he knows and does, from end to end, what others only know or do piecemeal, gives full directions and reasons for this step of the process. He uses a system of upward filtration, which, by the bye, was first designed by a man whose genius was never recognised till too late— the late Prince Consort. Not to speak of other advantages, the filtered sewage does not clog the pipes by which it is distributed. The sewage in the filtering tanks may be deodorised by carbolic acid or some other preparation of gas-tar, if it should be thought expedient.

The next point is, that there should be an adequate water supply, to carry the sewage from the closets to the outlet or filtering tanks. In the sewage squabble to which we referred at Bournemouth, it is said that the theoretical party, including, we fear, some members of our Profession, clamoured for a drainage system before there was a water supply! Now, any sewer-pipe or brick which is not self-cleansing is but an elongated cesspool; and it were far better to have one such place occupying a few square feet in a garden than one elongated foul pipe poisoning the air along a mile of road.

In the next place, we must observe that all experience points to the truth of F. O. Ward's alliterative axiom—"The rainfall to the river and the sewage to the soil." Mr. Menzies, who, like many others, ventures to write upon a subject without knowing what others have written before him, does scanty justice to one of the greatest geniuses of our age—for such we pronounce F. O. Ward to be—by his omission of his name. Every page in Mr. Menzies' book is an unconscious tribute to the truth of those principles which ten or fifteen years ago Mr. Ward in vain endeavoured to drive into the ears of the Metropolitan Sewage Commissioners. For health as well as for agriculture—for the sake of our fields no less than of our rivers—the sewage ought to be kept separate from the rainfall. The sewage flow in a day is constant and calculable; pipes may be accommodated to the quantity, so that the regular flow, with an occasional flush from a cistern, may keep them clean. The rainfall is most inconsistent and uncalculable. Perhaps a storm may bring down one-twentieth part of the year's supply in one day. If the sewage pipes are to be large enough to carry off storms, they are too large to be cleansed by the regular daily flow. If not large enough, there must be the clumsy expedient of storm overflows, as in the London system, which permits the river to be polluted. This admixture makes the sewage weakest when it should be strongest, for strong sewage should be applied during heavy rains. Moreover, it enhances all the expense of conduits, tanks, and pumping engines, and embodies the absurdity of most expensive works for dealing with rain water mixed with sewage, instead of allowing it quietly to run into the

river. London is done for. Every drop of rain that falls henceforth will be lifted by a steam pump, and carried down to vilify the sewage. Other towns, blessed with no such Board of Works, may take warning, and save the expense of useless works, whilst they get rid of a sewage which the farmers will be glad to take in all weathers.(a)

MODERN DERMATOLOGY.—No. VI.

Such of our readers as are unacquainted with recent works on diseases of the skin have probably been somewhat surprised at the confidence with which we have written of treating chronic eczema and lepra with success, at the small number of remedies mentioned, and at the simplicity of the treatment recommended. It has not been intended in these papers to note very fully or in much detail the modern practice in the treatment of skin diseases, nor to sketch even in outline anything like the whole of it, but only to point out in what way it especially and chiefly differs from the older practice, to show in what direction and on what points the greatest improvement has been effected. But it is in the simplification and certainty of treatment that modern dermato-pathology has made the most marked advance; as it has become more scientific, so has it improved as an art, using fewer means, and handling them with greater precision and success. And we have dwelt at some length on eczema and lepra, because of all the non-contagious diseases of the skin they perhaps show the greatest improvement in treatment.

The justifiable confidence with which modern dermatologists undertake their cure is very remarkable, when compared with the hopelessness of the tone in which they were written about some twenty years ago; palliation of the symptoms was almost all that was expected; a cure was to be rarely looked for, at least from Medical treatment; hope was placed in "change of constitution," in dentition, in puberty, etc., rather than in drugs or external applications. And at the same time, and almost as a consequence, the "remedies" recommended were bewilderingly numerous. Now, on the contrary, the skilful and experienced Physician may very generally confidently expect to really cure these maladies; and his means for doing so are few and simple.

These characters of the modern treatment of cutaneous diseases—simplicity and assurance of treatment—are very well shown in Dr. Balmanno Squire's work, "Photographs of the Diseases of the Skin." We recommend them especially to all students, be they old or young, graduates or undergraduates, who may be entering on the study of this branch of Medicine. Each photograph represents "one of the great classes of cutaneous disease," and is accompanied by a description of its symptoms, pathology, and treatment. This is short always, and very simple, but graphic, clear, and good. To those acquainted with the literature of cutaneous diseases, his directions for treatment may appear meagre and rather dogmatic; but they are sound and eminently practical, conveying the results of the writer's individual, and not slight, experience, and will never mislead. The illustrations are admirable; they are by far the best and most truthful representations of skin disease we have seen, and are, to our thinking, much to be preferred to the Sydenham Society's reproductions of Hebra's plates, which are of very inconvenient size, and are sometimes exaggerated to the verge of caricature. Dr. Balmanno Squire's illustration of psoriasis is very good. For treatment he recommends "arsenic, either alone or in combination with other remedies—such as quinine, iron, mercury, etc.;" and externally, tarry preparations, the huile de cade, creosote, and the like. Mr. Milton says—"If I were to rely exclusively on my own experience, I should say that time was lost in trying any remedy but arsenic, or any preparatory treatment for the arsenic, which should be begun with at once, and taken in the largest doses the patient can bear."

It has been seen that arsenic is very generally held to be the only trustworthy remedy in lepra or alphos, and that it is largely relied on in the treatment of chronic eczema. It is also very generally employed in many other cutaneous diseases, as chronic lichen, impetigo, prurigo, acne, inveterate urticaria, in some forms of ichthyosis, and in lupus exedens. Many of these disorders have been only lately rescued from the class of incurable maladies, and this chiefly through the determined and skilful use of arsenic. Among the labourers who have most contributed to this improvement Mr. Hunt takes a very prominent rank. In the preface to the first edition of his most useful little work on "Diseases of the Skin," published in 1847, he observes that "our knowledge of the treatment of the more intractable forms of cutaneous disease has not kept pace with the advancing pathology of the times," and that, "if an unfortunate patient is suffering under confirmed lepra, psoriasis, prurigo, lupus, or any other severe chronic cutaneous disease, there appears but little chance, under any treatment hitherto adopted, of his getting radically cured," but that the day has dawned which will see this "*opprobrium medicorum* consigned to the pages of history;" and in his late editions he is able to remark that this "prediction has been literally fulfilled," and that chronic cutaneous maladies have been transferred *en masse* from the category of the incurable to that of the curable maladies." The change is, as we have said, in a considerable degree owing to the employment of arsenic, which Mr. Hunt has taught most perseveringly. Mr. Milton remarks,—"I consider that Mr. Hunt merits the thanks of the world for the courage and industry with which he has worked out this subject," and, though he has had several eminent co-workers, no one will refuse him a large share of the merit due to those who have brought about the present improved state of dermato-pathology. It has, indeed, taken many years to convince Medical men not only that arsenic can act with great power on the nutrition of the skin, but also that, if skilfully given, it may be given for a long time together with perfect safety; but now every dermatologist enjoins its employment largely, giving, at the same time, more or less minute directions as to the manner and dose in which it is to be taken; for no true disciple of Esculapius pretends that while being powerful for good it is powerless for evil; we leave it to homœopaths and other quacks to prate of possessing remedies that will cure if rightly prescribed, but are without effect if erroneously taken. We allow that while arsenic is, if used rightly, a most invaluable remedy, it does require to be handled with caution and skill; but so employed it is eminently useful. Romberg observes, "No medicine has met with so much prejudice as arsenic. . . . My own experience leads me to assert that, in the numerous and various diseases in which of late years I have employed it, I have invariably seen an improved digestion, as marked by a better appetite, and have never observed any injurious consequences result from its use." ("Diseases of the Nervous System." Sydenham Society's Translation, Vol. I., p. 54.) To obtain from it only good, and all the good it is capable of, it must be given only in certain stages of disease, it must be given with certain precautions, and its use must not be hastily abandoned. In Dr. Frazer's useful and practical little work on "The Treatment of Diseases of the Skin"(b) directions are given for the employment of this remedy that comprise nearly all the rules needed for its safe administration.

"Give moderate doses, whatever preparation is selected.

"Let it be taken at or after meals, never fasting.

"Irritation of the conjunctiva, gastric pain, purging, or other symptoms of constitutional intolerance will demand its temporary suspension.

"Do not give it during febrile, catarrhal, or gastric attacks, or during the inflammatory stage of any eruption."

To these we will add two rules from an excellent paper on

(a) See also a pamphlet "Additional Statements by Mr. Wm. Menzies in Support of his Plans for the Drainage of Towns." London: Longman. 1865.

(b) Treatment of Diseases of the Skin. By Dr. W. Frazer, Lecturer on Materia Medica to the Carmichael Medical School. Small 8vo. P. 174. Dublin: Fannin and Co. London: R. Hardwicke.

the Uses of Arsenic, by Dr. Habershon, in the last number of "Guy's Hospital Reports:"(c)—"Although irritability of the stomach and bowels, as well as of the mouth and conjunctiva, may be induced by arsenic, these symptoms do not necessarily compel us to discontinue its use, for a diminution of the dose, and an admixture with an opiate may remove the symptoms.

"When very minute and continued doses induce a general sense of exhaustion, with compressibility of the pulse and loss of appetite, although there is no irritation of the mucous membrane of the alimentary tract, the arsenic must, for a time, at least, be discontinued."

Fowler's solution is almost universally the favourite preparation, and either it or the acid solution may often be advantageously given with preparations of iron.

Biett, Neligan, and others strongly recommend a solution of the iodide of arsenic in some chronic diseases of the skin in strumous subjects; and some Practitioners think highly of Donovan's solution, though this finds no favour in Mr. Hunt's eyes, who remarks, "If there be any medicine more dangerous and unmanageable than another, it is the compound of arsenic, iodine, and mercury, known by the name of "Donovan's Solution."—("Guide to the Treatment of Diseases of the Skin," third edition, 1857, p. 257.) The acid solution of arsenic, the liquor arsenici chloridi, has, for some reason, been omitted from the British Pharmacopœia, and two preparations have been added, viz., the arseniate of soda and the arseniate of iron. MM. Bergeron and Lemaitre, who have lately published some observations on the elimination of medicinal substances by the sweat, found that the arsenites of potash and soda were eliminated as arsenites of those salts, while the arsenite of iron was decomposed, the iron passing off in the urine, and the arsenic, "as an alkaline," with the sweat. Dermatologists differ somewhat in the mode of giving the remedy, *quâ* dose. Some, as Mr. Wilson, begin with a small dose, one or two minims of Fowler's solution, three times a-day, and gradually increase it up to the full dose; some giving as much as ten or twelve minims, while Mr. Wilson thinks "five minims is the maximum dose, and only admissible in alphos;" others, as Mr. Hunt, begin with five-minim doses, and when the system is fairly under its influence, continue it in smaller doses. But in whatever way the remedy is given, its use must be regularly and steadily persevered in, if necessary, for months together. As Mr. Milton justly observes, in his favourite and easy style, "If the patient is to give up arsenic whenever he is going out to see his friends, or when he has friends coming to see him; when he is away on business, or at the sea-side; when he is tired of medicine, or fancies it may not agree with him; in short, if he be going to take it in any way but the right way, he had better not take it at all." We will conclude our observations on the use of arsenic with a quotation from an admirable essay on this remedy by Dr. Begbie(d):—

"The curative properties of arsenic may be obtained in some instances before its physiological effects present themselves; but in order to secure its virtues as an alterative in the large class of chronic diseases which yield to its influence, it will be necessary to push the medicine to the full development of the phenomena which first indicates its peculiar action on the system. Arsenic, as a remedy, is too often suspended, or altogether abandoned, at the very moment when its curative powers are coming into play. . . I have never seen the loathsome scales of lepra or psoriasis drop from the skin, and leave a healthy cuticle, till the eye or tongue manifested that the system was under the influence of the mineral, and that for days or weeks together. . . One of the earlier signs of its physiological action is a minute papular rash, which, by-and-by, assumes the form of delicate scales, having a brownish colour, and giving to the skin an unwashed appearance; . . it will be well to continue its use in diminishing doses, or in moderate doses at longer intervals, maintaining for a time in the mildest form the exhibition of the earliest signs of its physiological action."

(d) Contributions to Practical Medicine. By James Begbie, M.D., F.R.S.E., Physician in Ordinary to the Queen in Scotland. Edinburgh: A. and C. Black; London: Longman and Co.

THE WEEK.

MEDICAL POLITICS.

We are glad to find that the Royal College of Physicians is going to take up the case of the Army and Navy Medical officers, and will no doubt place the matter in a proper light before the Government.—It is said that neither Mr. Paget nor Mr. Prescott Hewitt intend to present themselves for election into the Council of the College of Surgeons, and the hopes of the Surgical Profession are centred in Mr. Charles Hawkins and Mr. Turner. It is difficult to conceive of any one likely to make a more useful member of the Council than Mr. Charles Hawkins. Living in London, without any appointment in one of the large Hospitals, yet a thorough Surgeon, and enjoying the unlimited confidence of his brethren, fully conversant with the most advanced Surgery, a good man of business, of a frank and genial disposition, with large common-sense views, and the interests of no clique or set to protect—being, moreover, the official superintendent of the study of anatomy by dissection—he would, if any one, succeed in introducing those reforms into the College which are necessary to satisfy the Profession and to secure the proper education of rising Surgeons. On this point we may refer to Professor Owen's speech, and say unfeignedly that a change in the Court of Examiners of the College would further the study of scientific anatomy and physiology by at least half a century.—As to pharmacy and the Chemists and Druggists Bills, the current number of the *Pharmaceutical Journal* says:

"The proceedings of the Select Committee on these Bills have not been such as to inspire much confidence in the future. If the resolutions already passed be adhered to, any measure that may be framed in accordance with them will but imperfectly accomplish the objects contemplated by the originators of the existing Bills, and it is quite possible that further resolutions may convert what was a beneficial measure into one of an undesirable character. We cannot say that it would be impossible now to frame, upon the resolutions of the Committee, such a Bill as we should be prepared to accept; but there is some ground for apprehension that an attempt may be made to substitute, for a really good and comprehensive measure, one the effect of which would be to impose unnecessary and objectionable restrictions on trade, and, by recognising and establishing an imperfect and insufficient qualification for dealers in, and dispensers of, medicine, to discourage rather than promote the advancement of the art and science of pharmacy."

THE LATE ELECTION AT THE ROYAL SOCIETY.

The fortunate fifteen who this year for the first time append F.R.S. to their names may be divided into the two classes of those who confer honour on the Society by joining it, and those who derive honour from the Society by their admission. But as such a division, however tempting from its simplicity, might be considered invidious, we substitute for it one based on the respective professions of the candidates and the departments of science in which they are distinguished. Taking Medicine first, we have Dr. George Harley, Professor of Medical Jurisprudence in University College. Dr. Harley is known to our readers by the lectures we have lately published; but the physiological researches by which he obtained his election are scattered through a number of journals, English and foreign. They comprise papers on the production of Diabetes in Animals, Urohæmatin, the Blood and Urine in Pregnancy, Respiration, the Anatomy of a New Species of Pentastoma, the Chemistry of Digestion, the Anatomy and Physiology of the Supra-renal Capsules. Another successful Medical candidate is Dr. Robert McDonnell, of Dublin. He is the author of a number of Physiological and Anatomical papers, a Member of the Royal Irish Academy, and Examiner in Anatomy and Physiology in the Queen's University in Ireland. A third Medical man on the list is Mr. W. K. Parker, who, however, has won his Fellowship as a Comparative Anatomist, and therefore takes his place with

the naturalists. Pure mathematics have one representative in the list, in the person of the Hon. James Cockle, M.A., Chief Justice of Queensland. This gentleman has made a high reputation by his papers on the more abstruse departments of mathematics, in the Cambridge, Dublin, and other mathematical journals. There are three Astronomers—the Rev. William Rutter Dawes, known for his observations on the double stars and the umbra of a solar spot; Mr. Robert Grant, the Regius Professor of Astronomy in the University of Glasgow; and Mr. William Huggins, who has written papers on the Spectra of Nebulæ and of the fixed stars. The Natural Historians get three Fellowships: these are severally awarded to the well-known Ornithologist, Mr. George Robert Gray, the Senior Assistant of the Natural History Department of the British Museum; Mr. William Kitchen Parker, a General Practitioner of Medicine, the author of several papers on Comparative Osteology in the *Transactions* of the Zoological Society, and of some well-known papers on the Foraminifera; and to Mr. G. H. K. Thwaites, a botanist, the Director of the Royal Gardens, Peradenia, Ceylon. There are two engineers—Mr. Fleeming Jenkin, an author on Telegraphy and Electrical Engineering, and Lieut.-Col. J. T. Walker, the Superintendent of the Trigonometrical Survey of India. There is one chemist—Mr. George Gore, the author of three papers in the Philosophical *Transactions* on Antimony and Carbonic Acid; one geologist—Mr. A. Geikie, of the Geological Survey; one traveller—Sir F. M'Clintock, the Arctic navigator; and one representative of literature—the Poet Laureate. The premature death of Mr. Henry Christy, whose candidature had been approved by the Council, deprived the Society of an active ethnologist and palæontologist.

THE NAVAL EXAMINING BOARD.

We have just received the following curious piece of intelligence:—The Inspector-General of Hospitals from Greenwich, and the Deputy-Inspector-General of Hospitals from Woolwich, together with the Deputy-Inspector-General of Hospitals at Somerset House, have hitherto been employed jointly to examine candidates for Assistant-Surgeoncies in the navy. This Board, it will be remembered, did good service by rejecting a good many candidates during the past year, and the consequence is that the navy is now short of complement. To remedy this state of things, the Board of Admiralty have directed that the examinations in future shall be conducted by the Deputy-Inspector-General at Somerset House. The object is plain enough: a Board is not so manageable as a single individual may be, and the Admiralty calculate that with a single examiner there will be fewer rejections. We hear that under the new *régime* two candidates have been examined and passed.

PROFESSOR OWEN AT ST. MARY'S.

Professor Owen delivered a remarkable oration at the distribution of prizes to the Medical students of St. Mary's, Paddington. Our limits compel us to abridge it; so we may say that after some energetic remarks on the value of competitive trials, he goes on to discuss some of the most important questions relating to the true character and position of our Profession:—

"It is sometimes asked, Is Medicine a science? This question, like many others, is hardly reasonable or fair, the two terms being so unequal in degrees of complexity. So far as Medicine knows the cause and condition of a curable disease, and the one infallible cure, to that extent it is science. If Medicine has mastered the nature of a specific malady, if there be a specific malady, and has discovered the specific remedy, if there be such a thing as a specific, it may claim to be a science. I leave to the experienced Practitioner to determine what may be the proportion of the field of observation and practice commonly called 'Medical science' which is in the above defined condition; and what the proportion of that field in which the cultivators differ in their views as to the cause, the nature, and the remedy of disease.

"Your excellent professor of chemistry will tell you that, having a special aim in view, he adds a certain reagent to a given solution or mixture, knowing that it will produce such desired result—viz., a certain infallible decomposition and recomposition. The prevision and its fulfilment prove that he possesses a science. But, were other chemists to affirm that a different reagent would produce the same result, or that the solution, if left to itself, would produce it by spontaneous decomposition or recomposition; and if there were really grounds for such affirmations or diverse views of the case, you would then conclude that chemistry had not reached the scientific stage, and would hardly expect it to enjoy public confidence. In fact, we see at the present day that the public confide not so much in Medicine as a science as in the particular Practitioner. It is characteristic also of the present phase in the growth of Medicine, that the public are liable to be deluded and led astray by its shams; and not until Medicine becomes a science can such simulacra be expected to vanish, and quacks and quackery become extinct. Time was when disasters were deemed, in the literal sense of the term, to be the effect of malign influence of stars. Two or three centuries ago, the horoscope was cast, and believed to indicate the future destinies of the heir, by the same classes as now accept, in like faith, the infinitesimal globule. The astrologer then had leave to move in the same social scale, and to sit at the same tables, as now the homœopathist. Astronomy had not risen to its full development as a science. It is interesting, indeed, to consider how a public ignorant of, and careless about, the grounds and proofs of an established science, does in time come to believe in and trust it, to the exclusion of its simulacra, and the utter deposition and extinction of the quack professors of the same. I believe the public gain this faith by what the true science effects and what it predicts.

"By means of the data of astronomy, the seas are navigated, and remote parts of the earth reached with marvellous exactitude. Astronomy foretells phenomena to the day, hour, minute, even second of time: the interval—it may be years—after the prediction passes; and at the very hour, and fractional part of the hour, the event foretold comes off.

"The palæontologist, from a fossil fragment, infers that such a form of animal, strange, it may be, or gigantic, has existed in such an island; and commits himself a prophetic sketch of the same. Other parts are afterwards found; at length, perhaps, the entire skeleton. The public knows nothing of the laws of correlation by which the prevision of a form of life long passed away, and never seen by human eye, was gained; but it is struck by the fulfilment, and accepts or believes in the science.

"Medicine is occasionally called upon to prophesy in public; the rank of the patient requires a bulletin. Reference to some of these series of predictions and the actual results may partly account for the degree in which Medicine still halts, as a science, in public estimation. And so it comes to pass that the question continues to be asked, 'Is Medicine a science?'

"The great question for you, however, is, Can Medicine become a science? From every analogy of the progress of human intellectual endeavours to raise, by observation and experiment, a body of facts and phenomena to the status of true science, the reply to the latter question would be emphatically, Yes!

"Anatomy, physiology, pathology, or a knowledge of deterioration of structures, to the minutest degree in which the microscope can show such changes for the worse, in the fluids and elementary tissues of organs; chemistry, especially organic; the nature and powers of medicines—in short, all three bodies of doctrine worthy of the name of sciences must be cultivated—if possible mastered—as the indispensable basis on which a lasting superstructure of a true science of Medicine can be raised. Medicine can only become science by and through the subservient bodies of doctrine that have become science—the unknown must be reached by the known.

"In every age, the individual who has effected most to raise Medicine and Surgery to the rank of sciences has been the Practitioner who was most distinguished for his knowledge of science.

"John Hunter, besides being the greatest Surgeon of his time, was the best physiologist, the greatest comparative anatomist, and, what was then little if at all known to his compatriots, he held the most advanced views of zoological classification, and was the most experienced palæontologist.

"In considering the obstacles that impede the progress of

Medicine to the scientific status, I have been led to regard in that light, among other opposing influences, 'fees' and 'examination.'"

With regard to fees, the Professor speaks of the necessity of studying Medicine, including therapeutics, as any other experimental problem, and apart from the consideration of remuneration for each particular case. Then with regard to examinations:—

"Examinations differ widely in the work and qualifications of the examiners,—in the views and motives of aspirants to the office,—in the main end and aim of the test itself. In regard to the latter, the difference is such that it may be expressed by saying that some examinations are conducted to find how much, and others how little, a man knows. In the first category, those examined are ranked in the order of their acquirements; in the second, all alike receive a diploma, signifying qualification. And, as the weakest link in a chain gives the strength of the whole, so the scantiest measure of knowledge that enables the candidate to pass becomes that of the amount sought for by the examiners, and at the same time a test of their own qualifications for the office, and of the responsibility and trouble which they undertake in its performance.

"To exemplify the first kind of examinations, I would refer to the well-known arrangements at our old universities, in principle so pure, so effective in arrangements, as to gain for him in whom the highest amount of knowledge has been found the unhesitating applause of the less successful, which is echoed, without the slightest misgiving, by the country at large.

"In the composition of the examining body, old experience is combined with young vigour, soundest knowledge of settled principles, with minds fresh from the latest discoveries and amended views of science. The senior wrangler of one year may be associated with his teachers as an examiner in the next.

"The machinery is effective without being cumbrous. The teachers of the required subjects are stimulated thereby to impart the newest discoveries, and to set intelligibly before their pupils the latest phase of their respective sciences. 'Examinations' of this nature are helps, not hindrances, to science.

"*A board of examiners composed exclusively of old teachers or Practitioners*, and to whose diploma or pass-certificate the bulk of Medical students look as a main aim of their metropolitan studies, becomes an influential element in the consideration of the way in which, *e.g.*, anatomical and physiological science is to be presented by the teacher to his class. I believe that I do not err in supposing that, if the examinations in human anatomy and physiology by the board granting the diploma were conducted by a combination of young cultivators of those sciences with old anatomists and Practitioners; that if one or more men of justly merited public repute for their advancement of anatomy and physiology, and in the vigour of their intellectual work of imparting and expanding those sciences, were placed on the board of examiners—teachers would be stimulated to prepare their pupils to be tested in relation to more advanced conditions of those sciences, than there is any call for under the present state of the 'pass examinations.'

"The obstacles to such improvement in the examining board may be exemplified in the conditions of its existence at the Royal College of Surgeons of England. The administrative authorities of that College are concerned, both in purse and dignity, in themselves performing the work of examination. In purse, by the way and degree in which they remunerate themselves for such work; in dignity, because no member of the Council is eligible to the offices of vice-president and president of the College until he has been an examiner. As such, his remuneration being in the ratio of the number of persons examined, must now be of material importance.(a) Accordingly, the Council, twenty-one in number, elect out of their own body ten to be examiners, reserving to themselves the testing in all the required sciences and subjects, save midwifery, dentistry, and classics.

"I note this, therefore. as one of the impediments to the progress of Medicine and Surgery as sciences; an evil which will be abated in proportion as those to whom the Profession confide administrative power may approach in singleness of purpose and motive to the administrative bodies of our Universities in regard to the business of examination for degrees and diplomas.

"The Royal Society of Arts has recently given an example which the Royal College of Surgeons would do well to follow. On undertaking responsibilities connected with examinations of candidates, the Council of the Royal Society of Arts at once passed the self-denying ordinance that no member of the Council should be eligible to the post of examiner. Yet the Council always includes men well qualified for the office, but not every man so qualified, and seldom those who are best qualified.

(a) In the year 1817, the Council determined by bye-law, sect. xxii., that "Every member of the Court of Examiners who shall be present at the opening of any stated Court of Examiners shall be entitled to half-a-guinea; every member who shall be present at the adjournment thereof shall be entitled to half-a-guinea. And for every examination for the diploma, the examiners who shall have been present from the commencement until the termination thereof shall be entitled to the division of nine guineas, whether the person examined be approved or refused."

PARLIAMENTARY—THE METROPOLIS SEWAGE AND ESSEX RECLAMATION BILL—THE DISASTROUS MARCH FROM MHOW TO KIRKEE—THE BRITISH MUSEUM—THE UNIVERSITY OF LONDON.

In the House of Lords on Thursday, June 1, on the motion for the third reading of the Metropolis Sewage and Essex Reclamation Bill,

Lord Denman objected to what was really a great public undertaking being intrusted to a private company. Many scientific plans for the utilisation of sewage had been neglected, and one had been selected which in the opinion of most eminent authorities would be found to be impracticable. The experiment which it was proposed to make was hazardous, and would have the effect of delaying, if not of preventing, the permanent improvement of the metropolitan drainage. He therefore moved that the bill be read a third time that day three months.

The Earl of Hardwicke said it appeared that the promoters of this bill proposed to convert Maplin Sands into land fit for cultivation. Upon the faith of such statements many persons might be induced to invest money, and therefore it was well that it should be known that the most eminent authority—Baron Liebig—had declared the scheme to be impracticable.

Lord Churston said the committee had had contradictory evidence as to the practicability of the scheme, but the question of probable profits was one which only concerned those who chose to speculate in the undertaking.

Their lordships then divided,—

For the third reading . . .	49

Majority	—45

In reference to the subject of the fatal cholera outbreak amongst a detachment of the Royal Artillery on their march from Mhow to Kirkee, a march which is said to have been ordered by the military authorities in spite of most explicit warning, Sir M. Farquhar asked the Secretary of State for India whether his attention had been drawn to the account of the occurrence which had appeared in the newspapers.

Sir C. Wood said that no public report had been received on the melancholy occurrence to which the question of the hon. member referred. He was, however, sorry to say that there could be no doubt of its being true that a detachment had been ordered to march from Mhow to Kirkee, and that a great mortality had occurred in the course of the march. The number which had been mentioned included both women and children. There seemed to have been some misunderstanding between the military authorities and the officer of the detachment. A remonstrance was made to the authorities, and they at once countermanded the order for the march. He thought it only fair to say that the breaking out of cholera among troops on the march in India was by no means an uncommon occurrence. It by no means followed that in this case it was owing to the march taking place at a particular season of the year, as cholera in India broke out in otherwise healthy seasons.

In Committee of Supply on the vote of £161,841 for the Science and Art Department of the United Kingdom, several members spoke in terms of reprobation of the proposal to remove the Natural History Department of the British Museum to South Kensington.

In the House of Commons, on Friday,

Mr. G. Duff called attention to the claims of the University of London to be provided, at the national expense, with a building suitable for its purposes, and worthy of the position which it occupied among the educational institutions of the country.

Mr. Cowper admitted the usefulness of the University, observing that there was every desire on the part of the

Government to give to it an adequate accommodation; but he doubted the expediency of incurring the expenditure requisite to provide a special building.

The House adjourned until Thursday, June 8.

FROM ABROAD.—EXPERIMENTS WITH VARIOLA AND VACCINIA ON ANIMALS—EFFECTS OF DEVASTATING THE FORESTS IN FRANCE.

During a discussion which took place at the Académie de Médicine two years since upon the origin of the vaccine virus, one of the points which came most prominently into view was the question of the identity of variola and vaccinia, and the production of the latter by the transplantation of the former into the economy of certain animals. The Lyon Society of the Medical Sciences, not satisfied with the position which this question had assumed during the discussion, appointed a committee, of which MM. Chauveau and Viennois were prominent members, to carefully investigate the subject anew by means of numerous experiments. Last week M. Chauveau detailed to the Academy the principal results of an investigation which, although not a novel one, has never been before carried out upon the same scale and so systematically. Two large dairies, one with 160 and the other with 100 cows, were placed at the disposition of the committee; and as the history of the animals was well known, the fact of their not having already had cow-pock or aphthous fever was ascertained. On a series of 30 animals, taken indiscriminately as regards age and sex, magnificent pustules were produced by vaccine virus, the eruption remaining strictly localised. Upon another series of 20 vaccination was performed with human virus, and all perfectly succeeded but one, and that in young and old animals, and whether old Jennerian virus or that obtained more recently was employed. In a third series of experiments, 5 animals, that had a short time before been the subjects of aphthous fever, having been vaccinated, a fine eruption was produced, proving that this fever cannot, as has been attempted, be assimilated to cow-pock.

Next, 17 heifers or young bulls were most carefully inoculated with human variola, some in 1863 and others in 1865. In none of the animals did cow-pock follow, only very small, reddish papulæ appearing, which rapidly disappeared without leaving any crust. That these papulæ were simply the result of the inflammation produced by the puncture, having nothing specific about them, is, however, disproved by the fact that when 15 of these animals were subjected to vaccination, while in 3 of them there appeared rudimentary and ephemeral vaccine vesicles, 11 of the others were exempt from all eruption. This fact, which is regarded as new, proves that the papules produced by the inoculation of the variola really are a specific eruption, possessing the same relations with cow-pock as vaccinia and variola in the human subject. An experiment made by inoculating with some serosity scraped from these variolic papulæ furnished completely negative results.

The next experiment performed by the Committee was upon an infant, and we are somewhat curious to know how infants were obtained for these experiments, and under what pretext the Committee procured the consent of their parents. However this may be, an unvaccinated infant was inoculated with some of the serosity obtained from the variolic papulæ of the heifer. A single pustule resulted, which, after commencing like ordinary vaccinia, became surrounded by a number of secondary pustules, which, increasing largely in size, had by the eleventh day covered the whole surface and become confluent. A second infant, inoculated from the primary pustule of the first, also exhibited a general eruption, but without confluence. A cow inoculated from the initial pustules of the second infant, did not exhibit cowpock, but the papular eruption which is typical of variola in the cow.

These various series of experiments were repeated upon the horse and ass, five infants being successively inoculated from the variolar eruption of the horse; and, although the eruption became more sparse after each transmission, its power of inducing spontaneous variola in the human subject and inoculated variola in the horse was demonstrated as remaining. The following are the general conclusions arrived at:—1. Human variola can be inoculated in the horse and ox with the same certainty as vaccinia. 2. The effects produced by the inoculation of these two virus differ absolutely,—variola inducing in the ox an almost imperceptible papular eruption, and which, although much larger in the horse, can never be confounded with the vesicles with abundant secretion and the thickened crusts of the horse-pock. 3. The horse and ox can in general be preserved from variola by vaccination. 4. The inoculation of these animals with variola in general opposes the ulterior development of vaccinia. 5. Transmitted from ox to ox, or horse to horse, variola does not approach vaccinia in its nature. It either remains as it is, or becomes extinct. 6. Transmitted to man it gives rise to variola. 7. Retaken from man and transported anew to the ox or horse, it does not on this second invasion give rise to horse or cow-pock. 8. Thus, in spite of the evident relationships which in animals, as in man, prevail between variola and vaccinia, the two affections are none the less perfectly independent, and cannot be transformed into each other. 9. In vaccinating, then, by Thielé and Ceely's method, we practise the ancient inoculation, possibly always rendered benign by observing the precaution of only inoculating from the primary accident, but most certainly preserving all its dangers with respect to contagion.

At the same meeting of the Academy, M. Lanoix also presented a paper on "Animal Vaccination," derived from the observation of 800 revaccinations and 300 vaccinations. He concludes that the vaccination from heifer to heifer is always possible, and may meet a large demand for the virus. The virus does not thus become weakened, but its properties are more surely preserved, and for a longer time, by transmission through the animal than through the human economy. Vaccination almost always furnishes a positive result, and re-vaccinations give a superior mean success to the mean success of human vaccinations. Vaccination of the heifer is easily performed, and in the time of epidemics it becomes a powerful resource in consequence of the abundance of the supply it places at our command.

M. Becquerel has brought under the notice of the Académie des Sciences a very important subject—viz., the mischief arising from devastating the country of its trees. It has been often enough urged before, not only with respect to France but other countries, but seemingly with little avail, for M. Becquerel states that while from 35,000 to 36,000 hectares of forest are annually destroyed for the purposes of agriculture only 10,000 hectares are planted in the mountainous districts. If this state of things is to go on he predicts the most disastrous consequences, as the climate will be greatly changed for the worse and the system of waters entirely deranged. He has studied the influence exerted on the climate during the last thirteen years, and his numerous experiments prevent his entertaining any doubt in the matter. By the aid of his thermo-electrical apparatus he has ascertained that a tree, whether isolated or in the midst of a clump, acquires heat just like all inert bodies exposed to the sun's rays. By reason of the slight conducting power of the wood the tree does not present its maxima of temperature until about tw hours after sunset, and a certain time is required to bring it into equilibrium with the surrounding medium; and while for the leaves a few instants may suffice for this, the trunks of a large diameter may require many hours, or even the whole night. It will be readily understood how forests of a certain size may in this way influence the temperature of a country. The examination of the records of history and contemporary facts amply prove that the waters of the country have undergone great change, the inundations on certain rivers becoming more frequent and more devastating, while on the other hand, the sources in some valleys are dried up. When M. Becquerel points out that this destruction of forest

is due to the increased demand for wood, and the desire of proprietors to turn their possessions to more profitable account, he only shows how much more easy it is to deplore the evil than provide a remedy.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF OXFORD.

(Continued from page 382.)

The precise condition of the citizens of Oxford, in regard to their civic rights and endowments up to the period of the incorporation of the University, has not been very clearly determined. Ackeman, who closely follows Wood, assumes that the place "doubtless was of civic dignity in the early periods of the English history," but he gives no satisfactory evidence in support of the statement. It is inferred that in the reign of Alfred there was a provost of Oxford, who would be chief magistrate, as the provost of Glasgow is now chief magistrate of his city. In the latter part of the Saxon period there was, as we have told already, an Earl of Oxford made by Harold the Second, but whether the Earl exercised special jurisdiction is not recorded. In the commencement of the Norman period the town was in all probability placed under the control and governance of the Lord of the Castle, but in the reign of the First Henry the feudal bonds were knocked off, and a charter was granted by the King to the burgesses, while in the reign of Richard the First, the monarch, who was born in Oxford, placed the inhabitants under the same laws as the corporation of the City of London. Thus the municipal liberties of the town were in progress together with the gradual development of schools and halls, and when the time came for the erection of the colleges or separate residences for the students and the learned men, there was a perfect organisation of a civic character external to the University and, to some extent, independent of it. Henry the Third, in 1255, appointed to the mayor and bailiffs four aldermen and eight other legal persons to act with them as a Council, and laws were passed for protecting students from the laymen and the laymen from the students, for town and gown even at that early day might have been called "hammer and tongs" with all propriety.

The town itself at this period was small and badly built. In it and near it were many religious houses, the Abbey of Osney being the most important and imposing. The Franciscan Friars had one house at least, perhaps more, and the Black Friars and other orders had also established themselves. In these religious houses, and in the houses of the burghers, the clerks and students resided. The houses were for many ages rudely built of wood or plaster, and covered with thatch; but in the latter part of the year 1235 a great fire occurred, by which nearly the whole place was destroyed. Afterwards the inhabitants, in rebuilding the town, began to employ stone and "to fortify with tile and slate."

THE COLLEGES.

In my last chapter there was drawn out in the briefest possible outline a notice of the origin of the city of Oxford. We stopped at that point in the narrative when the University had become, by the will of the third Henry, an incorporation, when the positions of teachers and of scholars were defined, and when the relations of the separate colleges to the whole of the University, as a body, were set forth.

From this point we may travel by the side of the respective colleges, and in their history blend much, if not all, that we have space to record concerning the city itself; for now in truth this is a University town we are at, hardly more than that in name, and assuredly nothing more than that in reality.

Wood, of whom I made mention in the previous chapter, in his introduction to the colleges, teaches that before the colleges were built the scholars generally were educated and tutored in the houses of the burghers (called by the name of halls or inns); the scholars were supported either by the exhibition of the bishops, by the assistance of great and wealthy persons, or by their own patrimony; but some—and many of these were secular scholars—were educated in the religious houses, as in the Priory of St. Fridesswide and Osney Abbey. Afterwards the colleges arose, but these from very small beginnings, for all except Merton had their origin from only one tenement or hall.

The reader will remember that to King Alfred the honour is given of having founded the first schools of the city, and that tradition affixes to his acts the foundation of three schools—one for theology, a second for logic, and a third for grammar. From this assumed circumstance certain antiquarians have believed that the college known as University College is, in fact, a continuation or representative of the original schools of Alfred. This belief was at one time so firmly accredited that in the reign of Henry the Sixth certain windows were placed in the college, on which King Alfred was depicted and described as the founder. It does not, however, appear that there is any satisfactory reason to assign such an antiquity, as is thus surmised, to University College. I must therefore follow the usual order given to the colleges in point of age, and place University College second on the list.

Merton College.

The most ancient college of Oxford is Merton. It was transferred from Maldon, in the county of Surrey, by Walter de Merton, Bishop of Rochester, and once Lord Chancellor of England. To give good accommodation to his students, the Bishop erected and ornamented a building, which in the year 1267 was chartered and established for ever, *per nomen* "Domus Scholarium de Merton."

More than ordinary interest is attached by the true Oxonian to Merton College, because upon it he rests his claim to an antiquity for his University greater than any that can be claimed for the University of Cambridge. The Oxford men, following in the wake of the vigorous old scholar, who lived his lonely life at "Merton," assert that the founder, Walter de Merton, transferred his scholars, twenty in number, from Surrey to Oxford, because in that place, and nowhere else in England, general learning flourished. Further, the said Merton had about that time a house and manor at Cambridge, and seven or eight miles off another house and wide lands. *Ergo*, the Oxonian—Walter de Merton—of a surety would never have been so stupid as to buy a new place at Oxford, and take his scholars there, if Cambridge, where he had every convenience, had a ghost of a pretence at that time to be considered a school. To clench their argument, the Oxonians protest, that whereas Peterhouse was the first college in the University of Cambridge, and whereas there was no Cambridge worth naming before Peterhouse, Peterhouse itself is but a copy of Merton College, built by Hugh, the famous Bishop of Ely, after the true and original Oxford model. The care taken by De Merton in the foundation of his college was repaid. The discipline was good, and men already of great fame gave it their support; amongst others, the famous Roger Bacon—whom we Physicians ought to claim as our own, seeing that, although a Franciscan friar, he practised physic. Roger Bacon was content to join the College, and, either as reader or student, take part in the learning that was taught there. At this time Bacon held the first, though not the safest, place amongst the learned of his time: he was by common consent the first of mathematicians; he was the leader in perspectives, or in the science of optics, and he was one of the six great alchemists—the fourth in order, says Wood, of those chief chemists whom the world has ever produced; viz.—1. Hermes Trismegistus; 2. Geber Arabs; 3. Morienus Romanus; 4. Rogerius Bacon; 5. Raymundus Lullius Hispanus; 6. Thomas Paracelsus Germanus. The acquisition of Roger Bacon by the new college was an event of more importance to the future history of the spot than probably was known at the time or than is known now. Roger Bacon, in fact, is still but poorly understood, his real work in this world badly collated, if not lost, and the odour of his name not yet purified from the superstitions by which, while its owner lived, it was so grimly surrounded.

With the foundation of Merton College a change was naturally introduced in the position of the town and the townspeople to the University. Hitherto, as we have stated, the students lived with the burghers, and attended the schools only for the purposes of instruction: in other words, that system which has always been maintained in the Scottish Universities, and which the visitor to Glasgow or other famous northern seats of learning will find existing to this hour, was the order of the day at Oxford until the foundation of the colleges introduced a new system. What led to the change is not so easy now to state in one expression, for there were several converging elements. The monastic life had some influence, in the way, at least, of example. If the cloister favoured sanctity, surely it should also favour learning. This was a natural argument, and in its day it possessed a vitality which we can never again appreciate. Dissensions

between the burghers and the students was another probable cause of the change. These dissensions had often been very serious: in the year 1202 there was a disturbance of great magnitude, and as the burghers seem, from the account, to have had the best of the quarrel, and to have maintained their possessions, the professors and students, in order to bring about the severest punishment they could inflict, simply packed up their books and bags and set out to the good old town of Reading, which made them very welcome, and where they soon settled down to work. The Oxford burghers thereupon found to their dismay that they had reckoned without their host, and that, in plain truth, these rough-and-ready and perchance overbearing bookmen were after all essential to the well-being and very existence of Oxford. So before Reading had established such claims over the scholars as were invincible, the Oxfordian townsmen gave way, and the scholars returned to their hostels and schools in triumph—the independence of the burgher knuckled down to his necessities. There was yet a last cause for the establishment of the collegiate system—viz., the ambition of the founders of the colleges. It is as the leader in this movement for the advancement of learning that the name of Walter de Merton remains distinguished still amongst us. I know not whether the evil or the good prevails in the ambition to found a college and to leave it as a monument of the founder. A good and great man, one full of noble purpose and aspiration, may truly in this manner place himself fairly in history, the goodness of the intent expurging the vanity and sanctifying the deed; but, unfortunately, what a good, ambitious man, having means, may do for a good purpose, a bad, vain, ignorant, ambitious man may do for mere self, or even for hiding, under a falsely-assumed greatness, errors of the past, and great crimes. On the whole, the system does not bear the crucible without injury, nor is it a system to be perpetuated. What it has done, it has done in many cases well; if it has not been so free as we could wish, it has been retired and often sound, and it is to be confessed that, tried for some centuries by the side of the free system in Scotland, it bears out fairly. If it has not led to the practical and useful in knowledge, it has borne pre-eminent results in the development of theory; if it has had little to do in the quickening of the mechanical and physical sciences, by which this age is distinguished, and only distinguished in knowledge from the Platonian period, it has maintained and handed down to us that marvellous wisdom which Plato condensed, and on which all our moral and social greatness rests. In other words, if it has not educated the hands, and if it has in some senses even crippled the feet of the body scholastic, it has nourished the brain with much old learning that, like old wine, hath its virtues as well as its age.

The connection of our own Profession with the first college in Oxford is to us full of historical interest. In 1825, one of the wardens of the College was Dr. John Chamber, Physician to King Henry the Eighth, and afterwards, with Linacre, one of the founders of the College of Physicians. Chamber was a priest as well as Physician, and was the last dean of the King's Chapel at Oxford. He graduated in Medicine on October 29, 1531, and died in 1549.

The reference made to the graduation of Chamber leads to a word or so on the question of the first conferring of degrees in Oxford. The degree of "Doctor" was introduced probably about the year 1150, and Wood states that in ancient days such that were Doctors in any of the faculties were for some time called by the name of Regents, as Regent in Law, Regent in Physic, and so for some years continued, but they were not to take the place of Masters of Arts. Regarding the exercises that had to be gone through for the degrees, our authority is, however, nearly silent, the records of such exercises afford little information.

But to the Medical mind Merton College is *the* College, because there the most illustrious of our great dead was once a resident. The man I refer to was William Harvey. I have already in these pages sketched out his life, and have given such an estimate of his work as will bear, I trust, fair criticism, as an estimate in which all that Harvey did is accepted by the side of that which his contemporaries also did, and that which his predecessors had done. It now, therefore, only remains to be recalled that in Merton College the discoverer of the circulation had residence, and that in 1645 he was warden of the College, to its perpetual honour and his great comfort, at a time when he needed consolation.

Another celebrity of the College who followed Harvey was Dr. Jonathan Goddard. How few of my readers ever heard of Goddard before, and yet I do assure them he was a great man, a noted man, a bold man, and honest withal. I gather in respect of this brother of ours, that in the first part of his career he was tightlaced and puritanic, that he wore a pointed hat, shaved close, and mixed his potions with a goodly allotment of political argument, and profitable disputation. What our friend Mr. Jonathan Hutchinson, who would deprive us all of so mild a draught as threepenny worths of *Daily News*, who would shorten our *Times*, tear us from the *Telegraph*, whip us from the *Post*, allure us from the *Tiser*, drive us like out sailing comets from the *Sun*, shut out our beautiful *Star*-light, and veritably cut us off from the *Globe*—what he (the said Mr. Jonathan Hutchinson) would have done to Dr. Jonathan Goddard—with his ravings against kings, papacy, and prelacy, his writing prescriptions in Westminster Hall itself, and such-like offences—except openly cut him, I know not. However, as I have said already, Goddard was a sound man and much esteemed. He was private Physician to the Lord Protector Cromwell, and by his Highness's will was made warden of Merton College in 1551; he was also burgess for the University in the Little Parliament, and one of the Council of State of the Commonwealth. Whether when his Highness Cromwell left his people, and the scraping mob kneed it down to the wanton, who was (forgive me for saying the word) "restored," whether Goddard then became less political, is not clear; but one has an inkling that at all events he conformed to fate, and drank to his Majesty with the rest, for I find that after Oliver's death he ventured to go to London, and was on the first Council of the Royal Society. He died on March 24, 1674.

Merton College is governed by a warden chosen by certain of the fellows. It has twenty-four fellows, fourteen "postmasters," four scholars, two chaplains, and two clerks.

The college is a fine old building of Gothic style, and is possessed of a library that would alone repay a visit. Here there is a specimen of Caxton's printing of Chaucer's poetry; here antiquarian Wood, to whom I have often referred, dug out his treasures.

To the hall of the College there has been added a painting representing the founder, Walter de Merton, in his robes and mitre. De Merton was painted as pointing to his college, the monument he had reared to himself. The picture for many long days possessed a peculiar charm to the Medical world of Oxford, in that it was not only presented but was painted by a provincial Physician, of great reputation as a Physician in the last century, viz., Dr. Wall, of Worcester, once a Fellow of Merton. The genius displayed in this work has often given rise to expression of regret that Wall, who left only a local repute in physic—alas! now well nigh forgotten even in Worcester—should not have turned to canvas altogether, on which he might have written his name for the ages. This picture told a story, and truly it told a moral also. It said plainly what few think of that great local and temporary success—that is to say, brief, but all-absorbing popularity, after which there is so much strife—is often, perhaps *always*, the deepest, the most terrible curse inflicted on genius. Had Shakespeare been the great actor of his day, he had never been Shakespeare. Had the miserables among whom our Harvey lived foreknown how many heads above all the other men of his craft and time he stood, Harvey had never been Harvey; while Wall, the forgotten Physician, had now been Wall, the never-forgotten painter, had not the miserables among whom he lived been moved by some ideal conception, in which I warrant there was not a jot of real wisdom or fact, to depict him as many heads higher than the rest of his brethren, and to keep him from his true province—designed for him by nature—by making him believe with them, so as to be their exclusive slave, at the cost of his fame and his true mission.

I have the happiness to know that students of our modern medicine traversing the Medical library in stray searchings after that which may relieve them from the immediate grind of hard dry work do read these columns with some pleasure; and if I could direct such readers—who are to represent medicine in the future—to a lesson derived from our old histories, I should point to Dr. Wall. I should say to them, be you true to your own instincts and your own honest promptings, and if you feel you do and can excel—actually excel—in any given path, follow that out and out without fear and with earnest hope. If there be one who knows that he is by nature a painter rather than a Surgeon or Physician, let that student become a painter; it will be better for him, for his natural profession, for the profession he has left, and for the world. It is well, right well, to speak these truths in a time that is

essentially narrow, false to genius, and bigoted in set forms, phaseologies, and opinions;—it is right to warn the young mind that nothing is so unsound and cruel as that persuasive "practical" voice which would command all the mental faculties of another person into its own train, and there leave them on sheer emptiness;—it is right to tell the youth not to listen to those who would curb all his yearnings and aspirations, on the plea that the world only is satisfied with men of one idea, or one shock of ideas. I ask no apology for using an illustration that lies before me, for the purpose of commending the rising members of the Profession to let loose their own honest impulses, to test themselves for the points of their own strength; and, having found these, to trust them, whatever may be the temporary sacrifice or the immediate cost.

Some other Medical names, more than those I have named, were educated at Merton College, viz., George Owen, M.D., Physician Royal to Henry the Eighth, and remembered for the sum of one hundred pounds in the will of that crowned animal; Sir Thomas Clayton, M.D.; Dr. Robert Wyntle, the first of the Radcliffe travelling Fellows; and last, not least, Theodore Goulston, founder of the Goulstonian Lectures, who died on May 4, 1632, and long lived to study Aristotle and Galen, with some credit to himself and much pleasure.

University College.

I have already stated in regard to this College that it has been supposed to have had its origin from Alfred the Great, and is, in fact, the representation of the three foundation schools which he is reputed to have established. I have further shown that, according to the best authorities, this antiquarian hypothesis is unsound, and that the College, in point of date, probably stands nearer to our own time than does Merton College. The evidence appears to be conclusive that University College was founded by William of Durham, the Rector of Bishopwearmouth, some time before his death in 1429. The College is a fine building, and the hall, which was commenced during the period of the great English revolution, is very handsome. The library is exceedingly rich in old manuscripts.

The College is governed by a master, and maintains twelve Fellows, one Bye-Fellow, ten Scholars, and two Bible Clerks.

University College possesses a Medical history of a special kind, since it was here that the noted Physician John Radcliffe was educated after he had left his grammar-school at Wakefield. Radcliffe, a lad scarcely fifteen, entered the College in 1667, took his degree of B.A., and became what was called senior scholar. There being no fellowship for him at the University College, he transferred himself to Lincoln College, and graduated in Arts in 1672. Evidently intended originally for the Church, Radcliffe was led to Medicine as a more favourite pursuit, and, according to Dr. Webb, became an admirer of the famous Dr. Thomas Willis, at that time the Esculapian god of the metropolis of England. In 1675 Radcliffe took his degree of M.B., and began to look out for practice in Oxford itself; but finding it impossible to touch the ground held at that time in the city by Dr. Lydal, who played into the hands of the apothecaries, and having offended Dr. Marshal, the Rector of Lincoln College, he cast the dust of Oxford off his feet. He came to London, and settled in a fashionable spot in that dismal street near Covent-garden which the Bow-street runners have since made famous as the theatre on which they played their interesting manœuvres—Bow-street. In London Radcliffe soon found scope for his talents, or, I had rather said, his peculiarities; for he became the Abernethy of his period. His drolleries and eccentricities made him notorious, if not famous; and Dr. Webb, always so learned and so quaint, actually tells us that Radcliffe's patients often feigned illness and paid their guineas in order that they might have an opportunity of enjoying a few minutes' conversation with the humorous Doctor. These were patients, indeed! And I, for one, think it a crying sin that the race has died out. In the course of his life, Radcliffe held very important appointments. He attended the Princess Ann of Denmark, James the Second, William the Second, and Queen Mary. His eccentricity, however, was offensive to Dutch William, who, having shown his dropsical legs to the blunt Doctor, and having asked for a candid opinion as to his condition, received, as a reply from the Esculapian, "Why, truly, I would not have your Majesty's two legs for your three kingdoms."

Radcliffe had political sentiments, and the year before his death, 1714, was elected M.P. for Buckingham, but what figure he made in the House we have no record. He died on the 1st of November, in the year we have named—1714—his death being accelerated, it is thought, by the disfavour he obtained from refusing to visit Queen Ann in her last illness.

Radcliffe was buried at Oxford in St. Mary's Church, and his name is especially connected with the city, from his having established the Radcliffe Travelling Fellowships, and having left two great legacies,—one of £5000 for additions to University College, and £40,000 for the building of the famous Radcliffe Library, with endowments attached thereto, of which more will be said in the proper time and place.

GENERAL CORRESPONDENCE.

THE USE OF SILVER WIRE FOR SECURING THE PEDICLE OF AN OVARIAN TUMOUR.

Letter from Mr. I. Baker Brown.

[To the Editor of the Medical Times and Gazette.]

Sir,—In the interesting discussion on an ovarian tumour exhibited by Mr. Holmes, at the meeting of the Pathological Society of May 3, reported in your journal of last week, there are one or two remarks requiring correction:—

First, Mr. Henry Lee stated that it was the first time this plan (*i.e.*, securing the pedicle by twisted silver wire, and returning it into the abdomen) had been adopted in this country. In answer to this, allow me state that in the *Lancet* of December 20, 1862, p. 676, a case (No. 6) is reported in which I had pursued this plan on June 19 of that year. Besides this, the case related by Mr. Nunn, in which the Fallopian tube was split down three or four inches, and the rent closed by silver wire, occurred in my practice November 1, 1860, Mr. Nunn assisting me. It is published in the Obstetrical *Transactions*, vol. iv., p. 75, as Case 6; also in my work on Ovarian Dropsy, p. 231, and p. 276, as Case 25. Further, I have closed a wound in the uterus made during ovariotomy, November 21, 1861, by six silver sutures, the patient recovering and menstruating regularly afterwards (Obstetrical *Transactions*, vol. iv., p. 81, as Case 16, and in *Op. Cit.*, p. 244 and p. 280, as Case 35).

On numerous occasions I have secured adhesions, especially to the omentum, by silver wire, cutting off the ends. On September 9, 1862, I secured a mesenteric artery, which was bleeding freely, during operation by silver wire, the patient recovering.

Since the introduction of Mr. Charles Clay's adhesion clam, I have divided all adhesions and arrested hæmorrhage by actual cautery, and now divide the pedicle by the same method. The success attending this practice will, I believe, cause it to supersede all other methods of securing the pedicle in ovariotomy.

One other point requires explanation:—Dr. Graily Hewitt said that Dr. Tyler Smith was the first to cut the pedicle off short, and return it at once into the abdominal cavity. If Dr. Hewitt had said "the first in this country," he would have been right; but this same plan had previously been adopted successfully by Dr. Rogers, of New York, in 1829; Dr. Bellinger, of Boston, U.S., in 1835; and Dr. Siebold, of Darmstadt, in 1846. I am, &c.

I. Baker Brown.

17, Connaught-square, Hyde-park, W., June 5.

SEWAGE DIFFICULTIES.—ASYLUM SEWAGE IRRIGATION.

Letter from Dr. Robertson.

[To the Editor of the Medical Times and Gazette.]

Sir,—I have read with much interest the paper in your last number by my friend Dr. Clouston, relating the unfortunate experiment at sewage irrigation at the Cumberland Asylum. As opposed to his experience, will you allow me to add mine at the Sussex Lunatic Asylum, Hayward's-heath? The asylum contains 500 patients, and is situated on an elevated range facing the South Downs. The soil is heavy clay (the Sussex weald); but it has been well drained throughout since it came into the occupation of the county.

The asylum was opened for the reception of patients in 1859. No cases whatever of fever or dysentery or any diarrhœa, save such as naturally follows the course of phthisis, etc., have occurred during the six years the asylum has been open. The drainage and sewage of the asylum are mixed together, and pass in earthenware pipes through small tanks, made for the

purpose of watering the vegetable garden by pump and water-pots, direct on to the grass land, to which it is throughout the year applied, unfiltered in any way, by surface irrigation. The only precaution used is the daily addition of a mixture of carbolic acid, lime, and water to the sewage. This mixture is poured every morning into the garden tanks, and the yearly cost of this disinfectant is about £5. The sewage passes on the land entirely free from smell. I am constantly myself superintending the irrigation, and I never experienced the slightest inconvenience or unpleasantness. The meadows irrigated are within 225 yards of my quarters, and I should not have the slightest objection, were the sewage thus disinfected, to see it flow within twenty-five yards of my windows.

The result is a mine of wealth. We have nearly forty acres of meadow and Italian-rye grass thus irrigated, and I am now cutting the second crop of rye grass. I carried home the first portion of my hay crop on the last day of May.

The system of irrigation was planned and carried out under the advice of Mr. Alderman Mechi by Mr. King, C.E., who was also introduced by me to Dr. Thurnam, for whom I believe he has carried out similar works at the Wilts Asylum. The entire cost here was £3 an acre. The meadows before irrigation were hardly worth £1 an acre; I should now willingly rent them at £5 an acre. The manner in which the sewage rye grass increases the richness of the cream and butter is almost incredible.

In reading Dr. Clouston's paper, it appears to me that he erred in using the sewage undiluted by the water from the baths and lavatories. He also appears to have collected the solids in a large tank, and apparently not to have used disinfectants. Also he admits that the fluid sewage was roughly and unscientifically allowed to run over the fields, probably forming small pools and deposits.

Excuse, Sir, this hasty letter, written amid much pressure and work. I am, &c.,

C. L. Robertson, M.D. Cantab.

Hayward's-heath, Sussex, June 5.

THE HYPODERMIC METHOD.

Letter from Mr. Charles Hunter.

[To the Editor of the Medical Times and Gazette.]

Sir,—There are two or three points on which I would remark if you have space in your next number. As the Royal Medical and Chirurgical Society have deemed the subject of my paper worthy of examination by a committee, I would observe that most of the points alluded to in the discussion of the Society have been considered by me in the series of communications that appeared in the *Medical Times and Gazette* in 1858 and 1859. In them I compared the endermic, the lingual, the stomachic, and the rectal with the hypodermic method, and devoted one paper more especially to cautions and the mode of operating.

I believe I fairly considered the relative advantages of each plan, and I still think that for the administration of some medicines, more especially of hypnotics and anodynes, the hypodermic is the method most to be relied on for uniformity and certainty of action.

In your number for October 8, 1859, I even gave the preference to the rectal method in certain cases over the hypodermic. My subsequent more extended use of the latter plan in intestinal cases, as of obstruction, of ileus, of enteritis, colic, etc., inclines me to withdraw that preference, so quickly and effectually have I since found the relief afforded in such cases by the injection of the anodyne in the arm, the thigh, or over the abdominal parietes. (The latter is the most difficult site for painless introduction of the needle.) Besides, delay of effect is scarcely probable by the subcutaneous injection, whilst it is more than probable, from different causes, by the rectal method, and has occurred, as Dr. Stewart's case of delayed belladonna absorption showed.

Mr. Savory will, I think, find that strychnia is as rapidly absorbed from the cellular tissue as from the rectum. The $\frac{1}{12}$th of a grain hypodermically injected will tetanise a cat in one minute, and produce death in two minutes. The rectal administration of the same dose could hardly act quicker; it might be delayed, or even lost in part.

One word in reply to numerous inquiries. I do not inject into the skin, but into the loose cellular tissue beneath it.

I am, &c. Charles Hunter.

Wilton-place, Belgrave-square, June 6.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, April 5.

Dr. Barnes, President, in the Chair.

Dr. J. Braxton Hicks exhibited an improvement on the mode of fastening the rope in his écraseur, which will allow any length of rope to be used, thus doing away with the awkward and cumbersome addition of the endless drum of Weiss. Instead of using one hook or button on which to fasten the moving end, two hooks are now employed back to back, whereby two figure-of-eight hitches can be made, sufficient to keep the rope from slipping. Should, during an operation, the hooks come down to the end of the screw without having brought all the noose through the eye or severed the growth, the hitch can be undone, the hooks run up to the top of the screw, the ropes refastened, and brought down again as at the commencement. The hooks should be made as neatly as possible, but deep enough to hold two turns of rope.

Dr. Marion Sims exhibited a new form of Curette for the removal of uterine fungoid granulations.

Dr. Greenhalgh showed a new form of Uterine Tent made from the stem of the laminaria spiralis, the peculiarity being that it is a hollow tube instead of the solid stick heretofore used. He also showed a new Pelvimeter, in which the index-finger is made available for the purpose of measurement, the size of the pelvic brim being determined by a little contrivance fixed upon the examining hand.

The President exhibited an instrument which he had used for some time past for the purpose of dividing the cervix uteri in certain cases of dysmenorrhœa, metrorrhagia, and sterility. It resembled the scissors used for the same purpose by Dr. Marion Sims.

Mr. R. King Peirce showed a Fœtus, born at full time, and exhibiting at birth two lacerations: one extending through the integuments transversely across the abdomen, about the level of the scrobiculus cordis; a second one across the throat, exposing all the vessels and muscles of the neck. The two lacerations had all the appearance of incised wounds; but the evidence was clear that they had not been produced by any act of violence other than that of rapid delivery.

Dr. Tanner exhibited a Fœtus the subject of Hernia Cerebri and Hernia Umbilicalis. A portion of the membranes were also adherent to the cranium. He also exhibited a photograph of an Anencephalous Fœtus.

Dr. Adolph Rasch read a paper

ON A CASE OF ŒDEMA AFTER A FALL ON THE GRAVID UTERUS; PREMATURE LABOUR; RECOVERY.

The woman, at the end of the seventh month of her second pregnancy, fell down a steep flight of steps on her abdomen, and soon afterwards found herself swollen all over the lower half of the body. The œdema increased to such an extent that her Medical attendant considered her case hopeless. Dr. Rasch saw her eight days after the accident. She had enormous œdema of the belly from the navel downwards; the labia were distended into huge water bladders; both legs swollen; right hypogastric region painful on pressure; a good deal of albumen in the urine, but no casts; pulse quiet; tongue clean. She never had the slightest œdema before the accident. After a few days, Dr. Rasch induced premature labour, and the albumen and œdema then perfectly disappeared. Dr. Rasch considered the case interesting in point of diagnosis, and held that the œdema was produced by the pressure of the uterus on the vena cava inferior, which would also account for the albuminuria. The author then specially directed the attention of the Fellows to Breslau's mode of inducing premature labour by simply introducing and keeping in the uterus an elastic catheter.

Dr. Tyler Smith remarked that this operation was much practised by Professor Simpson in Edinburgh.

In reply to Dr. Graily Hewitt, Dr. Rasch remarked that a distended bladder could not have been the cause of the œdema, as there were no symptoms of retention. He also differed from Dr. Hewitt as to the possibility of coagula in the vena cava having caused the œdema, as they could not have disappeared so rapidly without symptoms of embolism. He (Dr. Rasch) could not explain the case otherwise than by pressure of the uterus on the vena cava, which was very favourably

situated for that condition where it passes over the right side of the sacral promontory.

Dr. Meadows read the particulars of a Case of Monstrosity, and made some

REMARKS ON THE INFLUENCE OF MENTAL IMPRESSIONS AS A CAUSE OF BODILY DEFORMITY.

Having first expressed his conviction in favour of the proposition that the mind can and does act in this way, he reviewed and combated the various objections urged against it, the principal one being the absence of any direct connexion between the nervous system of the mother and that of the fœtus through the umbilical cord. He, however, endeavoured to prove—or rather suggested the possibility, as it was not a matter admitting of any distinct proof—that mind, or the mental force, was not and could not be thus bound down, as it were, by the anatomical limits of the nervous structures; that it must have a power of action, if it has any action at all, throughout the entire organism, and in every part of it, whether it possessed nerves or not;—in other words, that its sphere of action was only limited by the configuration of the body. Hence it was inferred that in those tissues where the existence of nervous elements could not be demonstrated, the mental or nerve force might, as it were, pass across the intervening matter between any two parts where nerves did exist, just as electricity traversed space between any two conductors. The author then applied this reasoning to the case of the fœtus in utero, and offered an explanation of the mode by which mind thus acts upon matter by supposing a kind of correlation between mental and nerve force analogous to the correlation of other physico-vital forces, the nerve force being here the active agent in those nutritive processes upon the changes of which deformities depend.

Dr. Rasch said he had listened with great pleasure to Dr. Meadows's paper, which boldly took up what was generally left to women, but which certainly deserved scientific investigation. The belief in the influence of mental emotion on the formation of the fœtus was as old as it was general amongst women. The great difficulty was to establish facts, as the mothers always recollected something from their pregnancy after they found something abnormal in their children. Dr. Rasch had seen two cases which had somewhat struck him, and of which he had taken notes. Two boys from different parts of Germany were brought to him with scarcely any foreskin, looking exactly like circumcised little Jews, but without any cicatrices. Both women narrated, with great emotion, how they had seen during their pregnancies little Jews so cruelly treated that they could not forget it! They both had been present at the well-known Jewish rite. He ought to mention, however, that he had observed the same state in other little boys where no such story was volunteered, and where the mothers did not know that this state was abnormal. He considered this influence on the fœtus an open question, which he had made up his mind to help in solving whenever there was an opportunity of doing so.

The President observed that the instances most strongly bearing upon the question were those in which pregnant women stated explicitly the emotions supposed to influence the form of the fœtus in utero which they had undergone. One such case had been placed in his hands by Dr. Hassall, of Richmond. Certainly the facts of this were very remarkable, inasmuch as the event singularly confirmed the statement of the woman made before her child was born. Dr. Barnes remarked that malformations were common amongst birds as well as quadrupeds; and that in birds it must be concluded that any mental impression must be imparted in the earliest stage of development—*i.e.*, before the ovum was invested with the shell. He cited an anecdote from Captain Speke, which showed that in some tribes in Africa the belief prevailed that emotion in the father might produce monstrous births. The traveller had ordered his native huntsman to expose the embryo in a pregnant doe. He shrank from the task, fearing lest the kid striking his mind should metamorphose his wife's future progeny to the likeness of a fawn.

The Pritchard Case.—The trial of Dr. Pritchard, as already stated, has been definitely fixed for Monday, July 3. On Wednesday afternoon the prisoner was served, in the North Prison, Glasgow, with an indictment, charging him with having murdered his wife and mother-in-law by the administration of various poisons, including antimony, corrosive sublimate, and aconite. The document, which is somewhat voluminous, contains the names of upwards of seventy witnesses, and 150 productions.—*Scotsman.*

MEDICAL NEWS.

Royal College of Surgeons of England.—The following Members of the College, having undergone the necessary Examinations for the Fellowship, at meetings of the Court, on the 30th and 31st ultimo and 1st inst., were reported to have done so to the satisfaction of the Court of Examiners, and at a meeting of the Council on Thursday, the 8th inst., were admitted Fellows of the College:—

Alfred Bowyer Barton, F.R.G.S., The Green, Hampton-court, diploma of membership dated December 17, 1847, of University College; David Henry Monekton, M.D. Lond. and L.S.A., Rugeley, December 18, 1849, of King's College; Thomas James Vallance, M.D. St. And. and L.S.A., Stratford, Essex, June 3, 1851, of the London Hospital; John Wickham Barnes, L.S.A., Rutland-park, Sydenham, February 18, 1853, of the Charing-cross Hospital; John Sebastian Wilkinson, Davies street, May 8, 1857, of University College; Clement Smith Barter, L.M. and L.S.A., Paragon, Bath, April 18, 1859, of St. Bartholomew's Hospital; Edmund Holland, M.B. Lond. and L.M., Emsworth, April 19, 1860, of University College; John Langton, Bloomsbury-square, April 10, 1861, of St. Bartholomew's Hospital; William Domett Stone, M.D. St. And., L.M., and L.S.A., Lincoln's-inn-fields, April 10, 1861, of the Middlesex Hospital; William Powell, M.B. Lond. and L.S.A., Tower Hamlets Dispensary, April 11, 1861, of the London Hospital; Thomas Starkey Smith, M.B. Lond., Warrington, April 17, 1861, of University College; John Harward Hooper, C.M. and M.B. Lond. and L.S.A., Tenby, April 17, 1861, of St. Thomas's Hospital; and John William Teale, M.A. Oxon, Leeds, May 9, 1862, of King's College.

The following members of the College, having been elected Fellows at previous meetings of the Council, were admitted as such on the above occasion:—

Thomas Mills Beaumont, L.R.C.P. Edinb., Knaresborough, Diploma of Membership dated April 11, 1834; Samuel Day Fereday, Dudley, Worcestershire, November 11, 1836; Joseph Rickerby Donald, Paradise-terrace, Holloway, November 1, 1839; and Edward Berney, High-street, Croydon, May 3, 1841.

Licentiates in Midwifery.—The following members of the Royal College of Surgeons, having undergone the necessary Examinations at a meeting of the Board on the 7th, obtained the Midwifery License:—

John Roche, M.D. St. And. and L.S.A., Fermoy, Ireland, diploma of membership dated April 8, 1856; Thomas Aeoy, L.S.A., Hull, July 16, 1858; Samuel Rains, Manchester, January 21, 1863; John Tasker Evans, M.D. and C.M. Aberdeen and L.S.A., Hertford, April 12, 1864, of St. Bartholomew's Hospital; Augustin Barber Fry, L.S.A., Kibworth, Leicestershire, May 24, 1864, of Guy's Hospital; William Heath Strange, L.S.A., Streatley, near Reading, May 24, 1864, of St. Thomas's Hospital; William Melville Knipe, L.S.A., Rotherhithe, May 24, 1864, of Guy's Hospital; Thomas Collier, L.S.A., Bridgend, Glamorganshire, July 26, 1864, of Guy's Hospital; Philip Burnard Chenery Ayres, Bedford, November 15, 1864, of University College; Richard Bugden, Tachbrook-street, Pimlico, May 11, 1865, of the Westminster Hospital; William Cunningham Cass, Cowes, Isle of Wight, May 23, 1865, of University College; and Samuel Gourley, M.D. Glasg. and L.R.C.S. Edin., West Hartlepool (not a member).

Apothecaries' Hall.—Name of the gentleman who passed his Examination in the Science and Practice of Medicine, and received a Certificate to Practise, on Thursday, June 1, 1865:—

Thomas Drake Leigh, Shaw-street, Liverpool.

The following gentleman, also on the same day, passed his first Examination:—

George Birch, Guy's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Andrew, Edwyn, F.R.C.S. Eng., has been appointed Assistant-Surgeon to the 1st Administrative Battalion Shropshire R.V.

Bothwell, G. G., M.R.C.S. Eng., has been appointed Medical Officer for the Workhouse at Underwood.

Baker, W. Morant, M.R.C.S. Eng., has been appointed one of the Tutors to St. Bartholomew's Hospital and College.

Corbett, Mr. R. Delacour, has been appointed Resident Surgical Pupil to the City and County of Cork Hospital.

Duckworth, Dyce, M.D. Edin., has been appointed one of the Tutors to St. Bartholomew's Hospital and College.

Hawken, C. St. Aubyn, M.R.C.S. Eng., has been appointed House-Physician to Westminster Hospital

Martin, Paulin, M.R.C.S. Eng., has been appointed one of the Surgeons to the Abingdon Dispensary.

Noel, Vincent Edmund, M.R.C.S. Eng., has been appointed Resident Clinical Assistant at the Middlesex Hospital.

Pearse, George E. L., L.S.A., has been appointed House-Surgeon to the Westminster Hospital.

Royle, Octavian F. N., M.D. St. And., F.R.C.S., has been appointed Hon. Surgeon to the Westmoreland Orphan Asylum.

Steventon, William, M.D. St. And., has been appointed Medical Officer for the Presteign Union.

SHEPARD, Mr. M. L., has been appointed one of the Tutors to St. Bartholomew's Hospital and College.

SWINDALE, JOHN, M.R.C.S. Eng., has been appointed House Surgeon to the Royal Berkshire Hospital.

VERNON, BOWATER J., F.R.C.S. Eng., has been elected Clinical Assistant to the Royal Ophthalmic Hospital at Moorfields.

DEATHS.

HINXMAN, HENRY J., L.R.C.P. Lond., at Brisbane, Queensland, on March 17, aged 51, late of Lee-terrace, Blackheath.

LANGLANDS, ROBERT, L.R.C.S. Edin., at Nethergate, Dundee, on May 28.

MAGRATH, FFOLLIOTT C., L.R.C.S.I., Assistant-Surgeon H.M.S. *Hesper*, on board H.M.S. *Sovereign*, on his voyage to England, on April 9.

PHILLIPS, J. B., Surgeon, at Towyn, Merionethshire, on May 23, aged 69.

PRIOR, FREDERICK J., L.R.C.P. Lond., at Northfield House, Tewkesbury, on May 22, aged 47.

VACHELL, CHARLES R., M.D. Edin., at Charles-street, Cardiff, on May 26.

VERITY, F. S., M.D., J.P., at Melbourne, Australia, on January 20.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the College held on Monday, June 5, the following officers were elected for the ensuing year:—*President:* Samuel G. Wilmot. *Vice-President:* Richard G. H. Butcher. *Secretary:* William Colles. *Council:* Arthur Jacob, William Hargrave, Robert Adams, James Barker, William Colles, Hans Irvine, Robert Pentland, Thomas L. Mackesy, Awly P. Banon, Peter Shannon, Rawdon Macnamara, Hamilton Labatt, Benjamin M'Dowel, Edward Ledwich, William Jameson, Alexander Carte, James H. Wharton, George H. Hatchell, Albert J. Walsh.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—On Monday, the 5th inst., the annual meeting of the Royal Medical Benevolent Fund Society of Ireland was held at the College of Surgeons, Dublin, under the presidency of Dr. Jacob. The association was reported to be in a highly satisfactory state. A reversionary legacy of £4500 left by the late Mr. Carmichael, had accrued to the society through the death of his widow. Lord Wodehouse has accepted the office of Vice-Patron of the society, rendered vacant by the death of the late Earl of Carlisle. A new auxiliary has been formed in Tipperary; one is expected in Birmingham; and special efforts for the society have been made by Dr. Lord, of Poonah, in India.—*Saunders' Newsletter.*

ROYAL INSTITUTION OF GREAT BRITAIN.—GENERAL MONTHLY MEETING.—The general monthly monthly meeting was held on Monday, May 5, Sir Henry Holland, Bart., M.D., D.C.L., F.R.S., President, in the chair. Mrs. Elizabeth Beevor, Samuel Canning, Esq., Alfred Davis, Esq., David Painter McEuen, Esq., Joshua Metcalfe, Esq., Joseph Moore, Esq., Hamilton Noel Hoare, Esq., Henry Arthur Hunt, Esq., and Henry Lee, Esq., F.R.C.S., were elected members of the Royal Institution. The special thanks of the members were returned for the following additions to "The Donation Fund for the Promotion of Experimental Researches:"—Sir Henry Holland, Bart., Pres. R.I. (seventh annual donation) £40. The presents received since the last meeting were laid on the table, and the thanks of the members returned for the same.

THE HUNTERIAN MUSEUM.—The ship *Wagoota*, Captain Hay, which recently arrived at the London Docks from Hobar Town, has brought, in addition to her ordinary cargo of wool and oil, the complete skeleton of a fine sperm whale (*Physeter macrocephalus*) about sixty feet in length. Although the capture of this animal has been for many years a lucrative occupation to a considerable branch of our mercantile marine, our scientific institutions have hitherto profited very little by its wholesale destruction. The present specimen was taken last year off the south coast of Tasmania, and prepared at considerable trouble and expense by Mr. W. L. Crowther, M.R.C.S., being intended as a present to the Museum of the Royal College of Surgeons of England. It will form a valuable addition to the present magnificent series of skeletons exhibited in that institution, to which Mr. Crowther has already on several occasions been a liberal contributor.

SUPPLY OF MEDICINES FOR PAUPERS.—A return made by the Poor-law Board shows that in the following metropolitan Workhouses the drugs required for the sick are not supplied by the guardians, but have to be provided by the Medical officer:—Greenwich, Lewisham, St. Giles, Camberwell; Bermondsey, Rotherhithe, St. George, Southwark; St. Saviour, Richmond (except cod-liver oil); St. Luke, Chelsea; St. Mary Abbott's, Kensington; St. Margaret and St. John, Westminster (in part); St. James, Westminster; St. Martin-in-the-Fields, St. George, Hanover-square; St. Marylebone, St. John, Hampstead; Hackney, Holborn, St. James, Clerkenwell; East London, and West London.

IRISH MEDICAL ASSOCIATION.—The annual meeting of the members of the above association was held at the College of Surgeons in Ireland on Monday, the 5th inst. The chair was taken by Dr. Mackesy, who adverted to the grievances of which the members of the Profession had to complain, especially the ignoring of the claims of workhouse Medical officers to superannuation allowance by the Government, and the efforts which had been made by the Council to have these grievances redressed. It was suggested by several gentlemen present that the members of the Profession should use their influence at the forthcoming elections to extort a pledge from candidates for Parliamentary honours to support any fair and reasonable measure brought forward in reference to the subject. A number of resolutions expressing the views of the association on these points were adopted.—*Saunders' Newsletter.*

MEDICAL CHARITIES.—The friends of the following institutions will be glad to learn that Mr. William Hollins, of Over Wallop, Hants, who has bequeathed the bulk of his large property to charitable institutions, has not forgotten those in which our Profession more particularly take an interest, having left the sum of £17,700 to be divided in the following manner:—To the Brompton Hospital for Consumption, £1000; Bethlehem Hospital, £1000; St. Luke's Hospital, £1000; the Westminster Ophthalmic Hospital, £1000; the Deaf and Dumb Children's Asylum, £1000; Accident Relief Society, £1000; the Royal Free Hospital, £700; the London Hospital, £500; the Middlesex Hospital, £500; the *Dreadnought* Hospital Ship, £500; King's College Hospital, £500; St. Mark's Hospital, £500; Royal Infirmary for Diseases of Children, £500; St. Mary's Hospital, £500; the London Fever Hospital, £500; the Small-pox Hospital, £500; St. George's Hospital, £500; the London Ophthalmic Hospital, £500; the Great Northern Hospital, £500; the Westminster Hospital, £500; and University College Hospital, £500; to the Winchester Hospital, £2000; and the Salisbury Infirmary, £2000. These two provincial Hospitals will also take any surplus residue. We have thus the pleasure of recording in two consecutive weeks an imposing total of £34,700 bequeathed by two benevolent gentlemen to Medical charities alone.

MEDICAL QUALIFICATION.—DEPUTATION TO THE LORD-LIEUTENANT.—His Excellency the Lord-Lieutenant received on Wednesday a deputation from the University of Dublin, the King and Queen's College of Physicians, and the Queen's University. The following were appointed members of the joint deputation from the three corporate bodies:—Trinity College: Rev. Dr. Todd, Rev. Professor Haughton, and Dr. Stokes. The Queen's University: The Lord Chancellor, the Lord Justice of Appeal, Sir R. Kane, Dr. Corrigan, Mr. Adams, and Mr. Stoney, secretary. King and Queen's College of Physicians: The President, Dr. Lyons, Dr. Aquilla Smith. Mr. Power, Chief Poor-law Commissioner, was present. The Lord Chancellor and Lord Justice of Appeal were unable to attend, and Sir Robert Kane and Mr. Adams were also unavoidably absent. The object of the deputation was to bring under his Excellency's notice a recent order of the Poor-law Commissioners of Ireland, by which they direct that henceforth boards of guardians may receive as a Medical qualification the certificate of the Apothecaries' Company of Dublin as equivalent to a Medical degree or licence from the Universities above named, or from the College of Physicians. Memorials on the subject were presented to his Excellency. At the termination of a lengthened discussion, his Excellency concluded by stating that he should decline interfering with the order.—*Dublin Evening Mail.*

THE CLEWER HOSPITAL FOR CONVALESCENTS.—We have great pleasure in giving publicity to the following account of the proposed enlargement of the St. Andrew's Convalescent Hospital (at Clewer, near Windsor), for invalids of both sexes, under the care of the Sisters of St. John Baptist:—"The work of this Hospital has been carried on for upwards of three years in rented cottages, and has been so successful as to encourage an effort for its enlargement and permanent establishment. It is now proposed to build a house fitted to accommodate twenty-four men, eighteen women, and fifteen children, together with the Sisters in charge. Medical men of eminence are interested in the undertaking, and some are actively engaged as members of the Council in promoting its success. The Hospital provides careful nursing and Medical attendance for invalids who are disqualified for admission to, or have been discharged from, ordinary Hospitals; that as far as possible employment is sought out for patients

who on their recovery may require such assistance; that in cases of incurable disease, there is secured a quiet home during the remainder of life. A site of four acres in extent has been given, and a sum of about £3500 towards the building is already secured. The entire amount required for the main portion of the building now proposed to be erected, including every convenience recommended for the comfort and health of the inmates, is £7200. An additional sum of about £3000 will be required for the east wing, including a chapel, dining hall, chaplain's room, and offices, which, it is hoped, may be erected at some future period. Her Majesty the Queen has been graciously pleased to give a donation of £100 towards the building fund, with the promise of an annual subscription of £20 for the maintenance of a patient."

Collegiate Election.—The usual notice of the annual election of Fellows into the Council of the College of Surgeons has been sent to all the Fellows whose addresses are known to the secretary. The circular, which bears date June 2, states that the meeting will be held in the Hall of the College in Lincoln's-inn-fields, on Thursday, the 6th day of July next, at 2 o'clock in the afternoon precisely, for the election of three Fellows into the Council, in the room of Mr. James Moncrieff Arnott, a life member, resigned, and of Mr. Richard Quain and Mr. Alexander Shaw, going out in rotation. The circular has an enclosure containing extracts from the Charter and Bye-laws of the College, relating to the election of members of the Council, and it is to the second page of this enclosure to which we more particularly direct the attention of the electors at the present moment, as a neglect of the mode of procedure at this election may entail great disappointment on those gentlemen desirous of a seat in the Council, as well as to their friends generally. The Bye-law states distinctly that: "The place and time appointed for every meeting of the Fellows for the election of members or a member of the Council shall be announced in the *London Gazette* and in two London daily newspapers, not less than thirty days and not more than forty days before the day of meeting. Every Fellow desirous of a seat in the Council shall, *within ten days from the publication of the London Gazette*, in which the day of meeting for the election shall be announced, transmit or deliver to the Secretary of the College or person acting for him, a notice and declaration signed by himself in the following terms:—I, A. B., of C., Fellow of the Royal College of Surgeons of England, do hereby declare that I am a candidate for a seat in the Council of the said College; that I am in the *bonâ fide* practice of the profession of a Surgeon, and that I do not practise as an Apothecary"—together with other official notices which may be obtained on application to the Secretary. Now, as few readers of the *Medical Times and Gazette* ever see the *London Gazette*, it may be as well to inform them that the official announcement appeared in that paper on Friday last, the 2nd inst., consequently all papers must be sent in to the Secretary on or before Monday next. We are particular in drawing attention to this circumstance, as notwithstanding the report of so many candidates coming forward on the present occasion, it is stated that up to Thursday only two candidates had sent in their papers—viz., Mr. Turner, of Manchester, and Mr. Erasmus Wilson, of London, and, of course, the retiring members of the Council, Messrs. Quain and Shaw. The names of seven other gentlemen have been mentioned as likely to offer themselves—viz., Messrs. Charles Hawkins, Simon, Paget, Hewett, Holt, Ure, and McWhinnie. After Monday no papers can be received. A regret, in which many of our readers will participate, has been expressed—that Messrs. James Paget, John Simon, Prescott Hewitt, and John Erichsen do not offer themselves on this occasion. The name of Dr. Wiblin, of Southampton, has been mentioned as a good man to represent the provincial element with Mr. Turner, of Manchester.

Old "Conservative" Surgery.—Felix Würtz, a Swiss Surgeon of deservedly great note in his day, a contemporary of Ambrose Paré, was as strong an advocate of "conservative" Surgery as any of his modern successors. "I have related this case," he says in his "Practica," "in order to show you that you must not incontinently proceed to extirpate a limb, crushed or wounded to the last point though it be, as many Masters do at the present time, who, without considering and trying whether they can heal a part or not, at once amputate without any other form of trial, in order to exempt themselves from the time and labour which must be expended in order to cure and conserve the part. . . . . I do pray and faithfully exhort you not to amputate or cut off any part, though contused and half separated; for I have seen incredible things in the way of cure and reparation. I have myself preserved arms, legs, etc., in great numbers, which other Masters in Surgery had concluded and resolved to amputate, and which, by the grace of God, were healed well. No wooden leg will ever be worth that which we can retain."

Justifiable Homicide.—Mr. R. Debenham, Surgeon, of Heath-street, Commercial-road, has been charged at the Thames Police-office, on his own confession, with having caused the death of a man who was seen by him lurking on his premises at midnight on Monday last. Four attempts having been made to break into Mr. Debenham's premises in the course of the last few months, he was naturally on the alert, and at the time mentioned hearing a noise at the back of the house he got out of bed, and on looking out of the window saw the figure of a man crouching against the wall by the kitchen window. After summoning him several times, and threatening to shoot him, he cocked his pistol, and as the man still returned no answer he fired, and saw the man fall. Mr. Debenham states that he only intended to frighten the man, and did not intend to hit him. He immediately went to the station-house and informed the inspector of police. It was found that the man had been shot through the head and killed on the spot. A large number of gentlemen offered themselves as sureties for Mr. Debenham's appearance, and bail was accepted and the prisoner set at liberty. A coroner's inquest has been since held on the body, and the jury have returned a verdict to the effect that the deceased was shot accidentally by Mr. Debenham.

Training an Heir to the Throne.—It appears that her Majesty the Empress had a special reason for taking her children to Ischl. For some time it has been observed that the Archduke Rudolph, the heir apparent to the throne, has lost much of his fresh colour and healthy appearance, but the cause of the change in the child's health was not known to the public untill yesterday. A few days ago Dr. Löschner, a Physician in whom the Emperor and Empress have great confidence, was summoned from Prague, and, after having carefully examined the little patient, recommended temporary change of air, and a total change in the system of education. The Archduke, who is not 7 years of age, was not long ago taken out of the hands of his aja, or governess, and entrusted to the care of General Count Gondrecourt, who lost no time in beginning to give the child such an education "as would speedily make a man of him." The little boy was practically taught five languages at one and the same time by means of attendants of five different nationalities; he was regularly drilled, and every now and then he was awakened in the night in order that he might learn to have his wits about him. The results of such an absurd system of education were soon apparent, and the heir to the Austrian Throne is now at Ischl for the benefit of his health. General Count Gondrecourt, who knows how to handle a brigade as well as any man in the service, has got leave of absence, and the chances are that he will soon cease to be ayo, or tutor, to the Emperor's only son. —*Times' Vienna Correspondent*, June 3.

The "Times" a Good Splint.—A gentleman signing himself "Anglo-American, M.D." has written to the *Times* to point out the admirable qualities of that paper as an extempore splint. A friend of ours suggests that it must be on account of its "wooden qualities." However, we extract the account of the case in which the *Times* was put to so good a use. It certainly does credit to the readiness and handiness of the Anglo-American:—"I was at the Derby on Wednesday in company with my friend, Mr. H. B. A young man, an ensign in the 77th Regiment, in trying to enter a railway carriage as the train was backed into the depôt at Epsom, was thrown down by the side of the track, and his ankle was seriously injured by a wheel of one of the carriages. I happened to come to him soon after he was taken up from his perilous position. He was then standing on one leg, and was held erect by some of his friends. His agony was very great. I had him laid flat down on the sward, cut his boot open, removed it, and found the injury chiefly on the outer side of the ankle. The ligaments were here ruptured, and the parts were excessively contused and swollen. Without entering into any Surgical details, which would be here out of place, I may briefly state that splints and bandages were necessary to give proper artificial support till the patient could be taken home or to a Hospital. What was to be done? I had no such Surgical appliances. I was in a great hurry to

get home, and humanity forbad my leaving a fellow-being unattended. The thing that I needed was a bit of pasteboard, but how could we get it in time to leave in twenty minutes by the next train, for Epsom is at least a mile and a-half from the new station? Fortunately for me, emergeney always ealls forth resources. As I wanted a snbstitute for pasteboard, my first idea was to take my hat and cut it into splints. But just as I was on the eve of doing this, I pulled the *Times* out of my poeket, and folding it into the shape of a splint abont 13 inches long, and 3½ inehes wide, I placed it along the inner side of the leg, extending it below the ankle, and doubling the lower end under the bottom of the foot. I then asked for another newspaper, and my friend Mr. B. drew a *Punch* from his pocket, which, properly folded, was placed on the outer or injured side of the leg and ankle. I happened to have in my poeket a handful of fine cotton wool, which I placed under this splint. Three pockethandkerehiefs served to hold these paper splints securely in place. We gave our patient in the meantime a little brandy and water, and in twenty minutes after the accident we were in the train for London-bridge, where we arrived in about an honr and ten minutes.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Rheumatism.—Read Madden on "Change of Air." It is the fairest and most practical work for your purpose.

Philo-Alexander.—We cannot publish our correspondent's new reading of K.C.B. It is one of those things that belong to the unwritten.

A Subscriber.—A man with a degree may use it: but no foreign degree can be registered except under special exceptional regulations.

A Student, A Guardian.—There will be a Preliminary Examination in Arts at the College on the 20th, 21st, and 22nd inst. The fee is 15s.

A Fellow.—The annual festival will take place on the evening of the election. Mr. De la Garde, of Exeter, has consented to preside. Write to Mr. Hulme, of Gower-street, the indefatigable Hon. Secretary, who will, no doubt, enter you on the list of stewards.

A Manchester Fellow.—The rule observable on these occasions is to invito alternately a provincial and metropolitan Fellow to take the chair. It is stated that Mr. Wormald, the President elect of the College of Surgeons, will fill the chair next year.

J. H. B., M.D.—The list of Fellows in seniority may be seen on application to the Secretary of the College, but seniority does not rule elections now. Mr. Fergusson's return was a singular illustration of this fact.

Wet-nursing.—A correspondent, whose well-known signature, M. A. B., is often appended to communications in the journals devoted to sanitary and philanthropic objects, writes to us to complain of the sentiments we have expressed with regard to wet-nursing. We have such an unfeigned respect for M. A. B., and regret so much to see energies that might be employed with so much benefit to society absolutely squandered in barren and unpractical disquisitions, that we venture once more, in all humility, to put the truth and matter-of-fact of the subject in an intelligible light, promising that if we fail now we will hold our tongue in shame, and not mention wet-nurses for a year at the least. Nature is much more prodigal in providing babies than in providing the means of feeding them. In other words, many women have babies, living and healthy, but cannot suckle them. M. A. B. says, "Except in *very rare* cases, Nature unerringly provides the proper nourishment for the infant." We say that, instead of *very rare*, M. A. B. should say *very many*. We have a casual witness, Dr. Joseph Brown, the venerable and accomplished Physician of Sunderland, who, in a little book just published, and entitled the "Food of the People," laments the frequent and increasing inability of young women in towns to suckle their infants. If M. A. B. were to look at a hundred young town women, such as lose their teeth early, and were to feel their pulses and consider their stamina, she would see that they are far more ready to be married than able to suckle a baby. Secondly, some babies whose mothers cannot suckle them can be brought up by hand; others cannot. The task of rearing an infant by hand often requires the greatest patience, skill, temper, knowledge of variety of food, and money. Even with all these advantages, some infants cannot be reared on anything but woman's milk. If these facts be denied by M. A. B., of course there is an end of the argument. If admitted, let us go to the next point. Given a child which cannot be reared by hand, is a mother justified in hiring a wet-nurse? M. A. B. has read the story of the Judgment of Solomon too often, and knows the female heart too well, to hesitate to answer, Yes! What mother seeing her own infant dwining away would hesitate to accept the offices of a stranger? A mother's instinct is ample justification. Lastly, there are women, especially unmarried ones, who have babies which they positively cannot feed. The very generation and existence of a babe born out of wedlock is an anomaly. The English law throws the burden on the mother. The existence of the baby renders her infamous in the eyes of her own sex. There are no occupations that a poor woman can follow which enable her to earn enough to keep an illegitimate child, and so the child must starve. Wet nursing is a loophole for such women. By taking charge of the child of a stranger they are able to pay for the maintenance of their own child, who, probably, is better able to be reared by hand-feeding, and who can't be worse off anyhow. Therefore, the employment of a single woman as wet nurse may be the means of saving two infants' lives, if not that of the mother also. The idea of saving the lives of illegitimate children by forbidding the mothers from taking places as wet nurses is one that promises not much. Such mothers usually wish their children to die; and the wish is father to the fact. No Act of Parliament can make a woman keep her child alive if she has made up her mind that it shall die. We have seen wretched babies dying of famine whom the mother has refused to suckle. Who can make her? Meanwhile, instead of these profitless *logomachies*, the world is expecting from "M. A. B." a series of experiments and chemical analyses on the composition of cows' milk, under a great variety of food, with a corresponding series of experiments to demonstrate what the kind of cows' milk is which is best adapted for young babies. Curiosity and expectation have been raised, and await the promised information. The daily calculation of the weight and quality of the cow's food, the quantity of milk yielded, the chemical composition of the milk from day to day, compared with what it was before the experiment began and after it is over, the temperament and condition of the cows experimented on, and a comparison of their milk with that of other cows at similar periods of lactation, and the effects on the condition and excretions of the infants experimented on, would form a noble series of experiments, worthy any one of fortune, leisure, and benevolence.

Corrigendum—Dr. Bence Jones' Lectures.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I shall be much obliged to you if you will state that, at page 540, in my lecture on the Diet in Gout, an error of calculation has occurred. The quantities of nitrogen and carbon in eggs, meat, and bread require correction, so that the minimum diet in gout will not be so low as I have stated it to be. I am, &c.

31, Brook-street, June 5. Henry Bence Jones.

Poor-law Medical Relief.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—If you can find space for the following letter, I shall feel obliged, as it may be of interest to the Poor-law Medical officers. I am pleased to hear that the Workhouse Visiting Society have been so far successful in their deputation to the Poor-law Board as to have induced the President to appoint a Medical Inspector. I sincerely trust Dr. Edward Smith's appointment may be of a permanent character, and that the Medical Department of the Poor-law Board may yet be presided over by a Medical man; for, until that be the case, it will be in vain to expect a perfect system of Poor-law Medical relief. I am, &c.

12, Royal-terrace, Weymouth, June 3. Richard Griffin.

*** We are informed that Dr. Smith's appointment was not made on account of any representations of the Workhouse Visiting Society. We gladly join Mr. Griffin, however, in congratulating the Profession on the fact that Dr. Smith, as a Medical man, has obtained an Inspectorship. He will fulfil the duties of Inspector of one of the Midland districts, vacant by the death of Mr. Manwaring.

"12, Royal-terrace, Weymouth, June 3, 1865.

"My Lords and Gentlemen,—On Tuesday last, in consequence, I believe, of the printed letter sent by me to each of the Guardians of this Union, the subject of your circular letter, respecting cod-liver oil, quinine, and other expensive medicines, was again brought under the consideration of the Board. Mr. Gulson, your Inspector, was present, and informed the Board that the resolution of the Select Committee of the House of Commons on this question was only carried by a majority of one, and that the President of your honourable Board voted against it; but as there was a majority in favour of it, your honourable Board was bound to issue the circular letter. After this statement, no surprise need be evinced that the Guardians decided on leaving things as they are. My Lords and Gentlemen, I deeply regret that Mr. Gulson should have made this statement, as it will convey the impression to the public that your circular letter was never intended to be carried out, and thus bring into disrepute your honourable Board. Mr. Gulson made inquiry as to whether I was permanently appointed, and, on being answered in the affirmative, said, if I had not been, the Guardians could have given me notice to determine my appointment; he also said I had given your honourable Board a great deal of trouble. I need not tell your honourable Board that a statement of this kind must convey the impression that the Guardians have only to look out for a charge against me, and your honourable Board will not be slow in acting upon it. This may be a mistaken idea on my part, but I can assure you that a Medical friend said to me, 'Under the circumstances, I should say you had better resign.'

"My Lords and Gentlemen, I fully admit I have given your honourable Board a vast amount of trouble, but I beg you will recollect, as my excuse, that I am advocating the cause of the million and a-quarter of sick poor annually under treatment, and also that of the 3100 Medical officers to whom you pay a stipend so small that it averages not more than 3s. per patient. Pray bear in mind that the Select Committee on Poor Relief have by their resolution recommended that 'cod-liver oil, quinine, and other expensive medicines shall be supplied by the guardians,' thereby confirming the impression that the poor have not those medicines at present in such quantities as may be requisite. Mr. Alderman Sydney, on May 22, stated in the House of Commons 'that, although the State paid one-half the salaries of the Medical officers, those salaries were so

small that the Medical officers, being required to provide their own drugs, where stimulating prescriptions were required, the people only got counterfeit prescriptions.' (*Times*, May 23.) Surely, my lords and gentlemen, after this statement, made, as it was, by a member of the late Select Committee on Poor Relief, and in the House of Commons, too, you will not allow your circular letter to become a dead letter. For the sake of the poor, I earnestly entreat you to insist upon your recommendation being at once complied with, and, in part at least, carry out the wish expressed by Alderman Sydney 'that another Parliament would not bring its labours to a close without reducing our Poor-law legislation into a useful and well-digested code.'

"In your circular letter you 'request the guardians, however, to be good enough to consider whether an alteration in those arrangements as regards the supply of medicines referred to cannot be effected whenever new appointment of a Medical officer is made, or with the consent of the present Medical officers during the continuance of their existing contracts.' What are our contracts? Sec. xlvi. of the 4th and 5th Will. IV. directs guardians to appoint paid officers, and it empowers commissioners to determine the continuance in office, which you have done by an order; is also declares 'that when the said commissioners may see occasion to regulate the amount of salaries payable to such officers respectively, and the time and mode of payment thereof.' From this quotation it appears to me that, although a majority of your officers are permanently appointed by order, still you have the power at any time 'to regulate' the amount of our salaries. That need not, therefore, prevent your directing the guardians to carry out the instructions conveyed in your circular letter; but, my lords and gentlemen, allow me to observe that you cannot in fairness call upon your present Medical officers out of their scanty salaries to contribute towards the supply of that which the Select Committee believe is not now found to any great extent. If it be desirable that the poor should be furnished on a more liberal scale than at present with cod-liver oil, etc.—and I unhesitatingly say they ought to be—then call upon the guardians to consider the supply of these articles as extras, and independent of the salaries of the present Medical officers, and thus at once remove the stain cast upon the Medical relief of the poor both by the resolution of the Select Committee and the speech of Mr. Alderman Sydney. "I have the honour to be,

"My Lords and Gentlemen,

"Your obedient servant,

"The Poor-law Board." "RICHARD GRIFFIN.

DR. LEARED AND PROFESSOR HANNOVER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In an account of a new parasite discovered by me in the blood of the common turtle, published in the 13th vol. of the *Transactions* of the Pathological Society of London, I mention that I found associated with it certain fusiform ova, previously described in the *Dublin Journal of Medical Science*, November, 1860, by Mr. E. Canton as having been found adhering to the eyes of turtle. I have received a letter from Professor Hannover, of Copenhagen, informing me that the ova in question had been figured and described by him in his work on the Eye, published in 1852, and requesting that I would make this fact known. May I beg, therefore, that you will favour me by inserting this note in your widely-circulated columns. I am, &c.

12, Old Burlington-street, June 1. ARTHUR LEARED.

ARTIFICIAL FOOT AFTER AMPUTATION AT THE ANKLE-JOINT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In reference to Mr. Henry Lee's new method of amputation, permit me to quote the following case:—

A man living at South Cerny had his leg amputated at the ankle-joint. He had a good fleshy covering on the end of the stump, so that the difference in the length of the two legs was very slight. I made for him an artificial leg and foot in the usual manner, with pressure to be borne round the limb above the stump, leaving that quite free. About twelve months after he came to see me. He had cut away the upper part of his artificial leg, and the whole weight of his body rested upon the end of the stump. He told me he could walk better that way, as the pressure round the limb had caused it to waste away, and it hurt him so much that he removed it entirely. As long as he could keep the end of the stump from moving about in the socket, which I eventually accomplished, he could walk with perfect ease, and, he added, "could do as hard a day's work in the fields as any man in the parish." I am, &c.

420, Oxford-street, London, W., June 3. J. F. PRATT.

QUERY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—When, and of what, were artificial teeth first made in England? The following advertisement appears in an old almanack, "Rider's British Merlin: for the Year of our Lord God 1744. Printed for the Company of Stationers." If it may be trusted, we have not much improved since:—"Artificial Teeth, set in so firm as to eat with them, and so exact as not to be distinguished from natural. They are not to be taken out at night, as is by some falsly suggested, but may be worn years together; yet are they so fitted that they may be taken out and put in by the person who wears them at pleasure, and are an Ornament to the Mouth, and greatly help the speech; Also Teeth are cleaned and drawn by John Watts and Samuel Rutter, Operators, who apply themselves wholly to the said Business, and live in Racquet-court, Fleet-street, London."

I am, &c. D.

EPIDEMIC INFLUENZA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—During the past month an epidemic influenza, chiefly confined to children, has been, and still is, very prevalent in this district. In some twenty or thirty cases which have come under my own observation, the disease has in every instance first attacked the "baby in arms" with the greatest severity, and although spreading rapidly over the younger members of the family, becomes gradually shorter in duration and less severe in its characteristic symptoms, until, with the advanced age of the patient, it seems to have lost all power of further contagion—unlike the epidemics of 1803 and 1833, more especially the latter, in the month of April, when the weather was unusually mild. It is worthy of note that during the month of May we have had very sudden and extreme changes of temperature, with exceedingly high and cold north-east winds, and that on the day preceding the attack the little sufferer has invariably been exposed for hours in the open air. Although I am a firm believer in the theory that there exists some *temperies aëris occulta*, to which the disease is owing in the first instance, I cannot, in reason, abandon the notion of its spreading afterwards by contagion and personal intercourse.

I confess I am at a loss to assign a reason for the fact that the disease has not, as far as I am aware, attacked a single adult in the family, while several of the younger members have been very seriously indisposed. In every first case the peculiar symptoms of the epidemic have been well defined—sudden attack, face flushed, swollen, eye dull and watery, intense fever, oppression, and difficulty of breathing, with great languor and debility.

The treatment I have adopted is very simple, yet perfectly efficient. The hot bath, sinapisms to the chest in front and between the shoulders, an occasional alterative, with mild antimonials and expectorants, and, in the latter stages, with debility, bark.

I am, &c. HUGH W. THOMSON, M.D.,

Medical Officer Military Constabulary and Dispensary,

June 1. Belturbet, Co. Cavan.

APPOINTMENTS FOR THE WEEK

June 10. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

ROYAL INSTITUTION, 4 p.m. Mr. Edwin Chadwick, "On the Physical and Moral Condition of the English Wage Classes."

12. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

13. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.

ETHNOLOGICAL SOCIETY OF LONDON, 8 p.m. Dr. S. Nilsson, "An Attempt to Explain Stonehenge." Dr. Shortt, "An Account of a Religious Festival, comprising Leaf-wearing and the Hanging or Cheddul."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, Ballot, 8 p.m.; Meeting, 8½ p.m. Dr. Wynn Williams, "On Tuberculosis." Dr. B. Sanderson and Mr. Hulke, "Case of Sixpence in the Larynx for Ten Weeks." Mr W. M. Baker, "On the Hæmorrhagic Diathesis." Mr. Spencer Wells, "On Ovariotomy."

14. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

15. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

16. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

ORIGINAL LECTURES.

AN INQUIRY INTO THE NATURE OF THE PHENOMENA WHICH CONSTITUTE "INFLAMMATION."

TWO LECTURES DELIVERED AT
The Royal College of Physicians.

By LIONEL S. BEALE, M.B., F.R.S.,
Fellow of the College; Professor of Physiology and of General and Morbid Anatomy in King's College, London; Physician to King's College Hospital.

Of truly Vital Actions as distinguished from the Physical and Chemical Actions of Living Beings—Vital Phenomena of Inflammation—Of Vital Stimuli: Nutritive Irritability—Excitation and Irritation—The Nature of Irritation—Alleged Resemblance of Inflammation to Combustion—Oxidation not Increased in Inflammation—Of "Excess" or "Deficiency" of Vital Action—Of Living Matter and Formed Matter, and of the so-called Force-Conditioning Machinery of the Cell—No Analogy between Living Matter and a Lifeless Machine—On Inflammation—Changes in Living Matter—Of the "Cell" of different Tissues—Quickly Growing Structures Contrasted with Slowly Growing Structures—Changes in the Formed Material—Of Germinal Matter, and of its Origin—"Omne vivum e vivo."

(Continued from page 594.)

Of Germinal or Living Matter, and of Formed Material.

The conclusions I arrived at with reference to the nature of the phenomena occurring in the living portion of all living beings formed the subject of the first course of lectures which I delivered to the College in the year 1861. Since that period my views have been accepted by some physiologists, and I think no one has yet adduced facts opposed to my inferences. In those lectures I advanced reasons for the conclusion that every active tissue and every active cell consisted of matter in two distinct states, in the *living, germinal, plastic, or formless state*, and in the *lifeless or formed state*. Matter in the first condition is capable of endless increase, while matter in the last possesses no such marvellous properties.

And I adduced numerous facts which showed that all matter of living beings in the last or formed state had been at an anteeedent period of time in the living state, and that its composition and properties in the formed condition were to be ascribed to the changes which occurred when the matter was living. And in order to explain why the particles of matter assumed relations towards one another which were quite peculiar, and which could not be brought about by art, I was compelled to assume the existence of a peculiar power, or force, or energy which certainly differs in its essential nature from any of the external forces, and I therefore spoke of it as VITAL POWER. No one will be more ready to abandon the use of this term than I shall so soon as the phenomena which I regard as the consequence of its action shall have been shown to be due to the ordinary properties or forces of matter. But surely it is most incorrect to speak of the molecular machinery of the cell as conditioning force, after the same fashion as force is conditioned by a machine made by human hands, since no machinery of any kind can be demonstrated in the cell, even with the aid of the highest magnifying powers yet made. All that can be observed is a little soft, colourless matter, which exhibits no indications of structure. I endeavoured to show that in all cases there was a very great difference in properties between the living or germinal matter and the lifeless and formed matter of the cell, and I described how, by employing a uniform process of investigation, we could definitely distinguish the germinal matter from the formed material in all tissues, and in many instances prove that the germinal matter passed uninterruptedly into the formed material. I adduced many facts to show that the so-called intercellular substance was not deposited between cells at all, but was formed in precisely the same way as, and exactly corresponded with, what in other tissues is called cell-wall.

Of the Structure of the Cell or Anatomical Element.

The structure of any anatomical elementary part or cell is easily represented diagrammatically, thus (drawing on the board). This inner part, coloured red, I imagine to be the only part of the cell which is actually living, and which possesses formative power. The changes taking place in the outer part of the cell are physical and chemical changes. I imagine that all this outer material was once in the state of the inner matter. When we examine several cells at different periods of development, we observe great differences with reference to the proportion of this living or germinal matter to the formed matter, and this fact is of the greatest importance with reference to the changes occurring in inflammation. At first the quantity of formed matter is exceedingly small as compared with the quantity of germinal matter. The formed matter, as the cell lives, increases, and the explanation seems to be simply this,—that the nutrient matter is absorbed by the germinal or living matter, and at the same time that this absorption goes on a portion of the germinal matter upon the surface of the mass undergoes change and becomes converted into formed material, which is added to that which has been previously formed; so that the formed matter which was first produced gets pushed out further and further. In all cases the oldest part of the formed material is that which is most distant from the mass of germinal matter, and the part of the formed material which was last produced is that which is in contact with the germinal matter.

In this figure of a cartilage cell (pointing to a drawing) the germinal matter is seen to pass gradually into the fully formed cartilaginous tissue, so that the fact is almost demonstrated here that the hard material upon which the physical properties and general characters of cartilage depend was really once in the state of this soft, formless, active, living material which I call germinal matter. The changes which take place in the cells in cartilage during the formation of cartilaginous tissue are represented in several of these diagrams, but perhaps more distinctly in this one. This is a single cartilage cell; and even in the centre of its germinal matter the formation of cartilage has actually commenced. As the cell advances in age the quantity of cartilaginous material increases; the germinal matter becomes somehow or other *transformed* into the hard matrix of the cartilage. Perhaps during the transformation other substances are formed, but these, being in a state of solution, would be absorbed while the cartilaginous material gradually accumulates. As the tissue advances in age it undergoes condensation, and so becomes harder, and slowly acquires the characters which every one knows ordinary cartilaginous tissue possesses.

The bodies represented in all these drawings are different forms of cells. This is intended for a section of ordinary epithelium of the mouth or the skin. Here is one of these so-called cells. The outer part is formed matter, and the inner portion coloured red is germinal matter. I do not think that the formed material of the cartilage which I just now referred to is deposited in the intervals between the cells. I think there is no *intercellular* substance; that the cells are not formed first and intercellular substance deposited between them, but that the material called intercellular substance in fibrous tissue, cartilage, and other tissues precisely corresponds to what in these epithelial cells and in other tissues is called cell-wall.

The general structure and the general relations of germinal matter to formed matter may be easily shown in a few diagrams which I will venture to draw on the board. Let this represent an epithelium cell (diagram), this an oval blood corpuscle of the frog (diagram), this a liver cell (diagram), this a young fat cell (diagram), this a larger one (diagram), and this a fully formed fat cell (diagram). This is an ordinary cuticular cell. In the red blood corpuscle of the frog, this red portion is intended for the nucleus. I am representing all the germinal matter in the different tissues with red chalk, because the germinal matter absorbs carmine, and so exhibits this red colour in the specimens which we employ for ascertaining the relation of formed material to germinal matter. Although this is the coloured portion of the red corpuscle, I represent it with white chalk, because it is formed from the inner colourless portion, and corresponds with the formed material of the other cells.

In the formation of fat, the fatty matter is first deposited in the substance of the germinal matter, just as in certain cases in the central part of the germinal-matter, tissue may be formed closely corresponding to that which surrounds it. Fat is here deposited; it is added to that which is already produced, and at last comes to occupy the greater part of the so-called fat cell. Slowly these changes go on until the fat globule increases in size and extent, and occupies almost the entire mass. At the same time that fat is being deposited,

another change is taking place in the outer part of the germinal matter—this is undergoing condensation so as to form what has been spoken of as a cell wall. In this way the cell wall seems to be produced in these cases.

The fat and the cell wall both consist of formed material, and correspond exactly to the outer part of an ordinary epithelial cell or of a frog's blood corpuscle. The same general fact is noticed, too, in the case of the liver cell. You see little globules deposited in various parts of the cell; but there is no true cell-wall to the liver cell. A wall may be produced by the action of various chemical substances, but no cell-wall is developed in the normal cell. The probability is, that the wall in the adipose vesicle results from a little hardening taking place on the outer part of the soft, plastic material. I think that in the formation of bile the outer part of the cell gradually becomes altered by water, oxygen, and other agencies, and is slowly resolved into the constituents of the bile. It is in this way that secretion takes place. The outer part of the cell becomes disintegrated, and what was at one time *cell* becomes at a future time *secretion;* what was at one time liver cell becomes at a future time bile, and perhaps other substances. It is possible that by changes taking place at the outer part of the cell, biliary matters may be formed, and saccharine or amyloid materials produced. Although both these substances are soluble in water, the saccharine matters, being readily diffusible, pass through the capillary walls into the blood; while the biliary matters, not being diffusible, are retained in the interior of the ducts, pass into the gall bladder, the common duct, and so to the intestine.

There are many other tissues which may be represented in the same simple way. Take a common tendon. This drawing will represent, I believe, all that is to be made out in the anatomy of ordinary tendinous tissue. Here are the so-called cells or nuclei, and this is the so-called inter-cellular substance; but that it is formed from this germinal matter in the same way as the so-called cell-wall, is easily proved by tearing up fibrous tissue under certain advantageous circumstances. You may see the "nucleus," represented here, passing into a certain quantity of granular matter, which is soft and easily broken down; this matter gradually passes into the firm, hard, fibrous tissue of the tendon, so that there is a gradual transition from *the formless germinal matter into the formed tendon.*

Muscle is represented in an equally simple manner. Here are the so-called nuclei of the muscular tissue, and this is the formed material. As far as I can ascertain the contractile material of the muscle precisely corresponds to the fibrous tissue of the tendon; it exhibits transverse markings, possesses a peculiar structure, and manifests for a certain time, even after its removal from the body, certain peculiar, and, I venture to think, physical properties. Now, the same observation that I made with regard to the continuity between the germinal matter and tendon, holds with regard to the continuity between germinal matter and muscle; and not only so, but in certain cases, at the outer portion of a very fine muscular fibre, the appearance which I now represent on the board is sometimes seen. This is the so-called nucleus, and from it a certain quantity of soft material proceeds, in which no structure whatever can be demonstrated; this then passes into a thin fibre, requiring very high magnifying powers in order to demonstrate it satisfactorily, but it may be followed uninterruptedly into the contractile muscular tissue; and not only so, but there is reason for believing that during the formation of muscular tissue these masses are continually moving; that the entire nucleus, so to say, moves, and as it moves it leaves this material.

At one time I believe this nucleus occupied, for example, the spot to which I now point, instead of the position which it occupies now; but it is supposed to be moving in this direction, and as it moves the most posterior portion undergoes a change, and becomes converted into soft matter, and this matter gradually becomes converted into ordinary contractile muscular tissue. I believe that is the simple way in which muscular tissue is formed, and I believe that this material which exhibits the so-called "*vital*" contractility bears precisely the same relation to the nucleus or mass of germinal matter as the so-called cell-wall of a common cell bears to its nucleus.

A nerve may also be represented in the same way. There is the so-called "nucleus," and here are the fibres which pass in different directions from it. This is the formed material, and that the germinal matter from which it is produced. If you look at nerve at an early period of development you find this sort of appearance; and the same remark will hold good with reference to fibrous tissue and the other tissues to which I have adverted. The nuclei are all close together; but at a later period of development you find that the nuclei have increased in size, and the distance between them is considerably increased, and is occupied by what I would speak of as the formed material of the nerve, exactly corresponding to the outer part of the ordinary cuticular cell. As the tissue to which this nerve fibre is distributed, grows, of course the nerve fibre grows *pari passu*, and the distance between these portions increases. The quantity of formed matter in proportion to the germinal matter increases as the tissue advances in age. This holds good, I believe, in all animals, from the lowest to the highest, in disease as well as in health. There are other tissues that I might draw in precisely the same way, but I think these are sufficient to represent roughly the view which I hold, and I need not trouble the College with further detail.

The Force-conditioning or Living Machine.

Such, then, is the structure of the "cell" or anatomical element, or elementary part. In the living "cell" we have "*active matter*" and *passive* or "*formed matter*," which was itself active at an earlier period of time. This "cell" is the "*force conditioning*" machine of the advanced physicists and chemists, in which all the physical and chemical phenomena which make up its "*life*" take place. In disease as well as in health, this is the only "apparatus" in which the marvellous chemical analysis and synthesis can take place. Where, I would ask, is the machinery supposed to condition the force? If it be admitted that the soft, plastic, colourless, formless, germinal matter "conditions,"—where, I would ask, is there anything which "conditions" upon the same principles? Have physicists or chemists yet prepared any conditioning matter at all like it? and in the working how marvellously little loss of force as compared with the loss in a machine! However the "conditioning" may be brought about, it is quite certain that it takes place upon principles totally different from those upon which "conditioning" is effected by machinery. The word "condition" must be comprehensive indeed if it can be employed in speaking of the action of a thing with a very definite structure which we have ourselves made, and know all about, and also correctly applied to phenomena occurring in matter which is certainly structureless, of the nature of which we know very little, which we cannot make, and which differs from a machine in every particular that we can ascertain. Not one of the ideas which we attach to the word machine exists in living matter, and I think those who have used this word "condition" in speaking of the actions of living beings will find it rather difficult to define what they mean when they use it. But, not content with regarding the cell as a *force-conditioning* machine, and attributing its action to machinery which it does not possess, some modern speculators have not shrunk from calling living things machines,—and, though it will hardly be credited, a lifeless machine has been spoken of as a *creature!* In this way the desired impression that there is no real distinction between a living creature and a lifeless machine has been produced upon the public mind, and no little confusion of ideas has resulted.(a) Nor is it surprising that the school which propounds these views should stedfastly abstain from considering the matter from the simplest point of view.

(a) It is due to Dr. Tyndall that I should here give his own words:—"Molecular forces determine the form which the solar energy will assume. In the one case this energy is so conditioned by its atomic machinery as to result in the formation of a cabbage; in another case it is so conditioned as to result in the formation of an oak. So also as regards the reunion of the carbon and the oxygen—the *form* of this reunion is determined by the molecular machinery through which the combining force acts; in the one case the action may result in the formation of a man, while in another it may result in the formation of a grasshopper! The *form* of the motion depends on the character of the machinery." ("Heat considered as a Mode of Motion," second edition.) Dr. Tyndall doubtless considers it unnecessary to tell us how the wheels, and mills, and hammers, and pile-driving machines, and clocks and watches, and little Swiss birds were *formed*. He concludes we know something about that; but surely he should describe the atomic *machinery* he has discovered, or which he assumes to exist, in germinating cabbages, and oaks, and men, and grasshoppers. He might perhaps be able to show that the machinery of a water-mill bears somewhat the same relation to that of the little Swiss bird as the atomic machinery of a cabbage bears to that of a man. It seems very odd that Dr. Tyndall should teach people that the sun "*forms*" muscle and "*builds*" the brain, and yet that he should omit to tell them that such very rough and simple pieces of mechanism, comparatively speaking, as water-mills and windmills, and clocks and watches, are formed and built by the sun. Of course the sun, which can *form* a muscle and *build* a brain, must be able to perform such comparatively simple operations as raising a wall or building a house; but yet Dr. Tyndall does not *say* that walls and houses and clocks and watches are the *workmanship* of the sun, although he has affirmed that lilies, and verdure, and cattle are the sun's workmanship.

Instead of discussing the nature of the phenomena occurring in the simplest cell, and then passing on by degrees to the consideration of the complex actions of man and the higher animals, the disciples of the new school of thought apply themselves at once to the most advanced inquiry; and it is curious how ingeniously the discussion of the real question at issue is avoided. As I have before hinted, the steady investigation of the phenomena occurring in a mass of living matter affords results very unfavourable to the doctrines now taught, and proves that we really know much less than some of the most popular teachers would have us believe. Those who follow Medicine have to confess to the existence in times past and present of many erroneous Medical doctrines, but the most prejudiced and ill-founded views ever entertained were not weaker or less supported by facts and observation than the new dogma now so widely taught, that all the phenomena of living things, like the actions of machines, are due alone to simple energy or motion; and I do not believe that any scientific statement ever made was less justified by known facts than the assertion that living things are "the workmanship of the sun," or that suns resolve themselves into living things. It is very strange, but nevertheless true, that those who teach us that "*suns may resolve themselves (!) into floræ and faunæ*," are quite unable to show how a very minute portion of sun may resolve itself into a minute particle of living matter, such as a single microscopic fungus, or any other definite, single, living thing. This last or minor proposition is perhaps one of those problems which, in the language of the physicist, who regards living things as the sun's workmanship, transcends any conceivable expansion of the powers we now possess, while the first is one of those grand conceptions for the contemplation of which, according to its exponent, a certain *force* of character is requisite to preserve us from bewilderment! The new philosophy seems applicable to very large masses of matter rather than to the constituent particles of which these masses are composed.

Some of the facts of modern science are enunciated in the most ingenious manner. The words are so chosen that a sentence in which a fact is merely *affirmed* is mistaken by many a reader for one in which the *explanation of the fact* is announced, and by the introduction of two or three words, the meaning of which could not be explained in as many pages, the risk which the author incurs of the reader pausing to inquire if the great hard words mean anything or nothing is slight enough. In speaking of the phenomena occurring in living structures, we have only to talk of the changes occurring in "undifferentiated organic matter," the "process of differentiation," "force-conditioning atomic machinery," and so forth, and there will be little chance of our theories being called in question. If I speak of the plastic, molecular, organic protoplasmic substance of the organism differentiating itself according to the operation of external circumstances, and thus conditioning force according to the disposition of its molecular machinery, etc., I venture to think that there are few even here who would be disposed to argue the question, or to doubt for an instant that I had explained the whole mystery of life in a very few words. But, on the other hand, if I say "Here is a small piece of soft colourless stuff, into which various substances pass and become converted into similar matter; and that gradually some of this soft colourless material becomes resolved into new matter differing in composition from the original colourless material, as well as from the surrounding constituents, I state facts in words which a child could understand; but at every step I should be met by the inquiry "why?" or "how?" and numerous questions would be proposed which I could not answer. The natural inference would be that I really knew very little about the matter, and this inference would not be very wide of the exact truth. It must, however, be borne in mind that the very points upon which further information is required can be very distinctly stated in language intelligible to all. Nothing can encourage inquiry more than telling people what we know in the simplest, plainest way possible, and drawing their attention to what we do not know, or to what we cannot explain, and I am sure that all observers who earnestly desire to see knowledge advanced will support me in the view that scientific men should express what they have to say clearly and simply, and not confuse people less learned than themselves by employing high-sounding words, the meaning of which is at best doubtful and obscure, or ill-defined, and in but too many instances has not been clearly explained by the authority himself.

(To be continued.)

NOTES ON

CEREBRO-SPINAL MENINGITIS AS OBSERVED IN THE ARMY IN PORTUGAL.

By GEORGE GASKOIN, M.R.C.S.

Some two or three years since, when engaged in perusing and collating the statistics of a foreign army,(a) I first became sensible of the pathological importance of a disease which I may be allowed to call cerebro-spinal meningitis. As it occurred to me to read of an epidemic destroying in a limited area one out of scarce more than three of its victims among the civil population (105 out of 348), while among the military half at least of those attacked died—these, too, being mostly men of the finest and most promising physique; when I found, for instance, that four cavalry soldiers were seized on the same day in a country barrack—I may say struck with death, for all of them died in a few hours, under dominion of a train of symptoms of one definite type and character; when I took note that very many of such cases were of the shortest duration, dying considerably within twenty-four hours of entrance to Hospital, or scarce exceeding that period; when I observed that on the same day and hour of time eases of the same recognisable character has suddenly occurred at considerable distances apart, singly or in groups, with diminished or aggravated virulence, I naturally lent all that immediate attention to the details before me which such a disease, however removed from my experience, was calculated to command; but my thoughts being at that time somewhat pre-occupied, and the occasion not being urgent, and finding my Professional acquaintance had very vague notions on the subject, and were, indeed, possessed by a general indifference with regard to it, I did not at that time pursue the study further.

It may be that the amount of information which public anxiety has lately forced upon us leaves but little to be desired now in completeness towards understanding this disorder. I cannot but fear, however, that the facts and opinions adduced with great advantage to science at the Pathological Society and elsewhere by Dr. Murchison, supported as they are by other weighty opinions, may have the effect of abating the interest which attaches to it. If we are to regard cerebro-spinal meningitis as a variety of typhus, we shall miss much of the significance which attaches to it as a disease. There is nothing very novel in that view, which is, indeed, of the most natural suggestion. The disease has been elsewhere classed with pyogenic affections, such as puerperal fever and pyæmia with deposits, and it is liable to be confounded with typhoid fever, the diagnosis in some cases being not easy; occurring in a sporadic form, it passes mostly under this denomination, while its epidemies in their commencement are commonly referred to typhus. It has been termed a neurosis, or a pernicious remittent fever—a rheumatic or simply a cerebro-spinal affection. But the best observers have, notwithstanding, bestowed upon it a definite character of its own, with outlines which make it as recognisable as any other item in nosology. The name "blasting typhus" seems scarcely to cover the whole of the phenomena, nor are the causes, so far as these are determined, the same.

I have lately been strengthened in these ideas by a more attentive consideration of the comparatively recent epidemics during the years 1861, 1862, and since in the Lusitanian kingdom. Beginning in the hilly country on the right bank of the Tagus, towards Spain, this epidemic extended its ravages somewhat capriciously, with much violence, to the plains of the south, and even Lisbon and Oporto were not exempt.

Contrary to what occurred in the Strasburg epidemic of the years 1840-41, as described by Grisolle, the civil population in Portugal were affected to a greater extent than the military, and, among them, those who were in low circumstances furnished the greatest number of victims. Children were attacked in preference to adults, the occurrence of the disorder being rare in a person over 30 years of age. It began first in the villages near Monforte. The commissions which reported on the disease at first declared it to be an ataxic adynamic fever other than typhus, but soon they recognised its omogeneity with the French epidemics. They found no spur that year in the rye, nor any cause in the seasons, but attributed the *materies morbi* to the dung heaps and farmyard

(a) *British and For. Quarterly Rev.*, April, 1863, p. 389.

stuff which was abundant in the vicinity, and gave more weight to this element than to the inferior condition of the inhabitants. The disease soon invaded the town and barracks of Castello Branco, situated at about eight miles' distance from the spot first attacked. One fact to which I would wish to draw attention is, that infantry soldiers were with great rarity affected, but the cavalry suffered a good deal, and the patients were chiefly recruits—that is, soldiers new in the service. In the minute and excellent reports which lie before me from the hands of the Medical officers I see frequently repeated at 21 "sanguineous temperament," with varied result. But, how often fatal? The identity of the symptoms throughout shows the terrible eon of the complaint, and cases of cerebritis, meningitis, and typhoid fever are brought forward for comparison, and serve equally for contrast on the same page.

The series of acute symptoms, as observed in these cases in Portugal, may be thus described:—A well-marked chill, which varies from a strong rigor to mere coldness of the extremities; vomiting of food, with bilious matter often green; wandering pains in the limbs; only occasionally high fever; supra-orbital pain, shooting, it may be, with greater force into one eye; the organs of vision injected with blood, and lacrymation profuse; eyes shaded by the hand; cephalalgia of an aggravated description, creating anguish, expressed by screams; pains driving with torture down the back of the stiffening neck; the pain in the head aggravated by touch or pressure; an anxious expression of the face, which is sometimes flushed, but at others pale; drooping eyelids; fixed and fearful look; respiration irregular, imperfect, or frequent; voice weak; restless action; convulsions, with difficulty restrained by many hands; muscular pain, experienced alike in contraction and extension, or perchance early prostration, with total speechlessness and some degree of coma. In other cases—insomnia; command of ideas by day, but at night delirium, with great loquacity, or less often raging mania; thirst of intense kind; difficult deglutition. These symptoms were accompanied variously by a slow, a quick, full, weak, or normal pulse, a tongue generally moist and white; and if dry and brown, chiefly in the later stage; heat of surface below or above par, or normal; perspiration copious, and often viscid; urination and defecation difficult; urine limpid and without sediment of any kind; rachialgia; pupils, even early in the disorder, equally or unequally dilated; pressure on the head causing the sensation of an electric shock, or producing spastic actions in the limbs; dorsal decubitus; lethargy; filiform pulse; cold sweats; trismus; strabismus; jerking movements of the extremities; meteorism in the bowels; incontinence of urine; aggravated opisthotonos, followed by deeper coma; stertor, preceding death.

On inspection the meninges are found strongly injected, occasionally displaying patches of ecchymosis of some size. Substance of the brain with abundant bloody puncta; lymph and pus with lactescent or sanguinolent fluid may be expected to be found in the contents of the head and spine.

But the series of milder cases are not less interesting; drawing out to the period of a month to forty days, they often display in a marked manner, with more or less regularity, the features of accession and intermittence, which characterise in their decline fevers called remittent, which we are accustomed to distinguish from typhus in a definite manner, and which, indeed, we refer to a different class of causes; and here I may very well observe that humidity seems to enter as an element in epidemics of cerebro-spinal meningitis, and we cannot overlook the fact of its occurring in situations where the dung of animals mixed with vegetable material is collected in abundance: some special matter is necessary, no doubt, as a spark to light the train, if so poor an illustration may serve, but what that special remote cause is entirely baffles conjecture. The disease seems to affect the spring season, on the very verge of winter, and in the middle of March declines, appearing with greatly diminished frequency in the summer months. One feature I shall not omit to mention, which is, that in the cases which had a favourable termination, something of the opisthotonos—that is to say, a considerable hardness and contraction at the back of the neck—remained as the most lasting, the most permanent, and, in fact, during convalescence the only symptom. In rare cases also one pupil remained somewhat dilated. Here, then, we find a uniform basis comprised of scarcely varying symptoms, constituting a special disease, and gathering in its train attendant phenomena of a secondary character, less significant perhaps, but still commanding our attention. Such are the frequent occurrence of a considerable amount of epistaxis and a tendency to pulmonary effusion. The frequent occurrence of herpes labialis and the presence of those lumbrici to which so much importance was given in the attack of a similar epidemic on the cavalry at Versailles—a symptom which was more rare in Portugal, and which seemed to act merely as a predisposing cause, no less than the nostalgia or moral unhappiness which affects the youthful soldier.

Treatment by general and topical bleeding was fully tried; the same with quinine; both failed to give the relief expected by their advocates: as regards the last, it is not a matter of surprise, considering the morbid lesion which occurs. Mercury in the hands of the French had so wholly failed that it seems to have been used on this occasion but little. Ice was applied without marked benefit. The blisters which are so freely employed in treating fevers in Portugal are declared to have aggravated the symptoms. A more favourable opinion is given of the method of M. Chaufard, who recommends opium in occasional doses of three to four decigrammes. One of the Faculty used acetate of morphine in doses of half a grain night and morning; he says of it that all the patients submitted to its action, experienced alleviation from the very first, and on continuing it a complete cure of the paroxysms occurred, tending towards a regular convalescence, in spite of the opisthotonos, which was some time before it gave way.

It seems singular that in England we should hitherto have escaped to so great an extent from this class of epidemic. I will venture to address myself to any one who is acquainted with the ill-cared-for stabling in the metropolis, as to whether disease of an epidemic character does not in all probability originate in those confined localities,—I mean such affections as measles and whooping-cough, in addition to the bronchitis and pneumonia in early life, which are due to the powerful ammoniacal emanations which are concentrated there. I am reminded of the remarks of Von Siebold as to the advance in maturity and development of the ova of intestinal worms in moist and festering heaps of manure. If we indulge the view that the lower forms of life are operative in the production of disease, this analogy may be admitted as remote where there is nothing more apposite to assist the reason. It is a source of congratulation that the barracks of our cavalry are now receiving a desirable amount of attention.

It is with something of regret that I offer you a communication deficient in original observation—so different from what you are accustomed to receive. My desire is to make sources of information available which, though trustworthy, are still liable to be overlooked. I believe I may affirm that typhus is quite exceptional in Portugal, where remittent and intermittent fevers are the rule, and typhoid fever occurs with minor frequency. I leave all further comparison, however, to those who are, in a general way, more completely informed. Looking at the disease as an object of study, I know of nothing which surpasses it in interest. If the science of physiology has more to expect from pathological research than from its own independent endeavours, I know of none more calculated to repay observation, or which more invites reflection.

3, Westbourne-park.

HOLIDAY NOTES ON SOME CONTINENTAL SPAS.

(Second Series.)

By HERMANN WEBER, M.D., F.R.C.P.,
Physician to the German Hospital.

(Continued from page 517.)

ST. SAUVEUR.

St. Sauveur is situated near the village of *Luz*, in one of the finest valleys of the Pyrenees, about 29 miles from the station at Tarbes. The few clean-looking houses which form the baths of St. Sauveur are planted on a narrow terrace of a wooded precipice, 280 feet above the Gave de Gavarnie, or, as it is sometimes called, Gave de Pau, and 2525 feet above the level of the sea. The climate is milder than at Barèges and Cauterets.

The place is of comparatively recent origin, and is less frequented than Luchon and Cauterets, though it has been repeatedly visited by the Royal ladies of France, as the Duchesses of Berry and Angoulême, and the Empress Eugénie.

The two mineral springs employed are both characterised by sulphuret of sodium, and have separate establishments. The "*source de St. Sauveur*," or "*source des bains*," has a temperature of 93° ·3 F., and contains in the litre 0·0218 grm. of sulphuret of sodium. A bath of 300 litres contains about

6·3 grm. of sulphuret of sodium, about 30 grm. of chloride of sodium, and 18 grm. of alkaline and earthy carbonates and silicates.

The clean and neat-looking thermal establishment is provided with twenty cabinets de bains, two ascending douches, and a buvette.

The second source, "*Hontalade*," has, according to Filhol, a temperature of 72°5 F., and contains only 0·0198 grm. of sulphuret of sodium in the litre. The establishment of Hontalade is situated about half a mile from St. Saveur, and possesses eleven cabinets de bains, a grand douche, and a buvette, and some arrangements for cold hydrotherapeutic purposes.

The waters of Saint-Sauveur have only a very slight smell of hydrosulphuric acid; they possess to the feeling of the skin something peculiarly soft, "une onctuosite toute particulière," and are rich in organic constituents. They are considered as pre-eminently *mild* and *sedative*. This is probably more due to the lower temperature at which the baths are taken (90 to 95° F.) than to the chemical composition; it can, at all events, not be ascribed to a lower percentage of sulphuret of sodium, because other sources, as "la Reine" at Luchon, contain a smaller amount of this substance, and yet are regarded as much more exciting.

All ailments amenable to the sulphuretted waters in general are regarded as suitable for the treatment at St. Sauveur, especially if the more exciting influences of some other spas, as of Barèges, are to be avoided; but diseases of women stand in the foreground, especially chronic inflammation and neuralgia of the uterus, fluor albus from catarrh, or superficial ulceration of the os uteri, and conditions of weakness and increased nervous susceptibility produced by confinements, miscarriages, loss of blood. Women of a delicate, nervous, and rather lymphatic constitution are much more benefited than those of plethoric tendency.

The source, "*Hontalade*," is regarded as especially useful in cases of dyspepsia of various origin, of intestinal catarrh, and hemorrhoidal tendency. The fact that the establishment is situated on a rather steep hill, requiring always some exertion to reach it, enhances, in the majority of cases of this nature, its usefulness; but its situation is, perhaps, not quite so unexceptional in many cases of pulmonary affections, in which the "Hontalade" is likewise recommended with preference.

Drs. Fabas, Druène, Chamasson, Hédouin and Lecorché are intelligent Physicians, well acquainted with the peculiar merits of their remedy.

The hotels "de France" and "des Princes" at St. Sauveur offer tolerable accommodation at moderate prices; and if these should be occupied, the hotels at Luz ("des Pyrénées," "de l'Univers," "du Midi") may be recommended, and will be found as good and almost as conveniently situated. There are also furnished apartments as well at Luz as at St. Sauveur.

Some of the finest excursions in the Pyrenees may be made from this place, even by invalids, especially to the celebrated cirque de Gavarnie, to the pic de Bergons, to Cauterets through the gorge de Pierrefitte, and to Baréges through the gorge de Baréges.

The season of St. Sauveur is from the beginning of June to the end of September; but July, August, and the first half of September form the best part of it.

BARÈGES.

Scarcely five miles distant from Saint Sauveur is Baréges, in the valley of the Bastan (Department Hautes-Pyrénées, arrond. d'Argelès), elevated almost 4,100 feet above the level of the sea, reached either by the continually ascending carriage road from Luz or by the bridle path over the Tourmalet from Bagnères-de-Bigorre. It consists of a single steep, narrow street, lined with about 70 houses, and some wretched booths and cafés.

The aspect of the valley, surrounded by barren mountains, is wild and dreary; the climate is so rough as to render the place almost uninhabitable during a great portion of the year. The accommodation is rather inferior to that of most other spas of reputation. The bathing establishments are, as yet, imperfectly arranged; but the cures effected at Baréges are so striking that all the disadvantages just mentioned, and some others besides, are only slight drawbacks when compared with the immense benefit which may be derived, in well selected cases, from one or two seasons at Baréges. It is, therefore, not to be wondered at that every year between 10,000 and 15,000 real invalids, not pleasure-seekers, resort to this otherwise, as yet, not very prepossessing spa. During the height of the season the number of invalid visitors is often so great that many of them cannot find even the most modest accommodation at Baréges itself, and are obliged to take up their abode at Luz, about four miles distant.

The waters of Baréges, although employed already in the Middle Ages, probably did not acquire a general reputation until after the visit of the young Duc du Maine, the natural son of Louis XIV., and the pupil of Madame de Maintenon, who is said to have composed there some of her famous letters.

The esteem in which these waters are at present held in France is testified by the fact that the Government has erected at Baréges a military Hospital, where every year 168 commissioned officers and 400 other soldiers are admitted for two months each.

The praise which the late Mr. Carmichael, of Dublin, has bestowed on this spa, where he had been cured of an obstinate sciatica, is well known to many. He arrived there when it was so crowded that he had, if my information is correct, to wait fifteen days before his turn came for the first bath.

Sulphuret of sodium is the principal chemical constituent of the waters, which, as a whole, are considered as the most powerful, and also as the most exciting, in the whole Pyrenean group of spas. The temperature of the different sources varies from 18° to 45° Centigr. (64·4° to 112·5° F.); the majority of them, however, range between 32° and 40·6° Cent. (89·6° and 105·8° F.); the celebrated source "*Tambour*," or "*grande douche*," being the only one which has 45° Cent. (112·5° F.) The chemical composition may be considered as very imperfectly known, and new and more complete analyses are much wanted.

The following table, borrowed from Filhol's work (l. c., p. 341), shows the temperature, the proportion of sulphuret and of chloride of sodium, and the amount of alkalines contained in the principal sources(a):—

Noms des Sources.	Température.	Quantité de sulfure de sodium dans un litre d'eau.	Quantité de chlorure de sodium dans un litre d'eau.	Alcalinité.	Noms des Auteurs.
	Centigr. deg.	grm.	grm.	grm.	
Le Tambour (Gr. Douche) . .	45·00	0·0404	0·0831	0·0810	Filhol, 1850.
L'Entrée . .	40·80	0·0372	0·0219	—	Gintrac, 1841.
Lachapelle . .	31·00	0·0203	0·0697	0·0380	Filhol, 1850.
Polard . . .	38·00	0·0238	0·0458	0·0517	*id.* *id.*

Genecy . . .	32·00	0·0220	—	—	Constantin James.

Baréges is, as yet, much neglected with regard to the bathing establishments and the supply of the mineral water. The former defect is being remedied by the construction of a new thermal establishment, and by the improvement and enlargement of the military Hospital, which is a source of incalculable benefit to the French army.(b) The second defect, viz., the scanty supply of water, is likewise on the eve of being, at all events, to some degree, rectified by the utilisation of new sources, and by the better management of some of the older ones.

Hitherto the defects just mentioned have led to the necessity of sending the invalids to the baths at all times of the day, and of the night; and many of them have to leave their beds at midnight, to be carried to the douche or the cabinet de bains, or to the piscine, and thence back into the bed. This proceeding is described as by no means agreeable; yet the number of patients applying is so great, that they are often very happy to receive a ticket for the midnight bath. The scanty supply of water further obliges the Medical inspectors not to send too large a number of bathers at one time into the piscines. The crowded state of the military piscine, for instance, may be imagined when I state that it is about twelve feet long and seven feet wide, and that forty common soldiers or non-commissioned officers bathe in it at a time, while the

(a) A *litre* is equal to 35·21546 fluid ounces of distilled water. A *gramme* (grm) is equal to 15·4325 grains troy.

(b) This measure well deserves to be imitated by the English Government; and although the thermal spas of this country do not altogether resemble Baréges, yet excellent establishments of this kind might be formed at Bath or at Buxton; at the latter place the natural temperature of the water could be easily increased by artificial heat in order to increase the energy of the action according to the requirements of some morbid conditions.

number of commissioned officers bathing there at other periods of the day is restricted to twelve.

Near to the road from Baréges to Luz, rather more than half a mile from the former, is a small separate establishment of modest pretensions, called "*Barzun*," supplied by the source of that name. It contains a few cabinets de bains, two douches, aud a "buvette" (drinking fountain). The temperature of this source is 29·6° C. (85·3° F.) and the amount of sulphuret of sodium in the litre is 0·033 grm., but a more accurate analysis is a desideratum.

In considering the general character of the sources of Baréges, a prominent fact is their great durability, *i.e.*, that they do not readily decompose, and retain their sulphurets, when exposed to the air, longer than the majority of other sulphuretted springs. Filhol ascribes this durability to the small proportion of free silicic acid, and to the rather large proportion of alkalines contained in the water.

The waters of Baréges have the reputation of being more exciting in their influence on the nervous system and on the circulation, and, through this, more energetic in their therapeutical action than any other sulphuretted waters, and Dr. Ganderax, the chief of the Military Hospital, and Dr. Vergèz, one of the most experienced Physicians at Baréges, are able to support this view by many instances. Probably the comparatively great constancy of the water is a prominent cause of its efficacy in old wounds and other affections where the *local* action of the water is of especial importance. It ought, however, in considering the effects of the Baréges waters, to be borne in mind that the climate of Baréges is truly mountainous and possesses all the stimulant qualities of the Alpine climate. Many of the cures are, no doubt, due more to this influence than to the sulphuretted waters.

The diseases principally treated at Baréges are:—*Old wounds, diseases of bones, scrofulous affections, skin diseases, chronic rheumatism,* and *secondary syphilis,* with its complications.

The value of the Baréges waters in *old wounds* is well recognised throughout the whole of France and the Continent in general; it is the great benefit derived from their use in cases of this class, and especially in old gunshot wounds, which has induced the French Government to erect the military Hospital. Old wounds that have resisted every kind of treatment often heal rapidly at Baréges; painful cicatrices not rarely break out afresh, under the influence of these waters, in order to form, under their continued use, a healthy and painless cicatrix; foreign bodies lodged in old wounds are frequently expelled, or their extraction is rendered more easy. Partial anæsthesia and hyperæsthesia, the stiffness of joints, and the paralysis of limbs, which sometimes are the consequences of wounds of various kinds, are generally easily removed by the treatment at Baréges.

Chronic *diseases of bones and of joints,* as caries, chronic periostitis and ostitis, necrosis and their complications, are likewise often much more benefited by this spa than by any others.

Scrofula and *scrofulous affections* are generally placed at the head of the diseases specially fitted for Baréges; but I think that this assertion ought to be somewhat modified. It is quite true that the *torpid forms of scrofula,* manifesting themselves as glandular swellings, with and without ulceration, white swellings, caries of bones, etc., are very beneficially influenced, and sometimes even cured more quickly, there than at the muriatic saline spas; but in these cases it is not so much the scrofulous diathesis which is acted upon as the accompanying torpid and lymphatic constitution of the patients. The exciting influence of the Baréges waters causes under such conditions a greater activity in all the physiological as well as morbid processes, and removes through this not rarely torpid chronic affections, which originally were of a scrofulous nature. Most of these cases, however, occur in adults, and in many of them the scrofulous diathesis may have been abating long before the use of the baths, while the torpid state of the organism and the products of the disease (as the white swelling or the enlarged glands) had remained. Much less beneficial is the result in the majority of purely scrofulous affections, especially in younger children. In these there can be, I think, no doubt that the muriatic saline spas, especially those containing iodine and bromine (Creuznach, Ocynhausen, Nauheim, Hall, Reichenhall, etc.), are very superior to Baréges and to all the sulphuretted waters.

Diseases of the skin contribute a great contingent in all the sulphurous and sulphuretted spas. The effects of the Baréges waters in these complaints do not materially differ from those described under the head of "Bagnères-du-Luchon;" the latter place has, no doubt, some advantages by its greater variety of springs from the weakest, and the degenerated, which in irritable affections are the most useful, to the strongest; while Baréges, on the other side, combines with the influence of its waters that of its greater elevation, which is no mean agent in many conditions.

Amongst the *rheumatic affections* it is to the most chronic forms, especially those occurring in torpid constitutions, that the treatment at Baréges is applicable; but in many of them, as, for instance, chronic sciatica and lumbago, it is superior to every other treatment.

With regard to *syphilis,* to *hydrargyrism,* and to the complications of the two, the remarks made under Bagnères-de-Luchon are likewise applicable; but the more exciting action of Baréges may perhaps, in cases of doubtful syphilis, render it more energetic as a "test," by causing more rapidly, and with greater certainty, the appearance of the characteristic eruptions where the constitution is still impregnated with syphilis. I have had the opportunity of witnessing this effect in a most striking manner in several instances, and Dr. Ganderax, who showed me one of these cases, very properly quoted as a motto for Baréges with regard to the effect in question, the following words from an old treatise on spas:—

"Feriunt ad extus, quod latebat
ad intus."

Patients affected with diseases of the *respiratory organs* likewise not rarely resort to Baréges; but, although the bracing influence of the mountain air, combined with that of the thermal sulphuretted waters, may, in many cases, exercise a beneficial influence, yet the changeable nature of the climate and the frequency of fogs, or mists ("brouillards"), and of storms, render a lengthened stay at Baréges of doubtful value for pulmonary invalids.

With regard to the manner in which the waters are employed, the external application in the shape of the douche and the bath predominates over the internal administration, although the latter is used in many cases. The bath in the piscines is in general regarded as much more efficacious than the single bath. The temperature of the water in the military piscine when I visited it was 36°C. (96°·8 F.), and that of the surrounding air in the bath-room 31°·5 C. (88°·7 F.) The greater body of water in which the patient is immersed, the higher temperature of the surrounding air, and its greater impregnation with sulphurous vapours are advantages which even a crowded piscine possesses over a single bath. The water of the baths and piscines consists of pure mineral water, cooled, where it is necessary, by standing, but not by the admixture of common water practised at some other places The time during which Dr. Ganderax generally keeps the soldiers in the piscine is, I believe about fifty minutes. The grande douche he rarely applies, over fifteen minutes. The temperature of the douche is higher than that of the piscine; its action is very exciting, and causes frequently feverish excitation, which on the whole not rarely occurs during the treatment at Baréges. Dr. Ganderax pauses under such circumstances for a few days with the treatment, or uses a bath supplied by a less exciting source, and gives internally sulphate of magnesia, or a similar medicine.

The best time for the bath is either about one or two hours before, or three or four hours after breakfast, but the limited accommodation and the large number of patients oblige the Medical men to give the baths at all hours of the day and night; three hours, however, must elapse after the last meal before the bath is taken.

The water given internally, in general, does not exceed 300 grammes per day (about twelve ounces), which quantity is usually divided over the day, half being taken in the morning, half in the afternoon.

The duration of the invalid's visit to Baréges varies from three to six weeks, and more. The soldier's term is two months, and properly so, as a moderate and longer-continued application of the waters is preferable to a shorter and more energetic one. The term of two months allows, besides, to make the pause of some days in the middle of the treatment, which in almost all cases is very desirable.

The best time for Baréges is from the beginning of July to the first or second week in September, but the bathing season commences already in June, and terminates only towards the end of September. In addition to the Medical men already mentioned, Dr. Ganderax and Dr. Vergèz, to whom I owe much information, I cannot omit to name Dr. Le Bret, the

Medical inspector of the spa, well known by his scientific attainments.

The best inns are the hotels "de France," "de l'Europe," and "de la Paix;" they are not so good as those at Luchon or at Eaux-Bonnes, but yet they offer all the necessary accommodation, and the food, too, is sufficient for the generally increased appetite.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

HOSPITAL FOR SICK CHILDREN.

TWO CASES OF STONE IN THE FEMALE BLADDER—DILATATION OF THE URETHRA AND EXTRACTION—RECOVERY.

It seems strange that, notwithstanding the large statistics of this operation that have accumulated, the apparently simple problem how best to remove a stone from the female bladder should not yet have been solved. Such, however, is the case. Various operations have from time to time been recommended, but none has yet been accepted as wholly satisfactory by common or even general consent. The main question in the dispute seems to be how far, for the purpose of extracting a stone, the urethra may be dilated without risking the integrity of its sphincter, or, in other words, without exposing the patient to the danger of subsequent permanent incontinence of urine. All allow that a certain amount of dilatation is safe; but at what stage does it become dangerous? Upon this point the highest authorities differ very widely, as may be seen from the following extracts:—Mr. J. Lane, in a paper (a) on "Lithotomy in the Female," writes:—"It is, nevertheless, admitted on all hands that the urethral method (of extraction) is frequently followed by inability to retain the urine. The dilatation paralyses, or in some way injures the sphincter fibres at the neck of the bladder, and thus produces incontinence, which, though it may sometimes be recovered from, not unfrequently persists for the remainder of the patient's life. . . . Urethral dilatation should, therefore, in my opinion, be only practised in cases where the stone is of small size. To fix a maximum, I would say, in an adult not larger, certainly, than an acorn; and in a child, not larger than a horse-bean." On the other hand, Dr. Humphry (b) says:—"It is astonishing how wide the urethra may be dilated without tearing, if only sufficient time be allowed; and when it is torn in the extraction of very large calculi, it very soon recovers, and the patient is able to retain the urine." And a little further on:—"From a girl, aged 4, I extracted by the same process (dilatation of the urethra by means of small catgut bougies added one after another as the canal enlarges) a stone weighing three drachms and a half; from another, aged 5, a stone weighing two drachms; and from a third, aged 12, a rough stone weighing an ounce and a drachm, measuring in its smallest circumference three inches and three-quarters, and in its largest four inches and a half. They all recovered quickly and completely."

It is unfortunate that this question cannot be finally set at rest. Of course, every Surgeon would be anxious to avail himself of so simple a method as dilatation if it were proved he might safely do so; while, on the other hand, if dilatation is unsafe, those who practise it are exposing their patients to the risk of being afterwards placed in a most miserable condition, which, at present, at all events, Surgery is wholly unable to relieve.

It should be remembered that those who determine not to depend on dilatation are obliged to resort to operations which are open to serious objections. Some are by no means without danger to life, while others fail in the very particular upon which the dilatation method is condemned,—patients sometimes suffering subsequently from incontinence. Indeed, the unsatisfactory position of cutting operations may be estimated by the fact that some of the highest authorities have recommended the formidable supra-pubic as the best that can be performed. In a paper (published in the last volume of the Medico-Chirurgical *Transactions*) in which the results of a large number of cases treated in different ways are tabulated, Mr. Bryant strongly recommends *rapid* urethral dilatation, with the patient under chloroform, as the safest and most expeditious method of operating; "for calculi one inch in diameter in children, and even two inches in adults, have been safely extracted by this practice."

The two following cases are related as a contribution to the data from which a final opinion may hereafter be formed; as such, they are of value, as in both the stone was of large size, and recovery was rapid and complete:—

Case 1.—M. B., a healthy girl, 5 years old, was admitted into the Hospital for Sick Children on April 22, under the care of Mr. Smith. Her mother stated that micturition had been painful and over-frequent for about six months, and she had noticed latterly that the child was in the habit of putting the finger into the vagina "to push back the stone" before the bladder could be emptied. The stone was readily struck with the sound, and could be plainly felt through the rectum. It was removed on May 2. During its extraction it was necessary, after the urethra had been dilated as far as appeared safe, to obtain more space. This was done by partially dividing the inferior wall of the canal, and, as the stone was too large to pass the external parts, by dividing the anterior part of the perineum to the requisite extent. The slight swelling that followed the operation soon subsided, the urine was passed naturally within two days, and the child left the Hospital quite well on May 7. The measurements of the stone were: length, $1\frac{3}{8}$ inch; breadth, $1\frac{1}{8}$ inch; circumference, $2\frac{3}{8}$ inches.

Case 2.—M. R., aged 35, placed herself under the care of Mr. Dingley, of Argyle-square, having a swelling occupying the right lumbar and iliac regions of the abdomen, distinctly fluctuating, and appearing to be a collection of matter which had formed during an attack of pelvic cellulitis, from which she had suffered after her confinement a few weeks previously. When she had been a few days under treatment, she passed from the bladder a very large quantity of puriform fluid, and it was then found that the swelling referred to had subsided. She now became subject to frequent micturition and other symptoms of stone in the bladder, and upon sounding her two stones were readily detected. These were extracted by Mr. Dingley after rapid dilatation of the urethra under chloroform. The larger measured $2\frac{3}{8}$ inches in circumference and 1 inch in length; the smaller $1\frac{5}{8}$ inch in circumference and $1\frac{5}{8}$ inch in length. The patient was able to pass urine naturally within two days of the operation, and subsequently remained quite well. It was concluded that the swelling had consisted of the kidney dilated by the impaction in its pelvis of the calculi, which afterwards passed down the ureter into the bladder.

THE METROPOLITAN FREE HOSPITAL.

VASCULAR CORNEA AND GRANULAR LIDS OF NINE YEARS' STANDING—CURE BY PURULENT INOCULATION AFTER PERITOMY.

(Under the care of Mr. HUTCHINSON.)

The following narrative records the result of somewhat dangerous measures against a most intractable disease. The patient was a poor Irish girl, in rather feeble health, who for nine years had had her life made miserable by persistent ophthalmia, with granular lids and vascular corneæ. She had been for long periods under treatment at several of the principal Hospitals, and her temples were scarred by setons which had been kept in for months without benefit. Mr. Hutchinson remarked, when the girl was admitted, that if inoculation were suited for any cases this was certainly one for it, the corneæ being completely covered by vessels. He drew attention to the fact that it was in these cases that the measure was comparatively without risk—precisely the cases most needing it being those in which it could be done with impunity. The more vascular the cornea the greater the probability that no sloughing would follow, and *vice versâ*. In well-selected cases he had scarcely ever seen any harm result. Recently, it had been the practice not unfrequently to perform circumcision of the conjunctiva first, and then to inoculate a few weeks afterwards; and this was the plan he proposed to adopt. The following are the notes of the case:—

June 8, 1865.—B. S., aged 15, came to-day to report her condition, she having been discharged about nine months ago, and not seen since. It is just a year since her admission. She had then suffered from granular lids and vascular corneæ for nine years, and was only able to see the largest objects. She had been treated at various Hospitals and with great variety of treatment. A week after her admission Mr. Hut-

chinson performed circumcision, removing a broad belt of conjunctiva around each cornea, and being very careful to clear away every trace of tissue down to the sclerotic. About six weeks later but little benefit was apparent. Both eyes were now inoculated from those of an infant suffering from purulent ophthalmia in a moderately severe form. A fairly acute attack of purulent inflammation resulted, which was allowed to run its course, free ablutions only being resorted to. When the ophthalmia was subsiding a weak alum lotion was used. She left the Hospital three months after her admission. At present date, a year after operation, both corneæ are clear, with the exception of a degree of haze so slight that it requires very careful examination to detect it. There is no vascularity of the conjunctivæ, and the granulations under the lids have entirely disappeared. She can see perfectly. The eyes are at times a little irritable. The belt from which the conjunctiva was removed has been so perfectly restored that it is almost beyond belief that such an operation was ever performed.

THE LONDON HOSPITAL.

TUMOUR AT THE BASE OF THE BRAIN—DEATH—AUTOPSY—CLINICAL REMARKS.

(Under the care of Dr. HUGHLINGS JACKSON.)

This patient's case must be thought of chiefly as an assemblage of symptoms, and is altogether of more physiological than of pathological interest.

He had the form of amaurosis which we often meet with in diseases of the nervous system, viz., that consequent on inflammation of the optic nerves. Indeed, having now seen this kind of amaurosis very often, I should from it alone, if it were on both sides, diagnose intracranial disease. In this case it was the first symptom which drew my attention to the serious nature of the patient's complaint. After the autopsy I had no doubt but that the deafness had been really the first symptom; but the date of this was uncertain. Besides, we know far less about deafness as a symptom than we do about amaurosis, and therefore it is less of a warning. The marked changes in the eye in this case were great, considering the slight defect of sight the patient had at first.

In the above remarks I have used the loose term "intracranial" disease advisedly, as this kind of amaurosis appears to result from disease of almost any part within the head. For this reason, the manner of the causation of optic neuritis must not be discussed here, but after a consideration of many more cases. It is worthy of most careful attention that this patient had never had severe headache nor urgent vomiting—two things which so often attend optic neuritis.

The existence of spasm of the right side of the face is with difficulty accounted for, as the whole of the disease was on the left side. It may possibly have been due to irritation of the left fifth nerve; for Graefe has recently found that a form of spasm of the face depends on irritation of one or other of the sensory branches of the fifth, and that it is curable by division of the offending branch. The kind of spasm, however, to which he alludes is different—viz., histrionic spasm, and the branch of the fifth at fault is on the same side as the spasm, yet the manner of causation may, perhaps, be similar.

Then it is even more remarkable that there was no paralysis of the facial on the left side. This I cannot understand. The simplest explanation for the reader is, that I overlooked it; but I am confident that I did not, as I examined the parts supplied by each cranial nerve in detail.

In trying to put the symptoms of a cerebral case in order for diagnosis, we sometimes account for a local paralysis by supposing pressure direct or indirect on a nerve trunk. Now, in this case, although the fifth nerve was flattened, there was no affection of parts in its distribution. It is quite certain that we sometimes do get paralysis of nerves from pressure, and equally certain that we sometimes do not, even when the pressure appears to be considerable. This apparent contradiction admits of explanation. There is reason to believe that when pressure is very gradual nerve tissue bears it well, but that it does not accommodate itself to sudden encroachment. Had my patient lived longer, however, the pressure would doubtless at length have become extreme enough to have paralysed the nerve. I have (the day I write these remarks) made an autopsy on the body of a child, five months old, how died of hydrocephalus. There had been paralysis of the portio dura on the right side for at least one month, and on the left side for about two weeks before death. I found the facial nerves much elongated, and stretched on the walls of a bag of fluid situated at the base of the brain, and chiefly in the cerebellar fossa. Here the pressure must have been long exerted, for the child was hydrocephalic from birth, and yet very gradual, as it was by fluid. The case illustrates how much pressure nerve trunks will bear, and also that after extreme stretching they will become paralysed. Both cases taken together show how vague our diagnosis of cerebral tumours must still be until we have more certain evidence as to effect of local pressure on nerves and nerve centres. Probably the chief element to be taken into consideration in considering the effect of pressure is the rapidity with which it is exerted.

This case had also an interest to me in connexion with cases of locomotor ataxy then under my care. But the walk was different, and the ophthalmoscopical signs were different to those I have found in the amaurosis of ataxic patients. Amaurosis is a recognised complication of ataxy just as paralysis of the third nerve is. In what follows, however, I exclude this disease from consideration, as I shall shortly take an opportunity of speaking more in detail on it, and on the form of amaurosis which sometimes complicates it.

We all know how well a blind man can walk, but in some cases of amaurosis (I repeat I am now excluding locomotor ataxy), the patient walks badly. There are many causes for this. In some there seems to be real but partial paraplegia, and in others an inability to walk, although the legs appear to be strong, and although sometimes the patient can walk by the very slightest aid.

After a patient has become blind from neuritis he may ordinarily walk well, and yet sometimes he falls down suddenly or drags his legs occasionally. I do not say that this only follows amaurosis from neuritis. I merely mention the circumstances under which I have met with this kind of walking. In one case, from the blindness and from the hydrocephalus the patient had, I diagnosed disease of the vermiform process of the cerebellum. Whether this is correct or not, I cannot, of course, be sure, but from these symptoms I have known Dr. Gull correctly predict disease of this part of the nervous system. I by no means think, however, that the patient walked badly because the cerebellum was diseased,, but probably because the disease had involved also the neighbouring parts of the motor tract. In the following instance the left cerebellar hemisphere was smaller than the right, and the tumour grew from a small part of it. But to call it a case of disease of the cerebellum without qualification would lead to mistakes. Dr. Brown-Séquard does not believe that the cerebellum is the seat of the faculty of muscular co-ordination. He does not deny that defective co-ordination often co-exists with disease of the cerebellum, but denies that it is due to disease of that part. For although we have disorder of motion with disease of the cerebellum, this part may be much altered without any such disorder. The disease which involves the cerebellum frequently injures other parts near it. Now, it is easy to show experimentally, on pigeons, that an injury to the hemispheres of the cerebellum gives rise to defective co-ordination of movements. This is not the effect of the operation, as removal of a great part of the cerebral hemispheres—a more severe operation—produces no such defect. But the fact that when a pigeon, after removal of part of its cerebellum, recovers from the operation it regains power of co-ordination, shows that the mere absence of this part does not disorder movement. Dr. Brown-Séquard thinks that the motor defects which do occasionally attend disease of the cerebellum are owing to secondary affection of the motor tract near it. My patient's "tumbling about" was doubtless due to the pressure of the tumour on the pons, crus cerebri, and crus cerebelli.

I will now mention another case belonging to the same general category, but presenting certain individual peculiarities.

I have now had under my observation an amaurotic patient for four years, who has a singular difficulty in walking, and the amaurosis is very remarkable in this, that there are no ophthalmoscopical changes. The patient, four years ago, had the well-known series of symptoms—headache, vomiting, etc.—so often attending optic neuritis, after which she was quite blind, and her legs were, I do not say weak, but partly incapable. This patient cannot stand alone, and yet by the slightest assistance, by far too little to give her more than guiding power, she can walk several miles. And what is very noteworthy, she then appears to walk quite well. When sitting the legs appear strong, as she can resist extension

and flexion well, and can kick vigorously, and there is no loss of sensation. A suspicion of hysteria has occurred to me, but I feel bound to reject this lazy diagnosis, as the patient was only eleven years of age when the disease began, and, besides, there is a clear and circumstantial account of acute cerebral disease at the onset. I find by my notes that she walks just as she did three years ago, apparently neither better nor worse. Where the disease in this girl's case may be, I do not venture to give any opinion. The patient does not reel in walking, but as she cannot even stand by herself, it is impossible to try her way of walking alone. I mention these cases with the hope that Ophthalmic Surgeons and Physicians may work together in an inquiry of great scientific interest, as well as of great importance to our patients.

In a future communication on "Amaurosis in Locomotor Ataxy," I hope to show that there are great advantages in thus combining our efforts in one direction.

September 23, 1864, a man, 47 years of age, came to the Hospital for giddiness, and he mentioned, as if incidentally, that his sight was bad. I therefore examined the eyes with the ophthalmoscope, and found that he had considerable disease of each optic nerve. The discs were not to be recognised except by the convergence of the veins. The arteries were not to be traced. About three times the diameter of a normal disc was a patch of a reddish-white colour, in which the veins seemed partly to pass. On and around this patch were distinct dots of blood.

The patient, however, said that he could read, and he did read to me the smallest type I had with me—viz., about small pica (No. 8 of Jaeger). He said he read the newspaper every day.

He had walked to the Hospital, but did not walk very well. Still there was no marked paralysis anywhere; but he said the right leg was a little weaker than the left. He had twice fallen down. In the out-patients' room he seemed to walk pretty well.

When the giddiness came on (and it only came on when walking), he felt, he said, as if he should fall forwards if he did not rest himself against something. These attacks of giddiness occurred three or four times a-day. They appeared to begin, he said, at the back of the head. When he shut his eyes he could stand, and even walk; but he had great difficulty in doing so. But he did not at all walk like an ataxic patient. He had never had any pains in his legs.

There were two other local symptoms—viz., deafness on the left side, and attacks of spasm of the face on the right side. I saw the spasm myself, and am certain it was on the right side, as whilst it lasted it prevented my examining his right eye. It only lasted about a minute, and was a continuous drawing up of the cheek and a continuous closure of the eye. It was not the spasmodic tic of Marshall Hall, nor what is called histrionic spasm.

He confessed to having been a very drunken man, but said he had never had syphilis. He had no cardiac disease, and his urine was free from albumen.

I saw no more of him until November 26. He was then in the Bancroft-row Workhouse, under the care of Mr. Stephenson, to whom I am under great obligations for much help in investigating the case. The patient was then absolutely blind. I could now find the edge of the optic nerve, or rather its general position, as its edge was obscured in a gradual shading off into the fundus. The discs looked white, and seemed as if raised. There were no arteries visible, and the veins were exceedingly irregular. The fundus looked normal in general, but within about the distance of twice the diameter of the dise from its centre were recent effusions of blood, varying in size from a pin's head to four times that size.

He said that three weeks ago his sight began to get much worse, and that rather suddenly. As it failed after my ophthalmoscopic examination, he fancied it failed in consequence. He then began "to tumble about." He said, too, that he had had occasional sudden jerks in the arm, which threw him down; and he added, "they must have been in my legs too, as they threw me down." He had also had pain in his legs, of which I could get no more precise description than that it was a cramp, which came on suddenly and made him stumble.

I saw him again December 1, and then went carefully over the physiology of his nervous system, according to a written scheme I use. There was then no affection of any cranial nerve, except what was inferred from the deafness of the left ear. I may mention particularly that the right side of the face was normal. The deafness he had had, he said, four or five years. It followed an injury to the head; but this history is doubtful, especially as he himself was then drinking hard, and knew nothing of it at the time.

At this visit he was lying in bed; but his arms were strong, and besides he could perform small actions—*e.g.*, he buttoned his shirt readily. For the last day or two, however, he had had shakings of the left hand, and it was a little weaker than the right. There was certainly great loss of power in his legs, although when well supported he could walk. He had, however, to lean heavily on some one in front of him, and without help could not stand. He moved his legs quietly, not throwing them about in the least. He could stamp strongly, and could kick out his legs in bed. There was no loss of sensation in his arms or legs. This I tried carefully in several ways, including the use of the compasses.

I saw him no more; but I learned from Mr. Stephenson that he died suddenly on February 23, whilst getting his breakfast. Except that he had incontinence of urine and fæces, no change in the symptoms were noted.

Two symptoms were absent which we often find with the form of amaurosis this patient had—viz., vomiting and headache.

The autopsy was performed by Mr. Stephenson and by Mr. Mackenzie. The brain and spinal cord were removed, and were sent to me.

At the base by the left side of the pons there was a tumour. This side of the pons was much flattened, but all the nerves except the seventh pair were free from it. The fifth nerve passed betwixt it and the side of the pons, and was flattened, but otherwise looked quite normal. The portio dura at its origin looked normal. It passed betwixt the side of the pons and the tumour for a little way, and then its fibres seemed to spread themselves a little and to run into the mass or to be lost upon it.

The tumour was of the size of a large walnut, and was irregularly nodose, and firm, and elastic. Its section was of a rather dirty white, and looked semi-translucent, and at some points specked with red. Under the microscope there were seen free cells, nuclei, fibrillating tissue, and oil and fat globules in immense quantity.

As stated, it had flattened the side of the pons, and it seemed to have pushed back the cerebellum, with which above it was connected. It covered the crus cerebelli, and flattened it. It could be easily turned out of its position, except that to its fore part it grew from the piece of the cerebellum which in the normal situation is seen as if passing to the under part of the pons below the origin of the fifth nerve. And to this part it was apparently only attached by the membranes. It had cleared a space for itself by pressing forwards the cerebrum, and backwards the cerebellum, by flattening the side of the pons, the crus cerebelli, and crus cerebri. The optic tract was not uncovered, and the corpora quadrigemina were apparently unaltered. The only other points of importance were that (besides being pushed back) the corresponding lobe of the cerebellum was smaller than its fellow, and that the left optic thalamus appeared to be somewhat less across than the right.

K.C.B.—At the investiture of the Most Honourable Order of the Bath, held on Thursday, June 8, at St. James's Palace by H.R.H. the Prince of Wales in behalf of her Majesty, the following Knights Commander of the Order were invested by his Royal Highness with the Riband, Badge, and Star of the Military Division of the Second Class of the Order:—Sir James Brown Gibson, Director-General of the Army Medical Department; and Inspector-General of Hospitals Sir William Linton.

SHREWSBURY.—Mr. H. Robertson having issued an address announcing his intention not to claim the suffrages of the electors at the next election, Mr. William J. Clement, a Surgeon, has offered himself as a candidate. He appeals to his Professional brethren for assistance in electing one of themselves. The army and navy, the law and the Church, are well represented in Parliament, but the Medical Profession has only one advocate in the present House of Commons. If some Medical men had been in Parliament, they would not have seen such unsatisfactory and useless legislation on that very important subject, the public health. He will advocate those principles of civil and religious liberty and commercial freedom which have secured for the people their present great happiness and prosperity. He will give Lord Palmerston's Administration a cordial, but independent, support.

Medical Times and Gazette.

SATURDAY, JUNE 17.

THE PROFESSION AND THE GOVERNMENT.

In a recent article we took occasion to set before the Medical Practitioners of this country what we believe to be their political duties. We endeavoured to enforce the truth that the Profession has not only interests to protect, rights to be secured, and wrongs to be redressed, but that it is powerful enough to make its voice heard in the councils of the nation, and to enforce its just demands on Government, however reluctant to interpose on its behalf. As then, we now disclaim all political partisanship, and we wish our readers to do the same, except insomuch that they unite to form a party with the single end and aim of securing from the Ministry of the day that recognition which is due to the Profession they represent.

Had we wanted incidents to point our moral or give weight to our argument, they would have been supplied by the late debates in Parliament. Our readers are already aware of the manner in which the claims of Naval Medical Officers have been set aside in the Greenwich Hospital Bill. We cannot congratulate them upon any success having attended the efforts of Mr. Hennessy and Sir John Pakington to pledge the Administration to a fair distribution of good-service pensions to Naval Medical men. As usual, the interests of the Medical officers were tossed aside with the most supreme indifference by Naval Secretaries and Lords of the Admiralty. Had this question concerned practitioners of the law, that Profession is far too well represented in the House to allow us to doubt that every point would have been discussed with the most decorous attention, and a sincere desire on the part of Government to secure the support of the crowd of lawyers who are looking to a seat in the House of Commons as a necessary step in their Professional career; but, as it only affected the "Doctors," Her Majesty's advisers are far too discriminating to waste justice on people from whom they believe they have nothing to gain and as little to fear. With regard to the incidents of the debate, our readers will observe that Mr. Hennessy appears to have allowed himself to be foiled by the explanation given by Mr. Childers of Clause 5 of the Bill, in which the word "officers" is said to be used in a general sense, and that he withdrew prematurely, as the result showed, his amendment. The House, however, was well aware that in the Admiralty scheme for the division of these pensions Medical officers were conspicuous by their absence, and if either Mr. Hennessy or any other member of the House were inclined to be hoodwinked on this point by the bland assurances of Mr. Childers they were soon undeceived by Lord C. Paget, who with a pleasant touch of irony, after Mr. Hennessy's amendment had been withdrawn, expressed a hope that the hon. member had not withdrawn it in the belief that Medical officers would obtain any of the pensions, for really there was not the least chance of their getting anything of the kind. We strongly recommend Lord C. Paget to the consideration of the Physicians and Surgeons of Deal and Sandwich as a Naval Lord whose animus against the Medical Officers has been peculiarly conspicuous during his tenure of office. We regret that neither Dr. Brady nor Mr. Hennessy were in their places on Tuesday morning, when the Bill was again before the Committee, as even then there might have been a chance of reopening the subject.

Mr. Villiers's tone in replying to Mr. Neate on the subject of Poor-law reform, gives us but little hope that the opportunity which the Poor-law Continuance Bill affords will be taken for the purpose of introducing the smallest modicum of Poor-law Medical reform. Before the second reading of the bill a very temperate letter was addressed to every member of the House of Commons by the champion of the Poor-law Medical officers, Mr. Griffin. That letter fully exposes the inequality and insufficiency of the present rate of remunerating Medical men engaged in Union practice, and points out the fallacies on which many of the assertions made in the Report of the Select Committee on poor relief are based. We have no expectation, however, that the Government will be moved even by this appeal. Until there is in the House a compact phalanx of members, some of them Medical men, and all pledged to forward the claims of the Medical body, we have no hope of redress. The coming election offers another opportunity for the Profession to assert their power. We are glad to see that there are other Medical candidates in the field besides those we mentioned in a former article. Mr. Coulson is spoken of for one of the divisions of the county of Cornwall, and Mr. Clement has announced his intention of contesting Shrewsbury expressly in the interests of the Medical Profession.

We hope, therefore, that the new House of Commons will number more Physicians and Surgeons amongst its members than the last; but every member of our Profession can do something to make his voice heard there. No body possesses more influence over the enfranchised classes than the Medical; and if that influence is once exerted in behalf of the Profession, it will be suicidal for any Government to refuse to do them justice.

SEA-BATHING AND SEA AIR.

The appearance of a translation by Dr. Strange of an agreeably-written book on Sea Air and Sea-bathing, by Dr. Brochard,(a) induces us to make some observations on a matter of national importance. Speaking from our personal experience, we are not merely struck, but appalled, at the degeneracy of our town populations—a degeneracy which must increase as the towns increase. Let the wind blow from what quarter it may, it has to pass over miles of brickfields, of newly built villas, and of older dusty streets and roads, before it reaches the lungs of the central inhabitants of London. The smoke from thousands of chimneys darkens the sky; *blacks* fly in at every open window, and render cleanliness impossible, and oxygen in vain tries to bring a bloom upon cheeks when lost in that mixture of smoke, sewer vapour, pounded road-grit, and dried horse dung which constitutes the perfection of London air. We seem to have attained for the present the climax of healthiness in London. Zymotic diseases are repressed, doubtless, by the cesspool extirpating, and pipe draining, and whitewashing operations of Boards of Health; but there remains a greater and increasing evil,—a population pale, stunted, fragile; children losing teeth early; young women unable to suckle their babes; and all this too often fostered by well-meant but most ignorant efforts at improve-

(a) Sea Air and Sea-bathing for Children and Invalids. By M. le Dr. Brochard. Translated and edited by William Strange, M.D. London: Longman and Co. 1865. Pp. 190.

ment—the gathering together of children sweltering in crowded schools, breathing the emanations of their dirty skins and clothes, and undergoing a training which developes the brain at the expense of the muscles. These evils are clearly recognised by Monsieur Brochard, on the other side of the Channel. His work is a protest against the town-rearing and brain-forcing of children. Medical Practitioners of large towns, he tells us, complain that all the children of the present generation are drenched with anti-scorbutic syrups, cod-liver oil, and iodine, in a hundred forms. Excessive school-work for the better class of children, factory-work for the lower, anxiety of mind and close air for the clerk and shopkeeper, and dissipation for the class above them, all tend to nutritive decay; and for all these evils sea air and sea-bathing are recommended as the real antidotes.

The choice of a bathing place should always be left to the Physician, who will decide whether the agencies of heat and sun-light, or of a cooler and more bracing climate, are preferable. Dr. Brochard and his translator call attention to the great importance of sun-heat and light as sources of renovated vitality; and they advocate warm rather than cool bathing places. On this point their experience does not concur with ours, and we suspect the real way of expressing the truth to be—*some*, not *all*, warm sea-side places are better than some cool ones. But, most assuredly, the Practitioner will be disappointed if he recommends any bathing place indiscriminately. We have known patients who have passed weeks at some "relaxing" places in the Isle of Wight and Devonshire, who never knew what it was to eat with an appetite all the while they were there, and who came back worse than they went. *Certes*, for dark, bilious children, and for adults sallow and dyspeptic, commend us to the bracing air of our eastern coast. Moreover, neither author nor translator appear aware of the lateness to which sea-bathing may be carried on, especially in fine autumns. It seldom need be given up till the middle of November.

Nevertheless, we believe the essential to be, a free, gently-moving, and constant current of pure sea air, and that where this exists, few bathing places will disagree.

The picture which M. Brochard gives of La Tremblade, a bathing place on the western coast of Gascony, opposite the isle of Oleron, is very tempting. A firm, sandy beach, of easy incline, and extensive sandy downs inland, clothed with pine forests; what can be more desirable? Cliffs, rocks, boulders, and pebbly beaches are decidedly less safe. On such a sandy beach children, clad as slightly as serves for decency, should be allowed to paddle about all day. Such house accommodation suffices as will shelter from the occasional bad weather during the summer months; hard mattresses for night and for a mid-day snooze—(for this, after the manner of our Anglo-Saxon ancestors, we hold to be indispensable to delicate persons much out of doors in hot weather)—plain food, abundant and varied, and including milk and vegetables, are all that is needed.

We may then ask, whether, amongst the philanthropic and sanitary schemes of the day, it would not be possible to establish sea-side summer colonies for town children? Is there any accessible part of the coast with a sandy beach where it would be possible to raise up a set of shantics, or boxes, for the rough accommodation at easy rates of some of these poor children now pining in the hot smoky air of large towns? We strongly commend the various Sea-bathing Infirmaries at Margate, Brighton, and Hastings; but we want something for those who are not yet serofulous—prevention rather than cure.

THE Royal Academy of Medicine of Belgium and the Society of Medical and Natural Sciences of Brussels have nominated Dr. Edwin Lee as corresponding member.

MODERN DERMATOLOGY.—No. VII.

MODERN dermatologists have not succeeded in throwing much light on the pathology of that curious malady herpes zoster. The popular notion to which Pliny referred when he stated "Zoster appelatur, et enecat, si cinxerit," remains a popular belief still, and it does very rarely attack both sides of the body; but we think Mr. Wilson goes too far when he asserts that "it has never been known to attack the two sides of the trunk at the same time." Our impression is, that cases are recorded, and that lately, in the Medical journals, of the eruption appearing at once on both sides; we need hardly add that they were not fatal. But dermatologists are at variance as to whether it is a blood disease or a neurose. Mr. Jonathan Hutchinson read a paper on the malady at the Hunterian Society in February, 1863, in which, from an analysis of some seventy cases, he drew, we believe, the following conclusions:—"That it may occur at any age and in either sex; that it is not associated with any special form of ill-health; that it is non-contagious; that it rarely occurs more than once in the same person; that the eruption is never symmetrical, and always follows the course of a sensitive nerve; that it occurs, without preference, on either side of the body; that it cannot be produced by artificial irritation of the nerve-trunks; that certain special nerves are much more liable to be affected than others (viz., the third and fourth dorsal); and that it runs a definite course." If the malady is an exanthem, how explain the facts that it is unsymmetrical, non-contagious, and local? if it is a neurosis, why does it so rarely attack the same person twice—why can it not be produced artificially, by irritation of the nerves?

Von Barensprung (*Med. Chir. Rev.*, Jan., 1863) considers that it is due to an irritation of the special ganglia. But none of the hypotheses yet proposed will explain all the characters of the disorder.

Of the treatment we need not say anything; it is a severe affection only in the cachectic or the aged, and then quinine or arsenic internally, with sometimes opiates and belladonna, or chloroform, or the use of morphia hypodermically, will cure it. Prurigo is generally associated, at least, with dirt and cachexia. Romberg considered that it is an hyperæsthesia, the papulæ being secondary formations, the result of the pruritus. Barensprung holds that it is primarily an affection of the papillæ, the pruritus being secondary. It has long been known that it is sometimes caused by the presence of lice, and nearly all modern writers on skin diseases describe a prurigo pedicularis, or morbus pedicularis, but Dr. Balmanno Squire holds that the great mass of the cases of prurigo "is constituted by the form commonly known as prurigo senilis; that this disease is contagious; that it is in every case accompanied by the presence of the pediculus corporis, which is the invariable and essential cause of the disease, and not an accidental and only occasional complication of it; that in no case is the disease dependant either on derangements of the digestive organs or on hyperæsthesia of the skin; that the disease has hitherto been thought inveterate and most obstinate to treatment, merely because its cause has not been apprehended; and that it is one of the most easily remediable of diseases if means be taken to destroy efficiently the parasite." To effectually and thoroughly destroy the parasite requires, however, not a little care and attention, as the following case quoted by Dr. Frazer well shows:—"A gentleman of great practical experience had personally to superintend the toilet of an elderly female before he could discover the persistent cause of their presence (the pediculi); her hair was closely shaved, she had taken frequent warm baths, and changed her clothes repeatedly, yet the insects continued to make their appearance in numbers. After having all the ordinary garments removed, an old rupture-belt became visible, which had remained undisturbed on her as a fixture for years; its abstrac-

tion destroyed the headquarters" of the insects, and resulted in their permanent disappearance.

We fear, however, that it must be allowed that some forms of local prurigo, even in elderly persons, seem to be really due to hyperæsthesia, and that they are extremely obstinate, though arsenic will often in such cases prove of great value. Dr. Frazer relates a case of prurigo of the pudenda in a woman, about 50 years of age, which resisted every kind of treatment, general and local, and caused such misery that the patient committed suicide; happily a very rare result of skin disease, in our country at least. In this case no trace of papulæ or any other eruption could be discovered either before or after death.

It may, however, be doubted whether a disease which consists only of intense itching, without any papules, can be rightly termed prurigo; it had better, perhaps, be called simply pruritus. In prurigo formicans or senilis the suffering is often very severe, and, as Dr. Hillier remarks, has "been compared by different patients to hot needles piercing the skin, to the stings of a thousand insects, or to burning coals;" or, as Mr. Wilson says, "An abbé suffering from this complaint finds his illustration in martyrdom, in the 'gril de St. Laurent;' while a soldier compares his pains to being pierced all over with halberds." The amount of suffering produced appears to depend much on the temperament of the patient, the same degree of irritation producing very different degrees of suffering in different people; and in some it is very intense, so as to induce extreme melancholy. It seems probable, however, that the attention excited to the presence of pediculi as a cause will lead to the disease being much more manageable than it has been found to be hitherto. Dr. Hillier says:—"Since my attention has been directed to this point, I have very rarely failed to find these creatures in the folds of the shirt, or on the flannel vest. Of fifty-one cases under my care in the Hospital, the pediculus has been met with in thirty-five cases; in at least seven, no careful examination was instituted, and in several others clean linen had just been put on; so that the pediculi, if any existed, were left at home." So that his opinion comes to very nearly the same as Dr. Balmanno Squire's. If the neck, shoulders, loins, and thighs are the parts chiefly affected, it is especially probable that pediculi are the cause of the disease, the dress, the habitat of the insect, fitting most closely there. Prurigo podicis, or pruritus ani, often depends on the existence of ascarides, or on congestion of the portal circulation; and podophyllin had been found very useful. Impetigo capitis may also depend on the presence of the pediculus capitis. Dr. B. Squire asserts that "Impetigo of the scalp of constitutional origin always affects the anterior half of the scalp more severely than the posterior half; that there is another form of impetigo of the scalp depending entirely on the irritation of the pediculus capitis; that the latter form always affects the posterior half of the scalp more severely than the anterior half, and assumes usually the character of impetigo granulata, whereas the former appears most commonly in the shape of impetigo figurata." It is to be remembered also that prurigo, impetigo, and eczema may be caused by the presence of the sarcoptes hominis—the itch insect.

Hebra has some remarks on pustular affections of the skin well worthy of notice. He says "Pustular diseases of the skin described by authors under the name of impetigo, ecthyma, porrigo, etc., do not exist as essential diseases; they are merely accidental to, or the consequences of, other skin diseases, which are recognisable by other signs than those of pustular eruptions, and generally, indeed, before the pustular eruption appears. Consequently, in dealing with pustules of the skin, our business is not to trouble ourselves about the size, form, and number of the pustules, but to learn what that particular disease is which preceded the pustular eruption. We must remember that a large number of pustular diseases are produced by local irritation, and should, therefore, in the first place search for traces of scabies, of prurigo, of pediculi, etc. . . . The words impetigo and ecthyma should be either banished from medicine, or they should be used simply as generic terms, to indicate the presence of a large number of pustules. They represent no distinct diseases."

THE WEEK.

THE COLLEGE OF SURGEONS' ELECTION.

All the Professional friends and correspondents whom we have conferred with are pleased to learn that Mr. Charles Hawkins and Mr. Turner, of Manchester, intend to persevere in offering themselves as candidates for the Council of the College of Surgeons. Other names there are, of Hospital Surgeons of the highest repute, and never to be mentioned without respect, higher, too, in the lists, which will, it is now said, be brought forward. If this were a mere personal matter, those gentlemen should have that precedence which they lately declined. But it is not. It is not a question of nice etiquette, as to who shall sit in a certain seat, but of the entire policy and constitution of a body on which hangs much of the character and usefulness of the Surgical Practitioner—and all that hangs on that! If, therefore, for personal reasons, however admirable, any gentlemen declined to be nominated in their turn, it will not be a slight to them, but rather the contrary, if they are passed over for this time, and a preference given to the men who came forward willingly to fight the battle of the Profession.

PARLIAMENTARY. — VOTES FOR SCIENTIFIC INSTITUTIONS AND HOSPITALS—THE GREENWICH HOSPITAL BILL—PENSIONS FOR NAVAL MEDICAL OFFICERS—ACCIDENTS ON RAILWAYS—THE BRITISH MUSEUM ESTIMATE—THE UNION CHARGEABILITY BILL—THE POOR-LAW CONTINUANCE BILL.

In the House of Commons, on Thursday, June 8, in Committee of Supply, the following votes were agreed to:—£4059 for Magnetic and Meteorological Observations; £500 for the Royal Geographical Society; £1000 for the Royal Society; £2272 to defray the charge for Public Infirmaries, Ireland; £1600 to complete the sum voted for the Westmoreland Lock Hospital, Dublin; £700 to defray the charge for the Rotunda Lying-in Hospital; £200 for the Combe Lying-in Hospital; £5600 to complete the sum for the Hospitals of the House of Industry; £1500 to complete the sum for the Cork-street Fever Hospital; £600 for the Meath Hospital; £100 for St. Mark's Ophthalmic Hospital; £300 to complete the sum for Dr. Steeven's Hospital; £245 for Board of Superintendence of Dublin Hospitals.

The House went into Committee on the Greenwich Hospital Bill.

On Clause 5,

Mr. Hennessy said that he had an amendment to propose. This clause provided that pensions should be granted to "officers," but from a report signed by the Junior Lord of the Admiralty, which had been presented to the House, it appeared that according to the interpretation placed upon it by the Government, the term "officers" did not include Medical officers or chaplains. Chaplains were dealt with by a subsequent clause, and therefore Medical officers were the only class of officers who were excluded from the benefits of this Bill. This was the more unjust because the Commissioners who inquired into the state of Greenwich Hospital reported that the only part of the establishment which required no reform was that which was under the control of the Medical staff. The hon. member concluded by moving as an amendment that in Clause 5, line 12, after the word "officers," the words "Medical officers" be inserted.

Mr. Childers could not consent to the proposed amendment, as, in the first place, the words proposed to be inserted were superfluous, the word "officers" including Medical officers; and, in the second place, because the Medical officers not being deprived of any advantage by the scheme, were not entitled to any benefit from it.

Sir J. Pakington thought that engineers as well as Medical officers were entitled to participate in the benefits of the

scheme. The Bill was most indistinctly worded, and the paper which had been laid before the House for the purpose of explaining the Bill omitted the two classes of officers from the list of those who were to share in the benefits of the charity.

Mr. Moore inquired whether the Medical officers were to be excluded from sharing in the advantages of the Hospital.

Mr. Childers said they were to be included in the general word "officers." There would be two occasions annually when the matter could be discussed. In the first place, when the Orders of Council in reference to the Hospital were laid upon the table, and, secondly, when the vote in aid of the Hospital was proposed.

Mr. C. Berkeley remarked that the Marine officers were not included in the list of those entitled to participate in the benefits of the Hospital.

Sir F. Kelly said the Marine officers were expressly included in that list, while the Medical officers were as expressly excluded from it. Notwithstanding the assurance the hon. gentleman had given them that Medical officers were included in the general word "officers," some hon. gentlemen had doubts on the subject which might easily be removed by the two or three words necessary being inserted in the interpretation clause.

Mr. Childers would take care that the wishes of the hon. and learned member should receive attention.

Mr. Hennessy wished to know exactly in what position the Medical officers were to stand, as the only paper purporting to give a list of those who were to share in the advantages of the Hospital expressly excluded Medical officers.

Mr. Ayrton trusted the Admiralty would not extend the benefits of the Hospital Fund to any class of persons not entitled to participate in it. The charity was founded for the relief of seamen, and not for the benefit of officers of any denomination.

Sir J. Hay thought the matter would be much complicated by interpolating the words "Medical officers," those officers being included in the general term "officers."

Mr. Hennessy said after the assurance of the Junior Lord of the Admiralty that the Medical officers were included in the word "officers," he would withdraw his amendment.

The amendment was then withdrawn.

Lord C. Paget would be sorry if the hon. member withdrew his amendment on the supposition that Medical officers were intended to participate in the benefits of the scheme. Medical officers held appointments in the Hospital at present, and those appointments they would not be deprived of, so that, as they lost nothing by the scheme, they could not fairly hope to derive benefit from it.

In reply to Mr. Hassard,

Mr. Childers said the clause did not affect individuals, but simply operated to give pensions to certain classes. He should take care that the interpretation clause was so framed that the word "officers" should bear the usual construction.

After some further conversation the clause was agreed to.

On Friday, June 9,

Sir L. Palk called attention to a fatal accident on the Great Western Railway, and asked the Government to make inquiries with the view of ascertaining whether the safety of the public may not be better assured by legislative measures.

Mr. Milner Gibson observed that the law subjecting railway companies to responsibility in damages for any negligence made it their interest to guard against accidents. The fault of the late accident appeared to rest with the platelayers, and he knew not how legislation could prevent such occurrences. Considering the number of persons employed upon railways, the wonder was that more accidents did not happen. He agreed that there ought to be a communication between the guard and the engine-driver, and on some of the principal lines there was such a communication.

In moving the British Museum Estimate, Mr. Walpole, on the part of the trustees, gave the customary exposition of the condition of the establishment and its collections.

After a discussion of no great length, in a very thin House, the vote was agreed to.

On Monday, in the House of Lords, after a long debate and division, the Union Chargeability Bill was read a second time.

In the House of Commons, Mr. Villiers, in moving the second reading of the Poor-law Board Continuance, etc., Bill, stated that the Bill made no change in the constitution of the Commission, which it proposed to continue for three years, and that in the amendments it made in the law there was nothing novel. He briefly explained the nature and effect of the amendments, the object of which was to give more effective operation to the administration of the Poor-law Board, in accordance with the recommendations of a committee of the House.

In the course of the debate, Mr. Neate stated that he thought the Bill ought to be turned into a mere continuance Bill. The position of the Medical Profession in connexion with the relief of the poor was a matter which deserved to receive full consideration.

Mr. Villiers said he had been astonished to hear his hon. friend the Member for Oxford assert that the committee, having given their attention to the Medical question, it should have been dealt with in this Bill. The fact was, the committee reported that there were no sufficient grounds for materially interfering with the present system of Medical relief.

Mr. Neate begged to explain. He had not said that the committee had come to any opinion on the subject. What he had said was, that the subject was one which had been very much considered by the committee, and that it ought to be considered by the House.

Mr. Villiers said the committee had come to the conclusion that there was no sufficient ground for changing the present system of Medical relief. This, then, furnished no ground for postponing the Bill.

On Tuesday, in the House of Commons,

The Greenwich Hospital Bill being re-committed,

Mr. Ayrton moved to insert in Clause 20, after the word "schools," the declaratory words, "whether belonging to the Royal Navy or otherwise employed in any service afloat." He thought a portion of Greenwich Hospital should be set aside as a Hospital for the reception of merchant seamen when sick and disabled. It had now become necessary that the Hospital ship the *Dreadnought* should be done away with, and accommodation should be provided on shore.

Mr. Childers recommended that the amendment should not be pressed, as it was unnecessary and might be misunderstood.

The amendment was withdrawn, and the clauses were agreed to.

On the motion that the Bill be reported,

Mr. Henley, who did not reach the House till late in the discussion, protested against the manner in which he considered that this Bill had been smuggled through the Committee without any public notice that there would be a morning sitting.

FROM ABROAD.—THE RUSSIAN EPIDEMIC—HOMŒOPATHY IN THE FRENCH SENATE—PROSECUTION FOR ILLEGAL PRACTICE IN FRANCE.

A STATEMENT appeared in a recent number of the *Wiener Medicinische Wocherschrift* to the effect that, although the foreign Physicians who have been despatched to St. Petersburg by their respective Governments, in order to study on the spot the epidemic prevailing there, have been received with the utmost politeness and hospitality, they have been denied free access to the Hospitals and the means of investigating the nature of the disease, and this that its pestilential character may be the better kept from the public view. Dr. Van der Corput, the well-known Belgian Physician, and the delegate of the Belgian Government, warmly denies the truth of this statement, declaring that he cannot feel too grateful for the cordial reception he has met with at the Hospitals of St. Petersburg, Moscow, Wilna, etc., the doors of which are freely open to those who wish to investigate the epidemic. He testifies, too, to the admirable activity and solicitude manifested by the Russian Government in meeting the emergency, adding that the supposition that a Siberian or other pestilence is raging is absurd. Recurrent fever prevails amongst certain classes of the inhabitants of St. Petersburg, and is accompanied by a considerable number of cases of typhus.

Some sensation has been excited in Parisian Medical circles by the presentation of a petition to the Senate, nominally on the part of five *ouvriers*, demanding that homœopathy should be introduced into the Hospitals. In that august body such a demand will, doubtless, as it would among our own legislators, meet with many sympathisers, and a committee has been appointed to report upon it. Senator Dumas, the distinguished chemist, has been chosen as the Reporter, and although the fact of his being a Physician certainly did not procure him the post he holds in the assembly, it will enable

him to discharge the present duty with advantage to the community. The committee, before coming to its decision, has also appealed to the Administration of Public Assistance for its advice, and M. Husson, the Director of this, is said to have transmitted an extensive and decisive memoir on the subject. The Professional view of such a demand will, therefore, probably be satisfactorily developed; but we are somewhat surprised to find a writer usually characterised by great rectitude of views, M. Latour, maintaining in the *Union Médicale* that the proper mode of meeting the advances of homœopathy is to admit its pretensions, secure that in the long run, whether as teachers or practitioners, its votaries will exhibit their nothingness. "To bring discredit on their procedures, admit them freely to your chairs and your Hospitals; while if you wish to increase their importance, submit them to martyrdom and persecution." We had thought that a sufficiently long trial had, in various parts of the world, been accorded, and that the verdict returned was well nigh unanimous; and however little compassion we may feel for any of the consequences ensuing upon the vagaries of fashionable frivolity in Medicine, we must protest against those who have in their hands the grave responsibility of providing for the wants of the poor and ignorant trifling with this and coolly handing them over to a set of visionaries, as if the result were a mere matter of speculative curiosity in place of being always a question of health and strength, and often of life itself.

It is gratifying, however, to find that, although a clever writer may sometimes mystify himself with speculations like those we have adverted to, they have a very practical way of dealing with quackery in France. At the beginning of this year one Morel and his wife, and their accomplice, a Madame Redon, were convicted at the tribunal of Niort, at the instance of the Medical Association of the Deux-Sévres, of illegal practice of Medicine, and of swindling by means of animal magnetism. For the 326 instances in which illegal practice was proved, the fine was 10 francs each, the penalty being cumulative, therefore amounting to the sum of 3260 francs; while for the swindling they were condemned to another fine of 1000 francs and a year's imprisonment. Against this conviction appeal was made to the Imperial Court of Poitiers; but it was affirmed, the imprisonment being, however, reduced to three months, and the 1000 frane fine to 200 francs.

The most remarkable circumstance in this second trial was the speech for the maintenance of the conviction delivered by M. Camoin de Vence, the Advocate-General, and reported in the *Union Médicale*, July 6. In scientific precision, accuracy of knowledge, and lucidity of statement, this was a model, and seldom has the history and pretensions of animal magnetism been better detailed and more effectually unmasked. A few passages may give some idea of the effectiveness of this discourse:—

"Whenever a scientific truth has been in question, in spite of whatever obstacles may have opposed its early progress, still it has advanced; for, let who will say to the contrary, truth has always triumphed over error. But, side by side with the sciences which have successively enlarged our intellectual domain, there is also a long chain of the errors of humanity—great impostures, which reappear from age to age, based upon that irresistible impulse of man to believe in the marvellous. . . . It has almost always been females who have served as the instruments of this kind of manœuvre. And so it will be at all epochs when the object is to pretend inspiration and to assume an appearance of being above the ordinary events of life, the bent of their ideas, the temper of their mind, and the mode of their organisation naturally predisposing them to play this kind of part."

"If this woman Morel was enabled in her vision to see into the body, how comes it that she could not see its exterior? Why need she always inquire the age and sex? We can easily see how necessary these indications were to obviate errors of such a grossness that they would have undeceived the most credulous and the most blind. She was able to tell all the diseases of those at a distance who sent her a lock of hair, but she was unable to divine their sex."

"I will admit the reality of the cures, and will admit as many as you like, and more than you ask for. I only deny their dependence upon supernatural vision. They prove cunning, intelligence, a certain habit of observation, a skilful empiricism, and nothing more. Let me explain myself. Practitioners give, as a general rule, too much medicine, and they are well aware of this,—at least, the most experienced of their number. This excess must not be solely attributed to them, but depends in a great measure upon the patients themselves, who only consider themselves as well treated upon condition of being well drugged. All at once, some wise Physician makes his appearance, imbued with the old and salutary idea that nature is the *summa medicatrix;* or some charlatan arrives empirically at the same conclusion. Active medicines are suppressed, the economy, so to speak, breathes again, and nature pursues her beneficent work. This woman Morel always prescribed simples, and nothing but simples; and for whom? Why, for people the subject, for the most part, of chronic disease, and wearied of medicines. Surely the explanation of the success is as simple as were the remedies employed. Another reason is to be sought for in the effects of the imagination. Is there a Physician or *savant*, however renowned he may be, who can rival, in his power of affecting the imagination, a creature who sees while sleeping,—can look into the depths of organs, and can see what is invisible and does not even exist? And it is not only on moral affections—that is, on diseases without material lesion—that the imagination exerts its empire, for it also acts very powerfully on affections which have such lesions. Of this, striking examples may be found in the works of the princes of Medical science. Is it not an adage that faith saves in medicine? and this faith is the product of imagination, spreading calm in all directions, re-establishing order in the functions, and reanimating all by means of hope. Hope is the life of man, and he who can give him the one restores the other; so that two powerful reasons—the repose of the economy under the salutary influence of simple treatment, and the effect of the imagination—superabundantly explain the recoveries obtained by the skilful empiricism of Morel. Here, then, is a natural explanation of all these facts without having recourse to supernatural visions which everything rejects and nothing proves. If the magnetic sleep was pretended, the offence of swindling is incontestible."

We may congratulate the Medical Association at having a lawyer of his stamp at their disposal.

REPORTS ON NEW ARTICLES OF FOOD AND DRINK.

"EXTRACT DE VIN DE CHAMPAGNE CREMANT."

We have great pleasure in introducing to our readers a new and very important article of luxury and medicine, and will endeavour to describe it to the best of our power. It reaches us in half-pint capsuled bottles, bearing the label "F. Abelé, Epernay," and that of the London agent, Mr. Frederic Class, of 36, Crutched-friars. The cost retail is, we believe, 3s. 6d. per bottle, and not dear either.

Now for the stuff itself. What is it?—wine? liqueur? spirit? or what shall we call it? It is a most cunning compound of all. In the first place, it has abundant and most fragrant vinosity,—all the *bouquet* of the best Champagne. It is sweet, but not clammy, nor unclean on the tongue; it has great alcoholic strength, which is said to be due to fortification with brandy distilled from Champagne wine; and it is admirably and fully aërated with carbonic acid, so as to be truly *creaming*,—*i.e.*, to part with its carbonic acid slowly and gently, without froth and explosion; and it does not quickly become flat. Its taste is delicious, and it stands dilution with water well. The purposes to which it is applicable are, first, as a compendious mode of taking Champagne to picnics, etc., etc., for one bottle mixed with iced water would make a capital potation, though here, for our own parts, we keep our allegiance to wine unfortified. Secondly, for travellers. Thirdly, as a liqueur after dinner—*i.e.*, in the drawing-room—with the coffee, the true place of a liqueur. Refinement must never be lost sight of, nor should one elegant social custom be intermixed with an almost obsolete barbarism. When people over-ate themselves, *more Johnsonio*, on boiled pork with currant sauce, marrow puddings, sucking pig, and the like, o

dram of brandy was handed round, openly and notoriously to quiet an over-tasked stomach. Brandy was *Latin for the goose*, as the vulgar said and still say. So if people will overeat themselves now, and the stomach begins to calculate what is in it, let it have a sip of brandy, whiskey, or other strong dram to appease it. But to hand round a fragrant and delicate sweet liqueur, say white Curacoa, with cheese as a dram is, to our thinking, a want of refinement, and putting pearls where they are not appreciated. These fine liqueurs belong to another place—to the drawing-room with the coffee or tea. We trust our readers will pardon this digression on the true place of liqueurs, but really there is a right and a wrong in everything. Lastly, for the Medical Practitioner who desires an agreeable and effective stimulant in those so common cases of *lowness* in which one feels at one's wits' ends for something that will gratify the stomach and give a fillip to the nerves. If these observations, and those of our Commissioner on wines (now, by the bye, published in a separate book), have any weight with our Professional brethren, they will, we hope, induce them to take broader and truer views of the relations of Food to Life, and rise above the petty and miserable calculations of mere "carbon" and "nitrogen," which are now dignified with the name of "science." It is not "carbon" or "nitrogen" which the animal body wants, but certain, yet unknown and very complicated, compounds of these, and a great variety of these. We yet have to learn the laws through which a feeble, irritable frame, with a stomach to match, shall demand variety amongst things which are all alike to the mere chemist, shall reject all ordinary and "wholesome" food (as the common saying is), and shall create, as it were, an instinctive longing for what is popularly thought "indigestible," unwholesome, and noxious. What prompts a patient lying in bed, sinking with feebleness, spite of the most lavish administration of all that the stomach will keep down, to awake at 5 o'clock on a Sunday morning and cry out for lobster and beer, to take them greedily with instant benefit? The art of keeping feeble people alive is the art of suggesting and administering, under the guidance of instinct and experience, food in such variety as to supply the living material with what it will take to itself in one shape if it will not in another. We may have too great variety of drugs, because we cannot study and know them all; but we cannot have too great variety of food for the assimilative powers of the aged and feeble. As to our own experience of this latest member of the *materia alimentaria*, we can only say that when we had satisfied ourselves of the properties of the sample bottle submitted to us at our own table, we corked it up, and took it to the wife of a neighbouring Medical man, who for a month had been struggling with intense and almost fatal prostration after a distressing confinement, and who on that very day had had a relapse and threatening of sinking, from sheer exhaustion first, and some amount of swelled leg subsequently. Certainly no patient can speak more gratefully than she does of its *uplifting* effects; and so we commend it to our readers, to add to that not too long list of powerful alimentary cordials which we turn to when life and death are nearly balanced in the scale.

DR. BROWN'S CEREALINA.

This is described in the prospectus as—

"A new, delicious, and invaluable article of diet, superior in nutritive and digestive qualities. Cerealina is far more nutritious, digestible, and palatable than farina, maizena, corn starch, tapioco, arrowroot, sago, oatmeal, rice, or any other farinaceous preparation, and may be cooked in the same manner, the requisite proportions of cerealina being less than in any of the above-named articles."

We have submitted this article to the only manipulative and experimental test which is worth anything—namely, that of the accomplished divinity who rules over our own kitchen—and we have solemnly eaten the pudding which was the result of her labours. With the exception that it is somewhat darker in colour than might please every eye, the said pudding was unexceptionable; it was not thin and creamy like the puddings made of mere starchy matter (nice as these are when cold with fruit), but had something substantial in it, and nothing disagreeable. As regards quantities required, it is said to be economical. Therefore, whoever wants a change of nursery puddings may try cerealina. We have not the pleasure of knowing Dr. Brown, nor do we imagine that either of the scientific family of the Fusci now in existence will quarrel over his invention. If he wished for immortality, Dr. Brown should have given his Christian name and whereabouts. Whether he be now in the land of shadows, and whatever he have ever been anywhere else, we know not. The agent is Mr. Keith, 1, Ingram-court, Fenchurch-street.

The cerealina appears to be a combination of various flours, as of the wheat, Indian corn, etc. We do not hear of any new cereal plant, and suppose the discovery resides in the combination.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF OXFORD.

(Continued from page 611.)

Balliol College.

Balliol, or, more correctly, Baliol, the third in order of the great collegiate foundations of Oxford, is of less interest to the Medical world than the two that preceded it (Merton and University), to which we have already directed the attention of the reader. To the general scholar, however, it offers many historical features and traditions, of character. The early history invests it with place and degree. The foundation dates from the time of the Third Henry, viz., 1263, the forty-seventh year of that long-reigning monarch, but the College was not ready for occupation until the year 1268. The founder was a bold knight and one of the most loyal followers of Henry, by the name of John Baliol, commonly writ now as Balliol, but, if the old chroniclers are true, not writ in that way correctly. Baliol was the successor of a Baron of Baliol in France, who had made his way to England with the Conqueror, had entered "Bo-peep" Bay, came out of it again with his master, had landed at Hastings, had fought against Harold, and had been rewarded after victory. This baron's son Guy, in the reign of the First Henry was raised to great position, and was the Guy of Northumberland in those days. His grandson, in the time of Henry, inheriting the virtues and vices of his family, was feudal lord of Barnard's Castle, and husband of a lady of a royal line, Devorguilla, daughter of Alan Lord of Galloway, and of Margaret of Huntingdon, niece of Malcolm the Fourth, King of Scotland.

For many years Baliol of Barnard Castle did no more than enter into endless causes for his king; at last, in his old age, it seemed as though he had an impression that he might do something for his country, and his fancy took the turn of erecting the college at Oxford which bears his name. In this design he was warmly seconded by his wife Devorguilla, who, in fact, added to that which her husband had commenced, and completed his work. This noble pair are noted for having left behind them not a college only, but an only son, John Baliol, the competitor of Robert Bruce for the throne of Scotland, by the grace of "proud Edward" the First, for some time vassal-occupant of the throne, then a rebel, a prisoner, an exile, once more a small lord of Baliol, and, in turn, a dead lord in the land whence his ancestors came forth to join the Norman conquerors. The College of Baliol at Oxford thus outlived the house of that name, and not only survives a throne, but sustains the memory of the fact that in connection with its name there is a royal odour, perchance now weak from its journeyings and infinitesimal diffusion through six centuries, but just perceptible, and, as it were, faintly musty.

The College in its early days was famous for its library, which was completed as a building and enriched with good old books and MSS. about two hundred and ten years after the foundation. In the course of time numerous additions have been made to the College, and many innovations have been introduced; so that it is doubtful whether the Lord and Lady of Barnards would, if they could be called up again, recognise their collegiate child; at the same time they would have no occasion to be ashamed of the progressive steps by which what they would now see has been developed, and need have no regret at having laid the first stones of a home for many and distinguished scholars.

Baliol College is governed by a master. There are connected with it eleven fellowships and ten scholarships. The scholarships are worth about £75 a-year each, and are tenable for four years. There are in addition several exhibitions.

Exeter College.

Exeter College follows in point of antiquity on Baliol. It was, like Merton College, a transferred school or academy. Its founder was Walter de Stapleton, Bishop of Exeter, who, having a college or scholastic establishment at Hart Hall,

transferred his students from that place to Oxford, about the year 1320. A house of a collegiate character was built for the accommodation of the master and students, but by what name it was designated during the life of Bishop Stapleton, or whether it ranked as one of the colleges of the University, like Merton, University, and Baliol Colleges, is not quite certain. It was not until Stapleton had long been dead that the college bore his name, and perhaps hardly his name then, for another Bishop of Exeter had a hand in the work. In 1404 Edmund Stafford, of Exeter, bishop of the diocese, having endowed two fellowships, obtained permission of Henry the Fourth and of the authorities of the University to name the foundation Exeter College. In this condition the college remained until the eighth year of the reign of Queen Elizabeth, when Sir William Petre added eight fellowships. Petre had been educated at Exeter College, became a fellow of All Souls, and was at one time principal of a seminary called the "Peekwater." The life of this Sir William Petre would form an interesting volume. In the most troublesome period of English history, when feeling exceeded judgment, and men for the smallest offence were sent to the scaffold or the stake, Sir William lived on through four successive reigns, holding in every case a position among the advisers of the Crown. He was discovered as an able man by Thomas Cromwell, the expurgator of monasteries, and was one of the commissioners for inquiring into and reporting on the condition of those institutions in the reign of Henry the Eighth, and he pleased mightily that potent monarch by exhibiting a kind of terse wit which told nothing, and never conveyed an opinion. Like the hero of Crabbe, Sir Richard Monday,—

> He'd that calm look which seemed to all assent,
> And that complacent speech which nothing meant;
> He'd but one care, and that he strove to hide,
> How best for William Petre to provide.

Towards the close of the reign of Henry he was Secretary of State, and in the reign of Edward the Sixth he was Counsellor, devoting himself now to legal pursuits. Again he was Secretary of State in the reign of Mary, and took part—indeed, the leading part—in arranging the unhappy marriage of that unhappy woman. When Elizabeth succeeded he still retained his office for a considerable time, and was a member of her Privy Council during the remainder of his life, securing for himself the good graces of puissant Bess by falling headlong into the Reformation, and assuming, if not exercising, an almost rigorous sanctity. The secret of his success and of his steady progress in the midst of difficulties lay in the peculiar gift of holding his tongue. He was essentially a safe man, who locked up everybody's affairs in his own brain, and divulged nothing to their harm or his own. His regard for Exeter College sprang from his early education within its walls, and his addition of eight fellowships gave to the College a position which placed it on a par with its rivals. Another fellowship was added in 1636 by Charles the First, about the time when the difficulties of that monarch were beginning to shape themselves into that terrible form which he might then have crushed had he possessed even ordinary foresight. In the year 1700 the fellowships were increased by the bequest of a Mrs. Shiers, who left endowments for two more fellows of Exeter.

The College as a building has been largely increased, and very much modified from its origin. In 1620 the Rector, Dr. Prideaux, afterwards Bishop of Worcester, a man whose life also is in itself a history, built a large house in the College for the use of foreigners, who came to Oxford to hear his oral teaching on divinity, of which study he was Regius Professor. Afterwards, when the followers of Calvin —for Prideaux was a staunch advocate of Calvinian tenets— no longer flocked to Oxford, this house became a private residence, but in time was absorbed by the College. In 1620 Sir John Acland erected a hall. In 1622 a chapel was added by Dr. George Hakewill, and in 1788 a library was erected, to which, at considerable cost, many valuable, rare, and classical works were contributed.

The College at the present is governed by a Rector; it possesses fifteen fellowships, twenty-two scholarships, and nine exhibitions.

Amongst the Medical notabilities educated at Exeter I find the name first of an eccentric and successful man who in the reign of Charles the First went by the nickname of "Sir Simon the Rich," but whose real name was Simon Baskerville. Sir Simon was the son of Thomas Baskerville, an apothecary at Exeter, and was born in Exeter, in the year 1573; took the degree of B.A. in Oxford on July 8, 1596, and of M.D. on June 20, 1611. Soon afterwards he came to London, started in practice, and was made Physician to James the First. On the accession of Charles, Dr. Baskerville continued as Court Physician, and received from the King the honour of knighthood. He was contemporary with Harvey, and must, I think, have been the predecessor in office of Sir Alexander Fraser. Sir Simon's fame as a Practitioner was astounding. He is reported to have had a hundred new patients a week, and by the side of him his neighbour, William Harvey, who was revolutionising the Medical world by his immortal discoveries, cut a sorry figure as a practical man. Baskerville, indeed, was one of those who, being above forty years old at the time of the discovery of the circulation, did not believe in the fact, but looked on it as new-fangled, and practised in spite of it. One wonders now how a man could possibly practise at all without knowing the circulation of the blood; but Sir Simon practised to the tune of a hundred new patients a week, got a knighthood from the king, and, as the index of his success, the cognomen of "Sir Simon the Rich" from the people. He was a man to be envied in his day; but who would not rather now be the fiftieth representative of William Harvey than the actual representative of Sir Simon the Rich?

Another celebrity in Physic—if it be correct to call him a celebrity—who was educated at Exeter College was Gideon Harvey, a man who in his day was noted for setting the Profession by the ears, and specially for trouncing the College of Physicians and detecting their "frauds, plots, and intrigues against patients." Gideon was a Surrey man, born at Godalming, probably in 1625. He studied first at Exeter College, then for Physic went to Leyden and to Paris, taking his degree in the latter city. Returning to England and settling in London, he became on the Restoration Physician to Charles the Second, for whom he had acted as Physician-General to the English army in Flanders. He continued to attend Charles until his death, was chosen by William of Orange as his Physician, and was appointed Physician to the Tower. He lived, despite his quarrellings and the evil influence of eternal hot water, until the year 1700, when he became absolutely quiet, and has not been heard of since, and I fancy little read. He left a good many books, seven of which any one who likes may find in the library of the Medical Society of London. I had them all in hand once, and read on at them until I came to a certain one called "The Vanities of Philosophy and Physic," which soon transformed itself into the vanities of Gideon Harvey, and got pitched back straightway with a whole bundle of dusty stuff into the grim corner where probably it has reposed unopened for eleven years at least.

Oriel College.

Oriel College was founded by Edward the Second in the last year of his reign—viz., 1326—and at a period when one would have thought a King so miserable would have been thinking of other and more selfish objects. Our common histories seem to delight in running down the character of this sovereign, who, it is true, was indolent, we had almost said effeminate, and who carried favouritism perhaps beyond reason; but it is not fair to ignore his better qualities. He was essentially a man of literature, and an advocate of civilised progress. He could not beat the Bruce of Bannockburn, he could not intrigue so well as his own wife, he had less ambition than his own son, and he had poor strength with which to meet sufferings, of which he became, unhappily, very rich. I can scarcely imagine a more singular picture than this King flying, I had almost said, for his life to Bristol, and surrounded by numberless enemies, yet remembering meanwhile the city of Oxford, and keeping to his determination to have another college built there, himself the founder. In his design there is little doubt that he was stimulated to exertion by Walter de Stapleton, Bishop of Exeter, spoken of above as the founder of Exeter College, for Walter Stapleton was on intimate terms with the King, had charge of the Tower in his Majesty's name in 1326, and paid dearly for the honour, inasmuch as he was dragged during a riot to Cheapside, was beheaded on the spot, and had his head sent on a charger as a present to Queen Isabel. Edward founded the college with conveniences for the residence and maintenance of a provost and ten fellows. It remained for many years a small institution, as compared with its present dimensions. The hall was not built until 1637, and there was no library until the latter part of the eighteenth century. The first provost of the college was one Adam de Brom, who was almoner to Edward the Second, and who has the credit of having been the first to suggest to the King that the foundation of Oriel would do honour to his name.

The college is governed by a provost, and at present main-

tains fifteen fellowships, nine scholarships, and twenty-two exhibitions.

I do not find that any celebrity in Physic is specially connected with this College.

Queen's College.

This fine old building, raised opposite to University College, followed soon upon Oriel. It was founded in the fourth year of Edward the Third; or, at all events, the charter by which it received the title and the privilege of a college was granted by the king in that year—viz., on the 18th of January, 1340. The founder was Robert de Eglesfield, the confessor of Phillippa, the Queen of Edward; and the name of Queen's College was given in honour of Her Majesty. For many centuries this college was famous for certain ceremonials, which are rather singular than imposing. Thus, the members of the college were summoned to dinner by the call of a trumpet, and on New Year's-day the burser gives to each of the members a needle and thread, saying at the same time, "Take this and be thrifty." The tradition runs that this custom is taken from the words *aiguille et fil*, (*needle and thread*), a play or pun on the name of Eglesfield, the founder.

Another custom, not peculiar to this college, but made much of within its walls at Christmas time, especially in the earlier periods of its history, consisted in the procession of the boar's head, which massive ornament of the table was carried with great state on Christmas-day, the "setting" of the head being accompanied with an old song or rhyme, intoned or sung in Latin. There is an excellent story connected with the origin of this custom. It is said that when Queen's College was first built there was a wood at no great distance in which the wild boar roamed at pleasure, greatly to the terror of the college and the disadvantage of learning; for in those days, it would seem, the students, under no fear of proctorial criticism, delighted to stroll out into the woods and bye-paths, and, in the solitude of the great temple, read their fathers — their metaphysics, and their humanities. The wood to which I have referred had thus become a favourite haunt until the learned wild boar took unprincipled possession of it, and made it, in fact, his private study. For a long time this learned pig reigned unmolested,—a terror to Oxford in general, and the colleges in particular. At last, one day a student of Queen's College, absorbed in the contemplation of Aristotle, entered the wood, book in hand, in solemn meditation. A noise roused him to every-day thoughts, and lo! breaking through the thickets towards him, with a roaring noise and gaping jaws, rushed that merciless boar. Alas! for the student and Aristotle—especially Aristotle. What shall our student do? Fly?—that were madness. Fight?—that were impossible. Stand his ground?—there is something in that. So our student stuck his heel in the earth, threw off his mantle, and waited for the enemy, until he came—his mouth, as I have said, wide open—within arm's length, to find, by a desperate and dexterous thrust, the huge volume lodging in his throat. The learned boar had a capacious swallow, but Aristotle was too much for him; his roaring windpipe, a moment ago so loud, was choked up, and the terrible animal suffered death by what we in these days would call asphyxia. The deed accomplished, our student, a hero for life, must back to the College for his friends, who, returning to the wood, cut off the head of the boar, and on Christmas-day following carried it in triumph to the banquet table. This is a good story, but, unfortunately, there is a missing link in it, to the discovery of which I would respectfully direct the attention of the Antiquarian Society. The M.S. volume of Aristotle dissected out of that boar's throat is lost. It is not in the Bodleian, the Radcliffe, or the British Museum libraries. It is worth a thousand pounds to any scholar who can find it and prove its history. Will nobody try?

The library of the college was built in 1694, and in 1739 the college received what is called its new foundation. A wealthy man by the name of John Michel, of Richmond, in Surrey, having endowed it with £500 a-year, for the support of eight fellowships, four bachelor scholors, and four exhibitions.

The college at the present time is governed by a provost. It owns nineteen fellowships; has one chaplain, fifteen scholars, and two bible clerks; and it offers numerous exhibitions, the highest of which are worth £75, and the lowest £10 a-year.

Of the Medical notabilities connected with Queen's College, two call for notice. One of these was Dr. Fraunces, who was provost of the college in 1561, and was Physician to Queen Elizabeth. He was a man of some wealth and position, but added nothing, as far as I know, to the literature of Physic. The other Physician was Sir John Floyer, M.D., who was a student of the college. Floyer was born in Staffordshire, near to Stafford, in 1649; practised at Lichfield, and died there at an advanced age in 1734. He graduated in Medicine at Oxford on July 8, 1680. He had a very large and lucrative practice, and attained the honour of knighthood for his skill in Physic. Beyond being a Practitioner of repute, Floyer had some philosophical and theoretical talent, mixed up, however, with the crudities so prevalent in his time. He wrote a book entitled the "*Touchstone of Medicine, Discovering the Virtues of Vegetables and Animals by their Tastes and Smells;*" also works on the Preternatural State of Animal Humours; on the Nature of Fevers; an Inquiry into the Right Use of Baths; treatise on Asthma; a translation from the Greek of Sybilline Oracles; an Essay on the Best Means of Preserving Old Men's Health, with an Appendix on the Use of Inunction with Oil, and on the *Régime* of the Young; a Commentary on Forty-two Histories described by Hippocrates in the First and Third Book of the Epidemics.

But Floyer's best labour is displayed in what he calls the Physician's Pulse-watch; or, the Explanation of Feeling the Pulse and of Comparing it by the Pulse-watch. Floyer, in fact, may be considered the first man who examined the arterial pulse scientifically—that is to say, in relation to time, regularity, and tone. He made himself conversant with the variations of the pulse at different ages and periods, and reduced to a kind of order observations that previously were rudely and imperfectly conducted. Queen's College may be proud of Floyer Sir John.

REVIEWS.

Lectures on Pathology and Treatment of Lateral and other forms of Curvature of the Spine. By William Adams, F.R.C.S., Surgeon to the Royal Orthopædic and Great Northern Hospitals, etc., etc. Delivered at the Grosvenor-place School of Medicine in the Session 1860-61. Illustrated by Five Lithograph Plates and Sixty-one Wood Engravings. London: John Churchill and Sons. 1865. Pp. 334.

In this volume Mr. Adams gives, in eleven lectures, the result of a long series of post-mortem dissections at St. Thomas's Hospital, and of observations on the living subject at the Orthopædic Hospital and elsewhere.

Curvatures of the spine, Mr. Adams insists, are in no way analogous to those curvatures which are met with in the limbs, and which are due to overcontraction of one muscle or set of muscles. There is little analogy between the joints of the spinal column and those of the extremities. The erect posture is maintained—not by a rigid contraction of the spinal muscles, but by the anatomical mechanism of the spinal column. The muscles are not in a state of "*active tension*," but of "*vigilant repose.*" When flexion has occurred, the muscles on the convex side are mechanically stretched and rendered prominent. Those on the concave side are found to be flaccid; whereas, had the curvature been caused by the excessive contraction of muscles, it would have been the muscles of the concavity which must have been so contracted.

Mr. Adams passes over the various forms of antero-posterior flexion with comparatively short notice, and proceeds to discuss the question of lateral curvatures of the spine. According to Mr. Adams it is a mistake, and one which may lead to errors of practice, to suppose that lateral curvature of the spine ever exists as a normal condition. It is not even an exaggeration of a normal movement, for morbid lateral curvature of the spine often commences in the lumbar region, a region in which there is absolutely no provision for lateral flexion as a normal function. Lateral flexion is not merely a bending of the spine to one side or the other; it is in reality a horizontal rotation of the vertebræ. The bodies of the vertabræ may rotate to such an extent that in a very severe case their anterior surface may look directly to one side, and thus it may very easily happen that considerable lateral curvature may exist without any appreciable deviation of the spinous process. The bodies of the vertebræ are displaced, while the position of the spinous processes is but little interfered with. Lateral deviation of the spinous processes is not then to be trusted to as a means of diagnosis. A better sign is projection of the ribs on the convexity of the curve, and a sinking in of the ribs of the opposite side, this being evidently directly due to the rotation affecting the transverse processes. Mr. Adams denies that lateral curvature of the spine is neces-

sarily associated with rickets. The worst cases which he has met with were totally unconnected with rickets, and unless distinct symptoms of the affection be present, he thinks it wrong to assume its existence. It is important, indeed, to draw a broad line of distinction between those cases of lateral distortion which are due to rickets, and those which are independent of it, for in the former alone is the pelvis implicated. This fact is of great importance with reference to the advice to be given to deformed females as to marriage.

In diagnosing lateral spinal curvature, it must be borne in mind that oblique distortion of the pelvis is often simulated. The hip on the concave side is predominant, because the muscles on that side have receded.

Mr. Adams believes that the causes of lateral curvature are partly constitutional, partly local. Whatever tends to weaken the vital powers predisposes to the distortion, and thus we find it most frequently in girls. The local or immediate cause is constrained posture too long continued. Sometimes the abuse of horse exercise is sufficient. Lateral curvature of the spine may result from a habit of resting more on one hip than on the other. The whole weight of the body is thus transmitted through the articulatory processes of one side.

The articulatory processes are remarkably soft and imperfectly formed at the age of puberty; they become wasted by absorption, and as their position is latero-posterior, rotation of the vertebræ is the necessary result.

Mr. Adams details with care the symptoms of lateral curvature, and enters into the question of diagnosis. In the tenth and eleventh chapters he classifies the cases and discusses their treatment.

He classifies lateral curvatures according to their cause.

1. Cases essentially of constitutional origin, or in which the constitutional largely predominates over the local causes.
2. Cases depending upon constitutional and local causes in about equal degrees.
3. Cases essentially depending upon local causes acting mechanically so as to disturb the equilibrium of the spinal column.

For the first class of cases the treatment is, of course, mainly constitutional, consisting in the free exhibition of iron and of hypophosphite of lime. In the other two classes more careful local treatment is necessary. Gymnastic exercises Mr. Adams regards as rather preservative than curative, and as of most service when combined with recumbency during a considerable portion of the twenty-four hours. The hand swing, the elastic chest expander, and the act of drawing up a weight from the ground, are the most useful. Mr. Adams altogether rejects M. Guérin's plan of cutting the spinal muscles; he also rejects the system of mechanical extension of the spine, but he is a great believer in the system of supporting the spine by means of portable mechanical contrivances. He has invented a very ingenious "rotation plate" instrument to counteract the rotation of the vertebræ, which is always present in cases of so-called lateral curvature of the spine.

Mr. Adams deserves great credit for the patient way in which he has worked out his subject. There can be no doubt that he has advanced the branch of our Profession to which he has devoted himself. The only objection we would make is, that, however advantageous to the student may be the frequent repetitions required in lectures, to the busy Practitioner it is far more convenient to have information served up to him in a convenient form.

Cultura das Plantas que dao a Quina. Con cinco estampas Lithographadas. Lisboa.

On the Cultivation of Plants Yielding Quina. With five Lithographed Engravings. Lisbon, 1865. 8vo, pp. 117.

We welcome the appearance of the present publication as giving proof of the interest taken by the Portuguese in the maintenance of a cultivation in their colonies of plants so vital to the health of the community. The work, if our observation does not mislead us, seems to be of the same quality, if not identical with a series of articles published in the *Diario do Governo* on the same subject. It appears largely indebted to the industry of our countryman Howard, in his "Nueva Quinologia de Pavon;" at the same time, it is not without its obligations to the well-known work of Mr. Markham, "Travels in Peru and India," which has met with so much approbation. We recommend to the notice of our readers this further development of the subject, the more willingly as it serves to show that both the Portuguese and their government are alive to their immense opportunities and responsibilities in respect to natural science.

Manual of the Turkish Bath. Heat a Mode of Cure and a Source of Strength for Men and Animals. From writings by Mr. Urquhart. Edited by Sir John Fife, M.D., F.R.C.S., Senior Surgeon to the Newcastle Infirmary. London: John Churchill and Sons, New Burlington-street. 1865.

Have any of our readers ever passed along Jermyn-street on a cold, bleak, disagreeable day, when they were themselves harassed with overwork, or tormented by incipient lumbago, or irritated by some disappointment? Have they observed a large open door with some mystic characters engraved above it, while a chromo-lithograph stands guard at the threshhold, and displays the wonders of the Hammâm? If so, we hope that they have entered and undergone all those mysterious ceremonies, which, in the opinion of the uninitiated, are comprehended in the term "a Turkish bath." We hope so, because we think there are few things so thoroughly enjoyable to a used-up man as a Turkish bath when it is properly managed. At the door of the sudatorium all care is left behind; it is cast off with the shirt and other clothes. One sees one's fellow-creatures in a new aspect; a new train of ideas is excited. As the perspiration begins to flow, muscular pains cease to be felt, and a pleasing languor steals over the body, and inclines the mind to look at everything through a rosy-coloured glass.

After undergoing the buffetings of the dark demons who inflict torture with impunity by calling it "shampooing;" after being curried and whitewashed; after enjoying the delicious plunge into cold water and the swim, all too short; and after sitting for a certain time in the amount of clothing to which the Western Indians are partial, one emerges into the outer world refreshed and springy, with new energy and increased confidence.

When we first became acquainted with the Turkish bath, we were simple and ignorant enough to look upon it merely as a magnificent hot-air bath, which could not fail to be of use in some forms of disease, and which we knew from experience to be agreeable in health. We wondered that such a source of pleasure and health had been so long neglected, and we felt grateful to Mr. Urquhart for the part which he had played in introducing the bath into England. We now, however, know how worthless was our opinion. We have read Mr. Urquhart's book, and we have learned that the bath is a religion, and that it is a panacea. It cures all moral and physical evils. If men will only adopt it they will live peaceably all the days of their life, and they will drop off at length like fruit overripe. Mr. Urquhart has been a great traveller. He has observed much and reasoned much. He has been struck with the utility of hot air and the advantage of "the Turkish bath," and the idea has taken hold of his soul.

We think he must dream about sudatoria, and see piscina in the clouds. We are sure that he never looks at the sun without thinking of radiating caloric. It would, indeed, be astonishing if this were not the case, because Mr. Urquhart has already saved his life on four different occasions by radiating caloric; and there is no sufficient reason why he should not go on saving it for six times more.

It is fortunate for us that Mr. Urquhart is such an enthusiast. Did he not prize the bath above its real value, it is impossible that he could have succeeded so well in introducing it to this country. Mr. Urquhart has constituted himself the *missionary of the bath*, and if he occasionally becomes bigoted in his devotion to it, it must be remembered that he has also sacrificed much.

It must, however, be confessed that Mr. Urquhart is occasionally rather provoking. He is convinced that he is right, and he will listen to no arguments against the object of his idolatry. The skin must be heated and scraped according to the Turkish fashion, or he will have none of it. If he is nonplussed for an instant by some fact brought forward, he tries to save himself by denying the fact; and he occasionally makes statements which are, to say the least of it, extremely inaccurate. Thus, he tells us at page 60 that he has searched again and again in Celsus, and has found nothing to quote on the subject of unguents used in the Roman bath. If he has searched Celsus in vain, he ought to have recollected Horace. We quote from Creech's translation:—

> "I sleep till ten, then walk or read a while
> Or write for pleasure; 'noint myself with oil
> Not such as Natta pours, the rich, the base,
> Who robs the dying lamps to grease his face."

Now, Celsus scarcely ever mentions the bath without referring to the practice of rubbing the body with oil or unguents,—a practice which he strongly recommends in certain cases. Thus,

in the third section of the first book we find the passage—"Si balneum est, ante omnia in tepidario sedere; deinde ubi paulum eonquieverunt entrare et descendere in solium; *tum multo oleo ungi*, leniterque perfricari, iterum in solium descendere," etc. Again, in the fourth chapter of the first book, Celsus writes:—"Si in balneum venit, sub veste primum paulum in tepidario insudare; *ibi ungi* tum transire in calidarium," etc. We might quote passage after passage to show that the Romans were in the constant habit of using oils in the bath, but these will suffice. The point is interesting because the *rationale* of anointing appears to be the very reverse of that of the ordinary Turkish bath. In the latter the pores are opened; in the former they are closed up. In the latter the blood is brought into more immediate contact with the air; in the former an additional layer is interposed between the blood and the external atmosphere.

If we experience benefit in cases of consumption both from the Turkish bath and from inunction, are we still to believe that their action is diametrically opposed?

The volume before us is a collection of essays and of short-hand notes of conversations upon the Turkish bath. Mr. Urquhart, in his zeal to convert the Medical world to his way of thinking, invited Medical men to ask questions and suggest difficulties about the bath, while he answered them. The conversations were jotted down by a shorthand writer. We hope that the guests had notice that their words were being stereotyped, and that they afterwards had an opportunity of revising what they said. We are tempted to make this remark because the conversations read as if what Mr. Urquhart himself said were the only part which had been revised. We have read this book with much pleasure, and with much profit; but both would have been increased had the author only taken the trouble to make himself acquainted with the elements of physiology before he ventured to write on a Medical subject.

On Diseases of the Throat; their New Treatment by the Aid of the Laryngoscope. By Thomas Dixon, M.D., Physician to the Metropolitan Convalescent Institution, Physician to the Paddington Maternity Charity, etc., etc. London: Henry Renshaw, Strand. Pp. 101.

It is only lately that we have begun to have any just idea of the diseases to which the eye, the ear, and the larynx are subject; and the whole of the progress that has been made has been due to our improved means of physical examination of the organs affected.

A number of different conditions are no longer classed together under the convenient title of "amaurosis.'

A polypus of the external meatus auditorius is no longer treated with injections of tepid water or blistering behind the ears; and aphonia is now known to be due to a variety of different conditions of the larynx and vocal cords.

Dr. Dixon's little book is written with the avowed intention of urging the more frequent use of the laryngoscope in throat disease, and of pointing out the efficiency of the local treatment which it is now possible to employ.

By the recently invented instruments for pulverising fluids it is now possible to direct a stream of medicated fluid not only into the trachea, but also into the bronchi, and the results which Dr. Dixon has obtained show the great superiority of this treatment.

Dr. Dixon's chapter on follicular disease of the throat is very good; few will read it without profiting by it.

The College Lectures.—Professor Fergusson brought his course of lectures to a close on Friday, June 16.

Arts Examinations.—It may be interesting to students to know that there will be a preliminary examination in general knowledge of candidates for the diploma of Member of the College of Surgeons on Tuesday next, the 20th inst., and that those gentlemen who pass this examination, or those at the College of Physicians or Hall, can enter on their Professional studies on October next.

Death of a Surgeon of the Belgian Legion in Mexico.—M. Lejeune, a most promising Surgeon, 29 years of age, who had volunteered as Surgeon into the Belgian Legion, was killed by a ball while in the very act of dressing the wound of a Mexican soldier at the end of the recent engagement at Tacamburo. There seems to be no doubt but that he was shot intentionally.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

May 27, 1865.

I see by this morning's paper that the number of deaths for the week ending May 20 amounted to 283, being an increase of 16 on the corrected average of the last ten years. Amongst the causes typhus still occupies a too prominent position, numbering 48, or 34 above the average. Small-pox numbers 15, of which 4 are stated as having been vaccinated. I am not aware of anything in the way of local Medical politics of sufficient interest to require notice in your columns, and I will at once pass on to narrate a few cases presenting special points of interest. A few days ago I saw Mr. Bickersteth remove a very large calculus from the submaxillary gland. The patient, a Medical man, noticed, twelve months ago, an induration, which gradually increased without involving any of the surrounding structures. When Mr. Bickersteth first saw him the right gland was almost the size of a hen's egg and as hard as scirrhus, a circumstance that very naturally created apprehension in the mind of the patient as to the nature of his complaint. A small probe was introduced through the duct, and a grittiness at once suggested the presence of a calculus. In every other respect the patient enjoyed good health. Mr. Bickersteth determined to remove the calculus by the mouth, so as to avoid that risk of leaving a salivary fistula which would have been incurred by adopting the simpler method of extraction by external incision. The operation consisted in slitting up the duct on a small director until the calculus was reached; the opening was then enlarged, partly by dilatation with the finger and the cautious use of the knife, until there was sufficient room to allow of the introduction of an ordinary pair of lithotomy forceps. The calculus was then seized, but being rather soft had to be removed piece by piece. I should say that it was about the size of an ordinary walnut. Dr. Edwards finds that it consists of pure tribasic phosphate of lime, appearing under the microscope to be aggregated in very thin layers. Since the operation the patient has done exceedingly well; some slight induration, the result of inflammatory action, still remains. It is exceedingly rare to find salivary calculi of so large a size; usually we find them small, blocking up the duct and impeding the flow of saliva into the mouth. For the cure of organic stricture of the urethra Mr. Long and Mr. Bickersteth have been making use of rapid dilatation, and in the cases I have seen in the Infirmary the results have been most satisfactory. An accident occurred the other day that is worthy of notice. Mr. Bickersteth was dilating with Mr. Henry Thompson's instrument a stricture of many years' standing when a crack was heard, accompanied with a sudden closure of the blades, and on withdrawing the instrument it was found minus the lever by which the blades are separated. A bougie was introduced, but the lost fragment could not be felt. The operation being incomplete, Mr. Bickersteth at once proceeded, with the aid of another instrument, to finish it, in order, by enlarging the urethra, to give the fragment the best chance of escaping with the flow of urine. This was accordingly done, and afterwards a No. 12 bougie passed easily. The strangest part of the case remains to be told, for on examining the last-used dilator the blades were found separated by a considerable interval, and on looking for the cause the lost fragment was found lying with its long axis corresponding with that of the dilator. This was a most fortunate termination to an accident that might have resulted in serious consequences. A Tuesday rarely passes without our finding something that will repay a visit to the operating theatre of the Royal Infirmary. On Tuesday, May 23, there were several cases of interest, Mr. Long performed Symes' amputation at the ankle-joint for disease originating in the os calcis. Mr. Bickersteth excised the shoulder-joint for disease of long standing. The head of the humerus, as far as the anatomical neck, had been entirely removed by absorption. I have seen this excision practised here on several occasions with the best possible results. Mr. Bickersteth then introduced a patient whose knee-joint he had excised twelve months ago, for the purpose of removing some dead bone. As far as the excision is concerned the result is all that could be wished, firm union having taken place of the cut surfaces of bone. It is to be hoped that the removal of some carious bone will be the means of enabling the patient to reap the full benefit of an operation

which is rapidly gaining the confidence of our operating Surgeons. At the Northern Hospital, a few days ago, Mr. Lowndes had to resort to re-amputation in a case of painful stump. Symes' amputation at the ankle-joint had been performed at Queenstown twelve months ago with success as far as concerned the healing of the stump, but the patient had suffered ever since most severe pain. Several measures had been resorted to, but without success. As there was no alternative but amputation, Mr. Lowndes, being anxious to save the original heel flap, made a long posterior flap so as to enable him to remove about an inch and a half of the bone and the whole of the old cicatrix. Examination showed that the anterior and posterior tibial nerves, but more especially the latter, were very largely dilated, and firmly adherent to the cicatrix. Since the operation the patient has been almost free from pain.

Tuesday, May 30.—I have just returned from attending the operations at the Infirmary. Mr. Bickersteth performed lithotomy on a child, aged three years. The calculus was composed of lithate of ammonia. In his remarks on the case, Mr. Bickersteth, when alluding to the question of mortality, stated that he had now operated on thirty-eight children, and only one had terminated fatally. These figures show that in children lithotomy may be regarded as an operation attended with comparatively little danger. I ought to add that the lateral operation has been the one almost universally practised.

IRELAND.

DUBLIN, June 8.

IN my last letter I gave a brief account of some of the "surgical appliances" to be found in our International Exhibition; in my present communication I shall direct my attention more particularly to the departments of chemistry, pharmacy, and botany.

Messrs. Bewley, Hamilton, and Co., of Sackville-street, chemists to the Queen, exhibit, in the north-east gallery, a case of very elegant preparations produced in their laboratory under the superintendence of their able chemist, Dr. Aldridge. The specimens of citrate of iron and quinia, and of valerianate of zinc, are particularly beautiful. Aloïn, strained from the fresh juice of socotrine aloes without undergoing any chemical process, is exhibited. Dr. Aldridge detected the crystals in the juice in 1852, and exhibited them before the Natural History Society of Dublin about the same time that they were observed by Pereira, without being aware of the researches of the latter distinguished writer. Citrate of iron and strychnia, first produced in the laboratory of Messrs. Bewley and Hamilton, guaranteed to contain 1 per cent. of strychnia, is also exhibited. This salt, as met with in commerce, is said to contain very variable proportions of strychnia, which is obviously a serious disadvantage. Hydrocyanate of morphia, another preparation first prepared in their laboratory, was originally suggested to Dr. Aldridge by Dr. Evory Kennedy, and was a great favourite with the late Sir Henry Marsh, who made it, combined with ipecacuanha, the basis of a form of pectoral lozenges. It possesses the virtues of hydrocyanic acid in an eminent degree, and must consequently be employed with caution. It cost some trouble to make. When morphia is put into prussic acid, these substances mutually decompose each other. Dr. Aldridge proposed to prepare the salt by decomposing cyanide of silver by means of muriate of morphia, but in this process some of the silver is apt to be dissolved, and to give the product a most disagreeably metallic taste. He now prepares it from very pure cyanide of potassium, sulphate of morphia, and alcohol (specific gravity 810). The product is always more or less coloured, but this does not appear to interfere with its activity. Among the other contents of the case are very beautiful specimens of iron alum, saccharated sulphate of iron, iodide and bromide of cadmium, arseniate of potash, iodide of ammonium, etc., etc.

In the Mauritius Department, M. Bouton, Curator of the Colonial Museum, and Secretary to the Royal Society of Arts and Sciences of the Mauritius, exhibits a case of medicinal plants indigenous to, or naturalised in, that island, the collection being described in an octavo volume of 147 pages from his pen, entitled "Plantes médicinales de Maurice." The plants described in the work are used medicinally by the Creole Practitioners of the island. In the temporary absence of Mr. Morris, the Colonial Commissioner of the Mauritius, attending the Exhibition, I shall be able on the present occasion to speak only of those plants which happen to lie at the top of the case.

The first I shall notice is the *Papaya edulis*, the fruit of which, on being incised, while still green, yields a lactescent juice often employed in the numerous cases of intestinal worms occurring among the children of the servile class in the island. The anthelmintic property of this remedy is said to have been discovered accidentally by a negress, who, having charge of her master's piggery, observed that when she gave the animals green Papaw fruit cut into slices, they usually passed worms. As she had herself long suffered from the same affection, and had taken different remedies without success, she tried that which chance had thrown in her way, and was cured.

Desmodium cæspitosum, little trefoil, much used among the Creoles as a cooling depurative and laxative. A decoction of the roots is employed in herpetic affections. The plant enters into an empirical remedy against the endemic disease called *tambave*.

Trichodesma Indicum, Indian borage; *Scutia Commersonii*, *Rhamnus lucidus*; the bark of the latter shrub, the *bambara* of the natives, is tonic and astringent, and is frequently employed by the Creoles to check chronic diarrhœa and dysentery. Lomatophyllum reflexum, *bois de chandelle*, known in Madagascar under the name of *Hassn*; the bruised leaves are used as a vulnerary for the cicatrisation of wounds. The plant, which is said to be a powerful astringent, is employed in the treatment of dysentery. In the *Dictionnaire des Sciences naturelles*, it is stated, on the authority of Commerson, that this plant is "a very powerful emmenagogue, too often abused by the female slaves of Madagascar; it is sufficient for them to eat one or two of the young bunches to produce the effect they desire." *Chenopodium ambrosioides*, vermifuge, a plant of very strong and repulsive odour; *Davallia tenuifolia*, little fern, forms the basis of the popular remedies against the *tambave*; *Pæderia sessiliflora*, used in diseases of the skin, diffuses an odour of sulphuretted hydrogen.

The admission to the Exhibition being now reduced on four days in the week to one shilling, and the weather being lovely, there is a great increase in the number of visitors; nevertheless, the space is so extensive, and the points of attraction are so many and varied, adapted to all tastes and pursuits, that inconvenient overcrowding has not yet been experienced.

GENERAL CORRESPONDENCE.

NAVAL MEDICAL OFFICERS AND GREENWICH HOSPITAL.

[To the Editor of the Medical Times and Gazette.]

SIR,—The net result of the discussion on the Greenwich Hospital Bill, as far as the Profession is concerned, is that we have unmistakable proof that the present Administration are resolved to treat Naval Medical Officers with contempt, and that the opposition are pledged on their advent to power to do the Medical officers justice.

A good deal more might have been said by the friends of the Profession in the House of Commons on the conduct of the Admiralty in this matter; but the feelings of hatred against Medical officers is so ingrained in the present Board, that nothing like fair dealing could be expected at their hands. And in justice to Sir Jno. Pakington I must say, as I believe, that he would have failed to make any impression upon them by any motion the rules of the House might have admitted.

In the proposed distribution of out-pensions the Admiralty in their bill proceed on the assumption that those classes only should benefit who lose by the bill a few sinecure appointments. But these very classes have long been in the enjoyment of out-pensions together with their appointments, and the pensions now proposed to be given are in excess of those they already enjoy. Whereas, the Medical appointments have been such, and such only, as the exigencies of the service required. It is, then, a mere pretence to say that because Medical officers will still be required to perform active duties at Greenwich Hospital the mass are not entitled to out-pensions from the funds of that institution.

To crown all, and to show the utter want of principle of the Board of Admiralty, I would mention that a sinecure office of governor is made permanent by a decision of the House of Commons in committee on the bill yesterday, with the entire concurrence of the Junior Naval Lord. And I would now, with your permission, repeat the caution I gave in a recent letter to the rising generation of Surgeons to avoid a service in which their Professional status will not be acknowledged,

and from whose rulers the commonest justice must not be expected. For my part, I do not believe that in these days of open competition any man presents himself for admission into the navy who feels that he is competent to undergo a competitive examination for the army.

But be this as it may, permit me, in conclusion, again to say to young Surgeons, put not your trust in Boards of Admiralty, and to entreat the members of the Profession generally to estimate the merits of the rival candidates at the forthcoming general election from a Medical point of view.

I am, &c.

London, June 14. A Physician.

THE NAVAL MEDICAL SERVICE.

[To the Editor of the Medical Times and Gazette.]

Sir,—The late startling naval *Gazette*, showing that, in this time of peace—stagnant as regards the number of ships of war employed—the Admiralty are unable to muster half-a-dozen Assistant-Surgeons for the contingencies of the service, must open the eyes of the Medical Profession, and prove also to the Lords Commissioners at Whitehall how successful have been their efforts to degrade and lower the position of the naval Medical officer, and how fully appreciated such efforts are by young Medical men.

Various letters have appeared from time to time in your journal, each alluding to some particular grievance; but I hope you will allow me, in a prominent page of the *Medical Times and Gazette*, to give a very brief statement of the grievances we labour under in a more comprehensive manner, showing the disadvantages of the naval Medical officer, even as compared to the military Surgeon, whose complaints have, with justice, received so much sympathy from the Professional press.

I will state, *seriatim*, the chief causes which, I know, are calculated to render the naval the most unpopular of all the Medical branches of the public service.

1. The want of continuous service. The naval Surgeon is placed on half-pay at the termination of his ship's commission, the term of which is generally three and a-half years. He remains on the list, for a considerable time, against his own wish, losing a large proportion of pay, as well as full-pay service time. It is found that a loss is thus incurred equal to, on the very lowest calculation, twelve months in every five years, or five in twenty-five. A full-pay service of twenty-five years is necessary for retirement, and it is evident that the naval officer must, before he can claim such, have been upwards of thirty-one years in the navy, and be not less than 53 years of age, while his brother in the army does not lose a day on half-pay, and retires at the comparatively early age of 46 or 47, having been but twenty-five years in the service. This is the great and crying evil of the Naval Medical Service, as compared to the army; the full-pay and half, as well as retirement, being the same after certain terms of full-pay service.

2. The most unfair distribution of prize money. In the army prize money and allowances are given according to the relative rank of the Medical officer. In the navy the ship's carpenter, the boatswain, the young sub-lieutenant, and lieutenant of marines share equally in prize money with the Staff-Surgeon (Surgeon-Major army), Surgeon, and Assistant-Surgeon. Rank is entirely ignored.

3. The want of a regular roster for active employment from half-pay. If loss of time on half-pay must from time to time take place, officers should be called to full-pay service in regular rotation; and it should not depend, as at present, on favouritism, caprice, political or other influences. Each officer would thus know when his turn for service was approaching, and be enabled to make necessary arrangements.

4. The want of proper cabin accommodation. This should be regulated according to relative rank. At present no Assistant-Surgeon can claim a cabin, and in many of our large ships the junior does not possess one.

5. The very limited number of inspectorial officers on the active list. As Surgeons are only allowed by recent regulations to retain appointments in Hospitals, dockyards, or the marine corps for five years, the same rule should be extended to inspectors and deputy-inspectors general. Thus all officers of good character might aspire to future promotion, as in the army.

6. Honours, military and civil, are not fairly dealt out to the naval Medical corps. A gross instance of this neglect has been observed and most acutely felt in the recent distribution of the Order of the Bath.

7. The Medical naval officer has also been excluded from the out-pensions of Greenwich Hospital, although all other classes have been included under the new Bill introduced by Mr. Childers.

The above I believe to be the main grievances my class labour under, as compared with the sister service, which complains most justly of the treatment endured, and which complaints apply to us equally, in addition to those I have submitted.

I have to apologise for the length of this letter, but feel certain the importance of the subject at this crisis will be my excuse to you.

I beg also to subjoin a table of the present and proposed scales of pay, based entirely on the loss to the naval Surgeon by the rule of half-pay; the proposed rates only equalising the pay of the naval and army Medical officers.

I am, &c. A Naval Medical Officer.

Table Showing the Present Rates of Full and Half-Pay, with a Proposed Increase, in Consequence of the Loss of Time occasioned by being Placed on Half-Pay.

Present Scale.

	Daily.		Annual.		
	s.	d.	£	s.	d.
Assistant-Surgeon—*Full-Pay:*					
On entrance to the service	10	0	182	10	0

SUBCUTANEOUS INJECTION.

Letter from Dr. Alexander Wood.

[To the Editor of the Medical Times and Gazette.]

Sir,—Several of my Professional brethren have called my attention to a report in your paper for June 3 of a meeting of the Royal Medical and Chirurgical Society.

Mr. Hunter there gives an account of what he calls the "Hypodermic Administration of Certain Medicines." He is

reported to have said, "The hypodermic differs from the method of Wood."

To this I reply it does so merely in name. I called my method "subcutaneous," borrowing from the Latin; Mr. Hunter, in appropriating it, called it hypodermic, a Greek compound having precisely the same meaning.

He proceeds, "The injection was supposed to be efficacious simply through the localisation." Now, the theory may be wrong, but I still constantly see cases which other Medical men have attempted to cure by injections at a distance from the affected part, and which have yielded readily to the local injection properly applied.

But, after all, whatever credit be due for the introduction of this new practice ought surely to be his who showed the plan of using the cellular tissues as a medium for the introduction of remedies into the system.

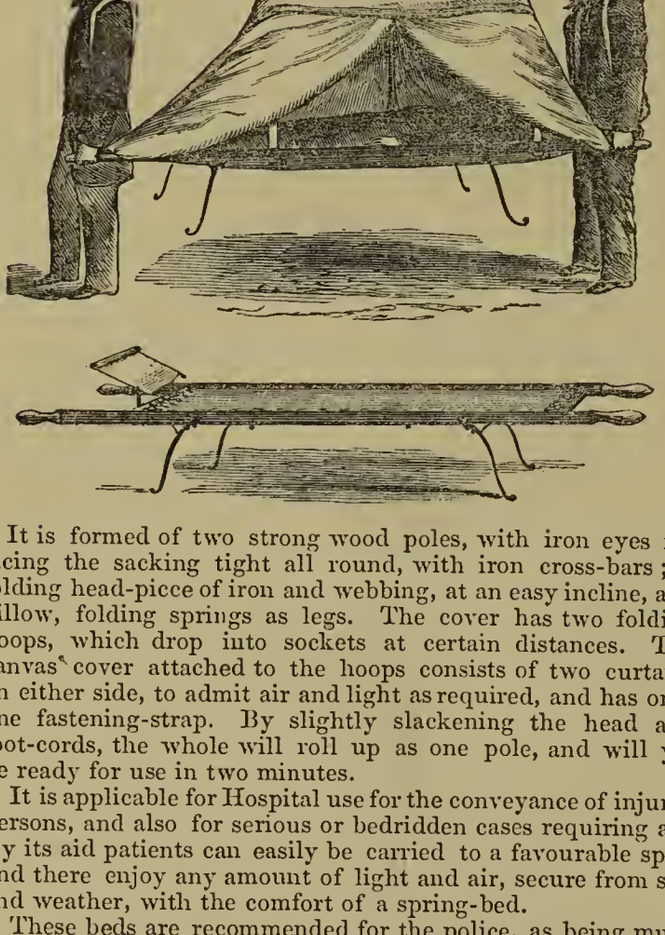
My paper has been translated into most foreign languages, and my practice is adopted over the globe; but, so far as I know, my claim to be the introducer of the practice has never been called in question till now, and certainly ought not to be so by one who has only slightly, if at all, modified some of the details. I am, &c.

Physicians' Hall, Edinburgh. ALEXANDER WOOD.

NEW INVENTIONS.

CAPTAIN RUSSELL'S STRETCHER.

THIS appliance, called "Russell's Camp Spring Stretcher or Dholee," obtained honourable mention from the Medical jury in the Exhibition of 1862. In the conveyance of injured men, it possesses the advantage of a flat, even surface, the avoidance of shock in changing bearers, and the ease of a spring-bed; and its cover protects from sun, weather, and exposure.



It is formed of two strong wood poles, with iron eyes for lacing the sacking tight all round, with iron cross-bars; a folding head-piece of iron and webbing, at an easy incline, as a pillow, folding springs as legs. The cover has two folding hoops, which drop into sockets at certain distances. The canvas cover attached to the hoops consists of two curtains on either side, to admit air and light as required, and has only one fastening-strap. By slightly slackening the head and foot-cords, the whole will roll up as one pole, and will yet be ready for use in two minutes.

It is applicable for Hospital use for the conveyance of injured persons, and also for serious or bedridden cases requiring air. By its aid patients can easily be carried to a favourable spot, and there enjoy any amount of light and air, secure from sun and weather, with the comfort of a spring-bed.

These beds are recommended for the police, as being much lighter than the rude stretchers now in use, and also as avoiding shock in change of bearers. The cover also prevents exposure. The straps enable a man to carry double weight, and leave his arms free for other purposes. Two can carry a weight that, with the ordinary stretcher, would require four. These stretchers would also be found most useful appliances at railway stations and in workhouses. They are manufactured by Alderman, of Soho-square.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of the gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, June 8, 1865:—

George Birch, Enfield-road, De Beauvoir-square; Richd. Jas. Andrews, Trinity-square, E.C.; Jas. Mortimer Fuller, Park-road, St. John's-wood; Samuel Gourley, West Hartlepool, Durham.

The following gentlemen, also on the same day, passed their first Examination:—

Thomas Frederick Hopgood, University College; William Spratt, Guy's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BLADES, CHARLES C., M.D. St. And., has been appointed Surgeon to the L Division of the Metropolitan Police.

BRICKWELL, JOHN, M.R.C.S. Eng., has been appointed House-Surgeon to the Royal Dispensary and Infirmary, Windsor.

GOODING, RALPH, B.A., M.R.C.S. Eng., has been appointed House-Surgeon to the Ipswich and East Suffolk Hospital.

HEAD, EDWARD, M.B. Lond., has been appointed Obstetric Physician to the London Hospital.

HOWARTH, GEORGE, M.R.C.S. Eng., has been appointed one of the Surgeons to the Bolton Infirmary and Dispensary.

ROBINSON, ALEXANDER H, L.K.Q.C.P.I., has been appointed to the Commission of the Peace for the Co. Tyrone.

TURNER, FREDERICK, M.R.C.S. Eng., has been appointed a Medical Officer to the Buxton Devonshire Hospital.

WADE, WILLIAM S., L.R.C.P. Edin., has been appointed Surgeon to the Police Force, Wakefield.

WILSON, M. S. W., M.R.C.S. Eng., has been elected House-Surgeon and Secretary to the West Norfolk and Lynn Hospital.

WINTER, JOHN, M.D., has been appointed a Member of the Legislative Council of the Island of Newfoundland.

DEATHS.

BROWNE, WILLIAM V., M.D. St. And., at Hayward's Heath Asylum, Sussex, on May 17, aged 40.

CLARKSON, J. JENKINSON, L.R.C.P. Edin., at Lausanne, Switzerland, on June 1, late of Lancaster.

COLE, EDWARD H., M.R.C.S. Eng., at Colaba, on April 14, aged 29, formerly of Great Plumpstead, Norwich.

COOK, ROBERT, Surgeon, of Gainsborough, in London, on June 4, aged 80.

DICKSON, —, M.D., at Gatehouse, of Fleet, on June 3, formerly of Lochmaben.

FOREMAN, ROBERT C., M.D. Edin., at Church-hill House, Brighton, on June 11, aged 43.

FURNIVALL, GEORGE F., M.R.C.S. Eng., at Egham, Surrey, on June 7, aged, formerly of H.M. 14th Regiment.

GARLICK, JOSEPH PRINCE, F.R.C.S. Eng., at 42, Park-square, Leeds, on June 4, aged 73.

KING, GILBERT LENNOX, Surgeon R.N., at Wyndham-street, Plymouth, on June 9, aged 32.

LUCAS, RUDD, M.R.C.S. Eng., late of Long Ashton, Bristol, at Clifton, on May 28.

MACLAGAN, DAVID, M.D. Edin., F.R.S. Edin., Surgeon in Ordinary to the Queen in Scotland, at 129, George-street, Edinburgh, on June 6, aged 81.

REVEIL, M., one of the *agrégé* Professors of the Paris Faculty of Medicine, and Professor at the School of Pharmacy, died suddenly on June 6, having recently suffered from some slight symptoms of angina pectoris.

RICHARDSON, Sir JOHN, C.B., F.R.S., M.D. Edin., late Inspector-General Naval Hospitals, at Grasmere, Westmoreland, on June 5, aged 78.

ROSS, ANDREW, M.D., St. And., at Chichester, on June 7, formerly of Waterloo, Hants.

SOUTHEY, HENRY H., M.D. Edin., F.R.S., at No. 1, Harley-street, Cavendish-square, W., on June 13, aged 82.

DEATH OF HENRY HERBERT SOUTHEY, M.D., F.R.S., D.C.L.—The death of this eminent Physician took place on Tuesday last, at his residence in Harley-street. Dr. Southey held the appointment of Lord Chancellor's visitor of lunatics, and was formerly Physician in Ordinary to George IV. The deceased was born in 1783.

DEATH OF SIR JOHN RICHARDSON, F.R.S.—This distinguished naturalist died somewhat suddenly at Grasmere on Monday last. He was born at Dumfries in 1787, and was educated at the grammar school of his native town. On leaving school at 14 years of age he entered the University of Edinburgh, and devoted himself to the study of Medicine. After passing through the University he entered the navy as Assistant-Surgeon, and served at the siege of Copenhagen in 1807. In consequence of the zeal and ability he displayed on that memorable occasion, and "for having served in the boats during a night attack upon a French brig in the Tagus," he was promoted in 1818 to be Acting-Surgeon of the *Hercule*, a 74-gun ship. During the war with the United States in

Canada and Georgia he served as Surgeon to the 1st Battalion of Marines, and in 1819 accompanied Sir John Franklin's Arctic expedition as Surgeon and naturalist. He also accompanied Sir John Franklin's second expedition in 1825, when he commanded two boats, in which he discovered the passage between the mouths of the Mackenzie and Coppermine rivers. In 1838 he was appointed by Lord Minto, then First Lord of the Admiralty, to be Physician to the Fleet, and in 1840 he was made Inspector of Hospitals. The deceased was the author of the "Fauna Borealis Americana," the "Zoological Appendix to Sir Edward Parry's Second Voyage," the "Icthyology of the Voyage of the *Erebus*, the *Terror*, and the *Sulphur*," and many reports and scientific papers. He received the honour of knighthood in 1846.

Death of Mr. Joseph Prince Garlick, F.R.C.S.—It is with sincere regret that we have this week to record the death of one of our highly-respected fellow townsmen, who, from being associated with some of the principal institutions of the town and district, will be missed from various public spheres of usefulness. Mr. Joseph Prince Garlick, Surgeon, died at his residence, Park-square, on Sunday, June 4, aged 72 years. He had for a short time been in a declining state of health, and his demise was not unexpected by his family and more immediate friends. As a Professional man, Mr. Garlick had long maintained a good practice, and he was not less respected by his Professional brethren than he was by all classes of patients who had experienced his great skill and mild and affectionate demeanour—by the latter often, almost as much as by the former, assuaging human suffering. In connexion with the Leeds Public Dispensary his name stands deservedly high, for he not only took an active part in the establishment of that excellent institution, but he was one of its Surgeons from its opening in 1824 to 1852, a period of twenty-eight years, during which many thousands of the humbler and poorer classes received the benefit of his Professional skill. In the Leeds School of Medicine, which is one of the most distinguished in the provinces, Mr. Garlick took a prominent position, along with other eminent Leeds Medical men, having been lecturer on different branches of science, including Anatomy, Physiology, and Surgery. The West Riding Medical Charitable Society—a society after his own Christian principles, and of which he was one of the founders, had the advantage of his personal aid for a long period, he having occupied the responsible post of Secretary for twenty-five years, and never having missed attending a single one of its annual meetings. Amongst the religious societies which had his warm support were the Pastoral Aid Society, the Church Missionary Society, and the Bible Society. Of the Leeds auxiliary of the latter he was for several years the Secretary, and of the Leeds branch of the Pastoral Aid Society he was for some years the President. He was a trustee of St. George's Church, and also of St. Stephen's Church, both in this town. His whole career, private and public, was one of uprightness and candour, liberality and charity, and he has departed hence in the well-merited esteem of his fellow-men. —*From the Leeds Intelligencer.*

The annual meeting of the Association of Medical officers of Asylums and Hospitals for the Insane will be held on Thursday, July 13, by permission of the President and Fellows, at the Royal College of Physicians. The President elect is Dr. Wood.

The ordinary monthly meeting of the Odontological Society was held on Monday, the 5th inst., at the Hospital, Soho-square, the President (Thomas Rogers, Esq.,) in the chair. Mr. Coleman called the attention of the Society to a case in which torsion had been unsuccessful, owing to the spiral shape of the fang, causing the tooth when turned, to come out of the socket. Mr. Woodhouse said his plan had been never to attempt torsion after the tooth had been through more than a year. Dr. L. Levison read a paper entitled "Some remarks on a few human skulls, as furnishing data in proof of the brain being under similar laws (organic) as induce the development or wasting of the muscular system; and that as most of these skulls are abnormal specimens, they furnish some suggestive explanations of certain forms of disease in the dental organs." Mr. Woodhouse read a paper "On the Use of Carbolic Acid in Dentistry." He said that carbolic acid in the operation of excavating a tooth for stopping, from its cauterising property, was exceedingly useful in rendering a fresh prepared surface of the cavity less sensitive before filling it. The acid was most useful in cases where the pulp was exposed, and where, without its aid, the general practice would be to destroy it. After describing the mode of treatment, Mr. Woodhouse read notes of cases prepared by Mr. Gibbons, in which the acid had been successfully applied to the treatment of sensitive dentine, exposed pulp, and alveolar abscess. A long and animated discussion followed, various members of the Society narrating cases where the application of carbolic acid had been most successful.

Overcrowding in the Dwellings of the Poor.—At a meeting of the Health Department of the Social Science Association, held at their rooms in the Adelphi, on Wednesday last, Dr. Lankester, F.R.S., in the chair, a paper was read by Dr. Hardwicke, "On the Evils of Overcrowding in the Dwellings of the Poor, and Means suggested for their Removal." Dr. Hardwicke pointed out that while other great sanitary improvements had been effected in the metropolis and elsewhere, comparatively little had been done to remedy the evils which were equally dangerous—the invisible poisons engendered by exhalation augmented by inferior house accommodation and overcrowding. After describing the deleterious effects of impure air, and referring to what had been done by various societies for many years past with little beneficial result, he proposed that parochial authorities, municipal corporations, and railway companies should be compelled to exercise powers which they possess of erecting house accommodation for the poor, that greater convenience should be given for suburban dwellings by cheap locomotion, that changes should be made in the duties and appointments of officers of health, an extension of the Common Lodging-house Act to compel registration and inspection of houses sub-let to several tenants, that the Board of Works should take charge of a systematic plan of cleansing, that the law might be adjusted for the purchase and transfer of land and houses like common property, and that the coroner should institute inquiry into the cause of disease and death produced by the neglect of sanitary precautions, and that such wilful neglect should be made penal. The meeting was unanimous in acknowledging the evil, but differed partially in the mode of dealing with it. Mr. Liddle, the Medical Officer of Health for the Whitechapel district, thought police supervision necessary, particularly at night, and doubted the expediency of establishing a "faubourg" in the suburbs, but rather that the poor should live more among the wealthy. Mr. Collins chairman of the Sanitary Committee of St. Pancras, described the difficulty of enforcing sanitary regulations, and thought that as the poor were entirely at the mercy of their landlords, the landlords should be compelled to let their property in habitable condition. Mr. George Godwin, F.R.S., thought that the only remedy was the extension of the provisions of the Common Lodging-house Act to inspection over houses where more than three families resided. Dr. Druitt and Dr. Buchanan gave numerous instances of the great necessity for a stricter system of supervision, the latter being in favour of registration. After some observations from Mr. Hastings, Dr. Hardwicke, and the Chairman, thanks were voted to Dr. Hardwicke for his valuable paper, and the meeting separated.

Pollution of the Thames at Kingston.—Vice-Chancellors' Court, June 9, 10, 13.—The Attorney-General *v.* The Mayor and Corporation of Kingston-on-Thames.—(*Before Vice-Chancellor Sir* W. P. Wood.)—The information was filed by the Attorney-General, at the relation of the Conservators of the Thames, for the purpose in effect of restraining the Corporation of Kingston from draining the sewage of the town and district into the Thames, and the case raised a question of the utmost national importance, affecting as it does not only the inhabitants on the banks of the Thames, but generally the population in the neighbourhood of all our navigable rivers, as the effect of the course proposed by the defendants will undoubtedly be ultimately, if not immediately, to neutralise the Main Drainage works now being carried on at such a vast expense, and turn the upper portion of the Thames into an open sewer dangerous both to health and life. Dr. Letheby, in his evidence, summed up the question as follows:—"This practice of making the rivers of England the receptacle of all the filth of the towns is becoming a monstrous evil, and will be, if it is not checked and corrected, a national disgrace; for although the effect at first is not very marked, yet little by little the solid part of the excrementitious matters accumulate, and in a longer or shorter time they become excessively offensive, killing the fish and destroying the vegetation." The Vice-Chancellor concluded his judgment in these terms: Looking at the provisions of the Act of 1847, the mere fact of draining into a navigable river was not in itself to be con-

sidered as a nuisance, since it was authorised to be done provided no nuisance was thereby occasioned. If, however, any case of injury to the cattle from drinking the water, or to the inhabitants on the banks had been at all established, then he should conceive that it was a case for interfering by injunction. But nothing like such a case was shown by the evidence. Further than this, some means of defecating or deodorising the sewage might have been applied before the nuisance actually arose. Was he, then, to stop the works of the defendants on a mere case of prospective apprehended nuisance? The Court would have full power to deal with the matter when any case of actual nuisance arose, and the proper course would be to dismiss the information, such dismissal being prefaced by a declaration that the Court was of opinion that the evidence did not establish the existence of any nuisance in respect of the works executed or intended by the defendants, or any case for the interference of the Court. The order would be without prejudice to any future proceedings on the part of the Attorney-General, in case the works should occasion a nuisance, and under the circumstances it was not a case for giving costs.

Bethnal-green.—On Monday an inquiry was held by Mr. Richards, Deputy-Coroner, at Bethnal-green, respecting the death of Frances Hogg, aged 48 years. The deceased lived with a married daughter, named Neale, in a room at No. 42, Old Nicholl-street. This house contained five rooms, in which lived twenty-eight persons. Each room was let furnished by the leaseholder at 3s. 6d. a-week. The sanitary condition of the place was described as something abominable. A short time since there was no water laid on for five weeks; and when the landlady, Mrs. Hurst, who lived next door, was applied to, she simply replied that the tenants should do as she did—do without it, or get it as best they could. The deceased got fever and died. Her son-in-law and her daughter were also taken with it. One of the witnesses who gave evidence on Tuesday last has been since seized with fever. Mr. George Bainbridge, surveyor to the Bethnal-green Vestry, gave evidence to the effect that there were drain pipes, etc., on the premises, and that the place had been put in repair twelve months ago by order of the Vestry. The landlord had been summoned to Worship-street Police-court once or twice, and fined. Witness never inspected a place until he was set in motion by the sanitary inspector to the Vestry. Dr. Henry Letheby, Professor of Chemistry, said that he inspected the premises in question on Monday last. The house was dilapidated, the ground floors and the flooring of the passages were decayed, permitting the escape of effluvium from the soil. The ceilings of the upper rooms were broken, and the water seemed to have flowed in from the roof. The yard was unpaved, and dirty; the closet, (which was now being repaired) was without proper drainage; the soil was received into a sort of pit, when it soaked into the earth for a considerable distance round. Close to the closet was the water-butt, which was uncovered, and open to the reception of filth and the offensive emanations from the closet. The neighbouring houses and Shepherd's-court and Inner Shepherd's-court, at the back, were in a similar condition, the water-butts broken and uncovered, and the privies overflowing with soil. The condition of the places was highly dangerous to the public health, and in his opinion it might at any time give rise to a serious outbreak of disease, which may pass beyond the locality. Such a condition of things could not have arisen without great neglect of sanitary supervision. The state of the yards, butts, and closets was not of recent origin; it was of old standing. Three persons within a month were attacked by typhoid fever. Witness believed that deceased died from typhoid fever, which had its origin in the putrid emanations from the soil and neighbourhood. Dr. Letheby, in answer to questions, said he had never seen a worse condition of things. There was a great want of proper inspection in Bethnal-green, not so much, perhaps, from unwillingness on the part of the officers, as from the want of a sufficient number to do the work. The evidence of Dr. Haycock, divisional Surgeon of Bethnal-green, went to prove that he was called in to the deceased on last Friday. He found her lying on an old sack on the floor. She was so dirty that he could not tell at first what was the matter with her; but she had typhus fever, and she died in half an hour. The coroner, in summing up, said that it was discreditable to the owner of the property—who held an exalted position—to draw a part of his income from places in such a condition; the intermediate party simply made money by grinding it out of the poor. There was certainly blame due to the sanitary officers for allowing such a state of things to exist to the danger of the general health. Mr. Bainbridge said that he believed the Marquis of Chandos was the landlord. The jury returned the following verdict:—"That the deceased died from typhoid fever, accelerated by the sanitary condition of the premises, No. 42, Old Nicholl-street, Bethnal-green, and the neighbourhood; and that the said condition was such that it was dangerous to human life, and showed great neglect on the part of the freeholder as well as the leaseholder of the premises, and also on the part of the sanitary and Medical officers of the parish; and the jurors further say that it appears from the evidence that there are not a sufficient number of sanitary officers for the inspection of so large a parish."

Collegiate Election.—The annual meeting of the Fellows of the Royal College of Surgeons of England appointed to be held on July 6 promises to be an unusually excited one, inasmuch as there appear to be no less than nine candidates coming forward to compete for the three vacant seats in the Council, caused, as already stated, by the resignation of Mr. Arnott, a life member, and the retirement, in the prescribed order, of Messrs. Richard Quain, of University College, and Alexander Shaw, of the Middlesex Hospital. These gentlemen, however, offer themselves for re-election, but will be opposed by the following gentlemen, given in seniority of Fellowship—viz., Mr. Thomas Turner, of Manchester, Surgeon to the Royal Infirmary and other Medical charities in that town, as also the author of some valuable contributions to science. He has been nominated by Messrs. Howitt, of Lancaster; Harrison, of Chester; Stubbs, of Liverpool; Southam, of Manchester; Teale, of Leeds; and Husband, of York. No. 2 on the list is Mr. William James Erasmus Wilson, F.R.S., of Henrietta-street, deservedly well known by his works on cutaneous diseases, as the author of the "Anatomist's Vade Mecum," and numerous contributions in this and other journals. He is nominated by the following gentlemen:—Messrs. Critchett, of Harley-street; Erichsen, of Cavendish-place; Adams, of Henrietta-street; Paget, of Harewood-place; Spencer Smith, of Queen Anne-street; and Henry Thompson, of Wimpole-street. No. 3 is Mr. Alexander Ure, of Upper Seymour-street, Surgeon and Lecturer on Clinical Surgery to St. Mary's Hospital, another valuable contributor to the literature of the day. He has been nominated by Messrs. Bowman, of Clifford-street; Dixon, of Portman-square; Erichsen, of Cavendish-place; Paget, of Harewood-place; Spencer Smith, of Queen Anne-street; and J. R. Lane, of Grosvenor-place. No. 4 is Mr. James Paget, F.R.S., of Harewood-place, Surgeon Extraordinary to H.M. the Queen, to H.R.H. the Prince of Wales, Surgeon to St. Bartholomew's Hospital, a member of the Senate of the University of London, late Professor of Anatomy and Surgery to the College of Surgeons, author of the Pathological Catalogue of the Museum of the College, and many other valuable contributions to science. He has been nominated by Messrs. Erichsen, of Cavendish-place; Coote, of Queen Anne-street; Thompson, of Wimpole-street; Hewett, of Chesterfield-street; Professor Owen, of the British Museum; and Bowman, of Clifford-street. No. 5 is Mr. Prescott Gardner Hewett, of Chesterfield-street, Mayfair, Surgeon to St. George's Hospital, late Professor of Anatomy and Surgery to the College of Surgeons, and another valuable contributor of papers to the advancement of science, this gentleman is nominated by Messrs. Hawkins and Lee, of Saville-row; Birkett, of Green-street; Paget, of Harewood-place; Cæsar Hawkins, of Grosvenor-street; and Savory, of Brook-street. No. 6 is Mr. Charles Hawkins, of Saville-row, the Government Inspector of Schools of Anatomy, and well known as the editor of the recently published works of Sir Benjamin Brodie; he is nominated by Messrs. Hewett, of Chesterfield-street; Lee, of Saville-row; Pollock and Broadhurst, of Grosvenor-street; Cartwright, of Old Burlington-street; and Powell, of John-street, Berkeley-square. No. 7 is Mr. Joseph Atkinson Ransome, of Manchester, Surgeon to the Royal Infirmary and other Medical charities in that town; he is nominated by Messrs. Windsor, Dumville, Southam, Mellor, and Fletcher, of Manchester; and Broadbent, of Altrincham. The candidates, therefore, for seats in the Council are Messrs. Quain, Shaw, Turner, Wilson, Ure, Paget, Hewett, Hawkins, and Ransome. Of the return of the retiring members there is great doubt expressed; indeed, the favourites openly mentioned are Messrs. Charles Hawkins, Paget, Hewett, and Turner. Several provincial and metropolitan Fellows have complained of Mr. Ransome offering himself in opposition to his distinguished townsman.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

The article entitled "Notes on Syphilis, No. II.," is unavoidably postponed this week.

We desire to call our readers' attention to a meeting to be held at St. James's Hall, Piccadilly, on the 22nd, the Bishop of Oxford in the chair, to consider the subject of domestic service.

Both Chemists and Druggists Bills have been abandoned for the present. With the evidence already obtained, and the report of the Committee, it is believed that Government will take the matter into its own hands, and prepare a Bill against the next session that shall deal with the compounding of prescriptions, the sale of poisons, and the due *status* and *differentia* of Medical Practitioners and chemists.

M.D., Paris.—Write for information to Dr. Francis Hawkins, at the Medical Registration Office, 32, Soho-square, London, W.

A Manchester Fellow.—You are too late. Monday was the last day for sending in applications. It is stated that the gentleman named purposes withdrawing; there may perhaps be another withdrawal.

J. H. B.—Dr. Tilbury Fox's work on "Skin Diseases" contains, perhaps, the "fullest" information; but either of Mr. E. Wilson's works, or Dr. Hillier's "Handbook of Skin Diseases," would, we should think, also give all the information required.

An Angry Member.—You cannot have read the advertisement which appeared from the College of Surgeons in this journal last week and in the current number. You *are* invited to the *soirée* by the Council, and have only to present your private card to the janitors to obtain admission. Official cards are only sent to high and official personages.

Poor-law Medical Reform.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I am sorry so frequently to trouble you, but events have transpired so unexpectedly during the last few weeks that it has been unavoidable, and I must again crave your permission for space to inform all the Poor-law Medical officers that a Poor-law Continuance Bill has been introduced into the House of Commons, and as I considered it would be a good opportunity to make a final attempt, this Session, to amend the Medical relief of the poor, I have forwarded a pamphlet on the subject to each member of the House of Commons, urging him to insist on clauses being introduced into the Bill now before the House.

I should have sent a copy of the pamphlet to each Poor-law Medical officer, but as I am already in debt, about £20, I do not feel justified in incurring further expense, but I have directed the printer to keep the type standing for a few days, to enable any gentleman to have a copy on forwarding six postage stamps to Mr. Sherren, Printer, Weymouth, or to myself. I sincerely trust that success will attend our efforts, and that the present Parliament will yet do us and the poor that justice for which we have so long toiled.

I trust every Medical man in the kingdom, but especially the Poor-law Medical officers, will without delay urge upon his member the necessity of Poor-law Medical Reform. I am, &c.

12, Royal-terrace, Weymouth, June 10. Richard Griffin.

The Subscription for Mrs. Walker, of Crick.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I have lately had the pleasure of forwarding to Mrs. Walker, of Crick, the sum of £6 9s., the result of a collection by George Harday, Esq., M.R.C.S., West Haddon, Northamptonshire, and shall feel greatly obliged if you will allow this acknowledgment to appear in your forthcoming number. I am, &c.

Upper-street, Islington, June 12. Henry Osborne, M.D.

Medical Etiquette.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Will you be kind enough to give me your opinion on the following case? The husband of an old patient of mine—and who is away for the benefit of her health on my recommendation—is suddenly taken ill. The friends send for the nearest Medical man. He attends the case until the return of the wife, when, she finding that her husband does not improve, sends a note requesting my attendance. In it she states she told my friend that she intended to do so, and does not ask me to meet him. After seeing and prescribing for the patient, and just when I am about to leave the house, the wife said, "Will you see Mr. C.?' and thinking that it referred to the treatment that had been previously adopted, I replied, "There is no occasion for it." Now, was I upon this remark, and considering my previous position in regard to the patient, bound to call upon Mr. C. to consult with him on the case? An answer in your "Notices to Correspondents" will oblige. I am, &c.

A Subscriber.

*** Certainly not bound; but it would have been an act of courtesy, might have cemented Professional friendship, and been of use to the patient.

Case of Incontinence of Urine.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Miss ———, aged 15, had suffered since infancy from incontinence of urine, which had resisted every form of treatment hitherto prescribed, and her parents, considering the case hopeless, had ceased to seek Medical advice. They contented themselves with providing for the comfort of other members of the family, by removing her sleeping apartment to as great a distance as possible, and with using such precautions as were in their power to alleviate the discomfort of the sufferer herself. She was never allowed to take any fluids after mid-day, and an attendant slept in her room, whose duty it was to wake her in the course of the night. The incontinence, nevertheless, was of nightly occurrence.

On January 18, 1864, she was placed under my care, and I passed externally a galvanic current from the hypogastric region to the sacrum. She continued under my care until May 2, during which period the galvanic current was applied twenty times; the treatment was then discontinued, a month having elapsed without a return of the distressing complaint. Up to the present time the cure has been permanent.

I am, &c. Richard Lawrance, M.D.

Connaught-square, April 8.

COMMUNICATIONS have been received from—

Dr. John Whitmore; The Secretary of the Odontological Society; Dr. Herapath; A Subscriber; Dr. Henry Osborne; Mr. Thomas Warner; Messrs. Trübner and Co.; Mr. W. Menzies; Dr. Alexander Wood; The Royal College of Surgeons of England; Apothecaries' Hall; Mr. Hastings; Mr. Claude Wheelhouse; M. A. B.; Mr. R. Griffin.

BOOKS RECEIVED.

Homes without Hands. By the Rev. J. G. Wood. Part 18. London: Longman and Co.

*** The engravings to this popular work are always good, and the whole thing calculated to entice young people to the study of zoology. The account of the *shrikes*, which impale on thorns the small animals which they make their prey, is very curious.

The Home Nurse, and Manual for the Sick Room. By Esther Le Hardy. London: R. Hardwicke.

*** This seems to be a new edition, with little or no alteration.

A Dictionary of Science, Literature, and Art. Edited by W. T. Brande, D.C.L., and the Rev. G. W. Cox, M.A. Part 3. London: Longman and Co.

*** Begins with "Cognizance," and ends with "Drift."

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

23. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

ORIGINAL LECTURES.

AN INQUIRY INTO THE NATURE OF THE PHENOMENA WHICH CONSTITUTE "INFLAMMATION."

TWO LECTURES DELIVERED AT
The Royal College of Physicians.

By LIONEL S. BEALE, M.B., F.R.S.,
Fellow of the College; Professor of Physiology and of General and Morbid Anatomy in King's College, London; Physician to King's College Hospital.

Lecture I. *concluded.*

Of truly Vital Actions as distinguished from the Physical and Chemical Actions of Living Beings—Vital Phenomena of Inflammation—Of Vital Stimuli: Nutritive Irritability—Excitation and Irritation—The Nature of Irritation—Alleged Resemblance of Inflammation to Combustion—Oxidation not Increased in Inflammation—Of "Excess" or "Deficiency" of Vital Action—Of Living Matter and Formed Matter, and of the so-called Force-Conditioning Machinery of the Cell—No Analogy between Living Matter and a Lifeless Machine—On Inflammation—Changes in Living Matter—Of the "Cell" of different Tissues—Quickly Growing Structures Contrasted with Slowly Growing Structures—Changes in the Formed Material—Of Germinal Matter, and of its Origin—"Omne vivum e vivo."

(Continued from page 620.)

Of the Changes in the Living Cell.

I would not give up the use of the word "cell," for it is short and convenient, but I would offer a somewhat different definition from that which is usually given. I would say that a *cell* consists of a certain quantity of living matter and a certain quantity of lifeless or formed matter; I would therefore speak of all these elementary parts as cells. If you ask me what is a muscle cell, I say (pointing to the drawing) this mass of germinal matter, with a certain proportion of formed material around it, is a muscle cell. Here is another muscle cell, and here is a third; here is a fibrous tissue cell, and here is another, and so on. In some cases the formed material corresponding to each mass of germinal matter is distinctly marked and separated from its neighbours, as in an epithelial cell; in other cases the formed material of one mass becomes fused into the formed material of another mass, as in the cartilage cells. The portion included in that line would be one cell of nerve. And so of all other tissues. The term "cell" may therefore be retained; but instead of speaking of the cell as consisting of nucleus, cell contents, and cell wall, I would speak of it as consisting simply of living matter and formed matter,—formed matter that was once in a living state, but which is now, when we come to examine it, in a lifeless state, which possesses no wonderful properties like germinal matter, and cannot reproduce matter like itself. Muscular tissue—to take, perhaps, the most elaborate and complex formed material which, according to some, exhibits vital contractility—cannot produce muscular tissue any more than the outer part of an epithelial cell about to be cast off from the surface of the skin or mucous membrane, can produce hard cuticular matter or soft mucus, like that of which it is composed, or the outer part of a liver cell produce bile or the other materials of which it consists. The only active material seems to be this living germinal matter in the centre, and as long as even a minute portion of it remains alive, so long you may say, the cell lives; but when the whole is dead, the cell can no longer produce new matter of any kind, and no longer exhibits any of those phenomena which we speak of as *vital phenomena;* it cannot form, alter, or absorb the various constituents; it cannot change the constituents into other materials; in fact, it is a lifeless mass. The outer or formed material is, I believe, perfectly passive. It is, no doubt, of great importance in regard to *physical and chemical changes;* certain fluids permeate it, others will not permeate it; but I believe that all these phenomena may be attributed to the physical or chemical characters of the outer formed material of the cell; while, on the other hand, the forming power—the power of converting pabulum into matter of a totally different chemical composition—is possessed by the germinal matter of the cell, and by this only.

I shall venture to draw your attention more particularly to these points, because it will be quite impossible for me to explain the notions I entertain of the nature of the inflammatory process unless I enter into this somewhat considerable detail.

For the production of formed material, and for the conversion of this material into the proper substance of the tissue, a certain time is required. It is really a slow process; so that we shall find that in all those cases where tissues are characterised by a large amount of formed material they have been slowly produced. All the hard tissues of the body have grown very slowly; while, on the other hand, those tissues which contain a large amount of germinal matter in proportion to the formed material, are tissues which have grown very quickly. We may contrast, for example, the different appearances which we observe in the villi of the intestine, or, rather in the cells upon the surface of the villi, with those of such a tissue as cartilage. We find, supposing these are stained with carmine, that the so-called cells upon the villus are close to one another, so that there is scarcely room for anything to pass between them. There can be little doubt that the nutrient material is absorbed by the germinal matter of these cells, which is stained red; that, in fact, the cells live upon the pabulum and grow at its expense. Then the very matter of which the cell is composed dies, and in dying it becomes resolved into other constituents, which pass onwards into the lacteal vessels or into the blood-vessels, and so become absorbed by other cells, and at length applied to the nutrition of the body.

If, on the other hand, you compare such a structure as this, in which the proportion of germinal matter is very great, with fully formed cartilage, in which the proportion is small, you cannot fail to observe a very great difference. Cartilage is a very slowly growing tissue; a considerable time is required for the formation and accumulation of the hard formed material. These remarks apply to diseased as well as to healthy tissues. The rapidly growing cancer contains a greater proportion of germinal matter in relation to the formed material, than the slowly growing normal tissue.

We may likewise contrast the same tissue at different periods of its life, and similar facts will be noticed. In the adult, there is an opportunity of doing this at any age in the case of the epithelium covering the skin, or the epithelium of the tongue. Here is one of the small processes from a compound papilla of the tongue, covered with a thick layer of epithelium. If you take a portion of tissue such as this, you find that the quantity of germinal matter is very great indeed, as compared with the quantity in a space of corresponding extent in the older tissue. As these cells gradually move away from the situation of the blood-vessels where the nutrient matter is poured out, the formed material increases, and the changes taking place in the cell become slower and slower. The changes going on in the youngest cells are active indeed compared with those going on in the most mature cells. The changes in cells which have already reached the surface have almost ceased; the germinal matter is reduced to a minimum, and perhaps in many of these cells that small quantity is not in a living state—the cell is *dead*, and is about to be cast off.

The formed material is at first invariably soft, and as the change goes on it becomes condensed, and in many cases contracts and loses bulk. I may adduce as an instance a common hair, in which, as is well known, the bulb exhibits twice or three times the diameter of the shaft, and contains a considerable quantity of germinal matter in proportion to that existing in the shaft. The shaft consists of flattened cells lying very close to one another; these cells are composed of a firm, hard material, with scarcely a trace of germinal matter. But the bulb is composed almost entirely of germinal matter, and as this matter becomes converted into formed material, contraction goes on; and this is, no doubt, the explanation of the diameter of the shaft of the hair being so much less than the bulb. It is the same in the case of vegetable tissues. Look at the growth of any rapidly-growing tree, such as the elder tree, and you will find that the new shoots are twice the width of the old stems from which they are growing. As the soft new tissue undergoes condensation, it contracts until it becomes of less diameter than the trunk or branch upon which it grew. These and many other facts to which I might allude show clearly that contraction and condensation take place in many tissues soon after they are produced, and that the hardest textures are soft when first formed.

Next, with regard to the changes taking place in the substance of cells under certain conditions. The *colouring matters*

in cells result from changes occurring in the germinal matter, but the colouring matter itself is not living; it probably results from the death of the germinal matter. The living material from which the coloured matter is produced is colourless. The petals of a coloured flower when young are perfectly colourless; but as the petals grow, the action of light and other external conditions cause the death of certain particles of germinal matter of the cell, and in dying, these become converted into beautifully coloured materials. The same holds good with regard to red blood corpuscles. The red material of the blood corpuscle is not living germinal matter; it is lifeless formed matter. Here we have the coloured matter in a frog's blood corpuscle. This part, represented brown, is formed lifeless matter; this, represented of a carmine tint, is in nature perfectly colourless, and consists of germinal matter. So, in the human subject, there are numerous blood corpuscles which consist partly of formed material diffused, as it were, amongst the germinal matter; and that this is so, is shown by the fact that the germinal matter which is living sometimes makes its way out of the general mass, leaving the coloured material behind it. The coloured matters of cells then result from changes taking place in the germinal matter.

Pigment is formed normally in certain animal cells; and there are certain cells in health containing no pigment, which nevertheless contain a considerable amount in disease. During the inflammatory process, or rather when the active changes have ceased, many cells develope pigmentary matter. Certain cells around the vessels of the brain are often seen to contain yellow colouring matter. In many parts of the body there are dark pigment cells containing a considerable quantity of dark granular matter, while the corresponding healthy cells do not contain any. No doubt in many cases this deposition of dark pigmentary matter depends partly upon imperfect oxidation.

I propose now to say a few words concerning the changes taking place in the germinal matter; for it is impossible for us to enter into the consideration of the inflammatory process without discussing briefly the nature of some of these changes. Many inflamed tissues differ from the healthy tissues principally in the greater amount of germinal matter that they contain. A tissue which contains a very small amount of germinal matter, like a tendon, may assume the character of tissue like the cells of the intestinal villus, which consist of a large amount of germinal matter.

Masses of germinal matter possess the power of movement, and are capable of dividing and sub-dividing. This is seen in the case of the white blood corpuscle, or the pus-corpuscle, or the amœba, or any mass of germinal matter not surrounded by a thick layer of formed material. Let one of these masses represent the "mucus corpuscle" which is embedded in soft viscid mucus. The living mucus corpuscle (as I mentioned in 1860) undergoes a change in form; portions of the mass move away from the rest, and the peculiar movements which are represented in this diagram can be almost invariably seen. These three outlines represent the different forms taken by one single oval mass in the course of a minute of time. The most curious changes occur in the form of masses of living matter, which are free to move in any soft material, and these precisely correspond to the changes which take place in the amœba and other cells of low organisation. In fact, if the pus from a case of disease of the bladder, in which the urine contains but a small quantity of urea and other constituents, be examined soon after it is removed, not unfrequently the pus-corpuscles will be seen to exhibit these unusual and irregular shapes [drawing on the board]. In some cases I have sought in vain for a single circular corpuscle; all, however, become spherical after they have remained for some time in the water.

While these cells are upon the surface of the mucous membrane they are moving and forming these various processes or outgrowths, and every now and then one of these processes moves a considerable distance from the parent mass, the little pedicle which connects it becomes broken down, and thus a new pus-corpuscle is produced. It is in this manner, no doubt, that the very rapid multiplication of pus and lymph-corpuscles and other cells, which is very striking in many diseased structures, takes place. At the same time that these outgrowths occur and are detached, the germinal matter continues to absorb nutrient matter and to increase. The germinal matter may divide in *all* directions, in *two* directions at right angles to one another, or it may divide in a linear direction only. These masses of germinal matter, originally continuous, may separate from one another, a fibre being drawn off, as it were, during the process. Rings of germinal matter may be formed in different masses, extending and growing round one another, and from these fibres may result. It is in this way that the interlacement of fibres so commonly seen, not only in nervous tissues, but in ordinary fibrous textures, is produced. The complex arrangement of fibres results from the arrangement and movements of the masses of germinal matter which gave origin to them, and without which they could not have been formed. There is reason for thinking that in certain instances new contractile tissue is formed in the very centre of an elementary muscular fibre, and that the so-called nuclei in this situation move from one end of the space in which they lie, to the other, forming the new fibrillæ as they go.

The germinal matter is, doubtless, alone concerned in reproduction. The formed material is perfectly passive. If a cell of common mildew be exposed to adverse conditions, it becomes surrounded by layer after layer of hard formed material, resulting from the death of the germinal matter, and at last perhaps it contains only a mere trace of living matter in its centre; but, when exposed to the action of moisture and a warm temperature, a change takes place, and this hard material, which is perfectly passive and dead, becomes softened by the action of the moisture, just as, under similar conditions, a mass of dry gelatine would imbibe moisture. It swells up, and becomes more permeable to fluid; nutrient fluid thus gets into the interior, and this fluid comes into contact with the small portion of germinal matter, which absorbs it and grows. As soon as the germinal matter increases, and makes its way through the softened envelope, it comes into contact with the nutrient material, and immediately grows much faster, and the width of the growing mass becomes very much greater after it has passed out of the original spore than at the point where it hasemerged. This is the explanation, I believe, of the extreme contraction always observed at the point of connexion between the branch as it grows away from the particle of mildew or other sporule or cell. In this way the germinal matter of the mildew increases in bulk when nutrient material comes into contact with it.(a)

With regard to the origin of germinal matter, this may be summed up in a few words. Every particle of living or germinal matter comes from a pre-existing particle of germinal matter. No doubt all in this theatre are well aware that upwards of 200 years ago Harvey, who, as Dr. Munk has truly said, was the greatest physiologist the world has seen, stated his opinion that all creatures came from ova. "Omne vivum ex ovo" is an aphorism as true now, if it be taken in its widest sense, as it was when Harvey uttered it; but, in order to make it apply to the results of recent observation and experiment, instead of *ovum*, let us say *germinal particle*,—"Every living thing springs from a germinal or living particle." It is curious that by a very slight alteration in the Harveian maxim a statement is made which, I believe, cannot be controverted in the present day—by an alteration in two letters only: "*Omne vivum e vivo*" is an aphorism which is unassailable, and which I venture to think will long remain so.

Oxford Commemoration.—Among those whom the University this year have selected for the honour of the D.C.L. degree appear the names of Dr. Christison, of Edinburgh, and Dr. Stokes, of Dublin.

Mr. Robert Debenham, the Surgeon charged with manslaughter, for having shot a supposed burglar on his premises, on the night of Whit-Monday, has again appeared before the magistrate. Mr. Smith, the prosecuting solicitor, stated that Sir George Grey had acceded to the request that the body might be exhumed, for the purpose of making a complete post-mortem examination. The inquiry was adjourned for another week.

Waterloo Day.—Sunday last was the fiftieth anniversary of the great battle, and it may not be uninteresting to our readers to know that of the 190 gallant veteran officers still surviving we have the following belonging to our own Profession, viz.:—Deputy-Inspector-General R. Dawn, M.D.; Assistant-Surgeon George Evans; Surgeon F. Gilder; Surgeon J. Harrison; Surgeon W. Hunter, M.D.; Assistant-Surgeon M. Kenney, M.D.; Surgeon R. A. Pearson, M.D.; Surgeon D. Perston, M.D.; Surgeon T. Smith, M.D.; Surgeon to the Forces, R. Scott, M.D.; and Surgeon W. H. Young.

ORIGINAL COMMUNICATIONS.

AN IMPROVED SPECULUM FOR THE EYE.

By J. Z. LAURENCE, F.R.C.S., M.B.
Surgeon to the Ophthalmic Hospital, Southwark

I SHALL briefly enumerate the disadvantages of the wire speculum in ordinary use for exposing the eyeball for operations and the remedies I have introduced in my own form of instrument.

1. The parts of the instrument which are directly employed in separating the eyelids are too short—they do not separate them in their entire lengths; in my instrument these parts of the instrument are increased to about seven-eighths of an inch.

2. These same parts are straight; in my instrument they are gently curved, in conformity with the natural curves of the palpebral sinuses; thus any separate and unnatural dragging on individual parts of the eyelids is avoided.

3. Whenever the patient resists, more or less violently, by powerful spasmodic action of his orbicular muscle, the separation of the eyelids by the wire speculum, the eyelids, especially the upper one, are forced down over or under the wires, so that the part of the eyeball exposed to view is materially diminished; indeed, in certain operations (*e.g.*, those on the cornea, iris, and lens), more especially when the eyeballs are much sunken or small, the action of the wire speculum is practically annihilated.

This disadvantage I have met by substituting for the wires, which should separate the eyelids, grooves of metal—troughs, if I may so say—which receive the eyelids and absolutely prevent their overlapping, and thus contracting the Surgeon's field of operation.

1. With the head-rest (described in a former number of the *Medical Times and Gazette*) fix the head; 2. With this speculum expose the globe fully; 3. With bulldog forceps fix the eyeball itself, and you may operate on the most unruly subjects and children without assistants, without chloroform (where the nature of the operation does not specially indicate it), with the greatest ease and certainty. My own experience in all kinds of operations on the eye of the preceding method of securing immobility for the purposes of operation is most favourable. I now submit it to others less prejudiced perhaps than myself.

The "groove speculum" is made by Messrs. Weiss, 62, Strand, London.

London.

A CASE OF ATTEMPTED SUICIDE BY CHLOROFORM AND PRUSSIC ACID.

By W. S. CARMICHAEL, M.D.

MARCH 28, 1865, 10·30 a.m., I was sent for to see a foreigner, 46 years of age, and of robust form, who had swallowed, about ten minutes before, two ounces of chloroform and half a drachm of Scheele's hydrocyanic acid mixed together. He appeared confused, but was sensible. I gave him an emetic of mustard, and afterwards a drachm of sulph. zinc, which operated freely. I then introduced the tube of the stomach-pump, and pumped in and out five or six tumblerfuls of warm water; his jaws being separated, and kept separate with the greatest difficulty. He was then carried to an easy chair near an open window. As his head was cooler than the rest of his body, cold water was not applied to it; but hot bottles were applied to his feet. Soon after he was taken to the window, and about an hour after he had taken the poison, his pulse became very small and weak. I gave him more than a glass of whisky, and a drachm of sp. ammon. ar. with water; he was not yet quite insensible, and was forced with some difficulty to swallow most of this. The pulse improved; the window was shut, and the chair inclined backwards, so as to lower his head a little. About one and a-quarter to one and a-half hour after taking the poisons he was quite comatose, his respiration being rather hurried, pretty full, and more or less impeded and noisy from mucus in the trachea, becoming occasionally inaudible when the respiration was less profound, and the trachea cleared. His pulse remained generally about 70 or 80, full, but very soft, becoming sometimes smaller and softer, on which occasions a feather dipped in whisky, sp. ammon. ar., and water several times, and applied to the tongue and palate, seemed to strengthen it; this was done every ten or twenty minutes, partly to moisten the tongue and palate, as the respiration was oral. The pupils were somewhat dilated, and did not contract on exposure to the light. About 1·30 p.m. I left him. 3·30 p.m.—He remained very much in the same state; legs rather chilly; friction and hot bottles ordered. 5 p.m.—Professor Christison saw him, and had him put to bed, where he could be more easily kept warm. 6 p.m.—Circumstances apparently unchanged; strong smell of chloroform; ordered his body and extremities to be carefully kept warm. 8 p.m.—I was sent for. There was slight convulsion of both arms; forcible pronation. Extremities cold, notwithstanding my repeated injunctions to keep them warm. Hot bottles and friction ordered. Cold water was not applied to the head, because it was already rather cold. 8.15 p.m.—I saw him again with Dr. James Duncan. Sinapisms to chest and legs ordered. 11.15 p.m.—There was a change for the better; no appearance of convulsion; he had turned on his side, and was moving a little; sometimes opened his eyes, but appeared bewildered; seemed to understand his wife when she spoke to him, but did not answer audibly. Ordered beef-tea and milk, with a little whisky or brandy.

29th, 8 a.m.—He was quite lively, eagerly shaking hands, like a person pleasantly excited by drink. Ordered the stimulant to be withdrawn. He remained in this state during the day; gradually becoming calmer.

30th.—8.30 a.m.—He was very desponding; said he was dying; had been vomiting; looked more bilious than usual; complained of pain in the lower part of the back bone, in the legs, arms, and chest; no pain in the epigastrium or in the head, except a feeling of fulness or pressure at the temples. Ordered soda powders with excess of alkali, a blue pill or two, some sp. ammon. ar., and wine or wine negus.

31st.—Rather better. Vomiting was troublesome for some days; brandy and water and claret alleviated it, and it gradually left him. No sleep.

April 7.—He still complains of weakness, of faintness on standing, of pain in the back, oppression at the chest, of occasional pain about the heart, which he has been troubled with for years, and particularly of want of sleep.

13th.—Almost the only complaint he now makes is of oppression at the temples, a feeling of bursting in the region of alimentiveness, a sort of tic, which continued till he left this part of the country, about April 20; it may have originated from the almost spasmodic compression of the jaws (trismus) during the first hour, and from the violent opposition which he made to their separation.

In this case half a drachm of Scheele's acid seemed to have little effect; the pressing together of the teeth may have been owing to it. The absorption of the acid may have been partly prevented by dilution with the chloroform, and its expulsion from the stomach thereby effected to a greater extent, and the chloroform may have acted as an antidote, the stimulant narcotic neutralising the pure sedative.

I have ascertained that a quantity of Scheele's acid, equal to that taken, and from the same store, contains fully one grain and a-half of pure acid.

About an hour after the poison was taken I expected that the patient would recover, because by that time most of the danger from the prussic acid might be supposed to be past; and we find that chloroform, considering the immense number of cases in which coma has been induced by it, is not a very dangerous poison; that serious danger is generally indicated at an early period by a striking failure of the pulse or respiration; and that death when it occurs seems partly owing to some defect of constitution, to the neglect of necessary stimulus, or to the want of fresh air from the mode in which it is generally administered.

3, Annandale-street, Edinburgh.

THE GRESHAM PROFESSORSHIP OF MEDICINE.—Owing to the recent death of Dr. H. H. Southey, of Harley-street, a vacancy has been declared for the Gresham Professorship of Medicine. The appointment, which was held for many years by Dr. Southey, is in the gift of the Corporation of the City.

Medical Times and Gazette.

SATURDAY, JUNE 24.

THIRD-CLASS MEN?

The *Irish Times* of June 6 contains a very interesting report of the annual meeting of the Irish Medical Association at the Dublin College of Surgeons, under the presidency of Dr. T. L. Mackesy. Of course, a large number of topics were discussed, and chiefly of a politico-Medical kind. The speakers urged upon the Profession the necessity for energy and unanimity of action in the approaching election. We advert to this meeting, however, mainly for the purpose of reproducing an extract from a letter received by the Chairman from the Director-General of the Army Medical Department. The communication bears date May 27 last, and states that—

"So far from being third-rate men, the majority of the successful competitors for his Department are above the average of those who pass through the schools, as is proved by the fact that, although all must have legal qualifications to practise both Medicine and Surgery, one-third of those who competed at the last examination failed to obtain the minimum number of marks required to qualify them for admission into the service."

We do not feel inclined to enter into a controversy with the Director-General as to the definition of a third-class candidate. One-third were too bad; the rest were good enough. Good official logic this. We will not adduce the common impression that the examination, once good, has been lowered till it has become ridiculous as a scientific test;—that the subjects of study have been reduced, and the age increased. Let us turn to a picture of the candidates, as drawn by one of themselves.

It was not so very long ago that a probationist contributed to a Professional journal his "Sketches of Life at Netley Hospital." These sketches came to an untimely end, for the name of the writer leaked out, we suppose, and, a gentle pressure being applied, he speedily recognised his indiscretion, and publicly expressed his regret, etc. One of his paragraphs, however, is too amusing to be buried in oblivion. After stating that Irishmen, as in all of the later sessions, are most numerous, he continues:—"Most of them are excellent fellows, both Professionally and socially, but it cannot be denied that there are some few whose appearance and bearing tend to lower very much the general character of Irish Professional men; but although we have this few amongst our ranks, yet they are the exception; and so far we are much above the Scotchmen, who are, without almost a single exception, men who none of us care to know. The Englishmen here are few in number, and we hope are not to be considered as typical specimens of that noble race. They include two classes, possessing characters totally different from each other—one set are, in their own opinion, very fine gentlemen; the other, perhaps, would find their level amongst the Caledonian candidates."

We are heartily glad that the London College of Physicians has seen fit to take up the cause of our Profession in the public services. Its influence, and the universal reputation which its President possesses for his moral and intellectual qualities, must ensure attention from the Government. We confess, however, that we range ourselves among the number of those who disbelieve in any great good being effected so long as candidates are forthcoming in sufficient numbers.

We have been compelled to study the grievances and wants of the Medical officers with a good deal of attention, and they may be summed up, we think, in the following:—1. A fair and honest construction of the original Warrant. 2. Some means for lightening the list of the junior ranks, and of accelerating and regulating the stream of promotion. No Assistant-Surgeon certainly should serve as such beyond twelve years. 3. An earlier retirement, say twenty years, which would have the effect of accelerating promotion and of maintaining a good supply of young men equal to the fatigues and exposures of a military life. 4. Some increase of pay for Surgeons, for at present a Surgeon, if he be a married man, can barely maintain himself and family with decency and respectability upon his pay.

MODERN DERMATOLOGY.—No. VIII.

We have shown that great and striking advance has been made of late years by dermatologists in the etiology of diseases, in the recognition of the essential differences and alliances between various diseases and forms of disease, so as to simplify and reduce the dimensions of their formidable nosology, in the simplification of their therapeutics, and in their powers for cure; but their most signal triumphs have been achieved over that class of maladies now known as "parasitic diseases of the skin;" and especially by the recognition of the vegetable parasites. The discovery, by aid of the microscope, that many, formerly most obstinate and intractable, cutaneous diseases are due to the presence of a vegetable parasite has resulted in the fact that these affections, instead of being the despair alike of doctor and patient, are now among the most easily and certainly curable of maladies.

Of the skin diseases caused by animal parasites we shall allude only to scabies, and about that we shall not say much. It is now almost universally acknowledged that the essential cause of this disease is the acarus scabiei or sarcoptes hominis. We are obliged to say only "*almost* universally," because we observe that Dr. Frazer remarks, "from a protracted series of investigations upon the subject of scabies, I am disposed to doubt that the acarus which so generally accompanies it is the real cause of the eruption;" and Mr. Hunt says, "the real cause of scabies is *dirt*. Dirt originates it, sustains it, propagates it. . . . . The acarus is an accidental result of dirt." Dirt may encrust a person to any amount and he may not have scabies, and scabies may exist without dirt. Mr. Hunt seems to consider sulphur absolutely essential to the cure of scabies; if so, surely something more than dirt is required to originate it? Perhaps, however, Mr. Hunt includes the acarus within the term dirt, on the Palmerstonian definition of this, as matter in the wrong place. Mr. Hunt speaks also of an "endemic scabies;" the "eruption consisted of pustules and boils," cleanliness "practised almost to a fault," sulphur, etc., failed to cure it; but it was got rid of by a "greater variety of food, and more exercise in the open air." Neither of these gentlemen would have written as they have, probably, had they had more exact ideas as to what scabies is. M. Bazin gives an admirably clear and precise definition of it. "On doit considérer la gale comme une affection de la peare, contagieuse, produite par l'acarus scabiei, caractérisée par une éruption specifique (l'éminence acarienne et le sillon), et par des éruptions inflammatoires symptomatiques, qui varient suivant l'âge de la maladie, l'âge du sujet contaminé, et les prédispositions individuelles."(a) Scabies, properly so

(a) Leçons Théoriques et Cliniques sur les Affections Cutanées Parasitaires. Par le Dr. Bazin. Paris: 1858. P. 222.

called, knows only one cause—the presence of the acarus scabiei; and the specific eruption—the acarian eminence and furrow—disappear with the destruction of the parasite, while the symptomatic eruptions—vesicles, papules, pustules—may remain for a varying length of time afterwards, according to the sensibility of the skin, the general state of health, and the previous duration of the disease. The amount and intensity of the pruritus caused also varies greatly with the degree of sensibility of the skin—in some it amounts to torture, in others it is scarcely more than a very endurable annoyance; but we fear that very few sufferers from it—in England at least—can be found to agree in the sentiment, attributed to James the First, that the itch is a disease fit for kings only—the titillation and excited scratching being so royally pleasant. Perhaps, however, the effect on Scotch skins is happier, though none of our dermatologists note any difference. We commend the point to their notice as a curious physiological question.

The hand is the principal and favourite habitation of the acarus, and the eruption which appears elsewhere is certainly to a great extent caused by sympathetic irritation (some authorities appear to believe that it is also due, in part at least, to the introduction into the system of some specific poison by the insect), but dermatologists differ as to the extent to which this obtains. Mr. Wilson says,—"The acarus scabiei in this country, and amongst cleanly people, has its habitation only in the hands; in foreign countries it is said to be more generally distributed, and to be found in other parts. Being present, therefore, only in the hands, the eruption which is thrown out upon the rest of the body is the result of an irritation communicated through the nerves." This statement is certainly too exclusive, for the acarus has been found elsewhere even in England—as on the nates and thighs, the feet, and the female breast, in the axilla, and, though very rarely, on the face. In France it is said to be very commonly found on the penis. According to M. Hardy, the disease in man commences on that organ much more frequently than on the hands.

"The treatment of scabies is expressed in a single word—sulphur." So saith Mr. Wilson, and so say, more or less decidedly, all dermatologists. The disease may, without doubt, be cured by iodide of potassium ointment, and by some other agents; but sulphur seems to be the quickest and most certain remedy, and the methods of applying it only differ in severity. Mr. Wilson, believing that the parasite inhabits the hands only, is content to apply the sulphur ointment there only, and to use sulphur soap to the rest of the body. His plan of treatment is certainly the mildest and least unpleasant. All the authorities speak of concealing the smell of the sulphur by the addition of oil of bergamot, or some other perfume, to the ointment. We remember that an eminent teacher at St. Bartholomew's used to call this "only adding a smell to a stink."

The common skin diseases due to the presence of a vegetable parasite are four in number—viz., Favus; Tinea tonsurans—of which there are three varieties—1. Herpes circinnatus, 2. Sycosis, 3. Herpes tonsurans; Alopecia areata; and Pityriasis versicolar. We have given the nomenclature employed by Dr. M'Call Anderson(b), but most, if not all, of these diseases, rejoice in many synonyms, whence has arisen no little confusion.

Mr. Wilson classes these diseases as "phytodermic or dermophytic affections," and denies that the so-called parasites are really vegetable growths. In the *Brit. and For. Med.-Chir. Review* for January, 1864, he published an article on the "Phytopathology of the Skin, and Nosophytodermata, the so-called Parasitic Affections of the Skin," in which he maintained that the parasitic growths are produced by granular degeneration of normal tissues. We have not space to give his arguments at all fully, but in his last work he says:—

"The morbid or phytiform tissue is composed of globular nucleated granules, and these granules have the properties of proliferation and growth; by *proliferation* they increase in number without change of figure; by *growth* they become elongated into diaphragmated cylindrical shafts, and have the power of throwing off shoots from point to point, and assuming a branched or phytiform character, the medium of growth being the division of their nuclei. In botanical language these elements are termed, the nucleated granules, *sporules*, or seeds, the cylindrical and ramified shafts, *mycelium*; and as they resemble in every respect mucedinous fungi, they have been classed with these vegetables, under the names of microsporon, tricophyton, and achorion. . . . . What is this phytiform growth? Is it, as we maintain, an alteration of structure of the elementary components or granules of the cell-tissue of the rete mucosum? or is it an independent organism—a plant originating from a sporule or seed conveyed accidentally to the skin, fixing itself in the skin, drawing nourishment from the skin? . . . . We maintain that we have seen the cells of the rete mucosum passing through those stages of growth which have converted their nuclei into granules, the so-called sporules; we maintain that the granular condition is the normal fœtal structure of the young epidermal cell, and that the morbid condition in question is an arrest of development of those cells at their fœtal stage, and the cause of their consequent modification of destiny, no longer to rise through those higher stages of animalisation which culminate in the production of horn, but doomed in their crude condition to the lowest function which belongs to immature organic matter—namely, proliferation. We can find no better word to express this degradation of structure than the term 'granular degeneration.'"

Mr. Wilson has been very fully and ably answered by Dr. Tilbury Fox in an essay reprinted from the *British Medical Journal*.(c) He shows that "the attributes possessed by the so-called parasites are sufficiently distinctive of vegetable bodies; they are, briefly, *structural*, *chemical*, and *vital*. *a. Structural.* We are able to distinguish the presence of cellulose externally, and internally the primordial utricle coloured by iodine; also the *tubed* mycelial form and fructification: the latter being unrepresented in animal structures. *b. Chemical.* Ether, chloroform, and spirit of wine render epithelial tissues transparent, and dissolve all fatty substances; while vegetable parasites remain unchanged. *c. Vital.* The parasites will grow when removed from the influence of living tissues, and away from the influence of the blood—a property which no one will accord to animal tissue." He further observes that when a specimen of one of these diseases is well and carefully "put up" for the microscope, the animal structures—hair, epithelial cells, and the like, undergo fatty degeneration, while the parasite will grow, freely, though not perfectly, the external air being shut out. We cannot quote him more fully, but the weight of argument certainly does not remain with Mr. Wilson.

Allowing that the parasite is a vegetable growth, some authorities (Mr. Jabez Hogg, *Transactions* Microscopical Society, vol. ii., 1859) assert that it is the result, not the cause, of the disease; to which it is answered that the true parasitic disease never exists without the parasites, and cannot be cured unless the parasites be destroyed or die.

Again, Dermatologists differ as to whether there is only one vegetable parasite or several in the diseases we have named. Hebra, Tilbury Fox, and others believe in one fungus only. Dr. Fox's opinion is that "there exists but one parasite common alike to the several so-called distinct kinds of tinea. The variations are mostly in the external characters, in the *superadded* rather than the *essential* conditions; the superadded concomitant states, by their variations, fully account for the

(b) "On the Parasitic Affections of the Skin," by T. M'Call Anderson, M.D., Fellow of the Faculty of Physicians and Surgeons, Physician to the Dispensary for Diseases of the Skin, etc. London: Churchill and Sons. 1861.

(c) "The Nature of So-called 'Parasites' of the Skin." By W. Tilbury Fox, M.D. Lond., etc. T. Richards, 1864.

observed differences in physical and minute appearances." Dr. Jenner (*Medical Times and Gazette*, 1857, and "Holmes's System of Surgery," vol. iv.), Dr. Hillier, and others support the opposite view. The whole subject of the vegetable parasitic diseases of the skin will be found most fully treated of in Dr. Fox's work.(d) Authorities differ also as to the influence of special conditions of the general health as to whether "a special condition of the soil" is necessary for the growth of the parasites. Certainly dirtiness is a powerful predisposing cause. Hebra very happily illustrates this in speaking of favus,—"In order to favour their growth and development (the germs), repose and a certain temperature and moisture are necessary. . . . . If one leaves an ink-bottle at rest for some time, there is soon a development of fungous matter to be seen, while this does not form if it is in constant use." The same may be noted in the solutions of gum in ordinary use,—"The same is the case in favus. In cleanly, well-to-do people, as well as in children who receive a rational physical education, it never makes its appearance, but only among persons who live in dirtiness and misery, in whose cases the combing and the cleaning of the hair is neglected."

Some fitness of soil seems clearly necessary to the propagation of the parasites, for though the diseases dependent on them are contagious, they are by no means contagious to all; but in what the necessary fitness consists is not known. As to treatment, there is happily little real difference of opinion. Mr. Hunt stands almost, if not quite, alone in the belief that these skin diseases can be cured without the employment of local means; his experience leads him to rely on the internal employment of arsenic for obtaining a perfect cure, but the general experience agrees with Dr. Frazer's—"I have not been fortunate enough to observe such results in any instance." In all the diseases, except pityriasis versicolor, it will be necessary, or at least well, to improve the general health and nutrition by the exhibition of tonics and cod-liver oil; and, of course, to remove any state of ill-health that may exist, and the affected parts must be cleaned from all crusts, etc., and kept clean; great improvement may be thus effected; but to *cure* the disease, the parasite must be killed, and killed effectually. The severity of the measures required will depend on the length of time the disease has existed, and the extent and depth of its ravages; we use the word ravages advisedly, for the parasite may have burrowed deeply into the cutis, have infested the hair follicles, and the hairs themselves, so as to render its total destruction, its wonderful reproductive powers being remembered, no easy matter. In bad cases epilation is necessary, but when necessary not very painful, if carefully done by means of forceps, for the hairs, being thoroughly diseased, are loosened. With that, or in less severe cases without it, some form of parasiticide must be employed—a solution of corrosive sublimate, or sulphurous acid, or iodine, will do; or a solution of hyposulphite of soda, with the addition of a little sulphuric acid. In tinea tonsurans of the scalp frequent blistering is also recommended; in alopecia, tincture of iodine, equal parts of olive oil and tincture of cantharides, and occasional blistering. In pityriasis versicolar milder measures will suffice, frequent washing with soft soap, and the use of sulphur soap, or a weak solution of corrosive sublimate. That sulphur will cure it we learnt years ago from a patient for whom we had prescribed sulphur internally, and who, arguing that if the sulphur were to be the means of cure, it could not be applied too directly, anointed himself with the electuary instead of swallowing it, and quickly rid himself of his skin disease.(e)

(d) "Skin Diseases of Parasitic Origin; their Nature and Treatment." By W. Tilbury Fox, M.D. Lond. R. Hardwicke. 1863.

(e) Besides the papers and works already mentioned, the following may be consulted with advantage:—"Reports on Parasitic Diseases," by Mr. Jonathan Hutchinson; and "Lectures on Parasitic Diseases," by Dr. M'Call Anderson, in the *Medical Times and Gazette* for 1858-59, and 1861. "Die Parasitären Hautaffectionem," von Dr. Kleinhaus. "Klinische und Experimentalle Mittheilungen aus der Dermatologie and Syphilidologie," von Dr. Heinrich Köbner. Both published by Enke, Erlangen. 1864.

The "madura foot," or "mycetoma," which is caused by that most terrible of all human vegetable parasites, the "Chionyphe Carteri," we do not notice, as it is happily unknown in this country; for a like reason we have made no mention of the true lepra or elephantiasis, though our knowledge of its pathology has been much increased lately, and very largely through the labours of the able and indefatigable pathologist to whom we are indebted for a knowledge of the true cause of "madura foot,"—viz., Dr. H. V. Carter, of Bombay.

We have only noticed, and very imperfectly, the advances made in the knowledge and treatment of the commonest skin diseases. The syphilides have been so ably noticed lately in this journal, in the articles on "Modern Syphilographers," that there is no need to say a word more about them. And now we must bring these papers to a conclusion, congratulating the Profession and the public on the rich reward that has attended the labours of those who have studied skin diseases as a part of general Medicine, and have brought to bear on them all the knowledge and science of accomplished Physicians and Surgeons. We have made no effort to award individuals the credit of particular steps in advance; but we cannot conclude without acknowledging that we are deeply and especially indebted to some of the German and French dermatologists, among whom we must, above all, distinguish Bazin, Hardy, and Hebra.

THE WEEK.

LORD PALMERSTON AND THE HOMŒOPATHS.

A PARAGRAPH has been going the round of the newspapers—chiefly, it is said, the religious ones—to the effect that Lord Palmerston has discarded his ordinary Medical attendants, and has entrusted himself to the hands of two homœopathic Practitioners—Dr. Quin, a Physician, and Dr. Ayerst, a Surgeon. We hear, on the best authority, that there is no foundation for this statement.

THE CHAIR OF MIDWIFERY AT UNIVERSITY COLLEGE, LONDON.

IN consequence of the retirement of Dr. Murphy, the Chair of Midwifery at University College becomes vacant at the end of the present Summer Session, as also the appointment of Obstetric Physician to the Hospital. It is considered very probable that the choice of the Council will fall on Dr. Graily Hewitt, whose high position as a writer, Practitioner, and teacher point him out as peculiarly fitted for undertaking the Professional and other duties of the appointments.

THE CONVERSAZIONE AT THE ROYAL COLLEGE OF SURGEONS.

WE may remind our readers of the *conversazione* to which Fellows and Members of the Royal College of Surgeons are invited by the Council, on Wednesday, June 28, at 9 p.m. Visitors are admitted on presenting their cards, and are requested to appear in evening dress. The annual dinner of the Fellows will take place at the Albion, in Aldersgate-street, on Thursday, July 6, at half-past 6, Philip Chilwell De la Garde, Esq., of Exeter, in the chair. Gentlemen intending to dine should forward an application, accompanied by Post-office order (on *Store-street*), for 23s., to E. C. Hulme, Esq., of 38, Gower-street, on or before Monday, July 3.

TESTIMONIAL TO DR. ALDIS.

WE learn that a meeting has recently been held by some Medical gentlemen and others, when it was resolved,—"That a testimonial be presented to Dr. Aldis in acknowledgment of the successful efforts which he has made in sanitary progress during a period of twenty-one years, and for the untiring energy with which he has fulfilled the duties of Medical Officer of Health to the parish of St. George, Hanover-square, for more than nine years." We know that in 1844 the Report

of the Health of Towns Commission contained some important evidence of Dr. Aldis—the result of his experience as Physician to the London, Surrey, and Farringdon Dispensaries. He subsequently joined the Health of Towns Association, the Metropolitan Sanitary Association, and assisted in establishing the City and Liberty of Westminster Sanitary Association in 1847, of which he was chairman of the committee during two years, while Lord Ashley, now the Earl of Shaftesbury, was President, and Lord Ebury, then Lord Robert Grosvenor, Vice-President. He also gave evidence before the Metropolitan Sanitary Commission when the outbreak of fever occurred at Westminster School and cloisters. During this period sanitary reformers met with much opposition in certain quarters, were thought to be visionaries, and were treated with a good deal of contempt; but the progress of knowledge, and of the sense of the duty of taking care of human life, buoyed them onwards in their inquiries into the causes of the great mortality occurring in towns compared with that of the country. They, moreover, devoted much time and money to the object in which they were engaged, and became the pioneers of that sanitary legislation which has produced immense benefit to the labouring population. Among these Dr. Aldis has had a very large share of earnest work; he was always one of that body of unrequited labourers amongst the poor—the Dispensary Physicians; he has delivered lectures to the working classes on sanitary subjects; in fact, long before he obtained the moderate emoluments of office, his time, purse, and brains were at the service of the poor and of those fellow labourers who desired evidence or information to strengthen their cause. Therefore, we heartily wish success to "the Aldis Testimonial Fund," which the following gentlemen, with others, have already consented to promote—namely, Viscount Walden; the Hon. and Rev. Robert Liddell, Incumbent of St. Paul's, Knightsbridge; the Rev. Messrs. K. B. Foster, J. Cooper, and Lusignan; Dr. Druitt, President of the Metropolitan Association of Medical Officers of Health; Drs. David Davies, Ince, S. Day Goss, W. H. Jones, O'Flaherty, W. Pearse, Yearsley, Synnot, Way, Walte, and Webb; Messrs. J. R. Lane, J. Teevan, C. A. Elliott, F. Hatchard, and J. Randolph.

We should be glad to see the names not merely of clergymen and Professional friends who may be willing to make their modest contributions out of good will to a veteran in a good cause, but those likewise of the owners of property whose poor tenants have been frequent visitants at the London, Surrey, and Farringdon Dispensaries; of the rich firms whose artisans have received the like benefit; and, above all, of the subscribers, governors, and other petty grandees of these charities, who have really been themselves reaping the benefits of the Dispensary Physicians' labours. Of all earthly delusions (unconscious ones, of course), few are equal to that of the people who think they have discharged their duty to the poor when they have doled out their annual one pound one, and got the "privilege of having one out-patient always on the books of the Charity." Of all the means of seeming to do good, this is the cheapest. A poor fellow-creature comes in labouring under illness: does our charitable personage—say any ordinary middle-class London resident—give food or clothing, or a bottle of wine, or a well-cooked joint of meat, or nice soup or pudding made in his own kitchen? or does he say, "Go to my Doctor, and he shall attend you at my expense?" Not a bit of it. He gives a *ticket* to a Dispensary, where the poor wretch gets bad drugs and no creature comforts, but only the glimpse of a compassionate Physician, who, perhaps, more weary and exhausted than any of the crowd who throng about him, smothers his disgust at their squalor and fœtor, and uses his well-gained acuteness and experience in detecting and prescribing for their ailments. Very probably the grandee who relieves a sick man at the rate of $\frac{21}{365}$ths of a shilling a day conceives himself entitled to rate the Doctor soundly for any fancied neglect; whilst all the while all the salt of human kindness, all that true influence of charity which acts as balm to the soul, which the poor have experienced, have proceeded from the words and acts of the Dispensary Physician. We fear we have been wandering from our subject, which is the testimonial to Dr. Aldis as a sanitary reformer and Dispensary Physician. If Dispensary subscribers think we have scolded them, we ask their pardon. *Quis talia fando temperet à* strong words? We entreat them to accept this wholesome practical truth, that a handsome donation to the Dispensary Physician is the fitting complement of the annual guinea to the institution itself. It is one of the truths that is not told at Dispensary sermons, meetings, and in circulars and "appeals." Dispensary work now-a-days is mere drudgery to the Physician. He cannot obtain scientific materials from out-patients, neither does he get repute amongst the wealthy. It is a mistake to create and to hold such offices; but for all this, the man who has done the work ungrudgingly and unflinchingly does deserve recognition at the hands of those whose instrument he has been in executing ever so imperfect an instalment of charity.

INQUEST AT RUNCORN.—ONLY A CHILD DROWNED.

When we have found it difficult to conceal our indignation at some particular instance of neglect or inhumanity committed by persons outside the pale of the Profession, although we may have confined ourselves to a repetition of the barest details, we have been accused in some quarters of sensational writing. In the subjoined case the actors were members of the Medical Profession. Fortunately for ourselves, however, it requires no comment. The report tells its own story, and points its own moral so unmistakeably that it would be impossible to heighten its effect. If the gentlemen concerned have not forgotten every dictate of humanity, the lesson has by this time been indelibly impressed; if otherwise, anything we might add would be powerless to deepen it.

"On Thursday morning last an inquest was held before James Nicholson, Esq., coroner, at the Bridgewater Arms, Runcorn, on the view of the body of a little boy, who was drowned in one of the locks on the previous Tuesday afternoon.

"Alice Wheeler deposed that she was the wife of Samuel Wheeler, captain of the flat *Exiphoid*, and the deceased, who was 8½ years old, was her son, and was with her and her husband, and other children, on board the flat on Tuesday afternoon, passing through the docks at Runcorn on their way to Winsford. She saw him safe on the deck when the flat was in the last lock, and on her returning from turning a bridge near at hand through which they had to pass she missed him. She went down into the cabin, and found the other children safe there. She asked where Samuel was, and her daughter Alice, five years old, said he was on deck. Such, however, was not the case, and she gave an alarm that her boy was in the lock. She got the lock stopped and dragged, and the body was soon afterwards found by a man named Samuel Bowyer. She sent for a doctor but he would not come; had he done so the child's life would have been saved. She would have paid him if he had come. Samuel Bowyer deposed that on Tuesday afternoon he dragged the lock No. 8, and found the body of the deceased. He frothed at the mouth, but he did not perceive him breathe. He was immediately taken in hand by persons, who rubbed him with salt, and gave him some brandy. She left him in their care. They used means for nearly an hour to bring him round, but were unsuccessful. Ann Higginbottom said she went to Dr. Mouritz, and requested him to come to the assistance of a little boy who had just been taken out of the water. He put on his hat and came to the door, and then asked her who would pay him. She said she could not tell, as the boy was not her own. He said, 'I cannot come; I am liked to be paid.' He then told her to go to the town's Doctor, Mr. Batterton, and went into the house again. She went to Mr. Batterton's, and saw a gentleman, who said he could not come. A conversation ensued, in which several jurors took part, and spoke in strong terms of the conduct of the Medical gentlemen in the town on such occasions. The Coroner said he regretted Mr. Mouritz had put his objection

in the shape of requiring a fee, as that gave it a very awkward appearance. Had he been in his place, he should have gone at once, as a matter of humanity, and he believed it was the practice of Medical men in most places. Mr. Waight said he was sorry to say that it was not the practice in Runcorn—an opinion which was endorsed by other jurors. The Coroner said Mr. Mouritz might, for aught he knew, be a gentleman with an extensive practice, and as these things were of common occurrence he might have deemed it necessary to lay down a line of conduct to prevent him being too much called upon. As to Mr. Batterton, he had no more right to go than Mr. Mouritz; for he, as town's Doctor, could only be put in motion by the relieving officer. The jury returned a verdict of 'Accidentally drowned,' and accompanied it with the following remarks:—'The jury regret to find from the evidence of Anne Higginbottom that Dr. Mouritz refused to attend the deceased, unless he should be paid for his services, and they think it very probable that, had Medical skill been at hand, the deceased's life would have been saved.'"

PARLIAMENTARY. — UNION CHARGEABILITY BILL — DISTRICT LUNATIC ASYLUMS (IRELAND)—ENGAGEMENT OF DR. SUTHERLAND.

In the House of Lords on Friday, the 16th, the Union Chargeability Bill passed through Committee.

In the House of Commons Mr. Blake asked the Chief Secretary for Ireland whether he had any objection to state if the Irish Government, before appointing persons to the office of Resident Physician to the district lunatic asylums, required satisfactory proof that they had acquired a practical knowledge of the treatment of insanity; and whether candidates were examined as to their fitness to be entrusted with the care and treatment of the insane by the inspectors of asylums, and a report made thereon to the Lord-Lieutenant.

Sir R. Peel said that full and ample inquiry was always made as to the efficiency of the Medical men appointed to lunatic asylums. He might mention that on a recent occasion the former Resident Physician of the Waterford Asylum was appointed to the Asylum at Castlebar, and the vacancy thus created had been filled, or was about to be filled, by the appointment of Dr. M'Kay, a gentleman whom the hon. member himself had very strongly recommended. The inspectors of lunatic asylums always endeavoured to obtain accurate information as to the qualifications of future Resident Physicians before the appointments were made by the Government.

On Monday, the 19th, Sir S. Northcote asked the Under Secretary of State for War in what capacity Dr. Sutherland was employed by the War Department; what pay and allowances he received; whether he was paid by salary or by day pay when actually employed, and if by day pay for how many days in the year he was employed on an average—from what vote of the Estimates the payment was made; whether the arrangement had received the approval of the Treasury; and whether there would be any objection to lay upon the table of the House a copy of the terms of his original appointment, and of any correspondence between the War Office and the Treasury on the subject.

The Marquis of Hartington said the House would recollect that at the conclusion of the Crimean war a Royal Commission was appointed to inquire into the sanitary state of the army. The result was that several sub-committees were subsequently appointed to consider and report upon the best mode of carrying out several of the subjects which had been reported upon by the Royal Commission. Dr. Sutherland, who had been a member of the Royal Commission, was appointed to serve on four of these sub-committees, and he still continued to serve on one, and the most important of them—that originally called the Barrack and Hospital Committee, and now called the Army Sanitary Committee. The duties of that Committee were to consider and report upon all questions relating to sanitary improvements in existing barracks and Hospitals, and the most healthy form of construction for new buildings. Dr. Sutherland's great experience and knowledge in such matters enabled him to render services upon the committee more valuable probably than those of any other gentleman who could be found. As to the rate of remuneration, it was fixed by the right hon. and gallant gentleman (General Peel) at £3 3s. a day, and afterwards, upon the recommendation of Mr. Herbert, then President of the Royal Commission, it was continued so long as he was completely occupied upon these duties. Dr. Sutherland's time had since been entirely occupied on the details of the business of the Sanitary Committee, and he therefore continued to receive the above rate of remuneration. His salary was charged to the sanitary vote of the Army Estimates. Under vote 14 a sum of £20,000 was taken for sanitary services. The arrangement made for the payment of expenses incurred by this committee was generally approved by the Treasury, and there would be no objection to lay upon the table all the correspondence between the War Office and the Treasury on the subject.

In reply to Colonel P. Herbert,

The Marquis of Hartington said he was unable to answer the question whether there was no officer of the army who was qualified to discharge the duties performed by Dr. Sutherland. It was the opinion of the present Secretary of State, and it had been the opinion of two or three of his predecessors, that these duties were better performed by Dr. Sutherland than they could be by any other person. He was unable to answer the question about Dr. Sutherland's superannuation; but should rather imagine that, under the circumstances, he was not qualified to receive superannuation.

The Greenwich Hospital Bill was reported, with amendments; no further mention was made of good service pensions for Medical officers.

In the House of Lords, on Tuesday, the 20th, the Union Chargeability Bill was read a third time and passed.

FROM ABROAD.—FERMENTING MILK AND RAW MEAT IN PHTHISIS —VENICE TALC IN WOUNDS AND BURNS.

Any one who announces a new cure for phthisis is at all events secure of an auditory, and Dr. Schnepp, with his treatment by *galazyme*, will form no exception; at all events, there is no mystery or quackery about his procedure, and, although it is probably destined to fail, as its numerous predecessors, he has said enough in its favour to induce others to test its efficacy. Dr. Schnepp, as an inspector of mineral waters at Eaux-Bonnes, belongs to a class of Practitioners who by preference seek for their remedies from among general measures and dietetic objects rather than from amidst the stores of the chemist. His attention was drawn to the great immunity from affections of the chest enjoyed by the nomadic tribes of Baschkirs and Kirghiz, who wander about the steppes of Eastern Russia, and attributed popularly among themselves to their great consumption of mare's milk while in the state of fermentation, and termed by them *kumis*. Although admitting, also, that the exposure to the free air enjoyed by these tribes and their almost exclusively animal diet may contribute to the immunity they enjoy, Dr. Schnepp has convinced himself that this abundant drinking of *kumis* plays no unimportant part in accomplishing the result, and he has determined to introduce an imitation of the practice. Of course, it can be only an imitation, as mare's milk in any quantity is not obtainable in France, and even that of asses, which M. Schnepp uses as a substitute, is so expensive an article that he is obliged to dilute it with the milk of the cow. However, this may be immaterial, as the mare's milk was originally used merely from its abundance in the countries where this practice originated. But if M. Schnepp cannot give us the original article, he can at least coin a scientific name—*galazyme* or *galactozyme*, or milk in the state of fermentation. In his experiments, conducted by adding yeast or other ferment to asses' milk, at a temperature of from 15° to 18° C., good fermentation was produced, small bullæ being disengaged from the surface, and a mild acidity, accompanied by a slightly vinous flavour, being developed. The milk retains its whiteness and fluidity, and may be thus kept in a state of fermentation during two or three days, or even for a longer period. It is administered as soon as the fermentation has become complete. But this would form a too expensive preparation for general use, and M. Schnepp undertook a long series of experiments with a mixture of cows' and asses' milk in different proportions, finding that two parts of the latter with one of the former submitted to a temperature of from 15° to 18° C. entered into fermentation in from ten to fifteen hours, and was

fit for use after twenty or twenty-four hours. A pleasant homogenous fluid results, disengaging abundance of gas, having the odour of new wine, and imparting a pleasant acidulous taste. The Basehkirs and Kirghis, after feeling their way a little with the mare's milk, so as to obviate the slight diarrhœa it at first produces, drink it in enormous quantities, commencing at two bottles a day, and going on to seven or eight, and in many cases even fifteen or sixteen. It is only during the great heats of summer, the drinkers remaining the while exposed to the open air, that these vast quantities are drank, a medium quantity being, however, from eight to ten bottles. It is found that, in proportion as the air is dry and hot, a larger quantity may be taken, and proves more efficacious, while in cold and wet weather less can be taken and less benefit even in proportion is derived. M. Schnepp, however, contents himself with much smaller quantities for his patients, beginning with half a glass fasting, and another in the evening, and increasing it gradually, according to its effects, the heat and dryness of the air, and the activity of the habits of the patient. In a few days as much as two bottles may be given, but he has not gone beyond the maximum of five bottles. While taking the galazyme, all other forms of milk diet, uncooked fruit, and acid or crude articles of food are prohibited, the patient taking his most solid meal at the middle of the day. As to the physiological effects of *kumis*, no accounts have been published, nor has the process of cure under its use been watched by Practitioners. One fact, however, has struck every one living near or among the nomad tribes resorting to it, namely, the rapidity with which a condition of *embonpoint* is attained, three or four weeks sufficing to render a patient scarcely recognisable. M. Schnepp has instituted some experiments by weighing his patients while taking the fermenting (not fermented) milk, with the following results:—1. A man, in the first stage of phthisis, 31 years of age, weighing 54 kilogrammes, increased to 55 kilos. in thirteen days, and to 56·300 kilos. in thirty-seven days, and six days after the end of treatment. 2. Another, aged 22, at the commencement of the second stage, increased from 61·250 kilos. in thirty-five days, and fourteen days after end of the treatment, to 63·800 kilos. 3. A chlorotic woman, aged 21, increased from 28·500 kilos. in thirty-eight days, and fifteen after the end of the treatment, to 31 kilos. 4. A woman, with softened tubercle, weighing 31 kilos., increased to 33·500 after twenty-five days of treatment. 5. A man, with softened tubercle, increased from 59·500 kilos. to 66·500 kilos. in fifty-four days, and twelve days after the end of the treatment. It is to be supposed, then, that patients treated with *galazyme* derive from it some powerful elements of nutrition which are not exclusively dependant on the fermentation, since the carbonic acid and alcohol derived from this are equally met with in English beer. Its first effect is to appease thirst and excite the appetite, and when too fresh it may give rise to the generation of wind and diarrhœa. If the fermentations be continued somewhat farther, these inconveniences cease, and constipation usually supervenes. Under small doses, the urine becomes clearer, more limpid, and larger in quantity, this increasing as the dose is raised. At first the pulse seems but little influenced, but after the dose of the milk has been raised, for some hours after this has been taken, it becomes slower, softer, and larger—and that in persons in whom all other articles of diet, of even a glass of new milk, give rise to acceleration of pulse. "Like the *kumis*, the *galazyme* gives rise to a peculiar kind of calm inebriety, attended at most with a little loquacity, and followed by somnolence or sleep, with a strong inclination to quietude of mind and body, and a marked indifference to everything."

M. Fuster, of Montpellier, has also his remedy for phthisis, producing, he states, marvellous results, even upon persons who seemed to have scarcely a day to live. All but those who would not follow out the regimen have at least prolonged their lives, and still live; while this means seem just as efficacious in subduing the symptoms of purulent infection. It consists in the exhibition of a mixture of raw meat and alcohol, but we have not yet seen its details.

For the treatment of burns, M. Gouyon recommends strongly, in a communication to the Academy des Sciences, powdered Venice talc (a silicate of magnesia and aluminium), which, perfectly inoffensive in itself, immediately on its application relieves the pain, cleans the wound rapidly, and favours the formation of healthy granulations. This simple and cheap substance is, indeed, applicable to all wounds, whatever their nature or character, adhering to their surfaces and following all their irregularities. It is best applied by a powder-box having very small holes. It is also an excellent hæmostatic in venous and capillary hæmorrhage. In bleeding from leech-bites and epistaxis it is also a valuable agent.

THE NAVAL MEDICAL SERVICE.(a)

(From a Correspondent.)

On the late occasion when the College of Physicians considered it politic to ignore the Report of their own Committee on the condition of the Army and Navy Medical Departments, rather than accept an incontrovertible document, which from the unpalatableness of its contents, might set the College at variance with State Departments, the whole Profession protested against their decision. It was felt that the important section of the Profession employed in the Army and Navy should be freed from a sense of injustice and neglect, and be bound by affection to their respective services.

It is in vain that the *élite* of our Profession shut their ears to the increasing cry of injustice that arises from the public services, and, ignoring the facts, state that there are no grounds of complaint. Ample evidence must have appeared to induce their Committee to put forth the statement which surprised the less inquiring portion of the College. The letters in our columns, which have been published from time to time, have been convincing enough of the necessity for some rigid examination into the best means of renewing the spirit of the Medical Department; and this necessity is again brought before us in a stronger light and more concise form by a pamphlet on the "Requisitions of the Naval Medical Officers, based on the Principle of Equality with the Army." The author, Dr. F. J. Brown, formerly an Assistant-Surgeon Royal Navy, who resigned his appointment in dissatisfaction with the status of the Medical officers, proves his deep affection for the service to which he once belonged and his desire to see that service amply furnished with the best talent from our Medical Schools.

In a few pages he displays the comparative disadvantages of the twin services in a more definite manner than has been done before; and not venturing to question the data with which he appears so familiar, we express our increased astonishment that any young Medical men once acquainted with the facts should adopt the sea service in its present state, provided that the land service remain open to them.

The comparative disadvantages are exposed under the heads "rank," "privileges of rank," "retirement," in the whole of which the Naval is shown to be inferior to the Army Medical officer.

In reviewing the vexed question of rank of these officers, whose duties are not those of command, he has placed it in a new light, by showing that the naval regulations prevent any clashing of army and navy commanding officers, when either is serving within the province of the other, reserving to the officer thus deprived of command, all the personal privileges and advantages belonging to his rank. Dr. Brown points out the error and invidious injustice of not extending this usage to the Medical officers of the navy.

Accepting the validity of the argument, we are disposed to widen the ground on which it stands, believing that under many circumstances the duties of the Medical officer cannot be performed without an exertion of his "directing authority," or the functions of command under another name, without

(a) "Requisitions of the Naval Medical Officers, based on the Principle of Equality with the Army." By Fred. James Brown, M.D. Lond. and Edin., F.R.C.S., etc. London. 1865.

which the discipline of Hospitals and the care of the sick cannot be effected and maintained.

The good of the soldier and sailor demands that this Medical authority, which exists in fact, should be rendered inviolable at the will of the so-called commanding officer, and we feel assured that where, through the good sense of individuals, this principle fully operates, it is always to the advantage of the public service. Our views coincide strictly with those expressed by Dr. Warren Webster, of the United States army:—

"Let me not be understood to ask for Medical officers enlargement of military authority, or increased rank, on account of mere personal advantages. Rather let the suggestion be placed upon the sole reason of the public good. He who, in army or civil life, attains deserved eminence in the Medical Profession of the United States, has little need of the gratification of military command. Army rank will, of itself, not give logic to the thought, clearness to the eye, or dexterity to the hand of the Surgeon, as he takes up the operating knife; but, if superadded to all needed Professional qualities, it *will* tend to give that soldierly *esprit* without which we may be Doctors, but not Army Medical Officers, who *prevent*, not less than cure disease."

Dr. Brown lays stress upon the fact that retirement from active service is not compulsory in the navy so early by five years as it is in the army, a regulation which brings sluggishness of promotion, destroys the chances of the seniors, and confines the better emoluments of the service to a few, in comparison with those of the army corps.

This must operate prejudicially to the class generally, as the prizes of the service are so much slower in rotation. "Whether it be wise or not to compel Surgeons to retire at 55, and inspectors at 65," it is the rule of the one department, and it is but fair to make it so in the other.

The question of optional retirement after twenty years' full pay service merits consideration, as with that contingency in view every Medical officer would strive to reach that bourne as early as possible, and then seeing no hope of advancement he may, while energy remains, seek elsewhere to improve his condition. Few possibly would avail themselves of the option, and the State would have secured a fair amount of service—"twenty years of the springtide of life," none but the really incapable falling short of that period of service.

To compare this with what happens generally in the service it would be necessary to examine, for instance, whether above 22 years of age other classes show an average of twenty years' full-pay service. It may reasonably be anticipated that such a standard fairly applied would exhibit results favourable to an optional retirement at the period stated, the more so as it still leaves a large margin for services that would be voluntarily performed by Medical officers whose career did not stop at that point. In our own day, when the temple of Plutus is more and more accessible to the class from which the Medical Profession rises; when by commerce fortunes accumulate a hundred times more rapidly and numerously than in olden times, the prospect of the Naval Medical Officer is by no means a promising one. Unless very fortunate in his career, he may calculate on the average reward of long service—years spent in various climes and absence from domestic comforts—an income that will increase slowly from £180 to £400 per annum, closing in an annuity of £337 for the remainder of his life.

This, we fearlessly assert, is but a moderate inducement to Professional men of good education and ordinary ambition to quit the open course of civil life. If to it we add the virtual exclusion of Naval Surgeons from the honourable distinctions which render old officers respectable in poverty, an exclusion which Dr. Brown proves to exist, there can be no ground of surprise that the Admiralty have arrived at the impossibility of deluding able Medical officers to enter the service they thus fatuously control.

This is rigidly the Professional view of the case, and Dr. Brown deserves the warm thanks of the Profession at large for having given it form; and a good augury attends this exposition, emanating, as it does, from an entirely disinterested source.

In the appendix to the pamphlet there are found quotations that prove the heroic Nelson to have been the advocate of Medical officers at a time when the state of the service seems to have been in most respects the same as it is now; for, in the long interval between that time and our own, the governing class seems to have maintained its superiority and exclusive advantages unimpaired. More than this, in the matter of emolument, it is convincingly displayed, in tabular form, that in fifty years the junior lieutenant and the junior Assistant-Surgeon have gone on, *pari passu*, increasing full pay 50 per cent; but there is a wide departure from equality from that point in their respective careers, "so that at length the junior captain has benefited 93 per cent., and the junior rear-admiral 90 per cent.," "while their equals of the Medical service have not exceeded 8 per cent in the increase of emolument, to meet the ever-advancing needs of our social state."

We feel that our Naval brethren may safely rest their claims for redress on the statements thus advanced.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF OXFORD.

(Continued from page 635.)

New College.

One of the most striking historical figures in English history is connected with New College, Oxford. I refer to William Wickham, or, as his name is commonly writ, William de Wykeham. Thomas Cromwell has the repute of having risen from the lowest to one of the highest positions in the nation, and Wolsey is quoted in similar and familiar example; but I doubt if either of them have any place by the side of William de Wykeham: they battled against less, they won less, and they left far less behind them. This Wykeham, Bishop and Lord Chancellor, takes his name from his birthplace, Wykeham, in Hampshire, a small town, in which William's parents lived on the smallest possible means in the smallest possible way. The boy grew up strong, and of some mental possession from the first—a boy of parts, who at play or work stood above his comrades, and who attracted the attention of older heads as a wise boy. Perhaps he wrote poetry, or showed skill in handicraft, and certainly he showed skill in letters, which was a branch then of mystery to the masses. At last his name, and he himself too, became known to a great lord in those parts, a feudal prince, whose word, as a matter of course, was the law, under the word of the King only—one Nicholas Uvedale, lord of the manor of Wickham. Nicholas, the wonderful man of his time, to whom men bent as they would not bend now to all the kings of the earth fused into one body and headpiece for the crown of the whole planet,—Nicolas, little weening that at the moment he was doing the only thing he would ever do to link his name with the future, sent the lad to Winchester to school, and some years later got him appointed secretary to the Bishop of Winchester. In all these positions William of Wykeham did well; he won golden treasures, and, what is more and better, he won golden opinions, so that Edward the Third, a very brave and far-seeing man, must hear enough of him to feel that he, Wykeham, would make a right royal servant. Wykeham, meanwhile, has turned architect and surveyor, and in this capacity he enters the king's service, signalising this part of his career by pulling down and rebuilding some three-fourths of the castle at Windsor, and building the famed castle of Queensborough, in the island of Sheppy. He also took to the improvement of ecclesiastical architecture, and in this character advanced in the moral not less than in the material science, for he ascended to the altars he had raised as priest before them. Once in holy orders, he rose rapidly, until he became Bishop of Winchester, and once in favour in the Church, he made the Church the step to his political ascendancy. One year after he was Bishop (in 1367) he was made Chancellor. He continued to hold high office under Edward until the close of the reign, and in the reign of Richard the Second he was again Chancellor. He died an old man, 79 years, in the early part of the fifteenth century, September 27, 1404.

To the theological scholar the name of William of Wykeham is of interest, because he reads in it the origin of that expurgation of monasteries which in later days became so decided a fact; for William himself, though not an expurgator, was a reformer of the monastic order. To the architectural scholar the name of William of Wykeham is of interest, because its owner mastered the art of the builder and sustained old grand designs, if not invent new ones. To the general scholar the name of William of Wykeham is of interest, because the name is set in history with Winchester School and New College, Oxford—Winchester School to be the preliminary residence, and New College the final scholastic residence of the student.

The New College was founded by the Bishop in the year 1379, and his patent of foundation from the Pope bears the date of that year; but it is recorded that previously—viz., in 1375—he had raised a preparatory house, and had received scholars into it. The foundation-stone was laid by the Bishop himself, with great ceremony, at eight of the clock in the morning of March 5, 1379.

On the first opening of the College, provision was made for a warden and seventy scholars, clerks and students in theology, canon and civil law, and philosophy. Twenty of these were permitted to study laws, fifty to study philosophy, and two astronomy. Nor was the gentle art of healing all forgotten: two of the students were to be allowed to study Physic, but all were to be in priest's orders. To show his gratitude to the school where he was educated, William de Wykeham linked his gift to Oxford with one to Winchester. Seventy of the Fellows and Scholars of New College were to be elected from Winchester School. The kindred of the founder were to be Fellows on admission; the others were to be Scholars for two years. Some privileges were also obtained for all the members—that, for example, of being permitted to undergo examination for degrees in their own society instead of the public schools.

Such was the gift of the famous Bishop of Winchester to this nation. A noble life picture his for English youth to contemplate. A representative man in every sense, he was great in all that he did, in building a house, building a fortune, or building a fame. He was essentially a constructive man, the only man who can live. He understood the synthesis of success. Any man can take to pieces, analyse, and tear up the past? But who can build on the present? That is the man who is to be. Is it not a fact, friendly reader, that when you recall the lives of men in our own Profession, and in all others, you find that no man ever bore fame who merely analysed and tore up? It is so. Those of our class who have lived a little longer than their deaths have been the men who have patched up neatly old and crumbling mental edifices which once were true and noble, but have decayed in the ages, have been oxidised, as we would express it physically, by time. Those who *always* live, and, though dead, speak to us with voice as soft and clear as ever over the silent chasm of thousand years—those were, like our friend William, constructors on new ground of new thought and action. But the mere analysis men, though they often fill a prominent part in their century, who tear up and do not rebuild, who would excavate the very planet, if they could, till the crust, with all that was on it, fell on their own heads—these rats die as they deserve, are resolved historically into their elements, and are seen no more.

I dwell on the name of William of Wykeham as a self-made man, who has gone through the struggle of the world, and lived beyond it—who has won and worn immortality even in the life that is. I admire his power, his perseverance, his generosity, and, above all, his grasp, or, as monad humanis would say in irony—his own one idea putting out every other light—"versatility." I like the motto of the good old Winchester prelate, "Manners makyth man;" so quaint it is and stript of the common reading, which implies that the bowing down of the poor body after endless scraping of it up means all manners and nothing more, I see in the phrase a good broad sense and business which savours of healthy success of long duration. Lastly, that little touch of family feeling about William, that his own kith and kin should have a home always at the New College and just the recognition of immediate residence; there is something in that of gentleness without offence which shows that there was a true and faithful heart beating in the breast of that priestly Lord Chancellor; architect and surveyor; born in a hut; buried in a grand tomb at Winchester, hands across breast, crosier by his side, and mitred crown on his head; founder of Winchester School and New College Oxford, and still an eloquent English preacher, though he has long closed his mouth, and the nation, legally or illegally, has transformed his faith. Preaching William of Wykeham, never finishing his discourse, age upon age, and always new and eloquent to those who will listen to him, is a subject, in fact, hard to leave when one is once under him. It comes natural to take out a pencil and jot down all he seems to say. The only way to escape him is to break from him resolutely; we must and will do it. Away! (a)

At the present time New College is governed by a master; it has thirty fellowships and thirty scholarships. The scholarships are tenable for five years, and are filled up annually, at an election, from boys educated at the School of Winchester. They are worth £90 a-year, including rooms and tuition. Of the fellowships, fifteen only are open to those who have been educated at Winchester or have lived for twelve terms as members of New College. The other remaining fellowships are without limitation. There are three chaplains to the College and three choral scholars.

Much of the old college still remains, little changed, though the revolutionary wars spared it not altogether, and though revolution of taste has altered many parts and added some. The chapel, once the pride of the University, so rich, so costly, was squared after the Reformation into the new order, and made cold and comparatively plain. A library was in modern days added, and the Hall has received, from time to time, decoration and redecoration and picture on picture. Altogether, it is a fine College, full of the old and the new not unhappily blended.

The Medical celebrities connected with New College are not numerous. In 1599 Dr. Martin Colepepper, M.D., was warden. Colepepper was in holy orders, and was Dean of Chichester. I do not observe that he added anything to Medical literature. In 1561-2 Dr. Raley, M.D., was a member of the College, and Queen's Professor of Physic. He was one of the Physicians to Queen Elizabeth; but he leaves no further scope for the historian than to write his name. There is only one other name in relation to New College to which I would call attention, and the owner of this name was not a Medical man. The name is that of Dr. Bruno Ryves, who was a member of the College, and afterwards was Dean of Chichester. He is of note as having been the originator of one of the earliest English newspapers, the paper in its day known as the *Mereurius Rusticus*. The writers on New College are fond to claim *Mercurius Rustieus* as the first newspaper. There was, however, prior to that a paper published by Queen Elizabeth's printer, Christopher Barker, and called the *English Mereurie*. It came out in 1588, then lapsed, and left the country without news, in print, until the year 1622. Then there started a paper called *The Certaine News of this Present Week*, edited by Nathaniel Butler; and contemporaneously with it, or a little later, there came out three "Mercurics," of which that by Dean Ryves was one—viz., the *Mereurius Anlieus*, *Mereurius Rustieus*, and *Mereurius Civieus*. *Mereurius Rustieus* was of much service in its way—it opened the royal road to free expression of thought; and we may pardon New College men for claiming for their famous house the honour that is due to it, and a little more, in regard to the introduction of the fourth estate into this realm.

Lincoln College.

Lincoln College was founded in the year 1427 by Richard Flemming, Bishop of Lincoln. Much of the College remains as in its first days. The founder raised it for the maintenance of a rector and seven fellows, but various benefactions have been made since, and at the present time it has a rector, twelve fellows, eighteen scholars, and two Bible clerks.

In this College Dr. Radcliffe, to whom I have already referred, became a Fellow after he had left the University College.

The College produced a Physician of great repute in the metropolis in the middle of the seventeenth century. This was Dr. Christopher Bennet, who was born at Raynton, in Somersetshire in the year 1617. He entered Lincoln College in 1632, took out his M.A. at Oxford, and soon afterwards his M.D.; then he moved to London and was raised to the Fellowship of the Royal College of Physicians, and soon obtained a large and lucrative practice. He wrote and published a book under the title "*Theatri tabidorum seu Exercitationes dianoeticæ cum historiis et experimentis demonstrativis.*" He made the disease phthisis pulmonalis his special study, and died of the disease (not because he made a study of it, by the way,) on May 1, 1655. He also published and enlarged a book written by a Thomas de Muffett, "On the nature, method, and manner of preparing all kinds of food used in this nation." The works were crude, and evidently unfinished.

The famous John Wesley was educated at Lincoln College, and became a Fellow in 1726, being soon afterwards appointed Greek Lecturer. From that College he went forth in due time to play the wonderful history which all men, however they may differ from him, accord to him; while the College, still the same as it was, and admitting none of his teachings as canonical, is not less ambitious to claim him as one of its sons.

All Souls' College.

All Souls' College was founded by Henry Chichele, Arch-

(a) The family of Lord Saye and Sele is lineally deseended from William of Wykeham.

*

bishop of Canterbury, in the year 1437. The college in past time had a warden, forty fellows, and six clerks, but now the society is formed of a warden, thirty fellows, two chaplains, two clerks, and two Chichele professors, one professor taking "International Law and Diplomacy," the other "Modern History" as his subject.

In the year 1536 a Physician by the name of John Warden, M.D., was warden of the college, and he held office until the year 1555, when he resigned: he was a scholar, but not a man of great Medical learning. After his time two members of our Profession, for whom we entertain much reverence, rose from this place, and adorned it each in his own peculiar way. I refer to Linacre and Sydenham. Linacre, who was born at Derby in 1460, and received his elementary education at a school at Canterbury, went to Oxford in or about the year 1480. He became a Fellow of All Souls' College in 1484, and some time later formed one of an embassy to Rome. Once in Italy, he remained there a long season, studied at the most noted of the Italian schools of letters and science, then in all their unfaded glory, and graduated in Medicine at Padua before returning to England. On his return he took up the Medical degree at his own University of Oxford, was appointed Physician to Arthur, Prince of Wales, and to Catherine, Princess of Wales, afterwards known as the unhappy queen of Henry the Eighth, and probably settled in practice in the metropolis. On the accession of Henry the Eighth Linacre was made Physician to the King, and by his influence succeeded in obtaining from the monarch the incorporation of the Royal College of Physicians. To further the interests of the College, which became a distinct and legal body in 1518, he left by will his house, situated in Knight Rider-street, to the Fellows, and during his whole lifetime gave them accommodation, and presided over their councils. Tired of physic, or having stronger predilections, he entered the Church in 1520, and became rector of Wigan. He died in London on October 20, 1524, and was buried in St. Paul's.

Linacre was not an original thinker or worker in Medicine, but a man of profound learning and great liberality. When at Rome he was intent on his studies in the rich library of the Vatican, and had the good fortune to secure the friendship and assistance of the Patriarch of Aquileia, Hermolaus. This noble Venetian, himself deeply interested in natural science and a close scholar of Pliny, probably turned the mind of Linacre from the political mission on which he was engaged to that scientific mission for which he was more pre-eminently qualified. Linacre read in the library of the Vatican two books—Aristotle and Galen; the first made him a philosopher, the second made him a Physician. In his after life he was ever a follower of Galen, and he translated into Latin the three books De Temperamentis, the De Methodo Medendi, and several other of the Galenic essays. Friend, the Medical historian, gives Linacre a first niche amongst our Medical worthies of the past, and the truly learned in physic ever since his day have held him to be the Father of English Medicine.

Sydenham, the next Medical celebrity of All Souls' College, and the last I shall have occasion to name in connexion with it, was born at Winford Eagle, in Dorsetshire, in 1624. He went to Oxford to study in 1642, during the revolutionary period, and was obliged to leave. I believe that he is claimed as having entered first as a student at Magdalen Hall, but he was afterwards at All Souls', and he received his degree of Bachelor in Physic on April 14, 1648. He took his Doctor's Degree at Cambridge, and then probably, as was the custom, went for improvement on the Continent. In 1660 he was in Westminster, beginning a large, but probably not very fashionable practice, and here he continued until his death, which arose from a choleraic disorder on December 29, 1689. He was buried in St. James's Church, Westminster. Various estimates, mostly very favourable, have been formed of Sydenham. Locke compared him to the "incomparable Newton," and Boerhaave said of him,—"Unum eximium habeo Thomam Sydenham, Angliæ lumen, artis phœbum." The moderns in England have followed him as a great man, rather, I fear, by name than by deed. His name is on all our lips; but I have never as yet met a man who practised in any way from him. In fact, we worship the name, and whenever we reach that pitch of worship the man becomes obscure and his work mystical. I have nothing to say against Sydenham; on the contrary, I believe that in his day he did good labour, like an honest observing scholar. I should grieve to see his name off our lists of history. But it is time to be just, and to give up idolatories. Sydenham, a representative man in his century, went out with it in reality. In the next century he held in history because there was nothing better in his line to come forth. He has floated along to us, and we have labelled him, in classical prudery, to a book society. But withal, who knows Sydenham, or, knowing him, practises as Sydenham practised? Himself with us this day, he would not be the Sydenham of old; nor would he, I take it, relish the manner in which he is accepted as authority. Let us, and All Souls' College, and Magdalen Hall, recognise Sydenham—"Angliæ lumen." But, let us recognise him as he was—Sydenham of the eighteenth century, *sans* stethoscope, *sans* microscope, *sans* thermometer, *sans* test-glass, *sans* chloroform, *sans* oxygen, *sans* everything with which the modern Physician is most familiar. Then, leaving him thus, let us go to our new tasks like men, *sans* Sydenham as a child's cry!

PROVINCIAL CORRESPONDENCE.

IRELAND.

Dublin, June 14, 1865.

In my present communication I shall revert to the Surgical departments of the International Exhibition. Mr. Morrison, of Edinburgh, exhibits a very imposing "pneumatic battery" for the painless extraction of teeth. The spectator is at once struck by the extent of the machinery brought to bear upon so small an organ. The principle of the apparatus is that of a *cold* blow-pipe. By means of an ice-chest and condensing syringe in connexion with a series of suitable hollow tubes, a stream of cold air is made to impinge in a jet upon the gum until the requisite degree of anæsthesia is obtained. After the extraction of the tooth warm air is made to play upon the part until it has thawed and been restored to its normal condition.

In the Italian department is a very interesting series of mineralised anatomical preparations, preserved without spirits by the process of the exhibitor, Domenico Messedaglia, of Brescia. The process, whatever it may be, seems to be perfectly successful, the preparations being quite dry and free from any unpleasantness, while the several parts are admirably seen. The principal specimens are: a human hand dissected, showing part of the muscular and the whole of the osseous systems, preserving the natural colour of the skin, of which a small portion is left as an example; a goat's kidney bisected, retaining its natural colour and freshness of appearance, the fat adhering; the trachea of a calf; a piece of brain; a snail preserved and subsequently broken in pieces; a lizard preserved intact. These preparations, of course, are not exposed to the public gaze, but will be shown to any one interested in such matters on application to the obliging superintendent of the Italian department.

The trusses, belts, and pads exhibited by Mr. T. P. Salt, of Birmingham, to which I alluded in my letter published in your impression of June 3 (p. 582), would appear from their excellency and finish to call for an extended description. They are models of good workmanship and of adequate contrivance. They may be classed under the following heads:—

1. *Orthonemic Trusses.*—These are an improvement on the old form, inasmuch as they afford that upward lifting force which is so great a desideratum in the construction of trusses, by means of the vertical springs, by the aid of which the pads exert their pressure against the hernial openings, and to which they are attached so as to permit of their freely rotating to a certain extent, to prevent friction and displacement, thus supplying every desirable motion; whilst, at the same time, all those movements which might affect the security of the truss are completely guarded against. The pads are made by a new and peculiar process, which does away with the cumbrous and uncomfortable stitching used in ordinary truss pads, by employing a metallic clip to bind together the various parts, leather, padding, etc., which form the cushion in the same manner as the Florentine buttons are made; this renders their surface and edges exquisitely soft and smooth. The workmanship and finish of the whole is of the best possible quality.

2. *Trusses with Patent Pads.*—These are ordinary trusses, of a superior quality, fitted with pads of the same manufacture as those employed in the orthonemic trusses, except that they are pear-shaped instead of being oval. They are of various qualities, the better class having their springs plated or gilt, to prevent rusting from the perspiration and moisture of the skin.

3. *The Uni Duplex Truss.*—This is an article suited for the foreign market, as a truss made on this principle can be made to serve for right, left, or double hernia, one of the pads, with its spring, being removable. The pads are the same as those of the orthonemic trusses.

4. *Children's Umbilical Belts.*—These belts are remarkable for their simplicity and facility of application. They consist of a soft elastic band, which hooks on to a small circular patent pad, by means of a pair of clasps which rotate upon the stud in the pad, so as to prevent displacement.

5. *Adult Umbilical Belts.*—These are similar to those last described, except that the pads are larger, and have a spiral spring coiled in their centres, which follows the protrusion in its return, and securely retains it within the abdomen.

6. *The Orthoreidic Abdominal Belt.*—This is an invention for the more effectual and comfortable relief of dropsy, obesity, umbilical hernia, etc., and for affording support during the period of gestation, or in enlargement of the abdomen, from whatever cause it may arise. For these purposes it is especially suited, as it admits of being enlarged with the increasing dimensions of the abdomen, and also affords an upward support in the direction of the muscles, instead of a straight one antagonistically to them, as is the case in belts which have their fibres of elasticity arranged longitudinally. The oblique pressure is obtained by arranging the fibres in the desired direction, and making the straps which fasten it to exert their pressure obliquely from the bottom towards the centre and top, thus completely supporting the bowels.

GENERAL CORRESPONDENCE.

THE NETLEY SCHOOL.

[To the Editor of the Medical Times and Gazette.]

Sir.—I am given to understand that military journals have boasted of the supply of candidates as a proof of the popularity of the Army Medical Service, and the groundless nature of the complaints. It would seem that the Horse Guards have invariably treated the members of our Profession with that amount of respect and consideration which was accorded to the rude leeches of a generation long past. If all I have heard of the quality and conduct of these Medical candidates, about whom there has been such boastful congratulation, be true, then the authorities have gone far to create some grounds for their opinion and conduct. I have been told, Sir, stories about unseemly contests with cabmen, exhibitions of drunkenness and dissipation, and many other expressions of a "gentle life" among these candidates, which forcibly illustrate the vulgarities of the extinct Bob Sawyer type of Medical student, and those sketches by the late Albert Smith which made one bite one's finger ends with indignation and vexation. We are told that these men are not third-class men, but I have heard of some of the candidates who could hardly tell you how many h's there were in "which;" men who knew nothing of the vernacular, much less of the meaning of scientific terms—men who were well nigh bereft of all language with the loss of their pocket Johnson. Mind, I do not say that all the men were of this stamp. Some were well-educated gentlemen, I know, and they viewed matters probably with the same amount of indigation as I do. If these rumours be true, Sir, the authorities are inflicting a great wrong on the soldier, the Medical Department, and, through it, on the Profession to which you and I, Sir, have the honour to belong. I am, &c.

Southampton, June. Medicus.

GREENWICH HOSPITAL AND NAVAL MEDICAL OFFICERS.

[To the Editor of the Medical Times and Gazette.]

Sir,—The Greenwich Hospital Bill passed its second reading last night, without one syllable being said by any honourable member on the unstatesmanlike conduct of the Admiralty in excluding Naval Medical Officers from all participation in the Greenwich out pensions, at a period when there is a complete dearth of candidates for Assistant-Surgeoncies, and when everything should be done to make the service popular.

Instead of directing the serious attention of the Government and the country to this lamentable state of things, some honourable members thought it more becoming to trespass upon the time and patience of the House by descanting upon the grievances of Sir Richard Bromley. And failing in their efforts to obtain for this much injured gentleman all that he desired, they appear to have allowed the bill to pass without further criticism. Young Surgeons can now judge for themselves of the advisability of entering a service which is governed by a class and for a class. In this, the latest instance of class legislation, they have the best possible evidence of the unwillingness of the Admiralty to treat their Medical officers with justice; and if young Surgeons will join the Navy with their eyes open to this wretched injustice, they will deserve the disappointment which in future years they will assuredly experience.

For my own part, I cannot be persuaded that any competent men do offer themselves while there are vacancies in the army at home and in India open to them. But, lest any one might through ignorance or inadvertence do so, I would, through your columns, beg to caution them to beware how they take a step which they will have cause to regret, and to select any service rather than the Royal Navy.

The present generation of naval Medical officers have much to thank you for, considering the frank and considerate manner in which you have opened your columns to their use, but above all for the very able and pointed leading articles which have appeared from time to time in reference to their affairs. For your criticisms on this precious Greenwich Hospital Bill they are particularly indebted to you. I am, &c.

London, June 20, 1865. A Physician.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, June 13.

Dr. Alderson, President.

Dr. J. B. Sanderson and Mr. J. W. Hulke gave an account of a

CASE IN WHICH A SIXPENCE WAS LODGED IN THE LARYNX DURING TEN WEEKS.

On November 2 the patient was conversing in a public-house, having a sixpence in his mouth, when something in the conversation having excited his laughter the sixpence disappeared, and immediately he fell to the ground suffocated. For about an hour there was excessive dyspnœa, which, however, subsequently disappeared so completely that on the following day he experienced no bad effect from the accident, excepting that he was unable to speak aloud, and had slight dysphagia. During the succeeding ten weeks he lost flesh and strength, but experienced no difficulty of breathing, either on exertion or otherwise; the voice remained as at first. On January 6 his breathing again became embarrassed. After lasting for some hours the dyspnœa suddenly ceased, apparently in consequence of his having tripped in going down stairs. On the following day he attended at Middlesex Hospital for laryngoscopic examination. The sixpence was seen without difficulty on the first introduction of the laryngeal mirror. It was horizontally placed in the glottis, below the false vocal cords, which covered a portion of its circumference at each side, being in such a position that a transversely oblong breathing space was left between its free edge and the arytenoid cartilages. Several attempts having been made without success to extract the coin through the upper opening of the larynx, by means of loops of wire specially contrived for the purpose, it was resolved to have recourse to laryngotracheotomy. An incision an inch and a-half long was made in the middle line from the thyroid cartilage downwards, the edges of which were held apart above and below with two pairs of Trousseau's dilators. The coin could be readily felt by forceps introduced through the wound. Several attempts were made to seize it, in one of which it was displaced upwards into the patient's mouth. At that instant the patient made a sudden gulp, the coin slipped out of reach, and the patient, who had become conscious, made signs that he had swallowed it; it was recovered on the following day. After the operation the patient progressed so favourably that he was able to leave the Hospital on January 18, feeling no effect from the accident, excepting that the voice was still husky and feeble. By February 20 it had regained its natural character.

The President said that several cases of this kind were on record, but none since the introduction of the laryngoscope. The case was one of great interest.

Dr. Webster referred to several cases on record, and especially to the well-known case of the celebrated engineer. He adverted to a case which occurred in his own practice in which a cherry-stone remained in the bronchus sixty-eight days, and was then expelled by coughing. Louis relates a case in which a small gold coin remained four years in the trachea, and Dupuytren one in which a coin remained ten years. John Stevenson, an old Covenanter, had a bit of mutton bone the size of half a hazel-nut in his trachea fourteen years and nine months, and then coughed it up and got well. M. Sue met with the case of a girl who had had a piece of chicken bone in her bronchus seventeen years. She coughed it up and got well. Dr. Webster then asked the opinion of the Surgeons present as to the advisability of opening the trachea in such cases.

Mr. Birkett said the object of the operation in Brunel's case was to enable the patient to take in enough air to enable him to expel it in coughing. Mr. Birkett then referred to the importance of Surgeons being provided with a fitting instrument to pass from the opening in the trachea in order to dislodge a body from the larynx into the mouth. He related a case in which a child was brought to the Hospital in *articulo mortis*, after having swallowed a piece of walnut shell. She recovered, but no foreign body could be detected in the larynx, at the operation, by a probe passed through the tracheal wound. Next day, by passing a larger instrument, an elastic catheter, a piece of walnut shell was dislodged into the mouth.

Mr. Henry Lee said that, in Brunel's case, Sir Benjamin Brodie's object in performing tracheotomy was really to enable him to seize the coin through the opening, but he (Mr. Lee) thought the advantage of opening the trachea was correctly explained by Mr. Birkett. Mr. Lee then related the case of a boy who swallowed a fourpenny-piece. It was supposed to have passed into the larynx, and every time the boy was reversed he was nearly suffocated. He was sent to St. Thomas's Hospital, and one day whilst there felt an inclination to vomit; he heard something chink against the water-closet, and was afterwards well. Mr. Lee repeated that he thought Surgeons had had an idea of putting forceps in to take out the coin, but he thought that Mr. Birkett's remarks showed that that was not the proper reason for performing tracheotomy in such cases.

Dr. Gibb observed that the case brought forward demonstrated the value of the laryngoscope in proving the actual presence of the sixpence, and showing its position in such a manner that its removal by the mouth was all but an impossibility. He thought, however, that if the laryngoscope had been used at an earlier period successful extraction without a resort to tracheotomy might have been successful, before the coin had assumed the horizontally fixed position it was seen afterwards to occupy; indeed, he was astonished the patient was able to breathe well at all under the circumstances, for in similar cases death was usually instantaneous from suffocation. Although well acquainted with the literature of the subject, he knew of very few cases indeed upon record where a coin of any kind occupied a similar position to that described by Mr. Hulke. When at Salisbury, in March of last year, he visited the Infirmary, and a case was related to him in which a bronze halfpenny was removed from the larynx of a young man by one of the Surgeons, after lodgment for some days, by cutting through the pomum Adami and separating the alæ, no inconvenience to the patient resulting. The position of the coin was vertical within the cavity of the larynx, and in a direction from before backwards, which readily permitted of its extraction, and had not exposed that obstacle to breathing which a horizontal or more or less oblique position would have done.

Mr. Solly related the case of a navigator who had been brought to St. Thomas's Hospital after having swallowed a pebble. He was then nearly suffocated. Mr. Solly opened the trachea with the double object of admitting air and relieving spasm. The patient was repeatedly reversed, but the pebble still remained lodged in the trachea. He went out and soon got drunk, and had a violent fit of coughing and died. At the autopsy the pebble was found lodged in one of the bronchi. Mr. Solly entirely agreed with Mr. Birkett and Mr. Lee in their explanation of the advantages of the operation. He then spoke of the advantage of the button-headed probang in extracting bodies from the œsophagus, and related a case in which he had hooked out a piece of mutton bone in a patient who was suffering from laryngitis in consequence of the irritation caused by the foreign body.

Mr. Durham related the case of a child who was seized with a "fit" whilst eating an apple. The child was apparently dead, but by artificial respiration was brought round after the performance of tracheotomy. The larynx was then carefully examined by pushing a probe up and by the finger, but nothing was discovered. Something larger than a probe, as recommended by Mr. Birkett, should have been passed up. The child, who had had several fits, had another attack and died. At the autopsy a piece of apple was found in the ventricle of the larynx. Had a laryngoscopic examination been possible, the piece of apple might have been discovered during life, but the real cause of death was tubercular meningitis.

Mr. Holmes Coote said that when the trachea was opened the patient could not cough. Hence, in opening the trachea, this way of getting rid of the foreign body was not applicable. He could remember several cases in which foreign bodies had been expelled by coughing.

Dr. Wynn Williams said that in Mr. Brunel's case an apparatus was contrived by which he was reversed. The advantage of tracheotomy in the case was that it prevented spasm of the glottis.

Mr. Henry Lee said that Sir B. Brodie had had forceps made on purpose to catch the foreign body. In reply to Dr. Webster, Mr. Henry Lee said the wound was kept open, and it was expected that the coin would have passed through it.

Mr. Spencer Wells said a drawing of the forceps which Sir B. Brodie had had made in the case was to be found in an article which he (Mr. Wells) had written in the "Cyclopædia of Surgery." They were very long, and were intended to reach the coin in one of the bronchi.

Dr. A. P. Stewart said that the great advantage of the operation was that it quieted spasm. To this Dr. Latham had attributed the chief advantage of the operation of tracheotomy in œdema of the glottis.

Mr. Thomas Smith begged to be allowed to add to the various means for dislodging foreign bodies from the larynx that had been mentioned, one other expedient,—namely, that of drawing through the larynx from below a small piece of sponge attached to a piece of silk. This plan he had adopted successfully in a case of laryngeal obstruction after tracheotomy, where a small tent of sea tangle weed had escaped into the cavity of the larynx, and had become lodged there. The thread in this case was passed on a probe through the tracheal wound and larynx into the mouth, and the sponge, being tied to the opposite end, and traction made the foreign body present itself in the mouth. The advantage of tracheotomy in these cases was obvious. If the foreign body were in the larynx, it allowed air to enter the chest freely, so as to give the full expulsive effect to coughing when the tracheal wound was for a moment closed; by means of it the Surgeon could, without danger to the patient's life, make attempts to dislodge the foreign body from below; while if the foreign body were in the trachea or bronchus, a large tracheal opening gave the best chance of escape. He related two cases—the one under Mr. Skey's care, the other under Mr. Paget's, at St. Bartholomew's—where a plum stone in one case, and a tamarind stone in another, were shot out from the wound by a strong expiratory effort within a few minutes after the performance of tracheotomy. He believed that attempts to seize moveable foreign bodies in the trachea by means of forceps were quite useless, while he could bear testimony to the value of Mr. Birkett's advice, that if attempts were made from below to push foreign bodies out of the larynx, a good sized elastic catheter should be used, and not a silver probe.

Dr. Wynn Williams said that one of his patients, whose trachea he had opened for epilepsy, on Dr. Marshall Hall's recommendation, could not cough unless he put his finger over the opening.

Mr. Hulke replied that it was a mistake to suppose that the operation was not directly successful in removing the coin from the larynx—for this was actually dislodged upwards into the mouth during the attempt to seize it with the forceps introduced through the wound. The present case differed from those brought forward during the discussion in that the coin was in the larynx, and not in the trachea or bronchi, and in its position being accurately known before the operation. Indeed, it was this exact knowledge of its position which determined the particular operation.

Dr. Sanderson remarked that among the most remarkable features in the case were the remarkable immunity of the

patient from dyspnœa during so long a period as ten weeks, and the absence, from first to last, of all symptoms of larnygeal irritation, although the sixpence was undoubtedly in the larynx during the whole time. This seemed to be accounted for by the singular passiveness of the patient's larynx, but by its relatively large size, and by the volume of his chest. Like most large-chested men, the patient breathes slowly—at the present time, five months after the operation, only twelve or thirteen times in a minute,—and is thereby enabled to make the better use of the air he takes into his lungs.

SYPHILISATION.

Mr. Henry Lee introduced to the notice of the Society a patient who had been sent from this country, and who was supposed to have been cured in Norway by Syphilisation, under the care of Professor Boeck. Mr. Lee stated that the patient was shown in order that the Fellows might have an opportunity of judging for themselves of the nature of the case, and of the effects of the treatment pursued. He (Mr. Lee) wished to be excused from giving any opinion upon either of these points upon the present occasion. Professor Boeck had honoured him by becoming his guest during his present short stay in this country, and he merely wished, as Dr. Boeck was unavoidably absent, to present the patient to the Society in Dr. Boeck's name. He (Mr. Lee) might, however, briefly state the principles upon which Professor Boeck professed to act, and some of the physiological results at which he had arrived. Professor Boeck believes that there are two kinds of infecting sores, one of which appears as a soft chancre, and subsequently becomes indurated. This sore has no period of incubation, and is auto-inoculable. The other infecting sore has a period of incubation from two to four weeks, is not generally auto-inoculable, and secretes only thinnish pus or a serous fluid. It was with this last-named secretion that Professor Boeck, as Mr. Lee understood, carried on his process. But inasmuch as naturally the chancre last named produced no inoculable pus, before the process can be commenced an inoculable secretion must be established. This is effected by constantly applying some sabine powder to the surface of the sore until an inoculable secretion is produced. This mode of artificially producing an inoculable secretion was based upon an original experiment of his (Mr. Lee's) own, in which he used sabine ointment for the same purpose. Having obtained an inoculable secretion from an indurated and naturally non-inoculable sore, Professor Boeck proceeds to make three punctures on the sides of his patient. At the expiration of three days, these points in their turn yield a puriform auto-inoculable secretion. This fresh secretion is then, in like manner, inoculated, and three fresh pustules are produced. In this way the inoculations are continued every third day, the inoculated matter being always taken from the last-formed pustules. It is found that the inoculations continually produce less and less effect, until at last no result follows. In this way a series of some twenty or twenty-five inoculations may be performed with the secretion of a naturally non-auto-inoculable indurated sore. Now, supposing that a series of twenty such inoculations had been performed, the inoculations first made would be sixty days old, and the tenth inoculations in the series would be thirty days old. If, at this time when, in the direct descent, no further effect can be produced with the inoculations last made, some of the secretion be taken from the tenth set of inoculations (thirty days old), that will be found to be inoculable again ; and, curiously enough, the series of inoculations from that set may be continued for the same, or very nearly the same, number of times as those previously made from the same source : that is to say,—if the total number of the first series of inoculations were twenty, then, if the secretion were taken from the tenth set (then thirty days old), ten more inoculations, and no more, may be produced from this source, so that the number of inoculations in the direct descent and those by collateral branches is in all cases nearly the same. When the life of this germ has been exhausted, some fresh matter is taken from another source, and the process recommenced. Fresh parts of the body—as the thighs—are then taken, and the process repeated until no further inoculations with this kind of matter can be produced upon any part of the patient's body. Immunity from inoculation from this kind of matter, from whatever source derived, has then been arrived at, and the patient is said to be "syphilised." It is found in performing these inoculations, that when a particular series has come to an end—at the expiration, we will say, of the twentieth set of inoculations—in a patient, A, and the same has occurred at the same time in another patient, B, that the sores which are still suppurating on A may, nevertheless, be inoculated on B, and B's sores, which would no longer produce any effect on himself, may nevertheless be inoculated on A. The two series of inoculations, which have come to a natural termination on the patients themselves, may thus be crossed so as to be continued. The seed, which will no longer grow in the soil in which it had been so often sown, will, nevertheless, take root in other ground, and, after it has continued there for a certain time, may be re-transferred to its original bed. Thus, in the case supposed, A's first series of inoculations will continue for sixty days, and B's series will continue for the like period. If, then, some matter from one of A's suppurating sores (say, from fifteenth set) be inoculated upon B, they will take, and this collateral series may then be continued ; and if, in like manner, the secretions from B's fifteenth set be inoculated upon A, the inoculations will take, and the series may be continued. After an interval, the secretions from these collateral series may again be re-transferred to A and B respectively. When a patient has been in this way syphilised so that no further inoculations can be produced from matter derived originally from an indurated chancre, Professor Boeck considers that he is proof against any fresh infection, and that he is cured of that which he previously had.

After these observations, the patient was, with the permission of the President, introduced to the Society, and the Fellows had an opportunity of investigating his case for themselves. On examining the patient, a small cicatrix appeared on the frænum ; this was depressed. On chest and thighs were a large number of cicatrices, some of them of considerable size, depressed, and showing that there had been evident loss of substance. Very extensive destruction had taken place at the back of the throat, extending forward through the entire length of the soft palate. The nose was depressed upon the right side, showing that there had been loss of substance either in the bone or cartilage in this situation. The upper lobe of the right lung was found to be, in part, consolidated. On the left leg was a circular cicatrix, in the course of the internal saphena vein, the remains of an issue which had been made to cure a chronic ulcer. The history which he gave was, that the ulcer on the frænum, the cicatrix of which was left, appeared in 1855 ; it remained open six weeks ; it was very painful, and bled ; it left no hardness. There was some swelling in the groin at the time, and this was treated by the external application of the nitrate of silver. The sore on the frænum appeared some six weeks or two months after he supposed he had exposed himself to contagion. About twelve months after this sore he had severe ulceration of the throat ; this got better and worse several times. There was at this period some loss of hair. He never had had any eruption on the body, and had never tasted mercury. He was 33 years of age, with a large pupil ; "all the family were weak in the chest." Had had ten brothers and sisters, all of whom had died of consumption. The patient, who wore a false palate, expressed himself in the strongest terms as being most grateful to Professor Boeck for having cured him of his disease.

OBITUARY.

CHARLES WITTEN CROWDY

Was educated at the grammar school at Marlborough, under the mastership of the Rev. J. T. Lawes. At the early age of 16 he became an articled pupil for four years to Mr. West, of Greenwich ; he then entered the Medical School of the united Hospitals of Guy's and St. Thomas's, where he remained as an attentive and working student for nearly three years, during one of which he was a dresser under Mr. Long. He passed the Hall and College in 1821 ; and for two years he became assistant to a gentleman in the country, of kindred tastes, between whom subsisted an affectionate friendship of life-long duration.

At this early period of his life his health became disturbed, and after consultations with eminent men of the day, Mr. Lawrence recommended him to apply to Dr. Prout (in 1823), by whose treatment, founded on a more accurate diagnosis, he experienced speedy relief ; with this distinguished and sage philosopher (whom Mr. Crowdy playfully denominated "the alchemist") he maintained an intimate Professional friendship.

In 1827 Mr. Crowdy settled at Brixton, where he succeeded in the course of time in forming an excellent practice ; but neither the doubts and anxieties attendant at the outset, nor the full employment of his time at the period of success,

diverted him from a thoughtful and studious course. Conscientious study and practice of his Profession, both as regarded his patients and his Medical brethren, were habitual with him; he never suffered those tastes to slumber which his early education and subsequent self-training had created; his Horace and Virgil were his not unfrequent companions; and even when at length actively engaged in extensive practice he habitually, during the summer months, employed an hour or two before eight o'clock breakfast in the pursuit of literature of the highest class; nor did he neglect the devotional callings which later in life he followed with more warmth and with deeper convictions.

He was subject to bronchial affections, and in the winter of 1843 and 1844 he had so severe an attack of pleuro-pneumonia that he was compelled to relinquish practice and to go to Torquay; thence to Madeira, and then to Italy, where he remained three years, employing himself partially in Medical practice and in varied pursuits, acquiring a taste for and knowledge of Italian literature. In 1849 he returned to England (becoming a Licentiate, and afterwards Member, of the College of Physicians), and practised at Brighton, where he speedily obtained the confidence, goodwill, and high appreciation of his Medical brethren, and was elected Physician to the Dispensary. His state of health during this period was frail, and in 1856, after nearly losing his life from a wound when engaged in making a post-mortem examination, he retired to Bath, where he died on April 25 last. During the last three or four years, when from various causes his health was declining, he was still pleasingly occupied in his varied intellectual resources; amongst them Medical and physiological science still maintained its deep interest; and, above all, his sincere and unobtruded religious principles became more strongly impressed on his mind—an habitual reading of the New Testament in its original language, and an increasing sense of personal religion, all marked the earnestness and reality of his convictions.

In conversation his language was correct, and at all times apposite and forcible, clearly expressing the sentiments resulting from a well-stored and thoughtful mind; and the same good qualities were conspicuous in his genuine and unstudied epistolary correspondence, which was unostentatiously interspersed with an occasional apt quotation and humorous allusions.

It is too common with the Medical Profession, and with general Practitioners more particularly, to complain of a want of due consideration towards them of the better classes, of their not holding that "status" (this is the word so frequently used) which they claim to be their due. The Medical calling, with its various accessories and accompaniments, in itself precludes its members from the pursuits and associations of fashionable life; but I venture to contend that an educated gentleman assiduously and conscientiously employing himself in relieving the sufferings of his neighbours will verily meet his reward, and by cultivating such arts and elegancies as graced the life of my departed friend, he will obtain a "status" in the social scale, where he will meet with congenial minds, and in which he will be valued and respected. T. W.

DEATH OF EDWARD DANIELL, ESQ.

We announce with deep regret the death of a much respected and well known member of the Medical Profession, Edward Daniell, Esq., lately of Newport Pagnell. Mr. Daniell died on Friday, the 16th, at Stoney Stratford, of the exhaustion consequent on a large carbuncular boil which had formed at the back of his neck about three weeks previously. During his illness he was attended with assiduous care by his two sons, Mr. Alfred Daniell, of Kegworth, and Mr. William Daniell, of Stoney Stratford. He was also visited several times, in consultation, by Dr. Richardson. For a time there appeared to be fair hope of his recovery; but three or four days before his death irritability of stomach and other unfavourable and depressing symptoms set in, and from that time he gradually sank. He had only a few weeks retired from active practice, and had left Newport Pagnell in order to spend the remainder of his days in retirement at Stratford. Mr. Daniell was a man of great ability and force of character. His love for his Profession knew no change and no alloy. He was fond of literature, and wrote and spoke with fluency, learning, and good style. He was a sound and far-seeing Practitioner, and was ready at all times to be engaged in every good and useful work. As the originator of the British Medical Fund, as a Medical reformer, and as a Poor-law reformer, Mr. Daniell is so well known that we need not dwell on his exertions in these departments. He was one of the directors of the Medical Provident Fund, and an active member for many years past of the British Medical Association. He was born in the year 1795, and is one of the few remaining scholars in Physic of whom Joshua Brookes was the teacher and almost the idol. Mr. Daniell's last contribution to literature was a sketch, life-like to the letter, of the poet Clare.

MEDICAL NEWS.

Apothecaries' Hall.—Names of the gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, June 15, 1865:—

John William Armistead, Leeds; Frederick Robertson Haward, Halesworth, Suffolk; Alfred Jones, Cardigan; Hy. Wm. Alex. Mackinnon, Portugal-street, Lincoln's-inn.

The following gentlemen, also on the same day, passed their first Examination:—

Barnabas Walter Lamb, St. Bartholomew's Hospital; William Square, St. Bartholomew's Hospital; Benjamin Neale Dalton, Guy's Hospital; Arthur Bowes Elliott, Guy's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Ashton, Thomas J., M.R.C.S. Eng., has been elected Honorary Surgeon to the Infirmary, St. Marylebone Workhouse.

Banbury, Richard, Surgeon Bengal Medical Service, has been appointed Superintendent of the European Penitentiary, the Central Gaol, and the District Gaol.

Brighouse, John, M.R.C.S. Eng., has been elected one of the Honorary Medical Officers of the Royal Pimlico Dispensary.

Colman, Walter, M.R.C.S. Eng., has been appointed Resident Surgeon to the Tower Hamlets Dispensary.

Cumming, Arthur J., M.R.C.S. Eng., has been appointed Surgeon to the Devon and Exeter Hospital.

Edye, John, M.R.C.S. Eng., has been appointed Consulting Surgeon and Honorary Governor of the Devon and Exeter Hospital.

Lycett, John, L.R.C.P. Edin., has been appointed Acting Medical Officer of the Royal Northern Sea-bathing Infirmary, Scarborough.

Slack, Henry W., L.R.C.P. Edin., has been appointed Surgeon to the East Dispensary, Liverpool.

Steventon, William, M.D., M.R.C.S. Eng., has been appointed Medical Officer to the Presteigne (Radnorshire) Union.

Sutton, H. G., M.D., has been appointed Assistant-Physician to the Hospital for Diseases of the Chest, Victoria-park.

DEATHS.

Bond, Charles, M.D. Edin., at Lutterworth, Leicestershire, on June 11, aged 42.

Cauty, Henry J., M.R.C.S. Eng., at 33, Norton-street, Liverpool, on Jun 11, aged 63.

Cunningham, Alexander, late Surgeon 86th Regiment, at Fettes-row, Edinburgh, on June 11, aged 82.

Edwards, Francis S., M.D, at New York, on June 1, aged 39.

Fletcher, John Wells, M.R.C.S. Eng., at Upton-on-Severn, Worcestershire, on June 16, aged 36.

Hampson, Adam, M.R.C.S. Eng., of Bolton-le-Moors, at Staplehurst, Kent, on June 9, aged 42.

Macy, Henry J., M.R.C.S. Eng., of Westown, near Bristol, at Gosport, on June 9.

Matthew, Thomas P., M.R.C.S. Eng., Staff Surgeon-Major, at Malta, on June 8, aged 45.

Nelson, Charles, M.D., at Pitcox, East Lothian, N.B., on June 12.

Odell, William, M.D., Deputy-Inspector-General of Army Hospitals, at Carrigafoyle Castle, on June 3.

Pointer, Henry, Surgeon, at 3, South-crescent, Bedford-square, W.C., on June 11.

Wilson, James G., M.D., at the Free Church Manse, Mary-hill, Glasgow, on June 10.

Royal College of Surgeons.—The half-yearly examination in general knowledge of candidates for the diploma of Member of this College took place on the 20th, 21st, and 22nd inst., when ninety-six gentlemen presented themselves, being an increase of seven over the corresponding period of last year; the ages of the candidates ranged from 15 to 32 years, giving an average of 18 years to each gentleman.

Collegiate Election.—The interest in the forthcoming contest for seats in the Council of the College of Surgeons increases. In some quarters a strong wish exists to secure the re-election of one of the retiring members. The expected resignation of more than one candidate has not yet taken

place; the nine candidates mentioned last week are, therefore, still before their constituents. The election will take place on Thursday, the 6th proximo.

THE COLLEGE SOIRÉE. — Several correspondents — members of the Royal College of Surgeons—have complained at not receiving cards to attend the *conversazione* on Wednesday next; these gentlemen cannot have paid any attention to the advertisements which have appeared in all the Medical journals for some weeks past, inviting the Fellows and Members desirous of attending simply to present their private address cards to obtain the entrée, when we think they will not be disappointed at the entertainment provided for them by the Council of the College.

POLLUTION OF RIVERS.—Instructions have been issued from the Home Office to the Commissioners appointed to inquire into the pollution of rivers, directing them to take selected river basins, illustrating different classes of employment and population, with a view to ascertain whether a measure absolutely prohibiting the discharge of the refuse of mines and manufactories into rivers, or absolutely compelling town authorities to carry town sewage on to the lands, might not be remedying one evil at the cost of an evil still more serious in the shape of injury to health and damage to manufacturers. The Secretary of State suggests that the following river basins might be taken:—1st, the Thames Valley, both as an example of an agricultural river basin, with many navigation works, such as locks and weirs, and mills affecting the flow of water, and many towns and some manufactories discharging their sewage and refuse into the stream from which is mainly derived the water supply of the metropolis; 2, the Mersey Valley, including its feeders, particularly the Irwell, as an example of the river basin most extensively polluted by all forms of manufacturing refuse, particularly that arising from the cotton manufacture, and processes connected therewith; 3, the Aire and Calder Basin, as an additional example of the same class, particularly in connexion with the woollen and iron manufactories; 4, the Severn Basin, for the same reason, but in particular connexion with the great seats of the iron trade; 5, the Taff Valley, in connexion with mining and industry applied to metals; and 6, a river basin, comprising a mining district in Cornwall.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Dr. Handfield Jones's Lectures on the "Pathology of Nervous Diseases," delivered before the Royal College of Physicians, will be commenced in our next Number.

Prof. Pirrie's paper on Acupressure shall appear as soon as the accompanying engravings are completed.

A review of *Mr. Solly's Surgical Experiences* is in the printer's hands. Bernay's "Notes on Chemistry," fourth edition, shall also receive an early notice.

Articles on "Sanitary Measures and Metropolitan Vestries" and on "Syphilis" are also ready for publication.

The Author of the *Report on Cheap Wines* purposes to send us from time to time a series of observations on articles of Food and Drink, especially new ones. The object will be, not merely to say what can be known of their properties and to make known their probable uses, but likewise to examine the hypotheses on which they are brought forward. Thus a picture of the state of Medical logic may be drawn from Nature.

A Surgeon, Tunbridge Wells.—The name of the individual alluded to does not appear in the list of Fellows of the Royal College of Surgeons of England.

Oxford.—The late row was disgraceful in the extreme to the young men implicated, and still more so to the authorities who neglected to vindicate and maintain discipline.

Poor-law Salaries.—The Ormeskirk Board of Guardians have voted Mr. Woods an increase of *seven* pounds *per annum* on his salary of £53, on which, as they confess, he is worse paid than a day-labourer. They think him sufficiently rewarded by the fact that his abilities and kind-heartedness have gained him a good private practice. There is no help for this. If Medical men will take such salaries, guardians, as men of business, may be excused for not giving more.

POOR-LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In answer to Mr. Richard Griffin's letter in your last issue, permit me to suggest, if Poor-law Surgeons were exempt from assessed taxes for one groom, one horse, and one trap, and that at all times they were allowed to travel toll free in their own districts, a great boon would be conferred on them. I am, &c.

Sussex, June, 1865. ONE OF THEM.

THE GRIFFIN TESTIMONIAL FUND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—At a meeting of the Committee on the 12th inst. it was unanimously resolved that the above fund should be finally closed on October 1st prox. Intending subscribers would oblige by forwarding their contributions. The following subscription has been further received:—Heynes Hardwicke, Esq., Saxlingham, 5s. Amount previously announced, £124 11s. 9d. Received at *Lancet* office, £9 9s. I am, &c.

145, Bishopsgate-street Without, June 21. ROBERT FOWLER, M.D.

CANDIDATES AND THEIR QUESTIONERS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—We look to your journal for a little liberality and good sense, so I hope you will let me caution my Professional friends against raising the anti-homœopathic cry at the coming elections. We do not like homœopathy, and know it to be an absurdity; but many of those who are deluded by it really know no better, and may be useful members of Parliament. If a man is a fool keep him out, whether homœopath or not; or if we decide to vote against homœopaths let us do so; but it is not a question that can be raised with credit or advantage to us. Men are not patients and homœopaths always and everywhere, and the least likely way to cure them of this delusion would be to get up a kind of No Popery howl against them. See this week's *Owl*.

I am, &c. COMMON SENSE.

COMMUNICATIONS have been received from—

Dr. MARSHALL HOLMES; APOTHECARIES' HALL; M.D. EDIN.; Mr. T. M. HARDING; Dr. J. FAYRER; Mr. T. OSBORNE WALKER; ONE OF THEM; Mr. CHARLES HUNTER; A PHYSICIAN; ETHNOLOGICAL SOCIETY OF LONDON; Dr. J. WARD COUSINS; ROYAL MEDICAL AND CHIRURGICAL SOCIETY; Dr. HARRY LEACH; Dr. ROBERT FOWLER; "WESTERN MORNING NEWS;" A SUBSCRIBER; Dr. HENRY BARBER.
