We have learnt with great satisfaction that a first volume of "Bartholomew's Hospital Reports" is to be published in October next. No one can, without deep regret and some shame, think of the immense number of facts lost and of the vast sources of knowledge wasted, year after year, in our large Hospitals; and the regular appearance of the Guy's Hospital Reports has been a standing reproach to all the other Hospitals and Schools. Last year we gladly hailed the appearance of a volume of "London Hospital Reports;" and we now heartily congratulate the St. Bartholomew's staff on their having at last determined to give to the Profession some account of their use of the vast Medical and Surgical riches annually entrusted to their care. The names of the gentlemen to whom the task of editing the promised volume is entrusted —Dr. Andrew and Mr. Callender—are a sufficient guarantee that that part of the work will be thoroughly and efficiently done. We understand that, though the first volume will proceed entirely from the staff of the Hospital, for future volumes contributions are asked from old St. Bartholomew's men all over the world—a new and, we think, a very good and commendable feature of the work.

OVARIOTOMY IN AUSTRALIA.

Ovariotomy is progressing in Australia. Dr. Tracy, of Melbourne, whose first successful case in the Colony we noticed last autumn, has had a second successful case, the details of which are given in the December number of the *Australian Medical Journal*. There were no adhesions, although the patient had been tapped six times. An unsuccessful case by Dr. Mac Gillivray, of the Bendigo Hospital, is recorded in the same journal. The patient had been *tapped forty-four times!* Yet there is every probability that ovariotomy would have proved successful if secondary hæmorrhage had not come on forty hours after the operation. The bleeding was found to have "proceeded from some small vessels in the divided adhesions, which had not bled at the time of the operation, and consequently had not been secured."

AMERICAN NERVE PATHOLOGY.

We recommend such of our readers as are interested in nervous diseases to possess themselves of the Report on Gunshot Injuries of Nerves, by Drs. Mitchell, Morehouse, and Keen, of the United States' Army.(a) Surgeon-General Hammond, with the scientific foresight which seems to have charactised all his proceedings, established a special set of wards in one of the military Hospitals at Philadelphia for the reception and study of injuries of the nervous system. Part of the results are before us in a report by the three gentlemen named; besides which are a series of smaller reports on special points, of which one only, on reflex paralysis, has reached us. The subject of reflex paralysis, which really embraces most of the phenomena of shock, is very instructively treated in the latter document; but the most interesting part is the account in the larger report of the lesions of nutrition in parts supplied by motor and sentient nerves when those nerves are injured, but not absolutely cut. The lesions of sensation and motion, the feelings of cold or of burning pain, the local eczematous eruptions, ulcerations, loss of hair, shiny skin, and other phenomena, and the means employed for their relief, well deserve study. Electricity in the Faradaic form seems to be brought forward as a really substantial remedy.

PARLIAMENTARY.

On Thursday, February 23, in the House of Commons, Mr. Black asked the Lord Advocate whether the penalty which was incurrable by the Medical Practitioners of Scotland

(a) Gunshot Wounds, and other Injuries of Nerves. By S. Weir Mitchell, M.D., G. R. Morehouse, M.D., and W. Keen, M.D. Philadelphia: J. B. Lippincott and Co. 1864. London: Trübner.

under the 41st section of the Act 17th and 18th Victoria, cap. 80, was repealed by the 14th section of the Act 23rd and 24th Victoria, cap. 83; and, if not, whether he intended to take the necessary steps to procure a repeal of that enactment, and so place the Medical Practitioners in Scotland on a footing of equality with the Medical Practitioners in England and Ireland.

The Lord Advocate said that the clause referred to had not been repealed, though the penalty had been considerably relaxed. He did not propose to introduce any measure on the subject.

It will be remembered that the law to which Mr. Black referred is one by which the Medical Practitioners of Scotland are obliged to sign death certificates under the penalty of certain fines. The manifest injustice implied by the State compelling an unpaid labour of this kind from a Professional class in one part only of the United Kingdom, and the unmerited degradation inflicted on a body of highly educated and loyal gentlemen by the threat of a penalty, renders the act peculiarly distasteful to the Profession in Scotland. It may be that the fine is reduced to a mere name, and that it is not as a rule enforced, but whilst the law remains on the Statute Book it is a standing insult to the Scottish Medical Profession. The Lord Advocate by refusing to repeal the obnoxious statute has lost an easy, and we should have thought a welcome, opportunity of conciliating an important section of his countrymen.

On Monday, in the House of Commons, Mr. Hardcastle asked under what prison regulations George Victor Townley, sent from Bedlam to Pentonville as an ordinary prisoner under sentence of penal servitude for life, was there allowed access to books of entertaining literature such as "Silvio Pellico" and "Gil Blas."

Sir G. Grey said that by the rules no books were allowed to be read by prisoners, except those approved by the Directors of Convict Prisons. On the appointment of a new Governor of Pentonville a few months ago he found that a practice had grown up under his predecessor of departing from that rule, and in certain cases allowing prisoners to receive books sent them by their friends. When, however, he found that the new practice was contrary to the rules, he put a stop to it.

On Tuesday, Sir W. Russell, in moving the second reading of the Metropolis Sewage and Essex Reclamation Bill, stated that it was founded on the evidence taken before the Committee which sat last year, which went to show that the only practical way of utilising the sewage of towns was by gravitation. The works of the Metropolitan Board, after the expenditure of some millions, had taken the sewage to Barking, and it was absolutely necessary that the matter should be taken up without delay if the bulk of the towns on the river were to be consulted. In dealing with the question there were three points to be taken into consideration—the necessity of diverting the sewage of the Thames; of rendering it innocuous in its application to growing crops, and of realising the greatest possible value for the manure in the interest of the ratepayers. Now, the scheme before the House proposed to remove the sewage from the Thames so that it would never return, for it was to be carried down forty miles along the coast. With regard to the second part, that of rendering the sewage innocuous by utilising it for growing crops, the scheme proposed to make a number of openings in a large culvert, so that it might be taken over an extent of 80,000 acres. But, as many farmers would during the winter months be unable and unwilling to receive it, it was proposed to utilise it over a certain extent of sea sands. With regard to realising the greatest money value for the manure, there was the present scheme and that supported by the authorities of the city of London, both of which had been thoroughly investigated by the committee of last year, and it was shown that whenever the hose and jet system had been used it had been found necessary, after a time, to abandon it, and that the only way of producing a profitable result was by the system of gravitation. There would, he thought, be a strong objection on the part of the inhabitants of Hampstead and Harrow, and other high lying places, to have a large sewer in their vicinity for the purposes of irrigation. He could, he might add, see no reason for postponing the committee for six weeks, seeing that the subject had been so thoroughly inquired into, and that its postponement would lead to legislation being probably put off during the present Session.

Mr. Crawford said he had been requested by the corporation of the city of London, as well as others throughout the metropolis, to move that the second reading of the Bill be postponed for six weeks. He wished it, he might add, to be understood that the question at issue was not one between the Board of Works and the city of London. It was stated that the principle of the Bill had been sufficiently discussed, but upon that point there was a difference of opinion, and he was informed that so high an authority as Baron Liebig had pronounced the scheme of Messrs. Hope and Napier to be a visionary scheme, which was not likely to be attended by any profitable result.

After some remarks from Mr. Tite and Mr. Caird,

Lord R. Montagu said that the concession of the sewage was placed in the hands of the Metropolitan Board, and they had given it to the promoters of this Bill. The House was therefore not in a position to choose between rival projects. The object of the amendment, as he understood it, was to consider all the schemes, so that the metropolis might receive as much as possible for its valuable sewage. The scheme was quite Protean in its various aspects. At first it came out as a plan for reclaiming certain quicksands. It then had for one of its features the utilisation of the sewage over 12,000 acres in Essex. The reclamation of the sands was now less relied upon than ever, but he did not regard the scheme as yet perfect. It would probably appear that there were other plans superior to it, and which would bring in a larger income. In the first place, the culvert would, he thought, go too near the river. In the second place, it was admitted by Mr. Thwaites that the sewage could only be utilised upon the land in Essex during five months in the year, and that during seven months of the year it would run into the Thames as it did now. The Metropolitan Board had doubtless felt that they would have placed themselves in a very absurd position if, after spending £5,000,000 to take all the sewage east, they had allowed a company to spend £5,000,000 more to conduct it to the west. The sewage of the north side of London ought to be used for the land on the north side by gravitation, and the sewage of the west in the same way upon the west side. He could not admit that the Metropolitan Board had shown any hurry in dealing with this question. So late as 1864 Mr. Thwaites stated that the Board had not considered the value of the sewage at all, and that they had not visited a single town where the sewage was utilised. He thought it very desirable to send this Bill to a Select Committee, because he believed that some plan might be adopted greatly preferable to the present scheme in a financial point of view. (Hear.)

Mr. Ayrton said it was impossible for the House to determine on the present occasion what was best to be done with the sewage of London. The question now before it was, how to deal with this Bill. The best way was to appoint what was called a hybrid committee, composed in part of hon. members who had a peculiar relation to the subject-matter of the Bill. (A laugh.) The House had better appoint a committee, constituted partly of gentlemen who had a knowledge of the subject, and felt an interest in it, and partly of gentlemen who were perfectly disinterested and impartial. Such a committee would be the best possible means of arriving at a practical solution. (Hear, hear.) The sooner the practical inquiry was to come on the better. There could be no good in postponing the inquiry for six weeks—(hear, hear),—and he hoped the House would not consent to any such amendment. (Hear.)

After some further discussion, the Bill was read a second time, and,

On the motion of Mr. Ayrton, it was ordered that the Bill be referred to a Select Committee of ten, half to be nominated by the House and half by the committee of selection, and that the committee be instructed to inquire into the most useful and profitable means of disposing of the metropolitan sewage on the north side of the Thames.

On Wednesday Sir F. Kelly's "Law of Evidence Bill," which enacts that accused persons are to be allowed to give evidence in criminal cases, was read a second time.

FROM ABROAD.—DEATH OF PROFESSOR GRATIOLET—DISCUSSION ON "VACCINAL SYPHILIS" (*continued*).

The death of Professor Gratiolet, the distinguished zoologist and anatomist, in the midst of apparent health, has spread a gloom through the Parisian scientific circles. His death was so sudden that he had only time to recommend his destitute

family to the care of the friends of science before he fell into a state of coma. His wishes in this respect will happily be fulfilled by the present enlightened Minister of Public Instruction, M. Duruy. In truth, it ought never to have been incumbent upon him to make the request, for talents such as he possessed should have met with a better appreciation. His career exhibits the difficulties which votaries of science have to struggle with, even in a country usually well enough disposed to appreciate their merit. Gratiolet, introduced into the Muséum d'Histoire Naturelle under the auspices of De Blainville, whose favourite pupil he became, was allowed to consume more than twenty years in a mere subordinate position, which did not even afford him the means of living with decency and comfort. Called upon to lecture as a substitute for De Blainville during several courses, he exhibited such remarkable Professorial talent that no excuse can be accepted for this not having been utilised and developed. He failed, however, to get appointed to his master's chair, and sixteen years passed away before another opportunity was offered him of exhibiting his remarkable abilities beyond a small circle of admiring friends. This occurred at the death of Isidore Geoffroy St. Hilaire, when the chair of zoology became vacant at the Faculté des Sciences. Gratiolet was appointed to fill it at the end of 1863, and the lectures which he delivered from it, as well as before a more miscellaneous audience at the Sorbonne, by their impassioned eloquence, luminous exposition, and profound knowledge, excited a true enthusiasm. It became a natural subject of regret and surprise that one possessed of such rare gifts had been permitted to struggle through the best years of his life upon a scanty pittance in a subordinate employment, furnishing no occasion for their exhibition. Every disposition to repair such neglect was now exhibited, but this came too late, for, just as affairs were brightening, the *savant* was cut off at the age of 49 ; and who can say that his death, thus taking place in the plenitude of his powers, has not been accelerated by anxiety, hope deferred, and the unsatisfied yearnings of one who, though modest in the extreme, was still well aware of the powers which he possessed ? The crowd of men of science which attended his funeral, and the eloquent addresses of Milne-Edwards, Broca, and others, testified that the appreciation of his qualifications as a *savant* and his attributes as a man, if tardy, is complete.

In noticing once more the prolonged discussion at the Academy of Medicine upon the transmission of syphilis by vaccination, we need not advert to the additional discourses of MM. Depaul and Ricord, which are, after all, but repetitions of what they have already said, couched in somewhat discursive phraseology. M. Devergie observed that, for his part, however the authenticity of the various reported cases may have been justly contested by MM. Ricord and Blot, he could entertain no doubt of the possibility of this transmission, having himself met with a convincing instance. He pointed out the immense difficulty in arriving at the truth in any matter relating to syphilis, owing to the extraordinary and often motiveless lies told by the parties concerned ; while the varying periods at which the infection produced by secondary syphilis manifests itself adds to the difficulty and obscurity of the investigation. Various cases of this transmission may not have been noticed, owing to the very different periods at which the vaccinal and syphilitic eruptions exhibit themselves distracting attention from their relation to each other. The fact of forty out of forty-six infants contracting syphilis after vaccination, as stated by Cerioli, is well-nigh conclusive, for never such a proportion of children could have been born with congenital syphilis. In the nursing establishment at Paris, where the condition of the children is watched long after they have left it, there are never observed more than from twelve to fifteen cases of congenital syphilis among the 2200 infants which come annually under its supervision. M. Devergie, although firmly believing in the reality of the transmission, considers that officially divulging it to the public would be most mischievous.

M. Briquet called attention to the subject in relation to Medical responsibility ; for if it be once shown that a Practitioner may be condemned in costs for a syphilitic vaccination, actions for all kinds of accidents supervening on vaccination will be instituted ; so that in fear of what may result the practice of vaccination may become greatly checked. M. Briquet, for his own part, cannot admit that the reality of the transmission has been sufficiently proved, and he believes that cases are found most numerous in those countries in which the imagination is most fertile. It is, indeed, stated that such cases are "prodigiously" rare—one in three millions, perhaps. But how different is this excessive rarity to what is observed with regard to other inoculable diseases, which are transmitted with such extreme facility. The Rivalta cases are, in M. Briquet's opinion, wholly destitute of the proofs of that reality which should be required.

M. Gibert regarded the present discussion as premature ; for the facts upon which M. Depaul's report is founded are so exceptional and unusual that they may well justify doubts. To alarm the public mind by official confirmation of such statements as these would be worse than imprudent ; and what good can come from submitting the doubts and uncertainties which exist to the appreciation of the utterly incompetent public authorities ?

In terminating our notice of this subject, we may quote the opinions of Dr. Sigmund, of Vienna, a deservedly high authority in all relating to syphilis, contained in a recent number of the *Wien Med. Woohenschrift*. Of the communicability of syphilis through vaccination he entertains no doubt ; and he puts the following queries :—1. Is there any difference in the appearances of the vaccine pustules when produced in syphilitic subjects ? Numerous as are the instances in which Dr. Sigmund has vaccinated and re-vaccinated syphilitic persons during the last eighteen years, he has never been able to observe the slightest distinctive mark in the pustules produced. 2. Does the general appearance of the child furnishing the lymph enable us to pronounce as to the presence or absence of syphilis ? While, as a general rule, syphilitic children are pale, thin, and ill-developed, there are instances in which they are of a completely healthy appearance, although eventually exhibiting well-marked symptoms of syphilis. Although congenital syphilis is usually apparent within the first six weeks, exceptions to this are not rare ; while when it does manifest itself at an early period it may not do so with sufficient distinctness to be appreciated. We can only pronounce with any certainty as to the state of health of children we have had several weeks under supervision, and when we are also exactly acquainted with the condition of their true progenitors. 3. Is the vaccine pustule itself the vehicle of the syphilitic poison ? This has been denied, and the infection in the cases in question has been attributed to the accidental inoculation of blood or serum. The point requires more exact investigation. 4. How can vaccinating from syphilitic children be securely guarded against ? When vaccination is performed from arm to arm, we must assure ourselves of the good condition of health of the children and of their parents, all doubtful subjects being excluded. When the lymph is intended to be preserved for future use, it should be taken only from individuals who have been submitted to supervision by instructed vaccinators, such supervision being continued a sufficiently long period after vaccination—viz., in the case of infants until at least three months after birth. An express organisation for the execution of such supervision should form a portion of our sanitary regulations. Until such Professional supervision is established, Dr. Sigmund denies the right of rendering vaccination compulsory. All the cases of the conveyance of syphilis by vaccination have occurred when the operation has been performed from arm to arm in

the absence of such supervision, while no instance has ever followed vaccination performed by the lymph furnished by the vaccination department attached to the Vienna Foundling Hospital.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF BATH.

THE SCIENCE HISTORY OF THE BATH WATERS.

(Continued from page 182.)

At the close of my last paper I gave the composition of the waters of Bath as preliminary to the study of their therapeutical action and value. I believe that the statements supplied included all that can be considered reliable in respect to chemical composition. There is, however, one report, not upon the waters themselves, but upon the sedimentary strata they deposit, which it would be wrong to fail to lay before the reader, not only because it is very interesting, but because it is from the pen of one of the ablest and most amiable of the representatives of Physic who has adorned our time —I mean the late Professor Quekett. It will be seen that the observations of Professor Quekett led him to conclusions respecting the origin and cause of heat of the waters different from those which have of late been commonly received and approved. I am indebted for this report to Dr. Tunstall's essay on the Bath waters, published in 1859.(a)

Mr. Quekett's researches were made on the sediment from the King's Bath. The examination was entirely microscopical :—

"I found," says the author, "the sides of the bath covered with an ochreous or rust-like sediment, and a large quantity of fine sand was brought up by the water and deposited in a reservoir, into which the springs open, about four feet below the surface. In a specimen I noticed fragments of wood, seeds, nutshells, and minute portions of charcoal. Some of the shells were covered with a well-marked coating of iron pyrites, whilst many pieces of the wood appeared to be pyritic throughout; others were quite black and firm like bog oak ; a few fragments were as black and as brittle as charcoal. I submitted samples of the water, sediment, and sand to a microscopic examination, with the following results :—The water contained no trace of animal or vegetable life, but in the ochreous sediment I recognised specimens of a recent *navicula :* the sediment itself consisted principally of granules of two kinds, one very minute, of a brown colour, formed the greater portion, the other was larger and more transparent, evidently siliceous, probably arising from minute particles of sand suspended in the water. The sand consisted of nearly equal sized grains of very transparent silex, mixed with vegetable remains, easily recognised by their black colour, and of a few rather larger grains which were semi-opaque ; when acted on by boiling nitric acid a copious effervescence took place, the semi-opaque grains, most probably calcareous, disappeared, leaving the silex unaltered; by continuous boiling the woody matter was also destroyed, leaving the sand remarkable for its transparency and brilliancy. Many of the vegetable fragments were more than half an inch square, and those most free from pyrites exhibited their structure well; I was enabled by section to recognise the oak and hazel, the presence of the latter was to be expected, as portions of nutshells were not only numerous, but the best to exhibit structure; most of these fragments abounded in pyrites, and an inky taste was very perceptible when they were applied to the tongue. The seeds were not numerous, but were coated with pyrites, looking as if they were bronzed; they were of two kinds, one smooth like a grain of wheat, the other streaked like the carraway ; when I inspected the sand and vegetable remains, I was reminded of what I had seen in the peat bogs in another part of Somerset, and I hazard the opinion—that the water in its course passes through a stratum of peat, that from it the sand and some of the vegetable remains are derived, and that a portion of the heat of the water might be due to the action of that agent upon pyrites."

Before leaving this department of my subject, I would refer to a suggestion by Dr. Daubeny as to the application of the heat that is evolved from the waters, and now is lost. Dr. Daubeny thinks that the water as it flows from the baths to the Avon might have its heat utilised for horticultural purposes. Supposing, he says, that the water issuing from the baths is forty degrees higher in temperature than that of the locality, it may easily be conceived how great must be the waste of heat when it is reflected that in every twenty-four hours no less than 181,440 gallons of water are emitted from the King's bath alone. Nothing, continues Dr. Daubeny, could be easier than to arrest this stream of water in its passage towards the river by causing it to flow through a coil of iron pipes let into the ground a few feet below the surface, so as to communicate its heat to the soil within a given area, until it had itself sunk to the temperature of the place. Without incurring further expense than this, such an arrangement would secure to the plot of ground placed under the influence of this adventitious temperature a "bottom heat" sufficient for the growth of early vegetables and for the cultivation of tender exotics. But if, in addition to this, a glass roof were provided to cover over the area so heated a winter garden might be obtained with scarcely any expense except the original outlay, by which the health and enjoyments of the inhabitants and residents of the city might be largely promoted. As there is some legal difficulty in applying the land near to the baths to this very excellent purpose, Dr. Daubeny points out that the water, without any serious loss of its heat, might be carried a distance of 830 yards to what are called the Sydney-gardens ; there, he says, it would be quite practicable to heat a considerable area by the waters so conveyed, and if they were, in the first instance, emptied into a small pond, and afterwards transmitted through the ground surrounding it by means of a coil of pipes gradually embracing a larger circle as they extended, nothing but the protection of an external covering of glass would be required for the cultivation of the gigantic Victoria Regia, and other tropical water lilies; whilst the borders of the pond would, at least, secure to the inhabitants of Bath the enjoyment of many of the trees and shrubs of warmer countries in the open ground of the garden, and a participation of a genial atmosphere during the most rigorous season.

The suggestion of Dr. Daubeny is one of singular interest to a city like Bath, where people go to be cured, and require every accommodation that art can afford. It is a suggestion essentially Medical, and for the Medical fraternity specially to consider.

The Therapeutical Action and Value of the Waters of Bath.

It is extremely difficult in considering the therapeutical properties of mineral waters to determine their actual value. Assuming that every statement be true respecting the cures effected at Bath, the question starts up, Is it the air or the water that cures ? Nay, the question lies deeper than that : Is it the change of life, the change of habits, of food, of hours, of rest, of work, mental or physical, that does the good that is done or is it the waters ? Without doubting that the waters may possess some peculiar virtue, I am sceptical enough to imagine that the virtues are confined to the locality, and that if an aqueduct for their conveyance were constructed to reach London, with heating apparatus by the way to keep up the temperature, the same number of cures, even in cases for which the waters are specifically beneficial, would hardly be effected in London as in Bath. In fact, I may cite a case of a gouty old gentleman who was cured by the waters at their source, and who had such unmitigated faith in them that—tell it not in Bath !—he positively stole a bottle full morning by morning from the Queen's Bath until he possessed a case of six dozen of the vintage—I beg pardon, I mean waterage—of 1859, an unusually favourable year. With singular pertinacity and secresy, this deplorable old reprobate, in order to hide his offence, ordered six dozen bottles of a famous Wiltshire beer, called, I believe, "Box Ale," and having emptied the bottles one by one and day by day in the most inscrutable manner, used them afterwards for holding the waters, deceived his innocent landlady on the South Parade by the assumption that said "beer" was going to London as a specimen of what could be brewed in Wiltshire, and as a blind left one bottle of real beer for herself to taste. Then, labelled "beer" and bottled as "beer," he unblushingly took his nefarious bargain to the railway station, chuckling in troth the while, booked it, got his own ticket, winked at the whole city of Bath as he left it, and came to the great city a triumphant cure, with *the* remedy in

(a) "The Bath Waters ; their Uses and Effects in the Cure and Relief of Various Chronic Diseases." By James Tunstall, M.D. London : John Churchill and Sons, New Burlington-street.

his possession, independently of any rule or regimen, Doctor to order the remedy, pump attendant to talk about it, or gossiping old maids, not too old to hope, to tell him how much he was improved. Alas all human expectations! Our adept at quiet larceny had not been in London one month before he again was gouty. He had indulged in port rather heavily, had smacked turtle, and had slept well. Now, then, for the cure. Into the wine-cellar for a bottle of the "Bath beer." A cold perspiration came over him in that dark and dismal cellar as the deception revealed itself. However, he was in for it, and must keep up good courage. His was a repetition of Macbeth—

> "If it were done, when 'tis done, then 'twere well
> "It were done quickly."

And so he hesitated no moment, but, taking a bottle of the stolen specific upstairs, with all the solemnity of Archimedes overturning the world with a feather, he drew the cork with a patent lever corkscrew. The water was sweet and still green—that was promising; the bottle was crusted—that was superb; the water was poured into a teapot, and it fizzed mildly—that was superber; it was set on the hob by a good fire, and in ten minutes it was actually as hot as though it had that moment issued from the pump-room—that was superbest and of all the most wonderful. To drink the usual quantity of Bath water out of Bath; to have the remedy under the thumb, as it were, and no one know of it; to get well and do the port wine as usual, or keep it in obedience by means so simple! 'twere enough to raise visions of the existence of a Metropolitan Bath Water Company, with unlimited capital and inexhaustible philanthropy. The usual draught was taken, and no connoiseur could have told it from real Bath water at the source. And now for the result. Did it cure? Shame on it; it did not; it simply made its recipient "vomit"—as he very unphysiologically expressed it—"like a horse." *Perseverentia!* he was a persistent man, and he would try to the end; he did so, but with no better result, and the formula he now draws from his experience is thus depressingly awful:—"Six dozen, sir, of Bath water out of Bath are not equal to one glassful in the pump-room; it is a curious fact, but I know it by experience, and I advise everybody, sir, to go to Bath for Bath water."

In noticing this important and very interesting case we feel bound to accept its teachings for what they are worth. I believe it has been urged by a learned local authority that the reason why the water could not be borne in London was, that the process of heating it artificially on a hob in a common teapot was foreign to the nature of the remedy. I will not discuss this delicate scientific point, because it would lead to a debate that might never terminate. My object is simply to show that Bath water, like Geronster, does not carry its virtues into the country nor yet into the metropolis; for the which I very much commend it as a good sensible water, that won't be played the fool with anyhow, nor allow itself to be applied except by those who know how to use it with all the adjuncts necessary for its success.

In the writings of the past two centuries the waters have been pronounced curative for paralysis, gout, and rheumatism particularly. They also have retained a certain amount of fame for lepra and other forms of chronic diseases of the skin. The arguments in favour of their value in cases of gout were, that they were agreeable to the digestion of the gouty patient, that they largely increased the action of the skin and kidneys, and that the bathing kept all the enunctories open. There is reasoning of sound character in these arguments; and one can imagine that, independently of any specific medicinal agent conveyed by the waters, they would exert the action described and greatly promote vascular motion and secretion. At the same time, it has never been assumed that the water could succeed without the regimen; and from the very first of Bath as a place of fashionable resort regimen has been enforced with as much pertinacity as the waters. Mark, then, the changes of life involved. A man or woman possessed of wealth and position came from town after a heavy season, when the Court was much gayer and more luxurious than we have ever seen it, and when wines were taken by the bottle where they are now taken by the ounce. They left, also, a crowded city, where the places of amusement were much more confined than now, and where all the widespread evils of a degraded sanitary system prevailed. They left London for Bath, and the first element towards their cure was fresh air; air not too cold to be unendurable and not too warm to be relaxing. They found it fashionable in Bath to live an easy, natural life, where the coffee-house replaced the tavern and the wine-table; they rose early and walked to the pump-room, drank the waters and perhaps bathed; after this they took a walk; and that over, they lounged in the coffee-rooms, sipped coffee, read the news, and discussed the events of the day. After a rest thus agreeable, they would retire to their lodgings, dress with care for an early dinner, and, like reasonable folk, see their Physician, and invariably have a fee laid for him in such an unobtrusive and conspicuous manner as should allow him to take it with all good breeding, as though it were a trifle not to be considered. The preparation for dinner made, the dinner itself was eaten leisurely, with little wine and few condiments—a plain though elegant repast, with much talking and mirth, and admiration of Beau Nash, in his day, or of Sheridan, and with a certain moderate practice of the "School for Scandal." After dinner another walk, and in the evening, quite early, a ball in the Assembly-rooms or the New-rooms, with Mr. Tyson or Mr. Dawson as master of the ceremonies; and if not a ball a concert or a play; but whatever it was all in good time, so that it were easy and even proper to retire to bed two hours before midnight. (b)

Who will take the trouble to read carefully the rules which the local poet thus wisely suggested will feel, I think, with me, there are few, very few diseases of a functional type that would not recover under such treatment. We have heard great talk lately of sanitary rules and regulations; but in the way of personal hygiene it would be hard for the most learned modern Professor to beat the Bath poet, whose inspirations, if they were obeyed out of Bath, would keep more sufferers away from that city than ever were enticed into it. In the present day the hygienic element in the treatment pursued at the waters is not less decisive than in the past; added to

(b) I find a poem, which was published in Bath in last century—say about 1760-70—which the visitor was requested to read and digest. The verse is not sparkling, but the sense is so good that it deserves place. The poem is called—

"An Easy Cure; or, a Prescription for an Invalid when at Bath.

"If, brother Hyp, you want a cure,
At Bath a lodging warm secure;
There drink the wholesome stream by rule,
When Nature's stream runs low and cool.

"Arise betime, to pump repair;
First take the water, then the air;
Next stroll to coffee-house, peruse,
With air of negligence, the news:

"Not caring whether party rules,
Provided no rebellious tools
Disturb the nation's public peace
Or interrupt your private ease.

"Frequent your church in decent dress,
There offer up religious vows:
Yourself to none but God address,
Avoiding foppish forms and bows.

"When you've your due devotion paid,
Walk on the North or South Parade;
If weather 's clear, in sun and air,
The best of whets, for food prepare.

"Then sparing take of lightest kind
To keep the vessels free from wind;
In wine and sauces don't exceed:
Luxurious tastes distempers breed.

"Nature refresh'd, let Nature rest,
With inward peace your mind digest:
Digestion's work is easiest wrought
By cheerful chat and little thought.

"Or to disperse black fumes away
At whist or ombre cheerful play;
Be unconcern'd at loss or gain—
A spirit ruffled raises pain.

"The mind unbent, your thoughts prepare
To bear a part in ev'ning pray'r:
That duty done, a draught repeat,
Concoction help with liquid heat.

"Then lounge at coffee-house, in chat
On various themes of God knows what,
Till two or more of friendly kind,
Of nature good, of cheerful mind,

"In sense and mirth agree to pass
The time till nine in circling glass;
Then home to sleep, and rise next light
With spirits lively, gay, and bright.

"Thus invalids from day to day
Must keep like clocks in constant way;
Must moderate be in meat and drink,
And rarely, very rarely, think.

"Must exercise, with gentle force,
On foot, or coach, or pacing horse;
Must rise and set at early hours,
And never work beyond their pow'rs.

"This course observ'd will thousands save
From pain, from anguish, and the grave;
Pills Nature vex, and weaken too:
These rules of health the man renew."

which all the appliances of modern Medical art are brought into vigorous action—indeed, it is difficult to find a successful case of recovery in which some important medicinal or hygienic adjunct has not, with the waters, been wisely and skilfully employed. Cod liver oil, iodine, iodide of potassium, quinine, and iron, are favourite remedies in combination with the waters. To show how severely in the present day the hygienic lessons are enforced, I cannot do better than quote the excellent and sound advice which Dr. Tunstall gives to those who, in these times, visit Bath to be cured. He remarks:—

"The first requisite to the invalid in the employment of any remedy is confidence, imparted by the hope of receiving benefit; and, as a class of remedies, mineral waters demand this confidence more than any others: far better not to resort to them at all, than to do so without a reliance on their efficacy. Another essential is complete tranquillity of mind, and absence of all mental anxiety. The patient who goes to a spa should leave all his troubles at home, or remain there until he can do so. It is presumed that he visits the springs to restore his impaired health, and this object should be his exclusive study during his stay. Thus, then, confidence and tranquillity are the first essentials to restoration to health.

Attention to diet is necessary in all states of disease benefited by the waters of Bath. Many of them, indeed, absolutely require it; and when so many diseases, relieved by them, owe their origin to irregularities of diet and indigestion—as gout from luxurious living; rheumatism, in certain cases, from hard beer and cider; and many diseases of the skin, from the constant use of pork and salted meats—it will be manifest that a strict rule in reference to this subject cannot be too forcibly impressed upon the invalid.

The patient should rise early, and take moderate exercise before breakfast; and avoid taking this meal in his bedroom, or, if obliged to do so, let him have his windows open for a short time, to admit the fresh purifying air. It is a great mistake to suppose that the admission of fresh air is prejudicial to the invalid; it only is so when the patient is exposed to a thorough draught. It is the close bedroom air which produces so much mischief in that stage of rheumatism in which the acute disease is subsiding into the chronic stage, and which renders the patient, on first leaving his bed, liable to suffer from the slightest breath of air.

For breakfast and tea, he may take as much stale bread and butter, or toast, as he can manage, with not more than two cups of black tea, or coffee, and one egg; but no meat or fish of any description.

He should take a moderate luncheon of biscuit, with one glass of good white wine, should he require it.

His dinner should consist of mutton, lamb, or beef, roast or boiled; boiled or roast fowl; he should eat sparingly of animal food, and avoid altogether all highly-seasoned dishes, green vegetables, and fish; and this meal should be taken in the middle of the day, in order that digestion may be fairly completed before retiring to rest.

Stimulants are to be avoided, more particularly the stronger kinds of malt liquor; the best beverage, if the digestive system be impaired, either by the long continuance of the disease, or the previous administration of powerful medicines, is very weak Cognac brandy-and-water.

The supper must be of the lightest description, consisting entirely of farinaceous materials, and should, in every case, be taken at least one hour and a-half before retiring to rest.

The bed should be comfortably warm, and not too luxurious or enervating; for, if so, it is likely to interfere with the salutary effect of the Bath water treatment, by causing too great a determination to the skin.

The clothing should be sufficiently thick to protect the patient from atmospheric changes, but not too warm. Thus, an underclothing of merino is better than flannel, and good cotton stockings far better than worsted. All unnecessary wraps are to be thrown away; for, however useful they may have been when the disease first appeared, they now only render the parts to which they are applied more susceptible to cold and local inflammation; and the same remark applies to bandages of every description, which interfere or restrict the free motion of the joints to which they are applied. Upon this subject I speak not from mere observation, but from personal experience; having had twice to resort to Bath for protracted courses of the waters, I am enabled to say that I have enjoyed a greater freedom from rheumatic attacks since I adopted this plan of clothing than I ever did under the warmer treatment which I before thought necessary.

Fortunately for those who resort to Bath for their health, the houses on the parades and streets adjacent were erected exclusively for the accommodation of the invalid. The pavement is on a level with the street doors, so that by means of the wheel chairs—which take their name from this city—even the cripple may enjoy the fresh air without fatigue, and partake, in some degree, in the amusements so necessary in his forlorn condition.

To all who can walk, I recommend free exercise in the open air. Bath is surrounded, at easy distances, by romantic walks and pleasing villages. With a view to interest the valetudinarian, I, while residing at the Bath Hospital, employed the leisure time spared me from more arduous labours in the preparation of a volume entitled 'Rambles about Bath and its Neighbourhood,' in order that he might know how to employ his time in healthful recreation. Such little excursions, chosen as they may be in Bath, even in the severest weather, so as to avoid the chilling breeze, will add variety to his amusements, and, by the occupation of his mind, forbid the contemplation of the supposed hopelessness of his case, and aid the efforts that may be made for the restoration of his health.

Bath, indeed, still preserves its Saxon reputation as the 'City of the Sick Man.' Its pump-room was erected that it might form a promenade in wet weather; and there is not a day, however cold, in which a warm and sheltered walk may not be chosen."

Turning to the composition of the waters, we find in them chemically no specific substances to which great virtue can be attached. The salts of lime, soda, potassa, and magnesia are not in quantities to raise the specific gravity of the blood to such a degree as to increase absorption to any particular extent; the iron is in infinitesimal quantities, and the iodine is almost mythical. Whether silicic acid has any peculiar virtue is as yet unproved; and to the carbonic acid no more can be attributed than would be attributed to it in soda-water. Sir Charles Lyell has expressed a view that the exquisitely minute traces of lithium, strontium, and manganese—substances which can only be demonstrated by spectrum analysis—may be of service. It is not probable that physiologists will bend to this opinion, or assume any more of these metals than that they enter the body to pass out of it by the urine. Spectrum analysis of the urine of patients drinking Bath waters in quantity would almost of necessity detect the substances in question in the urine, showing that they had passed through the blood unchanged.

It has been urged that the temperature of the Bath waters is curative in its tendency in cases properly selected. Here there is something that is feasible, for no one can fail to see that to expose the body, inside and outside, to the influence of caloric will quicken the circulation, increase secretion, and, in a degree, produce effects similar to those which are brought about by the Turkish bath. But it may be asked whether ordinary water heated to the same degree would not give rise to the same effects. Touching this point there is a remark made by my friend Dr. Tunstall which it would be unfair in me to omit; Dr. Tunstall says that a greater heat is borne when the Bath waters are used than could be tolerated were ordinary water used. Moreover, he adds, "the effects of a hot-water bath are relaxing and sedative, those of the hot thermal bath are bracing and tonic; there is no disposition to sleep after it, on the contrary, the brain is more active and the spirits more buoyant. The one produces loss of appetite and depression, the other an increase of appetite and exhilration." Certain physiological effects, I have been informed, have followed in some cases immediately after drinking the first dose of the waters. These effects are warmth of surface of the body, giddiness and quickened circulation. I do not know how many instances of this kind have occurred, neither could I ascertain that the precise phenomena had been accurately observed by an independent observer; they are rather the recorded experiences of those who have felt than of those who have seen, and they certainly cannot be considered as decisive when it is recalled how easy the imagination is made to play an active part in regard to so-called remedies. If I could have accepted all I have heard respecting homœopathic doses of inert matter, I must perforce have bowed to Hahnemann long ere this day.

The diseases in which the Bath waters exert a beneficial influence are placed by Dr. Falconer in the following order:—Disorders of the digestive organs, interrupted menstruation, leucorrhœa, anæmia, gout, rheumatism, lumbago, palsies, ischias, syphilitic and gonorrheal rheumatism, lepra, eczema, and psoriasis. In this statement and enumeration many

other Physicians of the present and of the past join heartily, and the evidence they offer is overwhelming, to the effect that recoveries from these ailments are signally successful in Bath. But, speaking in a physiological point of view, I do not conceive they have shown that the Bath waters *per se* are specific in these diseases: I mean in the same sense as quinine is specific in ague, iodide of potassium in some forms of syphilis, and arsenic in lepra. In a word, it is the whole treatment, not the special, upon which the success rests.

REVIEWS.

Medicines: their Uses and Mode of Administration. By J. Moore Neligan, M.D. Sixth Edition. Edited by Rawdon Macnamara, M.R.I.A. Dublin: Fannin and Co. 1864. Pp. 758.

In the preface to the fifth edition of this work, the late Dr. Neligan wrote—"When a book reaches a fifth edition, it scarcely requires a preface." We may assert with equal justice, that when a book reaches a sixth edition, it certainly does not require a review. The best deserved praise will not enhance its success, whilst any hostile criticism must fall harmless, as merely a dissentient voice weighing nothing against the general verdict. The circumstances, however, under which the sixth edition of Dr. Neligan's well-known work appears are peculiar. Its talented and laborious author is no more, and the work of editing the new edition, or, in other words, of remodelling it on the basis of the British Pharmacopœia, has been entrusted to Mr. R. Macnamara. From Mr. Macnamara's preface we learn that he was selected by Dr. Neligan some years before his death to be his coadjutor in the preparation of a new edition of the book. "Although," he writes, "all our arrangements were at that time perfected, still the commencement of the revision of the work was postponed until the appearance of the long-promised national Pharmacopœia; Dr. Neligan, although on the Pharmacopœia Committee, from a high sense of honour, steadily refusing to avail himself of his position, or to make any private personal use of the proofs of that work, which from his position had to be constantly submitted to his inspection." The result of this high-minded abstinence from using the advantages which his official position gave Dr. Neligan has been that the alterations and improvements in this edition are solely the work of Mr. Macnamara. We can give that gentleman a high meed of praise for the manner in which he has accomplished his task. We have carefully examined many of the new articles, and we find that both the therapeutical and the more technical portions represent fully and accurately the present state of knowledge. The prominence given to the therapeutical part of the book is completely in accordance with the title, and constitutes, perhaps, its chief distinguishing feature from other able works on Materia Medica. That a great deal of new matter has been introduced is proved by the fact that this edition exceeds its predecessors by 150 pages; nor does this increase accurately represent the additions, for as there is but now one formulary—that of the British Pharmacopœia—a large portion of space which was formerly devoted to the discordant formularies of the three rival Colleges has been saved and devoted to more useful purposes. That the work has been thoroughly brought up to the present date we may adduce two or three instances to prove: thus, if we turn to the article Lithia, under Antacids, we find a full notice of Dr. Garrod's opinions and researches; under Bismuth we have a mention of Schacht's liquor bismuthi, and Mr. Squire's solution of the ammonio-citrate; the article on the Calabar bean does not omit notice of Calabarised gelatine, nor of the recent poisonings by the bean at Liverpool. The invention of Calabarised gelatine is, however, ascribed to Mr. Squire, and the rival claims of Messrs. Streatfield and Ernest Hart are passed over in silence. In the article on Strychnia, Professor Haughton's experiments on the antagonism of nicotine and strychnia have their due importance assigned to them. Then, again, the value attributed by some to the bichromate of potash as an anti-syphilitic and its use as an escharotic have not been forgotten.

We hope we have said enough to indicate our appreciation of the care and industry with which Mr. Macnamara has edited the work of his deceased friend; and we cannot better close this notice than by extracting the short passage in which he pays a tribute to his memory:—

"Yet many circumstances seem to me, on the present occasion, to call for some prefatory remarks; foremost among which must be the sudden and unexpected removal from the sphere of his useful labours of the talented and highly-gifted person to whose pen is to be attributed the merit of the production of the five preceding editions of this work. A well-educated, well-read, practical Physician, an accomplished author, a sterling friend, hospitable and generous in all his instincts, our Profession sustained in the premature and unlooked-for death of John Moore Neligan a loss that at any time and in any country it could ill afford; but occurring as it did at a period when death was busy in our ranks—when many of the brightest names on our Professional roll were swept from it for ever—his death, in the very prime of manhood, in the very flush of honestly-won Professional success, was an event indeed as much to be deplored as it was unexpected."

PROVINCIAL CORRESPONDENCE.

EDINBURGH.

February 28.

This Session has not presented any subject of sufficient interest to claim a place in your pages; and were it not for the inclement weather, and the equally boisterous elements of the Profession of Medicine, I fear conversation would come to an end, and the great pride of Scotland—her language—soon become a dead one in the curatorship of some *Mac* Müller. (I beg your pardon, but I couldn't help it!)

The College Hall, so much required and so wisely planned by Professor Laycock, is, I believe, at present represented by a private house, under the superintendence of the Rev. Mr Sandford, who is fitted in every way by scholarship, and the other attributes of a young man's friend and adviser, to fill the office.

The Profession have here lost a most valued member in Dr. Girdwood, of Falkirk. He combined all the practical knowledge his extensive practice required with a mixture of poetry and metaphysics, like Joseph Henry Green, the friend of Coleridge. He was a tall strong man, capable of undergoing great fatigue, and quite indifferent as to what he subjected himself, so long as he relieved suffering. He was intimately associated with the most eminent men of his day. He had watched Liston and Syme climb the ladder, had encouraged Miller's enthusiasm, and watched with wonder and delight the first development of Simpson's various powers.

Like most really learned men, he was simple and unaffected. The white head on which, as on King René's, "the snows of time fell, but they could not chill it," would bend to the teaching of a student as readily as raise itself proudly to confute the ill-reasoning of a man. He is succeeded by his son, an excellent Practitioner.

In the Infirmary but little has been doing of late, and the only thing worthy of notice is the revival of an operation obsolete, I believe, for several centuries, except in Japan, Teleegoo, and a few similar places. History gives us many instances where offensive publications were publicly destroyed, and sometimes the authors executed, both proceedings being carried out by the common hangman, as no more suitable official could be selected. They say history repeats itself, and it has done so here of late. So far, too, was the history of this graceful piece of vindictiveness complete, that a public official—one who writes little books on great dogs, and represents Mr. Gladstone in the University Court—came in to see the public demolition of the offensive pamphlet.

The ceremony was conducted by Professor Syme, who took the doomed document into his class-room, and discoursed thereon. He then tore the pamphlet and cast it amongst the sawdust of the amphitheatre.

What else can one say, than that—

"'Tis true, 'tis pity,
Pity 'tis 'tis true."

Acupressure is gradually getting into general use, and has been used in the Infirmary on several occasions. Dr. Gillespie applied it in two cases last week—excision of the knee-joint, and an amputation of the foot; in both it did admirably. In short, it is *une affair finie*, and soon—with all my love for it, I say it—the ligature will be but a thread of the discourse of garrulous old age. Some few years ago your correspondent

was told by one of the Infirmary Surgeons that excision of the knee-joint was a delusion and a snare; since then he has seen this very man repeatedly perform it, and exhibit his cases as if he had originated the operation. Some day, perhaps, those opponents of acupressure will be showing a needle with some modification—perhaps a green eye and yellow point—and expressing their extreme satisfaction that "Heaven has placed this happy thought in their heads," and their friends will congratulate the "thought" on the softness and roominess of its quarters.

(From another Correspondent.)

I take the liberty of forwarding to you, by to-night's post, a copy of the *Edinburgh Daily Review* of yesterday, marking for your perusal a paragraph in it headed "Strange Scene in the University of Edinburgh." Strange, I daresay you will agree with me, is a mild epithet in the circumstances. I had yesterday a private account of Prof. Syme's most extraordinary display from an eye and ear witness (for both senses, as you will see, were very emphatically addressed), on the accuracy of which I can rely. For such of this as I will now give you, by way of supplementing the published report, I hold myself responsible.

The scene of the occurrence is mis-stated by the newspaper reporter. It was the operating theatre of the Royal Infirmary—not "one of the class-rooms of the University"—and the occasion was the delivery of a clinical lecture. A piece of very expressive pantomime, not recorded in the *Review*, is too good to be lost to the world. After tearing the pamphlet, the Professor handed the fragments to a dresser who stood near, and the young man was proceeding to lay the degraded (?) *brochure* quietly on the table, when the master snatched it angrily out of his hand, and threw it with violence into the dust-pan! Talk of the *odium theologicum* after this! For thorough-going, unblushing rancour commend me to the *odium chirurgicum* of the high places in our northern metropolis. The demesne of Surgery is Mr. Syme's; his fence has been leaped over, his preserves poached on, and annihilation (as far as possible) is the doom of the offender. Such an ebullition of impotent spite as that under consideration appears, at first sight, a not very fitting spectacle for embryo Medical Practitioners, but the Professor's example on this occasion surely cannot be catching, even to the youngest student of the class.

Seriously, shall a man of genius, employing his great powers for the noblest of purposes—the alleviation of human suffering and the preservation of human life—be subjected, on account of the very success of his labours, to unmerited insult without an indignant protest being entered on the part of that Profession of which he is one of the chief ornaments? I am not disposed to attach the same importance as the writer in the *Review* to the presence of Dr. John Brown on the occasion in question. Very probably he was there merely as the private friend of the Professor, and without the least idea beforehand of what was to be said and done. Might not the scene he witnessed have recalled to the author of "Horæ Subsecivæ" the droll last century anecdote he relates in the preface to that pleasant volume of a certain James Alston, porter and *factotum* to the Chemistry Professor of the day—the disgust of honest James at "their new fangled notions" coming to disturb his old-established easy-going "Phlogiston," and give him extra trouble preparing for the lecture, and the conflict, amid much perspiration and blasphemy, "between the old and the new"—between James, cudgel in hand, and the volant bladder of hydrogen gas, rising higher and higher the more it was attempted to bring it down?

Sad Anachronism in Medical Education.—The following is the paragraph from the *Edinburgh Daily Review* referred to in a correspondent's letter:—"*Strange Scene in the University of Edinburgh.*—It is often stated that when the notorious Surgical teacher, Paracelsus, wished to show his aversion to any particular author, he immolated the writings he dissented from in the presence of his pupils. We are not aware that this mediæval practice has ever been adopted in any of our Scottish Universities till last week, when it was followed out in one of the class-rooms of the University of Edinburgh. It looks like a plunge backwards into the dark ages. The occasion was as follows:—Professor Simpson has discovered a new method of arresting the bleeding in Surgical wounds and operations by temporarily compressing together the sides or tubes of the divided vessels by a needle, instead of tying up their open mouths by threads which remain for days as foreign bodies in the wound, and always kill or mortify the end of the tied artery. Dr. Simpson's new and simple plan of acupressure has been accepted with much more favour by the Profession than new practical suggestions usually are. But Mr. Syme, Professor of Clinical Surgery, without ever trying the plan, denounced it some time ago in most discourteous terms before the Medico-Chirurgical Society of London. Lately Dr. Simpson issued a quiet pamphlet, styled 'Answers to the various Objections against Acupressure, or the temporary metallic compression of arteries, adduced by Professors Miller, Erichsen, Neudörfer, Spence, Fergusson, and Syme.' Last week Mr. Syme took this pamphlet into his class-room, and, without attempting to answer the rather unanswerable arguments which it contains in favour of acupressure, he scolded at the author, and declared the pamphlet to be a piece of 'vulgar insolence.' 'Then came the dénouement.' (We quote from the letter of an accurate eye-witness.) 'With firm hand, teeth compressed, pale lines around his orbits, and altogether a most determined and savage expression, he tore up the pamphlet with his fingers, and gave the fragments to his assistants to be consigned to the sawdust box with other Surgical remains.' One important addition requires to be made to our notice of this indecent scene. The whole had given to it a kind of official character by Dr. John Brown, the assessor or representative of the Lord Rector in the University Court, accompanying Mr. Syme into his class-room on this special occasion, countenancing by his presence and patronage Mr. Syme's proceedings. We do not stop to discuss the question whether, by aiding in this unseemly exhibition, Dr. Brown did or did not dishonour the important trust committed to him by Mr. Gladstone. The whole transaction is likely, we hear, to come under the supervision of the University Court. As one of the seven members of that court, Dr. Brown, we are afraid, is not in a fit position to sit in judgment on the matter. If one of our fifteen judges of the Court of Session were to be present and assist at a street riot, would he not be regarded as having put himself in a condition in which he prostituted his office and rendered himself utterly incapable of exercising his judicial functions in that case? Would the Queen or Parliament not at once remove him if he committed so indefensible an indiscretion? We feel assured that the very high-minded and honourable Rector of the University will look upon this strange episode in modern University teaching with characteristic regret and disdain."

GENERAL CORRESPONDENCE.

GOUT.

[To the Editor of the Medical Times and Gazette.]

Sir,—Let me record a recent "experience" in gout for the benefit of fellow sufferers:—After a long interval, and many flying pains in the knee, ankle, foot; attacks of palpitation, of sudden headache, indigestion, etc., I was awakened with the same kind of pain and swelling of the instep which has ushered in my three previous fits. I was not too lame to walk, nor have I ever been so until the third day. Not having yet found any medicine of service, I determined to put a current theory to the test of experiment. If, I said to myself, gout is due to a *materies morbi* accumulating in the system—if that *materies morbi* be allied to any of the products excreted by the kidneys, a diuretic ought to be of service. Again, I said, there are few martyrs to gout who are not sent to some "waters" for an alleviation or a cure for their sufferings; now, water, if you take plenty of it, is a very certain diuretic, and it can be made diaphoretic too; besides, water can do no harm, like colchicum or other drugs may do if used in excess. Well, then, I resolved to drink water, and manfully began my treatment with a tumblerful of tepid water every twenty minutes for three hours after breakfast, my breakfast being a single cup of tea; my dinner at one o'clock was a plain Irish stew, with abundance of potatoes; a basin of soup, a bit of toasted cheese, and a pint of sparkling hock was my supper. The pain in the foot abated after dinner, and disappeared by night, but it was replaced first by pain in the knee, then in the "nucha."

Next day I awoke free from pain, but continued my plan of treatment; during the day flying pains in the back, the neck,

the knee, and the sole of the foot kept one alive to a sense of the danger of an imminent attack, and I was very weak.

The third day all the pains abated, and none deserved the epithet of severe till towards bedtime. The treatment was continued. The weakness at night was increased.

The fourth day all had disappeared entirely, and the exhaustion at night was reduced.

On the fifth day I returned to my ordinary manner of living and to my ordinary state of health.

Now, I do not say I am cured, but I do feel as if I had staved off a fit of the gout, and without having paid heavily for it. I will merely add that the water acted both by the skin and kidneys, and that beyond increase in quantity there was nothing very conspicuous in the state of the urine, either before or after the treatment.

I am, &c. An Hospital Physician.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The annual meeting of this Society was held at the Society's premises, 53, Berners-street, on Wednesday evening, the 1st inst. Mr. Partridge, the President, took the chair.

The ballot for the election of officers and council for the ensuing year took place. The following is the result of the election:—*President*—James Alderson, M.D., F.R.S. *Vice-Presidents*—Frederie Weber, M.D.; William Richard Basham, M.D.; Samuel Armstrong Lane; John Simon, F.R.S. *Treasurers*—Henry Alfred Pitman, M.D.; Spencer Smith. *Secretaries*—Henry William Fuller, M.D.; John Birkett. *Librarians*—Alexander Patrick Stewart, M.D.; Luther Holden. *Other Members of Council*—Andrew Whyte Barclay, M.D.; Edmund Lloyd Birkett, M.D.; Stephen Jennings Goodfellow, M.D.; Edward Meryon, M.D.; Henry Oldham, M.D.; Oscar Moore Passey Clayton, Holmes Coote, George Critchett, Charles Hewitt Moore, Alfred Poland.

The Auditors' Report, which had been previously circulated, was taken as read.

Dr. Greenhow: I beg to move that the auditors' accounts be adopted. I feel that I can move this resolution with great propriety. As one of the auditors I have gone into the accounts; the accounts speak for themselves, and it is not necessary that I should make any remark further than to point to the fact that we have this year rather a larger balance in the hands of the banker than we had last year. Last year we had £235; now we have £345. I would venture to make one further remark: the auditors were a little confused by the state in which the account from the publisher was brought before us. It was made out, I am aware, in the way in which these gentlemen usually make out their accounts, but it was so complicated that it was only with the greatest difficulty, and after devoting a great deal of time to it, that the auditors were able to ascertain its accuracy. I would suggest that in future years this account of the publisher should be examined by the Council before being sent down to the auditors, in which case the auditors would have nothing to do but to see that the account tallied with the statement laid before them. The Report requires no further remarks. With these remarks I beg to move the resolution.

Mr. Hawkins: I have much pleasure in seconding that proposition; but before it is put I wish to make one or two observations with regard to this account. I see on the receipt side there is, "Composition fee in lieu of further payment or subscriptions, fifteen guineas." Now, when the law was made with regard to the composition fees there was a distinct provision that those fees should be invested at once. Of course, if they are not invested there is no security to those who pay their life subscriptions that they shall have the advantages of the Society as long as they live. I feel some little interest in the sum, Sir, because I believe it is my own fifteen guineas. (laughter); and therefore I am very anxious to see that it goes to the right place. If the whole affair was wound up, then the only people who would have any interest in the property would be the life owners, and they would have to come upon the property for their division. If the composition fees are not invested, of course I shall not be able to appear as a creditor. I do not wish to move any resolution, but I wish to add as a rider to the resolution that the attention of the Council be called to the law which I have named—that all composition fees be invested at once. That fee was paid early in last year. Then, Sir, on the other side there is a balance in hand in "February, 1865." Now, this is an account purporting to end at the end of the year—December 31. Some two or three years ago the Council came to the Society and begged them to alter the mode of keeping their accounts from March to March, as they formerly did, and asked that they should be made up at the end of the year. One year, therefore, we had the account only for three quarters. Now, we have nothing to do with what the balance in hand in February was. That is not a matter of importance to us at all; but what we ought to know in this account is, what the balance was at December 31. The audit took place in February, but it might have taken place at any other time. I should like to add to the resolution that the attention of the Council be called to the necessity, according to law, of investing all composition fees, and that in future the balance shown in the hands of the treasurer shall be made up to the time at which the account finishes, and not to any other time.

Mr. Spencer Wells: I have also to move a sort of rider to the resolution which has been moved by Dr. Greenhow. I simply wish to call the attention of the Council to a matter mentioned at the last annual meeting. I mean the sum paid to this Society by the Pathological Society and the Obstetrical Society. It is called in the account "contribution." Now, sir, when I called attention to this subject last year, you, from that chair, as I found reported in the journals at the time, said that you would rather the rent were less than that difficulties should arise between the Societies. I do not know whether in the report which will be presented to-night we shall have any recommendation that this rent should be diminished; but I do think that we should let the new Council know that our feeling is against this large contribution. I see the sum is £63 from the Pathological Society and £42 from the Obstetrical Society, for fifteen meetings which the Pathological Society held, and for ten meetings which the Obstetrical Society held, that being at the rate of four guineas for each evening that these Societies occupy these rooms for two hours. I think this sum is too large, and that if it were reduced to one-half, or at the rate of two guineas for each evening, it would fully meet all the requirements of the case. I see by the account that the whole expenditure of this Society for house rent, taxes, lighting, warming, furniture, and repairs, amounts to £266 a-year. The rent we receive for the rooms held by the Society for the Relief of the Widows and Orphans of Medical Men and for the stables, and the contributions from the Pathological Society and the Obstetrical Society amount to £187 a-year. Taking that amount from our total expenditure for the purposes I have named, there is only £79 at which we stand for the whole permanent accommodation of this house and rooms. It would be quite fair to add to that sum the sum for the yearly interest of the thousand pounds which was expended on this house and property, and also some contribution towards the thousand pounds against the lease expires; but, adding all those things together, we shall still stand at a lower rent than the two societies pay us for the nights during which they occupy the room only two hours. I do not think that is fair to the other societies, and it would be more creditable to us if we stood upon terms of mutual obligation than, as we now do, supported by those two societies. I think it is undignified to stand before the Profession supported by those societies, and it would be more fair to them if we accepted from them only a fair and proper contribution, instead of demanding these high terms, which I think are causing ill feeling between us and them. I do not come here at all as a delegate from those societies, but I simply express my own individual opinion as a member of this society, and I give credit for candour to all other gentlemen who think differently. I do not see that there ought to be any warmth of feeling or sulky feeling about the matter. I believe that the gentlemen who support this high charge do so because they think it is the best thing for the Society, and I give them credit for the motive. I shall move as a sort of rider to the resolution, "That the attention of the Council be directed to the propriety of reducing the sums paid by the Pathological and Obstetrical Society to 30 guineas and 20 guineas, in place of the 60 guineas and 40 guineas which is now paid."

Dr. C. J. B. Williams: I beg to second that resolution. The remarks made by Mr. Spencer Wells and reiterated by myself on the occasion of the last meeting appear to me equally to apply to the present occasion. I did hope, from some of the words which were spoken at the last meeting, that the

high charge—I think I used the term extortionate charge—would be reconsidered. I never thought that the sum was regarded as such; but I believe that when it is fairly considered it will be seen that to ask the sum of sixty guineas a-year from a society pursuing kindred objects, and a society, I may say, which has distinguished itself in the same subjects as those to which this Society is devoted, and yet without in any degree interfering with us—such a society is not one which should be mulcted and sponged by heavy financial considerations on the part of this Society. I entirely think that the career of the Pathological Society of London is one of the brightest pages in the history of our science. I know of no society which has flourished and been productive of so much utility in so short a space of time, and which now, in so many ways, proves its utility and its hold on the affections of the Profession; and I think, such being the case, it is really the duty of this Society to hold out the right hand of fellowship to support it and aid it, instead of trying to squeeze to the very utmost what can be got out of its coffers. It appears to me that it would reflect credit on this Society if it aids it, not in an eleemosynary way, but considering that it works for the same end; and I think we ought to be proud of its co-operation. I am quite sure that the feeling with regard to the kindred Society will be of the same kind. If it is continually to be mulcted to this amount, I think probably, sooner or later, it must separate itself from this Society and establish itself elsewhere; and as a member of the Medical and Chirurgical Society I think that will be greatly to be deprecated; for although we have not succeeded in effecting the amalgamation contemplated, yet there is something like fraternity between these Societies, and I think it is very desirable that the appearance of co-operation should be kept up. As a member of this Society, I should be very anxious to see the Pathological Society hold its meetings in the rooms of this Society, and on terms more in accordance with the great object which both Societies have in view—the furtherance of the best interests of the Medical Profession.

Dr. Webster: Mr. President, I am very sorry that this subject should have been again brought before us, particularly after the discussion which has previously taken place. I should like to ask the Council whether there has been any representation on any application made from those societies upon this subject. If so, of course you will tell us what has been said; but I do not think that an individual member should come forward and advocate particular societies unless this subject has come to the Society officially. I have no doubt whatever that if there has been a representation from those societies to the Medical and Chirurgical Society, they will give it the attention it deserves. There is one expression which Mr. Spencer Wells has used, and which I regret. He talked of this Society being undignified in receiving the money mentioned. I do not think there is anything undignified. If I may presume to give my own opinion, I think it seems that the other societies are sueing *in forma pauperis*. They are excellent societies, doing a great deal of good; but I do not think it is a matter of much consideration to them whether they pay thirty guineas or sixty guineas. I should like to know whether there has been any official application. That is the proper way of discussing these matters. I am quite sure that this Society would take the matter into consideration if that has been the case. It has been said this evening that we should foster and aid these societies. That was done in the beginning. There was then a small rent charged; but when they became flourishing and numerous and rich, it was considered just to this Society that they should pay a proper rent for the accommodation furnished. If a better accommodation can be obtained, why the other societies will be perfectly justified in accepting it. I know there are members who think that this Society ought not to have any tenants at all, but I must say that I do not think so; I should be very glad to remain on friendly terms with the other societies, and aid them in their objects; but I do not think the rent is too high. I hope that what I have said will not be disagreeable to the feelings of anybody who has spoken on this subject.

Mr. Hawkins said the meeting were going from the real question; the discussion which was commencing had nothing to do with the accounts, or with the question of investing the composition fees.

Dr. Pitman, the Treasurer, said he thought he should be able to explain why the composition fees had not been invested. The fact appeared on the face of the accounts that they had not been able during the year to make use of the spare funds of the Society, so as to add to the capital stock, and when that had been the case it had always been stated on the accounts that the capital stock which had been purchased included all composition fees. In looking at the previous year's accounts he found that there were composition fees which were not invested, and as he was in a position to purchase £500 worth of capital stock, he stated that that included the composition fees not only in that year, but in the year preceding, which had not been invested. As there was only the fifteen guineas which had been mentioned received last year, it seemed that it might be desirable, as the Society were able to enter into a new year, and there might be other sums to invest in the same way, to reserve it and invest them all at once. There was no special law requiring that they should be invested within any specified time. The sum for fees received during the year was a very small one to invest, and he found that when that had been so, the practice had been to reserve it. He, of course, proposed to continue that practice. It was not his intention that the composition fee of fifteen guineas should be merged in the general funds of the Society. Another question had arisen with regard to the accounts. It had been said that there was a balance stated up to February, when the accounts should be made up to the end of December. He really did not see that that was the case. The accounts were audited in February, and the amount of stock standing in the names of the trustees at the time was stated, the receipts and payments being up to the end of December, 1864. The balance then standing at the bankers' was £345 17s. 2d. There had been some misconception as to that being the balance in hand to February. No payment had been made out of that £345 since December.

Mr. Hawkins said that there must be clerical error if December was meant. With regard to the composition fee, it was intended that it should be invested in the year in which it was paid. Inaccuracies had arisen in former years; but he apprehended that the receipt of that fifteen guineas ought not to be considered, for really the receipts were fifteen guineas less than appeared.

Dr. Pitman said that on his entering office he followed the practice of his predecessor, though, perhaps, that was not so desirable as the course Mr. Hawkins had laid down.

Dr. Barker said he should like to make a remark upon Dr. Pitman's statements with reference to the practice of his predecessor, he (Dr. Barker) being that predecessor. The reason why the composition fees were not invested was, in the first of the two years the Council thought proper to spend them, and in the second year it was impossible to invest them because there were no trustees.

Dr. Pitman: Then I am accurate as to my statement.

Mr. Hawkins wished a rider to be appended to the resolution calling the attention of the Council to the necessity of investing all composition fees.

The Chairman, in answer to Dr. Webster's inquiry, said that there had been no application made by the Pathological Society or the Obstetrical Society for the reduction of their rent. He thought the arguments which had been used were hardly correct. It was no duty of the Medical and Chirurgical Society to make the reduction. The Pathological Society had the means of investing sums, and he had no doubt they would increase. They could afford to indulge in an illustration of their printed volume, which the Medical and Chirurgical Society had never ventured upon. The real test of the accommodation given was whether the Pathological Society could obtain similar accommodation for the same money elsewhere. (Hear, hear.) He should be sorry, indeed, for the Society to enforce an unjust demand from any other society: one's personal feeling would be rather to fix the rent below the value. He did not concur in the opinion that he had heard murmured that it was not a great credit and honour to the Society to have other similar institutions meeting under the same roof.

Dr. Markham said he was very happy to second the proposal of Mr. Hawkins. He thought the matter a very important one.

Mr. Quain said a complaint had been made of the publisher's accounts not being intelligible. He had been in the habit of receiving publishers' accounts for some years, and he never could understand one of them, and he never knew any one who could. (Laughter.) He despaired of the Council doing it; and he did not think it would be wise of the Council to undertake to give a translation of the Society's publisher's accounts.

Dr. Greenhow said he had no objection to add Mr. Hawkins's rider to his resolution.

The resolution with the rider was then agreed to.

The Chairman said that the suggestion of Mr. Spencer Wells, which had been seconded, had not been disposed of.

Mr. Spencer Wells said he had simply to move that the attention of the Council should be called to the large sum paid as a contribution by the Pathological and by the Obstetrical Societies.

Dr. Wynn Williams asked whether those two Societies had not saved more money during the past years than the Medical and Chirurgical Society?

Mr. Quain said he was in the Council at the time that the Pathological Society obtained the use of the rooms, and he protested against the rent they paid, believing that it was unreasonably low. He would not use expressions corresponding to those which had been used, but he believed there was a little packing of the Council at the time. He protested against this Society being used for the purpose of any other Society in an unfair way. The money obtained for rent was not spent by the Council on themselves. They devoted it to the purchase of books and promoting the benefit of the Society.

Mr. Hawkins said he extremely regretted, for the sake of the Pathological Society and the Medical and Chirurgical Society, that persons had been so ill-advised as to bring the subject again before the meeting. He must with great deference protest against the language which had been used by Dr. Williams when he spoke of this Society as "sponging," as "mulcting," and as "extortionate." No member of any other society had a right to come there to advance his society at the expense of the Medical and Chirurgical. The societies which had been named had published their accounts in which it appeared that they were most prosperous, and he thought it would be a most absurd and impertinent thing on the part of this Society if they were to offer to lower the rent, which their tenants were now willing and well able to pay. The Medical and Chirurgical Society were bound to provide himself and others who had paid composition fees with a library and a room for meeting as long as they lived, and a vast sum of money had been laid out upon the premises. Many things were wanted by the Society. They were in need of very valuable works which were not strictly Medical — atlases, cyclopædias, and the like. He believed at the present time they did not possess a complete edition of the *Philosophical Transactions*. He would move as an amendment that the Council be recommended not to allow any other Society to meet in its rooms. Such a resolution would put an end to such remarks as had been made, and which were exceedingly unpleasant. He believed the Pathological Society to be all that Dr. Williams had said it was; but he thought nothing would be more lowering to their dignity than for this Society to go to them and offer to reduce their rent. He thought the best thing would be for the Council to say at once that in consequence of the extremely unpleasant discussions which arose, they could not let their rooms to any other Society. If there was to be a reduction to any of their tenants, it should be made in favour of the Society for the Relief of the Widows and Orphans of Medical Men, which was in the nature of a charity. They came at a time when rent was an object to the Medical and Chirurgical Society, but as that was not so much the case now, he should say that if their charter would allow it that the charitable society should have the use of its rooms without payment of rent.

Dr. Markham said he did not quite agree with the amendment of Mr. Hawkins, but he hoped that the Society would not be from time to time pestered with such discussions as had arisen, not now for the first time, but year after year. Many members knew that for several years the question had been brought before the Council. It had been most fully and warmly dismissed in the Council, and a long discussion, which was on record on the Minutes, had taken place, the result of which was a decision that no charge whatever should be made in the present rent. For two years the Pathological Society had come forward in two positions; first, in the position of begging and praying that we should out of kindness grant them something; and, secondly, in the position of sturdy beggars, who were threatening that they would take away their Lares and Penates—not always of the most sacred odour. He was a member of the Pathological Society himself, and he was surprised that they were still occupying those rooms after the observations made last year. He had no doubt that the Pathological Society had made inquiries with reference to other premises, and found that they could not get equal accommodation for the same money. Mr. Spencer Wells had not shown either that this society was charging an extortionate price or that the Pathological could obtain as good accommodation at the same rate or more cheaply. What right had the Pathological Society—a very rich and flourishing one, which magnified itself by the extensive plates in its *Transactions*—to ask the Medical and Chirurgical Society to do for it what it could not do for itself?

Dr. Quain said it was not his intention to make any remarks in this discussion, but when Dr. Markham had said that the Pathological Society appeared there last year in the form of a pauper, and this year in the character of a sturdy beggar, he felt bound to get up and deny the facts. The Pathological Society did not appear there at all. (Applause.) There had been no application from them. Mr. Spencer Wells appeared there as a Fellow of the Medical and Chirurgical Society, thinking it would be right to recommend to the Council what he had suggested; but the Pathological Society did not appear at all. It had been said that the subject had been brought forward year after year, but he thought that must be inaccurate; for though the Pathological Society had been in existence seventeen years, it was not until the last two years that they paid more than thirty guineas for the accommodation they had. They could not have appeared there to sue for the reduction of the rent which had never been demanded of them. There was no packing of the Council when the Pathological Society first came, but the rent was decided on in a fair way. Suddenly the proposal was made that the societies should amalgamate. He would most willingly have joined that movement, but there was no method of carrying it out. The Pathological were willing to accept the proposal, but they found it impracticable. Instantly they got notice that the rent would be raised from thirty to sixty guineas a-year. That was a literal fact. The Medical and Chirurgical Society tried to establish a pathological section, but failed to do so. The Pathological Society had been successful in its object. If the Medical and Chirurgical reduced their rent to what it was before, they would gladly avail themselves of the benefit.

Dr. C. J. B. Williams said that Mr. Hawkins had put the matter in so personal a point of view that he should not think it necessary to answer his remarks. He would, however, say that he stood there and argued as a member of the Medical and Chirurgical Society, irrespective of his connexion with any other. The remarks of Dr. Quain had rendered unnecessary an explanation which he should have given.

The Chairman said he wished to correct one observation that Dr. Quain had made. When the Pathological Society first came, the Medical and Chirurgical Society, whether justly or otherwise with regard to their funds, stretched a point, and accommodated them for an almost peppercorn rent. Perhaps Mr. Hawkins would not think it necessary to press the amendment, because to negative Mr. Spencer Wells' motion would answer the purpose.

The motion was then put, when there appeared four in its favour, and a large majority against it.

The Honorary Secretary, Dr. Fuller, read the Report of the Council for the past year. It stated that the number of members at the present time was 627. This was a smaller number than that reported last year. The difference, however, was not attributable to any actual decrease since that time, but arose from the names of certain foreign and non-resident members who had been dead for some years, but whose decease had not been communicated, being removed from the roll. There was really an increase of five upon the correct number at the corresponding period of last year. Twenty new Fellows had been elected twelve resident, seven non-resident, and one foreign. 348 works had been added to the library, exclusive of continuation of works already begun and periodicals.

Dr. Webster moved "That the Report of the President and Council just read be received, adopted, and circulated in the usual way." The Report was a very satisfactory one, and he hoped it would not lead to a discussion foreign to the spirit in which it had been drawn up, and that the time of the meeting would not be occupied with extraneous matter. It had been stated that the number of the Society had apparently diminished. That, of course, must occur occasionally in a numerous body; but the Society should be aware that this session more new members had been elected than on any previous occasion. The Report referred to the large sum

which had been expended on the library; but there was one fact which was not mentioned—that £73 had been laid out on one volume; and he believed that the Society now possessed the best collection of Medical portraits ever made. He thought the £73 had been well spent.

Dr. Wegg seconded the resolution.

It was then carried unanimously.

The Chairman said: I have to announce that at the last meeting of the Council the following resolutions were carried with a view principally to bring them before the notice of the present meeting, which would be essential to their being carried out, and to obtain the opinion of the meeting upon their desirability:—"Resolved, that the *Proceedings* of the Society in their present form be discontinued;" and, secondly, "Resolved, that the *Proceedings* as at present published be for the future published as an appendix to the end of the volume of *Transactions*, omitting the abstracts of those papers which are published *in extenso* in the *Transactions*." Many different opinions have been expressed as to the utility of the proceedings. They involve a certain degree of expense; but that is of minor importance. However, the Council would be happy to have your opinion upon that matter.

Dr. Fuller said that when the *Proceedings* were first decided on it was imagined that it would be possible to get them out every six weeks or two months, so as to keep the Fellows generally *au fait* as to what was going on. Practically it had been found impossible to do so, and it was found that the *Proceedings* were rarely issued more than twice a year. The first part was not published till the session was half over, and the second part not till the session was nearly terminated. In addition to that, the papers were published in the Medical journals the week after they were read, and therefore the *Proceedings* were unnecessary. Many of the Fellows had expressed a very strong opinion as to the uselessness of the *Proceedings*. They involved an expenditure of £55 a-year, taking the average of the last seven years. That included printing, binding, and postage. Many had complained that, being in the form of a pamphlet, they got laid aside, and were not available for reference afterwards.

Mr. Hawkins said that, as one of those who promoted the publication of the *Proceedings*, he must say that he received with extreme regret the recommendation of the Council for their discontinuance. Till they were established there was no record at all of the proceedings of the Society, except such papers as were culled from those which were read, and were thought worthy of publication in the *Transactions*. There was no record (and how glad would they now be to have such a record!) of the various Presidential addresses which had been delivered. Many of the unpublished papers, too, would now be valuable as a sample of the early writings of men who had afterwards become famous. With regard to the expense, it should be recollected that the £55 carried a portion of the expense of the postage of the circular and accounts, which were sent with the *Proceedings*. There was no doubt that the first intention of those who promoted the *Proceedings* had not been carried out. Dr. Fuller had said that it was impossible to do so. He (Mr. Hawkins) did not understand the word "impossible" in such a Society as that. If it could be done in the Royal Society it could be done in this Society. The *Proceedings* ought to be issued every month. It was true that the papers were reported, and well reported, in the public journals; but the Society should not be wholly dependent on such records. Unless the country Fellows of the Society subscribed six guineas for the *Transactions* they would be without a record. If the *Proceedings* were discontinued, the country members of the Society would have no record of what was being done unless they subscribed six guineas for the *Transactions*. The question had recently arisen whether the country Fellows might attend the annual meeting. It was decided two years ago that they might do so. He believed the discontinuance of the *Proceedings* would be a false economy, but they should be got out more quickly than at present. He should move "That the Society is of opinion that the publication of the *Proceedings* should not be discontinued."

Mr. Moore seconded the proposition. He believed that the Society had previously expressed its approval of the continuance of the *Proceedings*. There was now an addition to the proposal, which was that abstracts of papers not approved by the Council should be published with the papers which were approved. He thought, however, that that course would be objected to by the writers of the papers which were not approved, however eager the officers might be to make the abstracts.

Dr. Balfour said he completely concurred with Mr. Hawkins in disagreeing with the manner in which the *Proceedings* were published. There could be no reason why they should not be published at the end of every month, for there was a rule that no paper should be read before an abstract of it was given in. He hoped the Council would undertake to publish the *Proceedings* monthly.

Some further discussion took place, and the motion expressing an opinion that the publication of the *Proceedings* should be continued, and that they should appear more frequently, was then carried.

The President, in the course of the annual address, gave a brief review of the lives of the following Fellows of the Society who had died during the year:—Mr. Samuel Cartwright, F.R.S., Dr. Charles Hall Clark, Dr. James Bird, Dr. Thomas Sunderland Harrison, Dr. Richard Roscoe, Mr. Samuel Maclean, Mr. John Drummond, Dr. Archibald Robertson, Dr. Robert Dundas Thomson, Dr. William Senhouse Kirks, and Dr. Jones Quain.

It was moved by Dr. Quain, seconded by Mr. Dixon, and unanimously resolved—"That the best thanks of this Society be given to the late President, Mr. Partridge, for the able and efficient manner in which he has presided over the meetings of the Society during his term of office."

The President: I beg to thank you very shortly, but very heartily, for the kind resolution which you have just passed. I shall be happy always to promote the interests of the Society.

Dr. C. J. B. Williams moved "That this meeting desires to express its cordial thanks to the retiring officers of this Society and the other members of the Council for their interest in the advance of the Society during their year of office."

The resolution was seconded by Dr. Markham, and carried unanimously.

It was moved by Mr. Hawkins "That the cordial thanks of the Society be presented to the members of the Scientific Committee on the Uses and Effects of Chloroform—viz., Mr. T. B. Curling, Chairman; Mr. Bryant, Mr. Cartwright, Dr. Farre, Mr. Gascoyen, Dr. Harley, Mr. Prescott Hewett, Dr. Mackenzie, Dr. Marcet, Mr. Moore, Mr. Paget, Dr. Priestley, Dr. Quain, Dr. Sibson, and Dr. West; Mr. Sibley and Mr. Callender, Reporters; and Mr. Birkett, Hon. Sec. (*ex officio*), for the very able and zealous manner in which they have carried out their investigations, and also to the authorities of University College for the courtesy and readiness with which they have assisted in advancing the inquiry." He remarked that the total expenses of the Committee amounted to only £28 9s. 7d. He thought the Fellows would agree with him that if they had been three times that amount the money would have been well expended.

Mr. Spencer Wells seconded the motion.

The President in submitting it to the meeting said it was quite unnecessary to add to add a word on the subject for the purpose of expressing the gratitude of the Society to those who had taken so much pains to prepare such a valuable report.

The resolution was carried unanimously.

The meeting then separated, and the next was announced for the 14th March.

THE PATHOLOGICAL SOCIETY.

Tuesday, February 21.

Dr. Peacock, President.

The President, in taking the chair, remarked that, having had occasion to consult the index to the volumes of the Society's *Transactions*, by the Hon. Secretary, Mr. Holmes, he wished to express his opinion that it had been admirably prepared and was of great value, and that the Society was greatly indebted to that gentleman, and to Mr. Prescott Hewett, for having borne the expense of publishing it.

Dr. Wilks brought forward a specimen of

RUPTURE OF ONE OF THE AORTIC VALVES FROM INJURY.

A young man, aged 19, fell from a height on to his side, and was immediately brought to Guy's Hospital. He had struck his abdomen and lacerated his intestines, which caused his death in three days' time from peritonitis; he also had great oppression of the chest and difficulty of breathing, as if he had received other injuries; but the heart was not examined by auscultation. On post-mortem examination, besides the

laceration of the intestines, which had been the immediate cause of his death, one of the aortic valves was found to be torn completely through, from its edge to its base; not through the median line of the valve, but towards its side, as if it had been forcibly dragged away from its attachment. As there was no direct violence to the chest, Dr. Wilks supposed that the rupture occurred by a sudden and irregular contraction of the aorta, whereby the valve was unable to sustain the increased and irregular pressure of the blood upon it—a condition so unlike the ordinary regular and equal force to which the valves are subject.

Dr. Wilks also exhibited a specimen of

RUPTURE OF THE AORTA FROM INJURY.

A man on lifting a heavy cask was struck by the latter in its fall on the upper part of the chest, and was instantly killed. On examination of the body it was found that the upper piece of the sternum had been broken through, and blood was effused beneath. The heart was uninjured, as also was the aorta on its front aspect. Posteriorly, however, a transverse laceration was found, which half encircled the vessel, commencing at the under part of the arch and proceeding upwards to the origin of the left carotid artery. Dr. Wilks said it might be a question whether the laceration was caused by a sudden contraction of the aorta or whether it was caused by a simple bursting of the vessel from external pressure. He believed it arose from the last-mentioned cause; otherwise, it might be difficult to show why a sudden and irregular contraction of the aorta should in one case cause a rupture of one of the valves and in another a laceration of the aorta itself. Dr. Wilks said the case illustrated a fact which was constantly coming under notice—the injury of a deep-seated part from falls and superficial blows. In the case of the heart, a difficulty had often arisen in the mind of the Medical man, who could not explain how the organ could be ruptured on its posterior surface without any broken bone being present to account for the accident.

The President said that Dr. Quain had published three cases of rupture of the aortic valves, and he (the President) two cases. He had also collected others, in one of which only had the rupture been due to direct violence. He did not know any case in which the curtain of the valves had been torn down in the middle as in Dr. Wilks' specimen. Such cases were not common, and it was not easy to say how much disease and how much injury had to do with the rupture. Dr. Peacock related an instance in which rupture of the aorta occurred in a patient who had been crushed by the weight of a heavy casting mould. The rupture was, he thought, due, not to direct injury, but to the sudden effort. The rupture was between the position of the ductus arterius and the origin of the left subclavian artery, ordinarily the narrowest part of the thoracic aorta.

Mr. Spencer Wells thought the Medico-legal bearings of such cases ought to be considered. He related a case in point which occurred some years ago in his practice as a naval Medical officer. One man struck another. The man struck ran to a place where water was to be had, and quickly died. An autopsy was made, and the cause of death was found to be a rupture of an aneurism of the aorta into the pericardium. The question as to whether the aggressor was to be punished for manslaughter, or simply for striking, depended entirely on the Medical evidence. It was decided that there having been pre-existing disease, the punishment should be for a blow only. Probably in civil law the culprit would have been found guilty of manslaughter.

Dr. Sanderson said he thought it more likely that the rupture of the aorta occurred during diastole than during systole.

Dr. Wilks said that was what he meant to imply.

Mr. Gay then brought before the Society an infant five months old who had

MALFORMATION OF THE GENITALS.

The pubic region was much developed, and resembled that of a female child. The penis was irregularly developed. It was turned on its axis, so that it looked upwards and to the left. There was partial hypospodias. The prepuce was irregularly developed; the crura penis were not to be traced. Below was a scrotum, into which one testis had descended.

Mr. Holmes said that the chief point was whether the abnormal conditions could be remedied. The prepuce seemed to be larger on one side than on the other, and it would be interesting to see if the position of the penis could not be improved by removing a piece of skin.

Mr. Henry Smith said it had struck him that there was a redundancy of skin, and that Surgery might be of use in remedying the deformity. He was glad that a Surgeon so experienced as Mr. Holmes had made the suggestion.

Dr. Harley thought the origin of the deformity was very simple. The preputial orifice had been occluded, and the prepuce had burst at its side. The site of the natural orifice was marked by a small cicatrix, and the present opening was due to rupture.

Mr. Gay said he should hand over the case to Mr. Holmes, and should be glad to hear the result of treatment from him.

Mr. Holmes then exhibited a piece of intestine from a patient who had been operated on for

STRANGULATED FEMORAL HERNIA.

The condition represented by the preparation was, Mr. Holmes said, not uncommon, but was not spoken of in books. A man was admitted into St. George's Hospital for femoral hernia. It had been strangulated two days, but the symptoms were not urgent. Seven years before he had been operated on, and had since worn a truss, but the truss had not fitted him, and the gut had slipped down under it. At the operation the intestine was found to be much thickened, and as the ring was very narrow there was some difficulty in returning it. The patient died of peritonitis. The case was another argument against ill-fitting trusses.

Mr. J. Z. Laurence exhibited a

MELANOTIC TUMOUR OF THE ORBIT,

weighing 1 oz. 1½ dr., which he had removed ten months previously from a woman 62 years of age. The tumour had then been growing eight or nine months. The eye was protruded from its socket, but apparently not itself enlarged; it was insensible to light; the interior of the eye was illuminable, but no details could be observed. The patient had suffered great pain, which she referred to the temple and side of the head. Mr. Laurence removed the tumour, together with the eyeball, which was found to be firmly imbedded in its substance. The growth was enveloped in a firm pseudo-cyst of cellular tissue, and presented all the obvious and microscopical characters of melanotic cancer. The eyeball itself was free from all deposit whatever; the vitreous was fluid; the retina partly separated; the lens nebulous. The tumour recurred *in situ* in three months, when Mr. Laurence transferred the case to Mr. Weeden Cooke; in another three months the patient died, by which time the secondary tumour of the orbit had attained the size of a cricket ball and growths were found within the cranium. Mr. Laurence said he considered the case remarkable from the extremely acute course it had run, differing in that respect from the cases of melanotic cancer in the eye he had hitherto observed, and resembling rather encephaloid cancer of the eyeball as it occurs in children. Mr. Laurence, in corroboration of his opinion, instanced a second case of extensive melanotic cancer of the orbit, which he had removed some years ago; in this case no recurrence of the growth had taken place when he saw the patient one year and four months after the operation.

Dr. Hilton Fagge showed several specimens of

BRONCHIAL POLYPUS.

The specimens were from a girl, seven years old, under the care of Mr. Fagge, of Hythe. She died suffocated by a cast blocking up the bronchi at the bifurcation of the trachea. The child had been for some time subject to fits of spasmodic cough, relieved by expectoration, when one evening she expectorated a cast, and afterwards one every day. After one of these attacks the child suddenly died. At the autopsy, a large fibrinous cast was found blocking the bronchi. It extended into the right bronchus and overlay the left. The larynx and trachea were healthy. The structure of the cast was like that of those described by Dr. Peacock. In very few of Dr. Peacock's cases were the casts formed from coagulated blood. Dr. Fagge then mentioned a case which had recently come under his notice. The father of one of the students had in August an attack of hæmoptysis; for months afterwards he was troubled with cough. He then expectorated a cast, and got quite well.

In reply to a Member, Dr. Fagge said he was unable to give any account of the condition of the mucous membrane, as he had not seen it.

The President did not know any case of sudden death from bronchial casts. The majority of cases were children. He had not seen a case in a patient so young, the youngest of his patients having been ten years; the others were adults.

Dr. Hillier wished to know if diphtheria had been prevalent in the neighbourhood. The cast might have been diphtheritic, although the disease had not extended so high as usual.

Dr. Fagge said there was no epidemic of diphtheria.

The President suggested that drawings should be made of the specimens for the *Transactions* of the Society.

Dr. Broadbent gave particulars of a case in which, after death, casts were found occupying the bronchi of the whole of one lung; the other lung was tuberculous. He believed from the lamination of the casts that the material forming them had come from the air cells.

After some remarks by Dr. Harley and Dr. Gibb, Dr. Fagge said that he considered that the cast from the child was from the mucous membrane, and was not coagulated blood.

The President said there was little likelihood of confounding casts formed by a secretion from the mucous membrane with casts from coagulated blood. The first, he said, were glistening and white, and were composed of concentric laminæ, whereas blood clots were never white, but more or less dark coloured, and were not laminated.

Dr. Wilks said that Dr. Gull had long taught that casts were the result of the moulding in the tubes of material poured out in the air cells.

Dr. Sanderson said that Dr. Fagge's case resembled precisely cases met with in epidemics of diphtheria. There did not appear to be any material difference in the symptoms during life. Dr. Murchison had recorded such a case. Many cases of the kind had occurred in an epidemic of diphtheria at Launceston.

Dr. Dickinson exhibited some urine, and a drawing of the urinary sediment, from a man who had

INTERMITTENT HÆMATURIA.

The case was brought before the Society, not as any novelty in Medicine, for the disease had been described by Rayer in his work on diseases of the kidneys more than twenty years ago, and had occasionally been referred to by other writers; but from its comparative rarity it was thought that it might be interesting to the Society, more particularly as some similar cases had recently been brought forward by Dr. Harley.

Dr. Harley gave particulars of the further progress of his patient. He said that at first he had given him blue pill, and afterwards quinine and iron. The result had been very encouraging. He asked Dr. Dickinson if the quantity of urea was diminished or increased. In his patient's case it was double the usual amount; whereas in Bright's disease it was diminished.

Dr. Dickinson said that the amount of urea had not been ascertained by analysis, but from the specific gravity of the urine, which was sometimes as low as 1011, it might be supposed that it was not much increased. As to the effects of treatment, the man had been so often under the care of different Physicians that, as might be supposed, he had been the subject of every experiment on this head. But whether he was treated actively, with cupping on the loins, vapour bath, gallic acid or quinine, or whether he was left alone, the result was always the same. The hæmaturia ceased when the action of cold was withdrawn, and came on again with as much readiness as ever on the next exposure. Medicine appeared to have no influence on the disease.

Mr. Gay said that he had under his observation a case exactly similar in the symptoms, but the hæmaturia was ascribed to calculus, and not to cold, as it was invariably worse after exercise.

Dr. Dickinson said that his patient could take the most violent exercise without bringing on the hæmaturia.

PSOAS ABSCESS CONNECTED WITH TUBERCULOUS KIDNEY.

Dr. Dickinson brought forward the case of a young man who had been admitted with a psoas abscess in which the matter had proceeded from the kidney, which was stuffed with crude tubercle and pus. The matter had escaped from an opening in the back of the kidney at its lowest part, and had made its way into the psoas muscle, to which the kidney was adherent. It had resulted in an opening in the groin, and during life it was not possible to distinguish the disorder from the more common form of psoas abscess which follows from diseased vertebra. The difficulty of diagnosis was increased in this case by the fact that there actually existed caries of the spine, though not on the side on which the kidney was affected. The patient also had phthisis.

A case was also brought forward in which a man, 70 years of age, who had died rather suddenly of bronchitis and emphysema of the lungs, was found to have

ENCEPHALOID DISEASE OF THE PROSTATE.

The growth had extended from the prostate over the lower part of the bladder, and had narrowed the openings of both ureters. These ducts were much dilated, and the kidneys had become atrophied by pressure. No symptoms of the disease had been detected during life.

Mr. Jabez Hogg then showed a specimen of

EFFUSION OF BLOOD IN THE BRAIN OF A PATIENT WHO DIED WITH EPILEPTIFORM CONVULSIONS.

The patient, a man, 56 years of age, was found in a fit, the convulsions affecting the left side of his body. He had a succession of these, and before his death, thirty hours later, he had had twenty-six. Five ounces of blood were found effused in the right hemisphere of the brain. This large effusion of blood was due, Mr. Hogg considered, to the frequent and violent attacks of epileptiform convulsions.

Dr. Gibb exhibited for Dr. Logan

HYDATIDS FROM THE LIVER, PRODUCING GREAT ABDOMINAL DISTENSION.

They were taken from a boy who had suffered from abdominal distension for two or three years, which at last became so great as to destroy life. After death the belly was found to be filled with an enormous accumulation of hydatids, extending to every part, and so compressing the viscera as wholly to interfere with their functions. They were counted by thousands, and chiefly originated in the anterior border of the left lobe of the liver. None of the other organs were found to be diseased.

MEDICAL NEWS.

Apothecaries' Hall. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, February 23, 1865:—

Lionel Dixon Spencer, Newcastle-upon-Tyne; William Hughes Clarke, Bernard-street, Russell-square.

The following gentleman, also on the same day, passed his first Examination:—

William Matthews Bobart, Derby.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Budd, Samuel, M.D. Edin., has been elected Consulting Physician to the Exeter Dispensary.

Cooper, Frank W., L.R.C.S. Edin., has been appointed House-Surgeon to the Sheffield Public Hospital and Dispensary.

Earle, Lumley, M.D. St. And., has been appointed Honorary Medical Officer to the Birmingham and Midland Free Hospital for Sick Children.

Edwards, Joshua P., L.F.P.S. Glasg., has been appointed Medical Officer to the Tunstall Board of Health and to the Police.

Elliot, Dr. has been elected Consulting Physician to the Exeter Dispensary.

Fairbank, T., M.B., has been appointed Resident Medical Officer to the Metropolitan Free Hospital, Devonshire-square.

Horan, Patrick C., L.R.C.P. Edin., has been elected Medical Officer to the Workhouse and Fever Hospital of Cootehill Union, Co. Cavan.

Mackenzie, S. C., M.D., has been appointed Resident Medical Officer to the Chalmers Hospital, Edinburgh.

Shapter, Thomas, M.D. Edin., has been elected Consulting Physician to the Exeter Dispensary.

DEATHS.

Chadwick, John W., M.R.C.S. Eng., at King's Lynn, Norfolk, on February 14, aged 78.

Clark, John, Surgeon R.N., at Wycombe House, Hurstpierpoint, Sussex, late of Yarmouth, Isle of Wight, on February 23.

Connor, Shewbridge, F.K.Q C.P.I., at Carlow, Ireland, on February 17.

Evans, David, M.R.C.S. Eng., at Towyn, Newquay, Cardiganshire, on February 12, aged 45.

Gordon, John, M.D., at South Frederick-street, Dublin, on February 17.

Healy, William, M.B., Dub., at 9, Harcourt-street, Dublin, on February 22, aged 45.

Kirkpatrick, James, Surgeon, at Scalby-grange, Howden, Yorkshire, on February 13, aged 76.

Wakem, John W., M.R.C.S. Eng., at York House, West-square, Southwark, S., on February 28, aged 39.

Triple Birth.—On February 13, at 1, Devonshire-place, Wandsworth-road, the wife of Savill Coombs, M.R.C.S., of three daughters; all well.

Professional Honours.—At a recent meeting of the Obstetrical Society of Berlin, diplomas of honorary membership were conferred on Dr. Murphy, of University College; Dr. Henry E. Eastlake, of the British Lying-in Hospital; Dr. Leishman, of Glasgow; and Dr. Greenhalgh, of St. Bartholomew's Hospital.

University of Dublin.—At the Spring commencement held in the Examination Hall of Trinity College, on Shrove Tuesday, the 28th ult., the following Degrees and Licenses in Medicine and Surgery were conferred:—*Baccalaurei in Medicinâ*—Gulielmus C. Hassard, Jacobus Marshall Skelton, Adam P. Newman. *Magistri in Chirurgiâ*—Thomas Agmond Vesey, Henricus Josephus O'Brien, Johannes W. Y. Fishbourne. *Doctores in Medicina*—Maxwell Fleming, Robertus Bernard, R.N., Thomas Macdougall Bleckley. *Licentiatus in Medicina*—Rawson, Edvardus Albertus. *Licentiatus in Chirurgiâ*—Rawson, Edvardus Albertus.

The Admission of Lady Nurses into the Gloucester Infirmary.—At a special meeting of the Governors of the Infirmary the following resolution was passed, after a long debate—"That in the opinion of this meeting it is expedient that the resolution of the Weekly Board of the 29th December last, as to the admission of pupil nurses into the Infirmary, be not acted upon during the present year, nor afterwards, until the same shall have received the sanction of a special general meeting duly convened for the purpose."

Alleged Murder.—A case has lately occurred in the neighbourhood of Weston-super-mare, in which an open verdict given by a coroner's jury seems to have produced much dissatisfaction. The body of a young man named John Hooper was found in a wood. The Medical evidence appears to have been to the effect that there were no sufficient marks of violence to indicate foul play, and that the deceased had probably died from congestion of the lungs, the result of cold. There were, however, several suspicious circumstances connected with the case, and a subscription is being got up at Weston-super-mare for the purpose of instituting further inquiry.

Dr. Livingstone's proposed expedition to the district between the north of Nyassa and the south of Lake Tanganyka, assumes a substantial form. The Royal Geographical Society have held out the prospect of £500, the Foreign Office are understood to promise a similar sum, and a private friend and admirer of Dr. Livingstone's has given anonymously £1000. In addition to all this, it appears that Dr. Livingstone's position as Consul to the native races of Eastern Africa, with a salary of £500 a year, remains unmodified, though his duties as Consul at Quillimane have ceased. Adequate funds are therefore in existence for the maintenance of the expedition, conducted as it is proposed to be, in a simple and economical manner.—*The Reader.*

Surgical Mutilation.—A most affecting scene occurred the other day in a Berlin military Hospital. In going the round of the wards the King noticed a man who had lost both his arms and legs. The King inquired if there was anything he could do for him. The human torso, a victim of the late campaign, replied, "Your Majesty, have me shot." Deeply affected, the King replied that he could not possibly fulfil this un-Christian wish. Upon this the unfortunate man, flying into a passion, cursed the Doctors that had kept him alive. The King turned away crying.—*Times' Correspondent.*

Terrible Effects of Chloroform.—We hardly know whether, on reading the following case, we should simply admire the ready ingenuity of the prisoner's counsel, or, with shame and humility, acknowledge another of those lessons which the legal profession so often and so kindly reads us on our ignorance; for we must confess that, notwithstanding Medico-Chirurgical Committees and other modes of studying the effects of chloroform, this is the first time we have heard of its producing kleptomania. "Forewarned" is, however, or ought to be, "forearmed," and no doubt in future Medical men will bear this history in mind whenever they feel inclined to prescribe this fearful drug:—"Isabella Freeman, a well-dressed and respectable-looking married woman, described as of Barrett-grove, Bethnal-green, was charged before Mr. Cooke, at the Worship street Police-court, with shoplifting. Mr. Abbott said his client had been for some time past suffering from a disease for which she had been obliged to take medicine containing large doses of chloroform, and there was reason to believe that it was while she was under the influence of this she had reverted to a course which had, as he could not deny, before entailed punishment upon her. He asked the magistrate, under the circumstances, to deal summarily with the prisoner. Mr. Cooke said he must send her for trial."

Corrosive Sublimate and Stedman's Soothing Powders.—An inquest has been held at Wells on the body of William Coles, aged seven months, before Dr. Wybrants, coroner. From the evidence it appeared that a packet of Stedman's powders was purchased from a chemist in Wells a month ago. One of the powders was given to the child without injuring it. Another was subsequently given, and the child died in ten minutes afterwards. In the same packet, which was produced in court, there were ten grains of a deadly poison called corrosive sublimate. The wholesale druggist from London and the present proprietor of Stedman's powders attended, and after their examination the coroner adjourned the inquest.

Mrs. Partington Rediviva.—The good folks at Cheltenham are in a most excited state, because Parliament will not assuage their thirst at the expense of the source of the Thames. At a recent meeting to take into consideration their water supply, a Mr. Jackson announced that he was quite ready to set Parliament at defiance. He said he was prepared to enter into a contract with the town of Cheltenham to bring to Cheltenham without an Act of Parliament the water from the South Cerney spring, if the owners of land intervening would give their consent to the laying down of the pipes. This announcement was received with loud applause.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

M.R.C.S. Eng.—We cannot publish letters unless authenticated by the writers.

X. L.—We cannot recommend Medical men. Any Hospital Surgeon, or, if the case be constitutional, any Hospital Physician, or other Practitioner of eminence, will undertake the treatment of syphilis.

L.K.Q.C.P.—Candidates for the degree of M.D. of the Erlangen University must undergo an examination in writing, which lasts for some days, and another *vivâ voce*, which lasts for some hours. They need not reside there longer than the time necessary for examination. No Englishman can procure the degree unless his name appear in the Medical Register. The subjects of examination are:—Anatomy and Physiology, Pathological Anatomy and General Pathology, Special Pathology and Therapeutics, Surgery and Midwifery. The fee amounts to about £20. Degrees *in absentiâ* and without examination are not given. The Hall license we know is preferred by the Poor-law Board. We do not know that it is indispensable.

There can be no doubt that a Medical man who hires out his name and qualifications to any unqualified person who may take a shop, and call himself his assistant, commits a fraud on the public. It must be clearly shown that the "assistant" is the *bona fide* servant, and acts as the representative of his employer, before the master can recover.

Mr. Hugman begs to announce the following subscriptions to the "Norton and Medical Defence Fund:"—

Dr. Robinson, 10s. 6d.; R. Cuff, Esq., £1 1s.; Dr. Stevens, £1 1s.; Mr. Holden, 5s.; Dr. Goodfellow, £1 1s.; — Gibbons, Esq., £1 1s.; T. R. N. Mursom, Esq., 5s.; G. Yarde, Esq., 5s.; Mr. Mitchenor, 10s. 6d.; — Hugman, Esq., 10s. 6d.; — Goodhugh, Esq., 2s. 6d.; — Stagg, Esq., 5s.; E. Taylor, Esq., 2s. 6d.; — Steet, Esq., 2s. 6d.; Dr. Watson, 10s.; Dr. Ablett, 5s.; Borlase Childs, Esq., £1 1s.; H. M. Simmonds, Esq., 10s.; R. W. Lammerman, Esq., £1 1s.; J. P. Berryman, Esq., 5s.; Dr. Driffield, 10s. 6d.; Dr. Hughlings Jackson, £1 1s.; J. Byass, Esq., 1s.; M. T. Coleman, Esq., 5s; W. B. Woodman, Esq., 2s. 6d.; J. W. McWhinnie, Esq., 10s. 6d.; Anon., 2s.; Dr. Roberts, 10s. 6d.; J. Moncrieff Arnott, Esq., 10s.; — Murrell, Esq., 5s.; F. G. C. Edwards, Esq., 5s.; T. H. Graham, Esq, 5s.; Oswold Foster, Esq., 10s.; Edward Hall, Esq., 2s. 6d.

Griffin Testimonial Fund.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The following subscriptions have been further received on behalf of the above fund:—J. Thos. Muriel, Esq., Hadleigh, 5s.; G. C. Edwards, Esq., Ipswich, per ditto, 5s.; amount previously announced, £117 1s.; received at *Lancet* office, £7 17s. 6d. I am, &c.

Robert Fowler, M.D., Treasurer and Hon. Sec.

145, Bishopsgate-street Without, March 2, 1865.

The Bowen Fund.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—A meeting was held at the Medical Institution, Liverpool, on February 24, when it was resolved by the donors to the "Bowen Fund," unanimously, that the surplus—£49 10s. 6d.—be appropriated to the Medical Benevolent Fund. I am, &c.

H. D. Scholfield, M.D., Treasurer.

14, Hamilton-square, Birkenhead, February 28, 1865.

The Production of an Inverted Image by a Convex Lens.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—In my last letter "on the production of an inverted image by a convex lens," I left Mr. Cresswell but partially convinced of the error he was labouring under. I did not reply to Mr. Cresswell's second letter simply because I did not consider your columns should be occupied by optical education. But I do hope, after Professor Zehender's able exposition of the subject in his letter in your impression of to-day, Mr. Cresswell will see that he has *ad initio* been led by some will o'-the-wisp of his own fancy to dispute that, than which nothing is more firmly established in the whole science of geometrical optics. In fact, it is susceptible of the most rigid of proofs—that of mathematics—for which I beg to refer Mr. Cresswell to Mr. Parkinson's (of Cambridge) excellent "Treatise on Optics."

I am, &c.,

February 25. J. Z. Laurence.

The Naval Medical Service.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Will you allow me, through the medium of your valuable journal, to address a few words of warning to those students who, approaching the term of their Medical education, and casting about in search of a career wherein they may gain an honourable livelihood, are entertaining the idea of entering the Medical Service of the Navy?

The ill-treatment said to be endured by Medical officers at the hands of the executives appears to me to have been much exaggerated. In common with all officers, we are subject to the caprices of the captain of the ship, but, from our duties, are less so than are the executives, the paymasters, or engineers; and that the civil branches are sometimes snubbed, sometimes spoken of with a certain contempt, by the military branch cannot be marvelled at when it is remembered that members of the latter are brought up to command from a very early age, and thus naturally learn (and the Admiralty regulations on dress, rank, precedence, etc., seem specially designed to inculcate such knowledge) to rate themselves as much superior to those over whom they do now, or at some future time will, enjoy an almost absolute power.

I refer you to the Navy List for the various distinctions of coats, buttons, lace, devices, cocked hats, etc., by which the Medical officer is to be carefully separated and distinguished from his executive comrades. Trifles, you may well say these, but trifles become of moment when they are emblems of rank in a service where rank is all in all. It must be remembered that the executive uniform is the outward standard of rank; and every distinction from it further than what is absolutely necessary appears to me invidious. Yet I cannot entirely exonerate Medical officers from the charge of sometimes assuming to themselves functions to which they have no right whatever; but I believe that such "snobs" are a very small minority.

The Assistant-Surgeon must serve six years on full pay before he attains the rank of lieutenant; thus, at an age of 27 to 30 years he has a rank equivalent to that of a boy of 19 or 20,—equivalent, not equal, for civilian rank is merely nominal. He only enjoys a cabin on sufferance, and may at any period be sent to a hammock in the steerage as a sacrifice to the "exigencies of the service."

These and some other facts are real grievances, but they are the work of the Admiralty alone, and I believe that most executive officers are quite indifferent to any such invidious distinctions. But what the Assistant-Surgeon has most to complain of is that he has not only, in common with other officers, to suffer from the caprices of the captain, but has further to endure the caprices of the Surgeon; and I have no hesitation whatever in asserting that the Assistant-Surgeon receives much more insolence and petty tyranny at the hands of his Professional than at the hands of his military superior: for his duties, except in the absence of the Surgeon, are merely those of an apothecary's boy or of a first year's dresser: rolling of pills, making of powders, and attending to wounds not more complicated in their nature than a cut finger. It would be tedious to recapitulate all my experiences, all the facts of which I have knowledge, and I will merely give you the following instances of what I conceive to be very unprofessional conduct:—I have known a Surgeon make both his assistants stand like footmen behind his chair at the visit, and there execute his orders. I have known men forced to weigh each separate pill as they made them, spend a morning in tearing and rolling up bandages, etc., etc. I have heard Assistant-Surgeons rebuked by the Surgeon for presuming to differ with him on points Professional and non-Professional, and "blackguarded" for being a minute late at the morning visit; and I speak the literal truth when I say that similar practices are far from uncommon in H.M. ships.

Let those who aspire to tack R.N. to their names consider well these facts before they present themselves at the farcical examination at Somerset House, and expose themselves to the comfortable sneers of the departmental clerks, who style themselves Esquires and us plain Misters.

And what ulterior reward has the Assistant-Surgeon to hope for? After ten years' service, promotion to a Surgeoncy; after ten more, the nominal rank of Staff-Surgeon, equivalent to that of a commander (a rank rarely gained before 45 years of age, while the commander obtains his generally at 30 to 32); after twenty-five years' full pay, equal to thirty years' ordinary time, retirement on £337 per annum. Still, such an income is a competency even for a man over 50, and has the advantage of being a certain one. As affording such, then, the service deserves the attention of Professional students. I conceive the naval service worth the consideration of an unambitious Medical man, utterly destitute of any reasonable prospects of success in practice ashore. But to men who are not entirely unambitious, who aim at any eminence in their Profession or in any other pursuit of life, who have any love for liberty and independence, who have the smallest chance of success in civil practice, I most strongly recommend a strict avoidance of the Naval Medical Service, and of such discomforts and insults as have for three years been endured

By yours, &c.

"Cui fugit Interea fuoit irreparabile Tempus."

I enclose my card, but not for publication.

APPOINTMENTS FOR THE WEEK.

March 4. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

6. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

Epidemiological Society, 8 p.m. Dr. Smart, R.N., Deputy-Inspector-General of Fleets and Hospitals, "On Diphtheria in Bermuda." Dr. Swarbeck Hall, "On Vaccination in Tasmania." Dr. Lawson, Deputy-Inspector-General of Army Hospitals, "On the Epidemiology of the Cape of Good Hope and Natal."

Medical Society of London, 8½ p.m. General Meeting for the Election of Officers and Council. Dr. Sansom, "Chloroform in Surgery."

Royal Institution (General Monthly Meeting, 2 p.m.), 3 p.m. Prof. Tyndall, F.R.S., "On Electricity."

7. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

Ethnological Society of London, 8 p.m. Mr. Travers, "On the Destruction of the Aborigines of Chatham Island by a Maori Invasion." Mr. Hyde Clarke, "On the Inhabitants of Asia Minor previous to the Time of the Greeks."

Pathological Society, 8 p.m. Meeting.

Royal Institution, 3 p.m. Prof. Hofmann, F.R.S., "An Introduction to Chemistry."

8. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

Hunterian Society (Council Meeting, 7½ p.m.), 8 p.m. An Open Meeting.

Medical Society of London. Anniversary.

Microscopical Society, 8 p.m. Dr. Greville, "On Diatomance."

Obstetrical Society of London, 8 p.m. Mr. Rouse, "Marks on the Neck of a New-born Child." Mr. A. Harris, "Membrane Expelled some Days before Labour." Dr. Meadows, "Remarks on a Case of Monstrosity."

9. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Royal Institution, 3 p.m. Prof. Hofmann, F.R.S., "An Introduction to Chemistry."

10. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m. Prof. Ramsay, F.R.S., "On the Eozoön, or earliest known Fossil."

ORIGINAL LECTURES.

LECTURES ON CHEMICAL AND MECHANICAL DISEASES AND THEIR RELATIONSHIP.

By H. BENCE JONES, A.M., M.D., F.R.S.

Lecture III.

DISEASES OF SUBOXIDATION—ON THE OXALIC ACID DIATHESIS.

(Continued from page 220.)

On the Consequences of Oxalic Acid.

The formation of an oxalate of lime calculus in the kidney or bladder is the secondary disease which the oxalic acid diathesis produces. But for this mechanical complaint the chemical disorder would be of little or no importance at all. Hence the great object of detecting oxalate of lime in the urine is to prevent the formation of mulberry stone in the urinary organs.

In my paper in the 26th vol. of the *Transactions* of the Medico-Chirurgical Society, I state that out of 450 distinct deposits forming calculi, 135 times uric acid was found alone or mixed with other substances, and 163 times oxalate of lime occurred either alone or mixed with other deposits. In other words, the greater degree of acidity which is marked by uric acid crystals occurred rather less often than the lesser degree of acidity which led to the formation of the oxalic acid diathesis. In other collections the greater degree of acidity appears to have more frequently caused the formation of the calculi. From the analysis of many collections, Dr. Prout says, p. 590, "If a mulberry stone had not been formed and detained in the bladder, two persons out of about nine who suffer from calculus would not have been troubled with that affection." As he previously said that six out of nine had a nucleus of uric acid (or urates), it follows that imperfect oxidation to a greater or less degree gives rise to no less than eight out of nine cases of stone.

With regard to the mechanical effects of mulberry stone, they scarcely differ from those produced by uric acid. Usually the mulberry stone is rougher and harder than all other stones; and hence the roughness is more apt to cause blood by hurting the kidney or bladder, and greater mechanical force is required to crush this stone, and the fragments are sharper and harder than those of any other kind of stone.

In addition to the mechanical diseases of stone in the kidney, ureter, or bladder, the oxalic acid diathesis, or in other words, that degree of oxidation which causes the formation of oxalic acid instead of carbonic acid, may perhaps hereafter be found to produce secondary chemical disorders.

Thus in diseases which are accompanied with great difficulty of breathing or in extreme states of debility, as perhaps in asthma or at the end of different fevers, oxalic acid may accumulate in the blood or in the textures, and either alone or with the help of carbonic oxide gas produce a state of narcotic poisoning not to be distinguished in its phenomena from the effects of a fatal dose of morphia.

In the *Transactions* of the Medico-Chirurgical Society for 1849, p. 171, Dr. Garrod records a case of Bright's disease with effusion in the chest and abdomen, in which oxalate of lime was found in the blood; the patient became senseless eight hours before death, possibly, however, from urea in the textures.

On the Treatment of the Oxalic Acid Diathesis.

The treatment of the oxalic acid diathesis and the treatment of oxalate of lime in the urine are almost, though not altogether founded on the same indications. The cure of the oxalic diathesis is to be obtained by promoting oxidation in the body. In this respect this disease and diabetes have the closest possible resemblance. The best treatment for flatulent dyspepsia is the best treatment for diabetes. I must refer you, then, to all I have said on the treatment of diabetes for the fullest information on the treatment of the oxalic diathesis. I might sum all up, however, in four words—meat in moderation and weak spirit; nevertheless a diet as rigid as in diabetes need not be insisted on in this complaint, because it is often so slight an aberration from health that the functions of the body are scarcely interfered with, and if it were not for the formation of oxalate of lime it might often be altogether neglected.

Hence the treatment of oxalate of lime becomes of more importance than the treatment of the oxalic acid diathesis. Two methods may be simultaneously carried out—first, the amount of lime passing through the body may be lessened, and secondly, the formation of the octahedral crystals may be stopped.

The effect of diminishing the amount of lime taken into the body by the drinking water may be seen from what results when the quantity of lime in the urine is increased, either by adding it after the water is made or by giving lime salts as medicine. The following experiments among many others that I might give, are quite sufficient to show the importance of giving rain or distilled water when much oxalate of lime is found in the urine:—

250 c. c. of fresh nearly neutral urine were divided into five equal parts.

To the first part nothing was added; it was examined twenty-one hours afterwards, and gave no octahedral crystals.

To the 2nd. One drop of chloride of calcium solution, sp. gr. 1146, was added; octohedra were found.

To the 3rd. Two drops of ditto; octohedra.

To the 4th. Three drops of ditto; octohedra.

To the 5th. An excess; many octohedra.

Seven other experiments were made with different healthy urines.

Two equal portions of the same urine were taken, and chloride of calcium was added freely to one after it was passed.

Experiment 1.—The urine without chloride of calcium contained very few octahedral crystals; with chloride of calcium many small octahedra.

Experiment 2.—The urine without chloride of calcium contained no oxalate; with chloride of calcium plenty of octahedral crystals.

Experiment 3.—The urine without chloride of calcium contained urates and only a few octahedra; with chloride of calcium a large amount of octahedra, large crystals.

Experiment 4.—The urine without chloride of calcium contained no octahedra; with chloride of calcium exceedingly small crystals not quite distinct as octahedra.

Experiment 5.—The urine without chloride of calcium contained very few and very small octahedra; with chloride of calcium plenty of octahedra.

Experiment 6.—Doubtful increase of oxalate by adding chloride of calcium.

Experiment 7.—Doubtful increase.

If lime water or acetate of lime or carbonate of lime are given as medicine, oxalate of lime may be looked for in the urine.

C. W., aged 30, was admitted with chronic rheumatism into St. George's Hospital July 30. The urine was acid and perfectly natural, excepting that occasionally a little bladder epithelium was seen. Forty-five grains of acetate of lime dissolved in water were given thrice daily; in four days oxalate of lime crystals in plenty were found in the urine.

L. B., aged 26, admitted with slight rheumatism. The urine was acid and perfectly natural, except that it contained a quantity of pus cells, the result of gonorrhœa. Thirty grains of acetate of lime were given thrice daily for two days, and then forty-five grains for two more days, when much oxalate was found in the urine.

Distilled water or rain water are therefore likely to be useful when octahedral crystals are found in the urine. Even the removal of some of the lime from the drinking water by boiling it well, and then filtering it, or, better still, by adding a little carbonate of soda before boiling, may be of use in stopping the formation of oxalate of lime gravel in the urine.

It is quite impossible to stop all lime from going in or coming out of the body; and, therefore, by the anti-lime treatment, only a partial good can be done, and other methods of stopping the crystallisation must be adopted, or still better the oxalic acid diathesis must be removed.

The second method of treating the oxalate of lime deposit in the urine consists in stopping the formation of the crystals. Removing the oxalic acid diathesis would stop the crystallisation as surely as it would be effected if no lime could be allowed to pass out of the body; and though both these methods may be of use, a still more immediate effect on the crystallisation may be obtained by the mineral acid treatment.

Dr. Prout first ordered a mixture of one part nitric and

two parts hydrochloric acid. This is called nitro-muriatic acid. It varies in composition according to the temperature at which the acids are mixed and kept, and according to the time they remained mixed before they are used. Sometimes it is a mixture of nitric and hydrochloric acid, or it may contain chlorohyponitric, NO_2Cl_2, and chloronitrous acid, NO_2Cl, or even hyponitrous acid, HO_4, and chlorine. It is, no doubt, possible that a mixture of these substances may be more beneficial as a medicine than any one of them used separately; and if this can be proved to be true, such a mixture should be used; but the progress of our knowledge of remedies depends on the use of each substance separately, in order that the greatest possible clearness may be obtained as to the effect of each remedy; and, as it is by no means proved that so-called nitro-hydrochloric acid is superior in any respect to the mineral acids taken singly, I consider that an advance in clearness of intention, if not in power of treatment, may be obtained by using each acid separately, according to the properties which each must be considered or may be found to possess.

And first regarding hydrochloric acid. As this is more especially the acid of the gastric juice, it seems reasonable that it should be prescribed, more particularly when there is feeble digestive power; after long illnesses, when animal food begins again to agree, it should be taken almost immediately before each meal of animal food. Thus the greatest immediate use can be got out of hydrochloric acid.

Secondly, regarding nitric acid. This acid was at one time strongly recommended as a substitute for mercury in syphilis and in the liver diseases of India. Generally, it may be considered to promote secretion and perhaps oxidation; and with this intention it should be given so as to be absorbed before food enters into the stomach. If taken one hour or two hours before meals on an empty stomach, the nitric acid acts on the system and not on the food.

Thirdly, sulphuric acid has been always used as an astringent to stop perspiration, to stop hæmorrhage, to stop diarrhœa. It may be, therefore, regarded as the opposite of nitric acid in its action on the system; and to obtain the greatest action it also should be given in time to admit of its absorption before food is eaten.

Thus, then, rightly used, hydrochloric acid promotes digestion, nitric acid secretion, sulphuric acid constriction.

In addition to these special actions, there is a direct local action of these substances on the stomach. When used in small quantities, with care, they all probably render the stomach less irritable than it otherwise would be; but if the dose of any of them be too strong, it probably increases the sensitiveness of the mucous membrane, and may cause violent pain and spasm, increased chemical action producing altered mechanical and chemical actions in the mucous membrane of the stomach.

All these acids also have a distinct action on the urine. Although there is as yet no positive proof that dilute mineral acids increase the acidity of the urine at all to the same degree that dilute vegetable acids will do—for example,

Variation of the acidity of the urine during the day when three drachms of dilute sulphuric acid, sp. gr. 1·1077, are taken in water.

Variation of the acidity of the urine during the day when eighty-four grains of tartaric acid are taken in water.

yet, if the amount of sulphates, for example, in the whole quantity of water passed in twenty-four hours for three successive days when no sulphuric acid is taken is compared with the amount of sulphates in the whole quantity of water passed in twenty-four hours for the three succeeding days when sulphuric acid is taken, it is certain that dilute sulphuric acid taken in very large quantity does pass off combined or uncombined in the urine. Thethird day after half an ounce of dilute sulphuric acid, specific gravity 1·1084, had been taken daily, 43 cunces of urine were passed of specific gravity 1025·4. 12·95 grains of sulphate of baryta were precipitated from 1000 grains of this urine; when no acid was taken, 42 ounces of urine were passed of specific gravity 1023·4. These gave 9·19 grains of sulphate of baryta per 1000 grains of urine.

All the mineral acids lessen the tendency of the oxalate of lime to form crystals in the urine. If two equal portions of urine are taken, and the minutest quantity of mineral acid is added to one portion, whilst the other is kept for comparison without acid, oxalate of lime may be found in the urine to which no acid has been added, whilst in the other no crystals will form. The same action may occur when these acids are taken as medicine, and with nitric acid there is the additional recommendation that the oxalic acid diathesis itself may, by the promotion of oxidation, be lessened or, with perseverance, removed.

ORIGINAL COMMUNICATIONS.

HOLIDAY NOTES ON CONTINENTAL SPAS.

(Second Series.)

BAGNÈRES-DE-LUCHON.

By HERMANN WEBER, M.D., F.R.C.P.,
Physician to the German Hospital.

(Continued from page 171.)

Bagnères-de-Luchon is a small town, of about 3000 resident inhabitants, situated in the very heart of the Pyrenees, in the angle formed by the Gaves (torrents) la Pique and l'One. The distance from Paris, by way of Bordeaux and Toulouse, is about 628 miles, and rather less by way of Bordeaux and Tarbes. It lies in 42° 45′ north latitude, and 35′ east of London. Its elevation above the level of the sea is 2060 feet.

The valley of Luchon is one of the finest in the Pyrenees, it is less narrow than those in which most of the other spas are situated, and is surrounded by noble mountains, which are covered up to a considerable height with forests and pastures.

The *climate* of Luchon may be termed agreeable; the *summer temperature* is, owing to its elevation, only slightly higher than that of Paris; the extreme changes lie, according to Lambron ("Les Pyrénées et les eaux thermales Sulfurées de Bagnères-de-Luchon." Par le Docteur E. Lambron et

par T. Lezat. Paris. 1862. P. 371), between 42°· 8 F. and 98°· 6 F.; the changes are said to be sometimes rather sudden, but the extremes are, in general, only of short duration. The mean height of the barometer is 27·94 inches; the extremes are 27·47 and 28·41 inches; the sinking to 27·47 inches is very rare, and occurs almost only with the "vent d'Espagne" (south wind) and before storms. The humidity of the air is about the same as in the plains of the south of France, but the transitions are more sudden. The predominant winds are those from the west and south-west; the east wind is generally accompanied with fine weather; the south wind (vent d'Espagne) has a peculiarly enervating influence. According to Lambron and Lezat's observations, extending over five years, 38 days out of 109 (from the middle of June to the end of September) are perfectly fine; en 19 the mountains are quite enveloped in clouds, the sun never coming through; on the remaining 52 days the weather is variable. Rain falls only on 38 days out of the 109, and on 16 days out of these 38 there are thunder storms. The greatest heat occurs in July and August, but the heat is said not to be oppressive, except when the wind comes from the south. The nights are, even on the hottest days, much cooler than in the plains. On account of the surrounding mountains the sun appears in the morning a few hours later and disappears in the afternoon considerably sooner than in the plains.

On the whole the summer climate of Luchon may be called one of the most favourable among the Pyrenean spas; it possesses already, to some degree, the tonic qualities of a mountain climate, and agrees well with conditions of anæmia, weakness from acute disease, and various other causes, and especially also with chronic catarrhs of the respiratory organs, if the occasional sudden changes of temperature are provided against.

The sources of Luchon have been, without doubt, resorted to already by the Romans, as ample remains have been dug up at different times. Although most of these remains have been removed to Toulouse, yet several of importance may still be seen at Luchon, amongst which are a votive altar and some tablets. One of the latter bears the inscription,—

LIXONI DEO
FABIA FESTA
V.S.L.M.

It is by some supposed that the name "Luchon" is derived from this heathen deity "Lixon." The four letters V.S.L.M., which are met with on most of the tablets, may signify "*Votum solvit liberata (or liberatus) morbo*," or, according to other interpreters, "*Votum solvit libens meritum.*"

Bagnères-de-Luchon has more than fifty mineral sources, most of which are sulphuretted, a few only being chalybeate and saline. The variety existing in the different sulphuretted springs is very great, some of them ranging among the strongest, others amongst the weakest, in the Pyrenees. The temperature, too, varies considerably in the different sources, the "ancienne source, Sengez No. 4," having a temperature of only 82° F., the "source Bayen" of 150°·8 F.

It would be out of place to describe here all the sources; I will, however, insert the analysis of the most important of these, as given in Filhol's work ("Les eaux Minérales des Pyrénées," Toulouse, 1853, p. 265):—

Table indicating the Chemical Composition of the Principal Sources of Bagnères-de-Luchon.

Names of the Sources.	Sulphuret of Sodium.	Sulphuret of Iron.	Sulphuret of Manganese.	Chloride of Sodium.	Sulphate of Potash.	Sulphate of Soda.	Sulphate of Lime.	Silicate of Soda.	Silicate of Lime.	Silicate of Magnesia.	Silicate of Alumina.	Carbonate of Soda.	Free Silica.	Alumina.	Magnesia.	Organic Matter.	Total.(b)

The quantity has not been determined.

(a) The litre is equal to 35·21546 fluid ounces; the gramme to 15·4325 grains troy.
(b) Every source contains, besides, traces of sulphuret of copper, iodide of sodium, hyposulphite of soda, phosphates, and hydrosulphuric acid.

In connexion with this table it is to be observed that the chemical composition of the different springs of Luchon is not quite constant, but is subject to rather considerable variations. Thus the amount of sulphurets as indicated by the *sulphurometer* (c) increases simultaneously with a steady rising of the barometer, while a steady sinking of the latter is accompanied by a diminution of the sulphurets; the amount of sulphurets varies further with the temperature and the seasons, being greater during cold than during warm weather, and the periods of melting of large masses of snow are characterised by a diminished proportion of sulphurets. The quantity of other constituents, as of chloride of sodium, undergoes likewise at different times appreciable changes.

It would take up too much space to give a description of the organic substances contained in the waters of Luchon, a short account of them may be found in the general remarks on the Pyrenean Spas previously given.(d)

Of some importance amongst the sources of Luchon is the "source froide," because its water is used as admixture to that of other sources. The "source froide," by far the most abundant of all the sources of Luchon, possesses a temperature of about 60°F. and contains about 0·152 grm. of solid substance in the litre. Filhol has found in this spring no sulphurets, and only traces of hyposulphite of soda; the sulphates of lime, magnesia, and soda, silica, chloride of sodium, carbonate of lime, and organic matter are the principal constituents, with traces of oxide of iron and iodine.—Lambron, l.c., p. 432.

There are, in addition, several chalybeate springs at Luchon which contain sulphate of iron and almost all also alum. Their composition has not been accurately determined, and they are, as yet at all events, of only secondary importance, as compared with the other sources of Luchon, and will probably remain so, as all the chalybeate springs containing the sulphate of iron as their ferruginous elements are much less digestible than those containing carbonate of iron with an excess of carbonic acid, as Schwalbach, St. Moritz, Bruckenau, Spa, and others.

The thermal establishment of Luchon is the largest and most complete in the Pyrenees; it is about 290 feet long, and about 160 feet deep. The colonnade of white marble in front of the building makes an agreeable impression, although the style is not pure. The interior may be called handsome, and the arrangements, in general, good. All the sources of Luchon, with the exception of some chalybeate, have been conducted to this establishment, and are, therefore, concentrated in a small space, which is a great advantage to the Physicians and to many of the patients. The establishment contains two basins, or "piscines," for twenty persons each, a larger swimming basin ("piscine ou bassin de natation"), eighty-two separate baths,(e) with moveable local douches, twenty-eight other separate baths provided with the "douche percutante," seven grand douches, or "douches spéciales," furnished with the newest improvements, for the regulation of temperature, force, and volume, similar to those at Aix-les-Bains,(f) and, in addition, several "douches ascendantes" for rectum and vagina. A large room is devoted to the administration of the pulverised or minutely-divided thermal water to the fauces, the eyes, ears, etc. There is provision made for twenty-four "buvettes," or drinking fountains, of which,

(c) The name of *sulphurometrie*, or, according to the French way of spelling, *sulfurométrie* or *sulfhydrométrie*, has been given to Dupasquier's volumetric method of ascertaining the quantity of sulphurets in mineral waters. It is based on the fact that iodine added to a solution of hydrosulphuric acid or of a monosulphuret displaces the sulphur, producing hydriodic acid or an iodide.
(d) *Medical Times and Gazette*, 1865, vol. i., p. 170.
(e) The separate baths throughout the Pyrenees are rather small, as compared with those in the principal spas of Germany, and would certainly not lose either in comfort or efficacy if they were to be made larger.
(f) Conf., *Medical Times and Gazette*," 1861, vol. ii., p. 552.

however, as yet only eighteen have been established, viz., three in the building itself, and fifteen in its close proximity.

Adjacent to the establishment is the "*étuve sèche*," a kind of *sudatorium*, a semicircular excavation in the rock, heated by means of two of the sources ("la Reine" and "Bayen"), which, united, form a streamlet of a temperature of about 134° F., and, passing underneath the "étuve," communicate with it through an aperture which may be kept open or shut, according to the effect desired, the temperature of the "étuve" being in the former case between 100° F. and 102°·5 F., and in the latter between 91°·4 F. and 95° F.

There are further to be mentioned the "*galeries souterraines*," subterraneous passages, more than twenty in number, cut out of the rock, most by M. Francois, the well-known engineer, in order to follow the sources up to their emergence from the rock itself, and to conduct them in closed channels (in part of brick, in part of wood and china), with as little loss and alteration as possible to their places of utilisation. As these "galeries" are, in general, over six feet high, and almost five feet wide, they can likewise be employed as sudatoria, or as rooms for the inhalation of the gases. The temperature in the different "galeries" varies from 68° F. to 98°·6 F.; the air contains a considerable amount of hydrosulphuric acid, and is poor in oxygen.

With regard to the manner in which the various sources are distributed in the bathing establishments, it is important to know that several sources, which in themselves do not yield a sufficient amount of water, and which, by their chemical composition and the places of their emergence from the rock, seem to belong to each other, have been united into groups of sources, called "sources alimentaires." Thus, under the able direction of Filhol and François, out of the forty-eight thermal springs, ten groups or alimentary sources have been formed, which are conducted to reservoirs, and thence distributed to the different portions of the establishment. Those of the alimentary sources which possess a higher temperature than 95° F. are reduced to that degree by the admixture of water of the "souree froide"—a practice which appears very objectionable, and which might easily be remedied by the substitution of properly cooled sulphuretted water for that of the "source froide." The practice now in use may be quite harmless in those cases in which either a very weakly sulphuretted or only a common warm bath is required; but it is, no doubt, to be condemned, wherever a more strongly sulphuretted bath is indicated, as the effect of the admixture of the common cold water consists not only in the direct diminution of the percentage of the sulphurets, but also in a more rapid decomposition of the sulphuretted water.

All the sulphuretted waters of Luchon which at their sources are limpid, and have scarcely any smell of sulphuretted hydrogen, undergo alteration more or less rapidly, and more or less completely. Filhol, to whom we owe so much regarding our knowledge of the chemical composition of the Pyrenean spas, has carefully examined this important subject; and Lambron, too, has an instructive chapter on it. The water of the baths and piscines possesses, owing to this alteration, a different composition from that of the sources which supply it. The quantity of the sulphuret of sodium is considerably diminished, while sulphite and hyposulphite, sulphate, carbonate, and silicate of soda — substances which exist only in traces in the unaltered sources—are found in perceptible proportions. The different sources exhibit, however, great differences with regard to these changes. Some turn yellowish without losing their transparency, and gradually lose all their sulphurets by transformation into hydrosulphuric acid, which escapes, and into sulphites and sulphate of soda. Others become at first yellowish and then white, like milk by the precipitation of sulphur in the form of an emulsion. "*Blanchiment*" is called this phenomena of alteration, which is peculiar only to some sources of Luchon, Ax, Cadéac, and Molitg. The admixture of cold water increases the rapidity of decomposition, as shown by the source "*Blanche*" and source "*Ferras nouvelle*," which receive streamlets from the source froide already in the subterraneous passage. It is impossible here to enter more fully into this most pregnant question of the alterability of the various sources. As yet our knowledge on these points must be considered as very limited; thus it is not yet explained why some waters lose their sulphur rapidly, while others, to all appearance of the same chemical composition, retain it for a long time without decomposition. In this difference, probably, lies the cause of the difference in the physiological and therapeutical actions of waters seemingly of analogous composition.

A subject often overlooked, but of great interest, is the *composition and temperature of the air in the bath-rooms, the piscines, the douches, and étuves*. It is again Filhol (l.c. p. 291) to whom we owe much of our knowledge on this subject. The principal alteration in the localities just mentioned consists in the elevation of the temperature, in the admixture of water, vapour, and hydrosulphuric acid, and in the diminution of oxygen, part of which is absorbed by the sulphuret of sodium contained in the water. The inspiration during a lengthened period of air thus constituted cannot be without important physiological effects. Thus, during an hour's stay in the piscine at Luchon a man who is supposed to inspire 320 litres of air inhales, according to Filhol, 3 62 cubic centimetres of hydrosulphuric acid and at least four litres of oxygen less than under normal circumstances.

(To be continued.)

CASE OF

EPILEPSY, PAINFUL MENSTRUATION, AND PERIODICAL VOMITING, SUCCESSFULLY TREATED CHIEFLY BY MEANS OF ICE.

By JOHN CHAPMAN, M.D., M.R.C.P.

Miss D., aged 21, consulted me for the first time January 10, 1864. She is tall, thin, pale, and feeble. She suffered from the blue disease from birth until she was 16 years old, when she became of natural colour. Her head is abnormally small, the forehead especially so: mental power less than the average. She suffers from epileptic fits, which recur several times a-month: she had two fits last week. The fits last from one to four minutes. "She would sleep an hour or so after each fit," her mother says, "if allowed to do so." Began to menstruate when 12 years old; has generally, her mother says, been regular, and is four or five days poorly. She had, however, a slight show of menstruation at the end of last month, a fortnight after the previous period. About the time of becoming "unwell," or an hour or two after the discharge has begun, she is seized with violent pain in the lower part of the abdomen, the thighs, and along the back extending upwards as high as the cervical vertebræ. Her sufferings at each menstrual period are described as peculiarly intense, amounting to agony. They continue from five or six to twenty-four hours each time. On the last occasion they continued twenty-four hours. During the whole of the painful periods she vomits or retches continuously, and at these times her fits recur the most frequently. Appetite feeble; bowels constipated; hands and feet always cold; pulse 82, very feeble. To apply ice in each cell of the ice bag during thirty minutes three times a-day, one layer of flannel being placed between the bag and the back; to take a brisk walk after the first and second application each day. Ammonii bromidi, gr. iv., infusi calumbæ, ℥j., bis die.

January 19.—Has taken the medicine, and continued the ice, but only twice a-day. Has had no fit since last visit. The feet and hands have become warm. Pulse 64; tongue clean; bowels rather confined. To use the ice as ordered three times a-day, and to continue the medicines.

27th.—Became "unwell" on the 24th. The pain which she usually suffers lasted only about ninety minutes, and though she felt nausea during this time she vomited only twice. Has had no fit since last here; the feet have become quite warm; tongue clean; bowels open daily; pulse 52; ceased to menstruate yesterday. Continue in all respects as before, except to apply the ice-bag next the skin, and in addition to the medicine already prescribed to take before dinner each day ferri et quinæ citratis, gr. v.; infusi calumbæ, ℥j.

February 27.—Began to menstruate on the 19th inst. On the 18th felt a slight wave of vertigo, but did not lose her consciousness. On the 19th had "very slight pain" lasting about an hour, but neither vomited nor felt any nausea whatever. Was unwell about four days, more copious than formerly, the ice being continued during the period. Has had no fit of any kind since. Says she has "got very fond of the ice." Bowels open sometimes daily, sometimes on alternate days. They are open, her mother says, much oftener than formerly. To continue as before as soon as she has recovered from a cold which she took while at a party in a low dress, and in consequence of which the ice has been left off.

March 5.—Has been prevented by her cold from resuming

the ice during the last week. Meanwhile has not felt well otherwise, and has had one fit. To resume the ice at once; to continue the bromide of ammonium in infusion of calumba; and to take, instead of the citrate of iron and quinine, quinæ disulphatis, gr. 1; acidi sulphurici diluti, ɱ v., ex aqua, once daily.

I never saw this patient again; but, in answer to an inquiry which I addressed to her mother, I received a letter dated July 9, 1864. She says:—"After I last saw you my daughter continued in good health. We went on April 4 into Kent, and remained there some weeks; during this time she took her medicine regularly, but we could get no ice to speak of. Still she improved, and the sickness did not return; but instead of sickness (at the menstrual period), she could not, for some hours, rest, but turned in bed from side to side; after this went off she was quite well. This happened three times in nine or ten weeks. On May 30 we returned to town, where we have staid ever since, during which time my daughter has had two attacks (of pain and sickness at her menstrual periods); The first on the 9th ult., and the second to-day—this more severe than that on the 9th. Since our return to London, my daughter has not applied the ice, nor taken the medicine. I now intend steadily going on with the ice and medicine (the first you prescribed). I am glad to say that during all this time she has not, that I remember, had a fit; they used to be frequent."

Comments.—This case is peculiarly interesting in several respects, and not less instructive. The disappearance of the blue disease when the patient was about sixteen years old is very remarkable. Assuming the disease to have been due, as is most usually the case, to imperfect closure at birth of the foramen ovale, it seems not improbable that this orifice was finally closed during one of the patient's fits. (a) At the first consultation it was stated that the patient's menstrual function was "regular," and of ordinary duration —four or five days. Information afterwards obtained seems to prove that the first statements on this point were not quite accurate, and I believe that one important feature of the patient's malady was defective menstruation. Before the treatment began she had a slight menstrual discharge only a fortnight after the previous period, and when in February she continued "unwell" four days, the discharge was said to have been more copious than formerly. It is clear, indeed, that the treatment adopted caused this function to be performed more completely with respect both to its duration and copiousness. I must observe, however, that I do not regard the irregularity and inadequacy of the uterine secretion as causes either of the pain, the sickness, the constipation, the coldness of the extremities, or the fits from which the patient suffered. They were each, I believe, co-ordinate symptoms of one common cause—a congestive condition of both the spinal cord and the ganglia of the sympathetic nerve. When this condition was removed these symptoms disappeared. It is instructive to observe how quickly they denoted the beneficial change which was being wrought in the patient's system. On the first recurrence of menstruation after the treatment had been adopted the pain was limited to ninety minutes, and though nausea was still felt, vomiting occurred only twice. On the next occasion the pain, though it lasted about an hour, had become "very slight," and there was no vomiting and no nausea whatever. By January 19, the constipation of the bowels had already lessened; and by the 27th they had become open daily. In nine days from the beginning of the treatment the extremities had become warm, and they continued so. With the exception of a slight wave of vertigo without loss of consciousness on February 18, not one single fit occurred during the whole time the treatment was continued, and excepting the one fit which happened in the beginning of March while the treatment was omitted because the patient had taken cold, she continued quite free from attacks during six months—viz., from January 10 to July 9, 1864, the last date at which I heard from her.

(a) I am led to form this opinion by the recollection of a case (an account of which was published in one of the Medical journals) of a girl who suffered both from the blue disease and from hare-lip. When three years old, she underwent an operation for the closure of the lip. As a preliminary proceeding it was necessary to cut through and bend downwards the abnormally projecting premaxillary bone. In consequence of the presence of cyanosis, the Surgeon did not give chloroform. The division of the premaxillary bone caused such a shock to the patient that she fainted, and remained so long unconscious as to make the Surgeon fear she might not recover. At length, however, she returned to consciousness, and astonished him by the rosy hue of her lips and cheeks, now suffused with arterial blood; whereas up to the time of the operation, owing to the circulation in them of semi-venous blood, they had been blue.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

KING'S COLLEGE HOSPITAL.

LIGATURE OF BOTH EXTERNAL ILIACS FOR ANEURISM OF COMMON FEMORAL OF BOTH SIDES—SUCCESSFUL ON THE RIGHT SIDE—LIGATURE OF LEFT EXTERNAL ILIAC SOME MONTHS AFTERWARDS—DEATH FROM SECONDARY HÆMORRHAGE AND PYÆMIA—AUTOPSY.

(Under the care of Mr. HENRY SMITH.)

CHARLES B., aged 45, was admitted on May 30, 1864, with aneurism of the common femoral of both sides; a thin, spare-looking man; always enjoyed good health. No evidence of arterial disease elsewhere. His attention was first drawn to the fact of his having aneurism by noticing a swelling in his right groin about a fortnight before admission. The swelling on the left side appeared some few days afterwards. The aneurisms at the time of admission were about the size of a pigeon's egg. When he first came into the Hospital a horse-shoe compress was applied to his right groin; this caused great pain, and did not effectually control the pulsation, owing to the difficulty of keeping it in position. Carte's hernia apparatus was applied to the tumour on June 1, but was discontinued, owing to the pain and excoriation produced by it. Pressure was also applied to the left groin.

On July 11, Mr. Smith proceeded to perform the operation of ligature of the right external iliac as follows:—Chloroform being administered, he first made an incision about three inches long through the skin and fascia, parallel to Poupart's ligament, and about an inch above it. He next divided the tendon of the external oblique muscle and some of the fibres of the internal oblique on a director, then the fibres of the transversalis and its fascia in the same way. Pushing aside the peritoneum, the artery was readily found, and a ligature placed round it, and the external wound closed by three stitches. The lower limb covered with cotton-wool.

13th.—Leg warm and comfortable; suffered some pain in the abdomen, but was relieved by vomiting; abdomen tender, but not tympanitic. Beef-tea; 4 ounces of brandy.

14th.—Skin moist; tongue slightly furred; leg warm and perfectly easy; pulse 77, and regular. To take Ammon. sesquicarb. acid citrat., āā. ʒij.; aqua, ʒviij., 4tis hôris.

15th.—Thirsty; skin hot, but moist. Pulse 76.

16th.—Pulse 70; respiration 21 (during sleep).

18th.—No pulsation in sac of aneurism; external wound nearly healed.

The ligature came away on the 27th, on the sixteenth day after operation. Discharged on August 15.

Re-admitted on March 28, 1865, for ligature of left external iliac. Since his discharge in August he has been remarkably well in health, the right leg giving him no inconvenience beyond a little numbness. The cicatrix of the wound in the right groin is quite firm and hard, though there is a slight tendency to protrusion of the bowel, for which he has worn a truss. The tumour on the left side has increased slightly in size since he went out.

On May 7 a similar operation was performed to that on the right side. In this instance, however, the deep epigastric artery was tied, being divided in the operation.

8th.—Passed a very good night; leg warm; complains of a little pain over the abdomen; pulse 86; has a bad cough. Ordered tr. camph. co., ʒij.; mist. acac., ʒj.; aq. ʒviij. ter die.

The ligatures from the main artery and from the epigastric came away on May 22, fifteen days after the operation. He went on very well until the 25th, when hæmorrhage suddenly broke out, and he lost about four ounces of blood. Pressure was applied, and the bleeding controlled. A dose of morphia was administered, and a bag of ice applied to the wound.

The bleeding recurred at intervals up to the 27th. In the evening of the 27th Mr. Wood, in Mr. Smith's absence, opened up the wound to tie the artery higher up. When the ligature was placed on the vessel, blood was seen coming from below the point of ligature; a large clot was turned out, and a thick jet of blood was found to proceed from a large hole in the sac of the aneurism. Mr. Wood tried to put a ligature round the bleeding point, but the coats of the sac were rotten and gave way. He then plugged the sac with lint steeped in

tr. ferri. perchlor. The external wound was then closed, and a pad tightly strapped down on in. Pulse 104, after operation. Ordered eight ounces of brandy in twenty-four hours. With the exception of a bad cough, he went on well until the evening of the 29th, when he was seized with an attack of shivering, his abdomen being slightly tympanitic. Pulse varying from 136 to 140.

June 1.—Abdomen very tympanitic; violent vomiting. Death, June 2.

Post-mortem, *June* 4 (from Case Book, vol. 1).—The intestines much distended with flatus; no signs of peritonitis. The cellular tissue between the iliacus and psoas and peritoneum covering them was infiltrated with pus. The last ligature was found lying loose upon the muscles. Pus oozing from internal iliac and epigastric veins on left side. The circumflex iliac below the first ligature was pervious. The internal circumflex artery came from the back of the sac; the profunda was also involved in it. The external circumflex arose normally. The deep epigastric and obturator, which arose together, were both pervious. The superficial femoral was quite pervious and much enlarged. The common femoral vein was entirely filled with a firm coagulum. There were signs of suppuration in the sac itself, and a thin layer of lymph at the commencement of superficial femoral. There was an aneurism of the abdominal aorta opposite the second lumbar vertebra. Viscera healthy.

ST. GEORGE'S HOSPITAL.

EFFECTS OF WORKING IN PHOSPHORUS.

(Under the care of Dr. J. W. OGLE.)

James D., aged 34, a worker in phosphorus, applied, owing to bleeding from the gums, redness and soreness of the lining of the cheeks, the mouth feeling as if "all on fire," and irritated by the air breathed. In many parts patches of the mucous membrane were quite destroyed. He complained, also, of being heavy and dull, and inclined to sleep. The pupils were equal, but dilated. He generally worked with "white" phosphorus, and had been doing so for two years; latterly, he had worked in black phosphorus, which evaporates more than the other, and also at times had to work in arsenic and mercury. He stated that on previous occasions the mouth had been tender. He had lost flesh of late. No symptoms of other disease were discovered. He was ordered quinine and steel, with nitric acid, three times a-day, and a lotion for the inside of the mouth of tannic acid, spirits of wine, and the compound decoction, with the tincture, of bark. He gradually improved, remaining absent from the workshop and continued his medicines for a month, when he discontinued attendance, as being well.

PECULIAR HYSTERICAL CONDITION OF VOICE—TEMPORARY DYSPHAGIA IN SWALLOWING SMALL PORTIONS OF FOOD—RELIEF FROM VALERIAN, QUININE, AND ETHER, GALVANISM, AND SHOWER BATHS.

(Under the care of Dr. J. W. OGLE.)

Francis C., aged 37, a thin, excitable looking man, had for two or three years been liable to hoarseness, and also to dysphagia at times. In swallowing he could, when affected, always manage a large piece, but could not manage a small piece of solid food. There was no cough, but he had a thin, weak voice, exactly like that of a young girl. He had not lost flesh. He stated that at times his voice was quite natural, but that the peculiar squeaky character would be brought on by any exertion, also by cold air, and was worse at the change of weather. The pulse was natural; the various organs on close examination appeared sound. At first I gave him a mixture with oxymel of squills, but soon changed it for valerian, the chloric ether, and the compound steel pill. The throat was also galvanised every other day.

At the end of ten days he said he was much improved, and certainly his voice was better. Later on he took quinine and iron, and had shower baths every morning. After using the shower baths two weeks, he stated that he had not once lost his voice during their use, and at the end of three weeks more he observed that the exception was to lose the voice. Subsequently, he complained that after walking far or very quickly his voice would at times become squeaky. For three or four weeks more he continued his remedies, and then ceased to attend, but rarely having any peculiarity of voice, and never any dysphagia.

PULSATING TUMOUR (FREE FROM THRILL) ABOVE THE RIGHT CLAVICLE, WHICH PROVED TO BE OWING TO A BILOCULAR ANEURISM SPRINGING FROM A DISEASED AORTA—RUPTURED AND DISEASED AORTA VALVE FLAPS.

(Under the care of Dr. J. W. OGLE.)

James C., aged 47, was an out-patient, under the care of Dr. Ogle. He had enjoyed general good health until four years previously, when immediately after lifting a heavy weight he felt an uneasy sensation about the chest, and brought up a quantity of blood of a scarlet hue. Since that time he had brought up blood, with a considerable cough and dyspnœa which he had every winter. Two weeks before his application at the Hospital he noticed a tumour pulsating in the right side of the neck; this had remained stationary in size. His countenance was pallid, his lips blue, the conjunctivæ of the eyes yellow. There was much orthopnœa; the impulse of the heart was increased, the apex beating slightly to the left of the nipple, and there was a loud systolic bruit at the apex, diminishing towards the base, but from the base upwards again increasing towards the inferior clavicular region of the right side. Immediately above the right clavicle was a pulsating tumour, of about the size of a small orange, beneath the sterno-cleido-mastoid muscle. Over this a distinct bruit was audible, but there was no thrill connected with it. Loud musical râles existed at the lower parts of both lungs behind, and there was much cough, attended by thick mucous expectoration. The extremities were cold. The pulse was somewhat jerking, but the same at both sides. There was œdema of both legs. The tongue was coated, but moist; the bowels quite regular. I ordered him the tincture of digitalis 12 drops, with the spirit of chloric ether and camphor mixture, every six hours, and 5 grains of the compound storax pill every night. I only saw him once alive again, when I substituted the spirit of nitric ether and tincture of squill, with nitrate of potash, for the other medicine. He died suddenly three weeks after he first appeared at the Hospital, and I got permission to make an examination of the body at his own house. This I did with the assistance of Mr. Henry F. Smith and Mr. Cartwright.

On post-mortem examination I found the lungs much congested posteriorly, and the kidneys also very congested. The pericardium contained a slight degree of fluid. The heart was very large, its cavities much larger than usual, containing loose coagula, and their walls thickened. The walls of the arch of the aorta were occupied by much atheromatous and calcareous matter. The aortic valves were much thickened, and occupied by calcareous matter, and one of its segments was torn down from its attachments. Springing from the arch of the aorta was a bilocular aneurism, pressing upon and involving the large innominate vein; it was one of the compartments of this aneurism which had been felt and seen as a tumour above the right clavicle.

MIDDLESEX HOSPITAL.

A CASE OF INFLAMED SEROUS CYSTS IN THE GROIN AND PERINEUM SIMULATING STRANGULATED HERNIA.

(Under the care of Mr. J. W. HULKE.)

February 21, 1863, at twelve o'clock at night, a boy, aged 9, was admitted into Percy Ward. In his left inguinal canal was an elastic, oblong swelling that descended through the external ring, between the scrotum and thigh, into the perineum, as far as a line drawn between the ischial tuberosities, instead of taking the usual course of a rupture into the scrotum. The perineal end of the swelling was rounded and well-defined, while the upper end was obscure and lost at the external ring. The belly was tender. The groin and scrotum were red and œdematous, and the left side of the latter was distended with a solid swelling, evidently an inflamed testis, which was separated by a shallow vertical groove from the inguino-perineal tumour. He retched incessantly, and his bowels had not been open for three days. These symptoms were said to have begun suddenly, two days before, while he was in good health.

From its characters, its apparent escape from the belly through the internal ring, its situation in the inguinal canal, the constipation and retching, collectively, Mr. Hulke inferred that the tumour was probably an inflamed, strangulated hernia, complicated with orchitis, the latter probably due to the persevering use of the taxis; but the unusual direction of

the tumour after leaving the external ring, with the possibility that the retching was symptomatic of the orchitis, and the constipation accidental, occasioned him some doubts. The deviation of the supposed hernia into the perineum was the most suspicious point, since a rupture, at the boy's age, would almost certainly have been of the congenital variety, and its descent into the perineum would have been preceded by the misdirection of the testis to this region. An example of this had been seen by Mr. Hulke several years before, but in the present case the left testis was in its proper place, and the rupture was as plainly not in the tunica vaginalis.

The inflamed state of the parts precluding a further trial of the taxis, it was resolved to make an exploratory operation. An incision in the long axis of the inguinal swelling laid bare a thin membranous sac, deeply girt by the external ring. This was divided without relief. The sac was opened and about an ounce and a-half of clear yellow serum ran from it. It was an oblong cavity about one and a-half inches long, ending above in two short, blind diverticula at the internal ring, while below it communicated by a small aperture in the level of the middle of the scrotum with the perineal swelling. This was next laid open. It contained only serum and fibrinous clots, but a second deeper swelling was felt through its posterior wall. This was another cyst of less regular outline than the superficial one. Its only contents were an ounce of serum. It was now evident that the cysts were not a hernia. The boy was placed in bed and the wound poulticed.

The retching continued until 6 o'clock p.m. on the 22nd. His pulse was 128, and the perineum much inflamed. The belly was soft and painless. Constipation persisting an enema was given, but it was soon expelled without fæces. Next day the inflammatory swelling was greater, and his pulse had risen to 140. In the evening three grains of calomel were ordered, and on the following morning he passed three very copious stools. From this time the orchitis subsided. A small superficial abscess burst through the front of the scrotum. The cysts suppurated and were obliterated, and the wound healed soundly. At the patient's last visit, May 18, the only trace was a hard cord running from the back of testes to the groin and perineum. The connexion of the scar with the lower part of the spermatic cord makes it not improbable that the cysts originated in some of its structures, perhaps in an unobliterated portion of the vaginal process, and were really encysted hydroceles of the cord. Orchitis occurring, inflammation extended to them from the testes, and the scrotum being distended, the rapidly-enlarging hydroceles took the direction of least resistance towards the groin and perineum.

WEST NORFOLK AND LYNN HOSPITAL.

CASE OF DIAPHRAGMATIC HERNIA CAUSED BY A HEAVY WEIGHT PASSING OVER BODY.

(Under the care of Mr. KENDALL.)

[Reported by FLEETWOOD BUCKLE, M.D., House-Surgeon.]

JAMES G., aged 40, a strong, healthy labourer, in attempting to get on to the shafts of a cart (containing a ton of hay) whilst in motion, slipped and fell, and the wheel passed over his body obliquely from the right hip to the left shoulder, January 21, at 3 p.m. He was picked up and brought to the Hospital, where he arrived at 11 p.m. On admission he was in a state of collapse, and his friends stated that he had vomited a considerable quantity of blood. The right tibia and fibula were found to be broken, the skin lacerated, and a piece of the bone driven into the muscles of the calf forming a compound comminuted fracture. Slight bruise over right hip, none elsewhere; no ribs broken. The leg was set, and stimulants administered, when he seemed to rally a little, and passed a quiet night, with the exception of occasional sickness, each time bringing up a large quantity of dark, thin watery fluid.

On the 22nd he appeared a trifle better, but complained of pain and tightness across chest. The abdomen was flat, not tympanitic, nor was it tender. The sickness continued at intervals, causing but little pain. An effervescing draught with ammonia and burnt brandy was ordered every three hours. At 3 p.m. he complained of more pain in the region of the liver; a hot fomentation was applied, but had to be removed, as he said it increased his discomfort. Pulse 104, small. Skin warm. Bowels not open since accident. A beef-tea enema was administered and retained. 10 p.m.—Sickness continues; more tenderness over liver; pulse 120, small, sharp; resp. 24, thoracic; no respiratory murmur down left side, and resonance increased; free breathing down right side with some crepitation towards base; decubitus dorsal and inclined to right side; ice to suck. Omit all else by mouth; continue enemata of beef-tea every four hours.

January 23, 4 a.m.—Restless and wandering; skin warm and moist; pupils much dilated; pulse 124; resp. 38; more worried; no sleep; sickness continues. Unable to pass water, so drawn off by catheter; sp. gr. 1021, normal, no albumen. 12 noon.—Sickness not quite so frequent, otherwise same. 4 p.m.—More restless; aspect anxious; pupils widely dilated; pulse 136, smaller; resp. 32, short catching; sickness constant; increased pain over liver. From this time he gradually sank, the respirations becoming shorter and more difficult, and an accumulation of mucus obstructing the bronchial tubes of the right side, which he had no power to bring up. All enemata retained. Nothing passed by bowels since accident. Died quietly at 11 p.m., fifty-six hours after accident.

Autopsy Fourteen Hours after Death.—On opening the chest the diaphragm was found ruptured to the extent of four inches, from the tendinous portion downwards and towards the left side, a straight slit in the direction of the muscular fibre; through this opening the stomach, transverse colon, and about two feet of the small intestines had protruded, filling up the left side of the chest, compressing the lung against the spine, and slightly pushing over the heart. Other organs found healthy, but congested. Right lung in a state of œdema.

CASE OF FRACTURED PATELLA IN AN OLD MAN TREATED WITH MALGAIGNE'S HOOKS—GOOD RESULT.

Henry R., aged 70, a fairly healthy old man, in getting out of bed caught his toe in the clothes, and fell to the ground. On attempting to rise he found he had lost the power of extending his left leg. He was therefore brought to the Hospital August 31, 1864, at the time suffering severe pain in the knee-joint. On examination the patella was found to be fractured transversely, the lower portion being much the larger. The smaller fragment was drawn up about three inches, and considerable swelling had taken place into the tissues around. The fragments were brought into as close apposition as possible by means of pads, plaster, and bandage, and he was placed upon a fracture bed, with head and heels raised to relax the quadriceps muscle. As there was some difficulty in retaining the fragments *in situ*, it was determined to apply Malgaigne's hooks, which were accordingly fixed August 27, causing but little pain, and no irritation of consequence. Full diet and beer Ojss. daily. By October 8 the bones were found to be united, and the hooks were consequently removed; but unfortunately shortly afterwards he got an attack of erysipelas in the leg, followed by considerable œdema, which kept him in bed for another three weeks, when he was able to get about with the aid of a stick, a short back splint being applied. He was then made out-patient.

January 8, 1865.—Splint removed. Can bend knee well, and walk with the aid of stick. General health good.

February 28.—Quite well; gets about without assistance. A slight depression about one-eighth of an inch broad indicates the situation of the fracture.

DEATH FROM CHLOROFORM.—A remarkable instance of this occurred to Assistant-Surgeon Wagner, United States' army, at the Beverley Hospital, New Jersey. A private was admitted for a gunshot wound calling for amputation of the leg. Chloroform was administered during the operation without ill effect. Sloughing of the flap supervened, and the bones so protruded that on November 15 a second operation was determined on. At this time his general condition was favourable, and there was nothing in his appearance nor any symptom present to contraindicate the employment of chloroform, except nervous agitation arising from dread of the operation. About half an ounce of chloroform was administered upon a sponge, the room being well ventilated at the time. The patient had been under its influence about fifteen minutes when he began to sink, and in about five minutes death took place. Six Surgeons were present, and the ordinary means of restoration were tried in vain. At the autopsy the heart and lungs were found quite healthy. On the first occasion the chloroform had been administered in much larger quantities.—*American Journal Med. Science*, January.

SATURDAY, MARCH 11.

MODERN SYPHILOGRAPHY.—No. VII.—*Continued.*

THE COURSE, VARIETIES, AND PATHOLOGY OF SYPHILIS (INTERNAL SYPHILIS, ETC.)

(Continued from page 230.)

Before we discuss the facts which morbid anatomy has brought to light, we must call attention to M. Diday's late work,(a) which we had not read until after the earlier numbers of these papers were written.

In the "Natural History of Syphilis" we have the labours of a keen and sagacious observer conveyed to us by an extremely pleasant and acute writer. The work is bold in design, and abounds in original and suggestive doctrines. M. Diday has had the courage to watch the evolution of syphilis, and to study the natural course of the phenomena undisturbed by specific treatment. He has endeavoured to account for the various degrees of intensity of the syphilitic manifestations in different cases, and makes a plausible attempt to reduce the varied and conflicting phenomena of this disease to something like uniform laws. The work is too long, and contains too much "backbone" for us to give anything like a fair analysis of it. Let it suffice that the author is a strong supporter of the duality or non-identity of the poisons which produce the indurated chancre and the local venereal ulcer, and that he recognises two different types of *syphilitic* infection—the weak and the strong—as the result of his extensive series of observations. Discarding the hypothesis of the existence of several poisons, he regards differences in the sources of infection as the main causes of the different degrees of severity. He has endeavoured to classify the special symptoms by which the weak and the strong types of syphilis are marked, and he deduces very important therapeutical conclusions from his inquiry. Most of his conclusions have been already published and canvassed by the Medical journals, and we have ourselves had on many occasions to advert to his labours as a Syphilographer. We strongly recommend every one, however, to read the book for themselves.

Imprimis, we will speak of the morbid deposits which belong to the disease, and we shall then be better able to appreciate how far the character and condition of these products afford an indication of the forms, stages, and different conditions of health which belong to the disease.

The pathological course of syphilis—as far as it is patent to our senses—appears to proceed in that structure which is denominated the connective tissue, or modifications of it. There is a tendency to the production of a lowly organised lymph in various parts; for example, in the integument, the mucous membrane, the iris, the periosteum or bones, the cartilages of the larynx, the throat and tongue.

It is the interstitial effusion super-added to the original lesion, be this a pimple or abrasion, that constitutes the important anatomical feature of the true chancre. The impression which the touch derives from an indurated sore is,—that it is composed of a dense fibroid material. Such, however, does not appear to be the case—at any rate, where the induration is not of more than seven or eight days' standing. We had the opportunity of microscopically examining two specimens of induration recently. In the first, the tissues of the dermis and the more superficial layers of areolated tissue were swollen and infiltrated with new products, composed of cells,—granular and nucleated, and, for the most part, of very small diameter,—embedded in a granular basis. The sore had been exposed to some irritation, so that the cells upon the surface of the ulcer resembled ordinary pus. Around the periphery, however, they were small, granular, ill-developed, and bounded by cloudy bands of connective tissue, in the meshes of which were little depôts of new and very elementary growths. No new fibre existed apparently. In the second, a "ball" of induration, which had remained for four years after the healing of a chancre, was excised and examined. It felt like a small firm tumour, encapsulated by the connective tissues circumscribing it. The histological elements were essentially such as we have described: numerous cell growths, in some places still germinating apparently, and at others undergoing a fatty degeneration, and interpenetrated by delicate fibres of connective tissue. Upon the addition of the iodine test, which we had the curiosity to apply, a well-marked reddish-brown colour was developed.

Now, the character and pathological changes in these products of syphilis can be thus explained:—Being infiltrated into, and intimately combined with, the normal tissues, they give rise, according to their amount, to a papule, a tubercle, or Hunterian induration. These growths, possessing little succulency, and being often unaccompanied by inflammatory phenomena, it follows that the primary lesions of true syphilis possess a circumscribed firmness, different from a mere inflammatory swelling. By their disintegration at the surface of a sore, and by their absorption from beneath it, there may remain little or no loss of substance on their removal, or a band of fibroid thickening may exist in the midst of atrophied tissues.

The products which occur during the later stages of syphilitic cachexia are composed essentially of the same elements, and they appear to arise in the same way—a proliferation of nuclei in the cells of connective tissue.

When syphilitic exudations occur in internal organs we can understand how the functions of these will be impaired according to the amount and the site of the deposits, and the metamorphoses going on in such deposits. It can scarcely be asserted that they have any special and constant histological characters by which they may be differentiated from the products of other diseases. They possess, however, certain characters in common, which are very suggestive of their origin. They are frequently discovered in the bodies of syphilitics—as Dr. Aitken emphatically declares—and, when a history of syphilis can be traced, there does not seem to be much room for doubt.

The lesions, produced in the viscera by syphilis, may be grouped under the following forms:—1. Gummata, or Tumours; 2. Interstitial inflammations; 3. Cicatrices; 4. The amyloid or waxy degeneration of vessels and internal organs may also be reckoned among the remote effects of the syphilitic cachexia.

The *Gummata* are well-defined tumours, firm and elastic, or succulent and soft. They tend to undergo some shrinking, deliquescence or softening, and to assume the characters of a gummy or a semi-purulent fatty material, according to their age, site, and the quality of the morbid material composing them.

The *Interstitial Inflammations* are characterised by effusion of a material composed of cell germs and elementary fibre into the meshes of a parenchymatous organ. From the subsequent changes in this, we have various degrees of atrophy

(a) Histoire Naturelle de la Syphilis. Par le Dr. P. Diday. 1863.

and contraction, giving rise to furrows, depressions, and fine bands on the surface of organs, and to a peculiar form of cirrhosis in the liver—according to M. Lancereaux—or to an induration, softening, and interstitial inflammation of the kidney, lungs, etc.

The *Cicatrices* are but the markings and effects of some previous disease, appearing as puckerings, depressions, and furrows. Fibrous bands or cysts may frequently be traced in connexion with them.

The *differentiation* of these syphilitic products from inflammatory deposits, cancerous growths, fibrous and fibro-plastic tumours, tuberculous and scrofulous deposits, etc., is most carefully laid down by Dr. Aitken.

The exact changes which occur in the syphilitic affections of the brain and nerves have not yet been fully investigated, although the subject has had many inquirers—Continental and British. According to Dr. Wilks's experience, the new material has been observed upon the surface of the brain and involving the membranes. The character was uniform, and consisted in the union of the brain and membranes by a firm exudation, similar to that met with in other parts, the neighbouring bone not being necessarily affected, although this was once supposed to be the case.(b) Gummata and syphilitic nodules may also occasionally be found in the brain substance and in the tissue of the nerves, according to some observers.

Among the nerve lesions witnessed in syphilitic subjects, paralysis of a motor nerve of the eye is not uncommon: the third pair of nerves are the most frequently, then the sixth, and the fourth pair the least frequently affected. In these cases Von Graefe traced a constitutional taint in nearly half of those he met with. In Dixon's two cases,(c) a tumour—surmised to be syphilitic tubercle—was found in the substance of the nerve. We have ourselves seen more than once in syphilitic subjects, an affection of the orbit, giving rise to undue prominence of the eyeball, diplopia, pain, and lacrymation. Syphilitic affections of the internal eye (retina and choroid) are recognised forms of disease, and there are some very beautiful plates illustrative of the appearances under the ophthalmoscope in Liebrich's "Atlas d'Ophthalmoscopie."

Dr. Eade, of Norwich, published a highly interesting and suggestive paper, not long ago, upon "Syphilitic Albuminuria." He traced a connection between the renal symptoms and the syphilitic disease, and—what was of much practical importance—he showed that these cases were very amenable to the action of such remedies as iodide of potassium, etc. It is probable that these were instances of the interstitial inflammation of which we have spoken.

Not only may the presence of the syphilitic poison be the cause of numerous deposits in various organs, but it may induce an impairment of the constitution corresponding to the cachexia resulting from other diseases; and we may discern a similarity in the pathological products, as much the effect of the cachexia itself, probably, as of the syphilitic virus. There would seem to be good reason for thinking, for example, that amyloid degeneration may have as intimate a connection with the syphilitic as the tuberculous cachexia. Virchow and, quite recently, Dr. Grainger Stewart, of Edinburgh, have furnished some important evidence of this.(c)

Instances of the following may be occasionally met with in the subjects of syphilis who have, perhaps, been put fully under the influence of mercury at some prior date:—

An individual suffering from a wasting disease brings a history of the following train of symptoms:—Increasing weakness; increased flow of urine (50—200 oz. daily); increased thirst; ankles and feet œdematous after a day's exertion, but subsiding after a night's repose; urine of low specific gravity (1005 to 1015), slightly albuminous, and occasionally exhibiting a few waxy casts; some hypertrophy of the liver and spleen. Upon this, diarrhœa, bronchitis, general dropsy, etc., may supervene. These are the cases of amyloid kidney, so ably delineated by Dr. Grainger Stewart, and the syphilitic cachexia is undoubtedly one of its causes.

Our space will not permit anything more than the bare mention of those syphilitic diseases of the lung which mimic pulmonary phthisis so closely, and which, indeed, may be the product of the tuberculous and syphilitic diatheses combined.

The *syphilitic diseases of bone*—particularly the lesser forms of these, which are commonly overlooked—are particularly deserving of attention. Virchow declares that lymph is not only effused beneath the periosteum, but into the canals of the bone, and that either an ossification, or a softening and caries may take place. Traces of these affections are occasionally found upon the cranial and other bones of syphilitic subjects where no suspicion of them existed during the lifetime of the patient.

The reader is referred to Dr. Aitken's book (e) for an ably-written summary of all our present knowledge of these internal syphilitic lesions; and for the symptoms and pathology of congenital or inherited syphilis, he may consult the very admirable works of Mr. Hutchinson, M. Diday, and Professor Simpson.

The diagnosis is not wanting in practical importance, for the cases in which the syphilitic element is present cannot be so infrequent as imagined, and they possess, as a whole, marks which distinguish them from ordinary inflammations and diseases, and they are ofttimes very amenable to the action of appropriate remedies.

THE WEEK.

PROFESSORS SYME AND SIMPSON.

In another column we are glad to print a letter from Professor Syme, which goes far to remove the most offensive features of the public destruction of Professor Simpson's pamphlet. Of course Professor Syme is not obliged to give in his adherence to any new system of suppression of hæmorrhage, and the new operation of acupressure can but be benefited by the fullest discussion of all the objections which can be brought against it by so acute and experienced a Surgeon as Professor Syme. If the quarrel be merely one about supposed discourtesies of manner, we can only express our belief that if anything has fallen from Professor Simpson's pen which can be called offensive, he will be the first to retract it. If we venture to do so with due regard to delicacy, we will offer one word of comment on Professor Syme's letter. He seems to lay stress on the fact that the Professor of *Midwifery* has meddled with a subject strictly *Surgical*, as if the whole of Professor Simpson's labours on acupressure were a kind of intrusion on ground already appropriated. We believe the truth to be that the investigation into the safest and best mode of suppressing bleeding arose quite incidentally in the course of Professor Simpson's inquiries into the causes of mortality after Surgical operations, and on this point we must say that great benefit is likely to arise to humanity from the circumstance that an energetic Professor of Midwifery has done for Surgeons what Surgeons ought long ago to have done for themselves. No obstetric professor in Great Britain could go on calmly, with folded arms, whilst patient after patient was dying after parturition; and, comparing the lining surface of the womb after child birth to the equally raw and bleeding surface left after a Surgical operation, Professor Simpson inquires whether the same causes which destroy patients in the one condition are not found to

operate against the others also. The Surgeons should have been beforehand with Professor Simpson, and have done the thing themselves; but they have no right to be angry if he reaps the laurels which they themselves were too dignified, or self-satisfied, to stoop to gather.

THE PATHOLOGICAL SOCIETY'S "TRANSACTIONS" AND INDEX.

If ever book had special claims to the eulogy of a Medical journal, it is the new Index to the Pathological *Transactions*.(a) As we learn from a preliminary notice, and as every one engaged in the pursuit of any branch of Medical science must have felt, a general index to the enormous mass of matter dispersed throughout the fifteen volumes of the Pathological Society's *Transactions* was most desirable. But who could be found to undergo the labour of compiling? and whence the funds to defray the cost of the work? Mr. T. Holmes, than whom no one could be better qualified to do such a task with accuracy and lucidity, generously undertook the literary part; Mr. Prescott Hewett, whose presidency of the Society has been marked by more than usual activity, success, and harmony, undertook the cost, and has presented the volume in its present form to the members of the Society. The index is a double one—first of subjects, most minutely classified, then of authors, with an accurate list of their contributions. If Abernethy, whose attempt at classification of tumours from their resemblance to natural structures would now provoke a smile, could re-visit the scene of his earthly labours here, he would stare at the list of thirty-five tumours in the Index, besides about a dozen or more undetermined.

THE DIRECTOR-GENERAL'S RECRUITS.

We publish in another column a list of the candidates who have been successful in the examinations of the Army Medical Department. We may notice it as a fact that out of 77 gentlemen

9	,,	London.

COMPULSORY CERTIFICATES OF DEATH, SCOTLAND.

A special meeting of the Glasgow Medical Association was held on February 27, to consider the best mode of attempting to procure a repeal of that section of the Registration of Deaths Act by which the Medical Practitioners of Scotland are obliged, under penalty, to give certificates of death. In our Parliamentary report last week we noticed the curt refusal of the Lord Advocate to take any steps to relieve our Scotch brethren from this most unjust enactment; and it appeared from letters read at the above-mentioned meeting that appeals to the Lord Advocate had only elicited the certainly not very courteous response, that it was "no part of his Lordship's official duty to answer such questions" as were put to him about the working of the law, questions which "related to matters which might be made the subject of criminal prosecutions." It being thus amply evident that the Profession had nothing to expect from the justice or the courtesy of Government, the Association have determined, with the advice of Dr. Christison, to use all the strength of the Profession to bring forward a bill on the subject in the new Parliament. We hope every Medical man in Scotland will bear this subject in mind when candidates come forward at the General Election. It is quite evident that it is only by a determined exercise of their personal influence and power that they can hope to obtain the repeal of this obnoxious law, the insult and injustice of which are rendered more glaring by the fact that it applies to no part of the United Kingdom except Scotland. The Profession elsewhere may also note this as one of the many proofs that Government is always ready to demand and enforce gratuitous work from them, though never willing to afford them any protection or support—a mode of treatment to which it does not venture to subject any other of the learned Professions.

SOUTH AMERICAN BEEF.

For more than a year we have had on our table a parcel of some of the earliest imported dried beef from South America—the same, we believe, which was specially reported on by Dr. Mapother, of Dublin, who was amongst the first to recommend it to the notice of his Professional brethren and the public. Of late rather unpleasant rumours have been afloat respecting the quality of much of the beef which is at present offered in London for retail sale to the working classes. These rumours took a more decided shape on the appearance in *The Times* of Tuesday of a report of proceedings before the Lord Mayor, which resulted in the condemnation of a large quantity of beef, which had been seized by the City Inspectors at the shop of Mr. Harper Twelvetrees, in Bishopsgate. It appeared to us that the report was spiced with irrelevant matter, calculated to prejudice Mr. Twelvetrees in the eyes of the public. We therefore procured specimens of the beef that had been condemned in the City. The first was moist, salted beef, in large rolls. It looked of a good colour, had no unpleasant smell, and tasted quite sweet. We directed a piece weighing about three pounds to be soaked for an hour in cold water, then to be put into a stewpan with water; after about a quarter of an hour's maceration the first water to be thrown away, then more water to be added, with carrots, turnips, and onions, so as to make a stew *secundum artem*. Alas! when the beef had been stewed about three-quarters of an hour, on lifting the lid of the stewpan, the cook was almost knocked down by a disgusting odour, which, be it observed, had not been perceptible at the earlier part of the operation. Nevertheless, the cooking was finished and the dish presented; but no sooner was the cover removed than there was a general *move* on the part of those who were curiously expecting it; and a poor wretch from the streets was bribed to take it and throw it on the nearest dungheap. Evidently the meat had become tainted before it was cured, and the antiseptic process, though sufficient to arrest or disguise decomposition, still could not restore the meat to a fresh state; and so soon as it was softened and prepared for the stomach the ill odours began to revive. The *dry jerked beef* was also quite sweet to the taste; it looks like leather or gutta percha in strips, and when soaked and cooked, though a little hard and lean, was quite nice and relishable. We shall experiment further and report on it, and meanwhile hope that an occasional failure like this will not deter merchants from importing this much-needed beef, but that greater care will be taken in the original manufacture.

PARLIAMENTARY.

An important debate took place in the House of Lords on Monday last, on the subject of Military Hospitals. The Earl of Dalhousie, who opened it, is the nobleman to whom is due whatever credit may attach to the choice of the site and the erection of the Hospital at Netley. Nor did he, on Monday night, abstain from indulging in a fair *quantum* of self-gratulation on the success of Netley and a proportionate amount of reflection on those who had opposed the situation and the plans on which the Hospital is built. He said that he had visited Netley, and been assured by the Medical officers that its situation was not unhealthy.

"A Medical school had been established, and the arrangements made for the invaliding of soldiers who came from India and from our colonies were so complete that he was informed that within three weeks after their arrival such of

them as did not require Hospital treatment were discharged and forwarded to their places of residence without being exposed to or falling into the temptation of spending a shilling of the money with which they might arrive in this country. Under these circumstances he maintained that the success of Netley Hospital had been so great as to reflect upon those who in the first instance attempted to prevent its erection, and who had done their best to run it down as an establishment on which the public money ought not to have been expended. The only fault which he had to find was, that the quarters for the Medical officers had been curtailed of certain appliances, the plans for which were approved while he was in office, and all for a paltry saving of £4000 or £5000, which was struck off the Estimates by Lord Herbert when he was Secretary of State."

He then drew attention to the pier which is about to be ereeted for the landing of invalids at Netley, which, he said, would be insufficient to meet the wants of the Hospital. It would not extend far enough into deep water to allow transports to go alongside it. In reference to the new Hospital in course of erection at Woolwich, he said it had cost the public £200,000 :—

"He was prepared when he visited the building to see something singularly unique in its construction, but he found it was built upon the principles of those hygeists who, he thought, carried their opinions in this matter somewhat too far. It was certainly a most gorgeous Hospital, with a very handsome *façade*, in which there was no architectural fault. It was, however, built in blocks and wards of glass, in which, in his opinion, it would be absolute cruelty to put an invalid, as their lordships were doubtless aware that the first anxiety in illness was to relieve the brain and the eyes from too much light, whereas in these wards the plan seemed to be to introduce what he could only denominate as the glass and glare system. If intended for a flower show, the idea was admirable, or if for a museum, nothing could be more delightful ; but as a Hospital for the reception of invalids, nothing could be more absurd. The site was very unfortunate, as the building was erected upon the side of a hill, the foundations being laid almost entirely upon clay, and the result was that, to a certain extent, they had perished. He did not pretend to have any knowledge of engineering or of building, but he had inspected the building under the singularly favourable circumstances of being in the company of the contractor, his friend, Mr. Myers ; and although that gentleman naturally desired to gloss over these failures, there were so many formidable supports and buttresses still unremoved as showed him that the rents in the blocks were almost as likely to be fatal as 'the rent the envious Casca made.' The Hospital must have been built either for a general, a garrison, or a regimental Hospital. The site was wholly inappropriate for a general Hospital, and there did not appear to be any proposition for attaching to it any quarters for the residence of the Medical officers. With regard to the inappropriateness of its site, he need merely point out that army invalids coming from abroad in large transports, such as the *Himalaya* and the *Urgent*, which could ascend the river no higher than Gravesend, had to be transhipped into small steamers, which were obliged to discharge their passengers at the landing-place at Woolwich Arsenal, two miles from the Hospital. If it were intended for a regimental Hospital for the garrison at Woolwich, he thought the expenditure of £200,000 was most unnecessary, inasmuch as the garrison at Woolwich rarely exceeded 4500 men, and they possessed at present an exceedingly favourable specimen of the old style of Hospital capable of accommodating 330 invalids, although not more than 200 beds were ever required. When he visited that building the other day, he found that it required very little to adapt it to modern requirements. The new Hospital was to make up from 600 to 650 beds, which could never be required for the Woolwich garrison ; but, in any case, why remove the regimental Hospital from the situation where it was most required—namely, the vicinity of the troops who were to occupy it, and the residence of the Medical men who were to practise in it? Therefore, whether the building was intended for either a general or a regimental Hospital, he was prepared to show that it was not fit for the first, and that it was beyond the necessities of the second. He had further visited the regimental Hospital at Hounslow, which was also built upon what he would take the liberty of calling the glass and glare principle. It was a very pretty little Hospital, containing sixty-eight beds, but much larger than the necessity of the case required. Attached to it was a barrack for the accommodation of about five and a-half troops of cavalry. He found one wing of this Hospital shut and locked up, it never having been used ; but he was much gratified to find that the four small comfortable wards in which the worst cases of the Hospital were accommodated were as airy and quiet rooms as any of their lordships would desire in their own residences. The glass of the lower windows had been painted a dark green, in order to exclude that light it was the object of the designers to bring into the rooms. He was about to give credit for this to the commanding officer, but he was informed that it had been done by the directions of the Medical officers of the first regiment quartered there." He then proceeded to criticise the fittings of the Hospital, which he thought were too expensive, and in case of being broken entailed too great an expense for reparation. "He could not help thinking that all these, he must call them unnecessary knick-knacks in Hospitals were introduced partly from the habit which prevailed in the War Office of consulting hygienists not connected with the army. To a certain extent he believed he was to blame in this matter ; for at a time when it was absolutely necessary to put the Hospitals on a proper footing, and to adopt proper principles of hygiene, he did employ civilians for that purpose, because he did not find to his hand in the army gentlemen sufficiently educated in those principles, or, at all events, who had had experience in them ; but times had changed since, and the principles of hygiene were now studied by the Medical officers of the army with the same assiduity and zeal, and with the same desire to turn them to good account, as they were by civilians ; and when he looked at the *Army List*, he found that there was at this moment a branch of the War Department called 'the sanitary branch,' and that 'Inspector-General P. Logan, M.D.,' was at hand to advise the department in any matter of sanitary arrangement. He found also that in the Military Medical School at Netley one of the most distinguished authorities on the subject had been appointed Professor of Military Hygiene. Under these circumstances he could not see that it was at all necessary to have recourse to the advice of civilians ; but he was told that even up to this hour his old friend, Dr. Sutherland, whom he had consulted about the Hospitals at Scutari and other places, was still advising the War Office. The name of Dr. Sutherland was so hidden away on the list that he could not find out exactly where he was, but he had no doubt he was not far from the elbow of his noble friend, or from that of the Under Secretary for War. His noble friend ought at once to make up his mind to give up such a system, for he had connected with the Medical Department of the Army persons capable of advising him, and none more so than the Director-General of the Medical Board. In conclusion, he had to express a hope that in building Hospitals his noble friend would see that they were not merely Temples of the Sun, and that in building barracks he would see that they were something more than Temples of the Winds."

Earl de Grey, after referring to the alleged insufficiency of the pier at Netley, and stating that the present plan was adopted in consideration of the great difficulty of getting transports up to Netley at all, and that a new arrangement had been made, by which the Admiralty were to provide a special vessel for the conveyance of invalided soldiers from Spithead to Netley, directed his remarks to the subject of the new Hospital at Woolwich. He defended the "pavilion plan" on which it was built. By the pavilion plan was meant long galleries built out at right angles to a corridor, so as to leave light on both sides. That plan had been adopted in a new civil Hospital at Paris and in the new military Hospital at Vincennes. There appeared to be a great weight of competent authority in favour of the pavilion principle. The Woolwich Hospital was to be a general one, and to supplement that of Netley as a training place for Medical officers in the management of general Hospitals. Both it and the Hospital at Hounslow had been erected on the calculation that the sick would amount to 10 per cent. of the strength of troops, an average existing at the time of their construction. But recent hygienic measures had reduced the average to 7 per cent. With regard to the civil element in the counsels of the Secretary of War, his lordship said :—

"I think we ought to speak with gratitude of the great advantages we have derived from the assistance of civilians whose

*

suggestions for the improvement of the sanitary condition of barrack Hospitals have been adopted by successive Secretaries of State. With the noble earl, I look forward to the time when the Medical officers of the army will be possessed of as ample knowledge as any civilian upon the subject of sanitary hygiene. My noble friend alluded to Dr. Logan and to the Professor of Military Hygiene at Netley. Dr. Logan is a member of the Committee now consulting upon this subject, and the Professor of Military Hygiene is a civilian. That Committee was the work of Sir G. Lewis, who regarded its labours as of great value. There is, indeed, a Sanitary Committee which is consulted by the War Office. That Committee consists of the Quartermaster-General as president; of Dr. Logan, the head of the sanitary branch of the Army Medical Department, the head of the barrack-building branch, and Captain Belford of the War Office, who are *ex officio* members. The other members of the Committee are Captain Galton, who has done so much as an engineer for sanitary improvements, and Dr. Sutherland. I certainly think Dr. Sutherland is entitled to the gratitude of the country and of the Government for the services he has so long rendered. My noble friend consulted him, and placed him upon the first Commission, and I do not think the time has yet come when we can entirely dispense with the services of all those who were members of the Commission. There are three other members, who are specially appointed by the India Department. In dealing with this subject the Government is acting upon the experience of the Commission which was appointed by my noble friend, and that experience was confirmed by the Indian Sanitary Commission appointed by General Peel, and presided over with so much ability by my noble friend Lord Stanley, so that we have the latest as well as the first authority to sanction the course we have pursued."

After some observations by Lords Ellenborough and Longford and the Duke of Cambridge, the subject was allowed to drop.

In the House of Commons, Mr. Bentinck's motion respecting railway accidents, by which it was proposed to give Government power to inquire into the causes of accidents, and to examine witnesses on oath, and to issue regulations for the conduct of the traffic on railways, was negatived.

On Tuesday, in the House of Commons, Sir Fitzroy Kelly's resolution for the reduction and final repeal of the duty on malt was negatived by 251 to 171.

On Wednesday, in the House of Commons, Lord R. Montagu, in moving that the River Waters Protection Bill be read a second time, referred to the calls made for a measure of this nature, and the recommendations of the Committee of last year, upon which the bill was founded, and observed that he asked to have it now read in order that it might be sent before a Select Committee, where its details might be examined and improved. He then gave a graphic description of the evils and broods of secondary evils flowing from the pollution and contamination of our rivers by foul and disgusting matters which might furnish an acceptable nutriment to the land. Besides its pernicious effects upon the public health and public morals, he showed how this cause destroyed property, and sacrificed capital by killing fish and even cattle, and by raising the beds of rivers, and thus occasioning floods. He cited the evidence of Professor Acland, Mr. Rawlinson, C.E., and other scientific men, to prove that these evils were rapidly increasing and assuming a form of so much national importance as to demand a prompt and effectual remedy, which might be found in the utilisation of sewage by applying it to the land, thereby augmenting its fertility. He explained, in conclusion, the machinery of the scheme embodied in the bill, showing that no right or interests would be interfered with without the sufferers being amply compensated.

Sir G. Grey observed that Lord Robert had mixed up two distinct subjects, one of them being contemplated by the Sewage Utilisation Bill. He thought Lord Robert had failed to show that the present Bill provided a practical remedy for actual evils (which he had, however, greatly exaggerated), and that was the question before the House. In his opinion, it would be most unwise and inexpedient to adopt the scheme proposed in the Bill, which was not really sanctioned by the recommendations of the Committee. He then proceeded to examine the main features of the scheme, pointing out objections, and expressed a hope that the House would not adopt the principle of the Bill by assenting to the second reading.

Mr. Kendall opposed the Bill, as did

Mr. Jackson, who moved that the second reading be deferred for six months.

This amendment was seconded by Mr. Bright, who dwelt upon the serious consequences of passing such a Bill, and recommended that it should be withdrawn.

A long further discussion ensued, in which Mr. Selwyn, Mr. Hibbert, Mr. Adderley, Mr. G. L. Gower, Colonel Edwards, Colonel Sykes, Mr. Ferrand, Mr. Locke, Mr. W. Forster, Mr. Liddell, and other members took part, most of whom concurred in suggesting that this measure should not be pressed, though some legislation upon the subject was imperatively required.

Ultimately Lord R. Montagu, in his reply, said, under the advice tendered to him, he would withdraw the bill.

Lord R. Montagu then moved the second reading of the Sewage Utilisation Bill.

Sir G. Grey said he entirely concurred in the principle of this bill.

After a few remarks by Mr. F. Powell, the bill was read a second time, and ordered to be referred to a Select Committee.

FROM ABROAD.—RECONSTRUCTION OF THE HÔTEL DIEU—SPONTANEOUS GENERATION.

The members of the Paris Société de Chirurgie, at the period of their recent discussion on Hospital Hygienics, which was continued during ten meetings, thought that they had reason to congratulate themselves on at least partial success in attaining the object they had in view—viz., the prevention of the construction of a vast Hospital on the site of the present Hôtel Dieu. It was said that this discussion, characterised by great ability and by the unanimity of its condemnation of the erection of large Hospitals in crowded cities, had had its effects upon the municipal Administration, and that in place of the gigantic establishment intended a modest Hospital of some 400 beds would be substituted. Much satisfaction was naturally expressed, and the orators reposed on their laurels, gratified that the teachings of statistics and the conclusions of common sense had exerted their due effect. This turns out to be an illusion; for M. Velpeau has just communicated to the Society the fact that the Administration, after all its wavering, has determined to erect a Hospital with more than 800 beds. It has in view, in fact, not so much the true necessities of the case as the providing the site with an edifice which by its vastness and architectural proportions shall not discredit the magnificent cathedral in the vicinity of which it has the misfortune to be located. It will form part of the general plan of dazzling the Parisians by the grandness of its aspect, which has now become the rule in their capital, no matter what other considerations may have to be sacrificed. M. Velpeau, with that simplicity and confidence in the power of truth which it is pleasant, although somewhat surprising, to meet with in such a veteran, has recommended the Society to circulate among all the members of the "Conseil de Surveillance des Hopitaix" copies of the discussion which took place within its walls, in the hope that it is not yet too late to avert the impending mischief.

The Committee appointed by the Academie des Sciences to investigate the rival statements of MM. Pouchet and Pasteur concerning spontaneous generation, and consisting of MM. Flourens, Dumas, Brongniart, Milne-Edwards, and Ballard, has just made its Report. Spontaneous generation, it observes, is one of those questions met with during the cultivation of the sciences of observation which can never receive an absolute solution from experiment. It is a doctrine which has been debated from the remotest periods, and as nothing is more abundant than vague observations destitute of precision, arguments apparently derived from direct experiment have never been wanting to maintain its reality. These have disappeared before exacter observation, only to be revived at other epochs in relation to smaller organisms requiring for their detection and verification instruments of improved construction. The bodies brought under discussion became at last so minute that their detection may require instrumental aid of a perfection of which we have at present no conception. Awaiting this,

the doctrine is one of mere discussion, capable of being sustained by arguments on either side. With such discussions and merely opposite opinions the Academy can have nothing to do; as its mission has never consisted in adopting either this or that doctrine, but in verifying the facts on which the various opinions have been founded; and when any of these facts of capital importance are affirmed by the one side and denied by the other, it becomes the duty of the Academy to ascertain how far these are conformable to the truth and entitled to serve as elements of serious discussion.

Among the experiments brought forward in relation to spontaneous generation, there is one of striking importance, and which is regarded on all sides as capital. In a memoir published by M. Pasteur, he makes this affirmation—"That it is possible to take from a determinate locality a notable volume of ordinary air which has undergone no chemical or physical modification, and which will still be entirely unsuitable for inducing changes in an eminently putrescible liquid." To this M. Pouchet opposes the assertion that "on whatever part of the globe a cubic decimetre be taken, when this is brought into contact with a putrescible liquid in a mattrass hermetically closed, living organisms are constantly produced." The Academy named the Committee now reporting to superintend the experiments intended to justify the one or other of these statements. After some difficulty in arranging matters, the Committee met June 22, having determined that M. Pasteur should use a decoction of yeast and M. Pouchet an infusion of hay in their respective experiments, these being the putrescible fluids each had been accustomed to employ. M. Pasteur first presented three flasks filled with air on Mont Auvert in 1860, and containing yeast water. Transparency was found to be completely maintained, no organic matter being developed, and on analysis the air was found to contain its normal proportion of oxygen. Thus this air had been kept in contact with the yeast during four years at a temperature of 25C., without any alteration having been produced. M. Pasteur next filled to a third of their capacity sixty flasks with the decoction of yeast, closing, after two two minutes' ebullition, the narrow necks of the flasks by means of a lamp. Three test glasses were also filled with the decoction. The fluid in these last became turbid the next day, and myriads of bacteria were developed; the fluid in the flasks remaining perfectly limpid at the end of a month. The flasks were next divided into three series, and their necks having been broken with great precaution, air was allowed to enter them from three different localities—the interior of the great amphitheatre of the museum, the upper part of the dome of the amphitheatre, and the open air near some poplars at Bellevue. These three series in a day or two all exhibited organisms, but in very different proportions. Of the 19 in which the air was derived from the body of the amphitheatre, 5 only exhibited such, and 14 remained unaltered; of the 19 having air derived from the dome 6 produced living beings; and of the 18 exposed in the open air at Bellevue 16 underwent alteration. This last fact, the Committee observes, is just what would be expected, seminal germs being far more abundant in a meadow under the trees than in the middle of towns. But four of the vases, instead of having their necks hermetically sealed, had them much contorted and narrowed, but left open to the air. The fluid had undergone no more change than it had in the vases hermetically sealed at the period of the reading the report seven months after the experiment. This was attributed to the very slow manner in which the air gained access through the contorted neck, the germs in the air, if present, becoming in fact, deposited in some of the inflections of the narrow tube. This was proved to be the case, for the neck of a similar vase, which M. Pasteur had kept unclosed for three years, having been sealed, the flask was well shaken so as to detach the germs from the sinuosities of its neck, and in the course of two days numerous organisms were developed in the hitherto transparent fluid. The Committee declare M. Pasteur's observations to be rigorously exact, and conclude that "Fermentable liquids may remain whether in contact with confined air, or with air frequently renewed, without undergoing alteration; and when under the influence of this fluid living organisms are developed, it is not to the influence of its gaseous elements we must attribute this development, but to solid particles which may be separated from it by various means."

At an early stage of the inquiry M. Pouchet, refusing to be bound by the conditions which the Committee regarded as indispensable, withdrew from the investigations, not without being charged by the Committee with endeavouring to evade the true point at issue, and which he had at first formally acknowledged as such.

GYPSUM BANDAGES.

Our readers will not fail to have noticed the exceedingly practical and lucid, though condensed paper on the Gypsum Bandage which we published in the *Medical Times and Gazette* of last week from the pen of Dr. T. E. Stark, of Utrecht. It will be indeed a boon to the whole Surgical Profession, civil and military, when a few flannel strips, dusted with powdered plaster of Paris, and done up in tin boxes, can be substituted for a cumbersome apparatus of splints. In America, where the natural ingenuity of the people is stimulated by the necessities of their gigantic war, the gypsum bandage is in universal request; though even there they have scarcely attained to the perfectness and convenience of the form so well described by Dr. Stark. We have been favoured with the following woodcuts, the first of which shows the gypsum bandage cut open, in order that it may adapt itself, like an elastic mould, to variable sizes of the fractured limb. The second shows how a valve may be cut by inserting a sheet of paper at *a* whilst the bandage is being first applied, so as to leave an aperture for the scissors to cut two curved lines, ending at the hinge at *c*.

Fig. 1.

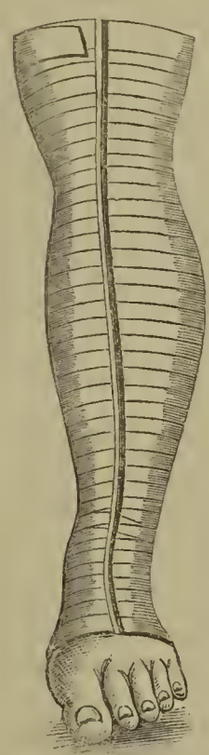

Fig. 2.

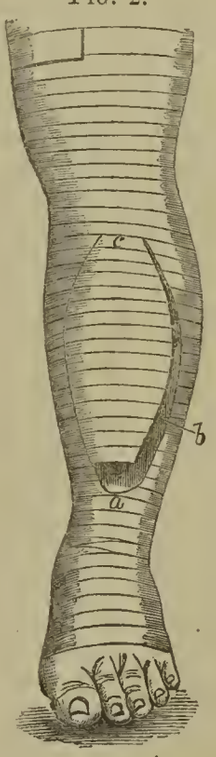

Popular Anatomical Museums.—The so-called "Anatomical Museums," which by the Profession here are considered a disgrace to the police management of London, seem to be in better repute at Vienna; for in the *Wiener Medicinische Wachenschrift* we find the following advertisement, headed by the figure of a cranium:—"Reimer's Anatomical Museum, the most famous in existence. Gentlemen admitted from 10 to 7 daily, and ladies Tuesdays and Fridays, from 2 to 7. Admission eighteenpence."

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF BATH.

MODERN BATH.

Modern Bath is a city of palaces in a basin of light: to descend into the city at sunrise on a bright morning is a pleasure for which one might be glad to live for the hour alone. At the same time, when the city is entered, and its streets and thoroughfares are being trodden, it is seen to be a busy city. In this respect it differs greatly from other fashionable places where health-seekers look for repose.

I said in a previous chapter that modern Bath waited for a pump-room before it became what could be called a fashionable, and therewith a wealthy, city. This is quite true; the old histories tell us that at the latter part of the seventeenth century few cities were poorer or more mean in appearance: its inhabitants were rude and unpolite, and it had no places of amusement or assemblies. A few families of distinction resorted there for about six or seven weeks in spring time, and when the company were numerous enough to form a dance they repaired to a bowling-green, open and exposed to the air, and, to the sounds of a hautboy and violin, reeled away. In 1703 one Captain Webster, a resident of the city, and amongst the selected, took the company to the Town Hall, and opened a half-guinea subscription. Next year a pump-room was built, and soon afterwards Captain Webster, who may be considered as the first master of the ceremonies in the city, was so fortunate as to secure for his aide-de-camp Beau Nash, who, in a little time became the leader of the merry life of Bath. At the request of the Physicians of the city, Nash induced the visitors to go to the Pump-room to hear a good band of music; next he persuaded the citizens to repair their roads, and anon he led them to build and decorate. In time, aided by the waters and the friendly Physicians, the father of modern Bath raised it from obscurity to be the most elegant and the most delightful city of Europe. There, says one of our last century authorities, there the young, the old, the grave, the gay, the infirm, the healthy, all resort as to a vortex of amusement. Ceremony, beyond the essential rules of politeness, is totally exploded. Every one mixes in the rooms upon an equality; and the entertainments are so wisely regulated that, although there is never a cessation of them, there is never a lassitude from bad hours or from an excess of dissipation. The young ramble about in a manner vastly enlivening and cheerful. In the morning the rendezvous is at the Pump-room; from that time to noon in walking on the parades, or in the different quarters of the town; thence to the Pump-room again; from the Pump-room to a fresh stroll, and then to dinner; from dinner to the theatre or the Rooms, and, after dinner, dancing, or cards, early to bed.

Modern Bath has not retained *all* these first and fashionable buddings of her fame and prosperity: she is still fashionable, but she blends with fashion utility. She retains all her beauty, but she has now a good strong back of honest work in her which sustains her lustily as well as proudly.

The occupations of the citizens at this time show a much more numerous collection of the industrial classes than would be assumed in the absence of statistical facts. Thus, of persons aged 20 years and upwards, the classes, six in number, into which they are divided, by the last census commissioners, stand as follows:—

Total of all classes over twenty years, 40,706

1. Professional classes	. .	2,299, or	5·6 per cent.
2. Domestic	,, . .	16,915, or	41·6 ,,
3. Commercial	,, . .	1,395, or	3·4 ,,
4. Agricultural	,, . .	2,810, or	6·9 ,,
5. Industrial	,, . .	13,319, or	32·8 ,,
6. Indefinite and non-productive		3,968, or	9·7 ,,

It would be impossible for me to convey to the reader in this limited history any detailed account of the buildings of this beautiful city. It will be most to the purpose to pass to the consideration of the principal points of Medical interest—the Hospitals.

THE BATH GENERAL OR MINERAL WATER HOSPITAL.

The Bath General or Mineral Water Hospital was founded in the year 1738 on a site where before a theatre had stood. The foundation-stone was laid by the Right Honourable William Pultney. The building progressed rapidly, and in 1742 it was ready for the reception of patients.

A remarkably liberal spirit actuated the founders of this institution. Implicitly believing in the specific value of the Bath waters in the cure of diseases which, without these waters, were intractable or incurable, they determined that the Hospital should not be local merely, but national. The Hospital, therefore, was raised on the principle that all poor sick persons in England or Ireland who should come to it should be admissible save and except those who belonged to the city of Bath itself; the latter, it was thought, being at the waters, could have all the advantages at little cost.

The proposition thus made and carried out in the most generous spirit told in the end largely in favour of Bath itself. It were impossible that an offer of relief such as was thus made could fail to bring many sufferers from all parts of the kingdom, and it was equally impossible that these could return to their native places cured, as they often were, without making known the means by which they had recovered, and distributing the fame of the remedy. In turn the wealthy strangers who visited the city took an interest in the Hospital, and favoured it; so that in time it gained a body of supporters, widely spread through the kingdom, and more numerous than pertained to any other similar charity. In the first attempts to raise this charity the noted Beau Nash again took a conspicuous part, and the admirers of this eccentric character are forced to excuse many of his faults and frivolities by referring to his natural benevolence and practical love of doing good. Beau Nash was seconded ably by Mr. Hoare and by a distinguished member of our own Profession—Dr. Cheyne. Dr. Oliver Goldsmith tells an excellent story in reference to the efforts of Nash to raise funds for the "Bath General." "The sums he gave and collected," says Goldsmith, "for the Hospital were great, and his manner of doing it was no less admirable. I am told that he was once collecting money in Wiltshire's Room for that purpose when a lady entered who is more remarkable for her wit than her charity, and, not being able to pass him unobserved, she gave him a pat with her fan, and said, 'You must put down a trifle for me, Nash; I have no money in my pocket.' 'Yes, madam,' says he, 'that I will with pleasure if your Grace will tell me when to stop;' then, taking a handful of guineas out of his pocket, he began to tell them into his white hat, one, two, three, four, five. 'Hold, hold,' says the Duchess, 'consider what you are about.' 'Consider your rank and fortune, madam,' says Nash, and continued telling six, seven, eight, nine, ten. Here the Duchess stormed, and caught hold of his hand. 'Peace, madam,' says Nash, 'you shall have your name written in letters of gold, madam, and upon the front of the building, madam;' sixteen, seventeen, eighteen, nineteen, twenty. 'I won't pay a farthing more,' says the Duchess. 'Charity hides a multitude of sins,' replied Nash; twenty-one, twenty-two, twenty-three, twenty-four, twenty-five. 'Nash,' says she, 'I protest you frighten me out of my wits; I shall die.' 'Madam, you will never die with doing good; and if you do, it will be the better for you,' answered Nash, and was about to proceed, but perceiving her Grace had lost all patience, a parley ensued, when he, after much altercation, agreed to stop his hand, and compound with her Grace for thirty guineas. The Duchess, however, seemed displeased the whole evening; and when he came to the table where she was playing, bid him 'stand farther, an ugly devil, for she hated the sight of him.' But her Grace afterwards having a run of good luck called Nash to her. 'Come,' says she, 'I will be friends with you, though you are a fool; and to let you see I am not angry, there is ten guineas more for your charity. But this I insist on, that neither my name nor the sum shall be mentioned.'"

The first Physicians appointed to the Hospital were Dr. Oliver, who was also Vice-Chairman, Dr. E. Harrington, and Dr. A. Rayner; the first Surgeon was Mr. J. Peirce.

Soon after the commencement of the Hospital—viz., in 1793—an Act of Incorporation was obtained. The Act underwent modifications in the progress of time, and in 1830 a new Act was obtained, by which the governors were enabled to construct baths on the Hospital premises; and in 1835 the law which excluded the inhabitants of Bath from taking part in the benefits of the institution was rescinded.

Rules for the Admission of Patients.

I have before me a copy of the rules for admission of patients published in 1783, and a useful epitome of the rules published by Dr. Tunstall, in 1860, in his essay on the Bath waters. It may be of importance to many readers to know how they must proceed in order to get a patient admitted into the Institution, and I therefore append from Dr. Tunstall the regulations at present in force :—

"Those only are admissible whose diseases are deemed capable of being benefited by the Bath waters, and which are, —palsy, gout, rheumatism; certain nervous derangements, in which the brain is not materially affected, among which St. Vitus's dance may be particularly noticed; leprosy, and other chronic diseases of the skin; dropped hands from lead, poisonous effects of mercury or other minerals; pain, weakness, or contraction of limbs; dyspeptic complaints, biliary and visceral obstructions, etc.

"It should also be particularly noticed, that when these complaints are accompanied with pain of the chest, cough, or spitting of blood; palpitation or other disturbance of the heart; evidence of too great a determination of blood to the head, acute inflammation in any part, or general fever, abscess, suppuration of the joints, or ulcer of any kind; or if epileptic fits have occurred; the waters are not applicable. And in cases of apoplectic palsy it is deemed necessary that six months should elapse after the attack before the patients are admissible.

"The eligibility of each case can be ascertained only by such circumstantial report as may enable the Physicians and Surgeons of the Hospital to determine how far the patient is likely to derive benefit by the use of the Bath waters, for which reason the report of each case must contain—

"1. The name, age, and parish of the applicant.

"2. A brief history of the disease, comprising its origin, date, progress, and present symptoms, mentioning the parts principally affected, and to what extent.

"3. A correct representation of the state of general health, particularly certifying the absence of all disorders which render the Bath waters inapplicable, as above enumerated.

"A blank form for making the report may be obtained of the Registrar. When practicable, such statement should be made by a Medical man acquainted with the case and sent to the Registrar, who will submit it to the Medical Board, who meet weekly.

"Accuracy of reports is important, for when, from defective or erroneous statements, improper cases are sent to Bath, they are immediately returned, to the great inconvenience of patients; and when sent from a distance, with considerable expense.

"In a few days notice will be given to the party applying whether the application will be admitted or rejected.

"If admitted, the letter to that effect will be accompanied by a blank certificate, relating to the parish settlement and poverty of the patient, to be signed by the minister, churchwardens, and overseers of the parish to which the patient belongs; but the patient is enjoined to remain at the usual place of residence until notice is received that a vacancy has occurred.

"On receipt of the notice of vacancy, the patient should proceed without delay to the Hospital, bringing the letters of notice and the certificate duly executed, as well as the caution money, which is three pounds for patients coming from any part of England or Wales, or five pounds for those from Scotland or Ireland.

"The object of the caution money is to ensure the means of returning patients to their respective homes when discharged from the Hospital, or to defray the costs of interment in the event of death. When not required for these purposes or for supplies of necessary clothing, when this is greatly deficient, the whole of the caution money is returned to the party who provided it.

"Soldiers may, instead of parish certificates, bring certificates from the officers commanding their respective corps, acknowledging them to belong to such corps, and agreeing to receive them back when discharged, in whatever state of health they may be. The same regulation applies to pensioners of Chelsea and Greenwich. With respect to all these, however, reports are to be transmitted and caution money provided, as in ordinary cases."

The Hospital with but little alteration remained until 1859; then it was determined, after a long consideration, to erect a new building, which should include day-rooms, a chapel, board-rooms, and other important additions. The first stone of the new building was laid on June 4th of that year, and the result was the present beautiful building, which, if it stood in a more open space, would be a model sick Hospital. The new and the old buildings are connected by a bridge-way on the first floor.

Those members of the Profession who attended the meeting of the British Association for the Advancement of Science last year will remember the Mineral Water Hospital as the centre of the natural sciences during that period. The entrance hall is spacious and handsome. On ascending the staircase we reach two large rooms—the men's day room and the women's day room; these rooms are very large, the first is seventy feet long, forty-three wide, and twenty-two feet high; the second is seventy-eight feet long, twenty-six feet wide, and twenty-two feet high. The other wards are also large and open, and in all there is excellent ventilation and warming. Connected with the Institution there is an exercise ground—or garden it were better to call it—for the patients, and a chapel, which, for classic beauty, could not be excelled. I know not what in the old time the Romans did at Bath for architectural excellency; but if they ever placed on that spot any more perfect art than this, which a modern architect—Mr. J. E. Gill—devised and carried out, they deserve even more credit than we, even in our blind admiration and contrast of everything that is not modern, are accustomed to award them.

The board-room of the Hospital, which is on the ground floor, and in which last year the physiological meetings were held, is alone worth a visit from the Medical traveller in Bath. There is one painting which is in itself a study. It represents Dr. Oliver and Mr. Peirce, the one Physician the other Surgeon to the Hospital in its first days, prescribing for their poor patients. Of the patients presented in the field one wears a countenance of hope and the other a face of gladness, as believing that the relief sought for has come at last. The Professionals, dressed in the becoming costume of the day, are holding what may be considered a casual consultation; they are neither of them sad, nor are they in the least affected. It is the fault of most artists who have essayed a Medical consultation to make the Doctors either mutes or buffoons, as though the vein of Drelincourt on the one hand, or of Molière on the other, must needs be the spirit of inspiration. In this picture the artist—W. Hoare, Esq., R.A.—has studied simply the natural, and has succeeded admirably. His Medicals are gentlemen who evidently are of easy manners and well to do, who know what to order for the sick at a ready and practised glance, who are in agreement and friendship, and who take what comes before as the business of their lives in a quiet and earnest spirit, unmoved, but not uninterested. The contrast of expressions between the patients and the Medical men is admirable, and a certain hardness which indicates just sufficiently, and not more, that the Mr. Hoare fell short of the very highest position in his art, is almost atoned for by the general effect. The governors and Medical staff naturally prize this picture much.

At the present time the Mineral Water Hospital holds 142 beds. From the commencement of the Hospital it has, I believe, received 42,000 persons, of whom more than one-fourth have been dismissed as cured.

The results which have been attained in the treatment of disease in this Hospital are without doubt very remarkable and beneficial. It is here that we would look for evidence of the real scientific value of the waters, and it is just to say that the Physicians have carefully endeavoured to determine the exact value which the patients derive from them; it is also fair to say that the opinion expressed by these observers, who have at all times been men remarkable for their powers of observation, is in favour of the specific curative properties of the waters. Dr. Falconer, to whom I have before referred, deserves special credit for the care with which he has attempted to analyse the facts presented to him.

From November 1, 1859, to the same date 1860, Dr. Falconer tabulated 156 cases, consisting of 113 men and 43 women, including cases of rheumatism, sciatica, gout, paralysis, lead paralysis, cutaneous affections, hysteria, chorea, hip disease, and injuries: a brief account of this analysis cannot but be of value.

Of the cases, 49 were cases of *rheumatism* in men, and 20 were cases of *rheumatism* in women. Their ages varied from 10 years to 70, and their occupations were varied. The average duration of each man in the Hospital was 62 days, and of the women 81 days. Of these, 62 were treated by the waters alone; the rest were treated with the waters and other remedies.

RESULTS.

Waters alone.

Men.		*Women.*	
Cured	18	Cured	5
Much better	14	Much better	8
Better	8	Better	5
No better	3	Improper	1
Total	43	Total	19

Waters and other Remedies.

Men—Cured, 3; much better, 2: better, 1. *Woman*—Better, 1.

There were also twenty-five cases of sciatica—twenty-one men and four women. The ages of the sciatic patients ranged from ten to seventy years. The men remained in Hospital for an average of fifty-one days each, and the women sixty-five days.

RESULTS.

Waters Alone.

Men.		*Women.*	
Cured	11	Cured	2
Much better	6	Much better	1
Better	4	No better	1
Total	21	Total	4

Three men were admitted in the year suffering from gout. Their ages respectively were thirty-five, forty-four, and forty-nine years. The average stay of each one in Hospital was one hundred and thirty-six days.

RESULTS.

Water Treatment Alone.

Cured	2	Much better	1

Five men and five women were admitted with paralysis. The stay of each man was seventy-four days on an average; of the women, twenty-seven days.

RESULTS.

Waters Alone.

Men.		*Women.*	
Much better	4	Much better	1
Better	1	No better	1
Total	5	Waters disagreeing	3
		Total	5

Twenty-two cases of paralysis from lead were admitted. They were all men, of ages ranging from twenty-three years to fifty-seven. Their occupations were very various. Twenty-one of the men remained in Hospital seventy-three days each on an average; the remaining one died after fifty-seven days of residence.

RESULTS.

Water Treatment Alone.

Cured	13	Better	1
Much better	7	Dead	1

Ten men and ten women were admitted for cutaneous affections. Ten of the men remained in Hospital seventy-nine days each; nine of the women, one hundred and eight days each, and one woman died after twenty-eight days.

RESULTS.

Men.

Waters Alone.		*Waters and other Remedies.*	
Cured	5	Cured	1
Much better	1	Much better	2
No better	1		

Women.

Cured	1	Cured	1
Much better	5	Much better	1
Better	1	Died	1

A case of *hysteria* in a woman, twenty-one years old, was cured in fifty-one days by the waters and other remedies. Two children with *chorea*, one aged seven and the other *eleven* years, were in Hospital twenty-six days each, and were treated by the waters alone. They were both discharged cured. One man, aged forty-four years, was in the Hospital for forty-four days for *hip disease*, and was treated by the waters. He was dismissed as "better."

There were also admitted three cases of *injuries*, two in men and one in a woman. The men were in the Hospital sixty-two days each; one was discharged as better, the other as no better. The woman, who was in the Hospital twenty-two days, was cured.

To the record of his cases, Dr. Falconer adds the following summary:—

SUMMARY OF RESULTS.

Waters Alone.

Cured	60

Much better	5	
Better	3	
Died	1	
		14
Total discharged		156

I have placed these results before the reader because I doubt not they represent a very fair estimate of the practice at Bath from the systematic employment of the waters. The observations are made by one of the most intelligent Physicians of the day, and by one who is unprejudiced and most careful in the collection of his facts. I must refer to the book of Dr. Falconer for the details of the cases, but I may state in brief that many of them were very severe, and apparently, according to the ordinary run of practice, intractable. There can be no doubt as to the correctness of the results, and there can be no less doubt that those results are excellent, such as few other Hospitals could show. Still, there remains unsettled the one question, the value of the waters—their *specific value*. To my mind, the exclusion of other remedies—I mean medicinal remedies, does not settle the question. To prove the case in favour of the waters, the other elements of treatment—the good food, the pure air, the freedom from overwork, the mental relief, the regular hours, the confidence inspired by the Physician—these have to be considered as connected most intimately with the word "*cure*." To prove the case for the waters it would be necessary to place an equal number of similar cases in the Hospital under precisely the same conditions, except in one particular. Half the cases should be treated with the thermal water, and the other half with ordinary water at the same temperature, the patients themselves not being made conscious of the difference. Then if, after twelve months' practice it were shown that there were a large balance of cures amongst those who had taken *the* waters, we should have before us direct proof that the said waters were essentially curative in character.

In the absence of such an exhaustive analysis as is above suggested, we cannot fairly say more than that the patients under treatment recovered. We may possibly say with great truthfulness and equal satisfaction that many cases of an extreme kind would probably not have got well unless they had been treated at Bath, and it would consequently be most unjust to deprive the fair city of one tittle of its fair and noble fame. At the same time, it is of the profoundest interest to Medical men to know the exact reason why recovery occurred. If we could be certain that more than 40 per cent. of special cases now in our Hospitals could be cured by these waters, it would answer well to let every Hospital in the kingdom have some of the remedy that now flows so swiftly into the sea by the Avon—at least, for internal administration. Or, again, if the waters do cure, it is certain that they cure because there is in them some special remedy or some compound which might, under experiment, be isolated and brought into general use, both as an internal and external remedy.

The most interesting and important of all the facts yielded by the results of treatment by the Bath waters relates to paralysis produced by lead. I confess that I have seen cases of lead paralysis resist every kind of treatment, medicinal or hygienic, while it is certain that in Bath very severe cases recover. The fact opens a suggestion. Can it be that in cases where the tissues of the body contain lead the poison can be eliminated by the mere imbibition for a long time of warm water, and that muscular tone can be restored by the same simple means? I have seen, in physiological experiment, paralysed muscles contract vigorously by the mere introduction into them of warm water, and we know that moderate dilution of blood leads to free secretion. It would be important, therefore, to ascertain whether treatment of lead paralysis by the

continued administration of three or four pints of warm water daily would give relief or effect a cure, and I trust that some members of the Profession who have many cases of the kind under observation will put this simple inquiry to the test of experience.

MEDICAL STAFF.

The present Medical staff of the Bath General Hospital consists of three Physicians and three Surgeons. The present officers are:—

Physicians.—Dr. Watson, Dr. Falconer, Dr. Coates.

Surgeons.—G. L. Wood, Esq., J. Bartrum, Esq., T. G. Stockwell, Esq.

Resident Medical Officer.—S. Roberts, Esq.

REVIEWS.

On the Temperature of the Body as a Means of Diagnosis in Phthisis and Tuberculosis. By SIDNEY RINGER, M.D., Professor of Materia Medica and Therapeutics at University College, etc. London: Walton and Maberly. 1865. Pp. 92.

In the work before us, the small size of which, by the bye, is not to be taken as the index of its value, Dr. Ringer extends his observations upon the temperature of the body in disease to the important class of tuberculous affections. His former papers have appeared in the *Medico-Chirurgical Transactions*, but, we think, that in this instance he had exercised a wise discretion in publishing his observations in a separate form, in such a form as shall ensure the general diffusion of the important results which have come out of them among the mass of the Profession. The observations upon which his conclusions are based are, he tells us, very numerous, but the cases which he relates amount only to twenty-four, and these suffice to illustrate the subject. Several of the cases narrated are accompanied by a diagram showing the daily fluctuations of the temperature of the body. The temperature in each case was taken in the axilla, and Dr. Ringer lays down the precautions necessary to render an observation so taken trustworthy. The general results which he has arrived at are the following:—

"1. There is probably a continued elevation of the (temperature) of the body in all cases in which a deposition of tubercle is taking place in any of its organs. 2. This elevation of the temperature is probably due either to the general condition of the body (tuberculosis) or to the deposition of tubercle in its various organs (tuberculisation). 3. This elevation is probably due to the general condition (tuberculosis) rather than to the deposition of the tubercle (tuberculisation). 4. The temperature may be taken as a measure of the amount of the tuberculosis and tuberculisation, and any fluctuations in the temperature indicate corresponding fluctuations in the severity of the disease. 5. The temperature is a more accurate indication of the amount of tuberculosis and tuberculisation than either the physical signs or the symptoms. 6. By means of the temperature we can diagnose tuberculosis and tuberculisation long before the physical signs and symptoms are sufficient to justify such a diagnosis. 7. By means of the temperature we can diagnose tuberculosis even when, during the whole course of the disease, there are no physical signs indicative of tubercular deposit in any of the organs of the body, and in which cases the symptoms (apart from the temperature) are inadequate to enable us to arrive at such a diagnosis. 8. It is probable that by means of the temperature we can conclude that the depositions of the tubercle have ceased, and that any physical signs that are present are due to obsolescent tubercle and the chronic thickening of the lung tissue between the tubercular deposit. 9. It is probable, though further observations on this point are necessary, that the temperature of the body affords a means by which we can diagnose between diseases in which the symptoms and physical signs are either too scanty or too much alike to enable us to decide between them."—P. 4.

The author then proceeds to consider these propositions seriatim. We shall limit our remarks to a few points only in the discussion. *a.* It might be objected to the first of Dr. Ringer's propositions that the elevation of temperature observed was due, not to the tuberculosis, but to the secondary complications, the most important of which were bronchitis and albuminuria. In reply to this he states generally that all the complications in his twenty-four cases were slight in amount: next, that in five patients suffering from more or less severe capillary bronchitis he found no elevation of temperature, and that in his tuberculous cases the elevation of temperature was in no way proportionate to the amount of bronchitis conjoined. As to albuminuria, he states that in several patients suffering from this condition there was no elevation of temperature discoverable. *b.* With respect to the temperature as a measure of the tuberculosis, Dr. Ringer says:—"In some cases the temperature is considerably and permanently elevated throughout the day. In others, though normal, or nearly so, at one period of the day, at another period it rises to a considerable height, whilst in other cases this rise is far less considerable. The first description of temperature is accompanied with very severe general symptoms, and an active deposition of tubercle: the second description with the severe symptoms, and with a less active deposition: and the third description is accompanied with but few symptoms, and with a very slow deposition of tubercle in the body: and lastly, in those cases in which the temperature becomes and remains normal, all the symptoms disappear, and the deposition of tubercle ceases."—P. 16. *c.* While discussing temperature as more trustworthy than either physical signs or symptoms, Dr. Ringer passes under review the more important of the latter class of indications. With respect to *weight*, he observes that this is chiefly regulated by the appetite, and if the appetite remains good, the patient may maintain or even increase in weight, though the tuberculosis be sufficient to elevate the temperature as high as it usually reaches in scarlet fever—that is, to 103° or 105° Fah. Then, with regard to the pulse, although the pulse and temperature in disease generally coincide, yet cases occur in which, with a considerable elevation of the temperature, the pulse remains normal, or nearly so. Besides, other causes beside pyrexia may increase the frequency of the pulse, such as debility or exhaustion, and even hysteria. *d.* Dr. Ringer, while discussing his sixth proposition, says that he "trusts that it has been shown to be probable that there is a *continued* elevation of temperature in all cases of tuberculosis and tuberculisation: and he is further able to state that, after very numerous observations of the state of the temperature in various diseases, with one exception, this continued elevation has been observed only in tuberculosis, rheumatism, and ague. . . Thus, if we meet with a case in which the temperature rises daily during a considerable time, if this be not rheumatism nor ague, it is probably tuberculosis. . . How long must the elevation of temperature continue before we can with probability suspect tuberculosis? The author thinks from ten to twenty days, each day adding considerably to the probability of the correctness of the diagnosis" (p. 29), for by this time inflammations and specific fevers would have declared themselves by their characteristic symptoms. *e.* The ninth proposition is illustrated by emphysema of the lungs, dilated bronchi, cancer of the lung, aneurism of the aorta, and diseases of the brain simulating tubercular meningitis. The subject is an eminently practical one, and the book ought to be studied by every Practitioner of Medicine.

A Treatise on the Chronic Inflammations and Displacements of the Unimpregnated Uterus. By W. H. BYFORD, A.M., M.D., Professor of Obstetrics, etc., Chicago Medical College Medical Department, 32nd University, Philadelphia. Lindsay and Blakiston. 1864. Pp. 215.

We have read this little book with much patriotic complacency, because, in reading, we were continually reminded that it is a re-echo of a voice with which we Englishmen are familiar.

We do not say this in any spirit of detraction: it is inevitable that an original thinker should make disciples, and that these disciples should seek to found little branch schools of their own, and propagate the doctrines with which they are imbued. It unfortunately happens that occasionally the original thinker arrives at incorrect conclusions. Still his doctrines become generalised, and the fruit of his teaching is often evident long after the teacher himself has recanted from his errors.

Every one knows that not very long ago a certain section of the obstetrical world made the discovery that almost every ill that female flesh is heir to is produced by ulceration of the cervix uteri. The idea was eagerly seized upon; it was delightful to think that every one could cure every uterine complaint with a small piece of lunar caustic: and the bubble grew and rose. Alas! its very growth was the cause of its collapse: it became so formidable that its real merits were inquired into. A Croonian lecturer took up the subject, and

showed clearly that it is a mistake to suppose that inflammation of the "uterine neck" is in gravity or frequency either superior to, or equal with, inflammation of the body of the uterus.

Dr. Byford is a disciple of Dr. Bennet's. He is a great believer in *eervieitis*, and the virtue of caustics. His book is carefully and well written, and abounds with little praetical hints of great value. There is not much that is new in it, but there is a good account of the symptoms, etiology, prognosis, and diagnosis of uterine inflammation. Many of the remarks on treatment, too, are excellent, for Dr. Byford is no mere extremist. On the contrary, he lays down the most careful rules for general treatment, insisting upon the distraction of the patient's attention from the state of her uterine health—an object, we think, which must be attained with difficulty as long as the local treatment is being carried on. Dr. Byford distinguishes between mucous inflammation of the cervix and submucous inflammation—the former accompanied by a feeling of soreness, the latter by a feeling of tenderness. The panaeea for the former is caustic, the treatment for the latter antiphlogistic, or, that failing, caustic. In almost all eases of endo-cervicitis Dr. Byford uses the stick nitrate of silver, and he lays considerable emphasis on the necessity of having a flexible *porte-caustique*, which may, like the uterine sound, be bent to any angle that is necessary. Among the inconveniences which Dr. Byford has seen arise from the prolonged use of nitrate of silver is atrophy of the uterus. He has known the uterus to become smaller than natural, its tissues to be condensed, and obstinate or permanent amenorrhœa to be established.

Where endo-cervicitis and submucous inflammation co-exist, the latter ought to be first treated; indeed, Dr. Byford confesses that there is some risk of this submucous inflammation being set up by the nitrate of silver treatment.

What are we to do? We are to keep the bowels open; and here we may incidentally say that Dr. Byford has a very good section on the treatment of constipation. We are, if necessary, to give calomel and opium, and we are to deplete the uterus locally by means of leeches and scarification. If the cervix be indurated and enlarged, we are to use caustic potash, with the object, as Dr. Bennet says, not of destroying so much as of inducing a change in the action of the vessels that will cause an absorption of the fibrinous deposit upon which the enlargement depends.

Dr. Byford, in his last chapter, treats of uterine displacements, which he seems to believe to result, in almost every case, from inflammation of the cervix uteri. He even here outstrips his master, for while Dr. Bennet believes that inflammation limited to the anterior wall of the womb may cause anteversion, while inflammation of the posterior wall may cause retroversion, Dr. Byford asserts that versions and flexions and all other displacements are often caused by inflammation of the cervix alone. With such views it is manifest that Dr. Byford must usually treat displacements by removing their cause. "But," he says, "there are cases where this cannot be done for various reasons, among which are the prejudices of patients and Medical men against the treatment necessary for the cure of inflammation, the impossibility of curing the inflammation when every opportunity is enjoyed, and even sometimes when the inflammation is removed there may be continuance of displacement with its symptoms." It becomes thus necessary to use pessaries, and Dr. Byford runs over the various forms with which we are all familiar: the globe, the ring, the disk, the stem, the lever. He thinks that the stem-pessary, while theoretically the best, can in practice be rarely borne; he believes that the ring formed by an elastic watch-spring will be found an efficient support in retroversion and in prolapse, and that the globe is the best form for anteversion. He is of opinion, however, that every case must be judged upon its own merits, and that the careful Practitioner will soon find out which is the best way of giving mechanical support to the uterus which he is treating. Unlike most writers on uterine displacements, Dr. Byford has not any "little modification of his own" to bring forward, and we think that his opinion is on that account all the more weighty.

The Laryngoseope; Directions for its Use, &e. By G. Johnson, M.D. London: R. Hardwicke.

These lectures were delivered last year at the Royal College of Physicians, and are devoted to the object of showing that laryngoscopy is not so difficult as to be suecessfully practised only by a select few, but that its difficulties may be easily overcome by a very moderate amount of praetiee and perseverance. We can commend Dr. Johnson's little book to those who desire to become familiar with the use of the laryngoscope.

On some Points Connected with the Pathology, Diagnosis, and Treatment of Fibrous Tumours of the Womb; being the Lettsomian Leetures on Midwifery and Diseases of Women delivered before the Medieal Soeiety of London, November and Deeember, 1863. By C. H. F. Routh, M.D. Lond., etc., etc. London. 1864.

In choosing fibrous tumours of the uterus as the subject of his Lettsomian lectures, we think Dr. Routh chose wisely. The subject is one of great importance. The lives of many women are constantly depending upon the amount of acquaintance which their Medical attendants have with it; and, as Dr. Routh tells us, its literature is widely seattered and not easily attainable, because the brilliant results which have recently been obtained by gastrotomy have not as yet found their way into class-books, but are for the most part scattered over the pages of home or of foreign journals.

To any one who pays particular attention to the treatment of the diseases of women, there is perhaps no subject of greater present interest than the differential diagnosis of ovarian and uterine tumours. Serious mistakes are from time to time committed, chiefly for the reason that uterine fibroids, as well as ovarian tumours, are occasionally eystic; that they contain fluid, and that fluctuation is consequently perceptible in them. It was but natural that Physicians and pathologists should have turned their attention to the manner in which this change was produced, and we are therefore by no means astonished that Dr. Routh enters at some length into the question. He relates five different ways in which the transformation may be effected—by sarcomatous transformation, by œdema, by eonversion into a cyst, by suppuration, and by fatty degeneration. We have no doubt that each of these changes may occur, and may each, in turn, account for the fluctuation occasionally perceptible in fibroid tumours. With all deference, however, to the Lettsomian lecturer, we believe that true eysts are to be found in fibroid tumours of the womb far more frequently than he supposes, and that their presence is generally to be accounted for by a prolongation of uterine glands into the substance of fibroid tumours in the way pointed out so ably by Rokitansky.

Ever since the publication of monographs upon obstetrical auscultation by Naegele in 1838 and by Depaul in 1847, the attention of the Profession has been directed to the stethoscope as a valuable assistant in the differential diagnosis of abdominal tumours. Dr. Routh appears to have taken great trouble with this part of his subject, but still we cannot altogether concur in the conclusions at which he has arrived. Dr. Routh distinguishes two varieties of *bruits de soufflet*, a tubular murmur due to compression by a solid body, of the large abdominal vessels, and a vesicular murmur generated in the uterine vessels themselves. The former sound is, according to him, rarely to be heard in pregnancy or ovarian disease, while in fibroid tumours both may be met with.

Now, we believe that it is quite true that a bruit may be produced by compressing the abdominal vessels, and that one slightly differing from it may have its cause in the uterine sinuses.

We even believe that in this way may be explained the supposition of an Italian Accoucheur, that the death of an intra-uterine fœtus may be diagnosed by the harsher thrill of the *bruit de soufflet*. We believe, however, that both murmurs may be heard both during pregnancy and in the course of ovarian disease, and that therefore the occurrence or non-occurrence will not aid us in differentiating those conditions.

We are again at issue with Dr. Routh when he asserts that the double aortie sound is to be heard only through solid tumours, and not through that formed by an ovarian cyst or by the pregnant uterus. We are convinced that in very many pregnant women the double aortic sound is to be heard through the gravid uterus. We have even seen one of the most distinguished European Accoucheurs deceived by this sound into diagnosing a twin pregnancy in a case where there was only one infant in utero. We think it a pity that Dr. Routh has attempted to revive the metroscope of Nauche. The instrument had a fair trial, and it was rejected because its inconveniences were great and its utility slight. It would have been but just had Dr. Routh, in rechristening Nauche's instrument, at least mentioned the name of its inventor.

That part of Dr. Routh's book which will be turned to by many with the greatest interest is where he speaks of the

Surgical treatment of fibrous tumours, of their enucleation, and of their removal by gastrotomy. Enucleation may be either primary or secondary, either completed by the operator at once, or effected by the artificial induction of gangrene. There are 27 cases of primary enucleation recorded; 19 of these recovered, giving a mortality of 29·6 per cent. There are 24 cases of induction of gangrene; of these 14 recovered, making the mortality 41·7 per cent. This clearly shows the danger of the latter method, and Dr. Routh, to make the cause of the greater mortality more plainly evident, points out that when it was the common practice to tie a uterine polypus and allow it to slough off the mortality of the operation was 40 per cent.

Dr. Routh has collected forty-eight cases in which gastrotomy has been performed for fibrous tumour, In fifteen cases no attempt was made to remove the tumour; in the other thirty-three the tumour was removed either in whole or in part. Of these, twenty-three recovered and ten died, giving a mortality of 80·3 per cent.—nearly the same as in ovariotomy. Dr. Routh divides the cases into several classes, and attempts to show that if the fibroid be extra-uterine it may be removed with comparative safety; but, if not, then the best plan is to remove the whole uterus and both the ovaries. Dr. Routh insists very strongly upon the removal of the ovaries, and instances several successful cases in which they were removed. It seems to us that in these cases the result was successful because the tumour had risen well out of the pelvis, and that the ovaries were removed because the tumour drew them up along with it. There can, however, be little question that in most cases when removing the uterus it is wise also to castrate. Were this not done, it is too probable that hæmatoceles and ovarian disease would be the consequence.

We have some difficulty in following Dr. Routh in what he says about the treatment of fibrous tumours by simple incision of the os uteri. He says, p. 117—"But a method which is likely to supersede in great measure these more bloody operations is simple incision of the os subsequently carried right through the tumour." He gives as an illustration a case in which the tumour itself was deeply cut into and dressed with oiled lint, so that sloughing was set up. We cannot see any difference between this treatment and the nucleation by gangrene which Dr. Routh has shown to be so fatal. At the very next page Dr. Routh includes this case among nine others in which "this simple plan of incision of the external os was practised with the best results." And as no details are given, we do not know whether "this simple incision" did or did not in all cases involve the tumour so as to cause its death. Further, we are informed that even "so simple an operation as opening the cervix has a mortality of 30 per cent.;" so that altogether we fail to appreciate the great advantages which this operation offers. We conclude by thanking Dr. Routh for his laborious research, which has enabled him to present his Professional brethren with the interesting facts which are to be found throughout these Lettsomian Lectures.

A Handbook of Obstetric Operations. By W. S. Playfair, M.D., M.R.C.P., Assistant-Physician-Accoucheur to King's College Hospital. London: H. Renshaw. 1865. Pp. 232. Price 6s.

We have long thought that a good handbook of obstetric operations would fill up a blank in the modern English literature of midwifery. Dr. Playfair has come forward to fill up this blank, and we cordially wish him success. A book of an exclusively practical nature is a great boon to the busy Practitioner who already knows his subject, but may wish to refresh his memory on details. On the Continent, Hatin, Kilian, Gustave, Braun, and others have supplied such books. In England Davis published his "Elements of Operative Midwifery" in 1825, but from that time to the present, with the exception of a handbook afterwards embodied in a general treatise of midwifery, there has been no attempt to meet the want we speak of.

Dr. Playfair's book consists of a number of short practical essays on the more important obstetrical operations. His plan is to take up each operation, and, after giving a short account of its history, to lay down its indications, and describe the manner of performing it. The essays are carefully written, and will be perused with interest. The most recent improvements in each operation are detailed, and in the article on "Transfusion of Blood" Dr. Playfair gives the results of experiments which he has himself performed on the lower animals.

The chief fault which we have to find with the book is that there is not enough of it. Dr. Playfair has been so anxious to condense, that he has made some serious omissions.

In his second edition he will probably see the importance of adding chapters on the management of prolapsed cord, the management of placenta prævia, the extraction of the placenta, and other points scarcely less capital. No doubt Dr. Playfair purposely omitted the consideration of these subjects, because he judged that they scarcely came within the meaning of what he wished to express by operative midwifery. Here, however, we cannot agree with him. The plugging of the vagina, the reposition of the cord, the extraction of an adherent placenta, are operations for each of which rules ought to be laid down in a work purporting to be "a guide in the trying emergencies of practice."

Dr. Playfair has been as sparing of his woodcuts as he has been of his letterpress. We hope that the next edition will be much more profusely illustrated, and that the woodcuts will be scattered over the book, instead of being collected, as at present, into a couple of plates.

The Works of Sir Benjamin Collins Brodie, Bart., D.C.L., Serjeant-Surgeon to the Queen, President of the Royal Society, etc. With an Autobiography. Collected and arranged by Charles Hawkins, Fellow of the Royal College of Surgeons. 3 vols., demy 8vo. Longmans.

(PRELIMINARY NOTICE.)

No higher or more lasting tribute can be paid to the memory of a thoroughly earnest man, who spent his life in useful and unremitting work, than the publication in a collected form of the results of his life's labour and thought. Nor is it possible for the friends of such a man to confer a greater benefit upon the Profession to which he belonged than by placing before it what he did, by showing how he worked and lived, and by directing attention to the results of his experience. For collecting and arranging Sir Benjamin Brodie's works Mr. Hawkins truly deserves the thanks of the Profession. The work is arranged in three volumes, and contains in all more than 3000 printed pages.

In Vol. I. we find the "Autobiography," perhaps the most interesting part of the work; "psychological inquiries;" several "introductory lectures," "addresses," and "orations," which will be new to most of us; and papers on Quacks, Homœopathy, Tobacco, and Special Hospitals.

Vol. II. contains Brodie's scientific researches; several papers from the Philosophical *Transactions;* his work on the Diseases of Joints; lectures on the Diseases of the Urinary Organs; and his Notes on Lithotrity.

In Vol. III. the reader will find several important papers; lectures on Pathology and Surgery; and forty different "Pathological and Surgical Observations," never before published. These were taken down by Dr. Reginald Thompson from Sir Benjamin Brodie's dictation during the winter of 1861-1862.

We may refer to an elaborate analysis of Brodie's works which was published in the *Medical Times and Gazette* soon after his death; but there is much in these volumes that is new, and we shall therefore give, at a future time, further notices of the life and works of this great Surgeon from Mr. Hawkins' "Works of Sir B. C. Brodie." In the meantime, we commend the volumes to our readers.

The book is published by Messrs. Longman, and printed by Spottiswoode in a very clear and good type. It is illustrated with copies of the medal presented to Sir Benjamin Brodie when he resigned the office of Surgeon to St. George's and a facsimile of his handwriting.

Practical Observations on the Hygiene of the Army in India. By Stewart Clark, M.R.C.S. Eng., Inspector of Prisons North-west Provinces, India. Smith and Elder. 1864. Pp. 162.

In 1862 Mr. Clark read a paper before the British Association on the best means of ventilating the barracks and other public buildings of India. His present work is of wider scope, and treats of food, water supply, the supervision of the soldier, drainage, the construction of buildings, prisons, and prison discipline, etc. The writer appears thoroughly conversant with the wants of India, and of the European resident and soldier. In the matter of ventilation, he is of opinion that ventilation by artificial means is in India absolutely necessary, that in hot climates natural ventilation will not proceed during

certain atmospheric conditions, and that "if fresh air will not go where we wish it, we must drive it." In the case of barracks, which in India are generally only one story high and cover a considerable area, economical ventilation is not an easy matter. His proposal is that ventilation should be carried on by means of fans driven by steam or bullock power through a system of underground masonry flues with which the barrack flues are to communicate. The fans are to be placed at least three hundred feet to windward of the barracks to prevent foul air being returned with the fresh. The full details of the plan are illustrated by a number of ingenious woodcuts. The author has some useful practical remarks on the influence of daily atmospheric variations on cholera and fever. He states it as a fact that at about 2 or 3 o'clock a.m., that is towards the termination of the period of dead calm which commences about 6 or 7 in the evening, a sudden change takes place in the atmosphere, more or less perceptible to the outward senses, although not always indicated by the thermometer. The sensation it produces is one of a decided fall of temperature in the air. Persons in health fall asleep under the agreeable change, but it is the time when fever patients should be carefully watched, for not unfrequently marked depression or fatal collapse are ushered in by it, and it is very frequently the period at which the first liquid stool warns of the approach of cholera. In the matter of diet, Mr. Clark thinks that the English Government have fed their soldiers, on the whole, too highly—with too large an amount of animal food. He believes one meal of meat per diem is sufficient, and traces the better health enjoyed by European residents at least in part to the abandonment of the daily luxurious luncheon—the *tiffin* which the novels of our younger days taught us to associate with nabobs, liver disease, and elephants. On the whole, we can speak well of Mr. Clarke's book, which contains much of useful information and ingenious contrivance, and many hints that cannot but be valuable to the young Medical officer who is starting for one of the three presidencies.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEBRUARY 28.

Mr. PARTRIDGE, President.

A PAPER, by Mr. J. W. HULKE, was read on a

CASE OF ICHTHYOSIS OF THE TONGUE.

Ichthyosis is a term provisionally applied by the author to an affection of the mucous membrane of the tongue, which consists in hypertrophy of its epithelial and papillary tissues. It is characterised by yellowish-white, raised, tough, leathery patches, which are clinically distinguished from syphilitic nodes, condylomata, and cancer. Mr. Hulke had seen but one case, which he relates.

Mr. BIRKETT, in 1853, saw a patient, an old sailor, who had a similar affection to that described by the Author. It had existed many years, and was merely an annoyance.

Mr. HOLMES COOTE remarked that he had published a similar case in Holmes's "System of Surgery," but had not given a name to the affection. It occurred in an old woman. There was no evidence of syphilis; it was not cancerous, but merely a thickening of the epidermis.

Dr. STEWART said that the year before last a gentleman from India came to ask him if an affection of his tongue was syphilitic or not. After due inquiries there was no ground for the slightest suspicion of that as a cause. He had had syphilis four years ago, but had got well of it, and then married. Mr. Henry Lee saw him, and thought he was free from syphilis. All sorts of detergents were applied, and the solution of the chloride of zinc had no effect. Dr. Neligan had described a similar condition of the tongue in a case which, after slight irritation, ended in cancer. His (Dr. Stewart's) patient was still in good general health.

Mr. PAGET said the affection described by the Author was sufficiently rare to warrant each member giving his individual experience. He referred to a specimen in the museum of St. Bartholomew's Hospital taken from a patient who died of cancer of the tongue, with disease of the lymphatic glands. Although ultimately the disease was cancerous, it had for ten years resembled the condition described by the Author of the paper. This patient also used to pare down the growth as if it were a corn. He (Mr. Paget) did not wish to imply that this form of disease was more likely to end in cancer when the patient became old than many other diseases of the tongue which were accompanied by irritation. The Author's case was the first of the kind placed on record, and was interesting as suggesting that diseases of the tongue should be studied in connection with those of the skin. Mr. Paget then related a case which was, he believed, an instance of ringworm of the tongue.

Mr. C. H. MOORE alluded to a case in which it was difficult to distinguish cancer of the tongue from other affections of that organ. He referred to a case then under his care in the Middlesex Hospital, in which there was an ulcer of the tongue, and opposite the growth was a patch of disease, like that described by the Author. There was also a similar patch on the cheek. Although it was clear that Mr. Hulke's case was not yet one of cancer, yet it would be a bold thing to assert that cancer would never occur in the part diseased. At present, although only an hypertrophy, it might afterwards become cancerous.

The AUTHOR then briefly replied. He had no doubt, he said, that the patches Mr. Moore spoke of in his patient's case resembled the masses on the tongue in his (the Author's) patient; yet the clinical history of the two cases was very different.

A paper, by Mr. THOMAS LONGMORE, was read, entitled,

REMARKS UPON OSTEO-MYELITIS CONSEQUENT ON GUNSHOT WOUNDS OF THE UPPER AND LOWER EXTREMITIES, AND ESPECIALLY UPON THE TREATMENT OF STUMPS AFFECTED WITH OSTEO-MYELITIS AFTER AMPUTATION NECESSITATED BY SUCH INJURIES.

The author commenced his communication by noticing the particular interest which had been excited amongst military Surgeons, especially French Surgeons, during the last few years in the subject of osteo-myelitis, or endosteitis, as it is called by some writers, after gunshot wounds of the extremities, and of its proper treatment. The interest arose, not from any belief that a difference existed between the nature of the inflammation of the medullary tissue when developed after gunshot injuries, and the corresponding inflammation occasionally seen after the ordinary injuries and amputations of civil life, but from the comparative frequency of its occurrence after gunshot injuries, and after amputations consequent upon them, together with its severe and obstinate character, often in men of previously sound constitutions, in military practice, contrasted with the comparative rarity of its occurrence in sound constitutions in civil practice. After the Crimean campaign, Dr. Valette, a French military Surgeon, who had had one of the large Hospitals at Constantinople under his charge during the period of the war, and again, since the Italian campaign of 1859, M. Jules Roux, the principal Surgeon at the large marine Hospital of St. Maudrier at Toulon, had both written at considerable length on the subject. Dr. Valette's observations were chiefly directed to this inflammation in its earlier and more acute stages, as witnessed amongst the wounded sent directly after the battles of Alma and Inkerman, amongst whom it had produced the most fatal consequences. The author remarked that in perusing Dr. Valette's reports, the conclusion could scarcely be avoided that the so-called osteo-myelitis, in a large number of the instances referred to, must have been truly cases of pyæmic poisoning, and that in all, the symptoms of the osteo-myelitis must have been greatly aggravated by circumstances tending to the development of pyæmia. Dr. Valette found all attempts to check the disease ineffectual, and came to the conclusion that all resections and amputations for the effects of this inflammation after gunshot fractures should be abandoned, and exarticulations substituted, the wounded being scattered at the same time in tents as widely as possible. M. Jules Roux's observations were made on the disease in its more chronic condition, and he was led to advocate the same views with regard to the necessity for exarticulation as had been advocated by Dr. Valette. M. Roux had under his care about 2000 soldiers who had been wounded in the Italian campaign, a considerable number of whom presented diseased conditions demanding consecutive amputation or other Surgical interference. At first M. Roux practised amputation, but with such unfavourable results that he was induced to try exarticulation in similar cases instead. This operation proved remarkably successful. There was no death out of twenty-two successive cases, among which were four cases of exarticulation

at the hip-joint. In a memoir on the subject which was read before the Imperial Academy of Medicine at Paris in 1860, M. Roux argued that when osteo-myelitis after gunshot wounds assumes a chronic form, amputation generally only takes away a portion of the inflamed bone, and in consequence of this incompleteness in the operation the disease is aggravated in the remainder. Hence, he asserted, the failures of secondary amputations for gunshot wounds of bones; and hence, also, in his opinion, the preference which ought to be given to exarticulation, or removal of the whole of the diseased bone, when a Surgical operation becomes indispensable. The views of treatment propounded by M. Roux has led to several protracted discussions at the Academy of Medicine at Paris. They were particularly analysed in an elaborate discourse by Baron Larrey, which he afterwards published. In this discourse Baron Larrey arrived at certain conclusions, six in number, with the general terms of which the author said he believed most English army Surgeons would agree. The following are the conclusions referred to:—1st. Osteo-myelitis after gunshot wounds is more frequent than has been hitherto supposed; but is not inevitable, and in most instances is a means of cure. 2nd. It may either be limited to a given point of the bone, extend itself partially, or invade the whole of the bone more or less quickly. 3rd. Every rational mode of treatment must be adopted in the first instance. We are encouraged to do so because we know osteo-myelitis is susceptible of spontaneous cure. 4th. Sometimes it necessitates resection, and sometimes consecutive amputation, and sometimes, in certain cases, exarticulation is preferable. 5th. The existence of osteo-myelitis is sufficient to explain the want of success which occasionally follows partial operations in bones affected with this inflammation. But, 6th. It does not justify the too exclusive proposition in Surgery, that resection of joints and amputations in the shafts of bones are to be abandoned for exarticulation in all such cases. The author of the present paper thought, however, that the settlement of the question of the proper treatment of chronic osteo-myelitis might be carried a step further in precision, especially in cases where want of success had seemingly followed partial operations on account of its presence. Many cases, he stated, came before military Surgeons, in which, after amputation had been performed in continuity for gunshot injuries, or for the effects of osteo-myelitis consequent upon them, the portions of the limbs left afterwards presented such diseased conditions as to necessitate further Surgical interference in order to avert fatal consequences from the patients. In these cases, where the morbid state of all the tissues is manifestly due to the continued osteo-myelitic action subsequent to the amputation, what is the course to be pursued? The arguments of M. Jules Roux would urge most forcibly in these cases, that exarticulation is the only treatment that can scientifically be adopted; and even according to the conclusions of Baron Larrey these would appear to be the "certain cases" to which he refers in his 4th conclusion, where curative treatment in the first place and consecutive amputation in the next place having failed, disarticulation would be the preferable course to follow. The author had been led to adopt a different conclusion; and, in order to show to the Society the grounds on which his conclusions had been based, he called attention, firstly, to certain preparations belonging to the Museum of the Army Medical Department from cases in which exarticulation had been performed or death had occurred on account of osteo-myelitis; and secondly, to the histories of some similar cases in which a cure had been effected without exarticulation being resorted to. The first three preparations exhibited consisted of the upper portions of three humeri. In each of these the history was—amputation at the middle of the upper arm for a gunshot wound, and exarticulation at the shoulder within a year afterwards for osteo-myelitis. The fourth preparation was one of the upper part of the femur which had been removed from the patient after death. Amputation had been performed in the middle of the thigh for a gunshot wound in India, and the patient died about a year afterwards from the effects of osteo-myelitis in the stump. There was every reason to believe that in all these cases the osteo-myelitis was due to the shock of the original gunshot injury, and not to any peculiarities in the amputation or other causes. To show that the simple shock of a gunshot wound is capable of giving rise to general endosteitis in a bone, another preparation was exhibited in which the entire shaft of the femur had been subjected to the action of this inflammation. In this case a musket ball had only penetrated the soft tissues and struck the bone, without producing complete or even a partial fracture of its substance. Another preparation of the upper half of a humerus was exhibited from a case in which the author had performed exarticulation for osteo-myelitis four years ago, before his attention had been turned to other modes of treatment. In this case the previous amputation had been performed for the effects of a kick from a horse, and the preparation was exhibited to show that the consequences of the osteo-myelitis were exactly similar to those which had occurred after the gunshot injuries. All the preparations above named showed that in each case extensive necrosis of the shaft had resulted from the endosteitis with which it had been affected; that the necrosed portions were well defined within fixed limits; that in no instance was the necrosis continued to apophysis, although in all the cases the apophyses were more or less in the condition known by the term "osteo-porosis;" and that the sequestrated portions of the shafts were surrounded by copious shells of new bone, as in cases of ordinary necrosis. Three cases were then related in which amputation at the middle of the thigh had been followed by osteo-myelitis in the stump, but in which cures had been obtained without exarticulation. The amputation had been performed in two of these cases for gunshot wounds, in the third for the consequences of a compound fracture from a fall. In each of these cases the removal of the sequestra left by the osteo-myelitic action was effected by Surgical interference, and a sound and healthy condition of the stump resulted. In the case first described, the patient at the time of his admission into Hospital at Fort Pitt, from India, had suffered so severely from the effects of the prolonged irritation to which he had been subjected, and the thigh-stump was so extensively diseased throughout, that at a consultation of the staff of the Hospital the removal of the stump at the hip-joint was determined to be the only course which held out a fair hope for the patient's recovery. Fortunately, before this serious operation was undertaken, a study of the preparations laid before the Society, and some others of a similar kind, led the author of the paper to determine, as a preliminary measure, to open freely the cicatrix of the amputation-wound, and to take steps for removing all pieces of necrosed bone that might be found within the remaining portion of the shaft. The operation was so conducted that, if necessary, it could have been converted at the time into amputation at the hip-joint, or this formidable operation be reserved for a subsequent resource, if the removal of the necrosed bone did not lead to cure. Complete success, however, attended the first effort: the dead portion of the shaft, which reached up to the trochanters, was extracted, together with some smaller detached fragments. The patient rapidly improved in all respects afterwards, and eventually walked from the Hospital with an artificial limb applied to the stump, which had become perfectly sound. The second and third cases mentioned were those of soldiers, who had suffered amputation of the thigh for gun-shot wounds, and from subsequent endostitic necrosis in the stump. In both cases the necrosed portions of the shaft were removed by gradual traction through openings in the line of cicatrix of the amputation-wound. In one of these instances, in which the man's limb had been smashed by a round shot just above the knee, at Lucknow, in 1857, an opportunity was afforded of examining the state of the stump five years after the date of the amputation. The stump was then thoroughly sound, and the man able to perform hard work and long journeys by wearing an artificial limb upon it. The motions of the hip-joint were perfect. The author of the paper stated his present conviction to be that if similar steps had been adopted, and the necrosed sequestra removed, in the instances brought before the Society in which exarticulation at the shoulder had been performed by himself and others, the stumps might have been similarly preserved; and that in the instances of the femoral stump, and the femur affected with endostitie necrosis, the lives of the patients might probably have been saved by such a proceeding. In cases where amputation had been previously performed, the amputation cicatrix should be opened for the removal of sequestra, or, if more convenient, the stump could be opened from other directions; where no previous amputation had been done, the sequestra should be extricated as in ordinary cases of necrosis. Though not a matter of such importance to avoid exarticulation of a humeral stump as it is of a femoral stump, owing to the danger to life in the latter operation, and the important use of a thigh-stump for the adaptation of mechanical contrivances for assisting in supporting the weight of the body, yet the author maintained the preservation of a humeral stump to be of great value to the

possessor, especially when the power of compressing it to the side is retained. An osteo-porotic condition of the articulating heads of the bones, corresponding with the condition shown in the preparations, will not interfere with a successful result if the necrosed sequestra be completely removed. The author alluded to a case in which he had removed a foot at the ankle-joint, in which, on sawing off the two malleoli, the extremities of both the tibia and fibula were seen to be extensively affected with fatty osteo-porosis; yet the ends of these bones became firm and solidified under an improved condition of general health, the removal of the source of irritation which had previously existed in their immediate neighbourhood, and the stimulus of use. There could be no doubt that the head and neck of the femur in the case of the thigh-stump which had been preserved by the removal of the sequestra, the largest of which was exhibited to the Society, was in a state of osteo-porosis at the time these sequestra were extracted. The amount of irritation to which the bone had been subjected, the length of time that had elapsed, together with the conditions observed in analogous cases where the opportunity of examining the conditions had been afforded, sufficiently established the fact. The author concluded by observing, that while adopting generally the views of Baron Larrey, before quoted, in reference to the nature, progress, and treatment of osteo-myelitis after gunshot injuries, the following appeared to be fair deductions from the facts and observations he had brought to the notice of the Society:—1st. In gunshot injuries of bone, it will be found for the most part—what might be anticipated from the intimate connexion which exists between the periosteal and endosteal investments of the bony tissues, and from the violent general mischief effected by the stroke or passage through them of a projectile—that all the structures participate not only in the immediate local destruction, but also in the extended inflammation which follows, whether the inflammation after a time subsides, and terminates in repair, or whether it continues in a chronic form. 2nd. There exists this difference between the inflammation of the endosteum and that of the periosteum: that of the endosteum has a special tendency after gunshot injuries to degenerate into a chronic condition analogous to that of suppuration in other tissues, to extend itself along the cancellated structure, and thus to produce disintegration and death of the bony substance; that of the periosteum, at the same time, will exist only to such a degree as to cause it to exert a protective influence by the formation of new bone around the diseased tissues, just as in ordinary cases of necrosis from other causes. 3rd. If amputation in continuity be performed while the endosteum is suffering from the inflammatory irritation excited by the violent injury to which the whole bone has been subjected, especially when this has assumed a chronic form, the endostitis will most probably still pursue its course, even though the divided soft parts may at first become healed, slowly inducing death, more or less extensive, of bony tissue, and, in time, the usual consequences of such a condition throughout the whole stump. 4th. The morbid condition of the endosteum does not usually extend from the shafts of bones into their apophyses. 5th. When amputation has been followed by these consequences, exarticulation should not in any case be resorted to for the removal of the diseased stump until the effect of complete extraction of the dead bone by proper Surgical interference has been ascertained. 6th. Experience shows that, even although a patient's constitution may be greatly impaired by the prolonged local diseased action to which it has been subjected; and though there may be every reason to conclude that the articular extremity of a bone is in the condition understood by the term "osteo-porosis," yet the complete removal of the endostitic sequestra may speedily be followed by restoration of the general health, and by a condition of the stump so sound and firm that it may be applied to any purpose of utility for which, according to its length and position, it may be competent.

Mr. Fergusson said the Society was under special obligations to the Author for his able and interesting paper. The principles he had laid down applied to civil as well as to military practice, and he regretted that examples from the field of civil Surgery had not been brought forward. It had fallen to his (Mr. Fergusson's) lot to see a number of instances like those described—viz., of gunshot wounds—and also of cases so exactly similar in results, though from other causes, that the two classes could scarcely be dissevered. The author had travelled over an interesting field, and it was scarcely possible to do more than make a few brief remarks on some of the points in the paper. The subject of inflammation of bone was one of great interest, and he fancied that even the most practised Surgeons could never tell to what extent inflammation would occur after an injury. There was a great similarity in gunshot wounds and in compound fractures. The matter formed after gunshot wounds produced compression, and this excited inflammation of the periosteum, or of the internal lining membrane, which he considered to be analogous to the periosteum. He considered the Author's views were correct, whether applied to military or civil practice—viz., the extraction of dead bone rather than amputation. He spoke for the good of Surgery when he stated his decided conviction that many cases of amputation for diseased bone were not required, the extraction of the necrosed part only being sufficient. He cordially agreed with the author that we should do all in our power to remove the sequestra.

Mr. Holmes Coote had listened with the greatest interest to the Author's paper. It occurred to him that cases of the disease described admitted of being classified under two heads. He related two cases in point which had occurred in civil practice. Mr. Lawrence removed a leg for disturbance in the circulation of the limb. The stump did not close. He amputated again, and afterwards for a third time. The man left the Hospital, but was still not well, and at another Hospital a fourth operation was performed. The bone in this case presented precisely the appearance described by the author. In another case a young man had his knee crushed; amputation was performed, and he got quite well. Afterwards swelling of the stump occurred; it inflamed, and necrosis occurred. A piece of dead bone was removed, and recovery followed. In some cases he thought the disturbance was due to the shock of the accident, and in others to disease creeping up the bone.

Mr. Barwell said the patient whose case Mr. Coote had related first in his remarks came to the Charing-cross Hospital, where the bone was disarticulated. He (Mr. Barwell) brought the specimen to the Pathological Society. The bone was softened, and also inflamed and thickened. He asked the Author if he believed osteo-myelitis always ended in necrosis. He had seen cases in civil practice in which inflammation of the bone had not been followed by necrosis. In reference to extension of disease after injury, he said that after excision of the knee disease sometimes travelled up, but never down. With regard to the practice of the Author, he had no doubt as to its superiority over that of M. Roux.

Mr. Birkett showed a drawing of a thigh-stump from which necrosed bone had projected several inches. It had been pulled at, and had gradually protruded. On admission at Guy's a little more force was used, the bone was pulled out, and the boy got well. In reference to the paper, Mr. Birkett said that the Author, having been much abroad, was perhaps not aware that the practice he recommended was generally carried out in civil practice in England.

The Author, in reply to Mr. Barwell, said that in all the cases to which he had referred necrosis followed. He did not bring forward the views contained in his paper in order to contrast military with civil practice, but because M. Roux's views had attained immense influence. He had been led to doubt M. Roux's views by observing specimens in the Museum, and then came to the conclusion that in cases in which the bones had been disarticulated, not only the limb, but life, might have been saved if the simple operation of removing the sequestra had been practised. Since he had forwarded his paper to the Secretary he had received from Dr. Fayrer, of Calcutta, a Surgeon of great experience in military Surgery, a pamphlet strongly recommending M. Roux's practice. He mentioned this to show the great influence M. Roux's opinions had had.

ANNUAL ADDRESS.

The President then delivered the annual address. After alluding to the continued prosperity of the Society, both as to its scientific labours and the matter of its finances, he proceeded to give obituary notices of the Fellows who had been lost to the Society by death since the last annual meeting. Some of these, he said, had been contributors to the *Transactions*, and had adorned their Profession by their eminent career. Amongst them were some who had long retired from active practice, and others who had been stricken down in the prime of life and in the midst of their labours for the advancement of Professional knowledge. The list included the following names, to some of which an abstract of the notices given has been appended.

Samuel Cartwright, sen., F.R.S., F.L.S., who died on June 10, 1854, at Nizell's House, near Tunbridge, aged 76. Mr.

Cartwright was born at Northampton, and, without the aid of any pecuniary support or countenance from family or friends, had attained by industry, perseverance, and Professional skill, the highest eminence as a Dentist. His life was traced from its commencement, and particular reference made to the energy of character and physical power which enabled him to bear the extraordinary exertions imposed upon him by his extensive practice. He was appointed Dentist in Ordinary to George IV., and numbered amongst his friends and patients the most eminent persons in every class of life. He was a Fellow of the Royal and of most of the scientific and Medical Societies in London, and was the first President of the Odontological Society. He had retired from practice since 1857.

James Bird, M.D. Aberdeen, F.R.C.P., died at his house at Gerrard's Cross, Bucks, on July 10, 1864, aged 67. The greater part of Dr. Bird's Professional life had been passed in India, where he was Physician-General of the Bombay army. He had long retired from practice, but took an active interest in all that concerned military Medicine, Surgery, and hygiene. He lectured on these subjects at St. Mary's Hospital, and had been Vice-President, Treasurer, and Lettsomian Lecturer to the Medical Society. The President gave a summary of his contributions to the literature of military hygiene and sanitary reform.

Robert Dundas Thomson, M.D., F.R.S., died August 17, 1864, aged 53, at Dunstable House, Richmond. Dr. Thomson was the son of a Scotch minister in Berwickshire, and his chemical studies were pursued under his uncle, Dr. Thomas Thomson, and subsequently under Liebig at Giessen. In early life he made a voyage to India and China. On his return he resided for a time in London, afterwards went to assist his uncle in the duties of the chemical chair at Glasgow, and subsequently settled in London, where he was appointed lecturer on chemistry at St. Thomas's Hospital. On the establishment of Medical Officers of Health, he was the successful candidate for St. Marylebone, and devoted himself assiduously to the duties of his office. He organised a system of inspection which was adopted by his colleagues in their parishes; and on their forming an association he was elected their president. He became a great authority in all sanitary matters, and applied his chemical knowledge to the elucidation of numerous physiological and hygienic inquiries. His health failed him during the last two years, and he died of malignant disease of the alimentary canal.

John Drummond, R.N., Inspector-General of Fleets and Hospitals, died at Dover September 17, 1864, aged 72.

Samuel Maclean, F.R.C.S. Ireland, died October 18, 1864, at the age of 46. Mr. Maclean practised as a dentist in Wimpole-street.

Richard Roscoe, M.D. Edin., M.R.C.P., formerly consulting Physician to the Westminster General Dispensary, died on October 3, at Humberstone, Leicestershire, aged 71.

Thomas Sunderland Harrison, M.R.C.P., F.L.S., formerly Lecturer on Midwifery at the Charlotte-street School of Medicine and Senior Physician to the Farringdon Dispensary, for many years a magistrate of the county of Somerset, died at Bath December 22, 1864, aged 64.

Archibald Robertson, M.D., Edin., F.R.S., Lond. and Edin., died at the West Mall, Clifton, October 19, 1864, aged 74. Dr. Robertson was for many years Senior Physician of the Northampton General Infirmary. In early life he had served for a short period in the Royal Navy. He retired from practice about ten years ago, but continued a warm friend and supporter of the British Medical Association, over which he once presided at Northampton.

Charles Hall Clarke, M.D., Edin., died at Stoneyhurst College on January 14, 1865, aged 49. Dr. Clarke was the son of a clergyman at Reading. After graduating in Medicine at Edinburgh in 1839, he went to Bath, and was there elected one of the Physicians to the United Hospital. He subsequently established himself in practice as a Physician at Florence, and, having become a Roman Catholic, was appointed Physician to Stonyhurst College, which appointment he held at the time of his death.

William Senhouse Kirkes, M.D., F.R.C.P., died December 8, 1864, at Lower Seymour-street, aged 41. Dr. Kirkes was born in 1823 at Holker, in Lancashire. In 1841 he entered the Medical School of St. Bartholomew's, and the memory still remains there of his industry, talent, and blameless life. He became M.D. in 1846, and having successively been Medical Registrar, Demonstrator, and Assistant-Physician to St. Bartholomew's, was elected full Physician on the retirement of Dr. Burrows in 1864. The fifth edition of his well-known "Handbook of Physiology" appeared in 1863. He was the author also of numerous papers in the Medical journals, and of a paper on "Embolism" in the Medico-Chirurgical *Transactions*, which was the first English essay on the subject. At the time of his death he was on the Committee recently appointed by Government to investigate the subject of syphilis. His last illness commenced while engaged on that Committee, whither he still persisted in going, and in a few days he fell into a state of constitutional collapse, with symptoms of pleuro-pneumonia and pericarditis. His mind remained remarkably clear up to a few hours of his death. Some extracts from a letter from Dr. Burrows were read, stating that he had never known a more perfect character, and speaking of his ardent and indefatigable exertions, both as a student and a teacher, his conscientious discharge of duties, amiable disposition and Christian principles, and his perfect submission in his last illness to the Divine will.

Jones Quain, M.D., died January 30, 1865, aged 71. Dr. Quain was a native of the South of Ireland. He graduated in Arts and Medicine at Trinity College, Dublin, and afterwards received his M.D. degree there. After spending some time in Paris, at the close of his college career, he came to London, and became one of the anatomical teachers at the Aldersgate School of Medicine, at which time he published his admirable "Elements of Anatomy," which was such an improvement on the systems previously used in the schools, and which, enlarged by a succession of able additions, has now reached a seventh edition. In 1831 he accepted the Professorship of Anatomy and Physiology in University College, and soon established his claim to rank amongst the most able of the lecturers on anatomy in the metropolis. On his resignation of the Professorship in 1835 he was appointed to a seat in the Senate, and since that period lived a retired life, mostly in Paris, devoting himself to literary and scientific studies.

The President then added a few remarks relative to the improvement of the Society's residence. He stated that the hope of obtaining apartments amongst other learned and chartered societies at Burlington House had for the present failed; and he made various suggestions as to changes and improvements in the premises of the Society, for the consideration of which he thought the present was, for several reasons, not an unfavourable time. The President concluded by thanking the Fellows for the considerate kindness and support which they had always shown him during his occupation of the presidential chair, and had no doubt the Society would continue its prosperous career under the auspices of the eminent Physician and accomplished gentleman whom they had that day chosen to succeed him.

The result of the ballot for officers and Council for 1865-66 was announced by the President as follows:—President: (a) *Dr. Alderson, F.R.S. Vice-Presidents: *Dr. Weber, Dr. Basham, *Mr. S. Lane, *Mr. John Simon, F.R.S. Treasurers: Dr. Pitman, *Mr. Spencer Smith. Secretaries: Dr. Fuller, Mr. J. Birkett. Librarians: Dr. Stewart, *Mr. Luther Holden. Other Members of Council: *Dr. Barclay, *Dr. E. L. Birkett, Dr. Goodfellow, Dr. Meryon, Dr. Oldham, *Mr. O. M. P. Clayton, Mr. Holmes Coote, *Mr. Critchett, Mr. C. H. Moore, *Mr. Alfred Poland.

Votes of thanks were given to the retiring President for the able and efficient manner in which he had presided over the meetings of the Society, to the retiring officers of the Society, and to the members of the Scientific Committee on the Uses and Effects of Chloroform.

THE WATER SUPPLY OF CHELTENHAM.—Mr. Parsonage, the chairman of the meeting at which Mr. Jackson amused his audience by defying Parliament, has written to the *Times* complaining of the report which appeared in that paper, and which stated that Cheltenham is "a watering place without an adequate supply of water for ordinary purposes." He indignantly asserts that the supply to the town is only too small for extraordinary purposes. The *Times'* reporter vindicates himself by quoting Mr. Parsonage's own words at the meeting, and by asserting that the favour with which the proposition of bringing to Cheltenham from Cerney a million gallons of water a day was received was a tacit admission of the want.

(a) Those gentlemen to whose names an asterisk is prefixed were not on the Council, or did not fill the same office, last year.

GENERAL CORRESPONDENCE.

MR. SYME AND ACUPRESSURE.

LETTER FROM PROFESSOR SYME.

[To the Editor of the Medical Times and Gazette.]

SIR,—The duty of a Surgical teacher requires him not only to inculcate the principles and procedures which promise to be useful, but also to warn his pupils against those that threaten to be injurious. When, therefore, the Professor of Midwifery proposed to suppress hæmorrhage by means of needles instead of ligatures, I did not hesitate to say that such a change of practice seemed to me uncalled for, inexpedient, and, in most cases, impracticable. It appears that the expression of this opinion gave offence to the Professor of Midwifery, who, in addition to his thick volume on the subject, has lately printed and extensively circulated a pamphlet in which my deliberate statements with regard to a subject strictly belonging to my own department of instruction are characterised as "foolish," and otherwise referred to in most offensive language, imputing not only ignorance of my Profession, but a want of good faith in teaching it. In noticing this publication it was not the mode of treatment in question, as has been most untruly stated, but the personal attack, to which I called attention, and gave the only reply it deserved. I am, &c.

Edinburgh, March 6. JAMES SYME.

LIST OF SUCCESSFUL CANDIDATES AT THE ARMY MEDICAL EXAMINATIONS.

THE Director-General of the Army Medical Department presents his compliments to the Editor of the *Medical Times*, and begs to enclose a list of the candidates who were successful at the competitive examination in August last, and who have passed through a course at the Army Medical School, showing the combined results of the examinations.

6, Whitehall-yard, London, March 6.

LEGAL INTELLIGENCE.

SUCCESSFUL PROSECUTION UNDER THE VACCINATION ACT.—A FINE INFLICTED FOR NEGLECTING TO BRING A CHILD FOR INSPECTION.

ON Wednesday, at the Marylebone Police Court, James Maunders, a cabman, was summoned before Mr. Yardley, at the instance of Mr. James George Gerrans, district vaccinator, for refusing and neglecting to cause his child to be taken to him for inspection upon the eighth day after vaccination, in compliance with the Vaccination Act, 16 and 17 Vic., cap. 100, sec. 3.

The defendant said: My wife was not well enough to take the child; besides, the child was ill. Another thing, I have already lost three children through vaccination. The scabs had dried up, and I did not deem it necessary that the child should be taken.

Mr. James George Gerrans said: I reside at No. 6, Wyndham-place. I am one of the vaccinators for the district, and am also appointed by the Vaccine Board. On the 20th of February the defendant's child was brought to me. I vaccinated it, and told the mother to bring it again on the eighth day following. The child has not been brought to me since.

Defendant: I did not want to have it done at all or taken to him, but he kept asking and pestering me about it.

Mr. Yardley: He was looking to your child's welfare. It was incumbent upon you to have it done.

William Denzelow was then called, and said: I am a student at St. Mary's Hospital. I went by request of Mr. Gerrans to the defendant's house on the same day that the child ought to have been brought. I forget the date or the day. I know it was the day the child ought to have been brought. I saw the defendant's wife, and told her to bring the child. She said she did not like, because some others had died before.

In reply to Mr. Yardley, defendant said he had no question to ask, but added, "I did not like to have my child taken there to be tormented by a lance, and then its poor little flesh scraped."

Mr. Gerrans: The defendant's child was the only one that I had for a week from which to get a supply of lymph, and on the day that the mother ought to have brought it I had at least a dozen children waiting in my Surgery to be vaccinated.

I sent Mr. Denzelow to her, and she would not come. The consequence was, I had to dismiss all the patients.

Mr. Yardley said that this being the first case under the Act, he would not inflict the full penalty of 20s., but would order the defendant to pay a fine of 5s., or in default to be imprisoned for seven days.

MEDICAL NEWS.

APOTHECARIES' HALL. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, March 2, 1865:—

Thornton Gerald Simpson, Westbourne-road, Arundel-square, Islington, N.; Henry Cornelius Libbey, 240, Dewsbury-road, Leeds.

The following gentleman, also on the same day, passed his first Examination:—

William Evatt Wright, Guy's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ADAMS, A. B., M.R.C.S. Eng., has been appointed House-Surgeon and Secretary to the Hants County Hospital, Winchester.

ANDERSON, J., M.D., has been appointed a Fellow of the University of Calcutta by the Governor-General of India in Council.

CARPENTER, ROBERT H. S., L.R.C.P. Lond, has been appointed Consulting Surgeon to the Northumberland and Durham Miners' Permanent Relief Fund.

CAUNT, WILLIAM, Mr., has been elected Dispenser at the Horncastle Public Dispensary.

DAVYS, FRANCIS J., L.K.Q.C.P.I., has been appointed Coroner of the Northern Division of the County of Dublin.

DIGGES, WILLIAM H., L.A.H. Dub., has been elected Resident Apothecary to the Meath Hospital and County Dublin Infirmary.

KEENE, FREDERIC, L.R.C.P.L., has been appointed Medical Officer for the Headley Incorporation.

POLLOCK, A. JULIUS, M.D. St. And, has been elected Physician to the Foundling Hospital.

PYLE, THOMAS H., M.R.C.S. Eng., has been appointed Consulting Surgeon to the Northumberland and Durham Miners' Permanent Relief Fund.

TUKE, JOHN B., M.D. Edin., has been appointed Medical Superintendent of the Fife and Kinross District Asylum.

WEBB, WILLIAM, M.D. St. And., has been appointed Surgeon to the Wirksworth District of the Derbyshire County Police.

DEATHS.

BELL, DOLWAY, L.F.P. and S. Glasg., at Bellgrove, Glenary, Co. Antrim, on February 17, aged 65.

CAMERON, HUGH, L.F.P. and S. Glasg., at Clackmannan, N.B., on Feb. 24.

CRICHTON, Sir ARCHIBALD W., M.D., D.C.L., at St. Petersburg, on February 15 (27), aged 74; for many years the Physician in Ordinary to the late Emperor Nicholas I. of all the Russias.

GILLESPIE, JOHN, M.D. St. And., at Constitution-street, Leith, on Feb. 20.

HASTINGS, A., Surgeon, at High-street, Warwick, on February 24, aged 46.

HILL, JOHN, M.R.C.S. Eng., at South Cave, Brough, Yorks., on February 23, aged 63.

HOWELL, GRIFFITH, M.R.C.S. Eng., at Llanchaiadc, Oswestry, on February 20, aged 32.

JACOB, ARTHUR E., M.D., late of H.M. 82nd Regiment, at Yea, Victoria, on February 7.

WILLIAMS, NICHOLAS, L.R.C.P. Edin., at Bride-cottage, Crookstown, Co. Cork, on March 1, aged 28. His career while a student in the Carmichael School of Medicine, Dublin, was most distinguished, as he carried off prizes in every branch of his Profession.

ROYAL COLLEGE OF SURGEONS.—The following members of the College, having been elected Fellows at previous meetings of the Council, were admitted as such on March 9—viz., Messrs. Henry Hemsted, Newbury, diploma of membership dated October 3, 1828; Charles Lindsay Cox, the Queen's Indian Army, May 18, 1838; Henry Pitman, the Queen's Indian Army, April 13, 1840; and William Yeoman Sheppard, Bristol, February 18, 1842. At the same meeting of the Council, Mr. Edward J. A. Trimmer, M.A. Cantab, was elected secretary of the College, in the vacancy occasioned by the decease of Mr. Edmund Belfour, who held the office more than half a century.

TESTIMONIAL TO DR. HAMILTON, OF FALKIRK.—A handsome silver epergne has been presented to Dr. Hamilton by the members of the Falkirk School of Arts, in recognition of Dr. Hamilton's valuable services to that Institution.

THE LEVÉE.—The *levée* on Wednesday was attended by the following members of the Medical Profession:—Mr. R. W. Beaumont, R.N.; Mr. Parr W. Hockin, Deputy-Inspector of Hospitals; Dr. E. L. M'Sheehy; Mr. W. Purcell, R.N.; Staff Assistant-Surgeon Frank Simpson; Sir Henry Holland, Bart.; Sir Rutherford Alcock; Drs. Sieveking, Francis Hawkins, Minter, James Brown Gibson, C.B., Arthur Farre, Frederick G. Reed.

MUNIFICENT BEQUEST.—The funds of University College Hospital will shortly be augmented by the handsome sum of two thousand pounds, bequeathed to the institution by Mr. Arthur Woodriff Jaffray, a wealthy and benevolent American merchant, formerly of St. Mildred's-court, Poultry.

PROFESSIONAL EXAMINATIONS.—The next preliminary examinations on the subjects of general education will take place at the Royal College of Physicians on the 28th and 29th inst., and at the Royal College of Surgeons probably in June next. At the latter institution the next primary or Anatomical and Physiological examinations for the present session will take place on Saturdays, the 8th, 15th, and 29th April, and the pass or Surgical and Pathological examinations for membership on the 22nd April and 6th of May. The examinations for the Fellowship will take place as usual in May next, when the Midwifery Board will also meet.

CAPITAL PUNISHMENT.—The Capital Punishment Commissioners met on Friday and Saturday, the 3rd and 4th inst., at No. 2, Victoria-street, Westminster, when the Duke of Richmond; Lord Stanley, M.P.; Mr. Horatio Waddington; Mr. Gathorne Hardy, M.P.; Mr. Charles Neate, M.P.; Mr. John Bright, M.P.; Mr. G. Ward Hunt, M.P.; and the Lord-Advocate attended. The Secretary, Mr. J. H. Patteson, was also present.

THE FRENCH MEDICAL CONGRESS.—The third Medical Congress is to be held at Bordeaux on October 2, and will continue its sittings during six days. Practitioners residing at Bordeaux will pay 10 francs, but non-resident Practitioners may obtain cards which will admit them to the Congress free of all expense by applying to the Secretary, Dr. Charles Dubrueilh, 1, Rue Victor. The following six subjects are to be discussed, but others may also be introduced at the option of members of the Congress:—1. Rheumatism. 2. Expectation in acute disease. 3. The malignant forms of furuncle and anthrax. 4. Sudden death following traumatic injury and in the puerperal conditions. 5. On the suppression of *tours* (receiving boxes at Foundling Hospitals), in relation to their effects on morals and society. 6. The external and internal parasites of man, and the means suitable for their destruction. Any member of Congress wishing to communicate written or oral observations on these or other topics should apprise the Secretary thereof before September 15.

ROYAL INSTITUTION OF GREAT BRITAIN.—General Monthly Meeting, Monday, March 6, 1865.—William Pole, Esq., M.A., F.R.S., Treasurer and Vice-President, in the chair. The decease of his Grace the Duke of Northumberland, K.G., F.R.S., the President, on February 12 last, was announced from the chair. Ernest L. S. Benzon, Esq.; I. J. Unwin Clarke, Esq., jun.; Henry H. S. Croft, Esq.; Woronzow Greig, Esq., F.R.S.; Richard Belgrave Jackson, Esq.; John Macpherson, M.D.; Farquhar Matheson, Esq.; Henry Wilkes Notman, Esq., F.R.G.S.; Charles Rogers, Esq.; James Vaughan, Esq.; Lieut.-Colonel G. F. Whitelocke; were elected members of the Royal Institution. The Chairman announced the following addition to "The Donation Fund for the Promotion of Experimental Researches"—Henry Bence Jones, M.D., Sec. R. I. (second donation), £20; S. R. Solly, Esq. (third annual donation), £20; Adam Murray, Esq., £5 5s. The presents received since the last meeting were laid on the table, and the thanks of the members returned for the same.

TESTIMONIAL TO R. GARNER, ESQ., OF STOKE-UPON-TRENT, F.R.C.S. and F.L.S.—A number of the friends of this gentlemen, most of whom have long experienced the advantages of his Medical skill, and have highly esteemed him for his unwearied attention to the duties of his Profession, have just shown their high appreciation of his public and private character in a very pleasing and practical manner. On Tuesday last there was to be seen at Mr. Farr's, coachmaker, Newcastle, a handsome new circular-fronted brougham, built in Mr. Farr's best style; a fine young horse suitable for the carriage, and fitted with a set of silver-mounted

harness, everything of the best, and quite complete. The carriage was purchased by the subscriptions of the ladies, and the horse and harness by those of the gentlemen. The cost of the set out is about £180, the whole of which has been most freely subscribed without any other effort than the simple suggestion that such a thing was going on. Testimonials are, it is true, very common in the present day, but all who know the many years Mr. Garner has gratuitously devoted his time and talents to the benefit of the North Staffordshire Infirmary, as one of its Surgeons, and the unselfish manner in which he has pursued his general Professional course with signal benefit to his fellow-creatures, will allow that this is a well-timed offering of esteem and commendation, and will join in the wish that he may be long spared to enjoy it.—*Staffordshire Advertiser*, March 4.

The Examination of the Spinsters of Lochend.—This scandal has drawn the attention of the Free Church General Assembly. At a meeting held at Edinburgh, Dr. Candlish called attention to the extraordinary advertisement lately published by the Free Church minister of Lochend in the *Inverness Courier*. The advertisement, it will be remembered, stated that all the young and unmarried women of Lochend had assembled in the vestry of the Free Church to get their characters "adjusted" by Dr. Campbell, in consequence of an imputation arising from the circumstance that the dead body of an infant had been found in Loch Ness, the certificate being that the Medical man had examined a number of young and unmarried women of Lochend, and had "no reason to believe that any of them had been recently confined." Dr. Candlish hoped that the local presbytery would lose no time in investigating the case, and should they fail in their duty he had no doubt that the next General Assembly would take cognisance of the matter.

Another Road Murder.—Dr. Wybrants, Coroner for East Somerset, has just been investigating a most mysterious case at Emborough, a small village, lying between the cities of Bath and Wells. This inquiry, which was twice adjourned, resulted in a verdict of "Wilful murder." The facts of this very remarkable case are as follows:—On February 8, William, the only surviving child of Mr. Charles Coles, aged 7 months, died very suddenly, in consequence of a powder administered to him by his mother, and which powder she supposed to be one of "Steadman's Soothing Powders," from a packet of which she took it. Death resulted in ten minutes. It appeared that on December 31 a woman named Ann House purchased of Mr. Habgood, chemist, Wells, a packet of Steadman's powders for Mrs. Coles, and that in January Mr. and Mrs. Coles themselves purchased another packet of the same powders. One was given to the child with a good effect, and the remainder were placed in a cupboard in the parlour. In the evening of February 8, Selina Young, the nursemaid, was sent by Mrs. Coles to the parlour for the powders, and she took them to where Mrs. Coles was nursing the child. Mrs. Coles took out a powder, mixed it with moist sugar, and gave it to the child, who died within ten minutes after. Mr. Cartner, a Surgeon, was sent for, and when he arrived he requested a Mr. Ham, who was present, to take charge of the remaining powders. He did so, and subsequently Mr. Cartner made a post-mortem examination of the child, and found that he had died of a collapse produced by corrosive mineral poison. On examining the powders given to Mr. Ham, he found that one of them contained ten grains of bichloride of mercury; the other powders contained none. Mr. Habgood, the chemist of whom the powders were bought, Mr. Faulconer, of 5, Queen's-row, Walworth-road, the proprietor and manufacturer of the powders, and Mr. White, the managing clerk of Messrs. Barclay and Co., the agents who supplied Mr. Habgood, were severally examined, and stated that by no possible means could poison have been introduced into the powder as issued by them, inasmuch as they were sealed and stamped with the Government stamp. It was further proved that Mr. Coles kept lump mercury in his house for the purpose of treating his sheep, and that Joseph Chard, the shepherd, also had a lump, which he had lost. Mr. Deane, of London, an analytical chemist, proved that the powders he examined contained particles of hair or wool, and also some dirt. He was of opinion that it was impossible that such particles could have entered packets in a chemist's shop. The Coroner summed up at considerable length, pointing out the incontestable fact that the child had been poisoned, and that poison had been substituted for the powders, as was proved by one packet of poison still remaining among the others. The jury returned an open verdict to this effect, which is substantially one of "Wilful murder against some person or persons unknown."—We mentioned this case in our journal of last week. Our readers will not fail to observe that the purity and proper preparation of the patent medicine were taken by the witnesses for granted, *because* they were sealed and stamped with the Government stamp!

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

We shall publish in our next the very interesting case of Excision of the Knee-joint, by Dr. James A. Grant, F.R.C.S., of Ottawa, Canada West. We shall also commence the first of a series of practical papers by Dr. Wm. Murray, of Newcastle. Our readers will remember that Dr. Murray published in the Medico-Chirurgical *Transactions* the first successful case of treatment of aortic aneurism by pressure.

Irenæus.—We think it was Lieut. Hawkey, of the R.M.

A Student of St. Bartholomew's.—A very good guide to the Medical schools of Paris was written by Dr. Wiblin, of Southampton. Inquire of Mr. Renshaw, Strand.

A Fellow, Bengal Presidency, at Home.—Having been elected in 1860, the Diploma could not be conferred on you until your return to England. Report yourself at once to the Secretary, as there will be a meeting of the Council on Thursday next to elect and admit to the Fellowship.

The Royal Medico-Chirurgical Society.—The debate of which we published a full report last week was well adapted to ventilate a principle, and will bear fruit in due time. It is not the question whether the Obstetrical and Pathological Societies are well accommodated for the sum they pay, and are content with their bargain; and as no complaint proceeds from these Societies, we must suppose that they are. The question is whether or not it is consistent with the dignity of the Medico-Chirurgical to exact anything like profit out of the younger Societies. It is a question in which differences of opinion may be amicably entertained by honourable men on either side, and it is quite fair that it should be fully debated and fully reported. For our own parts, we adhere to the principle that the *shop* element should not be allowed to enter the question, and that the Medico-Chirurgical Society might gracefully accommodate its tenants at a sum just sufficient to save itself from loss, and to replace wear and tear.

Epigram on Mead, from the Welsh.

Nectar of bees, not Bacchus, here behold,
Which British bards were wont to quaff of old;
The berries of the grape with Furies swell,
But in the honeycomb the Muses dwell.

—The original appeared in *The Times*, September 27, 1850.

Poor-law Medical Reform.

to the editor of the medical times and gazette.

Sir,—I shall feel obliged by your giving insertion to the accompanying letter, in order that the Poor-law Medical officers may know that I am not unmindful of their interests. During the last three months I have been in correspondence with Members of Parliament; but in the face of a general election there is evidently an indisposition to bring in a bill for Medical relief. One M.P. writes: "I shall see Mr. Villiers on the subject of your bills, and see what support we may expect from that quarter;" and in a postscript he adds, "I feel that it would be next to useless to attempt the passing of a bill or bills unless the Government would give some support. Unfortunately, the Profession is so disunited that all Governments can take advantage of us in our individual exertions; *not so the law.*" From this gentleman I have not heard since January 31—the date of the above letter—although I have addressed three letters to him. I am, &c. Richard Griffin.

12, Royal-terrace, Weymouth, March 7, 1865.

"12, Royal-terrace, Weymouth, March 6, 1865.

"My Lords and Gentlemen,—On the 2nd of September, 1864, I had the honour to receive a letter from you, in which you say, 'The Poor-law Board beg to inform you that the subject to which you refer has been under their consideration; but that they have not yet come to a decision as to the measures which it may be desirable to recommend the guardians of the different unions to take with reference to the resolution of the Select Committee on Poor Relief, as regards the supply of expensive medicines. The question, however, will receive the attention of the Board forthwith.'

"It is now just twelve months (March 11, 1864) since the Select Committee on Poor Relief recommended 'that in future cod liver oil, quinine, and other expensive medicines, shall be provided at the expense of the guardians, subject to the orders and regulations of the Poor-law Board;' and six months have elapsed (September 2, 1864) since your honourable Board said 'the question, however, will receive the attention of the Board forthwith;' and yet no order has been issued. I therefore trust you will not think I am too pressing in urging this question again upon the immediate attention of your honourable Board. If you are in any difficulty about the matter, and desire to have a deputation of Medical

officers to confer with you on the subject, I will willingly call them together for the purpose, on any day you may name, after allowing me two clear Saturdays to intervene, as it is only through the medium of the Medical journals that I can announce the fact to them. I was in hopes your honourable Board would bring in a bill this session to regulate the payments of your Medical officers, and not allow the present capricious mode of fixing the salaries, and giving some officers extra Medical fees and others none, to continue. It is perfectly clear, from the several amendments of the Select Committee, that the committee itself was far from being unanimous on the subject of Medical relief; and even their ultimate decision—'that there are no sufficient grounds for materially interfering with the present system of Medical relief'—clearly proves that there are grounds for interfering, although not *materially* doing so. I therefore trust your honourable Board will yet place the whole system on a proper footing.

"I have the honour to be, my Lords and Gentlemen,
"Your most obedient servant,
"The Poor-law Board." "RICHARD GRIFFIN.

SYPHILOGRAPHY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your article on Syphilography you mention the observations of Virchow, Wilks, Simpson, Aitken, and Hutchinson. Can you refer me to the most recent works on the subject by these or any authors?

Newcastle-on-Tyne, March 5. I am, &c. M.D.

*** Virchow: Cellular Pathology. By Chance.

Wilks: Guy's Hospital Reports, New Series, vol. ix.

Simpson: Transactions of the Epidemiological Society, vol. i., p. 2 Published by Hardwicke, Piccadilly.

Aitken: Principles of Medicine, third edition.

Jonathan Hutchinson on Inherited Syphilis.

Papers in *Medical Times and Gazette*, 1862, on Syphilis and Vaccination.

Diday on Infantile Syphilis. Sydenham Society.

THE BOWEN FUND AND THE MEDICAL BENEVOLENT FUND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg to acknowledge with many thanks the receipt of £49 10s. 6d. being the balance of the "Bowen Fund." I am, &c.

JOSEPH TOYNBEE,
March 7. Treasurer Medical Benevolent Fund.

FEES FOR MEDICAL EXAMINERS UNDER THE GOVERNMENT INSURANCES AND ANNUITIES ACT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I should be glad to know the opinion of the Profession on the scale of fees proposed by the Postmaster-General for the remuneration of Medical examiners under the Government Insurances and Annuities Act. It strikes me that a fee of 2s. 6d. will not compensate us for the time and trouble involved in examining proposers and filling up the forms; to say nothing of the responsibilities of such an office in the event of a policy being disputed. The distinction made between the fees paid for persons insuring for more than £60 and those insuring for less than that amount is also unjust to the examiner, who must devote as much time and skill to the one class of insurers as to the other.

I am, &c. HENRY S. TAYLOR.

Guildford, March 9, 1865.

BRANDIED WINE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg that you will insert in your valuable journal the following extract from the article "Wine" in the *Penny Cyclopædia*. The intrinsic truth of the statements contained in it, as well as the fact that the article in question comes from the pen of an eminent Physician, who is, perhaps, one of the most distinguished Œnologues in the world, will commend it to the attention of your readers. I am, &c. Δ.

"The addition of any distilled spirit to wine is always to be reprobated, as it destroys the finer qualities of the wine, making it flat and mawkish. That much alcohol is not necessary to the keeping of wine is clear, since the Rhine wines keep for a century, yet in these the quantity of alcohol is seldom more than eight or nine per cent. Dr. M'Culloch has forcibly pointed out the evils of adding brandy to wine in his 'Remarks,' p. 140. This practice is universal in the wines of Spain, Portugal, and Sicily which are intended for the English market. So far from assisting in preserving the wine, it decomposes it. However slow the effects of this decomposition may appear, they are not the less certain. The first and most conspicuous effect is the loss of that undefinable lively or brisk flavour which all those who possess accuracy of taste can discover in French wines or in natural wines, and a flatness which must be sensible, by the principle of contrast, to the dullest palate which shall compare the taste of claret with that of port, or that of hock or grave with Lisbon or Bucellas. It tends equally, although in a greater length of time, to destroy the union of the colouring principle, which is well known to be deposited in port wines, and apparently in a great measure from the action of this foreign substance. This fact explains why dishonest wine merchants add brandy to their port wines, to give them earlier the appearance of age, by producing the *crust*, a criterion by which no experienced or intelligent wine drinker allows himself to be misled. Moreover, no quantity of brandy can hinder the process of acetification, if the circumstances favourable to it are present. The only effect of adding brandy is to make the vinegar stronger, not to prevent its formation. The alcohol thus uncombined acts on the organs of the body in the same way as alcohol only diluted with an equivalent quantity of water. This is manifest even in the difference of the moral effects of unadulterated wine, in which the spirit is an integral element, and those of the coloured liquids which serve merely as a vehicle for a large portion of alcohol. The pure light wines of France and Germany produce an agreeable exhilaration of mind, very unlike the mere physical excitement, almost amounting to ferocity, which results from the largely brandied wines which are too much in vogue in England. The diseases, also, which attend spirit drinkers, chiefly disorders of the liver, are commonly met with among the consumers of wines to which brandy or whisky has been adventitiously added, though such disorders rarely, if ever, follow even the intemperate use of pure wine. Much, therefore, of the ill-health supposed to follow the habitual use of wine must be attributed to the alcohol with which they are adulterated, not to the wine itself. Certain it is that intoxication is a very rare occurrence among the inhabitants of the wine-producing countries. The light wines of France, of the Rhine, the Moselle, or the Amontillado and Manzanilla of Spain, to which brandy is not added, are much to be commended, as more wholesome and not very much more expensive; at all events, the health would gain where the purse suffers. This is a subject of great importance, as it is to be feared that habits at once discreditable and difficult to be relinquished are contracted by women by the use of these highly stimulating mixtures."—*Penny Cyclopædia*, Vol. 37, "Wine," pp. 464-5.

THE NAVAL MEDICAL SERVICE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—My attention has been drawn to a letter in your last number bearing the above heading. It is a very remarkable production, and the total absence of *esprit de corps* on the part of the writer may be designated as lamentable.

He professes to instruct intending candidates respecting the position and pay of Naval Medical officers, and to inform them of the treatment which they may expect. He takes especial care to warn them against the Surgeons whom he stigmatises as insolent and tyrannical. And why, forsooth? Simply because they endeavour to make their assistants do their duty. The idea of a Surgeon occupying a chair and giving orders to his assistant is gall and wormwood to him. He objects to dressing cut fingers, to compounding medicine, and, in fact, as far as I can gather, to doing anything at all. It is difficult to say what arrangement respecting duty would satisfy your correspondent. Probably he would not object to sitting in a chair and giving directions to the Surgeon.

He speaks of having been "blackguarded" for being a "minute" late; he probably means by "blackguarded" being found fault with. As to the minute, I fear it means at least twenty.

I will conclude by reminding your correspondent that the idea of liberty and independence in any "service" is simply ridiculous. It would not be a "service" at all if every one could do as he pleased. There is a state of bondage on shore as well as afloat. The man who grudges the small amount of work which falls to his lot on board ship would, it is probable, be badly adapted for pushing himself on elsewhere.

I am, &c. S.

COMMUNICATIONS have been received from—

Dr. JAMES ARNOTT; Dr. HARRY FOOTE; FRIENDS OF THE DOCTOR; Mr. JOSEPH TOYNBEE; Mr. R. GRIFFIN; S.; ROYAL INSTITUTION; Mr. JAMES SYME; M.D.; Mr. OLIVER LODGE; IRENÆUS; THE DIRECTOR-GENERAL OF THE ARMY MEDICAL DEPARTMENT; Dr. R. H. S. CARPENTER; Mr. JOHN CRESSWELL; Dr. WILLIAM MURRAY; Dr. T. MASSEY HARDING; APOTHECARIES' HALL; Dr JAMES A. GRANT; ANTHROPOLOGICAL SOCIETY OF LONDON; JUNIOR MEDICAL SOCIETY OF LONDON; Mr. HY. S. TAYLOR.

BOOKS RECEIVED.

On the Early Symptoms of Phthisis, and the Means best Adapted to Prevent or Arrest its Development. By P. W. Latham, M.D. Cambridge: Deighton, Bell, and Co. 1864.

*** A remarkably good graduation thesis, which augured well for the Professional future of its author. We are not aware that it contains any new points of diagnosis or treatment; but it gives some interesting cases observed by the author, and it is carefully and thoughtfully written. We notice one observation, however, which certainly is not in accordance with our experience. The author is opposed to the practice of painting the subclavicular space with tincture of iodine, on the ground that he has seen it frequently produce absorption of the pectoralis muscle. We cannot say that we have ever noticed such result, and should be almost inclined to suppose that he has mistaken an event in the natural progress of the disease for the effect of the application.

Le Congrés de Genève. Geneve: Jules Guillaume Fick. 1864.

*** The object of the Congress was the amelioration of the condition of the wounded in time of war. Representatives from sixteen Governments were present—viz., Baden, Belgium, Denmark, Spain, the United States, France, Great Britain, Hesse, Italy, Netherlands, Portugal, Prussia, Saxony, Sweden, Switzerland, and Wurtemburg. Ten articles of convention were agreed to by twelve of these Governments, the remaining four—viz., the United States, Great Britain, Saxony, and Sweden—being only omitted on account of insufficient powers having been granted to their representatives. The representative of Russia arrived too late at the Congress; but Austria, Bavaria, and the Papal Government declined altogether to take part in it. The result of the Congress is an honour to humanity and a sign of progress—it establishes the neutrality of the wounded, of the Medical officers, or others engaged in attending to them, and of the people of the country, and provides for this neutrality being properly respected.

A Contribution to the Anatomy of the Amphibean and Reptilian Retina. By A. W. Hulke. Reprinted from the Royal London Ophthalmic Hospital *Reports*.

*** An important contribution to Comparative Anatomy. Mr. Hulke says: "In all the species which I have examined (eight are described in his pamphlet) a uniform type of structure occurs; and this is subject to modifications which show how well founded was Müller's anticipation, that a special study would bring out specific characters, which would enable the anatomist, from the examination of a piece of retina, to name not only the class, but the genus and species."

Clinical Observations on Diseases of the Stomach. By B. W. Foster. No. 1—Gastric Ulcer Birmingham: Cornish, Brothers. 1864.

*** Two cases are here published. We have no desire in what we say to discourage the author from his proposed publication, but having regard to the serious inconveniences that arise to the reading public from the accumulation of pamphlets of all kinds in our drawers, etc., would it not be better if Mr. Foster reserved his observations until he could publish the whole together in one volume? He need be under no apprehension of the work falling "still-born from the press."

Lithotrity. By Charles Hawkins. London: Spottiswoode and Co. Pp. 40.

*** A reprint from Holmes's "Surgery," and also from the Medico-Chirurgical *Transactions*.

Dr. Guy's Contributions to Sanitary Science. No. 1—The Case of the Journeymen Bakers. London: Renshaw.

*** Dr. Guy proposes reprinting his contributions to sanitary science, scattered about in various forms. The collection of them will be acceptable, and not the less so on account of the philanthropic spirit which pervades his sanitary writings.

A Few Words on the Choice of a Microscope. By J. J. Plumer, M.A. London: John Churchill and Sons. 1865.

*** Thirty-one pages of very excellent advice. Eighteenpence would be well spent in the purchase of this little book by any one about to provide himself for the first time with a microscope.

On the Treatment of Rheumatic Fever in its Acute Stage Exclusively by Fever Blistering. By H. Davies, M.D. London: John Churchill and Sons.

*** A reprint from the "London Hospital Clinical Reports." We noticed this paper in our review of the first volume.

Practical Dietary for Families, Schools, and the Labouring Classes. By E. Smith, M.D. London: Walton and Maberly.

*** When "Modern Syphilography" no longer occupies our readers' attention, and "Modern Dermatology" is finished, we must invite our readers' attention to "Modern Trophology," and especially to Dr. Edward Smith's very laborious investigations.

The History of a Bit of Bread: being Letters to a Child on the Life of Man and Animals. By Jean Macè. London: Saunders, Ottley, and Co.

*** We say of this as of the former part which we reviewed some months ago, that it is a popular introduction to physiology, human and comparative, very well meant, but a little too diffuse.

On the Cause of the Respiratory Murmur. By A. T. Waters, M.D. Pp. 3.

*** A reprint from the *British and Foreign Medico-Chirurgical Review*. Dr. Waters believes the air-cells of the lungs to be the seat of the murmur, and that it arises from the impediment to the current of air entering the air-cells through the circular openings by which they communicate with the bronchi, and which are smaller than the cavity to which they lead.

The Brown Book for 1865. London: Saunders and Ottley.

*** A book of ready reference to London hotels, lodging and boarding-houses, breakfast and dining-rooms, metropolitan railways, public and circulating libraries, amusements, picture galleries, Hospitals, schools, charitable institutions, religious, learned, and artistic societies, post-offices, cab stands, police, fire, telegraph offices, etc., etc. All this for a shilling!

On the Relations, Structure, and Function of the Valves of the Vascular System in Vertebrata. By J. B. Pettigrew, M.D. Edinburgh: Neile and Co.

*** A reprint from the *Transactions* of the Royal Society of Edinburgh. An important paper.

Two Months of Fever Duty in the Glasgow Royal Infirmary. By W. T. Gairdner, M.D. Glasgow: William Mackenzie.

*** A reprint from the *Glasgow Medical Journal*. It contains brief notes of 126 cases, mostly of typhus.

A General Review of the Subject of Capital Punishment. By William Tallack. Office: Southampton-street, Strand.

*** There is a good deal to be said against as well as in favour of the total abolition of capital punishment. We are not quite sure that we agree altogether with Mr. Tallack; but we must decline discussing the subject with him now.

An Effectual and Simple Remedy for Scarlet Fever and Measles. By C. Witt. Fourth edition. London: Trübner and Co.

*** Inquiring amongst our *confrères*, we find very few who have given the carbonate of ammonia even a trial. Our own experience, so far as it goes, is in its favour, and we should be glad to see Union Medical officers using it and giving in the results of their observation.

Ideas, Opinions, and Facts. No. I.: Touching Clerical Celibacy. No. II.: Convents and Lunatic Asylums. London: R. Hardwicke.

*** These are controversial religious pamphlets. If the writer does not convince his antagonists, he will be sure to annoy them, which, perhaps, will please him as well.

Transactions of the County and City of Cork Medical and Surgical Society. Session 1863-64.

*** Reprinted from the *Dublin Quarterly Journal of Medical Science*. Contains several interesting cases.

Eighteenth Report of St. Mark's Ophthalmic Hospital, Lincoln-place, Dublin, 1863-4.

*** Dublin or London—it is everywhere the same. The governing board "especially request benevolent persons wishing to procure admission or advice for patients to inquire into their pecuniary circumstances, and to recommend those only who are really *fits objects for charity*." It is a cheap benevolence which expends other people's money for the benefit of one's own dependants.

Fifth Annual Report of the Cranley Village Hospital.

*** We have commended the plan of the Cranley Village Hospital before. We can only repeat our commendation.

Undine: a Tale, by Baron de la Motte Fouqué. Translated from the German by Anne Burden. Belfast: A. Mayne.

*** The profits will be devoted to the Belfast General Hospital. Miss Burden's translation of this unique tale seems done quite *con amore*.

The Chemist's Desk Companion, 1865. The Year-book of Pharmacy. Edited by C. H. Wood and Charles Sharp. London: 158, Aldersgate-street.

*** A very useful annual; containing references to the chief innovations and improvements in pharmacy during the past year.

Dictionnaire Annuel des Progrès des Sciences et Institutions Medicales. Par M. P. Garnier. Paris: G. Baillière. Pp. 500. Prix 5 francs.

*** The first number of a very useful annual. It contains, in alphabetic order, a short notice of most novelties in Medicine and its allied sciences, and with reference to most new books issued during 1864.

De l'Ataxie Locomotrice par le Dr. Paul Topinard. Paris: J. B. Baillière et Fils.

The Sixth Annual Report of the Herefordshire Medical Association. Hereford. 1864.

An Introductory Address delivered at St. George's Hospital, October 3, 1864. By W. E. Page, M.D.

The Turkish or Hot-air Bath. By J. Capper, M.D. Hastings: H. Diplock.

Illustrations of Dissections. By G. V. Ellis. Part 13. London: Walton and Maberly.

A Treatise on Military Surgery and Hygiene. By T. H. Hamilton, M.D. New York: Baillière Brothers.

The A B C Railway Guide. London: W. Tweedie.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29·749 in.
Mean temperature	42·1
Highest point of thermometer	52·7
Lowest point of thermometer	30·9
Mean dew-point temperature	36·8
General direction of wind	S.W. & N.W.
Whole amount of rain in the week	0·32 in.

APPOINTMENTS FOR THE WEEK.

March 11. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

Royal Institution, 3 p.m. Prof. Marshall, "On the Nervous System."

13. *Monday*.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

14. *Tuesday*.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

Anthropological Society of London, 8 p.m. W. Winwood Reade, Esq., F.R.G.S., F.A.S.L., "On Missionary Efforts amongst Savages."

Royal Institution, 3 p.m. Prof. Hofmann, F.R.S., "An Introduction to the Study of Chemistry."

Royal Medical and Chirurgical Society, 8½ p.m. Mr. Southam (of Manchester), "Aneurism by Anastomosis of the Scalp Treated by Setons and Ligature of the Common Carotid." Dr. Hillier, "On Congenital Hydronephrosis."

15. *Wednesday*.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

16. *Thursday*.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Royal Institution, 3 p.m. Prof. Hofmann, F.R.S., "An Introduction to the Study of Chemistry."

17. *Friday*.

Operations. Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m. Balfour Stewart, Esq., F.R.S., "On the Latest Discoveries concerning the Sun's Surface."

ORIGINAL LECTURES.

CLINICAL REMARKS

ON A CASE OF

CONTRACTED MITRAL ORIFICE, WITH AURICULAR-SYSTOLIC MURMUR.(a)

DELIVERED AT

THE GLASGOW ROYAL INFIRMARY,

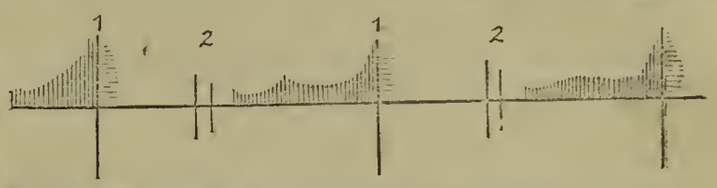
By W. T. GAIRDNER, M.D., F.R.C.P. Edin.

(Reported by Dr. WYBER.)

We have to-day an opportunity, which I am unwilling to lose, of discussing a disputed point in cardiac diagnosis; and although we have spoken about it before, and there are many other questions of practical importance at present demanding our attention, I shall give a few words, in passing, to this one. Many of you have heard me explain the importance of the pre-systolic, or, as I call it, the *auricular-systolic* murmur, as indicating a contracted mitral orifice, of which lesion, indeed, it may be said to be pathognomic, if we exclude a few cases of tricuspid obstruction, and some of disease of the pericardium, in which a more or less similar murmur may be present.

I show you here the heart of Jas. McL., who died a few days ago in Ward 7, and whose body was examined, in my absence, by the Resident Physician, Dr. Wyber. As the mechanism of the heart was found to be considerably deranged, it was preserved for your inspection. You observe that while the heart, as a whole, is very considerably enlarged, weighing, on being removed from the body and emptied of blood, twenty-eight ounces, or more than double the proper weight for the heart in a man of his size, the left auricle is dilated much out of proportion to the other cavities; so much so, that with a little stretching it would probably hold a very large orange. You have, on the other hand, the cavity of the left ventricle of a moderate size. With regard to the auriculo-ventricular valves, you observe that while the tricuspid orifice, without any other marked deformity, is somewhat widened, admitting nearly four fingers, the mitral is very much contracted, and does not fully admit the point of even one finger. The pulmonary and aortic semilunar valves are normal, though the aorta itself is rather small, owing probably to the relatively small amount of blood passing through the left auricle. The only valve that is the subject of distinct disease, therefore, is the mitral, and that disease is obstruction. I do not say that there was no regurgitation in this case. I believe there was. But as the two lips of the valve come pretty accurately together, and as the small size of the mitral orifice is due not to vegetations, but to a contracted state of the orifice, regurgitation, if present, must have been slight in amount, and entirely subordinate to the obstruction. One other fact that illustrates the condition of the circulation in this heart is the thickening and loss of translucency of the left auricle as compared with the rest of the endocardium, showing a stasis of the blood in this auricle; and in further proof of this stasis of the blood you observe that the auricular appendix is blocked up by a clot which, from its consistency, density, adhesive and granular character, has evidently been formed during life, and probably long before death. You have, therefore, multiplied proofs in this case that there was a very decided obstruction in the mitral orifice, the only question being whether there was not also a slight amount of regurgitation through the same orifice; and in connexion with this I wish to read you the facts of the case relating to the murmur, as reported in the journal at the time.

This man was twice under observation. He came into Hospital for the first time on September 13 of last year, and was dismissed improved on November 18. During this time he was subjected to very minute, careful, and repeated examination. He was readmitted on February 9, 1865, and he died on the 25th of the same month; but this time he was so ill that he was only examined sufficiently to satisfy my own mind that the physical signs were the same as on his first admission. Now, here is an exact diagram of the murmur as



Murmurs in case of Jas. M'L. Lengthened auricular-systolic; brief ventricular-systolic murmur; 2nd sound reduplicated, but free from murmur.

we figured it at the time, within forty-eight hours after his first admission, on the back of his Hospital ticket. In the journal of like date the murmur is described as a "distinct and protracted auricular-systolic murmur, followed by brief ventricular-systolic, at left apex." The murmur, as you observe here, beginning at a brief interval after the second sound, extends close up to the first sound, and there is a very short, almost doubtful, murmur after the first sound, but no murmur directly in contact with the second sound. Next day we noticed that "the ventricular-systolic element in the murmur is to-day indistinct and doubtful; otherwise the facts are the same as yesterday. The cardiac dulness is somewhat extended both to left and right; greatest transverse diameter is probably nearly six inches, but not quite distinct at right border." There was great dilatation of the heart, therefore, as ascertained by percussion, quite in consistency with what you observe here. We find also the following note:—"Tested at the apex, the first sound is decidedly the sharper of the two, insomuch that it might easily be mistaken for the second. Tested towards the base, the second sound regains its natural relation to the first, but developes a distinctly reduplicated character, which even at the apex serves to identify the sounds." Now, I wish to tell you that it sometimes happens in these cases that the first and second sounds are rather difficult to distinguish from each other on account of this peculiarity, frequent in cases of mitral disease, that the second sound is very much increased in intensity at the base over the pulmonary artery, while the first sound is somewhat similarly increased in intensity and sharpness at the apex, where, indeed, it often assumes very much the character of the second sound. But when the first and second sounds are in this manner difficult of distinction, though you can generally get out of the difficulty by employing a little extra care, the best way, beyond all question, is to employ this instrument, the differential stethoscope of Dr. Scott Alison. Putting one bell of the stethoscope over the apex and the other over the base of the heart, the erroneous impressions as to the sounds of the heart formed by the one ear are corrected by the other. In this case, however, the reduplication of the second sound was of great assistance in enabling us to identify the sounds both at the base and apex, and thus to come to a proper understanding of the rhythm of the heart.

You see, then, that we made a very careful examination of this case, and what made me particularly anxious that you should observe the facts of the murmur for yourselves was the circumstance that this was one of three cases which I published some time ago in the *Medical Times and Gazette*, and in regard to which I said that "if any one of these three cases should turn out to be other than a case of mitral (or just possibly tricuspid) obstruction I shall be the first to confess that the whole pathology and diagnosis of the subject, as I have hitherto viewed it, requires reconstruction." Now, one of these three cases died while my communication was in the hands of the printer, and the state of the heart is described in a foot-note.(b) This case of J. M'L. is therefore a second illustration of the significance of the auricular-systolic murmur in cases of mitral contraction; and if any of you wish to examine the matter still more closely, by referring to

(a) Formerly noticed in the *Medical Times and Gazette*, October 29, 1864, p. 460.

(b) This case was an exceedingly complicated one, and undoubtedly a difficult diagnosis. The murmurs were auricular-systolic and ventricular-systolic, with an occasional ventricular-diastolic murmur heard at the base and along the sternum. The facts, as stated in a condensed form in the paper above referred to, led to the inference that the case was "one of aortic and mitral disease in combination and possibly also of disease of the valves of the right side." The state of the heart revealed by post-mortem examination was briefly as follows:—"Mitral orifice of size only sufficient to admit the thumb, and the edges of the valve roughened with vegetations; similar vegetations on the free edges of the aortic valves, which were somewhat deformed and incompetent; tricuspid orifice just admitting two fingers, and evidently contracted, but without much shortening of the chordæ tendineæ, or roughness of the edges of the opening; pulmonic valves normal." See *Medical Times and Gazette*, as above, p. 462.

the journal of the ward you will find an exact description of the murmur as heard during life.

The third case which was noticed in the paper in the *Medical Times and Gazette*, viz., that of Mary O'M., has been dismissed from the Hospital improved, but we shall very likely see more of her. If she comes back you must not allow your scientific curiosity to make this girl the subject of uneasy inquiry; but I shall endeavour, if she is in a fit state for examination, to give you further opportunity of becoming acquainted with the auricular-systolic murmur. There is, however, another case of this murmur in the ward at present, and yet another case was only recently dismissed. These cases, indeed, are not at all rare, as you might suppose from the writings of some authorities. I have seen numbers of them every year since I began Hospital practice, and you cannot possibly fail to have many opportunities of observing them, although, perhaps, few cases are so perfectly clear and uncomplicated as that of Mary O'M, and even the case of J. M'L., now under notice. The more common form of disease is perhaps the combination, in about equal proportion, of mitral obstruction and regurgitation, each giving rise to its own characteristic murmur.

ORIGINAL COMMUNICATIONS.

ON NUTRITION.

By LIONEL S. BEALE, M.B., F.R.S.,

Fellow of the Royal College of Physicians; Physician to King's College Hospital; Professor of Physiology and of Morbid Anatomy in King's College.

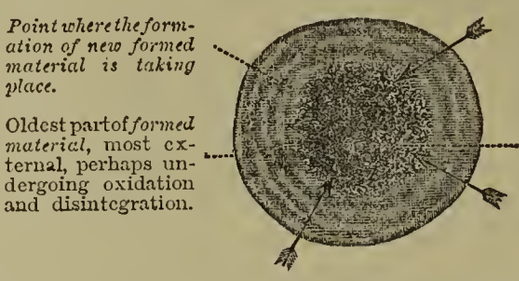
(Continued from page 222.)

THE third stage of the process of nutrition comprehends the conversion of the living or germinal matter into *formed material*, which is added to that already produced. I have endeavoured to show that the formed material results from changes in the germinal matter. It seems probable that particles of the germinal matter after going through certain stages of active existence lose their active powers or *die*, and that the formed material results from this death. The ultimate atoms of the germinal matter are constrained during life to occupy such relation to one another that at death they enter into combination to produce the peculiar formed material, among perhaps many other substances. The former would be deposited in an insoluble form, while the latter would pass away in a state of solution in water from the cell.

The composition and properties of the formed material necessarily depend upon the relations the elements were made to occupy or take up during life, and this is determined, I think, by that agency, force, or *power* which we are compelled to admit, and this I speak of as *vital power*. No *force* known can compel elements of matter to take up different and special relations to one another at the same temperature in the same animal, or effect the re-arrangement of the elements of the same pabulum so as to give rise to the production of such very different compounds as occurs in the case of different cells in the same organism. But, as I have before said, if any chemist or physicist should offer a reasonable explanation of the results occurring in different cells of an organism—nay, in any one living cell—without assuming the existence of some such peculiar agency or power distinct from ordinary force, his view would be at once received, and all would thenceforth cease to speak of vital power as distinguished from physical force. Hitherto, however, no chemist or physicist has ventured to discuss what really takes place in a single cell. Nay, I cannot help thinking that there is a strange indisposition on the part of those who have expressed themselves most strongly in favour of the physical force theory of life to discuss the question at all, or to answer the objections raised to their statements by physiologists.

The formed material, having resulted in the manner above-described, is incorporated with that already produced, or it is added as a distinct layer within previously existing layers. (See figure.) In the former case it will appear more or less homogeneous; in the latter, it will exhibit concentric markings; or it may be deposited so as to form distinct capsules one within the other. The outermost portion of the formed material is often ragged, and not unfrequently is seen to be undergoing disintegration. Sometimes it serves as a nidus for fungi, which live and grow at its expense, as may be seen in the case of the old epithelial cells upon the dorsum of the tongue.

The consistence of formed material varies greatly. It is always soft when first found, but becomes very hard in many cases, owing to the absorption of water and to other changes. Sometimes it remains soft, like ordinary mucus; and sometimes it is diffluent, and is carried off as fast as it is produced.



A living cell to show that the process of nutrition consists of

1. The passage of the pabulum through the formed material when it reaches the germinal matter.
2. The conversion of some of its constituents into germinal matter.
3. The conversion of some of the germinal matter previously existing into formed material which is deposited layer within layer, as it were, upon the *inner surface* of the formed material already produced. In many cases the successive layers are incorporated with one another.

The process of *oxidation* probably affects the outer and oldest part of the formed material chiefly, and, in some instances, occur in this situation only.

The formed material of a cell may then accumulate as the cell advances in age, in which case this part of the cell (formed material or tissue) is said to *grow* as age advances; or the formed material may be carried off as fast as it is formed, in which case the cell may remain without change in size, or it may even become smaller, although it absorbs a great quantity of nutrient pabulum. This is just the difference between the growth of tissue and those examples of secretion where the entire cell is not destroyed, and thus resolved into the products of secretion. The *formed material* of a cell may become oxidised or otherwise disintegrated and converted into *products of secretion*, at the same rate, and in the same proportion, as the germinal matter is converted into new *formed material*, to replace that which is removed, and the latter process may be exactly compensated by the formation of new germinal matter from newly absorbed pabulum.

Growth of Tissue.

Pabulum becomes germinal matter, while germinal matter is converted into new formed material, which is added to that which already exists, and, unless condensation, drying and shrinking occur, to compensate for the addition—increase of bulk and growth of tissue must take place.

Secretion.

Pabulum becomes germinal matter, while germinal matter becomes converted into new formed material. The quantity of old formed material converted into the products of secretion is exactly compensated for by the conversion of pabulum into germinal matter, and germinal matter already existing, into formed material. Hence much pabulum may be absorbed, much secretion may be produced and carried away, although the cell does not alter in size. No *growth* is manifested.

From the foregoing observations it will be noticed that I endeavour to make a sharp and definite distinction between the phenomena occurring in the *germinal matter* of the cell and those which take place in the *formed material*. I consider the formed material as resulting from the *death* of the germinal matter, and by the word death I mean that the matter cannot produce matter like itself; it has no inherent power of movement, nor any of those wonderful properties or powers possessed by matter when in the living or germinal state. I am aware that in considering tissue as dead matter I shall be met by many objections; but as the results of my observations compel me to accept this view, I will venture to offer a few remarks upon the general bearings of the question.

In an old epithelial cell of the mouth the outer part is invaded by fungi, and is therefore certainly *dead*, for the fungi are living at its expense. Living matter lives upon dead, never upon living, matter. If my observations are correct, the formed material of the epithelial cell corresponds to, or is homologous with, that of cartilage or fibrous tissue. If, then, the first is dead, I must admit the last to be so. Or, take the case of a living, growing seaweed, the outer part of which forms the nidus for other living structures. The matter upon which these are growing must be dead, and yet this dead matter gradually passes into the more

recently formed material, which was but a short time previously germinal matter. It would be indeed difficult to advance reasons for considering the old layers of the formed material to be dead and the young layers alive, while there is, as has been already shown, the widest difference between germinal matter and formed material. Surely, if anything is dead, the cortical cells of the free end of a hair or those at the extremity of a nail are dead. Nor are they less *dead* while they remain attached to the body than when removed from it; for if it be maintained that textures merely *attached* to a living body are for this reason *living*, while those detached are *dead*, the words *dead* and *living* no longer denote essentially distinct conditions or states of existence. If the matrix of cartilage or fibrous tissue be dead, the contractile material of muscle and the nerve fibre, which are homologous with it, must be equally dead.

To such an inference as this, no doubt, many physiologists will demur. My friend Dr. Carpenter, to whom my thanks are specially due for giving an excellent summary of my views, and for many interesting remarks of his own upon them, dissents from me in this particular. In his new edition of his well-known "Manual of Physiology," just published, he makes the following observations:—"In adopting to this extent the views of Professor Beale, the author cannot go the length with him of asserting that all 'formed material' has lost its vitality; since it does not follow that in losing its power of self-increase it has thereby lost the other attributes which distinguish it as a living structure. Nothing, for example, can more characteristically exhibit vital properties, as distinguished from any that can be ascribed to its physical or chemical nature, than *muscular fibre;* yet this belongs to the category of 'formed material.'"(a)

(To be continued.)

PAPERS ON

THE THERAPEUTIC AND PHYSIOLOGICAL ACTION OF REMEDIES.

By WM. MURRAY, M.D., M.R.C.P. Lond.

Physician to the Dispensary, and Lecturer on Physiology in the College of Medicine, Newcastle-on-Tyne.

No. 1.—On Digitalis.

Few drugs have been the subject of more conflicting statements than Digitalis, and yet there are none on whose action the Profession has more implicitly relied. The drug has a special action on three separate organs—the brain, the kidneys, and the heart; in proof of this, witness its decided action in delirium tremens, in dropsy, and in various forms of heart disease.

As the action of the medicine upon this latter organ seems to have been little understood, and is still scarcely established, although the observations of Dr. Handfield Jones and others have been well put forth, it therefore seems right to add any new facts or observations on the subject.

I have carefully observed from twenty to thirty cases of cardiac disease treated by Digitalis, from which the following conclusions have been drawn; some of these will be quoted as very decided cases showing the true action of the medicine. As the proposed explanation of the action of Digitalis accords fully with the ingenious and well-supported theory put forth by Dr. Anstie in his work on "Stimulants and Narcotics," it may be well to say that he holds that all true stimulants tend to bring tissue action to its normal standard; that when such action is in excess a true stimulant will reduce it, and when below par will bring it to its proper level; he proposes "that the word stimulant be restricted to agents which, by their direct action, tend to rectify some deficient or too redundant natural action or tendency." I believe that the action of Digitalis when properly investigated will confirm these views; and at the same time the investigation of its action will be materially assisted by bearing them in mind. I shall show—

1st. That digitalis will stimulate and strengthen a weak heart, and that the weaker the muscular tissue of the heart the safer will be the administration of the medicine.

2nd. That in a hypertrophied heart it will fail to reduce the pulse either in frequency or strength, and in such cases will prove dangerous.

3rd.—That in a weak organ, acting because of its weakness with great rapidity, it will reduce the number of its contractions, and, as it were, strengthen or tone them down. To strengthen and quicken the action of a weak slowly acting heart, and to reduce the number of the rapid strokes of a feeble heart is, according to Anstie, to do the work of a true stimulant, bringing action up to the normal standard on the one hand, and reducing it to that level on the other.

I. The following case is one of many in which the remedy has removed irregularity and intermission of the pulse, has given power to the heart when exceedingly weak, and increased the rapidity of its action:—

A lady, aged 50, had suffered for nine years from cardiac disease, and was in an extremity of suffering when I first saw her, having a very largely dilated and weak heart whose cavities were overladen with blood, and considerable disease of both aortic and mitral valves. A confused tumbling and heaving impulse was all that could be felt in the cardiac region, and feeble blowing murmurs supplanted the natural sounds of the organ. There was no pulse at the wrist, and the large vessels in the limbs had scarcely a pulsation in them.

A dropsy of the legs and belly was making fast progress, and the usual stimulants and diuretics had failed to give relief. Although thus pulseless and faint, with the heart in so weak and burthened a condition, I prescribed digitalis in doses of ten drops and upwards. In a day or two the organ began to beat more forcibly, the pulse came again at the wrist, the turbulent or confused action became replaced by a quiet steady stroke, the breathing, before laboured, became easy, and the dropsy began to disappear. In a week the patient was out of bed, and very shortly she so far recovered as to go about in her usual way. After this she lived for more than a year in comparative comfort and good health, when suddenly the organ again failed, and before digitalis could be administered she died.

I might add to this cases of aortic regurgitation with dropsy; many cases in which both aortic and mitral orifices were diseased with dilatation of the walls of the heart and a weak irregular pulse at the wrist; cases of simple weakness of the organ without appreciable disease; cases of dyspnœa from an emphysematous state of the lungs and sluggish pulmonary circulation—all of which were most decidedly benefited by digitalis. I would especially direct the attention of the Profession to the use of the drug in cases of bronchitis depending on sluggish circulation with weakness of the heart's action and emphysema of the lung.

I have alternated the use of digitalis with the strongest of our stimulants in some of these cases, and have been astonished at the superiority it possesses as a stimulant. From the observation of a few cases in which the drug has been given continuously for a lengthened period, I do not find anything like failure of the heart's action to occur under a month or six weeks, and then a few days of intermission will clear the way for a fresh course of the medicine. In dyspnœa the relief obtained is sometimes most marked. I remember a poor girl with frightful disease of the mitral orifice, having to rest on almost every doorstep on her way to my house, who was so relieved by digitalis as to walk to and fro with ease. I do not think, after trying it in almost all the affections of the heart, that there is a single disease or condition of that organ *attended by weakness* in which it may not be given with safety and benefit.

II. The next condition to which I would refer is that of hypertrophy. In this my experience is not large; but in one uncomplicated case of hypertrophy of the left ventricle without valvular disease, in a man who had an almost Herculean frame, digitalis was fairly and carefully tried. The heart's action in this case was rapid and at the same time very forcible; the digitalis not only failed to reduce this, but it caused an increase in the symptoms, and the patient almost fainted after trying it for one week, so that the medicine had to be changed to tinct. veratr. virid., from which decided benefit was derived. I might say that a converse experiment was tried in a boy with mitral disease and rapid action of the heart. Here tinct. verat. virid. failed to give the relief which was most effectually derived from Digitalis.

III. Lastly, as a cardiac stimulant, digitalis ought to reduce too great rapidity of action *when this depends on weakness*. In this respect the drug has been well tried, and almost universal testimony to its value has been given.

In inflammatory diseases, in fevers, in phthisis, it is acknowledged to reduce the rapid pulse. In one case of phthisis at present under my care, it does this, and most materially lowers the temperature of the body and relieves the daily hectic paroxysm. While, however, it checks the excessive rapidity of the heart's action, it does not, therefore, weaken its

(a) Manual of Physiology, including Physiological Anatomy. By William B. Carpenter, M.D., F.R.S. Fourth Edition. 1865.

force; so that, as a true stimulant, it brings the organ down to a slower rate of action, but at the same time affords it more power to do its work.

Thus it appears that the *physiological* action of digitalis is that of a stimulant, in Dr. Anstie's sense of that term; and that in its *therapeutic* properties it is especially useful in cardiac weakness, whether that weakness be accompanied by extremely slow or extremely rapid action. Further, its physiological action as a stimulant may be explained by supposing that in the case of the slow heart it improves the molecular arrangement of the sarcous elements, or that it excites the nerve centres from which the nervous power of the heart is derived; and in the case of the weak but rapid heart, it acts by strengthening that regulating or restraining (vital) influence which, while maintaining the activity of tissues at a normal rate, checks undue and riotous action in the same (Radcliffe). Lastly, let me say that as a diuretic it is at once the safest and best we possess, and the dose may vary from ten drops to half an ounce. This very day I have given nearly half an ounce in fifteen-drop doses every two hours to a child three years old, and by so doing have subdued a rapidly-developing general dropsy which was threatening the little sufferer's life.

P.S.—In some cases of mitral regurgitation accompanied by a loud distinct murmur, I have felt satisfied that Digitalis reduced the intensity of the murmur most decidedly, and in one case it seemed to disappear altogether.

EXCISION OF THE KNEE-JOINT.—RECOVERY.

By JAMES A. GRANT, M.D., F.R.C.S.E., M.R.C.S.L., etc.,
Surgeon, General Protestant Hospital, Ottawa, C.W.

Henry M., aged 39 years, a farmer, of regular conformation, and robust habit of body prior to disease attacking his knee-joint. Parents healthy, and neither consumptive nor scrofulous. Admitted into the General Protestant Hospital October 20, 1864.

History.—The infliction of the injury, which was supposed to have originated the diseased condition of his knee-joint, dates back about twelve years, at which time the joint was severely wounded by a drawing-knife. The convalescence from this injury was exceedingly tardy, months elapsing before the foot could be placed to the ground. The usual remedies, such as stuping, leeching, counter-irritation, etc., were all had recourse to, but with unsatisfactory results, there having remained a lingering pain associated with considerable uneasiness in the joint upon even the slightest pressure or most moderate exertion. As time rolled on the joint became painful at night, so much so as to interfere with rest and gradually reduce his system, the various organs participating more or less in that debility, which had its origin, doubtless, in pathological changes taking place in the joint, and just in proportion to the activity or inactivity of those structural alterations was to be observed an increase or diminution in the intensity of suffering. This train of symptoms continued with little variation throughout the greater portion of the time which elapsed from the date of the accident to his admission into the Hospital. A glance at his *physique* was alone sufficient to point out that changes of a most marked character were taking place in his system. The haggard expression of face, the general flaccidity of the muscular system, the loss of appetite, and tendency to occasional diarrhœa and night sweats, were highly characteristic of that general relaxed state of the system which results from long-continued and perverted functional activity of a joint, associated with, and depending upon, most marked organic change of structure.

Attitude of Patient—Appearance of the Joint Externally.—In the erect posture, the attitude of the patient was sufficient to point out the seat of disease, the limb having a flail-like appearance. The leg could not be extended; the flexed condition of the thigh, and consequently shortened condition of the limb, removed the substantial support of the sole of the foot, and substituted the slight support of the tips of the toes; and even on these the most moderate pressure was sufficient to excite pain in the affected joint. The outline of the limb gave an accurate idea of the distortion which had taken place; and the atrophied condition of the muscular structure of the thigh, possessing complete nervous sensibility, was in itself an index of protracted articular disease in the affected joint. The natural contour of the joint was lost, being considerably enlarged, irregular as to its outline, and possessing no small degree of solidity; more or less pain on pressure, which can be localised in particular spots, with a marked increase towards night; very slight motion in the joint, the limb constantly retaining its semi-flexed position. No sinuses were to be observed about the joint, and the integument over it presented only a moderate degree of discoloration. The flexed position of the limb and marked difference, when contrasted with the healthy knee, placed beyond a doubt the likelihood of the destruction of the crucial ligamentous connection, associated with articular structural alteration. On the slightest manipulation of the knee-joint, pain was produced, attended on several occasions with marked indications of syncope, and the parts when thus irritated seldom became free from pain for at least six or eight hours. The patella was firmly anchylosed anterior to the right articular surface of the femur, and on either side of the joint the hamstrings could be felt, tense, firm, and unyielding, in a perfect state of spastic contraction.

In this condition Mr. M. became an inmate of the Hospital, much reduced by occasional fever, night sweats, and attacks of diarrhœa. In consultation with the Medical staff—having made a careful examination of the joint as to the extent of bone diseased, the implication of surrounding parts, the non-co-existence of any internal organic disease, the dependence of fever upon the joint disease, and the favourable appearance of the patient, notwithstanding the duration of the disease (a period of twelve years)—the propriety of excising the joint was decided upon, the combined local and constitutional indications being favourable to such a proceeding.

November 2.—I excised the joint, adopting the U incision. The flap being carefully reflected, the quasi-joint was exposed, and the soft anterior tissues being divided, as well as the lateral connecting structures, its whole interior was rapidly brought to view, by flexing the leg backwards upon the thigh. The patella was first removed, and afterwards the articular surfaces of the joint were sawn off, from before backwards, with an ordinary amputating saw, the extent of bone removed being, from the femur, fully an inch and a-half, and from the tibia over three-quarters an inch. Two or three small vessels required a ligature. All clots being now washed away, and the sharp edges of the bone pared off, the leg was extended, the flap secured, and the limb, after being bandaged, was carefully placed in Butcher's box, thoroughly wadded, which answered every purpose most admirably; the entire operation being accomplished under the influence of chloroform. Half a drachm of liq. opii. sedat. was given immediately after the operation. 8 p.m.—Has had some sleep and feels comfortable; pulse 90; tongue moist. Opium repeated.

3rd.—Had a very tolerable night; finds the knee free from pain; rather copious oozing from the wound; it entirely ceased after the third day.

8th.—Knee dressed; looking well. No tension or inflammatory appearance about the sutures. Very slight discharge from the wound.

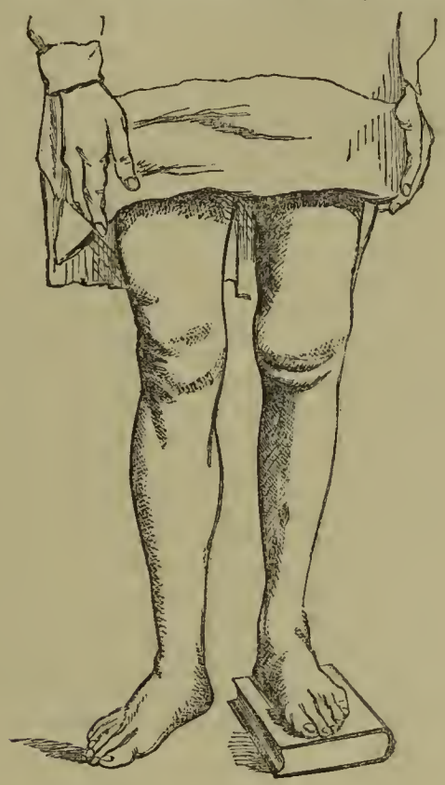
12th.—All the sutures were removed, not one having sloughed out, and the greater portion of the wound having united by the first intention. From this date the wound was dressed every two days, with simple cold water dressing, until all discharge had ceased, which was about the end of the tenth week. Three months previous to the date of operation an issue had been formed on either side of the joint. These had perfectly healed; but after the operation, at the end of the fourth week, reopened spontaneously, and discharged more or less until the end of the ninth week, at which time they completely closed. In fact, this spontaneous effort of nature appeared to modify the intensity of the inflammatory action, which might otherwise have taken place; for during the whole progress of the case no purulent matter could be detected except from the seat of the issues.

December 10.—The strength of the limb much increased, and from all appearance there is evidently some soft union between the bones and the external wound. The limb is quite straight, and the general health of the patient very much improved.

January 18, 1865.—The parts are firm, and he can move about the ward with ease, supported by a small crutch.

30th.—Drove to the city without any difficulty, and had a photograph taken, from which the woodcut was executed, giving a somewhat exact representation of the limb, now changed from deformed angularity, with œdematous leg and attenuated thigh, to a healthy-looking extremity, free from pain, and, although stiff, moved about with ease and freedom by a set of thigh and leg muscles, which have in a great

measure recovered their tonicity and corresponding healthy development. After the first week his system was supported by porter, in conjunction with beef-tea,—a point of vast importance where Nature has to build up parts of great extent, and in a system much debilitated by long-continued disease.



February 5.—He was discharged, to enjoy the home comforts of a rural seat, the limb being now quite strong and sufficient to support the body without any stick, and only 2¼ inches shorter than the opposite leg.

Pathological State of the Joint.—Integument over the patella immovably fixed down upon the bone; but laterally and posteriorly it possessed considerable mobility. Patella otherwise healthy, except in its ossific attachment. Interarticular structures entirely changed, the exposed substance appearing to be partly thickened synovial membrane associated with the well-known peculiar softening of the proper tissue of the ligaments, the result of degeneration combined with more or less infiltration of inflammatory products. Thus, by gradual softening, yielding, and successive attempts at organisation of the lymph effused—the result of a low grade of inflammatory action,—a description of connecting tissue was slowly built up, wedge-shaped, between the bones becoming further and further apart, and at the same time retaining the joint in its spuriously anchylosed condition. This structure being divided, and the joint exposed *in toto*, showed an absence of the proper articular cartilages, and a deeply eroded state of the articular facets of the tibia, from which there exuded a small quantity of sero-purulent material. The section of the bones afforded little resistance to the saw, and on the cut surfaces there were not to be observed any circumscribed patches of yellow induration of bone, such as have been described by the leading European pathologists.

Ottawa.

Laryngoscopic Demonstrations.—M. Fournié, the other day, exhibited to a large class a polypus of the larynx with the laryngoscope and the magnesium light. By the aid of a Plassy lamp he projected the luminous rays upon the mirror placed at the bottom of the throat. The image of the parts reflected upon the mirror being very small, he placed a biconvex lens in front of the mouth, and so enlarged it that it was distinguishable at the distance of several yards. M. Fauvel has for some months employed Drummond's lime light for the purpose of producing a brilliant flame in his laryngoscopic clinique. He prefers it to the magnesium light, as it is not liable to the interruptions incident to that, while it costs only fifteenpence per hour instead of a shilling per minute. M. Fauvel recently removed, by aid of the Drummond light, a polypus from the cordæ vocales.—*Gaz. des Hôp.*, No. 30.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ST. BARTHOLOMEW'S HOSPITAL.

NOTES OF A CLINICAL LECTURE ON SYPHILITIC DISEASE OF THE RECTUM AND COLON.

(Delivered by Mr. PAGET, Surgeon to the Hospital.)

Mr. Paget began by remarking that a great advance in pathology had of late years been made by the recognition of an important fact respecting constitutional syphilis. It was long supposed that this disease was limited to the skin, the osseous system, and such parts of the body as could be examined during life; and that the internal organs remained unaffected. It had lately, however, been clearly established that the internal organs enjoyed no immunity, but that they were occasionally the seat of lesions as definite and characteristic as any that were found elsewhere. This inquiry was by no means exhausted; for although it could now be said with certainty that some affections which till recently were looked upon as anomalous, and as belonging to no particular order, were in reality syphilitic in their origin, yet a distinct and sufficient description of many of them was still wanting. A valuable paper(a) published by Dr. Wilks on "Syphilitic Affections of Internal Organs" was by far the best that students could read on this subject.

Mr. Paget said the history of the patient upon whose case he was about to speak was briefly as follows:—She was admitted into the Hospital in November last, being at the time 28 years old. She stated that seven years previously she had been affected with syphilitic sores, shortly followed by a scaly cutaneous eruption. About a year subsequently she became subject to an itching about the anus, and a growth of skin appeared reaching a short distance into the rectum. Two years after this, a large ulcer formed in the neighbourhood of the anus, and she was received into University College Hospital. The ulcer was destroyed by the application of some corrosive fluid. The growth before mentioned was removed, and rectum bougies were passed for a stricture, which was already in process of formation. At the end of a fortnight, being much relieved, and her general health having much improved, she was made out-patient; but soon becoming pregnant she ceased to attend. The child she afterwards gave birth to was born dead. Three years ago she was admitted into St. George's Hospital, having, in addition to the previous disease of the rectum, a recto-vaginal fistula. The sphincter ani was divided; bougies smeared with unguentum hydrargyri were frequently passed, and she was placed under the influence of mercury by means of the calomel-vapour-bath. Under this treatment she improved rapidly, and was soon discharged. About two years ago, having in the interval borne another child, she applied at King's College on account of a relapse into her previous condition, and having received relief from the same kind of treatment as that before employed, she soon left the Hospital. In July last she became a second time in-patient at St. George's Hospital. The canal of the rectum was now so much narrowed that only a catheter could be passed through the stricture; her general health, which up to this period had been tolerably good, was beginning to fail, and suffering from sickness and diarrhœa for some days she lost flesh rapidly. After her discharge she remained for a few weeks at home with her friends, and was then brought to St. Bartholomew's.

At this time she was in a state of extreme emaciation and misery, and evidently suffering from pulmonary phthisis; so that any expectation of affording her permanent relief seemed hopeless. She continued to decline, and died on March 1st.

At the post-mortem examination, the lungs presented the ordinary appearances of extensive ulceration around tuberculous deposits, numerous cavities existing in the upper lobes, but no syphilitic affection could be detected; the heart was normal; the liver was rather large, pale, and tough, but it gave no reaction with solution of iodine, and exhibited no specific alteration; the spleen and kidneys were normal.

Mr. Paget continued:—The chief points of interest are in the characters of the disease found in the rectum and colon,

(a) Guy's Hospital Reports, Third Series, vol. ix.

which may be studied as an example of syphilitic affection of those parts. The anus of this patient did not present more than remnants and traces of the cutaneous growths which are generally significant of syphilis. They had existed in her, but they were cut away. The like may be seen, however, in a patient in Magdalen Ward, who has disease of the rectum just like the one before us. They are growths of skin grouped round the anus, in texture pinkish, soft, fleshy, glistening, moist, and thinly secreting; in shape irregular, flattened as if by mutual pressure, or pressure between the nates, sharp-edged, or conical. If they must be compared with something, they may be with cocks' combs, which, indeed, they are very like. After describing the differences between these growths and the warts and condylomata common in syphilitic patients, Mr. Paget said:—I will not venture to assert that these cutaneous growths are never found except with syphilitic disease of the rectum, but they are very common in association with it, and so rare without it that I have not yet seen a case in which they existed either alone or with any other disease than syphilis. In this rectum are found the results of wide-spread ulceration. Its whole mucous membrane is destroyed except one small patch, which is thickened and opaque. The exposed sub-mucous surface has a lowly tuberculated, undulating, uneven appearance, and is thickened by infiltration. In the early stages the tissue is soft, as if from recent inflammatory effusion, or œdema, but as the infiltration organises it hardens, becoming callous, with fusion of the mucous and submucous coats, and then contracts, and thus brings about the state of stricture. The affection commonly extends from the anus, as if by continuity with the excrescence, to about five inches up the rectum; but it is rarely so marked in the first inch of the rectum as it is higher up. Hence the chief seat of the stricture is usually from an inch to an inch and a-half above the anus. Of this diseased state, as of the anal growths, I will not venture to say that it is never seen except with syphilis. Certainly it is a frequent disease among syphilitic women; but perhaps other forms of ulceration of the rectum may, by long continuance and repeated irritation, acquire characters not distinguishable from these. But the doubts that might exist as to the specific character of the disease of the rectum, if we had it alone to examine, can in this case be removed by observing the connexion and continuity of the ulceration of the rectum with ulcers of the colon, which are altogether peculiar. On the mucous membrane of all parts of the colon there are ulcers of regular, round, or oval shape, from a-sixth of an inch to about two-thirds of an inch in diameter, with clean, sharp-cut, scarcely thickened edges, surrounded by healthy, or only too vascular mucous membrane. Their bases are for the most part level, flat, or with low granulations resting on submucous tissue, nowhere penetrating to the muscular coat, with no marked subjacent thickening or hardening. On some of them are ramifying blood-vessels; on some few there is at the centre of the base a small island of mucous membrane, giving to the ulcer an evident likeness to the annular syphilitic ulcers of the skin. At some places two or more of these ulcers, extending and uniting, have coalesced into a large ulcer of irregular shape, and rather deeper than the smaller, but in all general characters similar to them. By such coalescence some of the ulcers in the lower part of the colon are continuous with the ulcerated surface of the rectum, making it probable that at first similar forms of ulcers may have existed in the rectum, though now superadded thickening and partial scarring have destroyed nearly all traces of any primary shapes of ulcer. The ulcers of the colon are placed without plan or grouping, except that they decrease in number and closeness, and, on the whole, in size also from the rectum to the cæcum. In the cæcum there are none; in the ileum only one, very small and of rather doubtful character. The only question as to the diagnosis of these ulcers may be whether they are syphilitic or tuberculous. They are so different from all the forms of catarrhal, follicular, typhoid, dysenteric, and cancerous ulceration of the intestine that there is no need to compare them; but from the tuberculous they must be distinguished, not so much because of any near resemblance between them as because the patient had tuberculous disease of the lungs, and was therefore not unlikely to have it in the intestine. Here, then, are the chief grounds of diagnosis.

These ulcers are limited to the large intestine, and decrease in size and number from the rectum upwards—conditions which, I think, are never observed in tuberculous disease.

There is not a trace of tubercle—*i.e.*, of circumscribed crude or softening tuberculous deposit—in the submucous or any other tissue of the intestine; none in a Peyer's patch, or at the base or edge of any ulcer, or in the subperitoneal tissue below an ulcer.

The shape and other characters of the ulcers are quite unlike those of intestinal tuberculosis: they are regular, with sharp, even, well-defined edges, with level bases; they are not excavated; they do not extend through the submucous tissue; their edges are nowhere eroded or undermined, sinuous, thickened, or brawny, or infiltrated; the subjacent and intervening structures appear healthy, except at the rectum.

These ulcers are not grouped, and where, by extension and coalescence, they have lost their first shape they have acquired one altogether irregular, and have in no instance even tended towards that girdle-like shape, encircling the canal of the intestine, which is so characteristic in the large coalesced tubercular ulcers.

Thus, by negative as well as positive characters, these ulcers are clearly distinct from the tuberculous; and, as I have said, there is no other form of intestinal ulcer to which they bear even a remote resemblance. We are justified in regarding them as syphilitic by their occurrence in a patient with a complete syphilitic history; by their coincidence and continuity with a disease of the rectum and anus which is very rarely, if ever, seen except in those who have had secondary syphilis; by their likeness in many features to some of the admitted secondary syphilitic ulcers of the skin; and by their unlikeness to any other intestinal ulcers. Some, indeed, may choose to call them "lupous;" but to this name it would be necessary to add another to indicate the nature of the constitutional malady with which the "lupus" is connected, for lupus is not a single local disease depending on only one constitutional defect. It is in some cases strumous; in some tuberculous; in some syphilitic; in some it has a relation to cancer. If the ulcers in this colon are to be called lupous, they must also be called syphilitic.

Mr. Paget concluded by enforcing the importance of the study of syphilitic affections of internal organs. A mistake or oversight in diagnosis would lead to very serious errors in practice. Nothing could be greater than the difference between the proper treatment of syphilis and that required in tuberculous disease. The treatment adopted in all doubtful cases would, of course, be regulated by the diagnosis.

MIDDLESEX HOSPITAL.

CASE OF PIN IN THE LARYNX—REMOVAL.

(Under the care of Mr. HULKE.)

A WOMAN swallowed a pin which was in a piece of cake she was eating. She immediately felt a pricking in the left side of her throat and spoke with difficulty; her breathing was not affected. A Surgeon to whom she ran sent her to the Hospital. The House-Surgeon felt the pin lying at the left of the epiglottis, but could not seize it. An hour afterwards Mr. Hulke examined the larynx with the laryngoscope, but could not see the pin, though for a moment the rima was visible. The mucous membrane was congested. The examination was imperfect, owing to the excessive irritability of the throat. This was overcome with chloroform, and the head of the pin was felt lying against the left side of the rima, its point seeming fixed in the trachea. A convulsive cough drove the pin a little higher in the larynx, and it was hooked up with the finger nail. A little soreness and hoarseness remained for a couple of days.

A CASE OF TUBERCULAR DISEASE OF THE TESTES, VASA DEFERENTIA, VESICULÆ SEMINALES, AND PROSTATE, WITH ABSCESS OF THE LATTER BURSTING INTO THE BLADDER.

(Under the care of Mr. HULKE.)

The origin of tubercle in the testis has been placed by some persons in the secreting and efferent tubes, which it is said to distend till they burst and shed their contents; but a very careful and minute examination of the testes in this case led Mr. Hulke to regard the intertubular connective tissue as its source, a view in accordance with that expressed by H. Demme in Virchow's *Archiv*.

On December 31, 1863, a dwarfed, sallow tailor, aged 68, with the following history, was admitted into Pepys' Ward. He had always had fair health until his present illness, had been remarkably temperate, had married at 20 and reared a large and healthy family, and had never had gonorrhœa or syphilis. In August he noticed swelling of the right and then

of the left testis. In September he had occasionally pain above the pubis and in the perineum, and micturition was frequent and painful. Soon after this he observed pus in his urine. In December the right testis became very tender and painful.

State on Admission.—Worn out with want of sleep and pain; he could not stand without help. Both testes were enlarged and slightly hard. Both epididymes were very large, hard, and knotty; the right was very painful and tender, and its head was fixed to a red œdematous spot in the scrotum. The right spermatic cord was swollen and tender, and the inguinal glands were large. The prostate was very large and hard. He could not retain his water longer than half an hour, and voided the last drops with much pain and straining. It was always acid, occasionally clear, but often contained much pus, which usually escaped towards the close of micturition, the urine first passed being clearer.

In a couple of days an abscess in the right epididymis burst, and discharged a couple of drachms of thin, flaky pus. He grew weaker, and died in two days.

Dr. Cayley, who examined the body, found numerous traces of old tubercle in the lungs. The other viscera were healthy.

The testes and bladder were dissected by Mr. Hulke. The right testis with its epididymis measured $19\frac{1}{2}'''$ from front to back, and $29\frac{1}{2}'''$ vertically, $10'''$ of which belonged to the globus major. The connective tissue throughout the testis and epididymis was red and thickened. The epididymis, the back and the centre of the testis, contained an opaque, pale yellow, cheesy substance, in which a few traces of the normal tissues were recognisable. In the apices of the lobuli testis the tubuli were less wasted, and the cheesy substance was replaced by minute, translucent beads, scattered and aggregated in small masses. This was followed by a reddish band, in which the horny beads became fewer, and in the bases of the lobuli, near the surface, no abnormal appearances were noticed. The tunica vaginalis was thickened, and its parietal layer adhered everywhere to the testis and epididymis. A circular aperture in the head of the latter, about $4'''$ in diameter, was traversed by a fleshy button, which appeared to spring from the connective tissue rather than from the tubes, and protruded through the scrotum. The rough characters of the translucent, horny beads and the opaque cheesy substance were identical with those of tubercle in its miliary and crude forms. Two constituents were present, one originating within the other outside the tubes. The intra-tubular was a granular, opaque, oily *débris*, derived from the disintegration of imperfect epithelium shed into, and choking, the canal of the tubes, the walls of which were thick, and granular, and opaque from fatty degeneration. In the cheesy substance the walls of the tubules were broken, and their contents mingled with corpuscular elements of extra-tubular origin. Two forms of these corpuscles were seen: (*a*) roundish cells with a ragged indented contour, and granular, oily contents, without any nucleus, and not stained by carmine. These were functionally dead withering cells, (*b*) smaller, round, nucleated cells, taking a deep stain from carmine, and multiplying by division of the nucleus. On the one side they passed into (*a*), while on the other side they were traceable through intermediate forms to the corpuscles of the intertubular connective tissue. The left testis and epididymis were larger than the right. The head of the latter was riddled with small, ragged cavities filled with a puriform fluid, and the lower half of the body and the tail were hollowed out into two large caverns full of pus and broken-down tissue. The tunica vaginalis was much thickened. It adhered throughout to the testis and epididymis, except at the lower end of the former, where there was a small collection of flocculent serum. The bladder was contracted, its cavity not being larger than a pigeon's egg. Its muscular coat was very thick, and its mucous membrane was thick and purplish. Just behind and internal to the orifice of the right ureter, the vesical walls were pierced by a gaping, circular hole with ndurated edges, about $2\frac{1}{2}'''$ in diameter, which led to an abscess of the size of a nutmeg in the base of the prostate that ran backwards between the fundus of the bladder and right vesicula sem. The right vas deferens, filled with tubercle, ended in this abscess; the left was also full of tubercle. The prostatic ducts were distended with facetted, shining, translucent, brownish, laminated stones, ranging between $\frac{1}{6}'''$ to $1\frac{1}{2}'''$ in diameter: some of these had escaped into the abscess. A second abscess, thick walled and unconnected with the first, surrounded the membranous urethra, breaking into this through its upper wall, and also running upwards along the ligament. susp. penis in front of the pubis.

CASE OF EXCISION OF THE LOWER JAW.

(Under the care of Mr. J. W. HULKE.)

——, aged 29, a short, thin blonde, was admitted into Regent Ward, June 30, 1864, with a tumour of the lower jaw.

She related that eight years previously she began to be troubled by a soreness behind the second molar, which she attributed to the last molar that at that time had not cut the gum. Four years later the gum swelled; and a year later, as the swelling increased, the second premolar, the first molar, which was carious, and the second, were pulled out, some persistent source of irritation being suspected at their roots. They were all firmly fixed. The growth was not checked by this, and the jaw became less moveable, so that she could not take solid food. In June, 1863, the third molar fell out; it was carious. The following Christmas the gum was deeply lanced; no pus escaped at the time, but soon after a fœtid, ichorous discharge commenced.

At the time of her admission she was extremely emaciated, and feeble, and had a very sallow complexion. The right half of the jaw from the neck to the canine tooth was involved in a large, subglobular tumour, which distended the cheek, and reached upwards upon the zygoma, and backwards behind the lobe of the ear. It projected to a less extent into the mouth, thrusting the tongue towards the opposite side. The buccal surface of the mass was smooth and regular, except behind the canine tooth, where there was a small, bright, florid button, with constricted base. The alveolar line was not greatly distorted. An extremely offensive, glairy brown ichor oozed copiously from an opening in the tumour into the mouth. The mobility of the jaw was very limited, but it was sufficient to make it very probable that the tempero-maxillary joint was not invaded, and that the restraint proceeded from the impaction of the tumour in zygomatic fossa. Neither the skin nor the mucous membrane were structurally involved. The consistence of the mass varied in different parts; near the zygoma it had a bony firmness, while at the angle and along the lower border it was very elastic. Before the tumour appeared she was a stout, healthy woman, and she believed that none of her relations had had cancerous or other tumours. The growth had been by some persons (who were influenced chiefly by the patient's cachectic appearance) considered a cancer; but the absence of infiltration of the skin and buccal mucous membrane, and the freedom of the lymphatic glands at this advanced period—eight years after the first symptoms were noticed—were strongly against the correctness of this opinion.

Regarding it as a fibro-cystic tumour, Mr. Hulke next day disarticulated the left half of the jaw. Bleeding from the proximal end of the facial artery was prevented by compressing the vessel against the lower border of the tumour, and tying it and the enlarged transverse facial artery at once; its distal end bled slightly at the close of the operation, and required to be tied. The inferior dental artery bled very freely. While wrenching down the jaw in order to expose the attachments of the pterygoid and temporal muscles, it broke into several pieces, and in dissecting these out the internal maxillary artery was cut, but it was secured without trouble.

The greater part of the incision in the face healed immediately. During the first week she took milk and strong beef-tea freely, and ʒviii. of brandy per diem. After this she began to take solid food. She quickly acquired flesh and strength, and lost her cachectic look.

August 9 she was made an out-patient, but the final closure of the wound was delayed for several weeks by superficial necrosis of the cut surface of the mandible. She continues at this date in perfect health.

Treatment of Itch.—To the thousand remedies for the treatment of itch, each said to be more valuable than its predecessor, M. Metzel, of the Austrian army, adds another, which, he says, possesses the advantage, while it cures the affection as rapidly as any known means, never to induce consecutive eczema, which so often retards the cure. He terms his remedy phosphorised olive oil, and prepares it by boiling in a bottle closed by a bladder two drachms of phosphorus with a pound of olive oil. This is then allowed to cool, and the oil is decanted from any of the phosphorus which remains undissolved, great care being needed to prevent any of the undissolved phosphorus accompanying the oil, as it would irritate the skin.—*Rev. Med.*, February 15.

SATURDAY, MARCH 18.

MEDICAL EVIDENCE IN CASES OF RAILWAY ACCIDENT.

Parliament, by rejecting Mr. Bentinck's motion, has refused to take active measures for the prevention of railway accidents, and there seems no reason for believing that they will be lessened either in number or severity. The remedy which the law at present applies to the evil does not at all touch its mainspring. It is true that the penalty of heavy damages lessens the dividends of the long-suffering shareholders; but it neither affects the officials from whose carelessness most of the accidents arise nor is it felt so acutely by the directors as to oblige them to enforce strenuous measures of precaution. At least, such have been the results of existing legislation; and we do not know why the public should expect that railway accidents will decrease when no new machinery is to be adopted for diminishing them. For aught we see to the contrary, they are still likely to furnish plenty of fees to the lawyers, and, we are sorry to add, many an arena for the battles of Medical witnesses.

It is to the latter point we would draw attention. It would almost seem as if railway accidents were, like gun-shot wounds, injuries *sui generis*, and that this new species of Surgical disorder had not been long enough known to the Profession to allow a satisfactory insight into its pathology, symptoms, diagnosis, and prognosis. Criminal insanity, and such impalpable conditions, have their difficulties for the Medical witness, but to judge by what is constantly ocurring these are quite equalled, if not surpassed, by those attending the effects of a railway concussion. Take, for example, two cases which have just been decided,—First, that of Joseland *v.* the Great Western Railway Company, tried lately at Worcester, in which the plaintiff obtained a verdict and £6000 damages. The plaintiff's case was supported by Professor Erichsen, Dr. Hastings, Mr. Carden, and Mr. Everett, who all gave it as their opinion that there was injury to the brain and spinal cord, and that the plaintiff's ultimate recovery was very doubtful. The railway company, on the other hand, produced Mr. Skey, Dr. Wade, of Birmingham, Dr. Cooper, of Slough, Mr. Braddon, of Upton-on-Severn, and two other Medical gentlemen, who swore that the plaintiff (allowed to be an energetic man of business) was suffering from nothing but hysteria! The other case, Crofton *v.* the North Eastern Company, was very similar. A Durham farmer, hale and hearty, was run down in his gig by a train of coal trucks. A friend with him was so much injured by the collision that he died two days afterwards; but Mr. Crofton, although 62 years of age, managed to throw himself on one of the trucks, and held on until the train could be stopped. He rode home on a neighbour's horse, and has been ill ever since, under the care of Mr. Jepson, Dr. Heath, of the Newcastle Infirmary, and Mr. Teale, of Leeds. Mr. Jepson, on his first visit, five days after the accident, states that he discovered a broken rib, and all the three gentlemen depose that the plaintiff has been, and is, suffering from the effects of inflammation of the spine. Mr. Teale diagnosed inflammation of the intervertebral substances, and spoke of the possibility of disintegration taking place, and the patient becoming a cripple for life. On the other side, Sir John Fife, Mr. Robson Shiell, and Drs. Murray and Charlton, of Newcastle, declared that they could see nothing in the case but hypochondriasis; and Dr. Charlton said, that "as regards disease," he believed the whole affair to be "a sham." The jury, however, did not agree with him, and found a verdict for the plaintiff, with £1000 damages.

We are not going to criticise the evidence given in these cases. We have formed no opinion as to the side on which truth was to be found. We impute no motives to either party. We only ask, "What must the public, the bar, and the judges think of the value of Medical evidence with such scenes constantly taking place before them?" They will doubtless attribute to it a value, but it will be simply a money one; and who can blame them? We know well the difficulty of dealing with these cases—the disturbing force exercised by the pecuniary magnet on the system of many patients, and the care required in deciding the amount of credence to be given to subjective symptoms when objective are absent. But these difficulties afford no reason why the Profession should tolerate such exhibitions as those to which we have referred. In their effect they are utterly demoralising, and we do not see how our Profession can maintain its ground as a high-minded and liberal one if they are to be continued. We would throw out two suggestions which we think would go far to prevent them. First, that the Medical witnesses for the railway company should never appear in court until they have had full conference and consultation with all the Professional men who have attended the plaintiff, until they have examined the patient together, and mutually discussed and tested his allegations; and secondly, that the result of one or two cursory examinations should never be urged by one Medical witness as sufficient to counterbalance a weight of opinion formed by another after weeks or months of attendance on the injured person. Were these rules carried out honestly and frankly, we believe that these scandals, if not abolished, would be infinitely rarer.

MODERN SYPHILOGRAPHY.—No. VIII.

THERAPEUTICS OF SYPHILIS.

We are not going to inflict upon our readers a long dissertation upon mercury, nor are we going to enumerate, much less analyse and review, the works which have been written by mercurialists and non-mercurialists, whose name is Legion. What we desire to do is to state the results of our examination into this question, so far as these are in conformity with our own observation.

As to any deductions from colossal statistics of the treatment of venereal ulcers, wherein all forms of the disease are lumped together, they are simply as valueless as conclusions must be where diseases are massed together under one common term, without any regard to their affinity or dissimilarity. We must at once discard all the gonorrhœas, simple ulcers, and soft, suppurating sores, by stating that these form by far the majority of venereal disorders, and that mercury is unnecessary, and should never be employed for their cure. Our remarks, then, are limited to the subject of syphilis proper.

It has been found by experience that not only do different remedies exhibit very different powers, but that the same remedy is not equally useful in all stages and forms.

Taking syphilis as a whole, there is no known remedy equal to mercury; none so reliable; and to certain complications, such as iritis, syphilitic orchitis, etc., this applies even more strongly. The stages in which it is of doubtful efficacy are the primary and tertiary. Of the forms, the pustular syphilides are the least amenable to it, and the scaly, chronic papular,

and certain forms of chronic superficial ulceration the most so. For the tertiary stages, marked by diseases of bone and periosteum, unhealthy suppurative sores on the integument, the iodide of potassium is the best remedy. The above may, we think, be taken as a correct expression of the views entertained by the more moderate section of mercurialists.

Whilst most practical men of large experience are content to stand aloof from a controversy which is being fought out upon uncertain premises, and to take their position upon the ground of their own observation, it cannot be gainsaid that the non-mercurialists have effected a very considerable amount of good by their efforts.

Before entering more fully on the subject, let us premise that syphilis is like any and every other disease; not an entity to be met with so much mercury, but one which will require the same amount of skill and foresight as the treatment of any other dangerous and important malady.

We venture to think that sufficient attention is not given to hygiène. The patient should be warmly clad; live upon a good, but plain diet; take moderate exercise in the open air; use warm baths occasionally; and avoid stimulants, unless specially indicated.

It is neither necessary nor desirable to depress the system for the cure of syphilis. The disease in itself tends directly to induce a chloro-anæmic state; and it too often happens that the sufferers from it are the subjects of some debilitating conditions—congenital or acquired. In all cases it is essential to elevate the general health to a normal standard; and we should neglect no means so to modify our treatment as to meet the exigencies of the case. As in other diseases, individual cases will almost always present a physiognomy of their own. Not only is there no reason against, but every reason for giving steel, quinine, vegetable bitters, or cod-liver oil, as circumstances require, at the same time that we apply a specific remedy.

Almost all, if not all, chancres will doubtless heal in process of time without specific treatment, and when the induration is slight or of moderate amount *it* will also be removed in time; but when this induration is large and dense the sore may become chronic, breaking out again and again, or it may be transformed into a secondary tubercle and the induration may continue almost indefinitely—in most cases for months, in a few for years. Now, according to the observation of most, and in accordance with our own, these are the cases which denote a severe and chronic form of the disease under any circumstances. That these primary sores are, as a rule, beneficially influenced by mercury—not only more rapidly healed, but the induration more quickly dissipated—is the experience of most practical men. It is in these cases that mercury is most frequently and most persistently used, and any subsequent severity in the manifestations of syphilis is set down, and most illogically, to the mercury employed.

If a chancre be the portal through which the system is first tainted; if it be the "*continuing* source" of infection, as Dr. Humphry epitomises Virchow's doctrine; or even if it be a mark and effect of the general taint being already present, as many Continental writers, who have regard to the period of incubation which precedes its appearance, seem to think, its continuance must, nevertheless, be an abiding source of contagion to others, and, it may be, a focus of infection to the system, so that its early removal is not a matter of indifference; spite of the low appreciation in which the knife and caustics have been held by some high authorities (Dupuytren and Vidal). In practice we cannot determine, at early dates, what is the exact nature of any given ulcer. If it prove of the non-infecting type, then its progress is, without doubt, capable of being arrested by excision or destruction; if it be infecting, no harm is done. If a primary lesion can be excised thoroughly as well as early the practice seems to be good; but if no secondary symptoms follow, we can manifestly have no proof that the operation averted their occurrence. Mind, we do not say that excision or complete and early distinction of a *true* chancre may not to be regarded as very good practice in influencing the severity and duration of the consecutive phenomena, for it may, and must indeed, effect this if every primary manifestation be a present and future focus of contamination. But excision, at any rate, must have a very limited range for many obvious reasons—the site of the lesion, the presence of induration in the glands, and refusal on the part of the patient.

If cauterants be used, these must be of the strongest and most penetrating, such as fuming nitric acid or the stick of potassa c. calce. In passing, we may remark that a rapid and continued affusion of cold water wonderfully mitigates the pain after the application of nitric acid.

What are the signs in the primaries from which we may anticipate severe and protracted forms of constitutional disease? Of course we must not set aside the constitution, previous and present health of the patient, as indifferent elements in forming a prognosis, but we will confine ourselves to the features of the disease, and, here, an approximation to the truth is all we mean to aim at. The density, size, and extent of the induration, and its persistence, in the chancre and inguinal glands; the amount of ulceration in the chancre,—these appear to stand in some connection with the nature and severity of the subsequent phenomena.

Now, it must be conceded that, do what we will, secondary symptoms will almost invariably ensue after true chancre. Mercury does not *prevent*—save in the most rare and exceptional instances—the occurrence of secondary disease. Mercury, says M. Diday, has been obliged to abandon the pretension of so *radically* curing syphilis as to render all relapse impossible. Its claims to use in the primary stage are—that it dissipates induration, and heals ulceration quicker than any other remedy, and it has the power, at least, of delaying the appearance of syphilitic symptoms. Some excellent observers go further than this, we are aware; some—as, for example, Dr. Marston—believe that mercury does so modify, in some instances, the course of the disease that the ordinary external manifestations are slight, or do not appear, although the patient may exhibit indications of the syphilitic cachexia in his pallid aspect, impaired health, and liability to rheumatismal and other pains.

If, therefore, there be the history of a previous attack of syphilis, if the induration be moderate or small in amount, if the attendant ulceration be limited, if it do not prove very indolent, and can be healed by the application of local remedies, and the induration tends to disperse, and if, moreover, there be any *doubt at all* about the nature of the sore, mercury may be withheld. Wherever there is sloughing, rapid ulceration, etc., whether depending upon hereditary, constitutional, or other causes, mercury is a dangerous remedy, and requires to be used, if at all, tentatively.

Now for the so-called secondary manifestations. It is here that mercury appears to us of such undeniable utility that most practical men, and patients too, are agreed upon its use.

So far we have endeavoured to hold the balances even, and we must here ask ourselves two questions: Is the prolonged administration of mercury (such as Ricord advised, for instance) necessary or justifiable? Does mercury always effect a cure, and is it necessary in all cases?

To the first, we may say, that it is always better to try the effect of the endermic use of the mineral by the moist calomel vapour bath, or by inunction, before we administer it internally; and we must add that we do not believe that any such prolonged courses are needed or advisable. When mercury has been continued for a long period with the view of preventing relapse, the health may be much impaired, a cachectic aspect acquired, and a tendency to a diseased action in internal organs engendered. But it is no good contending for a position which has been long since surrendered, for no one gives mercury in the wholesale way which characterised Hunter's day. Acknowledging many of the evils alleged against

mercury, our own observation has led us to form very different conclusions from those advanced by the anti or non-mercurialists. We can only regard the long array of charges laid to its door as highly exaggerated expressions. *If mercury be exhibited with ordinary care and discrimination, and particularly if it be applied through the skin, there would seem to be little or no risk of injury to the constitution.* Among the large number of cases which we have so treated, we have never witnessed any of those disastrous effects described by many authors. Of this we are quite sure, that some of the very worst forms of constitutional syphilis have appeared in those who have either taken no mercury or very little, and, on the other hand, the instances within our own cognisance are now numerous wherein the most remarkable recoveries from severe forms of constitutional syphilis have been effected by the aid of mercurials where every other treatment had been tried in vain. Those who are most severe in their denunciations of mercury—those who would seem to regard the use of the mineral with the greatest dislike, and who would debit every bad symptom which may appear in the course of a syphilis to the mercury used, instead of the syphilitic virus—seem to have lost sight of the fact that mercury alone has not only never been proved to be capable of giving rise to the combination of symptoms witnessed in constitutional syphilis when specifically treated, but that all experiment and observation is opposed to the assumption. If there be one thing more certain than another, it is that mercury was not employed for the treatment of syphilis for many years after the epidemic in 1494-5. We possess a history of its dreadful ravages then, and the descriptions given leave no doubt whatever of the terrible scourge that it then was, and of the effects it produced upon the bodies of the sufferers and the minds of those who were eye-witnesses. Of a given number of cases of true syphilis not specifically treated, all will exhibit secondary symptoms of some kind, and of these a certain proportion will be of a severe and chronic type, and followed by the phenomena of the so-called tertiary syphilis. The proofs of these statements are too ample for us to do more than allude to them.(a) Let it suffice that many of the patients which served to swell the Hamburgh lists went elsewhere to be *cured* of later manifestations; of those treated by syphilisation, some have exhibited tertiary phenomena, and very many more will turn up, in all probability; and there seems to be very good reason for doubting whether any remedy, or any combination of remedies, be as efficacious as mercury in preventing the hereditary transmission through the germ.(b) M. Diday, of Lyons, has established, by direct observation, that out of forty-three patients in whom the natural evolution of syphilis was carefully watched, in seventeen the symptoms assumed such a serious aspect as to threaten permanent injury to the constitution, and with these he was compelled to have recourse to mercury.(c) Diday is among the *most moderate* section of mercurialists, and his *positive* results may be relied upon. But it must not be forgotten that the *negative* observations can never be equally certain, because we know too well, unfortunately, that syphilis may remain latent for long periods, and manifest itself after very long intervals. In looking over our notes of cases, we find that of thirty-eight primary syphilitic sores not specifically treated twenty-one exhibited a mild form, eight a medium form, and nine a severe form of constitutional syphilis. How far these results might be modified if we possessed all the subsequent histories of these patients we cannot say, of course.

In order that our readers should more clearly perceive the tenor and spirit of our remarks on the therapeutics of syphilis, we must call their attention to the following illustrations of the forms, course, and progress of the disease.

We venture to think that a grouping into mild, medium, and severe types will be found to have some foundation in nature. We assume that the description applies to the first attack, because, as we have said already, there are either no subsequent ones, or these are very modified. The present and past health of the patients tolerably good: the subjects of no inherited taint.

1. *Mild.* The chancre, as a rule, with but little induration, and affected with a slight degree of ulceration; the inguinal glands enlarged on one or both sides, and moderately so. Within from five weeks to three months, some enlargement of the cervical glands; vague muscular and articular pains; a slight febrile disturbance, perhaps, preceding the appearance of a dull-red, mottled roseola, with slight vascularity of the fauces, and very trifling loss of hair; subject to some manifestations of the disease, decreasing in intensity, at intervals, which become wider as the case progresses; iritis, if it appears, yielding easily to treatment; no (observed) tertiary manifestations.

2. *Medium Severity.*—Induration of chancre, and glands well marked and persistent; moderate degree of ulceration, which tends to become indolent and chronic; chloro-anæmia and osteo-copic pains pronounced; exanthem (later in appearance than in the mild) papular, scaly; marked congestion of throat, which at later dates ulcerates; sores on lips and buccal mucous membrane; iritis, occasionally tertiary symptoms (nodes, swelling of tendons, etc., with pustular disease of skin). Frequent recurrences of syphilitic manifestations, which last longer and have shorter intervals of quiescence than the previous form. The disease produces very important modifications of the health, but is chiefly dangerous to life from a connection with predispositions to other constitutional maladies (hereditary or acquired).

3. *Severe Type.* Induration large and chronic, in chancre and glands; ulceration well marked and phagedenic, sometimes extensive, and liable to return after healing; chloro-anæmia, loss of health, emaciation, loss of hair, well marked and gradually increasing, making up a cachexia; osteocopic pains severe; eruptions discrete, and affecting deeper layers of skin, or pustular and relatively later in their appearance; iritis sometimes double, and often chronic or recurrent; throat affection severe; tertiary symptoms very common, affecting scalp, bones, tendons, larynx, or subcutaneous tissues, and often accompanied by some symptoms referable to diseases of internal organs. If engrafted in one the subject of some hereditary predisposition the effects may be permanent, or the cause of death, from acting as the excitant to other morbid processes. Of course, it is not meant that these limits are arbitrary, for they are approximative only; nor is it intended that all the symptoms should be present in any given case, but that these will conform to one or other of the above types.

In the first variety mercury is not *required* at all for the primary and may be deferred to the secondary stages, and then only used when any of the symptoms become intractable or chronic, or in certain kinds of iritis, or when a scaly syphilide appears. Warm baths, aqueous vapour baths, steel and diaphoretics, with strict attention to hygiene, often prove sufficient to cause a disappearance, at any rate, of the syphilitic manifestations.

In the second variety mercury alone appears to exercise any influence on the absorption of the interstitial deposits (indurations) present in the primaries, and frequently heals a chronic or indolent sore, when every other remedy has been tried; but mercury very rarely prevents the occurrence of the subsequent phenomena. For the cure of the constitutional manifestations, mercury, in the form of calomel vapour-bath, is by far the best remedy, and it is almost invariably followed by *most marked benefit*, if employed with ordinary care and judgment.

In the third variety the mineral is also the most trustworthy remedy for the dissipation of the primary symptoms, and it may be used, unless plainly contra-indicated by some

(c) Nouvelles Doctrines sur la Syphilis.

constitutional causes, or a sloughy state of the chancre, particularly if the ulceration or unhealthy action in the sore advances when the mineral is employed. For the secondary phenomena it should be tentatively, and only endermically used with much discrimination, while the most diligent efforts are being made to raise the vigour of the body by tonics, good diet, etc. For the later stages mercury generally appears to be most injurious, but fortunately iodide of potass, in large doses, and iron here come to our aid as very reliable agents.

Dr. Wilks seems to us to have gone to the root of this question, in the paper to which we have already referred,(d) when he speaks of true syphilis and its sequelæ. The *effects* of the virus are shown in the albuminous deposition, while the *sequelæ* exhibit the degeneration of the tissues from the long continuance of the morbid action. Now, mercury opposes the first, but favours the second, hence the opposite views entertained about this drug.

Here our labours end. In these papers we have endeavoured to eliminate from what is on record many false or imperfect conclusions, and to reduce a large number of scattered fragments to a comprehensive whole. The task was as difficult in its nature as it has been imperfect in its execution. We must have exhausted our readers' stock of forbearance and good nature, and it only remains for us to express our thanks for their frequent exercise of these qualities.

THE WEEK.

SOUTH AMERICAN JERKED BEEF.

It will indeed be a public calamity if this, which promises to be so valuable an addition to the food of all classes, shall turn out to be worthless through want of care in the original manufacture. The proprietors of the Metropolitan Farina Company, Walmer-road, Notting-hill, whose very excellent malt flour for infants' food we shall shortly bring under our readers' notice, frankly invited us to take a sample of dry jerked beef from their stock, and to test and report upon it. It presented the usual white powdery appearance and cheesy smell when dry, but during the process of cooking exhaled a very disagreeable odour, and when brought to table smelled in such a way as to make us decline tasting it. There is not the least imputation on the respectable firms that sell it; the fault is in the article. As was shown some time ago in these pages, in an article termed "Ripe or Rotten?" our ideas of what conditions of food are wholesome must be formed solely from the appetite. Most of us would eat pheasant with a slight *fumet*, and some kinds of cheese absolutely stinking, with relish, and with no subsequent harm, whilst the slightest taint in butcher's meat or poultry would render it quite unbearable to the palate, and probably unwholesome in its after effects. We shall be glad to hear from our correspondents what their experience is. Dr. Ballard, at least, seems to have been more favoured than ourselves. We would also suggest the addition of a good dose of vinegar to the water in which the beef is steeped.

THE WINCHESTER CASE.

In another column we publish a letter from Dr. Fergushill-Crawford, one of the Consulting Physicians of the Hants County Hospital, in reference to an article which appeared some weeks ago in this journal under the title of "The Good Samaritan at Winchester." The *Hampshire Chronicle* for March 11, which our correspondent forwards us with his letter, contains a correspondence on the subject between Dr. Fergushill-Crawford, Mr. J. Bonham Carter, M.P., and the Rev. E. Stewart, the Chairman of the Hospital. With regard to the facts of the case, as stated in this journal, they are amply confirmed by the correspondence in question; indeed, it could scarcely be otherwise, as the contributor of the article only reproduced in a connected story the evidence of the witnesses at the Coroner's inquiry, for the most part in their own words. Mr. Bonham Carter, by styling our leader a "sensation article," implies that it was unjustifiably coloured to raise a sensation of indignation against some of the actors in the tragedy. We deny the justice of the imputation, and appeal to the article itself in proof. The writer of the article, as we have said, most carefully confined his narration to the evidence; he admitted no word of colouring, no epithet or expression of a denunciatory character. He allowed the facts to speak for themselves, and only set the picture in a frame of satire that relieved rather than enhanced the painful feelings which its intrinsic ugliness could not fail to raise. We are quite satisfied with the result. An examination has been instituted, the attention of Members of Parliament and other influential persons has been called to the facts, and we feel assured that no such deplorable "*mistake*" will ever occur again at Winchester. The rev. chairman has written a regretful letter, in which he acknowledges his error; and we are glad to believe him when he says it was one of judgment alone. The correspondence shows that he at least was not solely to blame. The House-Surgeon unhappily forgot his responsibility when he allowed the woman to leave the ward without a full examination of her condition. The whole case was of so terrible and, we are happy to believe, of so unique a character, that we, as Medical journalists, must have been held wanting in our duty had we not called attention to it; and the stern lesson which, with Mr. Bonham Carter, we would draw from it—that "evil is wrought by want of thought as well as by want of heart"—is one which neither Hospital officials nor any who have the lives of their fellow-men in their hands can afford to lose.

(d) Guy's Hospital Reports for 1863.

PARLIAMENTARY.

In the House of Commons on Thursday, March 9, Sir F. Kelly gave notice that on the following Thursday he should move for leave to bring in a Bill to regulate the qualifications of chemists and druggists.

On Friday, March 10, in answer to a question by Mr. G. Duff, Mr. Cowper said that the subject of a building for the University of London was still under the consideration of the Government, and that no decision had yet been come to.

Mr. M'Evoy moved a resolution that Her Majesty's Government should now adopt the recommendations of the Select Committee of 1858, to take into consideration the claims of Ireland to a grant of the half cost of Medical officers in unions, with the view of providing for the same in future, as is now the practice in England and Scotland.

The Chancellor of the Exchequer opposed the resolution, observing that the recommendations of the Committee of 1858 did not show sufficient reasons for adopting it; that it was not for the interest of Ireland to urge the principle of equality in local taxation; and that the general question of relative taxation had been recently referred to a Committee of the House.

The resolution was supported by Mr. Hennessy, Mr. Neate and Mr. Whiteside, and opposed by Mr. Peel.

Upon a division, the resolution was negatived by 37 to 34.

On Tuesday, March 14, in answer to a question by Mr. Ewart, Sir George Grey said that no order had been issued for the seizure of South American jerked beef either in London or in Liverpool. It was not till he saw the notice of his hon. friend's question that he knew of any seizure having been made within the metropolitan police district; but by a report of the police proceedings at the Mansion House a few days ago he found that the Sanitary Inspector under the Commissioners of Sewers had seized a quantity of meat that was unfit for human food. It was said to be South American jerked beef, but from the evidence given it would not appear to have been so. At least, it was condemned on inspection, not because it was South American jerked beef, but because it was not fit for human food. There was a question now pending whether, on the application of magistrates, South American jerked beef should not be used in gaols.

*

FROM ABROAD.—INJURIOUS INFLUENCES OF TOBACCO.

THAT most hopeless of all associations the "British Anti-Tobacco Society" has just met with unexpected co-operation on the other side of the Channel in the shape of a learned academician. M. Jolly places before the Academy of Medicine a sombre picture of the mischief alleged to be due to smoking, and although it is hinted that he will never have the courage to demand a vote upon his propositions in an assemblage of which, grave as it is, the majority consists of confirmed smokers, his paper contains facts which it is desirable to notice, although the affiliation of these with the consumption of tobacco may not always have been rigorously made out.

Smoking has well nigh superseded the more innocent, if more disgusting, practice of snuff-taking in France as well as in our own country, and the immense progress that it has there made of late years may be judged of by the revenue returns. In 1832 the tobacco impost only yielded 28,000,000 francs—having continued at much the same amount since 1792—two-thirds of these arising from snuff-taking and one-third from smoking. In 1842 the amount rose to 80,000,000, in 1852 to 120,000,000, and in 1863 to 216,000,000—the amount derived from snuff remaining all this time well nigh stationary, and that from smoking tobacco thus rapidly increasing. In all those departments also in which the consumption of tobacco per head is greatest, the proportion used for smoking very far exceeds that employed for snuff-taking. The quantities consumed in the different departments vary from 1795 grammes per head in the Nord to 102 grammes per head in Charente. Taking the mean of the maxima and minima, comprising provinces in which very little smoking occurs, as Bretagne and Limousin, the probable calculation is that 8 kilogrammes (16 lb.) of tobacco are annually consumed by each smoker, which is equivalent to 50 to 60 grammes of nicotine per head, *i. e.*, more than sufficient to kill a squadron of cavalry. Of course, confirmed smokers far surpass this modicum.

Official statistics show that in exact relation with this increased consumption of tobacco is the increase of diseases of the nervous centres (insanity, general paralysis, paraplegia, ramollissement), and certain cancerous affections. And it may be asked what else could be expected from the use of a substance so eminently poisonous that in its concentrated form it is only equalled in power by curare and prussic acid, while even in its ordinary condition its effects have been found so redoubtable as to have led almost to its discontinuance as a therapeutical agent. It is to be observed, however, that all the varieties of this plant are not endowed with an equal degree of activity, this depending upon the greater or less proportion of nicotine which they contain. The most recent analyses show us that this proportion may vary much; as, for example, from 2 per cent. in Arabic, Brazilian, and Havannah tobacco, to 2·29 in Maryland, 3·21 in Alsace, 6·9 in Kentucky, 6·58 in Du Nord, 6·87 in Virginia, and 7·35 in Du Lot tobaccos. If Orientals, Turks, Greeks, Brazilians, and Hungarians smoke to an excessive extent with almost impunity, this arises from the fact that the indigenous tobacco which they employ contains very slight proportions of nicotine, and sometimes none at all; while other nations, as the English, Swiss, French, Swedes, etc., suffer much more severely from the tobacco they make use of. It is a remarkable fact that up to the present time no case of general or progressive paralysis has been discovered in any of the numerous localities of the East, where tobacco of so eminently mild a character, or some succedaneum, is employed. M. Moreau in a careful investigation which he has made in the Hospitals of Constantinople, Smyrna, Malta, and all the Mediterranean islands, has not been able to detect a single case of this kind. "The cause is plain enough, and eminently physiological. In all the regions of the Levant they do not intoxicate themselves with nicotine or alcohol, or the ambition of fortune or glory, but saturate themselves with opium and perfumes, sleeping away their time in torpor, indolence, and sensuality. They narcotise, but do not nicotinise themselves, and if opium, as has been said, is the poison of the intellect in the East, tobacco may one day prove in the West the poison of life itself."

Another unfortunate circumstance in the history of tobacco has been the displacement of the pipe by cigars, which is almost universally the case on the Continent. The juices of the tobacco as well as the smoke itself are thus swallowed and introduced into the system, while to the general effects we have added those due to local irritation. The gums and lips become red and tumified, and the teeth suffer much from caries; but the most important circumstance is the frequency with which cancer of the lips occurs among smokers, and especially on the side of the lip on which the cigar or pipe is held. From this form of cancer women are almost entirely exempt. The predominance of cancer observed in women for almost all the organs ceases, too, with respect to the stomach, which is found to be more frequent in men in the proportion of 53 per cent. The danger from chewing tobacco in this relation is very great, especially as tobacco containing 6 per cent. of nicotine is usually employed, and that fasting. Organic affections of the stomach are of great frequency among sailors who indulge in this habit.

That an atmosphere charged with the products of smoking is to a degree poisonous is proved not only by the effects which it produces on those uninured to it, but also by the detection, by M. Melsens, upon the average, of a proportion of $\frac{7}{10}$ per cent. of nicotine held in suspension by the tobacco smoke. The mischievousness of such an atmosphere is further seen in the poisonous effects exerted upon the greater portion of the workpeople employed in tobacco manufacture, as evidenced by cephalalgia, loss of appetite, colic, vomiting, etc. Plants exposed to such an atmosphere soon become sickly and die, as, indeed, do birds; and although habit obtains for the workpeople an exemption from some of the evils they first suffered from, their cachectic appearance, disordered digestion, and the signs of premature old age too plainly indicate the character of their employment.

Passing over M. Jolly's general picture of the effects of tobacco upon the confirmed smoker, which has already been often drawn, we may again advert to its assumed effect in augmenting the number of mental diseases. It is especially general or progressive paralysis—a disease scarcely met with thirty years ago—which seems to be making such rapid advance under, as is supposed, the increased abuse of alcohol and tobacco. That insanity and affections of the nervous centres have enormously increased in France there can be no doubt, and this increase is found to be in men almost entirely made up of cases of progressive paralysis (now forming more than 60 per cent. of the total cases); and whenever in the asylums the history of such cases has been investigated, their dependence on the abuse of tobacco has been rendered obvious. In contrast with this is the rarity with which this form of the disease is met with in female lunatics. Among these paralytic lunatics, soldiers and sailors, who so much abuse tobacco, are found occupying the first rank. M. Jolly's investigations have induced him to come to the conclusion that this abuse of tobacco is far more operative in the induction of this paralysis than is the abuse of alcohol or absinthe which so often co-exists. Among other facts tending to prove this, he adduces this one:—In certain provinces of France,—as Saintagne, Limousin, Bretagne, etc.—in which there is but little smoking, and an enormous consumption of brandy, progressive paralysis is well nigh unknown.

Finally, M. Jolly draws attention to the diminution in the population of France, especially of men from thirty to fifty years of age and upwards, as compared with women of the same ages. At these ages, too, diseases of the nervous centres form a far more common cause of death among men than women. As remedies for the evils he has depicted so strongly, M. Jolly suggests that the importation and consumption of the more innocent forms of tobacco should be encouraged, liberating the French soil from the cultivation of its poisonous

tobacco in order to devote it to more useful productions. If this be impracticable, the aid of the chemist should be called in to free the indigenous tobacco of its excessive proportions of nicotine, replacing this poisonous principle with a variety of perfuming agents, which would render smoking not only less pernicious, but more agreeable. Lastly, let the public be well instructed as to the relative value of the different sorts of tobacco.

M. Bertillon, in the *Union Médicale* March 9, supplies some interesting facts in relation to the effects of tobacco on the mental powers, derived from an investigation made at the Polytechnic School in 1855-56. He investigated in 160 of the pupils who had undergone their examination, what influence the fact of their having been smokers had upon the results. As large a proportion as 102 of these pupils were smokers. It was found that in the classification by merit which followed the examinations that, while in the highest series a third or fourth of the pupils were smokers, in the lower series three-fourths and in the lowest series four-fifths were smokers. Again, while among 66 confirmed smokers their mean rank of 94·5 on their entrance into the school had sunk to 98·3, in the case of the 60 pupils who were not smokers their rank of 71 on entrance (already 23 ahead of the smokers) rose to 67·7 —being, as the result of nine months' work in common, 30 in advance of the smokers. This result of the inquiry as regards these limited numbers was conformable to the prior experience of the school.

TEXT OF THE CONVENTION FOR THE AMELIORATION OF THE LOT OF THE WOUNDED IN ARMIES IN THE FIELD.

[Agreed to by the majority of the European Powers on August 22, 1864.]

Art. 1.—The ambulances and the military Hospitals will be recognised as neutral, and as such be protected and respected by the belligerents so long as they contain sick or wounded. The neutrality should cease if these ambulances or Hospitals were guarded by a military force.

Art. 2.—The *personnel* of the Hospitals and ambulances, comprehending those engaged in the management, the sanitary arrangements, administration, and transport of the wounded, as well as the chaplains, shall participate in the benefit of the neutrality while it is in operation, and so long as wounded persons remain to relieve or succour.

Art. 3.—The persons mentioned in the preceding articles may, even after occupation by the enemy, continue to fulfil their functions in the Hospital or ambulance to which they are attached, or they may retire in order to rejoin the corps to which they belong.

Art. 4.—The *materiel* of the military Hospitals shall remain subject to the laws of war; the persons attached to these Hospitals may, on retiring, only carry away with them such things as are their own private property. On the contrary, under the same circumstances, the ambulance will retain its *materiel*.

Art. 5.—The inhabitants of the country who afford assistance to the wounded will be respected and remain free. The generals of the belligerent powers shall be authorised to preclude the inhabitants from appeal to their humanity and from the neutrality which will be a consequence of it. Every wounded person received into, and taken care of, in a house shall serve as a safeguard to that house. The inhabitant who shall have received wounded persons into his house shall be excused from lodging troops, as well as from a portion of the war contributions levied.

Art. 6.—Wounded or sick soldiers shall be received and taken care of whatever the nation they belong to. Commanders-in-chief shall be authorised to remit immediately to the advanced posts of the enemy soldiers wounded in battle, when circumstances shall permit of it and with the consent of both parties. Such as shall be considered incapable of further service shall, after recovery, be sent back to their country. The others may be also sent back on condition of not bearing arms during the remainder of the war. Evacuations, with those who direct them, shall be covered by an absolute neutrality.

Art. 7.—A distinctive and uniform flag shall be adopted for the Hospitals and ambulances. It ought in all cases to be accompanied by the national colours. A bracelet shall be adopted for the *personnel* rendered neutral, but the delivery of it shall be left to the military authority. The flag and bracelet shall bear a red cross upon a white ground.

Art. 8.—The details of the execution of the present convention will be regulated by the commanders-in-chief of the belligerent armies, according to the instructions of their respective Governments, and conformably to the general principles enunciated in this convention.

Art. 9.—The high contracting powers have agreed to communicate the present convention to the Governments which have not been able to send plenipotentiaries to the International Conference of Geneva, inviting them to become parties to it, with which object the protocol is left open.

Art. 10.—The present convention will be ratified, and the ratifications will be exchanged, at Berne within the space of four months, or earlier, if possible.

ROYAL VISIT TO BROMPTON HOSPITAL.—Her Majesty on Tuesday morning surprised the inmates of the Consumption Hospital, Brompton, by a visit. The Queen, attended by the Duchess of Roxburghe, Lord Alfred Paget, Colonel the Hon. Arthur Hardinge, and Dr. Jenner, arrived at the Hospital at 11 o'clock, and was received at the entrance by the Hon. Arthur Kinnaird, Mr. Philip Rose, Hon. Sec. (the founder of the Hospital), Dr. Roe and Dr. Cotton (the two Senior Physicians), and the principal officials of the Institution. Her Majesty walked through the four "galleries," called respectively the "Victoria," the "Albert," the "Foulis," and the "Jenny Lind," entering many of the wards, speaking to several of the patients who were confined to their beds, and bestowing upon all kindly smiles and sympathising looks. Her Majesty then visited the chapel (which was built by the chairman, Sir Henry Foulis), entered the vestry, and inspected the library; after which she expressed a wish to see the kitchens, with which, as well as with the larder and the steam apparatus for cooking and for raising the lifts for the patients and the provisions, the Queen appeared much interested. Her Majesty wrote her name in the visitors' book, and examined the vellum scroll containing the signatures of the late lamented Prince Consort and of the distinguished visitors who were present at the laying of the foundation stone of the new building by his Royal Highness, on the 11th of June, 1844. During her somewhat lengthened visit the Queen narrowly inspected all the arrangements, and by her numerous questions manifested much interest in the charity, which has long been honoured by the Royal support and patronage. In addition to repeated and emphatic expressions of satisfaction, Her Majesty was graciously pleased on leaving to signify her entire approval of everything she had seen. To the patients, of whom there are 210, the Royal visit was an occasion of intense gratification and interest. Among those honoured by special notice was one of the gallant survivors of the famous Balaklava cavalry charge. This poor soldier was an inmate of the Hospital for the third time since his discharge from the army, having on each occasion been sufficiently restored to health to earn his livelihood.

DOWNING COLLEGE.—An examination for four minor scholarships will be held in Downing College on Monday, May 22 next, and the two following days, and will begin at 9 a.m. on Monday. The examination will be chiefly in Classics and Elementary Mathematics, but some weight will be given to proficiency in French and German. Two additional papers will be set, one on Moral Philosophy, in connexion with the principles of Jurisprudence, and on the Elements of International Law, the other on the natural Sciences in connexion with Medicine—namely, Chemistry, including Analysis, Mineralogy, Botany, Comparative Anatomy, and Physiology; and in awarding two of these scholarships considerable importance will be attached to any special proficiency in the legal or in the Medical subject. Persons who have not been entered at any College in the University, or who have not resided one entire term in any such College, are eligible to these minor scholarships, which will be of the value of £40 per annum, and tenable for two years, or until their holders are elected to foundation scholarships. No one elected minor scholar will receive any emoluments until he has commenced residence as a student of the College. Satisfactory testimonials as to their moral character must be sent to the master by all candidates for these minor scholarships, on or before Wednesday, May 17. Foundation scholars will, by the same examination, be elected from among the undergraduates of the College. Further information will, if required, be given by the Rev. W. B. Pike, or John Perkins, Esq., tutors of the College.

THE MEDICAL HISTORY OF ENGLAND.

By B. W. RICHARDSON, M.A., M.D.,
Senior Physician to the Royal Infirmary for Diseases of the Chest.

THE MEDICAL HISTORY OF BATH.

(Concluded from page 263.)

BELLOT'S HOSPITAL.

In the reign of James the First the Hospital called Bellot's was erected. The founder, Thomas Bellot, Esq., was one of the executors of the famous Lord Cecil. The institution was raised in Bell-tree-lane, afterwards Beau-street, and was placed under the guardianship of the Corporation. The patients admitted were to be of the male sex only, the number was limited to 12, and two shillings and one penny a week was allowed each patient for maintenance. The patients were to use the waters for their cure. Caution money in the way of deposit has since been demanded, the sum to be laid down being £1. Mr. Bellot arranged that the institution should be open for six months in the year only, and that no person should remain in it under treatment for a longer period than twenty-eight days. The Surgeon who examined the sick before admission was to receive for his services twenty shillings a year.

In course of time the rules thus laid down were broken. The patients admitted were allowed to remain for the whole six months of the year while the Hospital was open, six women were admitted for six of the men, and a Physician as well as a Surgeon was appointed to the charity. The management of the Hospital also passed from the Corporation into the hands of the Charity Commissioners. In 1856 and 1857 an attempt was made to transfer Bellot's Hospital to the General Hospital, and to open in the latter a Bellot's ward as a recognition of the founder. In favour of this reasonable suggestion an able article was published by Dr. Falconer in the *Bath Express* of October 10, 1857. It was shown in that communication that the Bellot institution was physically and morally defunct, and that to try and resuscitate it were to lose time and money, and in the end only injure the younger and more vigorous institution. The argument, good as it was, failed on technical and legal points, and a charity which had fulfilled its mission was let remain; but the old building has been pulled down, and the internal arrangements have been improved as far as circumstances allow.

BATH UNITED HOSPITAL.

The Bath United Hospital took its present name and position on December 21, 1826. Originally there were two institutions—one called the Bath City Infirmary and Dispensary, the other the Bath Casualty Hospital. It was considered that the interests of the two institutions would be best conserved by amalgamation, and at the date given above this idea was carried out.

Administration.

Annual subscribers to the institution receive one ticket of recommendation for the admission of an in-patient for every guinea subscribed. The ticket is available one year only from the date of the subscription.

Donors of ten guineas have for life the same privilege as subscribers of one guinea; of twenty guineas as subscribers of two guineas; of thirty guineas as subscribers of three guineas; and so on in proportion. The tickets of country subscribers are only available for the immediate district in which the subscriber resides; while subscribers residing in the Bath union district can only recommend patients who have resided at least one month within the limits of that district.

Every clergyman or minister of a dissenting congregation who may make or authorise collections to be made in his church or chapel for the benefit of this Hospital receives a ticket of admission for an in-patient, and should the amount collected exceed ten pounds, then for every additional sum of ten pounds he is entitled to an additional ticket.

The Physicians and Surgeons have one vote each at all general and special general meetings; they are not eligible as members of the Managing Committee, but may be present at all meetings.

The Physicians and Surgeons are allowed to take pupils, under such regulations as they may jointly agree upon; the Trustees and Committee reserving to themselves the power to reprimand or expel any pupil behaving improperly or not conforming to the established rules.

It is the duty of the Physician's assistant to visit at their homes all such out-patients as are unable to attend at the Hospital, provided they reside within the limits of the district.

No cases of lunacy or recent venereal disease are received into the house, nor are chronic cases admitted, except at the express desire of the Medical officers, and with the approbation of the Weekly Board, previous to admission.

Suitable wards are reserved for the reception of domestic servants of subscribers of one guinea, or upwards, provided the payment of 10s. weekly, or such other sum as the Trustees and Committee may appoint, be secured to the Hospital for each servant. No servant while so paid for can be transferred to the ordinary wards.

All in-patients are discharged at the end of two months after their admission, unless the attending Physician or Surgeon certify to the Committee that there is a probability of their being cured, or of their receiving considerable benefit, by being permitted to remain longer in the house.

The Trustees and Managing Committee are empowered to make suitable provisions for supplying to the ruptured poor trusses at reduced prices, or gratuitously, according to the exigency of each case.

Sanitary Condition.

The Bath United Hospital is at this moment undergoing such important structural modifications that it is difficult to speak of it in correct terms. The original Hospital was not a very favourable specimen of internal arrangement. The wards were dark and devoid of art, and the faults which I have described in many other similar institutions were present. The deficiencies have long been felt, and much discussion has, I believe, been carried on in reference to the propriety of removing the Hospital to a new site or of rebuilding it altogether. The result has ended in a compromise; the Hospital remains on its original site; but it is undergoing modification and enlargement by the addition of an "Albert Wing." This wing is now being built, and the walls are about one-third of their intended height. There are also new residences projected for the resident Medical officers, and with these will be included a new chapel, an operating theatre, dormitories for the nurses, a museum, a library, a dissecting-room, and improved accommodation for the out-door patients. The whole will be completed at the end of the year 1866. The Albert wing will contain two wards, each capable of holding sixteen beds. The lower ward is to be 13½ feet high, 24 feet wide, and 62 feet long; the entire cubic space being 20,088 cubic feet, or 1255 cubic feet per bed. The upper ward is to be 15½ feet high, 24 wide, and 26 long, affording a cubic capacity of 23,064 feet, or 1441 per bed. The wards will be warmed by open grates, and for extra warming coils of pipes for the circulation of hot water will be provided, six pipes in each ward. The ventilation will be by flues from each end of the wards, terminating in extracting shafts. The water-closets will be external to the building, and the pipes from them, which are of earthenware, will run, externally to the building, into the main sewers of the city. The walls of the new wards will be lined with the local oolite, and the floors will be fire-proof, on Dennett's principle.

The water supply of the Hospital is from the Company's reservoirs, and is considered efficient. The cleaning of the floors is by washing and scrubbing; the floors are cleaned twice weekly.

BATH UNITED HOSPITAL.—DIET TABLE—DAILY ALLOWANCE.

B., Breakfast; D., Dinner; S., Supper; M. T. W. Th. F. Sa. Su., Days of the Week.

Diets.		Meat cooked.	Bread.	Potatoes.	Rice Pudding.	Tea.	Sugar.	Milk.	Butter.	Beer.

	Women	1 pint broth	3½ oz. B. D. S.	—	6 oz. D. M. W. F.	1 pint B. S.	½ oz. B. S.	½ pint B. S.	½ oz. B. S.	—

(a) On Wednesdays, men and women, D. broth 1 pint, bread 4 oz., rice pudding 6 oz., beer 1 pint.
(b) On Mondays, Wednesdays, and Fridays, D., broth 1 pint.
Tea may be exchanged for milk 1 pint.
Extras:—Chops, slices (4 oz. cooked meat), beef-tea (1 lb. meat to a pint), mutton broth, fish, eggs light, puddings, wine, spirits, porter.
No extras on full or half diets, except wine and porter instead of beer. The order for extras to be renewed daily.

The Nursing System.

The nursing staff consists of twelve nurses and four assistant nurses; the latter act as scrubbers, and attend to keep the wards clean. The twelve nurses act as day and night nurses, a certain number nursing by day and a certain number by night; these change duties about once a month. The whole staff is under the direction of a superintendent nurse, who has been educated at St. Thomas's Hospital, under the Nightingale Fund. In addition to these there are probationers training in the Hospital as nurses for the Home for Nurses, established in Bath.

Points of Practice.

The number of patients admitted into the Hospital yearly exceeds 1000. The following tables will show the practice of last year, 1864:—

A Statement of the Number of Patients admitted to the Bath United Hospital during 1864.

MEDICAL AND SURGICAL IN-PATIENTS.

Cured.	Relieved.	Died.	In the Hospital.	Total.
640	365	*90	56	1,151

* It may be proper to state that the mortality of the Hospital was considerably augmented by several cases dying almost immediately after their admission. Twenty of these were admitted, of which nearly all were patients who had met with such severe injuries as to prove fatal in a very short time. The fair mortality of the Hospital will therefore be 70.

Mortality.

The mortality of the Hospital, by Dr. Farr's method of calculation, is placed exceedingly high—viz., at 102·56 per cent. Only two other Hospitals stand above it, except the Liverpool Northern Hospital and the Manchester Royal Infirmary. On the ordinary method of calculation, based on the mortality of the three years 1862, 1863, 1864, I find the mortality to have been, on the admissions, 7·17 per cent. The Surgical mortality for the same period of three years was 6·26 per cent.

Chloroform—Administration and Accidents.

Snow's apparatus for the inhalation of chloroform was at one time used in the Hospital, but for the last seven years it has rarely been employed.

The ordinary method of administering chloroform is on lint folded into the shape of a hollow cone with an aperture left at the smaller end to admit air. Sometimes a napkin is used and held some little distance from the mouth and nostrils.

All the assumed necessary restoratives of suspended functions are kept at hand—such as ammonia, galvanic batteries, etc. There have been three deaths since the first administration of chloroform. One in 1853, one in 1862, and one in 1864. The case in 1862 occurred at an operation for removal of the inferior maxillary bone, and the death was mainly from debility, the patient not having eaten food for a long time.

Notes of the last Case of Death during the Inhalation of Chloroform, by Charles Gaine, Esq., Bath.—John D., aged 15 (a twin). "Had chloroform administered for a Surgical operation. There was nothing in the external appearance of the patient to contra-indicate its use, with the exception of some slight malformation of the sterno-costal cartilage of one side of chest. On auscultation and percussion, healthy sounds were elicited. The chloroform was administered on a small napkin folded into a hollow cone. There was little excitement apparent, though the heart's action for the first minute or so after commencing the inhalation was slightly increased; but the tone and character of the impulse were normal. The

respiration was natural, the eye steady, and the pupils of ordinary size. The time occupied, from beginning the inhalation to the commencement of the operation, was from ten to twelve minutes, and the quantity of chloroform used about three drachms by measure. The boy was quite composed nearly the whole time, and inhaled the chloroform without its producing any of the phenomena, presented in most cases, indicative of transition from stage to stage towards anæsthesia. The eye remained sensible to touch, and the pupils unchanged, until within ten or fifteen seconds prior to the commencement of the operation, and the pupils then contracted slightly; the muscles were relaxed; the pulse and respiration remained unchanged. The operation was now commenced, and simultaneously with the entrance of the knife the boy made two strong convulsive starts and screamed out, and almost synchronously with the second spasm the heart's action suddenly failed. Restorative means were at once employed to endeavour to resuscitate him, and persevered with for some time, and though there were two or three convulsive respiratory efforts, these were but illusory, and life may be said to have ceased when the heart failed.

The post-mortem examination revealed no morbid lesions in any structure; and the fibres of the heart, examined microscopically, showed no symptoms of fatty degeneration. The kidneys were lobulated, but healthy. The brain was very large, weighing 60·89 ounces avoirdupois. The blood was dark and very thin and opaque throughout the body, apparently deprived of its fibrin.

The Registrar's report of the number of operations performed in the Bath United Hospital from May, 1849, to December 31, 1864, is 844; in all of these probably chloroform was administered. There are many cases, however, in which chloroform is and has been administered for minor operations in the out-patients' Surgery—probably an average of three or four weekly; of these no mention is made in the books; so that the 844 cases are chiefly capital operations."

Museum and Library.

There is a museum attached to the Hospital, containing 580 wet preparations, and about 1000 other preparations. The specimens are pathological and anatomical. The anatomical preparations include some very valuable and perfect preparations in comparative anatomy; these latter are the work principally of R. T. Gore, Esq., the senior Surgeon to the Hospital, and so well and widely known in the world of science as the translator and editor of "Carus' Comparative Anatomy," 1827.

There is also a Medical library containing from 2000 to 3000 volumes; there is a fair proportion of classical works in the library, and most of our modern English contributions to standard Medical literature.

OTHER MEDICAL CHARITIES.

In addition to the two large Hospitals there are in the city eight other Medical Institutions.

The Bath Eastern Dispensary.

This is a general Dispensary that has been in existence more than thirty years, and has a staff of three Physicians, three Surgeons, and a resident Surgeon. It receives about 3000 patients, and patients are visited at their own homes. The Institution does much good work.

Medical Staff.

Physicians.—Dr. Blackmore, Dr. Sylvester, Dr. Fitzpatrick. *Surgeons.*—W. Bush, Esq., T. G. Stockwell, Esq., J. K. Spender, Esq.

The Bath Western Dispensary.

The Bath Western Dispensary is also a general institution for the relief of the sick poor. It has been established nearly thirty years. The patients treated annually are about 1200. This Institution does for the west of Bath what the previous one does for the east. It is very useful.

Medical Staff.

Surgeons.—F. P. Hoblyn, Esq., A. B. Brabazon, M.D., G. D. Freeman, Esq.

Bath Institution for Idiots.

This charity is for the treatment of children who are idiot or imbecile. It is capable of receiving twenty-two patients. It was the first Institution of the kind in England, and was established by Miss Charlotte White, now Mrs. Graves. The patients are divided into a better and lower class; but the lower pays a small sum towards maintenance—viz., £12 per annum. The Institution is of great service.

Medical Staff.

Physician.—Dr. Falconer. *Surgeon.*—W. H. Brace, Esq.

There is one other general Dispensary, called the Southern Dispensary, to which Mr. O. Tucker is the Surgeon. This Dispensary is self-supporting, to a certain extent. One shilling is charged for tickets for persons above fourteen years, and sixpence for those under that age. There are four special Dispensaries, two for the eye, one for the skin, and the fourth for the diseases of the chest. Of these (1), The Bath Eye and Ear Infirmary receives about 700 patients annually. Mr. Bush and Dr. Barrett are the Surgeons. (2) The Bath Eye Infirmary, which receives also about 700 patients, fifty being in-cases. Mr. Watson is the Surgeon. (3) The Bath Dispensary for Diseases of the Skin and Urinary Organs, which receives about 650 patients. Mr. Mitchell is the Surgeon. (4) The Bath Institution for Diseases of the Chest, which receives nearly 900 patients annually. Dr. Lloyd is the Physician.

MEDICAL SOCIETIES.

The Bath Pathological Society is the local Medical Society. It holds its meetings once a month for six months in the year; pathological specimens are presented, and short papers, on cases, are read. The members meet in the Board-room of the Mineral Water Hospital.

The Bath and Bristol Branch of the British Medical Association holds its sittings alternately at Bath and Bristol. This branch is one of the most influential of the branches of the Association, and has at various times exerted a powerful influence on the proceedings of the parent Association. For many years the branch was nobly represented, on almost all occasions, by two Bath worthies whose names will not soon be forgotten—I mean the late Mr. Soden and Mr. Norman.

There is also a Microscopical Society in Bath, in which the Medical element largely but not exclusively prevails. The members hold nine meetings a year, the Session opening in October and closing in June.

PAROCHIAL MEDICAL PRACTICE.

The Bath Union District is divided into eight divisions or parishes. The following table gives these districts, with acreage, population, Medical officers, and fees:—

District.	Acreage.	Population.	Medical officers.	Ann. salary
No. 1	617	15,013	F. Hanham, Esq.,	£34
,, 2	617	11,268	H. Massy, Esq.	£33

SANITARY CONDITION OF BATH.

Value of Life in Bath.

A very interesting discussion was raised at the Science Meeting at Bath last year, by Mr. R. T. Gore, on the mortality of the city and the causes of the mortality. On this point Mr. Gore said that the total population of the city, according to the last Census, and including the workhouse and the Hospital, may be taken at 52,500; and the total deaths as follows:—Lansdown, 341; Walcot, 280; Abbey, 290; Lycombe and Widcombe, 214; Bathwick, 91; total, 1224. To these must be added, for deaths of persons belonging to the city parishes—in the workhouse, 50; in the United Hospital, 67; total deaths, 1350. Population, as above, 52,500; deaths, 1350; ratio to population, 25·714; thus ranging from Bathwick 17·28 to, in the Abbey district, 27·09. Of the total deaths the numbers at certain ages were as follow:—Under 10 years, 41·63; from 60 to 100, 28·82; intermediate ages, 29·25. In the debate that followed on Mr. Gore's paper, Mr. Field stated that the population of Bath by the last Census was nearly one thousand less than in 1841. The rate of mortality in June, 1843, was but little more than 21 in the 1000; now it was $25\cdot\frac{7}{10}$ in the 1000.

The annexed returns, on the same subject, are from the Registrar-General's returns:—

Average Annual Rate of Mortality in Bath from all Causes, at Different Ages, to 100 *Living, during the Ten Years,* 1851-60.

	Males.	Females.
All ages	2·478	2·007
Under five	6·866	5·671
Five to ten	·693	·726

	Males.	Females.
Ten to fifteen	·434	·509
Fifteen to twenty	·594	·614
Twenty to twenty-five	·954	·603
Twenty-five to thirty-five	1·227	·813
Thirty-five to forty-five	1·667	1·097
Forty-five to fifty-five	2·363	1·572
Fifty-five to sixty-five	3·646	2 732
Sixty-five to seventy-five	6·658	6·106
Seventy-five to eighty-five	16·801	13·488
Eighty-five and upwards	34·681	30·325

Average Annual Mortality in Bath from different Causes, to 100 Living, from 1851 to 1860.

	Males.	Females.
All causes	2·478	2·007
Typhus	·080	·068
Cholera, diarrhœa, and dysentery	·113	·974
Other zymotic diseases	·246	·168
Cancer	·028	·061
Phthisis	·313	·231
Scrofula, tabes mesenterica, and hydrocephalus	·104	·068
Disease of brain	·314	·246
Disease of heart and dropsy	·147	·149
Disease of lungs	·379	·300
Diseases of stomach and liver	·117	·118
Disease of kidneys	·055	·019
Violent deaths	·107	·047
Other causes	·475	·458

Water Supply and Drainage.

The water supply of Bath is at this time being considered by the Corporation, with a view to its improvement. At present the water is from the Corporation Reservoirs, from private companies, and from wells connected with private houses. The water is hard, but clear and sparkling. The quantity is not thought to be sufficient for the present population.

The sewage of the city is in great part drained into the river Avon. The sewers are reported to be large and well constructed, but the flushing is not sufficiently effective. Many cesspools still exist.

Epidemics.

An outbreak of typhus fever occurred in Bath last year. The epidemic is remarkable in that it appeared to be of local and of spontaneous origin. Dr. Goodridge, who investigated the matter carefully, has shown that the disease originated in the Bath Refuge for the Destitute. The room in which the vagrants slept was badly ventilated, and the cubic space allotted to each was only 387 feet. The first case was in the Superintendent, and from him the disorder spread. Speaking of its course from the Refuge into the city, Dr. Goodridge has been good enough to forward me a report, which I subjoin:—

"The history of typhus in Bath in 1864 began with the outbreak at the 'Refuge,' as indicated in my 'Inquiry,' etc.; but it did not end with it. In the second week of June, after a lapse of upwards of six weeks from the discharge from the Hospital of the survivor of the 'Refuge' cases, one of the nurses sickened with this fever; and two days later a young man was admitted from Avon-street, one of the lowest quarters of the city, suffering from the same. The difficulty of believing that infection could have remained latent in the Hospital during so long an interval, particularly as not a single case of extension occurred at the time, led to a further inquiry, which elicited that the young man from Avon-street was really by a day or two the first attacked, and that the nurse (as appeared from circumstantial evidence) probably had had some communication with him. As to the source of this young man's illness, his testimony went to negative contagion; but beyond this the inquiry was not pursued. A succession of typhus cases now set in, amounting in the aggregate to one dozen, received into the Hospital in the space of two months. They were most of them, but not all, from the locality mentioned, which, it may be as well to add, is the chief resort in Bath of the Irish poor. Not having myself had the charge of the majority of the cases, I speak with some hesitation; but I believe I am correct in saying that they were generally mild in character. Only one terminated fatally, the subject being a man of intemperate habits and impaired constitution. No post-mortem examination was made—perhaps a rather unfortunate circumstance, as the prominence more or less of diarrhœa in all these cases tended anon to raise the question whether the fever were typhoid or typhus. The character of the eruption, however, which was usually very copious, seemed conclusive. In one case of my own, in which the diarrhœa was so urgent as to require the administration of acetate of lead, there was not even any delirium from beginning to end; yet the characteristic eruption and dusky mottling were present in abundance. Convalescence usually commenced after the end of the second week. Petechiæ were comparatively rare — indeed, in respect of gravity, there seemed to be a marked difference between these cases and the earliest ones of the man and woman from the 'Refuge,' which might aptly have been designated 'petechial' fever.' It was understood that, besides the cases received into the Hospital, there were a few others in the town that came under the hands of private Practitioners, but I have no certain information on this point. The popular notion was that the fever was produced by the heat and drought of the season, and the consequent bad state of the river. It will be observed, however, that the first typhus case in Bath was prior to all this. The fever in its course no doubt was more or less propagated by contagion; but the cases in the Hospital were uniformly placed in separate wards from the general patients, and there was not a single instance of spreading within it. By the end of August the epidemic (if it may be so termed) subsided, so that after September 3 there was not a solitary case remaining in the house. In the course of October, however, another was admitted; it was under my care, and I clearly ascertained that it was an imported case, the patient, a young man, having arrived in Bath ill from a town, and from a house in that town, where typhus was present. This was a rather severe case, the diarrhœa very urgent, but the eruption demonstrably that of typhus. He was discharged on November 1, and thus closed the history of typhus in Bath in 1864. The present Resident Medical Officer, Mr. Freeman, informs me that he has seen one or two cases this year in his visiting district, but otherwise I am unaware of its continuance.

It may be interesting to add that during 1864 the admissions into the Hospital of *typhoid* fever were *five*, of which one was a fatal case."

The Registrar-General includes Bath in what he calls the Bristol cholera field. He records, in 1849, ninety deaths in the Bath district, the population then being 69,800. There were also 101 fatal cases of diarrhœa. Divided into the sub-districts, I find that 17 cases of cholera and 13 of diarrhœa occurred in the Twerton district. The cases were chiefly amongst colliers and weavers, and took place in September, October, and November. In Bathwick there were 4 fatal cases of cholera, and 1 of diarrhœa. The cases occurred in August. In the Abbey district there were 10 fatal cases of cholera, and 19 of diarrhœa. Diarrhœa prevailed in January, March, April, and June, but the first case of true cholera did not appear until August. In Lyncombe there were 21 cases of cholera, in August and September. All the deaths occurred at Widcombe. In Walcot there were 18 fatal cases of diarrhœa. In Lansdown there were 21 cases of cholera and 21 of diarrhœa. In Batheaston there were 17 cases of cholera and 11 of diarrhœa; all of these occurred in the Bristol-road, Weston, during the months of August, September, and October.

In the year 1854 there were no deaths from cholera in the Bath district, but 79 from diarrhœa.

The inference to be drawn from these facts is, that between the years 1849 and 1854 either certain improvements must have been made in the water supply of the various districts and in the drainage of the city, or that no case of cholera was imported into the district.

There are no epidemics or endemics special to Bath.

Climate and Site.

The climate and site of Bath are equally advantageous for invalids, and few, if any, cities in England are so favourably placed for securing the essentials of health. The soil is porous and at the same time dry, for the city rests on foundations which are unexceptionable. The town itself may almost be said to be built of its own foundations, for the limestone is from the beds of the great oolite quarried hard by. In the north of the city is a stratum of Fuller's earth, on which the residences are built, and beneath this is the inferior oolite, upon which and the lias the city, generally, stands, while lower down there are the red sand stones and the marls. The surrounding hills protect the inhabitants from easterly and northerly currents of air, and the result is that the climate is exceedingly equable, its mean temperature being from three to five degrees above that of any other city in the kingdom.

These facts in reference to Bath as a residence for invalids are, to my mind, more important than the fact of the waters, and I have wondered why the Profession of the city have not dwelt more on the questions of site, climate, and scenery, than upon the mineral springs. If a large winter palace of glass were erected in Bath, and were warmed after the manner suggested by Dr. Daubeny—I mean by application of the heated water which now flows into the Avon—Bath would be made one of the grandest resorts in the kingdom, perhaps in the world, for sufferers from various affections of the chest. Up to this time the city has not been famous as a resort for consumptives, simply because it seems to be an idea that the waters are not specific in consumption; but Bath is, in fact, the *beau ideal* of a winter residence for this class of invalid.

THE BATHS.

The baths of Bath are derived from four springs. One spring goes to the fountain in the Grand Pump-room, to the Mineral Water Hospital, to the King's and Queen's Public and Private Baths, and to a tepid swimming bath. A second spring goes to the Cross Bath only. A third goes also to the United Hospital, to what is called the Hetling Pump-room, to the Royal Private Baths, and to the Hot Public Bath. The fourth spring—the Kingston spring—belongs to the Earl Manvers, and supplies the Kingston Baths, to which a Pump-room is attached. The three first-named springs are the property of the Corporation.

The facilities for bathing and for the use of the waters are as good as can be wished; and the baths are the King's Bath, the Queen's Bath, the Cross Bath, the Hot Bath. These exclude the baths called the Kingston. The King's Bath is open, and, as we have seen, of great antiquity. In the year 1699 a statue of King Bladud was erected in the bath, beneath which was placed a grand inscription in memory of that famous potentate, and on the left hand of the bath was another inscription in poetry, of which the two last lines are a sufficient specimen:—

> "God and the King are here our free imparters,
> God gives the waters, and the King the charters."

The bath is capable of holding between 51,000 and 52,000 gallons of water. The temperature of the water is from 100° to 116°.

The Queen's Bath is also an open bath, capable of holding between 18,000 and 19,000 gallons of water. The temperature of the bath is 102°.

The Cross Bath, so called from a cross erected in the centre of it by the Earl of Melfort, in commemoration of the Queen of James the Second having bathed in it, is capable of holding between 11,000 and 12,000 gallons of water; the temperature is 100°.

The depth of all these baths is about four feet.

The Hot Bath is an open bath, capable of holding nearly 10,000 gallons of water. It also has a depth of four feet, or from that to four and a-half feet. It was originally called the Hot Bath because it was thought once to be of the highest temperature. The water, however, in the bath does not exceed 105 degrees, and is not in the main higher in temperature than that of the King's Bath. The poor, under certain conditions, and the out-patients of the United Hospital, are allowed to use the Hot Bath.

The Kingston Baths include a shower bath and a douche, a bath-room, and a hot-air bath. They are fitted up with great taste, and with reference to every comfort. The composition of the waters is not essentially different from the water of the King's Bath.

I need only add in reference to this subject that there are private baths, douche baths, a swimming bath, and every convenience that can be offered in the way of bathing in Bath.

MEDICAL BIOGRAPHY OF BATH.

William Turner, M.D.—The first Medical writer of celebrity in Bath was Dr. William Turner, whose writings began to appear in 1557. Turner was Dean of Wells. Dr. Falconer, writing on Turner's "Treatise on the Bath Waters," as the earliest publication on the subject, says—"He (Turner) recommends several alterations in the baths for the benefit of the bathers, and for preserving the water clean, and states that the waters owe their chief virtues and strength to brimstone. Turner was born at Morpeth, in Northumberland, and died on July 7, 1568."

John Mayow, whom some of us know for his physiological researches—who, according to my view, first discovered the properties of, if not the substance, oxygen—is connected with the history of Bath, in which city he was accustomed to practise during the summer months. He wrote a treatise on the Bath waters, in which he showed an advanced knowledge of their composition. Among other things, he exposed a trick at that time practised by the guides, to show that the Bath waters gave a yellow tinge to silver. He also proved that the residue of the Bath water, after evaporation, did not deflagrate. Mayow was born in London on September 17, 1621, was a scholar of Wadham College, took a degree in civil law, and afterwards studied Physic. He died in September, 1679, and was buried in St. Paul's, Covent-garden. It was this Mayow who did the great experiment of showing the change of arterial into venous blood under artificial respiration.

George Cheyne, M.D., F.R.S.—Known amongst us as the author of works on "Theory of Fevers," "Fluxions," "Philosophical Principles of Natural Religion," and "The English Malady," is connected with Bath by a paper which he wrote in 1730, entitled "Observations concerning the Nature and Due Method of Treating the Gout, for the use of my worthy friend, Richard Tennison, Esq.; together with an account of the Nature and Qualities of Bath Waters." Cheyne was remarkable for his obesity. He weighed at one time thirty-two stones, but reduced himself considerably by following out a plan of diet now ridiculously called "Bantingism." Cheyne was born in the year 1670, and died at Bath in 1742.

T. Smollett, M.D.—Smollett, the historian, after becoming a domestic man, by marrying his beautiful Creole, Miss Lascelles, and after giving to the world his "Roderick Random," in 1748, took seriously to physic, and amongst other things published an essay, in 1752, on the "External Use of Water, with particular remarks upon the present method of using the mineral waters of Bath in Somersetshire, and a plan for rendering them more safe, agreeable, and efficacious." Whether he ever intended to practise in Bath is doubtful, for he seems immediately afterwards to have returned to literature, and to the production of those wonderful works in history and fiction which have rendered his name so distinguished. Smollett was born in the Vale of Leven, Dumbarton, in 1721, graduated at Marischal College, in Aberdeen, in 1750, and died at Leghorn in 1771.

William Falconer, M.D., F.R.S.—In the beginning of this century, perhaps no English Physician in the provinces held so distinguished a place as Dr. William Falconer, of Bath, in which city he practised for nearly half a century. In the rooms of the Medical Society of London his name stands foremost as one of the Fothergillian gold medallists of that venerable Society, and his prize essay on the "Influence of the Passions on Disorders of the Body" retains its place in our standard literature. He also wrote a book entitled "An Essay on the Bath Waters," which went through several editions; and he first collected by the pneumatic method the gases which escape from the waters. It is also possible that he was the discoverer of carbonic acid gas—a discovery usually attributed to Black. Falconer was born at Chester in 1744, and died in 1824. The present Dr. R. W. Falconer is the grandson of this Physician.

In our time the city of Bath has lost two of its eminent Practitioners—I mean the late Messrs. Soden and Norman. I have already referred to them, with due respect to their memories; and if I have no record to render of their scientific works, the regret belongs to the world and to me.

THE SECOND ROAD MURDER.—In the case of the child poisoned at Wells by corrosive sublimate, administered instead of Steadman's soothing powder, the coroner's jury have returned the following verdict:—"That the deceased came to his death by the administration of poison, having been substituted for Steadman's powders by some person or persons unknown."

THE ZOOLOGICAL SOCIETY.—The Council of this excellent Institution has just decided to appoint a Prosector in their Gardens to take charge of, and to dissect the bodies of animals which die in the Society's menagerie, and to perform such other anatomical and physiological work as the Zootomical Committee may direct, and to keep an accurate record of his dissections and observations for publication in the *Proceedings* or *Transactions* of the Zoological Society. Applications and testimonials for the appointment must be sent in on or before the 22nd proximo. The salary offered is £250. There are already so many good candidates in the field that the Council will have a difficult matter to make a selection.

REVIEWS.

A Treatise on Military Surgery and Hygiene. By Frank Hastings Hamilton, M.D., late Lieut.-Col., Medical Inspector U.S.A., Professor of Military Surgery and Hygiene, etc., in Bellevue Medical College, etc. Illustrated by 127 Engravings. New York: Baillière Brothers. 1865. Pp. 648.

At the commencement of the present unhappy war in America the author of this volume published a short treatise on military Surgery; the edition was soon exhausted, and in place of a new edition Dr. Hamilton has presented the Profession with an entirely new work—the result of his extended experience,—and a very excellent book it is. A great part is necessarily occupied by a discussion of gunshot wounds; but as the duties of a military Surgeon are far more extensive than the treatment of injuries, Dr. Hamilton discusses in separate chapters the subjects of general military hygiene, the examination of recruits, the arrangements for the hutting, billeting, etc., of troops, the conveyance of the sick and wounded, and other kindred topics. In our review of the book it is to these chapters that we shall especially direct attention.

The introductory chapter is occupied mainly by a discussion of the place which the Surgeon should occupy in a military organisation. It appears that questions of rank and privilege arise between the Surgeons and combatant officers in the United States army at any rate as frequently as they do in our own. Dr. Hamilton very properly claims for his *confréres* their rightful position, but he does so with a most commendable moderation of tone and language. The letter of the Act of Congress of February 11, 1847, declares that "the rank of officers of the Medical Department of the army shall be arranged upon the same basis which at present determines the amount of their pay and emoluments; provided that Medical officers shall not, in virtue of such rank, be entitled to command in the line or other staff departments of the army." But notwithstanding this, there have been those who have refused compliance with the law upon the ground "that Surgeons are non-combatant, and that to combatants alone, upon whom, they affirm, rest the hazards and responsibilities of war, rightly belong its honours." Most ably does Dr. Hamilton refute this reasoning, and we cannot refrain from quoting a portion of his remarks upon this subject. "If exposure to hardship and danger," he says, "is to be the ground upon which rank is to be conceded to officers of the army or of the navy, we think the claims of the Medical officers may be easily determined. The Medical officers are exposed to the same hardships on the march or in cantonments as the officers of the line; and, while the latter have to incur the hazards of battle only occasionally, perhaps but once in a campaign, the former may be said to be doing battle daily, being constantly subjected to the dangers of pestilence by their exposure to the contagions and infections of crowded and unwholesome Hospitals. . . . But as compared with the quartermasters or subsistence officers, the hazards of the Medical officers are undeniably greater. The services of the first are never required upon the field; whilst the Surgeons are expected to accompany their respective regiments until the action commences—and then only to retire to some position of comparative but not absolute safety." And then, after quoting numerous instances of fatality which have attended the conscientious discharge of military Medical duty, he proceeds—"Napoleon always called his Medical officers 'my brave Surgeons,' and we believe that no class is less amenable to the charge of cowardice than Medical men generally. They are trained in a Spartan school, under, if we may so term it, a law of ethics which allows no man to turn his back upon danger. Whatever may be the peril, they are expected to go wherever their services are needed. They make no ado about it; nor are their names often mentioned in the official reports; and still less often are they brevcted for soldier-like conduct; yet they go, wherever they are called, quietly about their business, alone or in small detachments, in rain and in snow, by night and by day, on the march and on the bivouac, through watchfulness and fasting and fatigue, into the midst of malaria, contagion, and battle. Indeed the men who can remain cool and self-possessed in the midst of deadly contagions ought to stand well the fire of musketry. Can any one suppose that the forty Physicians who never turned their backs, but fell with their faces towards the enemy at Norfolk, or any one of those thousands—our compatriots in arms—who have fallen on other fields, have died any less heroically than Warren on Bunker's Hill? or that they would have marched any less steadily upon the batteries at Fredericksburg than did the brave men under Burnside and Hooker? We think they were all brave men alike, and alike entitled to public gratitude."—P. 30.

The following constitutes the daily rations of the soldiers of the American army:—"Pork or bacon twelve ounces, or as their equivalents salt or fresh beef twenty ounces; twenty-two ounces of bread or of flour, or twenty ounces of corn meal, or one pound of hard bread. To every one hundred men there may be issued also daily ten pounds of green coffee, or eight pounds of roasted and ground coffee, or one and a-half pounds of tea; fifteen pounds of sugar; eight quarts of beans or peas; ten pounds of rice or hominy; four quarts of vinegar, and two quarts of salt. There is allowed also in addition to the above to every hundred men one gallon of molasses, and three times per week one pound of fresh potatoes to each man, provided of course they can be obtained. When beans, peas, rice, hominy, or potatoes cannot be supplied in the quantities or proportions allowed by regulations, an equivalent in value is allowed of any other proper vegetable food; as, for example, desiccated potatoes one ounce to each man, or mixed desiccated vegetables one ounce to each man. In case also it is thought proper, and when the supply on hand will permit, these desiccated vegetables may be issued instead of beans or peas, or instead of rice and hominy. Fresh beef may be issued daily instead of salted meats if a sufficient supply can be obtained and the health of the troops demand it. Moreover, at the discretion of the commanding officer, onions, cabbages, beets, carrots, and various other vegetables may be occasionally added to the ration," p. 78. Dr. Hamilton speaks highly of the value of desiccated vegetables as a prevention of scurvy. With respect to the supply of vegetables to the army, Dr. Hamilton complains that subordinate officers evince as a rule little interest and manifest no alarm so long as men are not dying in considerable numbers from scurvy. "Even the Surgeons," he adds, "are not always fully awake to the danger which is upon them when one well marked case of scorbutus is brought to their notice. It is not often we find more than five or ten striking examples of scurvy in one regiment at a time, but if there is but one it ought to furnish a substantial ground of suspicion that the physical condition of the whole, or nearly the whole, of the command is impaired."—P. 82.

The chapter on "General Hygiene of Troops," from which we are quoting, abounds in valuable matter. The subject of personal cleanliness, he points out, has a wider scope than commanding officers are apt to acknowledge. "When no attention is paid to habits of personal cleanliness, when garbage lies everywhere in the company streets, and the air has a noisome odour both within and without the tents, we have found the men slovenly in their habits of dress, negligent of duty, but particularly attentive to sick-call; their muskets are rusty and out of order; their knapsacks are badly packed; they are improvident of their rations, and their cooking is badly done; they fall into line slowly, and straggle on the march; they are insubordinate, mutinous, without drill and discipline. They have no *esprit de corps*, no self-respect, no manliness, no courage, and they will not fight. These are the links which compose the chain; with defilement at one end, and cowardice at the other, commencing in the camp at Alexandria, and ending in the rout upon the plains of Manassas. They are inseparable, and, in our opinion, whoever is responsible for the one is responsible for the whole."—P. 92. The clothing of troops, of course, occupies a portion of this chapter. In the controversy between the relative value of cotton and flannel next the skin in warm climates, Dr. Hamilton decides in favour of the latter.

Dr. Hamilton throws in his experience in testimony of the superior value of tents or marquées over any other arrangement for Hospital purposes. "In January, 1862, after having organised the Central Park General Hospital in the city of New York, we found it necessary, on account of the appearance of Hospital gangrene, to erect tents, and these tents, eight or ten in number, have been occupied ever since. In neither of these extremes of climate (the valley of the Tennessee, Stevenson, Alabama, and Bridgeport are the other places referred to) and of season has there been found any difficulty in rendering the tents comfortable. . . One single fact which we shall state ought to settle for ever the value of tents for Hospital purposes. While we have seen many hundreds of cases of Hospital gan-

grene which have originated in buildings temporarily occupied, in transports, and even in well-constructed pavilions, we have never seen a case which originated in a tent; nor can we call to mind a case which was not at once benefited, if not speedily cured, by a transfer to a tent. Upon this point the testimony of all Army Surgeons with whom we have conversed is the same."—P. 133. Our readers will recollect the powerful arguments of M. Lévy to the same effect, arising out of his experience during the Russian war.

It is somewhat enlightening to the uninitiated, who read sometimes about bayonet charges in narratives of battle, to find that throughout the two chapters of Dr. Hamilton upon punctured and incised wounds not a single illustration is to be found based upon any such event. None of the wounds in the cases narrated were bayonet wounds. The chapters upon Amputations and Exsections are well illustrated by woodcuts, and are calculated to afford good practical information to the young military operator. Dr. Hamilton is no great advocate for the employment of anæsthetics, as may be concluded from the following summary of his views upon this subject:—"Anæsthetics are of inestimable value in their effects as remedial agents; in their power to extinguish sensibility temporarily, especially during the performance of certain painful Surgical operations; in the control which they exercise over muscular action, thus facilitating the reduction of dislocations, and in very many other ways. Anæsthetics, however, produce certain effects upon the system which tend to prevent union by the first intention, and, consequently, they must be regarded as, indirectly, causes of suppuration, pyæmia, secondary hæmorrhage, erysipelas, and Hospital gangrene. Ether ought generally to be preferred to chloroform, as being less liable to destroy life immediately; but no anæsthetic ought to be employed when the system is greatly prostrated by disease or by the shock of a recent injury, or by the loss of blood, unless the patient exhibits an unconquerable dread of the operation or the operation is likely to prove exceedingly painful. It ought to be particularly borne in mind that by the loss of a large quantity of blood the action of absorption is greatly increased, and that consequently such patients come more rapidly under the influence of the anæsthetic. The above conclusions have been well considered and are carefully stated, and we respectfully ask that Surgeons will at least attach to our opinions sufficient importance to induce them to continue their clinical observations upon the subject. . . . We are compelled to say that our success in capital operations, especially in primary thigh amputations, has not been as good since we began to use these agents as it was before."—P. 621.

The chapter upon Hospital gangrene is written by Dr. F. H. Hamilton, jun., who expresses his opinion upon the superior value of bromine as a local application over all other methods of treatment. The following are his remarks upon the method of using it:—"1st. If the operation promises to be a painful and a tedious one, Dr. Goldsmith advises that the patient be rendered insensible by the use of an anæsthetic. This I consider of doubtful propriety, inasmuch as I regard the depressing influence of chloroform as a predisposing cause of the disease. 2nd. The wound having been carefully cleansed by thorough sponging with warm water and soap, should be freed from all dead and gangrenous tissue by means of a scalpel or scissors aided by the forceps. The healthy tissue should be denuded as far as possible. 3rd. The surface to be treated should now be thoroughly freed from moisture. This is most readily done with a swab of linen on the end of a probe, with which the surface is carefully dried. Do not omit to penetrate the pouches and recesses. 4th. If the pure bromine be used, a small glass pipette should be introduced into the bottle containing the liquid, and then, being carried to the surface to be cauterised, thoroughly applied to every part. Cavities may be reached by means of small portions of lint dipped in the bromine and then carried by means of an eyed probe or a pair of forceps into the desired portion. 5th. It is frequently beneficial to paint the surrounding tissues to the extent of an inch, perhaps, with a solution of bromine, using a drachm of the bromine in four ounces of water. 6th. Immediately after the application of the bromine an emollient poultice should be applied. This tends to allay any undue irritation, and favours the speedy evolution of the slough."—P. 577. He considers the permanganate of potash to be scarcely inferior as a local application.

We recommend our own young military Surgeons to study this book. They will find in it very much that they ought to know, and each topic discussed is treated fully, but without verbosity, and amply illustrated out of the experience of the author.

The Practical and Descriptive Anatomy of the Human Body. By Thomas Hawkesworth Ledwich, F.R.C.S.I., and Edward Ledwich, F.R.C.S.I., Lecturers on Human and Comparative Anatomy in the Original (now the Ledwich) School of Medicine, Peter-street, Dublin. Second Edition, Revised and Enlarged by Edward Ledwich, Surgeon to Mercer's Hospital, Dublin. Fannin and Co. 1864. Pp. 779.

This is a very good book, albeit to our mind it has some serious faults in arrangement which a systematic work ought not to have. But after all the best sort of book for the use of a student of anatomy is just such as will direct him in the prosecution of the study while working with his own hands upon the subject, telling him what to look for at each step of his dissections, and how to look for it, and assisting him to observe with his own senses; and such as will serve to refresh his memory thus stored at a time when the objects he has looked at and handled are not before him. Mr. Ledwich's book certainly is not one of this kind, but still such a work as this has its uses.

Curvatures of the Spine; their Causes, Pathology, and Treatment. By Bernard E. Brodhurst, F.R.C.S. Second Edition. London: Churchill and Sons. 1864. Pp. 93.

Mr. Brodhurst's book is one of the best upon this subject that can be put into the hands of the young Surgeon who, except at special Hospitals, has for the most part few opportunities of becoming practically acquainted with this branch of his Profession. Mr. Brodhurst writes lucidly and concisely, and his researches are illustrated by a number of excellent woodcuts. This edition has been entirely re-written. The first part of the book is occupied by an account of the Physiological Spinal Curves, after which the Pathological Curves are discussed, a section being devoted to the Anterior, Posterior, and Lateral forms of curvature separately.

GENERAL CORRESPONDENCE.

MR. SYME AND ACUPRESSURE.

Letter from Professor Simpson.

[To the Editor of the Medical Times and Gazette.]

Sir,—Considering Mr. Syme's well-known character, he is certainly the very last man in the whole Profession who ought to venture to complain to that Profession of any supposed "personal attack" upon him. But assuredly, when, singlehanded, I attempted to reply fairly and frankly to the various arguments against acupressure that had been adduced by him and other distinguished Surgeons, I earnestly tried to avoid all personal discourtesies, though I spoke out my opinions earnestly and strongly, as I was entitled to do. And I am sorry indeed that any one—even Mr. Syme—should take umbrage at the tone of my reply.

Even, however, had I answered Mr. Syme in a very different spirit, and forgot myself so far as to descend to the use of personal discourtesies, I would have done nothing more than imitate a very bad initial example in the matter set me by another—that other being Mr. Syme himself. In truth, when Mr. Syme complains, as he does in his last week's letter to you, of "personal attacks," the whole case is merely and purely a case of mistaken identity. For in May, 1860, a few months after acupressure was first suggested by me, Mr. Syme read a paper on aneurism—not to the Medico-Chirurgical Society of Edinburgh, of which he was then a member, and where he would have been answered, but to the Medico-Chirurgical Society of London—and in the discussion which followed, in answer to a set question by Dr. Thompson, he stated to a large meeting of the metropolitan members of our common Profession that the "individual" who had proposed acupressure did not know "the meaning of Surgical language;" that "this proposal (acupressure) was the merest nonsense," one of those tubs which are constantly thrown out to amuse the whale, more especially the female whale (a); and latterly he went so far as, in his public class, to compare

(a) See *Medical Times and Gazette* for May 5, 1860, p. 458, and the *Lancet* of same date, p. 446.

this "individual" and his proposed employment of acupressure to "a quack and his powders," etc. One who could thus discourse was surely not entitled to make any plaint regarding personal attacks, even had I demeaned myself so far as to retaliate with them.

In addition to the discourtesies which he was allowed to utter to the London Medico-Chirurgical Society, Mr. Syme, on the same occasion, adduced what he himself considered three objections to acupressure. In his letter to you of last week he states that this expression of his opinions and objections gave offence to me. It was, no doubt, intended to do so; but, in reality, these three "encyclical" objections of his appeared to me so very feeble and *effete* as not to be worth the trouble of answering at the time. But last year, when writing a reply to all the arguments urged in various quarters against acupressure, I replied to Mr. Syme's three objections amongst the rest,—not that I considered them of the slightest weight; but I believe my omitting to notice them would have been interpreted as more disrespectful than my exposing their utter weakness and strange irrelevancy.

The head and front of my offending seems to consist in my using the word "foolish" in a prefatory note to the reprinted "Answers to Various Objections" adduced by different Surgeons. Mr. Syme avers that I have characterised as "foolish" his "deliberate statements" and instructions with regard to the subject of acupressure. Now, assuredly I have done no such thing. I have not characterised his "deliberate statements" on acupressure as foolish, whatever my private opinion may be. I applied merely the term in question to one of his objections (his second) as being really and truly not an "objection," in any sense of that word, to acupressure at all, and as having logically no bearing on the subject whatever. This second "objection" against acupressure was that if the ligature were discarded, bleeding arteries might be stopped by torsion. Virtually it was no more an "*objection* against acupressure" than it was an objection against the Armstrong gun or the fortification of Woolwich. If we wished to avoid deligation, we might close the bleeding arteries by the application of a red-hot iron; but surely it would be held by every Medical man an absurd or "foolish objection" to acupressure to urge that hæmorrhage might be arrested by cauterisation. And, to my mind, equally and totally ridiculous or "foolish," as an "objection" against acupressure, is the possibility of arresting hæmorrhage by torsion.

But, as the unfortunate phrase has offended Mr. Syme, I regret that I used it, and I most willingly withdraw it, and permit him and my readers to substitute for it any other adjective which they think milder and more fit.

Mr. Syme further complains that I have held up his teaching as wanting knowledge and good faith. I am quite at a loss to know how he could possibly draw any such conclusions from any remarks of mine. In refuting Mr. Syme's arguments against acupressure, I had little or nothing to do but to cite the opinions which, on the points involved, Mr. Syme had published before the days of acupressure. Certainly the statements thus adduced and contrasted sometimes appear to contradict each other most painfully; but these contradictions of Mr. Syme were almost all made by Mr. Syme himself, and not by me. They were mostly confutations of Mr. Syme's Surgical opinions, not by me, but by Mr. Syme. I am not surely answerable for Mr. Syme now and again systematically confuting himself in regard to his Surgical opinions; and if he does not always agree with himself in his Surgical doctrines, surely I may disagree with them also. And I know of no reason why I may *not* differ on Surgical points from Mr. Syme, and why I may not freely express that difference, too. Nor am I without hopes that he may change his opinion on some Surgical points on which we at present utterly differ. I have always advocated ovariotomy. After virulently denouncing that operation for years, Mr. Syme latterly has given in his adhesion to its propriety. At first he opposed anæsthetics in Surgery—as strongly as he now opposes acupressure. Yet betimes he yielded on that question.

In his bitter opposition to acupressure, Mr. Syme objects to reasons solely from theory and hypothesis, and not from practice. He has not yet, I believe, in a single instance either himself used, or seen other Surgeons use, acupressure, and hence he is still entirely unacquainted with the subject practically. The Surgeons of the Hospitals of Aberdeen, Edinburgh, Glasgow, etc., who have employed acupressure are necessarily in a far better condition to pronounce judgment upon it; and their judgment as to its simplicity and efficiency would, I have reason to know, be totally the reverse of Mr. Syme's. I felt from the first that, considering Mr. Syme's advanced age and his temperament, there was little or no chance whatever of his ever adopting a practice so revolutionary as acupressure. But I hope that his non-adoption of it will not be considered by my Professional brethren any reason why I should cease to defend against him, and its other opponents, a practice which I conscientiously believe will, after a time, assuredly and beneficially supersede the ligature in most, if not in all, operations. Already in fifty months acupressure has spread more than the ligature did in fifty years. But Mr. Syme seems to argue that it ought to be rejected by him and other Surgeons because it was suggested by an obstetrician. He forgets that a busy, practical Accoucheur has as many operations to perform as some Hospital Surgeons. If there were any truth in such narrow reasoning, the accoucheurs should reject from their code of practice version of the child in arm presentations, because it was introduced by Ambrose Paré, the Surgeon who first suggested the ligature of arteries. Surgeons should resist on the same ground the employment of chloroform by their patients, because it was first introduced and applied in Surgery by an accoucheur. I am a Member of the College of Surgeons as well as Mr. Syme, and I believe I bespeak the general sentiments of my obstetric brethren (I know I speak my own) when I say that if Mr. Syme will invent (what we much lack) some new, better, and simpler method of suppressing puerperal hæmorrhages, we will adopt the practice without cavilling at the special quarter from which it comes. The healing art, it has been justly averred, is one and indivisible; and all the members of it are bound to try and strive for the advancement and amelioration of it alike as a science and an art in all its departments.

Lastly, Mr. Editor, allow me in all kindness to observe that I lament greatly, for Mr. Syme's own sake, that he persists in maintaining, in his letter to you, that in destroying my pamphlet publicly before his class—by tearing it into pieces with his fingers—he "gave it the only reply it deserved." I appeal on this point from the opinion of Mr. Syme to the opinion of every gentleman belonging to our common Profession whether or not this was a proper piece of ethical instruction on the part of any teacher of youth, and particularly on the part of one, as Mr. Syme is, of the twenty-four members of "The Council of Medical Education in the United Kingdom." If he offer any further remarks on acupressure in your columns, I hope he will preface them by first offering a due apology to the Medical Profession, and to his own Medical school in particular, for this indiscretion. I am, &c.

Edinburgh, March 14. J. Y. Simpson.

P.S.—A correspondent of yours, in your number for March 4, page 237, alludes to the painful fact that Dr. John Brown, the representative or assessor of the Lord Rector in the University Court, was present at Mr. Syme's lecture on the occasion on which he immolated my pamphlet; and he suggests that probably Dr. Brown was there without having the least idea beforehand of what was to occur. I am very sorry indeed to contradict this. At first I believed it impossible that he could have been present, or at least could have remained present. But when I asked him, in presence of some mutual Medical friends, he stated both that he *was* at the lecture and that he had gone to it knowing that my pamphlet was to be attacked. How much higher a position would have been taken by Dr. Brown if, instead of abetting Mr. Syme in his unacademic proceedings, he had, as Mr. Syme's chief friend and adviser, kindly and honestly counselled him against them.

SOUTH AMERICAN BEEF.

Letter from Dr. Ballard.

[To the Editor of the Medical Times and Gazette.]

Sir,—With the present high price of butchers' meat—so high that one wonders how a proper proportion of wholesome animal food can find its place in the diet of the poor—the recent importation of South American beef, about which much has been written in the daily papers and in our periodicals, is of sufficient importance to render Medical men careful how they discourage its use on the one hand, or lend themselves to puffing it on the other. The few lines which you devoted to the subject last week induces me to believe that you will not be unwilling to find room for some practical observations upon the subject.

The South American beef appears in the shops in two forms —in the one it is dry, in large hide-like pieces; in the other it is moist and compressed. The first sample of the moist compressed meat that I saw was brought to me by Mr. Bradley, the Surgeon of the Pentonville Convict Prison, several weeks ago. As I saw it in bulk it was in the form of a large compressed block, made up of layers, fat and lean alternating in the section. The beef had been salted. After keeping for a few weeks exposed to the air the surface became rusty, and some of the beef, both the lean and fatty portion, dark and decomposed. When the sample was newly opened it had a strong *cheesy* odour, so strong as to be offensive at a considerable distance in a room. This meat had been sent to the prison from Liverpool. The offensive cheesy odour became more apparent during the process of cooking. The Governor of the prison informs me that the *loss* in cooking amounted to 50 per cent. In his experience the loss on boiling fresh meat for the prisoners' rations, including loss from bone, is about the same. But, then, much of this loss in the fresh meat consists of extractive matters, which are utilised by the liquor being converted into soup. In the case of the South American beef the quantity of salt drawn out in the cooking would have rendered the liquor valueless, even had no loss of extractive matters taken place in the process of salting. When it is considered that the price of the South American beef was 3d. per lb., while the contract price of fresh beef is 5½d., it will be seen that, had this meat been eatable, there would have been no saving effected by its use.

The next sample came under my notice in this way:—At the beginning of last week one of my sanitary inspectors informed me that some South American beef was on sale at an oil shop in my district, and that having inspected it he did not think it was fit for food, and asked me whether he ought to seize it. I told him to be careful, and that I would see it myself. Accordingly, I visited the shop with him, and found that at his recommendation the sale had been suspended, and all the meat put back. Both kinds of meat were in store. The dry, hide-like pieces were rusty on the surface, and had a very slight *tallowy* odour. The rustiness was similar to that seen upon a flitch of bacon. I cut out a piece of the fleshy part, and munched it, but as, with the exception of its being highly salted, there was nothing disagreeable in its flavour, I told the tradesman that I could not object to its sale. The moist beef was in the form of a large roll consisting of flattened strips, fat and lean alternating, the whole roll being tied round with string. Most of the thinner strips had a membranous layer on one side of them, as if they were portions of the abdominal parietes of the ox. This, too, was salt, and the roll possessed the *tallowy* odour more strongly developed than in the dry beef. I could not bring myself to apply the same test to this, and left the beef put back as I found it. Since then I have had some of it cooked in the form of an Irish stew, of which Mr. Bradley, another gentleman, a member of my vestry, and some of my own family, partook, as well as myself. No selection of pieces was made; it was cooked as fairly cut from the roll—fat, lean, and membrane all together. It was first soaked in cold water for twenty-four hours—this was the time I was recommended to soak it, but probably it was rather too long,—and the water was changed once. Two pounds, after soaking, weighed 2¾ lbs. It was now gently stewed for about 2½ hours, with onions, carrot, turnips, and potatoes. There was nothing at all repulsive in the odour of the mess when brought to table —indeed, it smelt very savoury. Two of my children, knowing what it was made of, declined it; another, however, ate his dinner from it, and reported that "it wasn't very bad." Mr. Bradley ate a plateful of it, and my other friend only a little bit of the lean meat. The latter remarked that what he ate had a slightly tallowy flavour, and would not eat any more. Mr. Bradley and myself, who ate the stew fairly, coincided in our verdict. The meat was coarse, but quite tender. It was wanting in meaty flavour, and some of it tasted tallowy. Some pieces had no tallowy flavour, and on discriminating further it was found that the less agreeable pieces were those to which portions of membrane or fat were attached. One piece that I had was so tallowy that I could scarcely swallow it. The general conclusion that I arrived at was that, putting the nutritious quality of the meat out of the question, the sample I used (which, I was assured by a director of the Company, was a fair sample of that which they supplied) was not unwholesome, and that although it may not exactly suit the fastidious appetite of such as get but little active bodily exercise, it may be very acceptable now and then as forming a cheap meal for a man who has become hungry from hard bodily labour. Probably the meat would have been more pleasant had all the membrane and fat been removed before cooking, but then fat is a very important dietetic element in meat. Of course I informed the tradesman from whose shop the sample came that I could not object to the continuance of the sale.

I have been informed by Mr. Richardson, a director of the South American Beef Company, that only one cargo has been imported, and he accounted to me for the manifestly unwholesome character of the first sample I saw by stating that some damaged dry beef had got into the market, and had been manipulated prior to being offered for sale, the salt having been removed and treacle having been used subsequently in preparing it; but that the Company had nothing to do with this. It is to be hoped that future importations will be of an altogether better quality. I have myself no doubt that, were a more careful method of preservation adopted, there is here a promising field for the employment of British capital.

I am, &c.

Edward Ballard,
Medical Officer of Health for Islington.

Islington, March 11.

"OUGHT BUBO TO BE RESOLVED?"

[To the Editor of the Medical Times and Gazette.]

Sir,—Your correspondent, Gwynne Harries, M.B., London, in your number of the 11th inst., seems very sanguine of the ultimate success of his views on the treatment of bubo when he so confidently asks "Twenty years hence shall we find a man who bedaubs an advancing bubo with iodine?"

With your permission I will make a few observations on the subject. In the second paragraph of his letter he says "It is not now necessary to determine whether there are two distinct lesions coupled under the name of chancre." Now this is a point long since determined, and on which is based the present treatment of the affection in question. He also appears to be of opinion that the presence or absence of bubo determines the nature of the sore. On this I cannot agree with him, and I would consider it very bad Surgery to wait for the appearance of the groin complication to determine one's treatment of the primary sore: in some instances you might wait for an unlimited period, for how often do we see a soft chancre heal without any bubo and followed by no secondary affections?

It is not my intention here to enter into the much vexed question of syphilisation, which has of late so much occupied the Profession at home and abroad.

The present universally received doctrine on syphilis teaches that there are two distinct varieties of local sore or chancre, *hard* and *soft*. This, if my memory serves me right, is M. Ricord's division.

The hard or Hunterian or true infecting sore is most usually single. In its treatment mercury is generally considered necessary; by some indispensable. It is followed by an indurated condition of the glands in the groin, which show no tendency to suppurate, and attended by the usual train of secondary and tertiary complications, as scaly eruption, excavated ulcer of tonsil, periostitis, nodes, etc. A person labouring under this form is not exempt from contracting the next.

The soft or non-infecting chancre is generally multiple. Although an alterative course of pil. hyd. is usually administered, mercury is not necessary in the treatment of this form, and should not on any account be given if the sore show a tendency to slough. This has greater proximate dangers than the hard—viz., plurality, tendency to slough, and consequently hæmorrhage and bubo. The dangers of the hard are remote, and it is unnecessary to specify them. I consider the soft chancre to be a local sore without a tendency to constitutional taint, the groin affections being the result of the irritation of the sore which has a tendency to multiply and spread, not being limited by a hard base as the infecting chancre is.

In cancer of the penis we have an indurated condition of the glands in the groin similar to that produced by the hard chancre; now, if the soft has a tendency to implicate the constitution, why does it not follow the same course as the hard chancre and cancer, which are, undoubtedly, constitutional affections, and like them give rise to induration instead of suppuration?

Again, granting for a moment Mr. Harries' hypothesis to be correct, would our experience in the two modes of treatment warrant us in adopting his views? I hold it would not—*e.g.*, take a case of ordinary sympathetic bubo: if we succeed in "putting it back" by the usual means the patient is all right in a short time, but if, on the contrary, our endeavours do not succeed, he is often brought to the brink of the grave and takes months to recover. I have seen strong men so reduced by a suppurating bubo as to be unable to rise from their bed without assistance. I hold the same to be the case with a bubo following a soft chancre, and I think no man in his senses should, for a moment, hesitate between the very doubtful possibility of a slight constitutional taint, and the frightful debility and disturbance produced by a sloughing bubo.

Take a case in point: a person of tubercular tendency contracts a soft chancre, and in the course of time tenderness in the groin is developed. Now, if this is treated in the usual way and "put back," the chancre has no accelerating effect on that tendency; but if it be treated on Mr. Harries' plan the chances are three to one the patient dies of rapid consumption.

I think I have now said sufficient at least to show Mr. Harries the necessity of pausing well before broaching such dangerous doctrines.

I wish it to be understood that these observations are made not for the purpose of inviting a newspaper discussion, nor yet with a wish to cram my opinions down other people's throats, but, in the spirit of good fellowship, to deprecate the publication of a theory which, if acted on by the inexperienced, might be fraught with such dangerous results. Apologising for trespassing so far on your space, I am, &c.

Dublin, February 19. A Dublin Surgeon.

THE WINCHESTER CASE.

Letter from Dr. A. Fergushill-Crawford.

[To the Editor of the Medical Times and Gazette.]

Sir,—You will see that your article of February 11th, entitled "The Good Samaritan at Winchester," has been partly the means of provoking a correspondence respecting "the case of Sarah Pearce, the navvy's wife," which has been published in the Hants county newspaper, and of which I send you a copy.

The chairman of the County Hospital, whose letter does honour to his candour and goodness of heart, admits that "there was a great and melancholy failure of the objects for which the Hospital exists when the poor dying woman was dismissed from its ward." At the same time he declares that "he had not the smallest suspicion that she was in a dangerous condition." And no one can doubt from the tone of his letter that this declaration may be implicitly relied on. Nor will any one possessed of charitable feelings refuse to listen to his appeal when he says, "I cannot acknowledge, indeed I feel sure that no one who knows me could suppose that I intentionally exercised any cruel or harsh authority in acting as—on the spur, and in the hurry of the moment—I did."

I myself, after a connection with the Hospital for nearly fifty years as Physician or governor, can bear witness that during that long period there has never been a chairman who displayed more deep felt interest in all the duties of his office; more particularly in studying to promote the comforts and welfare of the patients.

If the writer of your sarcastic article wishes to know how the rev. chairman performs his sacred functions as a pastor of the church, he must not repair to "the Cathedral of Winchester," with which he has no connection; but if he will seek out a small retired village a few miles distant, and inquire of his parishioners, he will find that he is an exemplary and faithful minister, with a benefice of £300 a-year, and that among the poor and afflicted in his parish he is really and indeed "the Good Samaritan."

I am, &c. A. Fergushill-Crawford, M.D.

Winchester, March 11.

Medical Charities.—Miss Elizabeth Hervey, late of Park-street, Grosvenor-square, has just bequeathed to St. George's and King's College Hospitals and the Cripples' Home £250 each, and moreover, directs that these legacies be paid free of duty.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

Tuesday, March 7.

Dr. Peacock, President.

A report was read on Mr. Mason's case of

DISEASE OF THE PROSTATE.

The reporters, Mr. Henry Thompson and Mr. Mason, believed the disease was the result of chronic inflammation, and that it was not scirrhus. From the naked eye appearances it had been at first considered to be cancer both by Mr. Mason and Dr. George Johnson.

Dr. Semple exhibited on the living subject

A RARE FORM OF SKIN DISEASE, KELOID OR MOLLUSCUM.

The patient was a child, 2½ years old, who presented over the left eyebrow, between the eyebrow and the eyelid, a hard, round tumour of the size of a large pea, of a red colour, and discharging a small quantity of sero-purulent fluid at its summit. This tumour had existed for six months. On the chest, on the left side of the sternum, near the clavicle, was a hard tumour of the size of a small pea, and of the same colour as the skin; this tumour had existed two years—indeed, since the child was six months old. On the forehead there were two or three other hard tumours, of about the size of a millet seed, not painful to the touch. These tumours appeared to correspond in many respects to the keloid or cancroid tumours described by Alibert, although his description was so vague that it was difficult to give an exact definition of what was meant by authors in writing of keloid tumours, for some represented them as projecting, globular, or oval masses, while others regarded them as resembling the scars of a burn. If the tumours were not keloid in the child now produced for inspection, they belonged to the equally rare disease, molluscum.

Dr. Hare showed a specimen of

ULCER OF THE STOMACH.

The patient, a woman 76 years of age, had had no stomach symptoms until a few weeks before her death. She then began to suffer from pain after food. She was admitted for copious hæmatemesis, which had ceased when she came in. It recurred the same day, and she died by syncope. As had been diagnosed during life, an ulcer was found at the lesser curvature of the stomach. Its base was formed by the pancreas, and the hæmorrhage was from a perforation of the splenic artery.

Dr. Hare also showed a specimen of

PERFORATION OF THE SEPTUM VENTRICULORUM.

The perforation was not complete, as the lining membrane of the right ventricle was intact. It was at the base of the heart.

The President asked whether Dr. Hare regarded the specimen as one of malformation or of disease. When in Vienna during last autumn Rokitansky had shown to him (the President) three somewhat similar specimens, and appeared to regard them as due to changes in after life.

Dr. Hare said that, as the heart was healthy in every other respect, the defect was probably a malformation, and not due to disease.

Dr. Julius Pollock showed a specimen of

RUPTURE OF THE CHORDÆ TENDINEÆ OF THE MITRAL VALVE.

The patient, a woman 42 years of age, was under the care of Dr. Johnson in King's College Hospital. She had had rheumatic fever when 16 years old, and again when 37. Eleven weeks before her death she was suddenly seized with darting pain in the chest, palpitation, and dyspnœa. When admitted she still had dyspnœa and hæmoptysis, and the latter was aggravated by coughing. It was difficult to make out whether there was a bruit or not, but Dr. Johnson diagnosed that there had been rupture of the chordæ tendineæ. One of the chordæ tendineæ was found at the autopsy floating loose, and its free end was tipped with a fibrinous mass.

Dr. Bagshawe showed the

URINARY ORGANS FROM A MAN WHO HAD SUFFERED FROM SUPPRESSION OF URINE FOR TEN DAYS.

The left kidney was found to be occupied by large cysts, the true structure was quite destroyed, and the ureter was im-

pervious. The right kidney weighed seven ounces, and was little affected by disease; the orifice of the ureter into the bladder was occupied by a blood-stained plug. The ureter was but little dilated. In the first four days there were no symptoms, and there was no desire to micturate until the eighth day. Tensive uneasiness in the right lumbar region, a cold skin, and other indications of collapse, with great restlessness, increased during the last two days of his life. There was no coma throughout.

Dr. Leared showed a

GALLSTONE.

A lady consulted him for attacks of severe excruciating pain, to which she had been subject twelve years. Dr. Leared diagnosed gallstone. Two years afterwards she passed one. Dr. Watson had remarked how very rare it was to find gallstones when looked for, and in this sense the case was a rare one.

Dr. Hillier showed a

PORTRAIT OF A PATIENT THE SUBJECT OF TRUE LEPROSY—(ELEPHANTIASIS GRÆCORUM).

The patient was a man, 58 years of age, a native of Ireland. He had been an engineer in India, and had drank freely. He had a chancre, and had been salivated for it, but had never had any secondary symptoms. Face, arms, and legs were affected; his voice was hoarse, and in parts there was considerable loss of sensation. He died of typhoid fever. The autopsy was made in Dr. Hillier's absence, and, unfortunately the nerves and spinal cord were not examined.

Mr. J. Z. Laurence referred to a case which had been shown to him by Schrœder van der Kolk. There was considerable anæsthesia, and the patient had lost several toes.

Mr. Balmanno Squire showed the

PHOTOGRAPH OF A PATIENT THE SUBJECT OF COMPLETE ALOPŒCIA.

Except on the eyelids, there were no hairs on the body. It had begun by bald patches on the head, which next extended to the whiskers, and thence over the whole body. Iodine applications had been used with no benefit. In a case somewhat similar, the iodine had arrested the progress of alopœcia.

Dr. Fuller showed a specimen of

ANEURISM OF THE BASILAR ARTERY.

The patient had had a blow on the head in the Crimea, and ever after had been subject to fits of excitement on taking stimulants. He had, however, been only actually ill for five days before his death. He first had an attack of diarrhœa, and then an attack of convulsions. He got apparently well again, but the day before his death he had a second attack of convulsions, and was unconscious, but not apparently paralysed. At the autopsy blood effused from a ruptured basilar aneurism was found at the base of the brain and also in the spinal canal.

Dr. Murchison related a case in which, after epileptic attacks for some time, death resulted from rupture of an aneurism of the middle cerebral artery.

Dr. Buchanan showed specimens illustrating

CHANGES IN MUSCLES IN TYPHOID FEVER.

It had been pointed out by Zenker that there was a peculiar kind of degeneration of muscular fibre in typhoid fever, and these changes were not found in typhus. Dr. Buchanan showed the microscopic appearances. There was fatty degeneration within the sarcolemma, and, in some specimens, a waxy degeneration.

Dr. Wilks showed a specimen of

ULCERATION OF TRACHEA, PROBABLY SYPHILITIC, OPENING INTO THE AORTA.

The patient had suffered for a long time with great difficulty of breathing, as if there was some pressure on the trachea. On examination of the chest and the larynx no disease could be discovered. The man died rather suddenly, after bringing up some blood. It was then thought that he must have had an aneurism of the aorta. The post-mortem examination showed that the whole of the trachea was much diminished in size, from a chronic ulceration, thickening, and contraction, which had involved the mucous membrane and submucous tissues. In some parts there were dense fibrous cicatrices. The appearance exactly corresponded with what is seen in syphilitic disease of the larynx, and the patient was said to have had syphilis. A small perforation had taken place just above the bifurcation direct into the aorta.

MEDICAL NEWS.

Apothecaries' Hall. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, March 9, 1865:—

Henry Maturin, Lymington, Hants; Edward Wood Forster 5, Victoria-terrace, Newcastle.

The following gentleman, also on the same day, passed his first Examination:—

Thomas Howard Brocklehurst, Manchester School of Medicine.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Brougham, J. P., M.D., has been appointed a Fellow of the University of Calcutta by the Governor-General of India in Council.

Bruce, H. A., M.D., has been appointed a Fellow of the University of Calcutta by the Governor-General of India in Council.

Davidson, Samuel, M.D. Aberd., has been appointed to the Commission of the Peace for the County of Aberdeen.

Gavin, William A., M.R.C.S. Eng., has been appointed to the Commission of the Peace for the County of Aberdeen.

Gunn, R., M.D., has been appointed House-Surgeon to Gray's Hospital, Elgin.

Kehoe, T. B., L.R.C.P. Edin., has been appointed Assistant Resident Medical Officer to the Cork Fever Hospital.

Lochhead, James L., M.D. Glasg., has been appointed Surgeon to the Greenock Gaol.

Reid, James, L.R.C.S. Edin., has been appointed to the Commission of the Peace for the County of Aberdeen.

Smith, W. F., M.B., has been elected Physician to the Public Hospital and Dispensary, Sheffield.

Wallace, Jas., M.D., has been appointed Admiralty Surgeon for Greenock.

Wilson, James, M.D. Aberd., has been appointed to the Commission of the Peace for the County of Aberdeen.

Woodman, Samuel, L.R.C.P. Lond., has been appointed Resident Medica Officer to St. Mary's Hospital.

DEATHS.

Blegborough, Hy., M.D. Edin., at Richmond, Yorkshire, on February 26.

Holland, George Calvert, M.D. Edin., at Sheffield, on March 7, aged 64.

Ladbury, John E., M.R.C.S. Eng., at Kidlington, Oxon, on March 9, aged 64, formerly of Upper Fitzroy-street, W.

Lynn, C., M.D., at Westgate, Newcastle-upon-Tyne, on March 1.

Plimmer, George, L.R.C.P. Edin., at Melksham, Wiltshire, on March 1, aged 63.

Smith, Chas., C.M. Glasg., of Newton Stewart, Wigtonshire, on February 28.

Turner, Thomas, M.D. Cantab., at 81, Curzon-street, Mayfair, W., on March 10, aged 93.

White, Richard, L.R.C.S.I., Assistant-Surgeon 23rd Regiment, at Delhi, India, on January 6.

Sir Rutherford Alcock, F.R.C.S.—This distinguished member of our Profession, who holds the appointment of Her Majesty's minister at Japan, has just returned with his family to England.

Royal College of Surgeons.—At the last meeting of the Council, Mr. F. Carpenter Skey, F.R.S., late President of the College, and Mr. Samuel Cartwright were elected members of the Dental Board, the term of office having expired of Messrs. Lawrence and Rogers. The Board now consists of Messrs. South, Arnott, Skey, Bell, Tonies, and Cartwright. The number of persons who have received the certificate of qualification in Dental Surgery from this College now amount to 280.

Apothecaries' Hall.—Dr. W. P. Brodribb has been appointed Secretary to the Court of Examiners of the Apothecaries' Society, an office vacant by the resignation of Mr. Alfred Randall.

The Margaret-street Infirmary for Consumption.—A legacy of £200, free from duty, has been bequeathed to this institution by the late Miss Brodie, of 7, York-place, Portman-square.

At a meeting of the Glasgow Medico-Chirurgical Society, held in the Faculty Hall, on Tuesday, March 14, the following gentlemen were elected office-bearers for the present year:—*President*—Dr. Ritchie. *Vice-Presidents*—Dr. S. Orr, Dr. Robert Paterson. *Council*—Dr. J. G. Wilson, Dr. Prichard Partick, Dr. Maclaren, Dr. Naismyth, Hamilton, Dr. W. T. Gairdner, Dr. Yeaman. *Secretaries*—Dr. Adams, Dr, Macleod. *Treasurer*—Dr. Coats.

The Hunterian Museum.—Some valuable additions have recently been made to the above collection, in the articulated skeletons of an adult and a young female gorilla, and an adult male and young chimpanzee. The collection of mounted skeletons of the great anthropoid apes in the College museum is now one of the richest in Europe. The new cases for the better display of the osteological series are now being fixed, and when completed will form one of the most striking features in the museum. The suggestion made by Mr. Flower (the worthy successor of Clift, Owen, and Quekett) was at once adopted by the Council, regardless of the great expense of these cases.

Poisoning by Arnica and Opium.—An inquest was held at the Swan Hotel, Alton, on Tuesday last, before Mr. J. R. Trodd, County Coroner for Hants, on the body of Mr. William Madgwick. The deceased, who it appears was suffering from a slight attack of chronic rheumatism, retired to rest about 10 o'clock on the evening of Saturday, the 11th inst., previous to which he procured an arnica liniment, composed of four drachms of arnica, two drachms of tincture of opium and compound tincture of camphor, to apply externally to the part affected by the rheumatism. This liniment he had been in the habit of using in a similar manner when suffering from rheumatism for the last six years. He also procured a pill and black draught, and on retiring he took the pill and intended to have taken the draught on the following morning. Both the draught and liniment were placed on a dressing-table in his bedroom in two small phials, which, although received from different chemists, were of the same size and shape, and the contents of both nearly of the same colour. About 6 o'clock on the following (Sunday) morning an attendant, who slept in the next room to the deceased, had her attention called to him by his knocking as if in need of assistance. She went to him, and on entering his room found him sitting, partly dressed, by the side of his bed, and he informed her that he had swallowed the liniment by mistake, instead of the black draught, and that on discovering what he had done he had afterwards taken the draught. She instantly informed the housekeeper what had happened, and Dr. Leslie was immediately sent for, who promptly attended, and found the deceased suffering from constriction of the throat, and experiencing great difficulty in breathing. The most energetic measures were immediately taken by Dr. Leslie to allay the effects of the poison; emetics were administered, the stomach pump was applied, and the whole contents of the stomach removed, but the efforts were unsuccessful, the active principles of the arnica having been rapidly absorbed, causing spasm of the glottis, and death from asphyxia. The jury returned a verdict of "Accidental death," and recommended that, for the preservation of human life, there should be a special enactment or a general rule to provide that all chemists should on issuing any poisonous liquid use a bottle of a different shape to that containing harmless drugs.

The Lochend Scandal.—The Free Church Presbytery of Inverness, at a meeting on Tuesday last, took up and disposed of the too-famous Lochend case. Four male heads of families made explanations. The substance of those statements was that in the examination of the women at Lochend nothing more indelicate took place than in the case of wet nurses when applicants for situations; that the practice was not unusual in the surrounding districts when any special or extraordinary circumstances called for it; that personally the minister had nothing to do with the examination, and never interfered with it; that the parents of the women examined sent for the Doctor without the knowledge of Mr. Macpherson; and that they considered the church and vestry as their own property, and that they could use these for the purpose required; but, if they had erred, they craved the Presbytery to attribute it to ignorance. Mr. Macpherson, the minister, "expressed his regret for having committed an error of judgment," and, in reply to a question, said he had mentioned in the pulpit that the impression was current that the mother of the child found dead had come from some other place than Lochend, because of the good character of the district, and that he understood that the parents had sent for a Doctor to examine the women of Lochend. The Presbytery declared Mr. Macpherson "liable to censure" for "having given countenance to a proceeding fitted to wound and shock every feeling of propriety;" and also expressed "the astonishment and serious regret of the Court" that, even through ignorance, the people of Lochend should have promoted and published such a transaction.—*Scotsman*.

Odontological Society.—At the monthly meeting of this Society held on the 6th inst., Thos. Rogers, Esq., President, in the chair, a letter was read from Dr. Weber, of Paris, accompanying some specimens of vulcanite and enamel, which were distributed among the members. Mr. T. Bate produced two specimens (teeth) found in a Roman cemetery during the excavations at Plymouth—the one showing, he said, that the ancients two thousand years ago were liable to suffer from toothache caused by decay; the other showing that in the development of teeth at that time the same laws seemed to hold good as were occasionally found now—namely, that the premolar was retained after the other teeth were developed. He regarded them as objects of antiquarian interest rather than physiological. Mr. Ramsay brought the patient he had introduced at the previous meeting, in order that the Society might judge of the progress of the case—one of cleft palate. He said the boy had practically worn the instrument only since the 18th inst.; but, notwithstanding his short practice, had much improved in his articulation. The boy read a few lines, and the President and others expressed their satisfaction at his progress. After a short discussion, Mr. Ramsay promised to read a paper explaining his method of treatment at the Society's meeting in May. The discussion of the papers read at the last meeting followed, in which Messrs. Cattlin, Tomes, Hulme, Vasey, Bate, Rymer, and Mummery took part. Mr. Bate mentioned a question put to him by Dr. Darwin whether any dentist had seen a third deciduous molar, and, if so, whether such a case was ever known to be hereditary. The President said he had seen three bicuspids on one side of the lower jaw; but he had no knowledge of the previous history. The thanks of the Society were accorded to the authors of the papers, and the meeting adjourned.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Inquirer.—You cannot do better than go to St. Mary's.

Dr. E. W. Sullivan.—We know of no such enactment.

C. B.—English watering places, with Hospitals or Infirmaries with beds:—Bath, Clifton, Buxton, Harrogate, Scarborough, Cheltenham, Leamington, Tunbridge Wells, Brighton, Southampton, Hastings, Dover, Bournemouth, Ryde, Isle of Wight, Torquay.

Corrigenda.—The Medical Editor of the forthcoming St. Bartholomew's Hospital Reports is Dr. G. N. Edwards, and not Dr. Andrews, as was stated in our number of March 4. In Dr. Ussher's letter on "a Midwifery Question" (*Medical Times and Gazette*, February 25), the name of Dr. Morris should be George Selwyn, not G. J.

The Norton Defence Fund.

Mr. Hugman wishes us to acknowledge the receipt of the following subscriptions:—T. H. Graham, Esq., 5s.; Oswald Foster, Esq., 10s.; Ed. Hall, Esq., 2s. 6d.; R. S. Francis, Esq., 5s.; Henry Lyell, Esq., 10s.; Dr. Gregeen, £1; J. Hargraves, Esq., 5s.; R. Elsdale, Esq., 5s.; Sine nomine, 2s. 6d.; From Lower Norwood, 5s.; James Stuart, Esq., 10s.; Dr. Ellis, 5s.; T. H. Fenn, Esq., 2s. 6d.; Messrs. Garlick and Cuff, £2 2s.; Dr. Rogers, £1 1s.; Dr. Essex Bowen, £2 2s.; J. Chapman, Esq., 10s.; Dr. Goss, 10s.; C. C. Balding, Esq., 5s.; Henry Boxall, Esq., 10s.; Dr. J. Evans, 5s.; W. Jarvis, Esq., £1 1s.; H. Fitt, Esq., £1 1s.; A. Percival, Esq., £1 1s.; — Hayward, Esq., £1 1s.; F. Gethen, Esq., £1 1s.; C. Hyde, Esq., £1 1s.; M. Rowell, Esq., 10s. 6d.; W. Wright, Esq., £1 1s.

Griffin Testimonial Fund.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—The following subscriptions have been further received on behalf of the above fund:—Dr. John Ewens, Blandford, 5s.; Dr. Barker, Bedford, 5s.; N. Godfrey, Esq., Turvey, per ditto, 5s.; Dr. Sprigge, Great Barford, per ditto, 5s.; J. F. Williams, Esq., Cranfield, 5s. Amount previously announced, £117 11s. Received at *Lancet* office, £7 17s. 6d.

I am, &c. Robert Fowler, M.D., Treasurer and Hon. Sec.

145, Bishopsgate-street Without, March 15.

Application of Tincture of Iodine to the Chest in Phthisis.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—In your notice of Dr. Latham's book on phthisis, I observe that this author objects to the application of tincture of iodine to the subclavian space in phthisis, on the ground that he has frequently seen it, when thus applied, produce absorption of the pectoralis muscle.

I never before saw this point noticed as an objection to the application of iodine over the muscle, and I cannot but think, with you, that the muscular waste is but an event in the progress of the disease. Nevertheless, the fact of such an effect of the iodine being even suggested as possible confirms me in a fancy that I have for applying tincture of iodine in and about the axilla of the side believed to be affected with tubercle, in preference to applying it over the thickness of the great pectoral muscle. I have thought that absorption is more rapid from the axilla, and I hold that the iodine exercises its beneficial action more by being absorbed than by acting as a counter-irritant.

I am, &c.

John C. Thorowgood, M.D., M.R.C.P. Lond.,
Assistant Physician City of London Hospital for Diseases of the Chest.

Finsbury-circus, March 11, 1865.

Government Life Insurance Fees.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Would you be kind enough to say what I should do in regard to accepting the office of Medical referee to the Government life insurance connected with the Post-office? You have most likely seen the circulars issued, proposing to pay the Medical man from 2s. 6d. to 5s., according as the amount insured is under or over £60. What is the general feeling of the Profession upon the subject? It has little lucrative advantage to recommend it: it may be a question whether we should not disregard personal considerations and assist Government in carrying out their project for the public good. I am, &c.

March 13. Village Surgeon.

There is nothing derogatory in taking a half-crown fee. Commissioners for taking affidavits do it over and over again.

Consanguineous Marriages.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Since A. R.'s letter, which appeared in your number of January 14, I see a paper has been read at the Academy of Medicine by M. Voisin (see *Medical Times and Gazette*, January 28, 1865), which confirms his opinion that these marriages are harmless. Now, it is very desirable that the popular notion (which, in spite of A. R.'s notion that cousins will marry if they have a mind to, has a considerable deterring effect) should, if false, be removed, and my apology for intruding on your space must be my desire to see the subject discussed in your columns in such a way as may quiet the scruples of those who want some authority for disregarding tradition, or show those scruples to be well founded. I am glad A. R. intends recurring to this subject. I am, &c.

March 13. X.

On the Production of an Inverted Image by a Convex Lens.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Immediately after the publication of my last letter on this subject, I received a note from Mr. J. Z. Laurence, declining to carry on the discussion any longer in your paper, on the ground that you would soon refuse to insert any more letters on the subject, but inviting me to come to his house to explain my views; to which I replied that it was very uncertain when I should be able to spare a day to come to town, and mentioning at the same time what seemed to me farther proofs of the truth of my position; since which I have not had the pleasure of hearing from him. I do not flatter myself that he has found my arguments unanswerable, as in that case he would doubtless have written to say so, so the probability is that he has thought no more about it, and I have long since regarded the matter as dead and buried; but as you have this week inserted a letter from Dr. Zehender, of Berne, reviving the subject, perhaps you will be kind enough to find space for a few words more from me, the more so as I think Dr. Zehender cannot have clearly understood my meaning, as he says that if what I assert be true, "all we know about optics is erroneous." What he means by this I cannot imagine, unless he has understood me to say that no image is formed in the air,—a thing I never said nor meant to say. That the image is formed there I know full well, and that it can be made visible by being received on smoke or dust, or any unpolished surface; but I deny that it can be seen, at least when formed by lenses of short focus, by the naked eye, because the eye can only focalise nearly parallel rays, and the rays, after crossing to form the image, are widely divergent. That it can be seen by the aid of another convex lens placed at its focal length from the image, as in Dr. Zehender's second experiment, is, of course, true enough, because by that means the rays are rendered parallel; the combination is, in fact, the simplest form of telescope, and Dr. Zehender will find the fact alluded to in my first letter. But with regard to the binocular experiment, I can assure Dr. Zehender that I have honestly tried my utmost to persuade myself that I could see the image at the focal point, and taken every means I could devise to cross my visual axes as he directs, but without the slightest success; and why he should think that I might succeed even better than himself when he can hit the place to within the twentieth of an inch, which seems to me as near perfection as possible if he was ignorant of the focal length of the lens he was using, I cannot imagine. I suppose I am not wrong in assuming that all the gentlemen who have honoured my communications with their notice admit as an established fact that the eye can only focalise nearly parallel rays, and if they do so, how do they account for its being able to focalise the very divergent beam that the rays from, say, a two-inch lens form after having crossed at the focal point? If they will explain this, and also how it is that a disk of one-eighth of an inch in diameter placed at the farther focal point of such a lens can blot out all the picture that appears on the lens, while it scarce affects the image thrown on the screen, and how it is that a strip of paper placed on the lens, or between it and the nearer focal point, can obliterate so much of the picture on the lens, but scarcely interfere with that on the screen, if they are one and the same; they will do more to convince me of my error than by any amount of instructions to teach me to see what I cannot see, and I will give up the question of the visibility of the image, and admit that it is my own stupidity which prevents my seeing it. Till they have done that I do not see that I can be reasonably expected to trust their eyes in preference to my own.

I do not admit the truth of the explanation of the disk experiment given by Mr. Laurence (the only person who has attempted to give one), viz., that it acts by stopping the central rays, because it would do that more effectually by being struck on the lens, and it is not only the central rays that are stopped, but all those which, falling on the lens, are capable of entering the eye, which is not the case if it is stuck on the lens; and, moreover, why should stopping the central rays have so much more effect on one image than the other, if they are both the same?

But how easily are all these difficulties explained if the two images are not the same. As the eye can only appreciate parallel rays, those which it receives from the lens must be parallel, and to be so after refraction through the lens, it is obvious they must emanate from the farther focal point; or, to reverse the matter, draw parallel rays from the eye to the lens, they will, after refraction, meet at the farther focus, cross there, and proceed to the points of the landscape represented on the lens; therefore a disk placed at that point will interrupt them, and an equally small aperture in a diaphragm allow them to pass.

Thus Dr. Zehender will see that I am not attempting to upset the whole theory of optics, but merely trying to show that the generally received explanation of a certain phenomenon is incompatible with a well-known fact, while a perfectly satisfactory one can be given consonant with all laws of optics.

I have endeavoured to make my meaning as distinct as possible at any sacrifice of elegance, as your correspondents do not seem to have clearly understood my former letters, and if I have now left anything indistinct, I can only say that I shall have great pleasure in forwarding them diagrams if they will favour me with a note, though I can hardly think them necessary. I am, &c.

Winchmore-hill, March 1. John Cresswell.

APPOINTMENTS FOR THE WEEK.

March 18. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

Royal Institution, 3 p.m. Prof. Marshall, "On the Nervous System."

20. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

Medical Society of London, 8½ p.m. R. Barwell, F.R.C.S., "On the Prevalent Mismanagement of Common Forms of Joint Disease." Dr. Brunton, "On the Treatment of Tapeworm by Male Fern and Kamala."

21. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

Ethnological Society of London, 8 p.m. Clements R. Markham, Esq., "On the Arctic Highlanders." Dr. Rae, "On the Esquimaux."

Pathological Society, 8 p.m. Meeting.

Royal Institution, 3 p.m. Prof. Masson, "On Recent British Philosophy."

22. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

Hunterian Society, 8 p.m. Dr. H. Davies, "On the Treatment of Acute Rheumatism by Free Blistering."

23. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Royal Institution, 3 p.m. Prof. Masson, "On Recent British Philosophy."

24. *Friday.*

Operations. Westminster Ophthalmic, 1½ p.m.

Royal Institution, 8 p.m. Prof. Westmacott, "How Works of Art should be Looked at."

ORIGINAL LECTURES.

LECTURES ON
CHEMICAL AND MECHANICAL DISEASES AND THEIR RELATIONSHIP.

By H. BENCE JONES, A.M., M.D., F.R.S.

Lecture IV.

DISEASES OF SUBOXIDATION.—ON ACID GRAVEL.

In this and in the following lecture on gout I intend more particularly to bring before you the mechanical and mechanico-chemical consequences of the acid diathesis—that is, of excess of acidity.

The relationship that exists between chemical disease and mechanical disease cannot be more clearly set forth than in the production of gravel or stone from errors in the chemistry of life.

I have dwelt only on chemical disease in the two first lectures on diabetes and acidity, and I have given you a particular instance of chemical error and of its mechanical consequence, or secondary disease, in the last lecture on the oxalic diathesis; I intend now to occupy your attention with the mechanical consequence of acidity in general; and I shall have occasion to show you that this secondary mechanical disease may produce tertiary chemical derangements vastly greater than the original primary chemical wrong out of which the secondary mechanical disease arose.

I have already explained to you the causes of acidity. I have now more particularly to dwell upon one of the results of that acidity; in short, on the nature of the gravel that is caused by excess of acidity, the means of detecting it, the symptoms it produces, its consequences or complications, and its treatment.

On the Nature of the Gravel that is caused by Over-acidity.

Generally speaking, it may be said that all the albuminous substances of vegetable or animal food, before they are thrown out of the body, pass through the stage of uric acid. A particle of albumen absorbed into the blood from the food may become part of an organ and serve the purposes of life, and then undergoing change become resolved into uric acid, then into urea and oxalic acid, and finally into urea, carbonic acid, and water; or the particle of albumen may go through a shorter circuit, and without becoming part of any organ or texture it may be transformed into uric acid, and ultimately pass off as urea, carbonic acid, and water.

Thus uric acid, like sugar, may come from two sources—first from the food, and secondly from the textures; and as sugar is one of the results of healthy chemical action, through which, generally speaking, every particle of starch must pass, so uric acid is one of the substances through which each particle of albumen in health passes before it is thrown out of the body. When more food is taken into the blood than is wanted for the muscles, nerves, and textures generally, the excess is thrown out in a more or less perfectly oxidised form by the kidneys, skin, and lungs; it may be as uric acid, or if further changed as urea, oxalic acid, and water; or if burnt, as far as possible, as urea, carbonic acid, and water; or different portions of the albumen may be thrown out in all these different states at the same time.

The excess of uric acid in the urine of those who have just taken an excess of albuminous food, whether animal or vegetable, is very easy of proof.

The quantity of uric acid in the urine I found to vary (see *Philosophical Transactions*, Part II., 1849, p. 235)—

	Grains.	Grains.	Sp. gr.
Before food (mixed diet)	from 0·048	per 1000 of urine	1026·3
	to 0·17	,,	1023·1
After food it varied	from 0·39	,,	1021·0
	to 0·92	,,	1031·1
On vegetable food—			
Before food . . .	0·049	,,	1024·0
After food . . .	0·636	,,	1026·2
On animal food—			
Before food . . .	0·049	,,	1024·8
After food . . .	0·77	,,	1029·9
After three days of animal food only the highest amount was	1·022	,,	1027·8
After three days of vegetable food only the highest amount was	1·010	,,	1025·6

The second source of uric acid is in the muscles, nerves, and other textures of the body. Wherever albuminous substances exist—that is, in each portion of the body—integration is continually balanced by disintegration, and one of the products of this disintegration of albumen is uric acid, which, returns into the blood and, more or less oxidised, passes off by the kidneys, and is found in the urine when no albuminous food at all has been taken for many days.

Derived from either source, uric acid exists in combination with alkalies dissolved in a more or less alkaline fluid in the blood. In the cells of the kidneys and elsewhere a process of oxidation occurs; other acids are produced, and the alkaline urates are made into more acid urates, which pass out of the kidneys to the amount of six to ten grains of uric acid daily dissolved in an acid fluid which is continually varying in acidity. Hence the composition of the urates in the urine is continually differing at different times.

In a paper in the *Journal of the Chemical Society* for 1862, vol. xv., p. 201, I have shown that in health potass, soda, and ammonia are all combined with uric acid in varying quantities, and these mixed urates constitute the ordinary granular amorphous deposit which is soluble in the warm urine. In three analyses I find—

	First Analysis.	Second Analysis.	Third Analysis.
Uric acid . .	94·36	91·06	92·11
Potassium . .	3·15	3·78	5·06
Ammonium .	1·36	3·36	1·61

These acid urates are sometimes combined with uric acid, forming still more acid urates, corresponding to quadoxalates, from which a portion of the uric acid is set free even by washing the amorphous sediment with water. If any acid acts on the acid urates they are decomposed, and uric acid is set free more or less quickly, according to the strength and temperature at which the acid acts. Thus, if in the cells of the kidney by oxidation mineral, vegetable, or fatty acids are produced, the urates are decomposed either in the tubes of the kidney, the pelvis of the kidney, the ureter, or in the bladder. Hence any acid whatever except the acid of extreme oxidation—carbonic acid—may give rise to uric acid gravel. Whatever the acid that may be taken in excess in the food, or whatever the acid that may be thrown on the kidney by inaction of the skin, or whatever the acid that may be produced in the stomach or in the kidney itself, if it decomposes the urates it may give rise to uric acid gravel. Acid phosphate of soda is not able to set free uric acid from the urates: free acid must be present; and hence free uric acid is the most delicate test of other free acids in the urine.

On the Means of Detecting the Acid Gravel.

In contradistinction to white or phosphatic gravel, and to black or oxalic gravel, this may be called red or uric gravel; but colour, though striking, is apt to mislead. Pure uric acid is as perfectly white as phosphate or oxalate of lime, and, though uric acid attracts to itself the colouring matter of the urine, and so becomes reddish-yellow, yet there may be next to no colour to attract, and so the gravel may remain white, and then chemical reactions or microscopical appearances can alone determine the nature of the deposit.

The chemical test for uric acid is very characteristic. The smallest portion of sand or gravel heated with nitric acid at a gentle heat is immediately oxidised. Among the products is murexan, which gives, with ammonia, the richest purple murexid, and by this reaction uric acid may be always known. Thus, however, you cannot determine whether the uric acid is free or in combination. Chemically this may be partially determined by fully oxidising the sand or gravel: if, on combustion, an ash remains, the uric acid is combined with some fixed base; but ammonia is volatile, and thus the surest method of determining whether the uric acid is combined or free is to observe the deposit as it passes in the urine with the microscope. Moreover, thus a single crystal of uric acid can be recognised; a quantity much too small to be tested chemically can be determined microscopically with certainty. Of course, errors of observation may arise, but the practised eye will learn to recognise the various forms of uric acid crystals, and possibly the peculiarity of form may lead to a knowledge either of the acid which set the uric acid free or of the composition of the fluid in which the uric acid was set free.

Having determined that free uric acid is present, it is of importance to know how soon the crystals form after the urine is secreted by the kidney—whether they form in or out of the body. For this the urine should be passed into a bottle or

glass and examined immediately, and if no crystals are then seen every few hours a fresh examination should be made; and thus the amount of acid which is acting on the urates may be estimated and counteracted.

On the Symptoms Produced by Gravel.

When the red sand only forms after the urine is passed, it causes no symptoms whatever; but the acid or acids in the urine, which after a time liberate the uric acid, these may produce irritability of the bladder or of the urethra. Over acid urine sometimes causes excessive frequency and urgency of making water. The mucous membrane may be made so irritable that inflammation and all the symptoms and appearances of violent gonorrhœa may be produced; or the muscular texture of the urethra may be irritated, and spasm ending in spasmodic stricture may occur.

These chemical irritations do not, strictly speaking, proceed from the red sand; they come from the cause of the red sand; but they are necessary accompaniments of the mechanical irritations which the gravel occasions; and these we have now to consider.

As the gravel may form in the bladder, the ureter, or the kidney, so the mechanical irritations may begin in these different positions, and the symptoms will vary according to the part that is irritated.

We will take the mechanical symptoms produced in the kidney first, although the formation of gravel in the kidney is a sign of the greatest degree of acidity, because the urine only remains a few seconds in the kidney, whilst it may remain some hours in the bladder. The acid in the kidney must be much stronger, in order to set free the uric acid, than it need be in the bladder to produce the same effect, because less power in longer time produces the same result as a greater degree of acidity in a shorter time.

As long as the gravel is small, and lies unmoved in the pelvis of the kidney, no symptoms occur. During rest no microscopical or chemical signs or general symptoms show the presence of a foreign body in the kidney; but if sufficiently rough motion is made, then the gravel moves in the kidney, and, slightly scratching the surface, blood is mixed with the urine. The injury to the pelvis of the kidney may be far short of causing pain or visible blood; there may be so little that chemical tests for albumen may give no reaction of that substance; but yet the microscope may show distinctly a very few blood globules. These may come with motion and cease with rest. With much motion, much blood will come, and be visible in quantity in the urine; and this may occur without the least pain. So that I often ask my patient with hæmaturia from this cause whether he would know that anything was wrong if he were blind, and the answer is usually positively no.

Gradually as the gravel increases in size in the kidney, slighter motion brings blood, and pain, and uneasiness in the loin. Distension of the colon, with flatulence, when it presses on the kidney, causes considerable pain.

If the gravel does not pass into the ureter, very little pain arises until the increase of size leads to pressure on the kidney and absorption of structure. I have seen cases in which I have no doubt that calculi have been in the kidney for very many years. In proof of this I may mention, from among many others, the following cases of seventeen, twenty, and probably of fifty years' duration.

A needlewoman, aged 47, was admitted into St. George's having had occasional attacks of pain in the left side with blood in the urine for seventeen years. On deep pressure in front, below the left hypochondriac region, a hard oval tumour could be distinctly felt. The urine was acid; specific gravity 1015; contained blood and pus cells, plenty of vibrios, but no crystals of uric acid nor oxalate of lime.

A clergyman, aged 41, consulted me for the appearance of blood in the urine, which he had seen for twenty years. The urine was thick from urates, acid to test paper, and contained a few blood globules. He had been obliged to give up hunting because it brought on the blood in the water. I saw him occasionally for some years, and always with the same appearances in the urine.

An officer, aged 61, told me that for twenty-four years he had been subject to attacks of pain in the left lumbar region, with blood in the urine. Warm bath and rest always gave relief to the pain and stopped the blood. He had had innumerable renal attacks, without passing any stone, but was able to travel each year on the Continent without much inconvenience.

A carpenter, aged 61, consulted me for a continual pain in the left kidney. Sometimes a dead heavy pain, at other times most acute during work or when walking. He is then obliged to throw himself down on his back and side until the pain passes off. If detained even for a few minutes after his usual meal times the pain is often most acute. Any excitement will "either increase or subdue it." I found that the urine had the slightest trace of albumen and most distinct evidence of blood globules. There was no pus, no increase of mucus, and no crystals of any kind. The urine was acid. He said that when eleven years old the pain first came on very suddenly with blood in the urine. The pain had never since entirely left him, and the blood has very frequently been in the water. Latterly the pain had become more constant and more severe. For fifty years through an active life this man had probably had a stone in the kidney.

The symptoms produced by gravel in the ureter are much more severe than those produced by gravel in the kidney. The instant the gravel or stone produces mechanical pressure violent pain comes on. The funnel form of the commencement of the ureter allows the gravel easily to escape a short distance from the kidney; and hence after some sudden jerk or even a turn in bed the pain begins suddenly and is referred to the kidney itself. Through nervous sympathy, vomiting soon follows, according to the size of the gravel or stone and the size of the ureter. The narrow passage is more or less quickly passed, and with a slight obstruction at the still less elastic entrance into the bladder the mechanical impediment is over, and the symptoms cease.

The symptoms produced by gravel or small stone in the bladder correspond with those produced in the kidney. At first there are no symptoms at all; violent exercise may produce microscopic appearance of blood, but until the gravel tries to escape, or is thrown by contraction of the muscular texture on the neck of the bladder no pain is felt. Gradually as the stone increases, or the bladder becomes irritated and wants to contract frequently, blood becomes visible, and pain on motion and on emptying the water becomes severe. This pain is referred to the extremity of the nerves at the end of the penis. The flow of urine is momentarily broken by the gravel or stone stopping the passage. If the stone is small enough or the urethra large enough the foreign body escapes into the tube, and in a longer or shorter time it is driven out.

Although gravel may stop in the urethra and gradually increase there until mechanically removed, yet it is very unlikely that it should begin to form there. If the crystallisation commenced there the passing urine would rapidly wash the crystals away before they caused any symptoms; so that the urethra does not suffer primarily from wrong chemistry. But the peripheral pain of the glans penis, and the scalding of the urethra from the acid urine, and the mechanical injury which the sharp fragments of acid stones occasionally produce in the urethra after lithotrity; these all show that even the penis does suffer from mechanical secondary disorders arising from primary chemical complaints.

(To be continued.)

ORIGINAL COMMUNICATIONS.

SIX CASES OF OVARIOTOMY IN PRIVATE PRACTICE.

By T. SPENCER WELLS, F.R.C.S.,
Surgeon to Her Majesty's Household and to the Samaritan Hospital.

Between the end of November, 1864—the date to which the cases of ovariotomy are brought up in the first volume of my work on Diseases of the Ovaries—and the end of January, 1865, I have completed this operation nine times. Three of the cases were in Hospital. One of them proved successful; two patients died. The particulars will, I understand, appear among the "Hospital Reports." The six private patients all recovered; and the cases appear to be of sufficient interest to warrant the publication of the following notes:—

Case 1.—In November, 1864, I received a note from my friend Mr. Lawrence, a naval Surgeon, asking me to see a Peruvian lady who had come from South America for the purpose of having ovariotomy performed. She was 33 years of age, married, but childless: she had had one three months' abortion. Since her arrival in England she had been under the care of Mr. Savory, of Stoke Newington, with whom I

first saw her in consultation, and found her looking older than she really was, with a sallow complexion, and thin, but not excessively so. The temperature of the surface of the body was normal, although she complained of the coldness of the climate. There was no œdema of the extremities. The general health was very good; the lungs and heart healthy; the pulse 90; the urine normal. The girth at the umbilical level was 37 inches; the distance from the umbilicus to the ensiform cartilage, 8½ inches; to the pubic symphysis, 8½ inches; to the right ilium, 9½ inches; to the left ilium, 9 inches. The abdomen was occupied with an irregular tumour, which reached up as high as the epigastrium, but did not occupy either hypochondrium. In some places the tumour felt solid; in others it evidently contained fluid. The abdominal parietes were tense; there were no lineæ albicantes nor dilated veins. There was no tenderness on pressure, except at one spot just above the umbilicus. The catamenia first appeared at the age of 16, and had always been scanty. They were next expected about the 27th of November. There was no leucorrhœa. The uterus was slightly pushed over to the left side: it was freely moveable. The cervix and os were normal; the tumour could not be felt from the vagina. On inquiring into the history, I could trace no hereditary weakness. The patient resided at Calloa, in South America (a sea coast town). She had first observed a swelling on the left side about three years before coming to Europe. At this time she had a feeling of weight and oppression. Two years later she appeared to have had an attack of peritonitis. My diagnosis was "multilocular ovarian cyst, left side, no adhesions, pelvis free." We prescribed some steel and arranged to operate soon after the next menstrual period. On the 7th of December the menstrual flow ceased; and on the 13th I performed ovariotomy with the assistance of Dr. Wilson, of Glasgow, Mr. Toulmin, of Hackney, Dr. Ritchie, and Mr. Savory. Dr. Parson gave chloroform. The incision was commenced an inch below the umbilicus, and extended downwards four or five inches. There were no parietal adhesions: the omentum adhered slightly to the upper part of the cyst. The pedicle sprang from the left side of the uterus. It was from two to three inches long, and as broad as two fingers. It was secured in a small clamp, and kept outside without traction. There was no bleeding except from the abdominal incision. A piece of omentum was cut off, three vessels tied with fine silk, and the ends of the ligatures cut off short. The right ovary was healthy. The wound was closed with four deep and one superficial silk suture. The only peculiarity in the operation was, that a large multilocular tumour, weighing upwards of twenty pounds, was removed through a small opening, by successively tapping cysts one within the other. No fluid escaped into the peritoneum, and no sponging was needed. The diagnosis was verified in every particular. The patient recovered without a bad symptom. I removed the sutures on the third day. On the nineteenth day the bowels were moved for the first time by an enema. There was no inconvenience from the nineteen days' constipation. The clamp was not removed, as it gave no inconvenience, and did not fall off till the twenty-first day. This patient called upon me lately in excellent health, and is soon to return to South America.

Case 2.—In December, 1864, Dr. Bateman, of Canonbury, sent me a patient who was the subject of ovarian tumour. She was an unmarried servant, 27 years of age, of good constitution, and born of healthy parents. Eight years previously she had observed a swelling on the left side of her abdomen, low down. It was tender to the touch, but not otherwise painful. She had always menstruated very freely; her first period came on when she was 14, and the flow usually lasted a full week. Seven weeks before I saw her the patient had strained herself, and the tumour had increased very rapidly in size since. The last menstruation had occurred three weeks before her visit to me. She was a well-nourished woman; she was troubled with cold feet, but otherwise the temperature of the skin was normal. The tongue was clean, the appetite ravenous, the bowels habitually constipated. She slept well, and had excellent spirits. Breathing was perfect, the lungs in good order, the vesicular murmur being, however, a little weak in the right lung. She slept best on the right side. The heart's tones were normal; the pulse 88. The urinary system was in good order. The girth at the umbilical level was 33 inches; the distance from the umbilicus to the ensiform cartilage, 10 inches; to the pubic symphysis, 7½ inches; to the right ilium, 7 inches; and to the left ilium, 8 inches. A fluctuating tumour filled the lower part of the abdomen, reaching three fingers' breadth above the umbilicus, and extending more to the left than to the right side. The left loin was dull; the right was clear on percussion. The abdominal parietes were only moderately thick; there was no tenderness on pressure. The uterus was virginal, central, but far back. The tumour could be felt per vaginam between the uterus and the bladder. This patient was admitted into the Samaritan Hospital, and on December 18 I wrote in the Hospital Case-book, as my diagnosis—"Unilocular ovarian cyst. No parietal adhesions. Uterus free, but tumour is felt in front of it." As there were then in the Hospital two cases of pyæmia, with pyæmic scarlatinoid eruptions, I had the patient removed to a lodging in the neighbourhood on the 22nd. Before leaving the Hospital, Dr. Greenhalgh, one of the Consulting Physicians, saw her, and approved of ovariotomy. I performed the operation on December 23, with the assistance of Dr. Nicholson, of Antigua, Dr. Ritchie, and Dr. Wright. Dr. Parson gave chloroform. A four-inch incision was made, and the cyst extracted after it had been emptied. The pedicle sprang from the left side of the uterus. It was not thicker than a single finger, but was closely connected with the meso cæcum; so that when the clamp was kept out there was a very tight pull upon this fold of peritoneum, although there was but little on the uterus. The pedicle was temporarily secured with a clamp; it was then transfixed, tied in two halves with twine, and then surrounded with a silk ligature. All the ends were cut off short, and the stump was returned. There was a little bleeding from a superficial vessel near the lower angle of the wound, which required a ligature. The left ovary was healthy. The wound was closed by five deep and three superficial sutures. It is curious that, although the tumour was first observed on the left side, and there was persistent dulness in the left loin, while the right loin remained clear, still it was the right ovary which was diseased. For the first three days after the operation, there was a troublesome cough and wheezing at the chest. On the third day the catamenia appeared. On the fourth day I removed the stitches. Some of the suture tracks had suppurated, and the edges of the skin had not united well. The pulse was 96; the catamenia persisted. On the fifth day the catamenia were scanty. On the ninth day great relief was obtained by breaking up a scybalus mass in the rectum and procuring a motion by means of an enema. After the twelfth day the patient had a very severe attack of influenza. She got quite over it, and was sent back to the Hospital, on January 16, three weeks after the operation. The edges of the skin were then still ununited, although the deeper portions of the opening were perfectly closed; but she left the Hospital on February 1, 1865, and has since called on me in excellent health.

Case 3.—In the winter of 1862, an unmarried housekeeper, 39 years of age, consulted Mr. Chavasse, of Birmingham, with reference to a tumour which she had recently discovered in her left iliac region. It was well defined, firm, and of about the size and shape of an ordinary breakfast roll; and Mr. Chavasse had little hesitation in referring it to the ovary, although it did not produce much constitutional disturbance. Iodide of potassium was tried both internally and externally, but with no satisfactory result. The tumour, on the contrary, began to increase rapidly in size. Mr. Chavasse therefore advised the patient to consult me, and I saw her in September, 1863. She was a delicate-looking brunette; she came of a healthy family, and she had lived a quiet retired life nine years as companion to an invalid lady, and three years as housekeeper. When quite a girl she had had one or two chest attacks. The girth at the umbilical level was 32½ inches; the distance from the umbilicus to the ensiform cartilage, 7½ inches; to the pubes, 8 inches; and to either ilium, 8 inches. The abdomen was occupied by a tumour, which reached upwards to the left hypochondrium, leaving the epigastrium, right hypochondrium, and right iliac regions free, but extending beyond the mesian line several inches, on a level with the umbilicus. The tumour was evidently moveable. Fluctuation was to be perceived, but seemed to be due to peritoneal rather than to cystic fluid. There was neither crepitus nor tenderness on pressure, nor bruit. The catamenia remained quite regular. From the age of 25 they had been rather excessive during ten years, but lately there had been less flow. The uterus was pushed to the left side of the pelvis. The cervix was moveable, but the body appeared to be incorporated with the tumour. The os was soft. The vagina was shortened by the tumour, which could be felt pressing behind and to the right side of the uterus. My diagnosis was—"Multilocular (semi-

solid) ovarian tumour: portion in pelvis closely surrounding uterus." I told the patient that ovariotomy was her only resource, but I left the question of time to herself. During the next twelve months the patient was troubled with pain, dysuria, and a hacking cough. I saw her for the second time in October, 1864, and tried to relieve these symptoms. She came again in December. The tumour was much larger; the patient was scarcely able to get about; she was annoyed by frequent nausea and abdominal tenderness. The catamenia were still regular; the uterus was moveable; the tumour was still to be felt in the vagina, but it now appeared to be moveable. The catamenia came on on December 28. On January 2, 1865, the umbilical girth was 38½ inches; the distance from the umbilicus to the ensiform cartilage, 10½ inches; to the pubes, 10 inches; to either ilium, 12 inches. Emaciation was now very considerable. The temperature of the skin and the extremities was normal. There were neither varicose veins nor œdema. The tongue was white, the appetite capricious, flatulence troublesome, and the bowels habitually confined. Breathing was free; there was a slight hacking cough, but no expectoration. There was a slight tendency to pigeon-breast. The right lung was compressed by the liver, which rose as high as the fifth rib, and gave rise to mucous crepitation; a friction sound was audible an inch below and to the right of the right nipple. The heart was a little displaced upwards and inwards. On the 10th of January I performed ovariotomy, with the assistance of Dr. Evans, of Hertford, Dr. Ritchie, and Dr. Wright. Chloroform was administered by Dr. Parson. The incision extended from the umbilicus seven inches downwards. There were no adhesions. The Fallopian tube and a double layer of broad ligament ran across the front of the cyst. These layers were raised and divided, care being taken not to cut any of the large veins or cork-screw arteries seen in the broad ligament. The cyst was emptied and easily withdrawn. The pedicle was as thick as two fingers, very long and very vascular. It was secured in a small clamp, and kept outside without any tension whatever. There was not an ounce of blood lost during the whole operation. The opposite (left) ovary was about twice its normal size, and cystic. I opened one cyst in it, of about the size of a filbert, and evacuated some reddish fluid. The wound was closed by six deep sutures of Scotch twine, and four superficial ones of silk. During the operation nineteen pints of fluid were evacuated; the tumour itself weighed from eight to nine pounds, and consisted of a large mass, from which hung a semi-detached tumour, which had been sunk in the pelvis. The slight enlargement of the left ovary, and the small pendulous portion from the large tumour of the right ovary explained the manner in which the uterus had been felt surrounded by the tumour. The tumour was sent to the museum of the Royal College of Surgeons. The patient vomited once, just as she was recovering from the chloroform. At four o'clock the pulse was 109, thready; the chest oppressed; the respiration moaning; pain in abdomen great. Twenty minims of laudanum were thrown into the rectum. An hour after operation the pulse was 96; there was much retching, with mucus. In the first three hours after operation fifty drops of laudanum were given. The patient was easier, the pupils slightly contracted, the skin warm, and covered with perspiration. Later in the evening cramp became very troublesome in both legs. The patient passed a tolerable night, but was much troubled with constant wheezing at the chest. At 8 o'clock in the morning of the first day the pulse was 96, the wheezing persistent. An attempt was made to alleviate it by causing carbonic acid to be inhaled at intervals of four hours. This gave a little temporary relief. In the afternoon I cut away some of the slough; there was no pull on the clamp; the patient looked well. At night the pulse was 88; the patient was pretty well, but had been sick, and was restless and wheezing.

Second Day.—At 10 a.m. the pulse was 96, and soft; but the aspect was much depressed and almost jaundiced. There was tympanites and frequent vomiting. No flatus passed downwards; the rectum was empty, very flaccid, and dilated; the vagina was cool, the uterus free; there was no fluid in Douglas's space; no pull on the clamp; and, remembering the remarkable results of M. Beau's quinine treatment of peritonitis, I determined to try quinine in large doses by the mouth and rectum. At 11, champagne and laudanum were given by the mouth. At 12, ten grains of quinine, in two pills, were given. At 2 the pulse was 102; ten grains of hydrochloride of quinine, dissolved in one ounce of water, were thrown into the rectum. The intestines were now much distended with gas. There was great pain. The tightness of the bandage was complained of. A tube was passed into the rectum, but no gas passed. At 4 o'clock there was a free escape of flatus through the rectum-tube. At 5 some more flatus escaped. Twenty-five minims of laudanum were given by the mouth; there had been no sickness all the afternoon. At 6·30 the pulse was 128, full and soft; the patient felt much better. At 8·30 5 grs. of quinine were given by the mouth, and at 10 ten grains were given by the rectum.

On the *third* morning she was very restless; the face was dark; the pulse 130. The tympanites was, however, less, and flatus continued to pass by the rectum. There was no vomiting. From 1 a.m. till 5 pain was complained of. At 5 fifteen drops of laudanum were given by the mouth. At 8 a.m. she seemed better. The pulse was 101; the urine loaded, not scanty. Ten grains of quinine were given by the rectum. There was a little blood-clot in the vagina. At 9·30 a.m. the pulse was 112 to 116, full and soft; the aspect somewhat better. A little ringing in ears and palpitation showed that the system was saturated with quinine. Tympanites was considerable; I therefore Faradized the epigastrium, and in 15 minutes a fluid stool passed. At 1·30 the pulse was 110, with two or three distinct intermissions in the minute. At 4 the pulse was 108, the abdomen much distended, the urine not scanty. The patient asked for an oyster. At 6 Faradisation was repeated. Shortly afterwards the oyster taken two hours previously was vomited unchanged. Till 11 p.m. everything taken by the mouth was vomited. At 11 p.m. the pulse was 102, intermittent. The patient's face was dark, and drawn into deep furrows; she said she felt she was dying. The abdomen was much distended and was now painful to the touch. There was no pelvic effusion, no great heat of vagina; the uterine epistaxis persisted; the urine was still secreted. A soap enema was given; much flatus and a little fæculent matter came away. The bed was changed, and 35 minims of laudanum given by the mouth in a little champagne. For an hour there was a little quiet; but the vomiting soon recommenced, and the patient had a bad night. She refused stimulants; but at 5 a.m. next morning beef tea and port wine were injected into the rectum.

On the *fourth* morning the pulse was 108. There was occasional sickness; but flatus was passed by the rectum. A mustard plaster checked the sickness. During the day the nutritive injections were continued every three hours.

During the whole of the *fifth* day the patient remained tolerably easy. There was little distension; the urine was abundant; the pulse 120. Towards evening the bowels were moved spontaneously; and as afterwards the patient was very restless, one-fifth of a grain of morphia was injected under the skin at 6 p.m., and repeated at 11. Each dose was followed by refreshing sleep, lasting some hours.

On the *sixth* day the pulse was 112. The patient felt better, and said she was quite easy. There was no distension. I removed all the stitches, and found that the wound had healed, except in one spot, where there was a little discharge between two of the stitches. The bowels were moved four or five times during the day. Fifteen drops of laudanum were added to the enemata. The patient was now out of danger; her appetite returned; her pulse fell; and she slept well at night. The clamp came away on the thirteenth day. Occasional flatulence was relieved by cajuput oil. A tonic was administered, and in three weeks from the day of operation the patient was able to return home.

I have given the progress of this case after operation at some length, because I believe the quinine and the Faradization were both of very essential service. I do not remember a case where so rapid a pulse, such persistent vomiting, such extreme tympanites, so jaundiced a skin, such scanty concentrated urine, and such general depression, ended in recovery, and the commencement of the improvement followed the use of the quinine, while the good effect of the Faradization was evident at every application.

I have had an excellent report of this patient since her return to Birmingham.

(To be continued.)

PATRIOTIC FUND.—The Royal Commissioners of the Patriotic Fund have appointed Dr. Armstrong, Deputy-Inspector-General, Royal Navy, to be a member of the executive and finance committee of the Fund.

HYDATIDS PASSED BY THE URETHRA, PROBABLY FROM THE KIDNEY.

By MICHAEL T. SADLER, Jun., B.A., M.D., Lond., etc.,
Honorary Surgeon to the Beckett Dispensary, Barnsley.

On July 17, 1864, I was called to see B. F., a warehouseman, aged 42, tall, spare, rather sallow. He complained of severe pain in the region of the left kidney, extending downwards towards the pelvis, which had prevented sleep throughout the night, and was attended with nausea and vomiting. I gave him opiates, and recommended hot fomentations, etc.; and, knowing that he had been similarly affected on previous occasions, desired him to send me anything unusual that might be passed with the urine. The pain continued with somewhat less severity, and on the 24th he felt something give way at the seat of pain and pass down into the pelvis. Then, on attempting to urinate, he found the urethra obstructed by a transparent globular bladder filled with water. Having removed this, others succeeded, and it was an hour and a-half before he got rid of all of these bodies, which numbered about twenty. The pain continued, but less severe, and on August 8 he felt the same sensation of motion in his back as before, and then passed six or eight more cysts; after which he felt much relieved. He brought me all that he had passed on both occasions. They were clearly hydatids, varying in size from that of a pea to that of a walnut, transparent globular, containing clear fluid, and many of the larger ones having smaller cysts within them. The larger ones had been for the most part ruptured in their passage; but many of the size of a marble were entire.

Under the microscope, the cyst-walls were seen to be beautifully laminated, and to be covered on their inner surface with granular matter, containing innumerable minute daughter-cysts. No distinct hooklets could be found.

The history he gives is, that twenty years ago he fell backwards from a height of four or five feet. This was followed by a severe illness, with much pain in his back, and in a few days he passed a quantity of these hydatids, and ever since has had a precisely similar attack once in every four or five years. The pain is always in the left renal region, and always relieved after passing the cysts.

He has never to his knowledge suffered from tapeworm, but admits that when young he was particularly fond of eating raw meat, and especially raw bacon.

REPORTS OF HOSPITAL PRACTICE
IN
MEDICINE AND SURGERY.

ST. THOMAS'S HOSPITAL.

A REPORT OF THE CASES OF PYÆMIA WHICH OCCURRED DURING THE YEAR 1864.

[Communicated by Mr. SUMMERHAYES]

During the year 1864, eight cases of pyæmia occurred in the temporary building of St. Thomas's Hospital at the Surrey Gardens. The disease was confined to the male Surgical wards, Accident and King's, in which the total number of occupied beds is generally between seventy and eighty, King's Ward having a small majority. Four cases took place in King's Ward, and an equal number in the Accident Ward; but two of the patients who died in King's Ward were, for a time, and previously to the setting in of their pyæmic symptoms, in the Accident Ward. The immunity of the female Surgical Ward—Queen's—from the disease seems referable to the extreme rarity of severe external lesions, such as compound fractures, among the women admitted, or, possibly, to the minor frequency or intensity in their constitutions of the dyscrasia which undoubtedly springs from habitual intemperance in alcoholic drinks. It is right to add that the roof of Queen's Ward is much loftier than the roofs of the Accident and King's Wards, above which Queen's Ward is situated, and the female patients have, consequently, more cubic inches of air allotted to them individually than have the males.

The three earliest cases occurred in King's Ward, the dates of their deaths being respectively February 14, April 23, and June 10; the last of the three was in the ward at the time of the commencement of symptoms of pyæmia in the second, and the second at the time of the commencement of the same symptoms in the first. The next four cases occurred in the Accident Ward, the dates of their deaths being respectively June 23, July 4, July 4, and August 15; the second of the four was in the ward with the first, and the third with the second; between the admission of the fourth and the death of the third a period of eleven days intervened. The eighth and last case of pyæmia took place in King's Ward, the date of his death being September 4; but it is to be observed with regard to this case that, for eight days after his admission, he lay in the Accident Ward, and was not removed thence until symptoms of pyæmia had plainly declared themselves in a fellow-patient.

The patients in King's Ward were, on July 12th, removed to a temporary ward erected in the grounds, and were not brought back until July 27. During the interval an attempt was made to purify their ward; the walls, ceiling, and floor were washed and re-washed with solutions of chloride of lime; the paintwork was thoroughly cleaned, and all the bedsteads, linen, and furniture were taken out and cleansed. One death from pyæmia occurred subsequently in the ward on September 4, but, as above stated, the man who died had, on his admission, lain for eight days in the Accident Ward not far from the bed of a pyæmic patient.

On July 27 the patients were removed from the Accident Ward to the temporary building, and on August 2 were brought back to their old places. In the interval the ward was cleansed in the same way that King's had been. Symptoms of pyæmia set in on August 7 in a patient who had been for twelve days in the ward while it was yet uncleansed; near him for three days after the commencement of his ill-omened symptoms lay the eighth and last case of the year, afterwards removed to King's Ward, where the disease attacked him also, after the lapse of a period of thirteen days.

August 15 for the Accident, and September 4 for King's Ward, are accordingly the dates of the latest cases of pyæmia at St. Thomas's Hospital in the year 1864, and up to this day (March 16, 1865) the disease has not re-appeared. *Cæteris paribus*, therefore, the purification of the wards in the manner and at the times above stated, would seem to be immediately concerned in this change for the better. But if the cleansing of a ward and the removal by its means of all such material relics of old cases of pyæmia as may be supposed to adhere in minute and microscopic forms to beds, walls, and flooring, be confessed to have a decided influence in checking the spread and interrupting the continuity of the disease, how, it will still be asked, does the pyæmia originate? Where must we look for the *prima materies morbi*? We may conceive the probability of the disease having its origin in the foulness of the atmosphere of a crowded ward, where the foulness is not the result merely of limited space and insufficiency of breathing-air, but is rather explained by the charging of the atmosphere with gaseous or minute solid emanations from a large number of raw suppurating surfaces.

Should pyæmia re-appear in either of the wards of St. Thomas's Hospital, it will be interesting, and indeed obligatory, to observe accurately the maladies of all the other patients in the visited ward, and more especially to note the number, size, and condition of all wounds and raw surfaces. It is a matter of regret that this investigation was not made at the dates of the first appearance of the disease in King's and Accident wards during the year 1864.

The symptoms which were recorded during life in the eight cases are given below in a form that is tabulated with reference to date, this seeming to be the most useful arrangement. Four tables are so made of the life-symptoms under the following heads:—(a) Condition at admission, (b) progress from admission to the commencement of symptoms of pyæmia, (c) commencement of the symptoms of pyæmia, (d) progress from the commencement of symptoms of pyæmia to death.

The post-mortem appearances are given in a fifth column; and lastly there is a table in which the treatment and any peculiarities of the particular case are noted down. The cases are arranged in numerical order, according to the dates of their attacks, (1) being the earliest, and (8) the latest.

The post-mortem reports speak only of morbid appearances, and such as appear to throw some light on the nature of the disease. Where the condition of certain viscera or parts of the body is undescribed, they are to be considered to have been healthy or but slightly affected or unnatural, only in a manner distinct from, and unrelated to, the usual evidences of pyæmic poisoning.

Name, Age, Occupation, Ward, Date of Admission.	Condition at the Time of Admission, Nature of Disease or Accident, etc.	Progress from the Time of Admission up to the Date of the First Symptoms of Pyæmia.	Commencement of the Symptoms of Pyæmia.	Progress from the Commencement of the Symptoms of Pyæmia to Death.	Post-mortem Appearances.	Treatment, Remarks, etc.
1. Thos. K., 49, baker; Accident Ward, Jan. 4, 1864; King's, Jan. 23.	A pistol-bullet wound. Brought to the Hospital directly after the accident. Compound fracture of right index finger: carpo-metacarpal joint of thumb extensively opened. Great laceration of the outside of hand; blackness of the torn soft parts. Amputation of thumb and forefinger at carpo-metacarpal joint; adjustment of flaps by wire sutures. The patient seems to be a very nervous man. Says his average daily drink is Oij. ale.	Jan. 5 to Feb. 8:—Jan. 5.—Restless; slightly delirious; tongue moist; pulse weak, fast. 9th.—Quiet; pulse 120; hand looks unhealthy. 13th.—Restless; hand darkish redness and swelling, extending a little way up the forearm; pulse 110. 21st.—Less swelling; bone exposed at wrist, seemingly dead; pulse 90. 23rd.—Amputation of forearm, two inches above wrist; tongue moist; pulse 100; appetite good. 27th.—Has improved since the operation; healthy discharge. 29th.—Pulse 100; feels better. Feb. 1.—Small slough at right elbow, exposing a bit of the inner condyle of humerus. 3rd.—Pulse 84; looks better; is somewhat nervous, as, indeed, he has been all through his illness. 7th.—Pulse weaker, 104; stump looking well; discharge from it much diminished.	Feb. 8.—Rigors in the night, followed by sweating; pulse 100, small; tongue moist, clean; margins of stump red & swelled.	Feb. 9 to 14:—Feb. 9.—Has a yellowish tinge of complexion: tongue dry, with white fur; pulse harder, 120; eats and drinks with good appetite; a little foul sloughing at inner corner of stump. 10th.—Shivering again, followed by sweating; tougue brown; pulse 120; stump looking pale and inactive. 12th.—Face distinctly yellow; some dyspnœa and cough; pulse weak, 120. 13th.—Restless; got out of bed in the night. 14th.—Greatly increased dyspnœa; loud rhonchi heard in chest; cannot speak: stump pale and shrivelled. Died 12.30 p.m.	Feb. 15.—Little union of stump; pus extending superficially upwards from it nearly to the elbow; arteries and veins of forearm free from disease; lungs œdematous; injection of the bronchial mucous membrane; a small abscess in the cellular tissue outside the larynx; an abscess in the right lobe of the liver as large as a hen's egg, externally firm, fibrinous — internally, soft, yellowish, fœtid, like pus.	The treatment had been stimulant from the beginning; at the end wine ℥vi., gin ℥vi., were being given daily. Morphia had been administered freely to subdue restlessness. The stump was dressed with warm water dressing.
2. David G., 55, coal-porter; Dec. 30, 1863; King's.	Readmitted after 1 month's absence Since he left no change has taken place in his diseased foot, and he has now come in to have it removed. There is now a large wound in the dorsum of left foot; through its florid granulations numerous sinuses lead down to tarsal bones, which may be felt exposed. He is in good health.	Dec. 31 to April 9, 1864:—March 30.—No change of importance up to this day. Removal of first metatarsal and internal cuneiform bones. April 1.—Extreme redness and fulness of the inside of diseased foot; health disordered.	April 9.—Severe rigors, followed by sweating; foot much inflamed; looks very ill in face.	April 10 to 23:—13th.—A large collection of pus evacuated on inside of foot. 14th.—Pulse 126; swelling at carpo metacarpal joint of left thumb; swelling towards outside of foot, tenderness reaching some way up the leg in the direction of the internal saphena vein; tongue brown, cracked, dry. 15th.—Pus evacuated at outside of foot; tenderness along the course of left femoral vein, which is felt hard and cordlike; pulse 116; tongue brown. 16th.—Pulse 128; rigors, lasting one hour, this morning; swelling at wrist opened, and pus evacuated; great prostration; respirations 44 per minute. 18th.—Delirious; breath sweet smelling; eyes vacant; no cough; no jaundice; pulse 120. 20th.—Respirations 44; chest everywhere resonant: no harsh sounds; tongue dry, brown; no action in foot. 23rd.—Died.	April 23.—Lungs unaffected; liver healthy; abscess in right iliac foss; fœtid pus; the whole of tarsal bones bathed in pus and partially necrosed; the articular cartilages of ankle-joint half destroyed, and the tibia slightly necrosed at its lower articular end; an abscess cavity reaching up behind and in connection with the ankle-joint, bathing the posterior tibial vessels in pus. These vessels seemed to be healthy: there was only a little non-adherent clot in the veins.	Treatment was stimulant. In the end ℥x. brandy were given daily. Near him in the ward were three cases of ulcers of the leg, one case of extensive caries of the sternum, one of amputation of the leg, and one of necrosis of tibia lately operated upon. No erysipelas in the ward. Case No. 1 died six weeks before any operation was performed on this man's foot. They lay at different ends of the ward, which is a very large one. The dresser has not dissected for months.
3. William H., 21, clerk; March 16; King's.	Swelling and pain at outside of left foot. A small sinus near external malleolus, conducting inwards to exposed bone. Disease commenced two years ago, when he sprained his left foot badly.	March 17 to June 8:—March 31.—Red swelling at inside of arch of left foot; incised, pus discharged freely. April 19.—Swelling redness about either ankle and adjacent part of tarsus; abundant thin discharge from wound and sinus. May 18.—Some carious portions of the external malleolus removed; probe passed freely into ankle-joint, and the surface of astragalus felt rough and uncovered. 23rd.—Abundant discharge from the last wound. 28th.—A collection of pus below internal malleolus incised. 30th.—Amputation of leg just above malleoli, there having been profuse arterial hæmorrhage from the wound at outer side, which it was difficult to control. The bleeding was discovered by himself on the night of the 28th inst. At the time of operation his face was blanched and his pulse extremely weak, 170. Very little blood was lost in the operation. On examination of the removed foot, caries of astragalus, os calcis, and lower end of tibia was discovered. There was no sequestrum. June 1.—Pulse 128: no sickness; very thin serous discharge from stump; some tension; posterior flap looks dark; the stump has neither been dressed nor washed as yet; he takes food, and sleeps well. 3rd.—A poultice is on the stump; discharge free; pulse 100. 6th.—A small slough has separated at the back; tongue clean, red glazed; pulse 104. 8th.—Headache; loss of appetite.	June 9.—Shivering this morning, followed by sweating; sickness; redness & fulness about stump; pulse 134.	June 10 to 16:—10th.—Another shivering fit last night, and a third this morning; face paler, anxious; stump looking dark; œdema of the lower part of the leg; tongue dry; skin hot; pulse 160. 11th, 10 a.m.—Pulse 120; end of fibula exposed; feeling better. 9 p.m.—Has just had rigors; pulse 160; pain in chest. 12th, 9 a.m.—Pulse 130; tongue dry, red; thirsty; is irritable; lower end of tibia exposed. 9 p.m.—Pulse 200. 13th.—Pulse 132; stump black and sloughy; tenderness in the right hypochondrium; is weaker. 14th.—Diarrhœa thro' the night; cough, expectoration tough and rusty. 15th.—Diarrhœa continues; is at times for a short while unconscious; breathing quick; pulse very feeble: skin over head of fibula has given way. 16th.—Died.	June 16.—Stump unhealthy; vessels of limb natural; a quantity of turbid serum in right pleura. In the lower lobes of both lungs, and in less number in the upper lobes also, were found many fibrinous masses, varying greatly in size — some decolorised and yellow; others dark red: the former were here and there softened in their centres, and contained pus. The bronchial tubes were congested, and contained semi-purulent mucus. A minute abscess was found in the substance of one of the small muscular bands on the inside of the right ventricle. The pericardium contained a small quantity of turbid fluid. In the right lobe of the liver were several considerable abscesses, the pus being thin, greenish-yellow. In the spleen were some partly decolorised fibrinous masses, a little softened. The intestines were healthy.	The third case of pyæmia in King's Ward during the year 1864. No. 2 died April 23. Treatment: May 29, eggs xii., brandy ℥xx. 30th, eggs vi., brandy ℥x., sherry ℥viii. June 2, brandy ℥iii., ale Oj. 14th, brandy ℥vi.

Name, Age, Occupation, Ward, Date of Admission.	Condition at the Time of Admission, Nature of Disease or Accident, etc.	Progress from the Time of Admission up to the Date of the First Symptoms of Pyæmia.	Commencement of the Symptoms of Pyæmia.	Progress from the Commencement of the Symptoms of Pyæmia to Death.	Post-mortem Appearances.	Treatment, Remarks, etc.
4. Hugh D., 25, carpenter; Accident Ward; May 3.	A superficial wound, two or three inches long, running obliquely across in front of the right patella. No evidence of wound of the knee-joint. The wound brought together with wire sutures, the limb extended on a back splint, and cold water dressing applied to the knee. Is a rather sickly-looking young man.	May 4 to June 10:—May 4.—A good deal of pain on firm pressure about the knee-joint; some swelling; loss of appetite; tongue white; thirst; pulse sharp, 84. 12th.—A slight blush reaching upwards from the wound; fulness about knee; no localised fluctuation; rigors have not occurred; thin discharge from wound; pulse soft, 120; tongue red, moist; sweats much. 21st.—Incision at inside of joint; a large quantity of brownish pus discharged. 23rd.—Discharge continues free; pulse 100. June 3.—Free and foul discharge from wounds; pus burrowing upwards among the muscles of thigh; joint much swelled. 4th.—Circular amputation of thigh at junction of its middle and lower thirds. On examination of the removed limb, the joint was found to contain much unhealthy pus, which extended some little distance upwards, both before and behind. The posterior portions of articular surfaces of tibia and femur were denuded of cartilage; anteriorly the cartilage was soft, but adherent. 6th.—Pulse 124, restless; tongue dryish, glazed, red; free purulent discharge from wound; thirst. 9th.—Very weak; no appetite; pulse 124; much discharge from stump.	June 10.—Rigors last night, followed by sweating; more rigors during the day.	June 11 to 26:—June 11.—Look very ill; more rigors, followed by sweating. 13th.—Pulse 140; face white, anxious, sunken; tongue red, glazed; appetite gone; stump looking inactive, little tenderness in it. 18th.—Tongue dry, glazed; pulse 120; sleeps well; takes food; cough; quick breathing; some rusty expectoration. 25th.—Death.	June 27.—No union of stump; femoral vein healthy; its extremity plugged with adherent clot; femoral artery containing very little clot; the lower lobes of both lungs congested and partially consolidated; three or four abscesses about the size of a cherry on the posterior part of lower lobe of the right lung, each surrounded with a small quantity of fibrin.	This was the first of a series of cases of pyæmia occurring in the Accident Ward during the summer months. Treatment had been stimulant from the beginning. In the end wine ʒxii. were given daily. The stump had been dressed from the first with lint soaked in chlorinous lotion.
5. William R., market gardener; May 15; Accident Ward.	Accident happened fifteen hours ago; was knocked down and kicked by a man. An oblique, irregular wound in the lower part of middle third of right leg, leading to an oblique fracture of the tibia. Simple fracture of fibula two or three inches higher up. No apparent bruising. Health good. Average daily drink Oij. ale. Wound brought together with wire sutures, and an ice-bag applied to it. The limb was extended on a Liston splint.	May 16 to June 28:—May 19.—Thin serous discharge from lower part of wound; sutures remain; wound united at upper part; purple discoloration reaching backwards and inwards from wound. 23rd.—Sloughing at wound; foul discharge from it; tissues around baggy; eats and drinks well; tongue slightly coated, moist; skin hot; pulse 80, full. 26th.—Broken ends of tibia exposed by removal of slough; a small intermediate piece of tibia seen detached from the two main fragments; wound 2 in. to 2¼ in. in diameter; man looks ill; pulse 96, soft; is weak and feverish. 30th.—Intermediate bit of tibia removed; little action about wound; great difficulty in maintaining correct apposition of the broken surfaces of tibia; pulse 84, weak. June 11.—Lower end of upper fragment sawn off; it was found to be partially necrosed. 13th.—Tongue clean; pulse 92; feeling better; eats well. 18th.—Continues to improve; wound widely open; suppurating freely.	June 28—30.—Several shivering fits; pulse very small and indistinct; looking much worse in face.	July 1 to 4:—July 1.—Evidently much worse; breathing quick and harsh. 4th.—Died.	July 5.—Extensive suppuration of the soft parts near the wound; external and internal saphena veins thickened, and contained in the middle of the leg firm clot, partially decolorised and tapering upwards. Below this, the clots were soft for some distance, and close to the wound pus was found filling the veins. The posterior tibial and peroneal veins were in much the same condition as the superficial veins. The anterior tibial veins appeared healthy. Pus was found in the ankle-joint, and the articular cartilages were thinned. There was necrosis of the upper and lower fragments of the tibia for some distance from the point of fracture. Microscopical examination of the medullary contents of the necrosed portions showed oil globules and granular matter only; no pus cells. The pus contained in the veins showed well-marked corpuscles, while that obtained from the soft parts displayed much granular matter, together with less distinct corpuscles. In the lower lobe of the right lung were many yellow fibrinous masses, some containing a little pus in their centres. In the substance of the prostate gland were numerous minute pyæmic deposits, some of which had suppurated. There was a small abscess in the left psoas muscle, and another in the anterior abdominal wall. The right common iliac vein was filled with dark softening clot; the right internal iliac with pale clot, partially suppurating. The right external iliac and upper part of right femoral vein were filled with decolorised clot, which was hollowed out in two or three places by pus-cavities. The lower part of the right femoral vein contained dark, healthy clot. On left side the iliac and femoral veins were healthy.	The second case of pyæmia in the Accident Ward. Stumulants wer given up to a daily allowance of brandy ʒviii.

Name, Age, Occupation, Ward, Date of Admission.	Condition at the Time of Admission, Nature of Disease or Accident, etc.	Progress from the Time of Admission up to the Date of the First Symptoms of Pyæmia.	Commencement of the Symptoms of Pyæmia.	Progress from the Commencement of the Symptoms of Pyæmia to Death.	Post-mortem Appearances.	Treatment, Remarks, etc.
6. John R., 22, bricklayer; Accident Ward; June 6.	Compound comminuted fracture of right tibia and fibula at junction of middle and lower thirds. Little apparent bruising. Average daily drink Oij. porter, with a small quantity of spirits. Has not felt well of late. Two small intermediate fragments of tibia removed, wound closed with wire sutures, good position secured, and the limb fixed on a short outside splint with an ice-bag over the wound.	June 7 to 30:—June 9.—Little appetite; has shivered a little; thirst; tongue moist, white; pulse sharp, 120; not much fulness or redness about the wound; sutures remain. 10th.—Feels very weak and low; tongue furred, moist; some diarrhœa; wound looking foul; warm-water dressing substituted for ice-bag. 21st.—Is weaker; a charcoal poultice is laid over the wound. 24th.—Pus found burrowing deeply among the soft parts near wound. 27th.—Pulse 120, feeble; tongue dry; does not sleep well; wound foul. 28th.—3 p.m.: circular amputation of the leg near the knee. 9 p.m.: Pulse 120; tongue dry; large abscess opened in right buttock. 30th.—Pulse 120, feeble; appetite bad, taking only fluid nourishment; right knee-joint swelled.	July 1.—Rigors this morning for half an hour, followed by profuse sweating; pulse 130, very feeble; tongue dry, red; face changed, anxious, & pinched; a slougby spot on the margin of stump; no primary union.	July 2 to 4:—2nd.—Incision at outside of right knee; much pus; ice-bags applied to knee. 9 p.m.—There have been two shivering fits to-day, each lasting half an hour. 3rd.—Two distinct fits of shivering; was quite delirious last night; pain in the right hypochondrium; vomiting; pulse 140, very feeble; tongue dry; skin hot. 4th.—Died.	July 5.—Bed sores over sacrum; abscess cavity in right gluteal region; raw surfaces of stump suppurating; exposed surface of medullary cavity of tibia covered with pus; abscess in right knee-joint, which had been opened; articular cartilages partially destroyed; veins of stump and femoral vein healthy—the latter containing some non-adherent, partially decolorised clot; the lungs contained a few small yellowish fibrinous masses, which had softened in their centres.	The third case of pyæmia in the Accident Ward. The treatment was stimulant; in the end brandy ℥iii. and wine ℥vi. were given daily.
7. Samuel C. H., 20, labourer; Accident Ward; July 15.	Was knocked down by, and buried under, a load of dirt. Compound fracture of left tibia in its middle third; simple fracture of fibula on the same level. The wound over the fracture of tibia was small, and had been made by the projection of the upper fragment. The wound was closed by wire sutures, an ice-bag applied to it, and the limb set on a back splint. The man is in good health. Average daily drink, Oij. ale.	July 10 to August 7:—July 18.—Health very much disordered; does not sleep well; tongue dry, whitish; skin very hot; pulse 120; blush around the wound; no appetite; thirst. 24th.—Fluctuating swelling with redness in the neighbourhood of the wound; tongue clean, moist; pulse 96; appetite fair; skin cool; has had no rigors. 28th.—The swelling has burst at outer side; a little foul discharge from it; the sore formed looks sloughy, and a small piece of very white bone (tibia) is seen at its bottom. August 1.—Swelling has not extended; tongue brown; pulse small, 120; appetite not so good. 3rd.—Sore looking healthier; tongue dry, brown; pulse 108. 5th.—Ill odour about wound; tongue brown, dry; pulse 104.	Aug. 7.—A shivering fit of five minutes' duration this morning, followed by heat and sweating; skin hot; pulse 100; tongue brown; free discharge from wound.	August 18 to 15:—8th.—A second shivering fit. 11th.—More rigors this morning; has changed much in face; cheeks pale, sunken; eyes bright; voice low and unsteady; pulse 112; skin hot; tongue dry, coated; less action about wound, which is cleaner, and has less redness and swelling about it than before; the pus is thin and greenish. 15th.—Death.	August 15.—Skin and conjunctivæ slightly jaundiced. In the lungs were found many fibrinous masses, mostly yellow; some softening in the centre, and containing pus; others firm, and only partially decolorised, varying in size, most numerous at the base of the right lung. The liver contained a few small yellowish cretaceous masses in the posterior part of the right lobe close to the surface; it was otherwise healthy. The prostate gland contained numerous small, yellow, fibrinous masses, some of which had softened, forming small abscesses. At the wound the ends of the bone (tibia) were seen bathed in fœtid pus; and a good deal of the medullary cavity was exposed from the obliquity of the fracture. On making a section the tibia was found to be necrosed for some little distance from the broken ends; beyond this necrosed portion the bone was congested for some distance. There was no necrosis of the fibula, the fracture of which was unexposed in the wound. The medullary cavity of the tibia near the fracture contained pus and oily matter. The abscess at the back of the leg communicated with a posterior tibial vein, and the cavity of the vein for two or three inches above the point of communication was filled with pus; beyond this distance the vein was plugged with adherent clot, and its walls were inflamed. Above the adherent clot, and reaching to the popliteal vein, free, firm clot existed, and the coats of the vein were natural. The pus from the lungs, prostate, and vein showed, under the microscope, ill-formed, indistinct corpuscles, and much granular matter.	The fourth case in the Accident Ward. Charcoal poultices were kept on the wound from July 24. Supporting diet. Stimulants up to the quantity of brandy ℥iv., porter Oij. daily.
8. Samuel P., 65, carman; Aug. 2, Accident; Aug. 15, King's Ward.	Wheel of dray passed over left leg. Comminuted fracture of the tibia in its middle third; a very small wound over the intermediate fragment. Fracture of the fibula on the same level, having a small wound over it. No evident bruising. Health fair. Average daily drink, Oij. ale.	August 3 to 28:—August 5.—Limb in good position; tension at seat of injury; no redness or fluctuation; face a little flushed; not much appetite; eyes bright; hands unsteady; seems excited and nervous; did not sleep well last night; pulse 66; tongue clean, moist. 8th.—More tension and pain at seat of fracture; slight blush also; tongue clean; is strange in his manner. 11th.—Pus is being discharged freely from the wound; extension of the blush and swelling; pulse 64; can be made to answer rationally, but chatters without meaning unless you press a particular question. 15th.—Decidedly better; quieter in manner; has more sleep; wound has enlarged considerably, and is discharging healthy pus freely; the intermediate fragment of the tibia is moveable at the bottom of the wound; pulse 68; tongue clean. 17th.—Removal of the intermediate fragment, which was partially necrosed. 20th.—Thin pus lying at the bottom of the wound. 22nd.—Pus bagging a little; has not a free exit; granulations of wound healthy; pulse 72. 24th.—Wound lessening in size; tongue clean; pulse stronger.	29th.—Yesterday rigors, lasting half an hour, and followed by sweating; does not look as well as he did; eyes very bright; face flushed most; not complaining of pain; respiration undisturbed; tongue dry, rather dark behind; pulse 84, soft.	August 30 to Sept. 4:—Sept. 2.—Has shivered daily since the last report for some ten minutes; wound looks singularly dry and inactive; what little discharge there is from it has not the appearance of pus; pain and fulness about the left knee; tongue dry and brown at its base; he is quiet; complains of thirst; skin hot; cheeks sunken; pulse 118. 3rd.—Slightly jaundiced; pulse 124, very irregular and intermittent; no respiratory râles; no tenderness in the right hypochondrium; does not regard things about him, and is with difficulty roused; tongue dry, dark. 4th.—Died.	Sept. 5.—Skin and conjunctivæ yellow; fractured ends of tibia dry, white, and bathed in pus; the medullary cavity of the tibia contained pus. The medullary membrane was examined microscopically, and found to be inflamed for a distance of one inch from the end of the upper fragment; above this it was natural. The left knee-joint contained pus; its articular cartilages were softened. A number of pyæmic deposits were seen in the lower lobes of both lungs: the majority of them were firm—a few only were softened. In the liver similar deposits existed; some as large as a walnut. The internal saphena vein contained no clot. The veins of the medullary membrane were examined under the microscope, and found to contain fluid blood only.	Was in Accident Ward for eight days with Case No. 7. Treatment. — Tinct. ferr. mur. ℥xv. ter. die. ex aqua from Aug. 17—31. Stimulants. —In the end and from August 11, wine ℥x. were being given daily.

Medical Times and Gazette.

SATURDAY, MARCH 25.

THE MEDICAL COUNCIL.

The meeting of the Medical Council has been definitely fixed for Tuesday, April 4th. It will therefore take place at a somewhat earlier period this year than last. On this point we understand that some discussion has been raised; the Scotch branch council wishing for an earlier, the Irish branch council wishing for a meeting at a later period. Had the meeting been postponed as desired by our Irish friends until after Easter, all hope of accomplishing a change in the Medical Act during the present session must have been abandoned. May would have counted some of its early days before the proposed amendments could have been brought before the House of Commons, and as the duration of the present Parliament is not expected to extend to the end of June, no one could fairly look for Medical legislation in such a House at such a period. If the Medical Council be really in earnest on this subject, we can see no reason why a Bill should not be introduced and read a first time in the House of Commons before it rises for the Easter recess on April 13. If, on the other hand, the Council be not in earnest, but should unfortunately be disposed again to waste its time in talk, we can well conceive that nothing will be done in legislation this year, nor probably in any year to come. We have no desire to criticise rigidly the proceedings of this body. It is comparatively a new one—composed of very heterogeneous elements — each element imbued with special characteristics—often very antagonistic to each other, and all requiring time to settle down and amalgamate.

That time has now been given. Seven years' of apprenticeship are quite sufficient for a member of the Medical Council to acquire a knowledge of his business, and we shall expect to see some definite and useful results of this experiment. If the results be unsatisfactory, we trust that the next attempt at legislation will be a successful one, and that its object will be to do away altogether with what must then be deemed a piece of cumbrous and costly machinery. Let us have a good scheme of Medical education—a Medical register in which confidence can be placed, and a British Pharmacopœia which can be made use of, and we shall then be prepared to wish the Medical Council a lengthened career of usefulness and prosperity.

COLONIAL MEDICAL ETHICS.

We have received from the Island of Jamaica several newspapers containing portions of the evidence given at an inquest held on a man who died at the Public Hospital after an operation for the removal of a broken piece of catheter from the urethra. As far as we can gather from the imperfect information which has reached us, the following were the principal points in the case:—The deceased, Richard Bailey, age 66, was admitted a patient of the Hospital, on January 11, on account of difficulty in passing water. Mr. Fiddes, who was at that time one of the Surgeons to the institution, found that he was labouring under an impervious condition of the prepuce. This he relieved by a cutting operation on January 16. He then found that the glans penis had been destroyed by previous disease. On January 20 Mr. Fiddes retired from the office of Surgeon to the Hospital, and the Medical and Surgical management of the institution was undertaken by Dr. Bowerbank and Dr. Anderson. This last-named gentleman took charge of Bailey, and, as we suppose, in consequence of what appeared to him the occluded state of the urethra, on January 27 he introduced a No. 2 catheter, and tied it in the bladder. From an accident—stated by one of the patients to have been caused by the man getting out of bed, and hitching the instrument in the iron bedstead—it broke, and a portion six and a-half inches long was left in the urethra. The removal of the retained piece by urethral forceps does not seem to have been attempted. Drs. Bowerbank and Anderson stated that there was no such instrument in the Hospital. Dr. Field, who, we believe, is the resident Medical officer, managed, however, to introduce an instrument by the side of the broken portion into the man's bladder. The foreign body remained in the urethra for nine days. It was then extracted by dividing the posterior portion of the canal. The man sank after the operation, and at the post-mortem examination it was found that the kidneys were in an advanced state of disease—wasted, contracted, and hardened—and that the coats of the bladder were greatly thickened. The integuments of the scrotum were distended with sero-purulent effusion, and the wound in the urethra appeared sloughy and unhealthy.

We believe that had such an unfortunate case happened in any other part of the civilised world, or even in Jamaica at any other time, it would not have been made the subject of a legal inquiry. Whatever may be said about its Surgical management, it was clearly a case which presented no ordinary difficulties, and the practice pursued by the Surgeons in charge of it was, by every rule of Medical ethics, entitled to at least the fair and charitable construction of their Professional brethren. We suppose that nobody doubts that Messrs. Anderson and Bowerbank acted to the best of their judgment and skill, and if every Medical man who meets with an unlucky case were liable to be summoned before a coroner's jury on some hypothetical point of practice when no charge of criminal neglect or Professional incompetence could be sustained against him, who in his senses would practise the Profession of Medicine? But our readers may remember that the state of Medical politics in Jamaica is at present anything but tranquil. Dr. Dunn and Mr. Fiddes, the former officers of the Hospital, resigned their posts in consequence of a dispute in which Dr. Bowerbank was a party opposed to them, and they were succeeded by the latter gentleman and his partner, Dr. Anderson. The case of Richard Bailey happening immediately after this change in the Hospital staff was no doubt freely discussed and commented on. It appears that Drs. Bowerbank and Anderson, so far from shunning inquiry, courted it by requesting that an inquest might be held. They gave it as their opinion that the man's death was mainly due to the bad hygienic condition in which he was placed, to bad ventilation, a pestiferous atmosphere, a filthy state of the ward, and to diarrhœa, which prevailed in the Hospital at the time. Dr. Allen, another Medical man who gave evidence, seemed to think that death was principally to be attributed to uræmic poisoning. None of these suppositions, however, were admitted by the former Surgeons to the Hospital. They allowed their brethren no quarter in the matter. We quote a few extracts from Mr. Fiddes' evidence as specimens of the friendly concern which he evinced for the reputation of his successors. "I consider that the omission of Drs. Anderson and Bowerbank to withdraw the broken catheter immediately after the accident, and their using no means for obtaining the

necessary instrument for its extraction, was a most culpable error on their part, an error which ultimately led to the death of Richard Bailey. At the end of nine days' retention of this instrument, they proceeded to execute a measure for the removal of it; and I have no hesitation in stating that the means which they adopted for this purpose were most unjustifiable and unwarrantable." . . "I repeat that, in defiance of this principle of Surgery" (that operations should not be performed on the urethra and bladder when disease of the kidneys is present), "the patient was subjected to a Surgical operation which was unjustifiable and unnecessary." . . . "I may state, in conclusion, that I consider Richard Bailey's death is entirely attributable to the unskilful Surgical ordeal to which he was subjected in the Hospital by Drs. Anderson and Bowerbank; that the treatment of his case was conducted without science and without the exercise of ordinary judgment; that his death has been the necessary and inevitable result of such errors; and that the attempt which has been made by Drs. Bowerbank and Anderson, to attribute the fatal result to bad ventilation, filthiness of the wards, pestiferous exhalations, and other causes, is as illogical and as absurd as if a Surgeon were to say that a patient who had a carving knife driven through his liver might probably not have died had he not unfortunately neglected to wash his face and comb his hair on the day of the accident!"

The Caribbean Islands were, we believe, discovered by the countrymen of Gil Blas, and whilst reading the account of this inquest we are tempted to suppose that the code of Drs. Sangrado and Cuchillo still regulates Professional relations in those favoured climes. We hope that the Jamaica public are edified, and that they will entertain a proper respect for a Profession in which the members so readily sacrifice each other to the public good.

MODERN DERMATOLOGY.(a)—No. I.

For many years two or three Practitioners have reigned almost supreme as specialist authorities on diseases of the skin, and original English works on dermatology have been very few in number. Dictionaries, encyclopædias, and systems of Medicine contained a chapter or two on the subject, and at rare intervals there appeared an incomplete monograph, as that of Burgess; but Erasmus Wilson's book was for a very long time the only full and complete work produced by an English author. During the last year or two, however, there has been a sudden and copious outpouring of monographs on skin disease, the above list forming but a portion of the wealth so vouchsafed us. If the student ever felt inclined to complain that he had only "Hobson's choice" when he asked what was the best English work on skin diseases, he will not, we hope, be so ungrateful as to groan under the *embarras de richesses* now presented.

We should feel greatly obliged to any one who would tell us what is the real exciting cause of this violent eruption of human dermatology. It is not within our knowledge that there has been of late any great and rapid advance in our comprehension of the physiology and pathology of the skin sufficient to explain it. Had there been any remarkable increase in the frequency of skin diseases, this would fully account for an increased and wider spread anxiety on the part of the Profession to set forth the healing powers of Medicine; but though we have heard it alleged that scabies has been much more generally prevalent since the Crimean War, we have not heard of any alarm as to other affections of the skin. Is there a suspicion that one or more of the thrones of the healers of skin diseases may, or must ere long, be vacant; and hence a struggle as to who shall show himself most worthy to grasp the sceptre? Has the "ôte toi que je m'y pose" principle had any share in exciting so many pens into activity? It has been suggested to us that, perhaps, members of our Profession have themselves been suffering to an unusual extent from these maladies, for personal familiarity with a disorder has not rarely led to a close and successful study of its pathology and treatment. We hope, for the sake of the estimable authors of the works above enumerated, that this explanation has no foundation in fact; but we should, as a matter of physiological curiosity, like to know whether or not dermatologists suffer much from disease of the skin. We cannot help fearing this may be the case; for it is, we believe, an admitted fact that continued concentration of the attention on any organ of the body is capable of exciting functional, if not organic, disorder of it. We doubt whether any one can attentively read through the list of works at the head of this notice without a feeling of irritation, more or less severe, being excited in some part of his cuticle—an irritation, however, as transient, we trust, as superficial; but we confess that we do not, without considerable fear of possible consequences, undertake the duty of such close and prolonged study of all these works as is necessary to qualify us for the task of reviewing them. "Fais ce que dois, advienne que pourra" is a grand old *dévise*, and, thinking of it, we summon up courage for the work before us.

The first difficulty that meets any one who attempts the study of skin diseases is the terrible one of classification,—the despair alike of students and of teachers, of writers and of readers, but which seems to possess an irresistible fascination for dermatologists. Nearly every writer on diseases of the skin first quarrels with all existing classifications; then confesses that the time has not yet arrived for a perfect classification; and then, instead of adopting the least imperfect of those already propounded, proceeds to modify one of them, and so to make confusion worse confounded, and to add to the bewilderment of the unhappy student. Thus, Dr. Hillier gives us Willan's classification, Hardy's, Hebra's, Dr. A. Buchanan's, and one of his own. Dr. Tilbury Fox supplies "a series of comparative tables, illustrating the systems of Alibert, Willan, and Bateman, with Dr. Gull's modification, Mr. Erasmus Wilson, Startin, Cazenave, Buchanan, Hebra, Hardy, and a mixed form" of his own. Mr. Williams only treats of "skin diseases of constitutional origin," and actually does not classify them anew, but is content to use Bazin's classification for some forms, and Hardy's for others. Mr. Wilson gives us an interesting chapter on classifications and principles of classification from Plenck's days till now, and furnishes a new system of his own; but Mr. Wilson is a veteran student of dermatology, and won his spurs as an author in that field many years ago, and we look with very different feelings on a new classification from him and on one from a recruit.

All classifications may be broadly divided into (*a*) those which are based on the *visible* characters of the disease, and are *anatomical* or *pathological*, as Willan and Bateman's; and (*b*) those which are called *natural* classifications, founded on the *nature* and *cause* of the diseases. The latter are *etiological* and *therapeutical*, such as Alibert's, Hebra's, and Hardy's. It is, perhaps, generally acknowledged that the first are especially

Handbook of Skin Diseases for Students and Practitioners. By Thos. Hillier, M.D., Lond., M.R.C.P., Physician to the Skin Department of University College Hospital, Physician to the Hospital for Sick Children. London: Walton and Maberly. Pp. 367. 1865.

A Clean Skin: How to Get it, and How to Keep it. Skin Diseases of Constitutional Origin: their Etiology, Pathology, and Treatment. By John Wilkin Williams, M.R.C.S.E., of St. John's College, Oxford, late House-Surgeon to the Lock Hospital, London. London: Simpkin, Marshall, and Co. Pp. 114. 1864.

Treatment of Diseases of the Skin. By Dr. William Fraser, Lecturer on Materia Medica to the Carmichael School of Medicine. Pp. 174. Dublin: Fannin and Co. London: Hardwicke. Edinburgh: Maclachlan. 1864.

Skin Diseases: their Description, Etiology, Diagnosis, and Treatment; with a Copious Formulary. By Tilbury Fox, M.D., Lond., Senior Physician to St. John's Hospital for Skin Diseases, Physician to the Farringdon General Dispensary, Author of "Skin Diseases of Parasitic Origin," etc. Pp 314. London: Hardwicke. 1864.

Photographs (coloured from life) of the Diseases of the Skin. By Alex. Balmanno Squire, M.B., Lond., Surgeon to the West London Dispensary for Diseases of the Skin, Lecturer at St. Mary's Medical School. Nos. 1 to 5. London: J. Churchill and Sons.

The Classification of Skin Diseases; containing a Tabulated Arrangement of all the Principal Modern Classifications, and a Modified Scheme. By W. Tilbury Fox, M.D., Lond. London: Hardwicke. 1864.

adapted for aiding in diagnosis—are *educational;* but it is objected that though they enable the student to readily recognise a disease, they teach him nothing as to its cause and treatment. It will not be denied that the anatomical basis of classification obtains in general medicine,—we speak of pleuritis, pneumonia, and bronchitis, of pericarditis, carditis, and endocarditis, and so on—and that, therefore, to adopt this basis for a classification of skin diseases has nothing unusual in it; but neither will it be denied that, could we always state correctly the cause of disease, the "natural" system of classification would be the most perfect and most scientific; but for how many skin diseases are authorities agreed as to causation? Take a very common one—herpes zoster; some will say it is a blood disease, others a neurose. Even in what many term "parasitic," but Mr. Wilson "phytodermic" diseases, the greatest difference of opinion prevails as to nature and causation. Dr. Tilbury Fox ("Classification of Skin Diseases," p. 14) says:—"In Mr. Wilson's essay you will see the theory broached, that the favus matter is produced from the development of the nuclei of pus cells; that the fungus is not vegetable, or, if vegetable, that it exemplifies the conversion of an animal into a vegetable product. We are certain of our cancers, our atrophies, and hypertrophies, but of our commonest skin diseases we know little, *ex. psoriasis.* Even in lichen we are not agreed as to the seat of the papules. Wilson and Cazenave say they are seated at the orifice of the secretory follicles; Hebra, Hardy, and others, that they are new formations." We quite agree with this writer when he adds:—"It seems to me, looking the state of things fairly in the face, that we cannot, in the present state of pathology, make much advance on the old system, and that we ought to use great care and discretion in the introduction of any new arrangement and detail which, as time advances, will probably be refuted and displaced." He goes on to ask, "What, then, are we to do in the meantime?" We should be inclined to reply, "Use that existing classification which seems to you the best; granted it is imperfect, but why add another which you must allow will also be imperfect?"

We believe that for working and teaching purposes the best system is the Willanean, enlarged according to actual advances in knowledge; but we are far from objecting to a "natural classification" also; though much of it must be based on hypothesis it may be very valuable for pointing out the directions in which inquiry tends and knowledge is to be sought, for helping on researches as to causation, etc. What we do object to, though hopelessly, is, that every writer on skin disease should deem it necessary to burden us with a new classification. Did he thereby extinguish and replace all former ones—was he like—

> "The priest
> Who slew the slayer,
> And shall himself be slain,"

it would not so much matter; but unfortunately all the proposed classifications—*live,* we were going to say, but that perhaps would be too complimentary, but all—*exist,* to perplex and harass the students. None are bad; the most purely "natural" are partially "anatomical," and those which profess to follow the Willanean system, as Dr. Tilbury Fox's, are based on the "joint consideration of anatomical characters and the nature of causation (as far as this is known)."

Mr. Wilson has, as we have already said, by many years of labour in practice and teaching, fairly earned the right to propose a system of classification: he remarks that "*a natural classification* is the want of the hour; and a natural classification, if it could be obtained, would, without doubt, be an important gain to our science. Alibert invented such a classification. Hardy revived it; but we must confess that neither the classification of Alibert nor that of Hardy is such as to meet with our approval." He has himself in years past given a "physiological classification," and an "etiological classification," but finds that "neither was the thing we sought." Now he proposes a "classification that has at least the merit of being formed out of a practical material, and embraces every cutaneous disease at present known," and he calls it a "*clinical classification,*" "as arising out of the analysis of a large number (1000) of cases of disease."

"If," he writes, "we reject pathological lesions as the foundation of a classification, we may be led to ask, which is the *commonest* disease of the skin? The determination of this question naturally establishes a point of commencement and a standard of reference, while the remaining diseases may possibly fall into their proper places in a systematic arrangement, naturally, and as a matter of course. Thus, if it be shown that the commonest disease of the skin is eczema, we may take the leading characters of eczema and establish a group of *eczematous affections.* Now, as eczema is a disease which is not limited to a part, or to a single tissue of the skin, but is general in its invasion, and capable of attacking every region of the cutaneous surface, we may follow up eczema with three other groups possessing a similar generality of character, and, like the eczematous group, each represented by a substantive disease: for example—erythema, which we will take as the type of erythematous affections; pemphigus . . of bullous affections; and Furunculus . . . of furuncular affections. After these general affections, we may consider next the affections of the nerves, the vessels, and the relations subsisting between the vessels and their contained blood. These will furnish us with three groups—viz., Nervous, Vascular, and Hæmic affections. After the tissues in general, . . we may take the disorders of development, nutrition, and growth. . . We may next turn from disorders common to the skin to what may be considered as specific affections . . Zymotic affections. The peculiar disease Alphos may be taken as the type of Alphous affections; Struma will typify Strumous affections; Syphilis, Syphilitic affections; Cancer, Carcinomatous affections; and Elephantiasis, Leprous affections. Having disposed of specific affections, there remain the affections of the special apparatus of the skin—namely, the hair and hair-follicles, the sebiparous apparatus, the chromatogenous apparatus, the sudoriparous apparatus, and the nails. Lastly, we may add a group of Traumatic affections, and one of Phytodermic affections."

In all twenty-two groups. Mr. Wilson himself probably hardly hopes that dermatologists generally will accept his "clinical classification" so far as to deny themselves the pleasure of making each another new one, but it does appear to us practical, and well worthy of consideration.

THE WEEK.

PHARMACOPŒIA FOR INDIA.

We announced some months since that a scheme for the publication of a Pharmacopœia specially for India was under the consideration of the Indian authorities, and that it had been submitted to the Governor-General for his opinion. We are now happy to learn that the scheme has been sanctioned, and is forthwith to be carried into execution. The object of the proposed work is mainly to bring in an official and succinct form to the notice of Medical officers serving in India the physical and chemical characters and therapeutic application of those indigenous plants and drugs of India, which, though not officinally recognised in the British Pharmacopœia, have been proved by European experience to be possessed of valuable medicinal properties, and which may, in many instances, be advantageously substituted for more costly imported articles. The preparation of this work (subject to the control of a committee) has been entrusted to Mr. Edward John Waring, of the Indian Medical Service, the author of a "Manual of Practical Therapeutics," whose numerous contributions on the subject of Indian Materia Medica in the *Indian Annals of Medical Science* and *Madras Quarterly Journal of Medicine* for several years past prove that he is peculiarly well qualified for the undertaking. The members of the committee at present in London, comprising Sir Ranald Martin, President; Drs. Wright and Thomson, the great Indian botanical authorities; Dr. Forbes Watson, Mr. Daniel Hanbury, and Mr. Waring, had an interview with Lord Dufferin, the Under Secretary of State, on Wednesday last, previous to commencing their labours, the results of which,

if judiciously conducted, will doubtless have an important bearing on the progress of Medicine in our Eastern Empire. We wish the undertaking every success.

QUACK ADVERTISEMENTS.

We learn from a respected correspondent that the *Oxford University Herald* of March 4 contains many most objectionable advertisements of the "Manly Vigour" class. Can Mr. Vincent, the publisher, be aware of the moral poison he is thus disseminating? It is curious to notice the turn which many of these advertisements have taken. They now harp upon that string which we hope our respected Wine Commissioner has put a great deal out of tune—the phosphorus myth. Now that this has fallen into the hands of the quackish fraternity, we shall have the satisfaction of seeing it abandoned by respectable wine merchants and by writers of Medico-chemical puffs of wines. Here are specimens:—

"*The Phosphorised Nervine Tonic.*—The new Chemical Combination of Phosphatic Salts, Quinine, Iron, etc., containing all the Essential Constituents of the Blood, Brain, and Nerve Substance. Great philosophical and chemical research has led to the discovery of this invaluable remedy in its present perfect state, agreeable to the palate, and innocent in its action, still preserving its wonderful properties, affording immediate relief, and permanently curing all who suffer from wasting and withering of the nervous and muscular tissues, total and partial prostration; and every other exhaustive derangement of the system. It regenerates all the important elements of the human frame. 'As phosphorus in a state of nature illumines the darkness, so the exhausted frame revives when impregnated with its electrical properties.'

"Prices—11s. per bottle, or four 11s. bottles in one, 33s.; and in cases containing three 33s. bottles, £5, which saves £1 12s., packed securely and sent to all parts of the world."

"*The Invigorative Nervine Essence.*—The most scientifically prepared and most powerful nutritive cordial ever introduced; restores to their normal condition all the secretions, on the integrity of which perfect health depends. It is a specific for debility of all kinds, and from its containing among other ingredients pepsine and phosphate of soda will prove highly beneficial to the nervous and dyspeptic. Price 8s. per bottle, or four quantities in one for 22s."

We only hope that pepsine will not fall into bad hands.

THE PROPOSED PALACE OF JUSTICE.

It is now almost certain that the law courts are to be brought together under one roof, and that we are at last to have a "Palace of Justice" worthy of the metropolis. Several sites have been proposed, but that which seems to meet with most approval is the ground bounded on two sides by Carey-street and the Strand, and on the other two by Bell-yard and Clement's-inn. Here, a space of more than seven acres may be obtained at a comparatively moderate price; and, by a wholesale clearance, it may be fitted to receive the new edifice. At present, the ground is covered with houses, and densely populated. A Fellow of the College of Physicians, formerly connected with the Carey-street Dispensary, writes to the *Times*, and says that the neighbourhood is overcrowded, that some of the houses are hotbeds of disease, and that it will be a very good thing to pull them down and to disperse the inhabitants. It is estimated that 384 houses will have to be sacrificed, containing a population of about 4000 individuals, and those chiefly of the poorer class. It is all very well to break up a *rookery* and to build handsome and commodious law courts, but what is to become of the people who are thus turned out of house and home? Some may be inclined to reply,—"Let them avail themselves of the workmen's trains, which have lately been started on two or three of the railways; let them live in the outskirts of the town, where they will find better accommodation at a lower price and in a purer air." We are glad that the system has been begun; we are happy to hear that a large number of mechanics now live in the suburbs and travel backwards and forwards to their work. But, even after the system has reached its full development, there must remain a large balance of poor whose occupations compel them to live in town. Many of those who inhabit the alleys and courts between Carey-street and the Strand are engaged at Covent-garden-market or at Clare-market, and have to be at their posts late at night and early in the morning. It would be impossible for them to live at a distance. Where are they to go? What is to become of them? We were glad to observe that in the debate which took place in Parliament on the subject of the new courts of justice, the interests of the poor were not forgotten, and there is reason to believe that the Government may do something by building, or encouraging others to build, houses for the poor in the neighbourhood of the proposed site. If this is judiciously done, the concentration of the law courts may be something more than a boon to lawyers and their clients. It may be a great sanitary improvement, by breaking up an overcrowded district, by leading some of the humbler class to remove into the suburbs, and by providing better accommodation for those who are obliged to remain in town.

PARLIAMENTARY.

In the House of Commons on Thursday, March 16, in his speech on the Army Estimates, the Marquis of Hartington stated that the diminution shown this year in the Medical vote arose simply from the reduction of the force engaged in active operations in New Zealand, and the total cessation of the operations carried on last year on the Gold Coast.

On Friday, on the motion for the second reading of the Union Officers (Ireland) Superannuation Bill, Colonel Dickson said that he approved the Bill, but wished it so altered as to include Medical officers and the clerks of Unions, who certainly were entitled to superannuation after long and faithful services.

The Bill was read a second time.

Sir F. Kelly obtained leave to bring in a Bill to regulate the qualifications of chemists and druggists.

The Bill was then brought in and read a first time.

On Monday, in Committee upon the Army Estimates, £246,544 were voted for the Medical establishment, services, and supplies.

On Tuesday, in Committee of the whole House, Sir J. Shelley moved for leave to bring in a Bill for regulating the qualifications of chemists and druggists in England and Wales. As the hon. and learned gentleman opposite (Sir F. Kelly) had already a Bill before the House upon this subject, he proposed, if the motion were agreed to, to fix any future stages of his Bill for the same days as those on which the Bill of the hon. and learned gentleman was set down, so that, if necessary, they might both be referred to a Select Committee.

Sir F. Kelly said that as soon as he was acquainted with the provisions of the Bill about to be introduced he should be happy to communicate with the hon. baronet, and between them a measure might be agreed upon calculated to work satisfactorily. If, however, as he had some reason to believe, the measure of the hon. baronet went beyond his own in many particulars, he should be sorry to risk the loss of some one Bill of a practical nature this Session by striving after objects which might prove to be unattainable.

The motion was then agreed to, and leave was given to introduce the Bill.

FROM ABROAD.—ELECTRICAL ANÆSTHESIA—THE SEINE MEDICAL BENEVOLENT SOCIETY—TAXING OF MEDICAL CERTIFICATES—FUNCTIONS OF THE PANCREAS—QUEER ADVERTISEMENTS IN THE GERMAN MEDICAL JOURNALS.

In a short article in the Lombardy *Gazetta Medica*, March 13, an account is given of a demonstration made by Dr. Rodolfi, at the Brescia Hospital, in the presence of a large number of Medical Practitioners, of the power of the electrical current to induce local anæsthesia. This is complete enough to admit of the execution of painless Surgical operations, although it does not appear that any such have as yet been performed; and it is remarkable in its extreme duration, three days being spoken of as a common period. It seems that women (especially when nervous or hysterical) are more susceptible of its action than men, and it fails to produce any

anæsthetic action in about 6 per cent. of the individuals submitted to it. In the case of a woman acted upon before the witnesses, anæsthesia of the hands began to be induced ten minutes after the application of a continuous current from a Bunsen's pile with six elements; and another woman was exhibited in whom complete anæsthesia had affected the whole surface above the diaphragm for three days. An hysterical subject manifested general anæsthesia, with paresis of movement of the limbs, and submitted to have her tongue traversed with a needle. In her case the anæsthesia continued from ten to fifteen days, gradually diminishing. The intellectual faculties continue in these cases quite undisturbed. In one of the cases experimented upon anæsthesia could not be induced, which Dr. Rodolfi attributes to the aversion the patient felt to the presence of so large a number of spectators.

In the matter of Medical benevolent societies, the French Practitioners seem well provided, for besides the Medical Association, which is comparatively a new institution, some six years old only, there are a great number of local societies of greater age. The parent society of all these, that of the Department of the Seine, has just made its report for 1864, from which it appears that its receipts for that year amounted to 31,970 francs, and its disbursements to 30,697 francs, 13,295 of these being, however, invested in the funds. Seven members received among them 4050 francs, and 19 widows 10,080 francs. Still, it is a matter of much surprise in France, as with ourselves, that so small a proportion of the Medical Profession join these societies, although we believe that this proportion is larger in France than here; and the practice of insurance of lives being much more general among ourselves, may account somewhat for the difference. However, it seems that while in the Department of the Seine there are about 2000 Medical Practitioners, only 987 of the number belong to one or other of the provident associations. The Seine Association makes a vigorous appeal for further co-operation from the Profession, showing that not only has it disbursed 200,000 francs among its members, and 37,000 to needy persons not members, and is in the possession of a capital of 300,000 francs, but that it has often used its influence in the support of the public rights and privileges of the Profession, and in the detection of imposture.

The Medical Practitioner in France comes in contact with the tax-gatherer oftener than we do here, for besides the imposts he has to discharge in common with the rest of the community, he has to pay a considerable sum annually, like solicitors do among ourselves, for the right to practise. The revenue officers have recently hunted out an old impost, which had been allowed to fall into disuetude, and insist upon its payment—viz., the signing of every kind of Medical certificate on stamped paper, under a penalty of 60 francs. It is true that the stamped blank form only costs sixpence, and the Practitioner may insist upon its being brought to him by those who desire his signature. In practice, however, and in poor localities, this, it seems, will give rise to great difficulty; for in a country so bound up in red tape as France, certificates are in constant demand, and that very frequently by the indigent classes. In fact, one of the Practitioners recently threatened by the revenue officers had merely given a certificate to an indigent person, stating that it was impossible for him to go to the Hôtel de Ville of the town he lived in. The matter has been brought before the Council of the French Medical Association (which it will be seen is far from being merely a benevolent society, but one actively interfering in all matters important to the Profession), and this body has consulted its standing counsel as to how far the demand is legal or may be resisted. His opinion is in favour of the legality of the demand made by the Administration, and he considers the person who is liable to the fine is not he who uses, but he who signs the unstamped certificate. The Council of the Association have next to deliberate as to the possibility of getting the law altered.

MM. Corvisart and Schiff having been engaged during 1859 in a series of experiments upon the functions of the pancreas and the influence of division of the pneumogastric nerves on these, deposited an account of the results in a sealed envelope at the Academy of Sciences—as is the habit with some of the second order of French *savans*, though with what useful object it would be difficult to say. M. Schiff having subsequently dissolved partnership in the property of the vital secret by publishing an account of these experiments in Germany, M. Corvisart requests a publication of the paper on the part of the Academy, which he would otherwise have regarded as premature.

The conclusions are as follows:—1. In the absence of gastric digestion, although the stomach may be full of solid or liquid aliments capable of inducing by their contact with the stomach a sympathetic or reflex action on the pancreas, this latter does not act, the formation of the ferment essential to the digestion of azotised aliments not taking place. 2. In spite of the absorption by the stomach of a considerable quantity of aliments, in the condition of aliment—that is, not having undergone the digestive transformation—the pancreas remains inactive, and gives rise to no secretory elaboration. 3. That which is required to produce active secretion on the part of the pancreas, and for its efficacious ferment to become elaborated in abundance, is the absorption of digested aliments or peptones. These peptones may be the result of either the peptic digestion of the individual or of a pepsine foreign to the individual or even to his species. 4. Dextrine exerts an analogous effect. 5. The pneumogastric nerves exert no direct effect upon the elaboration of the pancreatic ferment, for, notwithstanding their division, providing that peptones or dextrine be absorbed by the stomach, the pancreas may secrete its ferment in abundance. The influence of the pneumogastric is indirect, operating through the gastric digestion. 6. It is by the stomach and not the intestine that the absorption must take place. 7. In one word, the effectual pancreatic secretion in question is dependent upon the arrival in the blood of determinate and special materials—the gastric peptones and dextrine.

We have often been surprised at the character of some of the advertisements which appear in the German Medical journals. We copy the following from a leading Vienna journal—the *Allgeneine Medizinische Zeitung*:—1. "Remedy for Tape-worm.—On receiving, postage free, the sum of five florins, I will communicate to any Medical man a remedy which will certainly expel, without any danger, tape-worm in two hours. Dr. Stoj, Vienna General Hospital." 2. "Dr. Pattison's Gout-wadding, a preservative and curative agent in gout and rheumatism of every description, as also for pains of the face, chest, joints, etc., etc., etc. Packets at a florin each with directions and testimonials gratis." 3. "Dr. Pearce's patented Stomach Essence, a distinguished remedy in all affections of the stomach, indigestion, acidity, gastralgia, etc. Price one florin per bottle. The valuable character of this essence is shown by the testimonials of many thousand credible persons of all nations." It would seem that some of the English quack medicines are being patronised in even Medical circles in Germany.

THE LEVÉE.—At the levée held Wednesday, March 22, by H.R.H. the Prince of Wales, by command of Her Majesty, the following members of our Profession were presented:—Surgeon Daniel John Doherty, 13th Prince Albert's Light Infantry, by Colonel Lord Mark Kerr, C.B. Assistant-Surgeon J. R. A. Douglas, 4th Royal South Middlesex Militia, by Lieutenant-Colonel J. Scriven. Assistant-Surgeon John Elliot, M.D., Bengal Army, on his return from India, by the Secretary of State for India. Sir Ranald Martin, by Sir Charles Wood. Assistant-Surgeon J. J. M'Dermott, Bengal Medical Staff, by the Secretary of State for India. The following attended the levée:—Drs. Armstrong, R.N.; George Moore, R.N.; and Thomas Watson Lavies; and Mr. Fergusson.

REPORT ON CHEAP WINE.—NO. XIV.

(By our Special Empirical Commissioner.)

A few more words on port wine and sherry—How port wine is made—Effects of alcohol on wine—How to make old dry port—Past and present prices—The wine disease—Exportation of British spirits to Portugal—Oxford port—Hospital port substitutes—Sherry and its counterfeits—Good Marsala.

THERE are some facts about the stronger wines in common use, and especially about port and sherry, that really deserve serious consideration on the part of the Practitioners who prescribe and the public that drink them, whether as an ordinary article of diet or for the relief of weakness or disease.

With regard to port wine, there is no secret as to the method employed in manufacturing it; for the very best is a manufacture rather than a natural product, and is the result of natural processes checked and modified, and as I think perverted, to suit an unwholesome taste.

I have said over and over again that the natural proportion of alcohol in wine and other fermented liquors is about 20. often lower, as in the light Bordeaux and German wines, somewhat higher in the south of France, Greek, and Spanish. It may possibly rise to 26 or 27, and by the evaporation of the watery parts of wine from casks may rise to 30. Still, practically speaking, all wine above 26 per cent. is artificially fortified, and more especially if it range, as sherries do, from 32 to 40, in port from 34 to 42.

Now the following statement may be relied on as an account of the composition of port wine of the first quality. It was given to me by one who has a better right to know than most men:—

COMPOSITION OF PORT WINE OF FIRST QUALITY.

To the pipe of half-fermented must is added, to check fermentation—

	25 Galls.	of brandy	=	37·5 proof galls.
Say	5 ,,	elderberry juice to colour		
	6 ,,	more of brandy	=	9· ,,
	2 ,,	,, after racking	=	3· ,,
	1 ,,	,, on shipment	=	1·5 ,,
	39 liquid galls.			51· ,,
	76 of wine.			
	115 galls of port wine.			

Taking the probable strength when half fermented at 14° (the highest natural strength known being 28°), the strength would thus be about 42°, or a little above it.

In considering this statement, let me ask my readers to ponder on the quantity of alcohol; the quality thereof; the effects of alcohol upon wine, as wine; and the result as a beverage for civilised beings.

The *quantity* is such that a glass of port wine equals in strength more than two-fifths of a glass of brandy. As to *quality*, it is not brandy, but English rectified spirit. The effect of alcohol upon the wine is, first, to check fermentation and preserve a certain lusciousness; but then the wine, imperfectly fermented, tends to ferment again, unless held in check by further doses of alcohol; secondly, the addition of brandy really robs us of so much wine—we lose the virtues of the grape juice; thirdly, the effect of brandy upon wine is to kill it as wine; to precipitate colouring and extractive; to make it prematurely old and tawney, without the precious perfume which really old wine has. Perfectly fermented wine will keep, however weak it be, in alcohol. Wine imperfectly fermented, whether that imperfection result from the constitution of the grape, as is alleged to be the case in the South of France, or from defects in manufacture, or from *malice prepense*, as in Portugal, can be preserved from decomposition by the addition of strong alcohol. This addition, which the French call *vinage*, and which they regularly apply to the wines of four Southern departments, the Bouches de Rhône, le Gard, l'Herault, and les Pyrénées Orientales, does to the wine what it does to all vegetable juices; for example, to the juice of dandelion, when the *succus taraxaci* is prepared. It makes the wine turbid; precipitates albuminous matter, which ought to have been got rid of by fermentation; and when they have settled, and the wine is racked off, it is much better able to bear carriage. We can now understand how *fruity* port can be rapidly transformed into the *prime port, old in the wood, tawney, and very dry*, which is sometimes offered to the ignorant at low prices. A good dose of spirits and a little wine will make a tawney liquid, thin to the palate, but fiery to the throat, with scarce a smell of wine in it, and with little, if any, crust on the bottle or cork, which there must have been if the wine had grown old, and deposited its extracts in bottle. The phrase *old in the wood* applied to cheap port really means this:—Here is a liquid with little extractive matter. A man of common sense, who knows that port wine ought to have a good deal of extractive, will naturally look to the cork and the bottle to see if it has been deposited there as a crust by lapse of time; and if so, he will naturally expect good flavour, softness, and no prominent alcoholic taste. But this cheap dry port has no crust and no flavour, and a *very* prominent alcoholic taste. The wine merchant vows that it dropped its extractive through age in wood. *Credat Judæus!* Any one who knows the virtues of spirit, and who tastes it raw in the dry port, knows better. Yet, alas! so little is a common-sense knowledge of wine prevalent, that I have actually had new, tawney, almost wineless, alcoholised port, of choking strength, offered to myself as a *bonne bouche!!*

Then as to the effects of port wine upon civilised man, if there be one fact better proved than another, it is that it cannot be drunk habitually in small quantity, nor yet be resorted to as an occasional luxury in larger quantity with safety, by large numbers of our population. Ask any four men of forty and over, and three will say, "I can't drink port; I am afraid of the gout." It is curious, on looking through the evidence given before the Committee of the House of Commons on the Wine Duties, in 1852, to see even then how the veteran wine merchants and an old grower, who were examined, spoke of the taste for port wine as "vicious," and as "declining." Mr. H. Lancaster speaks of the consumption then as declining year by year, in proportion to the population. Mr. T. G. Shaw, whose valuable work on "Wine, the Vine, and the Cellar" I have more than once quoted, described the taste for port unmistakeably going down in 1852, and so did Mr. Cyrus Redding, author of the well-known treatise on Wine. At and before that day, abundance of evidence was laid before the English public of the misdoings of the Portuguese Government, and the manipulations of the wine-growers, and how the last were compelled to make and send a wine unnaturally sweet, strong, and black.(a)

Still there is no denying the fact, and it would be very ungrateful to deny it, that the old port wine was an admirable medicine when we wanted to pull a poor wretch up out of a fever or other state of intense debility. Good port wine of the right sort, which answers to the description given it by Forrester—"lively and clean on the palate, dry flavoured, with an enticing bouquet; colour varying from pale rose to bright purple; perfectly transparent and mellowing with age, the rose becoming tawny, and the purple ruby, both of which colours are durable"(b)—such port wine, I say, though good as an alcoholic medicine, yet if of higher alcoholic strength than 30 was not fit for the ordinary drink of healthy persons. It would give, and did give, the gout. It was serviceable as a tonic in cases of great debility; but then, as now, a light, unbrandied wine was demanded by all who had taken the trouble to investigate the subject, as necessary for the habitual beverage of healthy persons, and they demanded it on the score of morals no less than of health.

Whilst, then, I grant all that need be said in praise of port wine, I must add that there is one fact which puts us in an entirely different position with regard to it, from that of ten years ago; and that is *price*. There was cheap port wine then—there is none now. Prices have risen 30 to 100 per cent. Fifteen years ago I bought some of the best port in the world, of 1844, of one of the first wine merchants in London, at 48s. What do we get at 48s. now? (c) A liquid intensely strong, and with little or no port wine in it; red Tarragona, or some other cheap wine, and a little port, fortified up to 42°. I affirm that when benefit is derived from such port wine, it is from the alcohol, and that it would be better either to buy a cheap red wine that has no

(a) See "Report of Minutes of Evidence on Import Duties on Wine." Ordered by House of Commons to be printed, June 18, 1852.

(b) "A Word or Two on Port Wine." Edinburgh: Menzies. 1844.

(c) This very day I asked a man, who had been accustomed to dine at a City tavern for the last thirty years with a Masonic lodge, "What do you drink?" "I drink claret; I can't touch port." "Is the port good?" "Yes, but very dear. Common port used to be 5s., now it is 8s., a rise of 60 per cent."

price added for the name "Port," or else to give an equivalent of brandy.

In order to make it clear that to get port wine equal to that of ten or fifteen years ago, we must pay almost double the price; or, if we pay equal price, that we don't get half the wine, let me quote from the admirable "Reports of H.M. Secretaries of Embassies and Legations on the Effects of the Vine Disease. Presented to both Houses of Parliament, and printed 1859."

The production of port wine was 94,122 pipes in 1851. It fell to 14,673 in 1856; it was 17,353 in 1859. Wines of this last vintage, says Mr. Barron, the Secretary of Legation, require a more than average proportion of alcohol. This used to be supplied by the native brandy, which alone could be legally used, but by a decree of September, 1858, foreign spirits might be admitted. The value of port wine has doubled since 1848; in the former year crude wine was valued at 84 milreis per pipe, in the latter at 171. So much for the effect of the vine disease in decreasing quality and increasing price. Now for a few official words on port wine generally.

No port wine can be shipped from Oporto to England, unless "approved," and unless it receive a "bilbete," or ticket of approbation, from persons authorised by Government. "To be 'approved,' port wine must possess certain qualities which the grape juice alone cannot impart. It must possess body, sweetness, and colour enough to qualify it for 'benefiting' other wines, or in the words of the law,—*para si, e para dur*. This disposition is founded on the notion that port is required by us principally for blending with other wines. This has led to the production of that artificial, thick, strong, and sweet compound in such great demand for tavern use in England. *A simple unloaded wine cannot lawfully receive a 'bilbete,'* but must be shipped under a purchased one."

Pure port wine, unknown in this country, unbrandied and unsweetened with Jeropiga—(for so the compound of elderberries, grape juice, and brandy is called which is used to colour and thicken the wine) is a wine of Burgundy character, and quite unlike the stuff commonly known as port.

To conclude this part of my subject, I will give a short quotation from Ridley's Monthly Circular for March, 1865. Speaking of the exports of British spirits during 1864, it says:—"Our best customers are the Portuguese wine growers, who have taken upwards of 1,500,000 gallons to fortify their unfermented juice.

"In 1864 we took from the Portuguese 3,342,820 gals. port wine.
,, They took from England . 1,500,000 ,, of spirit."

He must be dull indeed who does not see that in paying high prices for port wine we are really buying back the British spirits that were engendered on the banks of the Thames.

(To be continued.)

REVIEWS.

Nouveau Dictionaire de Médécine et de Chirurgie Pratiques. Tome Deuxième: Ame—Aor. Paris: Baillière and Son. 1865. Pp. 797.

The subjects treated of in this volume are in continuation of the letter A, and amount altogether to forty-three. Some of them—as the articles on "Amputation," "Anæsthetics," "Anus" (which includes its diseases), "Anæmia," "Aorta" (including its diseases), "Aneurism," and "Antimony,"—are lengthy and exhaustive, and are excellent summaries of the present state of our knowledge and of ancient and modern practice. The illustrations are also well selected and well executed. Some of the articles, as those upon certain drugs, are judiciously short, but the intention to omit nothing that might by any possibility be sought for in a Dictionary of Practical Medicine is amusingly evidenced by the introduction of a curious little article upon "Anthropophagy." The writer collects into this a number of tales showing the connexion of anthropophagy with the varieties of insanity. We are somewhat astonished to learn from M. Barallier, who writes the article on "Anti-scorbutics," that, notwithstanding the prolonged experiences of the British navy, now reaching over more than a century, the official use of lime-juice in the French marine only dates from the period of the Crimean war. He tells us that the honour of having brought about this happy innovation is due to Professor Gallerand, of Brest, who observed the good effects of its use in the English ships while cruising in the *Cleopatra* in 1855, apparently in their company. Well, the "Dictionaire" is inaugurating a new epoch. It is to be hoped that never again will British experience take a hundred years to cross twenty miles of salt water.

We shall on this occasion content ourselves with a single extract from the volume, and shall select for the purpose M. Lorain's account of the operation of iron in the treatment of anæmia. Experience having decided on the value of iron as a remedy, M. Lorain says:—

"Two theories have been advanced, one of which has regarded the iron as entering into and combining with the blood; the other has seen in the iron merely a stimulant to the digestive mucous membrane. The partisans of the former theory have aimed at finding out the most readily absorbable preparations, such as are most capable of being modified by the blood and of entering into combination with it. These efforts have resulted in an extraordinary multiplication of pharmaceutical preparations and in an excessive employment of the iron. This infatuation is even now far from being at an end, notwithstanding that bitters have again been received into favour, and that the physical excitants (hydrotherapeia) have made some progress in Professional opinion. So far as the physiologists are concerned (C. L. Bernard), it is a matter of demonstration that the salts of iron exercise a special action upon the gastric mucous membrane. All parts of the mucous membrane which they come into contact with assume a more active circulation. The iron is thus a direct excitant of the digestive organs, and this property suffices to explain the success met with in so many cases in which chlorosis or anæmia are maintained by dyspepsia. Is there any need to say that anæmia will be treated according to the malady which keeps it up? One patient has one sort of anæmia, another patient another sort. The leading treatment is that which takes up for its motto '*Sublata causa tollitur effectus.*' In Medicine, the most difficult thing is not to treat a disease, but to recognise it, and it is often merely satisfying oneself with words to designate a malady by a symptom, and to say such and such a symptom requires such and such a remedy. Do we not know that the organism shows itself in that condition which we call a morbid symptom under the influence of a host of different causes? It is necessary, therefore, to rise to the source of the anæmia, and not to confound under the same name and the same therapeutical *régime* a patient with cancer, one suffering from phthisis, and a chlorotic girl. To administer iron to every anæmic patient as a panacea would be to be guilty of a serious mistake."—P. 214.

Again, we advise British Practitioners to possess themselves of the volumes of this work as they come out. No important contribution to Medical or Surgical science is overlooked up to the very date of publication.

The Use of the Laryngoscope in Diseases of the Throat; with an Appendix on Rhinoscopy. By Morell Mackenzie, M.D. Lond., M.R.C.P., Physician to the Dispensary for Diseases of the Throat, etc. London: Hardwicke. 1865. Pp. 154.

This book is well calculated to popularise the method of investigation which passes under the name of laryngoscopy. It is throughout amply illustrated by well executed and very clear wood cuts, showing the form and mechanism of all the instruments employed in the practice of it, and also the method in which they are severally used. It is one of the best books for a beginner that we have seen. Although the book is in octavo there is not much upon a page, since the publisher has taken advantage of the comparative cheapness of paper to give the reader the benefit of a large type with good spaces between the lines. This is one method, and to our mind one of the best of methods, of utilising the boon of the Chancellor of the Exchequer, for to those who read extensively the character and size of the type is of no small moment.

The first chapter is devoted to the history of laryngoscopy. It occupies 33 pages, a large space considering the size of the entire book; but as the author probably thinks this matter of more importance than we do, and also necessary to ensure completeness, we shall not quarrel with him on this account. The second chapter describes the laryngoscope and the method of illumination. The third the principles, practice, and special difficulties of the art of laryngoscopy. The fourth describes the healthy larynx as seen by the aid of the instrument. The fifth the accessories of laryngoscopy, such as magnifying instruments, the self-holder, head rest, and the arrangements for making evident to others that which the

operator is himself viewing. The sixth chapter enters upon the application of remedies to the larynx, such as powders of various kinds, solutions, galvanism, etc. The seventh describes the operations upon the larynx. And the eighth contains some very brief remarks upon the manipulation of laryngeal instruments. So that it will appear that the subject is fully although concisely discussed.

It is not at all necessary for us to follow Dr. Mackenzie through the whole of his chapters. We shall just quote in conclusion the author's remarks upon the "special difficulties" of the practice of the art, with a view to give our readers an idea of his style of writing, for we have no doubt ourselves that the book will meet with a rapid and extensive sale.

"The difficulties solely dependent on the Practitioner's want of dexterity have been already considered; but a few words must be devoted to those in part due to the patient. The obstacle may be either undue irritability of the fauces, a peculiar action of the tongue, or a pendent condition of the epiglottis. As regards faucial irritability, it is to be observed that, though this condition sometimes exists of itself, it is far more often caused by the clumsiness or inexperience of the Practitioner. Most patients can be examined with facility at the first sitting, and only a small proportion require any training. With timid patients—especially women—on first using the laryngoscope, it is well to place the mirror for a second on the back part of the palate, without being too particular about seeing anything. By introducing the mirror once or twice in this way, the patient's confidence is secured, and a more fruitful examination may afterwards be made. For reducing an unusually irritable condition of the fauces, the internal administration of the bromides of potassium and ammonium has been recommended; but my experience has proved the total inutility of their employment. Some advise that the patient should be directed to inhale a few whiffs of chloroform; but in those rare cases which present much difficulty I have found the best effects result from sucking ice for about two minutes before the mirror is to be introduced. The most irritable fauces cannot resist this plan. The conformation of parts sometimes causes some difficulty. Thus when the tongue is drawn out, it sometimes forms an arched prominence behind, which causes trouble in introducing the mirror, and difficulty in seeing it when *in situ*. It is due to reflex action, and will be best avoided by pulling the tongue less out than usual, keeping it level with the mouth (that is to say, not holding it down towards the chin), and by cautioning the patient not to strain. Enlarged tonsils sometimes embarrass the operator. In this condition a small oval mirror should be used. An unusually large or pendent epiglottis causes a more serious impediment to laryngoscopy. When the valve is very large, it sometimes shuts out the view of the larynx; but the same result is more often caused by unusual length or relaxation of the glosso-epiglottidean ligaments. In the production of high (falsetto) notes, the epiglottis is generally raised, and this also happens when a person laughs; the observer will therefore do well to take advantage of these physiological facts. In a certain number of cases, however, the epiglottis remains obstinately pendent. For elevating the valve in these cases, various instruments have been invented (by Voltolini, Bruns, Fournié, Lewin, and others), and I have myself had one contrived which has proved useful in some cases. Most of the instruments hitherto invented, however, cause so much irritation that they cannot often be employed with advantage. When the epiglottis covers the larynx in the manner described, the laryngeal mirror should be introduced lower in the fauces, and more perpendicularly than is usually suitable. In almost all cases the arytænoid cartilages surmounted by the capitula Santorini can be seen, and from them we can judge with tolerable certainty as to the mobility of the vocal cords; the state of the mucous membrane of the larynx in other parts cannot, however, be safely inferred from the condition of that which covers the arytænoid cartilages."—P. 60.

The above extract occupies in the original just three pages.

The Science and Practice of Medicine. By Dr. Aitken. Third Edition. Griffin and Company.

Upon the publication of the second edition of this work we gave it the warm welcome of a hearty and strong approbation. It is a gratification to the reviewer of a really good book—second only to that felt by the author himself—when he finds that his judgment has been ratified by the thorough success of its publication. In little more than six months Dr. Aitken, tells us, the second edition was exhausted, and a new one demanded. In the execution of the present one the author has performed his task most conscientiously and thoroughly. It bears the marks of a careful revision, and much new matter has been added. The third edition forms the latest and most scientific work on Medicine with which we are acquainted.

FOREIGN CORRESPONDENCE.

GERMANY.

Berlin, February 8.

During the late Schleswig-Holstein campaign, Professor Von Langenbeck, (a) who acted as Surgeon-General to the Prussian army, made, amongst many other similar operations, five times the resection of the ankle-joint in cases where the bones were crushed to such an extent that many Surgeons would have decided upon amputation of the leg. Von Langenbeck is of opinion that amputation may in many cases be dispensed with not only where the ankle-joint has been opened by a gunshot wound, but also where the bones constituting the tibio-tarsal articulation have been considerably injured. Where projectiles have passed transversely through the malleoli and the talus, a complete recovery may ensue without anything being done but incising the joint for the purpose of providing an exit to the pus, and extracting bone splinters which may be present and are accessible to the Surgeon.

It is a curious fact that the resection of the ankle-joint has many times been performed, since the end of the last century, for complicated fractures and dislocations, and for caries; amongst others by Messrs. Gooch, Moreau, Cooper, Jäger, and Textor; but that in none of the numerous wars which have been waged since that time has the same operation been made in gunshot injuries of the ankle-joint. M. Velpeau, it is true, states in his treatise on operative medicine that a Mr. Read had, in a case of gunshot wound of that joint, sawn off the lower ends of the tibia and fibula, and that a useful foot had been the result. Most authors quote this case, after Velpeau, as one of resection; but on close analysis it appears that the operation, which was performed after the battle of Fontenoi, in 1745, consisted merely of the extraction of fragments of bone from the crushed ankle-joint, and not of resection, which latter was not known before 1768. Nevertheless, the case in question, which is fully mentioned in Faure's prize essay on amputation (1759), is one of great interest, and shows how much may be done by conservative Surgery.

Neither in the Crimean nor in the last Italian war has the resection of the ankle-joint been performed. Recent authors on Military Surgery, such as Demme and Legouest, reject the operation altogether as unsuitable. Now, Professor Von Langenbeck had, since 1850, four times performed it in private practice. In all these cases there had been long-continued suppuration after injuries. In two of them there had been complicated dislocation of the foot; in the third, dislocation of the foot, with fracture of both malleoli; in the fourth, that of an old Russian officer, the ankle-joint had been crushed in the battle at the Alma by a Minié ball. In the first two cases a piece of the tibia, three inches long, was resected; in the third, both malleoli and the surface of the talus; in the fourth, a piece of the tibia, four inches long, and the largest portion of the talus. In all these cases the periosteum was completely preserved, and the cure resulted without shortening, abundant osseous tissue being formed. In the second and fourth cases there was anchylosis; but in the first and third a moveable ankle-joint resulted. These two latter patients are now frequently seen by the Professor, and they are able to walk to any distance without inconvenience.

In consequence of the good results thus obtained, the Professor determined on setting out for the Schleswig-Holstein campaign to perform the operation whenever suitable cases might offer. He did it five times between May and August, 1864. All were late operations. One patient died of Hospital gangrene; all the others recovered. Two were Prussian soldiers; three Danish prisoners captured in the island of Alsen. In the first case a rifle bullet went into the malleolus internus and came out of the malleolus externus of the left foot. Both malleoli and the upper surface of the talus were resected, the piece taken out being two and a-half inches long.

(a) This gentleman has had titles of nobility conferred upon him for his eminent services during the late Danish war.

The joint is now anchylosed; but the patient is able to walk for a quarter of an hour at a time without inconvenience. There is no shortening, and the formation of new osseous tissue has been so abundant that the circumference of the leg operated upon is much larger than that of the other. In the second case the malleoli were splintered into seventeen pieces to the length of three inches. The re-section was done, but the patient died ten days afterwards of nosocomial gangrene. In the third case the lower end of the left tibia and fibula were fractured by a bullet, which went into the crista tibiæ, and came out at the back close to the tendo Achilles. The foot was considerably dislocated. A piece of the tibia, four inches long and broken into fourteen fragments, was removed, and the cure was quite satisfactory. In the fourth case the bullet went into the joint just below the malleolus externus, and went out by the middle of the internal malleolus. A piece three and a-half inches long, being the lower end of the tibia and the upper surface of the talus, was removed. The cure was complete about two months afterwards. In the fifth case there was total crushing of the ankle-joint, with considerable dislocation of the foot. Both malleoli and the whole of the talus were removed, and the cure was complete in about two months afterwards. The last three patients, however, when last heard of, had not yet commenced walking.

All these operations were done altogether sub-periostally; the periosteum, which was very much thickened, being torn off the bone in connexion with the fibrous envelope of the malleoli and the ligaments. The interosseous membrane was always most carefully spared, and this is a circumstance upon which much stress should be laid, because this membrane, being closely allied to the periosteum in texture, according to Von Langenbeck's observations, probably always becomes ossified, is completely amalgamated with the newly-formed bone, and serves to increase the bulk of osseous tissue. The Professor has, in his operation, never laid bare nor injured any tendons, vessels, or nerves. He has sawn through the bones with his stitch-saw by comparatively small incisions. If only one bone was crushed, this one only was removed, and the other bones left undisturbed, even if they were transverely fractured. The cutaneous incision was always made on the inner surface of the tibia or the outer surface of the fibula, but never before or behind these bones. If both malleoli had to be removed, a perpendicular incision was made on the middle of each bone. The operation was, as a rule, not connected with much difficulty, only in the fifth case it proved troublesome, as the whole of the talus had to be removed. The wound was always united by sutures, only a small opening being left for the escape of pus; after that the plaster-of-Paris splint was put on, and the wounded part rendered accessible by cutting a hole into the bandage. A day or two afterwards the splint was soaked with a solution of resin in ether, whereby it was rendered waterproof, and then local baths were employed. In most cases the first splint was left on unchanged for three or four weeks.

Real "Molluscum contagiosum" is such a rare disease that a few remarks on a curious case of this affection which was lately observed in Professor Ebert's clinique may be of interest. The patient was a little girl, aged 4, of scrofulous habits, who had two years ago suffered from caries of the os cuboideum; soon afterwards small tumours of a size varying from that of a pea to a walnut appeared on the eyelids, the nose, the forehead, temples, lips, chin, and cheeks. They secreted a putrid and most offensive semi-fluid mass. When she was brought into the Hospital she had altogether 107 such tumours, of which there were 15 on the left, and 16 on the right eyelid, entirely closing up the opening of both eyes. In the centre of these tumours there was a small dark point, which was deeper than the circumference, being evidently the opening of a follicle. When the tumours were compressed by a pair of pincers, or by a thread laid round their base, a fatty white core was pressed out through the points mentioned. On being examined by the microscope, it appeared that they did not consist of fat or sebum, but of epidermis-cells, covered by a layer of large cells devoid of nuclei, such as are found in cancroid tumours. Ligatures were passed round the base of the largest of these tumours, after which they became black, dry, and fell off. Putrid pus formed on the surface, and an application of chlorine water was then made. There was some erysipelas of the left side of the face, which, however, soon subsided. In those tumours which had not been operated upon, considerable suppuration now took place, after which they became much smaller and drier, and within a short time disappeared altogether under the influence of good food, cleanliness, baths, and cod-liver oil. Two months after admission there were only very few small white tumours in the neighbourhood of the eyes left, and the great disfigurement of the face had quite disappeared. A month afterwards, however, fresh tumours were formed, and a violent blennorrhœa of the conjunctiva supervened. These fresh tumours were not nearly so large as the previous ones, and gradually disappeared after having reached a certain size. At present the child is almost entirely cured, there being only a few traces left of the affection.

In order to settle the question as to the contagiosity of these tumours, Professor Virchow, at a time when the affection was at its acme, inoculated a dog with the contents of these tumours, which were also rubbed into the skin of the animal. These experiments, however, failed. Professor Ebert then inoculated himself with the same, first on the arm, and afterwards on the forearm, but equally without success. An idiot child was afterwards experimented upon, but in this case also there was no result. It was therefore believed that molluscum contagiosum was not a really contagious malady, when it was remarked one day that a child, whose bed was nearest to that of the patient in question, had three of the same tumours on the left eyelid, and in the course of time she got no less than nine of them. The children had been frequently playing together, and it was therefore quite probable that some of the secretion might have got into the follicles of the second child, and there gave rise to the same disease.

Professor Virchow considers the contagiosity of these tumours as established by the case related above. He says that these cases are exceedingly rare, and that the expression "Molluscum contagiosum" is by many, and chiefly by English authors, indiscriminately used for all sorts of little tumours, more especially for small encysted atheromata with excessive formation of connective tissue. He has examined several of these tumours, and could at first not satisfy himself as to whether the openings, which could be distinguished at the surface, were pre-existing apertures of follicles, or if they were caused by ulceration, and pressure of the mass from below upwards. The microscope showed that the several nodes were exceedingly similar to that form of tumour which is generally designated as epithelial cancer or cancroid. The apertures communicated with a number of long canals, which were filled with a mass consisting of an exterior layer of epidermoid cells, and an inner portion which looked like fat. In the same way we notice in cancroid tumour of the lower lip, after ulceration has commenced, deep fissures and holes which lead into canals and tunnels. But there appeared this difference between the two, that the molluscum nodes proceeded directly from the follicles, and there was only production from the surface, but the parenchyma was nowhere affected; while, on the other hand, cancroid tumour is a parenchymatous formation which can only secondarily proceed outwards, after the skin has been broken, and ulceration commenced. The mass which filled the centres of these molluscum canals, consisted chiefly of round, small, shining, corpuscles, which lay closely together and looked like heaps of cells filled with fat. But when they were more carefully examined, it appeared that they did not consist of fat, but of albumen. These corpuscles are formations which also occur in cancroid tumour, and are most probably formed endogenuously in cells, after which they become free. They are no doubt the vehicles of contagion; being the only thing which is foreign to the system, and being also found in cancroid tumour, which is notoriously infecting. By reason of their very small size they are peculiarly suited to penetrate into the smallest openings of the skin, and to be smeared, as it were, into the hair-follicles, where these are somewhat open. Professor Virchow has, therefore, endeavoured to find out whether phenomena of motion may be observed in them. They have the habitus of cells, which in other places are found to be contractile. But he has never as yet observed anything else but imbibition of liquids, and consequent change of shape in the former, but no spontaneous motion.

It would, therefore, appear that there are three different species of "molluscum." The originally so-called tumour, which belongs to the connective tissue class, Virchow proposes to call *Fibroma molluscum*; the one that has just been described might be called *Epithelioma molluscum*. Between these two principal forms stands that which is described by English authors as *Molluscum contagiosum*, but which is in reality a perfectly closed node, consisting of epidermis cells surrounded by loose connective tissue. The author who has

most offended in this way is Mr. Toynbee, who has described "*Mollusca contagiosa*" of the external and middle ear, which are perfectly closed sacs without an opening, and cannot, on this account, be contagious, as it has been proved a long time since that there must be an open orifice, if tumours are to be transmitted.

GENERAL CORRESPONDENCE.

CONSANGUINEOUS MARRIAGES.

[To the Editor of the Medical Times and Gazette.]

Sir,—Thirty years ago my attention was directed to this subject by the gentleman with whom I "served" my time as apprentice, and from that time to the present it has engaged my attention. My inquiries have embraced the lower animals, as well as man and individuals in every class of life. They received a special stimulus when I was applied to for an opinion on the subject, first by a cousin who has married my own sister; secondly, by other cousins who would not take such a step without Medical sanction, and who have abstained from uniting.

The opinions I was educated in were,—1. That a marriage between cousins was more frequently a barren one than were unions "out of the blood." 2. That deaf-mutism was a frequent result of such marriages. 3. That struma, insanity, and idiocy were such common consequences that it was a wonder if the offspring of cousins escaped them. 4. That breeding "in and in" spoilt the value of "stock."

The conclusion which experience has induced me to come to is that there is some truth in all these propositions. 1. I know two cousins, members of very prolific families, who are the only barren couple; yet, on the other hand, I know cousin couples quite as prolific as other people. 2. My information about deaf-mutism is second-hand, and by no means conclusive. 3. I do not know a single cousin couple who have a healthy set of children. I do know many who have struma in one or other form, or idiocy as the rule, rather than the exception, in every one of their families. 4. My information is second-hand—from a breeder and from papers he has sent me from time to time—and tends in both ways.

Unfortunately, I have never yet met with a cousin couple whose Medical pedigree was faultless. Such good pedigrees may and do exist in man; they frequently do in the bovine, ovine, and canine species.

The breeder's experience is that a union between faultless parents, even though they may be as closely related as father and daughter, brother and sister, etc., produces a faultless offspring; but that if there be a Medical flaw in the family history of either parent, that the flaw appears in the offspring in an exaggerated form.

Considering how few amongst ourselves are untainted by some hereditary disease, we can readily imagine how the doctrine has become prevalent that the marriages of consanguinity are bad. A consumptive father stamps a better mark on his children if he selects a thoroughly healthy country-bred wife than if he had paired with another consumptive. Few children will escape insanity, gout, syphilis, or other hereditary disease if both their parents have one or other in their "blood." Nor will their constitution be good if a father bring one disease and the mother another when they form their union. In few words, bad bloods mixed together make worse; bad blood mixed with good is better than a union of bads; good bloods, *cæteris paribus*, reproduce their like.

Now, in mixed marriages one party may be unblemished; in cousin couples if one have a taint the other often shares it, for cousins are the offspring of two brothers or two sisters. But it may happen that one cousin in a couple has a faultless family history, while the other is tainted by some hereditary flaw. In this case the offspring are better than they would have been if both had been tainted, but not so good as are offspring of strangers in blood under the same circumstances. This fact is one difficult to establish in the human race, from the limited opportunities we have of observation, but it has been established by breeders of cattle, etc. If a couple, then, have both the same taint the chance of its becoming intensified in their offspring is indubitable. If there is no flaw in the family history, there is no greater probability of disease appearing in the offspring than would occur in any other couple. This conclusion is borne out by appeals to stock breeding; it is further borne out by an appeal to the vegetable world. Most plants bear both the male and female element in the same flower—some on different flowers, and some on different growths, it may be many miles apart. Yet the seeds respectively arising from brother and sister (so to speak), from cousins, and from strangers, are all equally good. Yet, when the gardener wishes for a hybrid he always selects the most perfect specimen he possesses, that the seedlings may have the best virtues, and as few of the vices, of their ancestors as is possible.

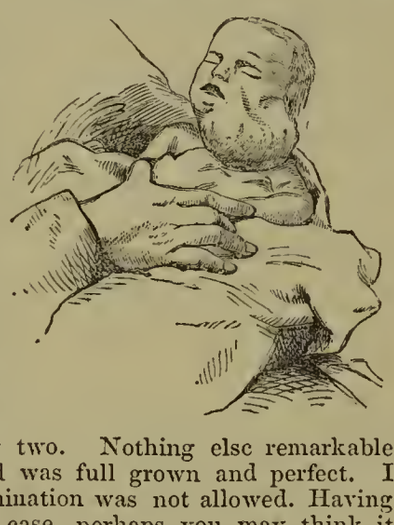
The moral is simple,—cousins of thoroughly good stock may marry fearlessly; cousins with a family taint ought to shun a closer relationship. I am, &c. T. I.

CASE OF CONGENITAL CERVICAL TUMOUR.

Letter from Mr. James Ferrier Clarke.

[To the Editor of the Medical Times and Gazette.]

Sir,—The child, of which the enclosed is a photograph, was born September 20 of apparently healthy parents, who had previously produced healthy children. The child gradually sank, and died October 8. The photograph was taken a week before death. The tumour, which had not altered in any way since birth, was covered by healthy skin, was soft and movable, feeling like a number of enlarged glands contained in a bag of fluid, and unattached to the sternum or ribs. The sublingual glands were much enlarged. It was necessary to divide the frænum linguæ, from which an ill-conditioned sore resulted. Shortly after birth a purulent discharge was observed from the left ear, which ceased in a day or two. Nothing else remarkable presented itself; the child was full grown and perfect. I regret a post-mortem examination was not allowed. Having never met with a similar case, perhaps you may think it worth inserting. I am, &c.,



James Ferrier Clarke, L.R.C.S.I., L.C.P.I.

Farnworth, near Bolton, October 10.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, March 14.

Dr. Alderson, President.

The President, in taking the chair for the first time, tendered many and grateful thanks to the Society for the honour they had conferred upon him. Such honours, he said, pointed to advanced life; but when he looked around him at the memorials of those who had previously occupied the presidential chair, he felt that increasing years had fairly won their consolation. His predecessors had achieved varying amounts of Professional reputation and worldly success, and on that score he would not compare himself with them, but he would yield to none in will to develope the interests of the Society. He thus dared to hope that in his hands the Society would suffer no diminution in its influence and importance. He was fully aware of the responsibilities of his position, and relied on the Society for liberal support in cases of difficulty.

Mr. George Southam related a case of

ANEURISM BY ANASTOMOSIS OF THE SCALP TREATED SUCCESSFULLY BY SETONS AND LIGATURE OF THE COMMON CAROTID.

The patient, a married female, aged 28 years, had been suffering from the disease for upwards of eight years. She became an in-patient of the Manchester Royal Infirmary in May, 1864. The temporal artery and its branches, with the exception of those distributed around the eye and forehead (which, though visibly distended, were not pulsatile), were much enlarged, some of them almost to the size of the little finger, and communicating to the hand a distinct arterial thrill.

The occipital artery and its branches were also similarly affected, though in a less degree. Pulsation was only slightly checked by pressure on the trunks of these vessels, but was completely suspended by compression of the common carotid. An ulcer had formed over the parietal protuberance, which had bled rather freely on several occasions. An attempt was made to remove the lint from the ulcerated surface; but arterial hæmorrhage supervened to so great an extent that the bandages were immediately replaced. On the following day, having taken the precaution to have the requisite appliances for the arrest of hæmorrhage at hand, the compress was removed in the presence of several members of the Hospital staff. Profuse hæmorrhage followed from the ulcerated surface, which occupied a space of about an inch and a half in diameter. Pressure with the fingers failed to stop the effusion of blood, escaping as it did from countless sponge-like orifices. Lint steeped in a solution of perchloride of iron was also applied, and the carotid compressed; but the blood continuing to flow, with the consent of his colleagues, Mr. Southam proceeded to place a ligature on the trunk of the common carotid, which had the desired effect. Seven days after the operation the vessels of the scalp were soft, flaccid, and apparently bloodless; but very feeble pulsation could be felt in the course of the temporal artery. Four setons of worsted, about four inches in length, were now passed through the vessels, one across the temporal fossa, the others through the parts of the scalp where the vessels were most distinct. The week following, some of the vessels near the original sore were found distended, and slightly pulsatile. Three setons were inserted through them, and another about a fortnight afterwards at the posterior part of the occiput, where a vessel about an inch and a-half in length could be distinctly traced pulsating slightly. From this period the case proceeded satisfactorily, and on the 12th of August she left the Hospital quite well, with the exception of a small ulcer at the back of the ear, which was the remains of a slough that had taken place in that part. At the end of December there were no signs of any return of the disease. The author remarked that the success of the plan of treatment adopted in the above case afforded a prospect of bringing this hitherto unmanageable complaint more effectually under the control of the Surgeon. At the time of the patient's admission into the Hospital, the disease had arrived at a stage when prompt measures were absolutely necessary for the preservation of life. According, on the supervention of hæmorrhage, ligature of the carotid was immediately resorted to. But the unfavourable results which have frequently followed deligation of the carotid for aneurism by anastomosis of the scalp induced the author not to rely solely on that method of treatment; and the further progress of the case showed that if other means in addition had not been employed, no permanent benefit would have resulted from the operation. This need excite no surprise, for the operation to be successful must either permanently cut off the circulation through the diseased vessels, or lead to their obliteration—conditions which, however probable when the disease is confined to a single vessel, and assumes the ordinary form of aneurism, are not likely to follow when several are affected, as in the present case, involving the entire temporal system, with its arteries, veins, and capillaries. For the blood in the vessels after deligation does not coagulate, but readily finds its way into the general circulation, and the vessels remaining unchanged become again distended as soon as the circulation through the anastomosing branches is re-established. But, despite these drawbacks, deligation, even when not required for the suppression of hæmorrhage, has its advantages; for the temporary interruption which it causes to the circulation through the diseased structures affords a favourable opportunity for the application of other remedies. Setons were therefore resorted to as soon as there were indications that the scalp was supplied with blood sufficient for reparative purposes. They were applied at intervals wherever any return of pulsation showed itself. It is unnecessary to dwell on the futility of trusting to setons only in the treatment of these cases. They have so repeatedly failed that their success in the present instance must be attributed to the quiescent state of the circulation produced by the ligature of the carotid. In confirmation of this view, the author referred to the case of a young lady who was under his care several years ago, whose index finger and thumb had become, through enlargement of the vessels, twice the natural size. Some of the vessels were in circumference as large as goose-quills, and gave a livid-bluish appearance to the fingers. Not the least pulsation or arterial thrill could, however, be discovered; and the vessels could be partially emptied of their blood by pressure. Three fine worsted setons were passed from the hand to the apex of the finger. Others were inserted at intervals. At the end of six months all evidence of the disease had disappeared. Deligation of the arteries, therefore, prior to the insertion of setons, does not appear necessary in all cases of aneurism by anastomosis. The disease is an affection of arteries, veins, and capillaries, varying in its characters according to the extent to which each of these structures is implicated. Deligation, therefore, seems to be required where the arterial tissue is principally involved, or where the enlargement of the capillaries has taken place to such a degree as to enable the force of the heart's action to communicate its impulse through the capillaries to the blood circulating in the veins. Similar considerations will also determine the extent of deligation, which, except where severe hæmorrhage occurs, need, in the majority of cases, only be applied to the smaller arteries. Though setons were employed in the case now related, yet galvanism, the injection of perchloride of iron, and other similar agents, may, in some instances, perhaps, be advantageously substituted; and even the risks attending ligature of the arteries may, by instrumental or digital compression, be occasionally obviated.

The President said that ligature of the carotid seemed a large operation for so limited a disease. However, it had been successful, and there was, he added, nothing so successful as success. He thought that photographs showing the conditions of parts both before and after cure would have been valuable.

Dr. Sibson said that he had communicated the paper for Mr. Southam, and unfortunately Mr. Southam was unable to attend on account of illness. He (Dr. Sibson) had no remarks to make on the general subject, but would draw attention to the fact that the carotid had been tied to arrest hæmorrhage, and not as a means of cure. Yet this having been done, the further treatment by setons was much advanced, and altogether the case was a good piece of Surgery.

Mr. C. H. Moore said the ligature of the carotid was not for the cure of the disease, but for the arrest of excessive arterial hæmorrhage. It was quite a different question whether such aneurisms required ligature of the vessel for their cure. In some it would not be necessary; in others, the predominance of large arteries might, perhaps, be so great as to demand the operation. He had seen a case in which the tumour was as large as that described by the Author in which (under Mr. De Morgan's care) cure had been effected by setons repeatedly passed, by needles, over which were placed caoutchouc rings, and by threads carrying perchloride of iron. By these means the tumour became so much less that the patient could leave the Hospital. Five years later he came under the care of Mr. Nunn. He then had an overlap or fold of skin in the position of the tumour, but no trace of the former disease. There was an abscess, of the size of two eggs, which occupied the site of the tumour. Mr. Moore then referred to vascular tumours of the scalp in children, which sometimes attained a formidable size, and then occasionally attempts to cure them were followed by inflammation and death. He had had no experience of tying the carotid in such cases, but when a large vessel was open and it was impossible to tie it or the vessels entering the tumour one after another, it would be necessary to tie the main trunk.

Mr. Savory said the case was interesting in another point of view. There was no rule in Surgery more insisted on than that we ought to tie an open vessel at the seat of injury. Often, however, it was impossible to do so, and Mr. Southam's patient's case was an instance of local and profuse hæmorrhage, controlled by ligature of a vessel at a distance. This case would encourage Surgeons to tie at a distance when the point injured could not be reached.

The President stated that Mr. Harry Lobb wished to show to the Society

A NEW METHOD OF APPLYING ELECTRICITY TO THE BODY FOR THE TREATMENT OF SOME FORMS OF DISEASE, WITH A DESCRIPTION OF THE APPARATUS.

Mr. Lobb said: The present methods of applying electricity to the body are, I consider, in many respects faulty. It has therefore struck me that a better plan might be contrived. It is a desideratum to be able to apply a voltaic current of known intensity persistently and continuously to any part of the body for any desired time. To effect this I have had woven a material of silver wire and cotton in such a manner that

either the wire or the cotton can be made to come to the surface. This material can be applied next the skin, and can be made to fit any part of the body, either covering a part or the whole of a limb, or to cover an organ or a small surface. It can be either applied with the metallic surface to the skin or the cotton can be moistened, as it is constructed so as to absorb moisture, and applied to the integument. To the end of the silver wire a covered conducting wire is soldered to the material. The method of application is as follows:—The organ, part, or limb is completely covered with the material; the nervous centre supplying the organ, part, or limb with nerves is covered with another portion of the material, each having a separate conducting wire leading from it. These wires are led to a small portable voltaic battery supplying sufficient electricity to penetrate the part, and can be modified according to the amount of surface to be acted upon, according to the nature of the disease, etc. The battery can be arranged for quantity by increasing the amount of surface of the elements, or intensity by increasing the number of the elements. To test the intensity of the battery, a galvanometer may be introduced into the circuit, and when this indicates that the current is passing, the number of elements of the battery should be noted; or a voltameter may be introduced into the circuit, and when the water is decomposed it shows that there is a current from several more elements in the battery used than is necessary to penetrate the part. The advantages claimed for this arrangement are, that a persistent and continuous current of voltaic electricity, of known quantity and intensity, can be made to pass through any portion of the body for any specified time; that this current can be applied generally over any large surface, through a limb, or can be localised in any part, organ, surface, etc., however circumscribed; also an interrupted current from an electro-magnetic or magneto-electric battery can be applied by means of this conducting material with the same ease by the Surgeon. Thus the current may be applied by the patient at any time during the day or during the night; or without removing the clothes the Surgeon may apply any required current to the patient; or a persistent measured current may be caused to pass day and night or for a specified time, the patient carrying about his person a portable battery. The apparatus, woven material, etc., were exhibited and explained.

After remarks by the President, Dr. Harley, and Dr. Fuller,

Dr. Thomas Hillier related a case of

CONGENITAL HYDRONEPHROSIS, IN A BOY FOUR YEARS OLD, REPEATEDLY TAPPED—RECOVERY.

The patient was born with great enlargement of the abdomen, simulating ascites, for which it was mistaken, till he was nearly 4 years old. It was then ascertained to be an enormous cyst springing from the right lumbar region. From its great size it caused difficulty of breathing and prevented his walking. The cyst was tapped in front, and 102 fluid ounces of clear non-albuminous fluid was drawn off, having all the characters of dilute urine. The fluid rapidly re-collected, and on a second tapping was found to be albuminous and purulent, but still to contain a considerable quantity of urea. Attempts were made to establish a permanent fistula anteriorly, and then posteriorly; but on each occasion the fluid after a time ceased to flow. Much irritation and depression followed the several tappings, so that the patient's life seemed to be endangered. After one of the operations a quantity of fluid was passed from the bladder exactly similar to that from the cyst, and quite unlike what was usually passed from the urethra; a temporary communication thus obviously being established between the cyst and the bladder. The patient has now been left without operation for some months, and has regained his strength; but the cyst remains, varying from time to time in size, and his urine is often purulent and fetid. It is presumed that there is some congenital malformation of the right ureter which renders it liable to occlusion, but admits, under some circumstances, of the passage of fluid. Cases of congenital hydronephrosis due to obliteration of the ureter were quoted, proving fatal in infancy; one, a case of an enormous cyst, apparently a dilated kidney, from obliterated ureter, in a woman who lived to the age of 23 years; and one of double hydronephrosis in a youth who lived to the age of 17 years. In the latter case the ureter on one side was much constricted, and on the other entered the pelvis of the kidney obliquely, and was guarded by a valvular obstruction. Expectant treatment, the author observed, seems to be the only measure indicated. Extirpation of the cyst is inadmissible from the dangers of the operation, owing to proximity to the sympathetic ganglia, and to the liability to hæmorrhage and peritonitis. Tapping was recommended in case of distension so great as to endanger life. It would seem that when the distension reaches a certain point, the ureter allows of fluid to pass down it.

The Author said he would have brought the patient, but not knowing the time at which the paper would be read he was unable to do so.

Dr. Webster protested against the use of French words in the paper; for instance, gramme and metre. It was far better to adhere to English words. He felt strongly on the subject, and he added the Society would think it strange if in any communication he were to introduce a Spanish or a Russian word.

The Author said it was impossible to adopt the volumetric system of analysis without French weights and measures.

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, February 1.

Dr. Barnes, President, in the Chair.

Drs. Cassells and Trend were elected ordinary Fellows.

Dr. Bathurst Woodman exhibited specimens of

CHANCRE AND FIBROUS TUMOURS OF THE UTERUS.

Dr. Greenhalgh exhibited a

POLYPUS,

weighing upwards of a pound and three-quarters, which he had removed from the uterus of a woman 40 years of age by means of a pair of curved scissors. The author insisted on the necessity for cutting away these growths, and the desirability of removing them *in situ*, rather than making forcible traction on the uterus for the purpose of bringing them within easy reach of the operator.

Mr. I. B. Brown read a paper

ON A NEW METHOD OF SECURING THE PEDICLE IN OVARIOTOMY.

The author observed that hitherto there had been three distinct methods of securing the pedicle: first, by ligature, allowing the ends to hang out, as practised by Dr. Clay, of Manchester (the pioneer of ovariotomy in this country, who had steadily led us on to our present successful results), and by Lane (the first Surgeon in London who performed this operation) consecutively; secondly, by clamp, as first suggested by Hutchinson, and followed by many others; thirdly, by cutting off the ligature short and closing the wound, as first successfully practised by Rogers, of New York, in 1829, by Dr. Bellinger, in America, in 1835, by Dr. Siebold, of Darmstadt, in 1846, and recently by Dr. Tyler Smith. The first three gentlemen's cases were all successful, and the last-named gentleman has also had great success. Mr. Brown said that his objections to the first method had been the length of time required for the ligature to come away, which varied from nine days in his own practice to a month in that of others; to the second, the frequent severe pain caused by the dragging of the pedicle, or the pressure of the clamp itself; to the third, the unsuccessful results in his hands following its use. Having repeatedly used the actual cautery of late, employing Dr. Clay's instruments, in burning adhesions off the omentum and elsewhere, he had been gradually led to the conclusion that the actual cautery might be employed in treating the pedicle itself. Consequently, on December 28, 1864, he tried it upon a patient of Dr. Burchell, of the Kingsland-road, a lady, 47 years of age, who had had three children, the youngest twenty-one years since. The disease was first discovered by Dr. Burchell in August last, and so rapidly increased as to lead Dr. Barnes and Dr. Tanner to recommend extirpation some short time before he (Mr. Brown) saw her. As the abdomen then was very large, the skin shiny, and the general health rapidly suffering, he performed the operation by Clay's large incision. There were many adhesions laterally and posteriorly, the bleeding from which was checked by the actual cautery; and finally the pedicle, being secured by a clamp, whilst a very large multilocular mass of cysts was removed, was thoroughly seared by actual cautery and allowed to drop. The wound was then closed in the usual way, and it healed in a week, the patient being convalescent in a fortnight. Mr. Brown thought that if this plan was found by repetition to be successful, it would very materially lessen the

dangers of the operation, and consequently ensure a greater number of recoveries.

Dr. Routh stated that Mr. Brown's previous and successful experiments in the removal of the omentum by a red-hot iron would prove the best reply to Dr. Tyler Smith, as to the probable conduct of the peritoneum where a pedicle was removed in the same manner.

Mr. Brown, in reply to several speakers, said that the objection urged by Dr. Tyler Smith, of the slough being injurious to the peritoneum, had been answered by the questions put by Dr. Routh and replied to by Dr. Greenhalgh: that he (Mr. Brown) had, for four years past, repeatedly used the actual cautery in burning adhesions and arresting hæmorrhage, and in no one of the cases so treated had he had a death; and he thought that the objection ought not to deter others. He did not allude to the écraseur, because he thought there was not sufficient time in ovariotomy to use it safely; and he did not think it probable that it would ever come into use on that account. In answer to an objection that white heat might be detrimental, Mr. Brown said he did not go quite so far as to use white heat, but he stopped just short of it. To the objection of Dr. Parsons, that there was fear of hæmorrhage in case of sickness after the use of the cautery, Mr. Brown re-replied that whilst it was well known that many patients had died from hæmorrhage where the ligature was used, he did not think, judging from his past experience and the results of Veterinary Surgeons in spaying the sow, that there was any probability of hæmorrhage where the cautery was steadily and thoroughly applied.

PRESIDENT'S ADDRESS.

The President rose to acknowledge the honour conferred upon him by the Society. In this election he said the Society had followed the principle under which it had attained its present position of unexampled prosperity—namely, that of recognising work. He adverted to the success the Society had thus achieved in linking itself to fellow-workmen in all parts of the world, and trusted that the Society would be the means of challenging for English midwifery that place in the Republic of Medicine which it eminently deserved. English midwifery presented the singular characteristic that it was based upon home or domiciliary practice; whilst elsewhere it was mainly dependent upon lying-in Hospitals. The Society had, therefore, the charge of vindicating home midwifery, of showing that it afforded ample means for observation and for advancing obstetric knowledge. The main argument urged by the advocates of the Hospital system was that Hospitals were necessary for instruction. But home practice in England still asserted a practical superiority in its eminent success. He cited Harvey; the Chamberlens, the reputed authors of the forceps; Edmund Chapman, who first taught the use of that instrument; Sir Fielding Ould, who laid the foundation of our knowledge of the mechanism of labour; Giffard; Smellie; William Hunter; Denman; Macaulay, the first to practise the induction of labour; Perfect; and the first Rigby, who, as a country Practitioner, made those observations and drew those classical descriptions of uterine hæmorrhage which are still reverenced for their truthfulness and sagacity. The President then expressed his belief that Physicians and statesmen abroad would be impelled to re-examine the great question of the expediency of taking parturient women away from their homes. The provisions for the study of uterine pathology in our English schools were then discussed. Recently a new department had been instituted in our educational Hospitals for this purpose. But the position and duties of the "Obstetric Physician" remained still undefined. The President submitted the following proposition:—"The work of the obstetric Physician embraces the treatment of the diseases of the female generative organs, including the disorders and lesions, general and local, which result from pregnancy and parturition." Of course, in founding a new special department something must be taken both from the Physician and the Surgeon. If the Obstetric Physician were to enjoy any status at all, it could only be on this condition. The difficulty in adjusting relations arose chiefly on the Surgical side, probably because it seemed an anomaly for a man bearing the title of a Physician to be meddling with Surgery. But in point of fact, the Obstetric Practitioner was necessarily a compound of the Physician and the Surgeon; his Surgical character was implied in the word "obstetric." Custom, which imposed upon him the general title of Physician, could not alter the nature of his functions. Just as the study and treatment of the diseases and lesions of the generative organs had been neglected until taken up by Obstetric Practitioners, so they would be again if abandoned by us. It was to obviate this neglect, to encourage the study, that the new appointment was made. To make the office and to cut off the very material for study was inconsistent. As an illustration, there was the modern appointment of an Ophthalmic Surgeon to our Hospitals. It was given to Surgeons; but they treated all diseases of the eye, even including those of constitutional nature, which Physicians had always treated. If the Surgeon said, "The Obstetric Physician must give up all operations," the Physician might as reasonably say, "The Obstetric Physician must give us all that requires Medical treatment." For example, puerperal fever, which is not more a consequence of labour than is a slough of the vagina or vesico-vaginal fistula. This reasoning would simply lead to the annihilation of the Obstetric Practitioner, and is a manifest *reductio ad absurdum*. The President then called upon the Fellows to imitate the example of the Royal College of Physicians and the Royal Medical and Chirurgical Society, by opening a corporate album for the preservation of photographs of their Fellows.

(To be continued.)

MEDICAL NEWS.

Apothecaries' Hall. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, March 16, 1865:—

John Henry Caffry Constable, St. George's-road, Southwark; Danie Hendry, Great Howard-street, Liverpool; John Craigie, Fairlight-villas Hackney; William Vicary Snow, Vicarage-lawn, Barnstaple.

As an Assistant:—

William Brown, Blackstone-street, Liverpool.

The following gentlemen, also on the same day, passed their first Examination:—

Roger Portington Goodworth, London Hospital; Robert Walter Ceely, London Hospital; John Henry Gray, London Hospital; Mowbray Jackson, St. Bartholomew's Hospital; John Henry Croft, Guy's Hospital; William Binorton, St. George's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Aspray, Charles O., M.D. St. And., has been appointed House-Surgeon to St. Peter's Hospital, Berners-street.

Foster, Balthazar W., M.D., has been elected Physician to the Queen's Hospital, Birmingham.

Girdwood, J. M. E., M.D., has been appointed Surgeon to the Prison, Falkirk, N.B.

Knowles, Mr. R. H., has been elected Dispenser to the Leeds Dispensary.

Metcalfe, Fenwick, M.R.C.S. Eng., has been appointed House-Surgeon to the Torbay Infirmary and Dispensary, Torquay.

Moore, Charles F., M.D., L.R.C.S.I., has been elected Medical attendant to the South City Dispensary (No. 3), Peter-street, Dublin. He has also been elected Assistant-Physician to the Cork-street Fever Hospital.

DEATHS.

McCollah, John R., M.R.C.S. Eng., at Reeth, Yorkshire, on March 8, aged 54.

Jollye, Edward W., M.R.C.S. Eng., at Norwich, on February 20, late of Loddon.

Eckford, Robert, late President of the Medical Board of Bombay, at Jersey, on February 27, aged 90.

Hillmann, William, Surgeon, at 1, Argyll-street, Regent-street, W., on March 11, aged 81.

O'Hara, Malachi C., L.R.C.P. Edin., at Kilkelly, Co. Mayo, on March 1, aged 37.

Oliver, T. H., late Surgeon in the West Norfolk Militia, on March 4, at Southdown, aged 92.

Rule, John, M.R.C.S. Eng., at Maidstone, Australia, on December 18, aged 86.

The President of the Medical Council has issued cards of invitation to a conversazione on April 5.

The College Lectures.—Professor Huxley will bring his course of twenty-four lectures "On the Structure and Classification of the Mammalia" to a close on Friday next, the 31st inst., and after the ensuing examinations Professor Fergusson, F.R.S., will deliver six lectures "On the Progress of Surgery during the present Century," in continuation of his course of last year.

Sir Rutherford Alcock will succeed Sir F. Bruce as Envoy Extraordinary at the Court of Pekin.

The late Dr. Falconer.—It has been decided that the memorial in honour of the above lamented gentleman shall consist of a bust, to be placed in a London scientific society, and a scholarship to be founded in connexion with the University of Edinburgh. An influential committee has been formed, and upwards of a thousand pounds has been subscribed towards the accomplishment of these objects.

Royal College of Surgeons of England.—It may be interesting to those members of the Profession desirous of prolonging their studies in the Museum of this institution to know that the Council has extended the time for closing it until 5 o'clock from March until August, instead of 4 o'clock, as heretofore. The Library is open also to the former hour. The Histological Collection is now open to the inspection of members of the College, and visitors introduced by them every Wednesday between the hours of 11 and 5 o'clock.

The Royal Society.—There are no less than fifty-three candidates for election into this Society, and as usual the Medical element is large, as represented by the following names, viz. :—A. L. Adams, M.B., A. Armstrong, M.D., W. Baird, M.D., J. C. Bucknill, M.D., Professor Robert Grant, W. A. Guy, M.B., G. Harley, M.D., B. Hobson, M.B., E. C. Johnson, M.D., Henry Letheby, M.B., W. A. Lewis, M.B., R. McDonnell, M.D., Charles Murchison, M.D., Sir J. P. Olliffe, M.D., C. B. Radcliffe, M.D., J. R. Reynolds, M.D., E. H. Sieveking, M.D., and A. T. H. Waters, M.D. From this it will be seen that the Council of the Society have an ample number from which to select the fifteen out of the fifty-three, including the above, to be recommended for election. The selection will be made known in May, one month before the day of election.

Downing College, Cambridge.—On May 22 there will be an examination for four scholarships of the value of £40 each. The examination will be in classics and mathematics, with a paper on the Natural Sciences in connection with Medicine (namely, chemistry, mineralogy, botany, comparative anatomy, and physiology), proficiency in which will have much weight in the awarding of one at least of these scholarships. The examination is open to students who have not yet entered at the University. Those who are elected will be expected to reside at the College. For further information apply to J. Perkins, Esq., Downing College.

Chemist and Druggists.—Sir Fitzroy Kelly has laid before the House of Commons a Bill for the protection of the public against unqualified chemists and druggists compounding prescriptions. The Bill requires that all persons commencing business after this year shall either be pharmaceutical chemists, or be examined and passed by the examiners under the Pharmacy Act, and registered as chemists and druggists under this Bill. But chemists and druggists in business before the end of this year, and their assistants, if of age, are to be entitled to be registered without examination. The register is to be printed for sale annually. The fees for examination and registration are to be fixed by a bye-law to be made in accordance with the Pharmacy Act.

Medical Charities.—The great interest taken in the Medical Institutions of this metropolis by our gracious Queen, as evidenced in her frequent visits to them, appears to have had its influence on other ladies, two of whom have, in addition to large sums to other charities not strictly Medical, left nearly £3000 to the following, viz. :—The Royal Westminster Ophthalmic Hospital, £200; the Infirmary for Consumption, Margaret-street, Cavendish-square, £200; the Hospital for Consumption, Brompton, £100; the Cripples' Home, £300; Idiots' Asylum, Redhill, £200; Samaritan Hospital for Women and Children, Edward-street, Portman-square, £200; the Cancer Hospital, Brompton, £100; Establishment for Invalid Gentlewomen, £200; Orthopædic Hospital, Oxford-street, £50; St. George's Hospital, £100; the Middlesex Hospital, £100; University College Hospital, £100; and Guy's Hospital, £100. The above munificent sums have been bequeathed by Miss Julia Olivia Brodie, of York-place, Portman-square, to which may be added the following, left by Miss Rachel Semage, of Oxford-terrace and Stoke Newington :—£100 to each of the following Hospitals,—viz., The German, the Royal Free, the North London, the London Fever, the Middlesex, St. Thomas's, the Margate Sea-bathing Infirmary, and the Hospital for Incurables. To the Charing-cross Hospital and Stoke Newington Dispensary, £50 each.

The Victoria Cross to Medical Officers.—This much-coveted honour has just been conferred on two Assistant-Surgeons — viz., Dr. Manley, R.N., for distinguished acts of bravery at Tauranga in endeavouring to save the life of the late Captain Hay; and to Dr. Temple, R.A., for distinguished bravery in bringing in the wounded at Rangariri. The *Sydney Morning Herald* for last March gives a full account of the investiture of these gentlemen with the order of valour by Lieut.-General Sir Duncan Cameron, K.C.B., by command of Her Majesty. In his observations before all the staff and men formed in square, the gallant General said how "much it redounded to the credit of the Medical Department that so many of its officers had distinguished themselves by acts of individual gallantry and bravery. Out of the small numbers of officers composing the department in New Zealand, no fewer than four had been decorated with the order of the Victoria Cross, including the head of the department, Inspector-General Mouatt, who had earned himself that coveted distinction by noble services rendered in the Crimea; and another officer, Staff-Surgeon Home, who had distinguished himself in India. During the war in New Zealand all present could bear testimony to the skill, untiring zeal, watchful care, and attention with which all the Medical officers had performed their arduous, onerous, and responsible duties. Their duty required that they should follow the troops under a hostile fire, and amid the deadly assaults of the enemy; and how nobly and devotedly they had behaved." General Sir Duncan Cameron then advanced, and attached the cross to the left breast of each of the gallant recipients, amidst great cheers.

Plain English.—At the York Assizes on March 22, a Medical witness stated that he found the patient suffering from a bad black eye, whereon the judge, Mr. Justice Willes, courteously thanked him for speaking plain English, instead of telling the jury that the plaintiff was suffering from ecchymosis of the oculus.

Charge against a Medical Man in Glasgow.—The case in connexion with which Dr. E. W. Pritchard has been taken into custody is undergoing investigation at the hands of the authorities. As usual, however, in such cases, everything is done in private, and it is impossible as yet to obtain any definite information as to the circumstances which have given rise to suspicion. It appears that Mrs. Pritchard some four weeks ago was seized with illness, her complaint being described by her husband as gastric fever. Mrs. Taylor, her mother-in-law, came from Edinburgh to wait upon her, and of course resided in Dr. Pritchard's house. About three weeks since Mrs. Taylor was suddenly seized with severe illness, and despite the efforts of a Medical gentleman whose aid was called in, died within a few hours. Her body was removed to Edinburgh, and there interred. As for Mrs. Pritchard, she appeared for some time to be in a fair way of recovery. At the end of last week, however, she had a relapse, when she was attended by the same Doctor whose services had been engaged for her mother. But in this case also Medical skill proved of no avail, and death supervened somewhat suddenly on Saturday last. Dr. Pritchard conveyed his wife's remains to Edinburgh on Monday, although the interment was not intended to take place till Thursday. Meanwhile the attention of the authorities had been somehow or other called to the case as one which called for investigation, and the result was that the Doctor, on his return from Edinburgh on Monday evening, was apprehended by the police at the railway station. On Tuesday morning, although he was not taken before the magistrates, it was intimated publicly in court that he was detained for examination as to the sudden death of his wife, and the case was forthwith remitted to the Sheriff. The post-mortem examination of Mrs. Pritchard's body, which was made in Edinburgh on Tuesday afternoon, resulted, it is understood, in the decision of Drs. Maclagan and Littlejohn that there were no natural appearances to account for death. The stomach and its contents were accordingly handed over to Dr. Maclagan for chemical analysis.

The following statistics of the diminished mortality in Paris are published in the report of a Medical board to the Prefect of the Seine. The report extends over a period of twenty-four years. In 1841 the population of twelve parishes (which, however, is not the exact translation of *arrondissement*), amounted to 935,000 persons, and 1 death in 36 is proved. In 1864 the number of deaths was 1 in 40 inhabitants. This is clearly the result of the increased volume of air which circulates in parts of the metropolis where wide

streets and open boulevards have replaced the narrow passages and crowded courts of old Paris. Another evident cause of this diminution of mortality is the immense increase in the quantity of water supplied to the inhabitants. In 1840 but 65,000 cube metres were distributed in twenty-four hours, whereas in 1863 133,258 cube metres were supplied to the populace during the same space of time, and we are promised in a short time that we shall have 300,000 cube metres of that element at our disposal daily. The drainage of Paris has increased in proportion. In 1840 there were 36,000 metres of sewers, whereas in 1863 the sewers of Paris attained the surprising length of 350,000 metres—that is, 90 leagues. Another cause of the increased salubrity of Paris is the immense number of squares and open gardens which have been created for the use of the people. It must be remembered that in Paris the aristocratic custom of keeping the squares of the city carefully locked for the use of the upper ten thousand is utterly unknown. Even the Empress's reserved garden in the Tuileries is alike enjoyed by the children of the artisan, as well as by the heirs of coronets, during the summer and autumn months, when, in fact, it is in all its beauty. In Paris and its environs people's parks are unknown, because every spot of ground not the property of a private individual is laid out for the enjoyment of the people; and every improvement in Paris has increased the number of their gardens. In 1853, 216 hectares of Paris were laid out in squares, boulevards, &c., which were ornamented by 69,125 trees. On the 31st December, 1863, the space thus laid out had been extended to 328 hectares, and the number of trees to 89,335.—From the *Morning Star*, 18th March, 1865.

A St. Petersburg letter says:—"The contagious malady which has been for some time raging in the Russian capital is acquiring fearful proportions. Several hundreds are being carried off daily. The hygienic measures prescribed by the Committee of Public Health have been thus far of little avail. The same epidemic fever has appeared at Moscow, and there are fears that, from the prompt communication which at the present moment exists between St. Petersburg and Warsaw, the malady may reach the latter city, and thence spread over the rest of Europe."

Poisoning by Opium.—A woman named Bibby has been convicted of the manslaughter of her child at the Manchester Assizes, and sentenced to fifteen months' imprisonment. The dead body of the child was found secreted in a corded box at the Euston-station. It was supposed that the child's death was caused by an over-dose of laudanum carelessly administered by the prisoner, who was in the habit of giving it six, eight, or ten drops at a time under the name of "quietness." The post-mortem examination showed congestion of the lungs and fluid blood in the right cavities of the heart. No opium was discovered in the stomach.

Successful Medical Defence.—A female servant at Trowbridge lately brought a charge against her master's butler of "feloniously administering to her a quantity of some noxious thing, unknown, for the purpose of producing miscarriage." The girl said that when she informed the defendant of her pregnancy "he said he would get her some medicine to take to destroy the child; he afterwards gave her something in half a wine glass full of water. She took it four times a-day, but without any effect; it had a bitter taste." The defence was a Medical one, although no Medical witness appears to have been called. Mr. Slack, a lawyer, who defended the prisoner, quoted Dr. Taylor to the effect that medicines which are given to produce abortion would produce poisonous effects, causing violent irritation of the intestines, and such results being wanting in this case it was not to be supposed that any drug of the kind had been administered. The magistrates, without requiring any further evidence, dismissed the case.

Acupressure and Chloroform at Nazareth.—The following is an extract from a letter dated January 9 from a Turkish Surgeon, P. K. Vartan, L.R.C.S.E., practising at Nazareth, in Syria, to Dr. Handyside, of Edinburgh:—"A married woman, aged 25, mother of four children, was brought to me from a village distant about ten hours' ride from Nazareth, suffering from disease of the ankle-joint, involving both tibula and fibula in the mischief. I found it necessary, therefore, to amputate through the middle of the leg. I used, of course, acupressure, which I find both easy and less prejudicial. I did not succeed in obtaining union by the first intention; but this I imputed in great measure to the unsound state of the bones, which nine days after the operation suppurated freely. On the twenty-sixth day the wound was quite healed, and the patient could walk with her crutches. I need scarcely mention how much the natives' wonder is excited at witnessing the effect of chloroform. Certainly my patient was doubly grateful: for amputating her limb and for saving her the pain of the operation. She is a Moslem by faith; and as she, her husband, and other Moslem friends departed from Nazareth, they poured out their hearts in thanksgiving for the benefits they had received."

The Endoscope.—On Wednesday, the 15th instant, at at a meeting of the Medical Society of the King and Queen's College of Physicians, Dublin, held in the New College Hall, Kildare-street, Dr. Francis Richard Cruise, of the Mater Misericordiæ Hospital, exhibited an endoscope which he has been using for some time past, and read a short paper explaining its practical utility in the diagnosis and treatment of many obscure forms of disease, especially those of the rectum and urino-genital organs. Dr. Cruise's endoscope is a modification of Desormeaux's, and possesses the great advantage over it of an illuminating apparatus so brilliant, and easily admitting of such perfect adjustment, that little or no previous training is required to enable the Practitioners to obtain a satisfactory view of deep cavities which heretofore have been generally looked upon as quite inaccessible to sight. Amongst these we may specially mention the bladder and urethra, the rectum beyond the reach of the finger and speculum, the cavity of the cervix, and even of the body of the uterus, the nasal fossæ, pharynx, cavities of ovarian cysts, abscesses, wounds containing foreign bodies, and so forth. Dr. Cruise's paper was enriched by the details of a number of obscure cases in which he had used the endoscope, to the entire satisfaction of numerous Medical men in Dublin, amongst whom we may mention Professor Robert William Smith and Dr. Fleming, of the Richmond Hospital; Dr. Hayden, of the Mater Misericordiæ Hospital; Dr. Robert McDonnell, of Jervis-street Hospital, and others. This instrument, which has been thought of and talked about for the last thirty years, has from time to time attracted passing attention and then sunk back into oblivion. M. Segalas would appear to have originated the idea of endoscopy, which he soon abandoned as impracticable, and the late Mr. Avery, of London, paid much attention to it. Sir Philip Crampton, also, is said to have taken up the matter at one time, but no result followed. It would appear that of late years M. Desormeaux, of Paris, has been the only worker in this unexplored field, and to his perseverance unbounded credit must be given. This negligence would appear to be mainly due to the difficulty of obtaining a satisfactory and manageable illumination. Dr. Cruise has undoubtedly removed this difficulty, and now, for the first time in this country, the endoscope has been proved an unquestionable success, and likely before long to modify and correct our opinions respecting certain obscure ailments, and to serve materially in their treatment. It is unnecessary to enter into details of the means by which Dr. Cruise obtains the admirable illumination and adjustment in his instrument, as we understand he is about very shortly to publish in one of the Medical periodicals an account of it, as also a *resumè* of the work hitherto accomplished by its use. We think it only justice, however, to notice his labours and improvements, and the very favourable reception his communication met with on Wednesday, and to give him the credit of priority in following up in this country the study of the long-neglected endoscope, and demonstrating, for the first time in Dublin, its unquestionable value as an aid in diagnosis and treatment.

The Samoan women, like most women in savage life, make no preparation for the birth of their children, and very speedily recover; of which the following instance was narrated by Mr. Pritchard:—"Puaaolo was the wife of Tamaalii, who lived at Fasitootai, in the island of Upolu, Samoa. There was nothing remarkable about her person or habits to distinguish her from her countrywomen. Like them, during pregnancy, she attended to the usual duties of Samoan women without interruption, and without preparation for the 'coming event.' Amongst other things, she continued to make *tapa*, or native cloth, the manufacture of which necessitates sitting up to the middle in water two or three hours for several successive days (in the first operation of scraping the bark of the paper mulberry, *Brussonatia papyrifera*, of which it is made). On one occasion, while thus busily engaged, and merrily singing her native songs, with other women, all in the water, she complained of pains in her back, and went off to the bush on the banks of the river. In

about a quarter of an hour she returned with a fine baby-boy in her arms, whom she had delivered without any assistance. She washed and suckled him, and soon he was fast asleep. He was then laid in several folds of *tapa* on the banks, where he slept soundly while she finished her work, and when the party separated she took her boy home. He is now living with his mother at Fasitootai, and is named Matauli (dog-face), and is a fine healthy lad, about ten years old. The woman and her husband were both in my service at the time. This is an exceptional case, though the Samoan women think but lightly of the pains of childbirth. They suckle their children until about two years old. I have seen women who threw their breasts over their shoulders to have them out of the way; and I have seen children standing at their backs suckling from behind, when the breasts have been thrown over the shoulders to allow the mother the free use of her arms."—*Mr. Pritchard at a Meeting of the Anthropological Society of London.*

LOCAL PREVALENCE OF CALCULOUS AFFECTIONS.—Professor Heyfelder remarks that there are regions in which even fully employed Surgeons never have an opportunity of operating for stone, seeing that it is never met with within the range of their practice. This is the case, for example, with the region of the Moselle from its source to its junction with the Rhine. On the other hand, in other regions, so frequently is the affection met with that it may be truly described as endemic, as in Upper Swabia, the chalk formation of the Jura Alps, some portions of the Austrian Empire, Dauphiny, and the Governments of Kowno and Moscow, in Russia.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Trichina Spiralis.—Sets of specimens may be had of Messrs. Churchill, post free, for 6s. 6d.

The Metropolitan Farina Company, Walmer-road, Notting-hill, W.—We notice with pleasure the honourable mode of conducting business by this Company. So soon as our esteemed Commissioner has brought his Reports on Wine to a close, we must set him to work on the Malt Flour.

Jerked Beef.—We have met with a perfectly good specimen at the shop of Russell and Co., 171, Brompton-road, S.W. After maceration and boiling, it is quite sweet, not too salt, and tastes very much like an overdone bit of English boiled beef. It would make a capital stew with vegetables, and, if grated or powdered up, would do well as a thickening to a soup made of peas, carrots, onions, etc.

A Competitor.—The awards for the prizes in question will be made in the ensuing month. H.M. Minister at Japan, Sir R. Alcock, won two Jacksonian prizes, viz., 1839, "On the Nature, Symptoms, and Treatment of Concussion of the Brain," etc.; and in 1841, "On Injuries of the Thorax, and Operations on its Parieties." He is an Honorary Fellow of the College.

Errata.—In our report of the annual meeting of the Medical and Chirurgical Society (p. 238) Dr. Webster is made to say (p. 241) that "£73 had been laid out on one volume." Dr. Webster said that the £73 had been laid out in purchasing Mr. Squibb's collection of portraits. In the same report Dr. Markham is said to have seconded Mr. Hawkins' resolution. The seconder of the resolution was Dr. Stewart.——We beg to correct a verbal error in our impression of last week. In the Medical History of Bath Mr. Mitchell is stated to be the Surgeon to the Bath Dispensary for Diseases of the Skin and Urinary Organs. The report should read Mr. D. Michael, *not* Mr. Mitchell.

WINE DUTIES.

(From *The Times.*)

SIR,—The following tabular statement shows the result of four years' experience of the reduced duty on wine, compared with the four years previous to the alteration. 1860 is excluded, as there was an intermediate rate.

It is seen that the consumption in 1864 exceeds that of the average of 1856 to 1859 by 4,364,669 gallons, and that the revenue is less by £642,866.

It is further seen that the annual additional quantity is a little more than half a bottle for each person.

	Average of years.	Gallons.	Rates of duty.	Revenue.	Bottles for each person.	Population.
1856 to 1859	4	7092046	Cape, 2s. 11d. Others, 5s. 9d.	1962133	1 5-10th	28300100
1860	—	7358192	On all, 3s.	1144794	1 5-10th	—
			s. d. s. d. s. d. s. d.			
1861	1	10787091	1 0 1 9 2 5 2 11	1219533	2 2-10th	28980575
1862	1	9803028	1s. 2s. 6d.	1123603	2	—
1863	1	10478401	—	1214762	2 1-10th	—
1864	1	11456715	—	1319267	2 2-10th	29570500

Such, then, is the result of what is sometimes miscalled the great measure of the reduction of the wine duty; and it will never be much better while the absurdity continues of charging 5s. per dozen on every description that is brought over in bottle, and 2s. 6d. per gallon on all that is of the kind that the people of this country have been compelled during nearly two centuries to drink. The risk of loss of revenue was at first assigned as the reason; but, although many desire the continuance for the same object that they opposed any reduction, none now attempt to defend the cause of the enactment.

Let there be a uniform rate of 1s. per gallon on every wine, weak or strong, imported in glass or in wood, and, before two years are over, wine will be as much used here as it is in the northern States of Europe,—even where beer is good and plentiful. In Paris the duty, etc., is about 1s. per gallon, and the estimated annual consumption of each inhabitant is 185 bottles. Instead of 185, let us estimate 12 bottles in this country; and even with that small quantity the revenue would be three millions, instead of the present miserable £1,319,267.

The various rates of duties, of degrees of strength, of difference if in cask or in bottle, etc., make the subject so intricate, difficult, and troublesome that it seems impossible to get any member to take up the question.

A few nights ago, upon the discussion about malt, strange assertions were made about wine; but what can be expected after seeing the uncontradicted statement of even the President of the Board of Trade, that "wine from France pays a duty of 22 per cent., from Portugal of 30 per cent., from Spain of 29 per cent. ?"

I may add that the average consumption (or, more correctly, the wines on which duty was paid) was:—

	From Portugal.	Spain.	France.	Cape and Australia.	All other countries.
On the average from					
1856 to 1859 ..	2201307	2810831	625932	582041	871935
In 1864	2832217	4974112	2304242	76983	1269161

London, March 13. THOMAS GEORGE SHAW.

POOR-LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I shall feel obliged by you affording me space for the annexed letter from the Poor-law Board, it being the reply to the one dated March 6, and inserted in your journal of March 11. It has been said that "language was given to enable us to conceal our thoughts;" which is verified by the wording of the letter from the Board. I believe our appointments and contracts are two different things; and even where the former are permanent the latter can at any time be altered; therefore, perhaps it may be intended to enter into new contracts with the Medical officers, and readjust on equitable principles all the salaries. I trust it may be so.

Allow me here to explain that the M.P. to whom I referred in my last letter as not having replied to my communications since January 31 has forwarded to me a letter, dated March 6, in which he explains that domestic affliction and absence from England were the causes of the long delay. He also says:—"I quite agree with you that some such measure as that drawn by you should become the law of the land, as the present state of the law is not only unsatisfactory, but unjust to the Profession and the poor. When you first addressed me on the subject of my introducing a bill this Session, I thought I should have been able to do so with effect; but I regret that circumstances will prevent me taking an active part during the present Session. —— is greatly opposed to an alteration of the law, and county members will not hear of any alteration. There must be something very wrong in the Profession when it is unable to make itself felt in a political sense throughout the country. Attorneys have their organisation, and when any question relating to them comes before the House it is not only heard but duly considered."

From the above quotation I greatly fear that nothing can be done by the Poor-law Medical officers this Session. If, however, the Poor-law Board still continue obdurate, we must, like the lawyers, become politicians, and at the next election refuse to give a vote without a promise that each member will aid in obtaining from Parliament an equitable adjustment of the claims of the Poor-law Medical officers, which is all that we ask, and which no honourable man ought to refuse. I trust the Medical men of Wolverhampton will insist upon Mr. Villiers giving this pledge, as I cannot but feel he is our great opponent.

I am, &c. RICHARD GRIFFIN.

12, Royal-terrace, Weymouth, March 20, 1865.

"Poor-law Board, Whitehall, 18th March, 1865.

"Sir,—I am directed by the Poor-law Board to acknowledge the receipt of your letter of the 7th inst., on the subject of the supply of expensive medicines when required in the Medical treatment of sick paupers.

"The Board direct me to inform you that they have given much consideration to the subject referred to in your communication, and have caused various inquiries to be made as to the best course of proceeding, to carry into effect the recommendation of the Committee on Poor Relief on this point.

"In the cases of new contracts which are entered into by boards of guardians with their Medical officers, the Board are endeavouring to secure, in the most practicable manner, the objects suggested by the Committee; and they will not lose sight of the subject, if any further proceedings for the purpose should appear to them to be practicable.

"I am, Sir, your obedient servant,

"ENFIELD, Secretary."

CREAKING OF THE KNEE-JOINTS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Can you or any of your readers advise me what to do in the following case?—A gentleman, of active habits, has complained some time of a disagreeable creaking noise whenever he bends his knee-joints, and,

after moderate exercise, a feeling of weakness in the joints. He says himself that he fancies the "lubricating matter" must be deficient. Is he far wrong? Can anything be done for it? I am, &c.

M.D.

[*** The treatment appropriate for chronic rheumatism.—ED.]

Unqualified Medical Assistants.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Should you think fit, I beg to forward the subjoined for insertion in your esteemed journal. Referring to a letter from Mr. Willet, Northwich, Cheshire, which appeared in your columns, I do not think that gentleman has any just cause of complaint. When the Medical Act becomes more generally understood by the public, I do not doubt but what one result will be to improve the *status* of qualified assistants. Surely it is no less a misinterpretation of the Act for a qualified Practitioner to be entitled to recover for Professional services of an unqualified assistant than it is for the quack or illegal Surgeon to claim for the services of his registered partner. The public have now a right (and which is slowly making itself asserted) to demand that all Professional services, charged as such, should be tendered by registered Medical assistants; and it is clearly illegal to act otherwise. The qualified assistant would then take a better position, and not be, as he too often is now, a generally useful factotum. I am, &c.

March 15. MEDICUS.

"Ought a Bubo to be Resolved?"

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The difficulty raised by Dr. Harrics seems to me to be only a theoretical one. A bubo that has a tendency to suppurate will, I apprehend, be very difficult to disperse by any means which we possess, and certainly will not be "put back" by the mere application of iodine locally; at least, suppuration often occurs under such treatment. Should, however, a bubo disappear while iodine was being applied, the result must not be necessarily attributed to the remedy, but rather to some change having taken place in the constitutional condition of the patient. On the other hand, it would be a hazardous presumption to say that we have the power, by local or other remedies, of determining a suppurative action in an indurated bubo; and it remains with those who propose such a plan of treatment to prove that they have the means of carrying it out. I am taking for granted that Dr. Harries would not attack the enlarged and indurated lymphatic glands by escharotics or the knife; but if such be the method he proposes, he must be aware that most Surgeons look upon the non-suppurating bubo as one of the signs that the system is already infected, and that such a plan of treatment would be very like "shutting the stable door when the steed is stolen," though less harmless in its results. I am, &c.

W. SPENCER WATSON.

The Temperature of the Wine Cellar.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Your Special Empirical Commissioner, in last week's *Medical Times and Gazette*, speaking of clarets, says:—"Let me say that *cold*, in any shape, does not agree with these wines. They taste best at 58°—60° Fahrenheit." Messrs. W. and A. Gilbey, on the contrary, say, "Clarets and all wines that have undergone perfect fermentation are less affected by cold, and are better in a temperature of no more than 45° Fahrenheit." (See annual circular for 1864.) This shows us how much even men of great experience differ on common things. One would have thought that the temperature of the wine cellar for the different classes of wines would have been a settled point long ago. The stronger wines, the wines of Portugal and Spain, according to the Messrs. Gilbey, are kept in greatest perfection in a temperature of "36° Fahrenheit." If these statements of the Messrs. Gilbey are correct, they show us that the same cellar will not keep all classes of wine equally well, and that if we want to keep our wines in perfection it will necessitate a division in our wine cellar, the one compartment being kept at a higher temperature than the other. This might easily be effected by leading hot water pipes through it, by keeping the gas burning in it night and day, or by keeping a fire on in an open grate, or by any other contrivance that will generate heat. Good wine is a desideratum for the community at large, and more especially for that portion of the community with which the Medical man is more intimately connected—namely, the sick; and therefore it is of no slight importance to know the temperature in which the different classes of wines can be kept in greatest perfection. This could very easily be ascertained experimentally, in a cellar constructed as I have specified, by keeping a portion of claret bottled from the same cask in the different compartments. A single winter's experience would be sufficient to determine whether claret kept best at a temperature of "58° or 45° Fahrenheit." I am, &c. AN OBSERVER.

December 14, 1864.

Note.—I dined with a gentleman last winter who said "he could not understand his port wine; for during the summer it was perfection, but it had now become so dull and turbid-looking that he was ashamed to present it to any one." The flavour of the wine was still good; but it certainly had anything but an inviting appearance. It was kept in a very cold cellar—far too cold for this class of wines, or perhaps for any class. He has made an alteration in his cellar since; I hope for the better.

The Blister Treatment of Acute Rheumatism.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—You would much oblige me by inserting in the *Medical Times and Gazette* the accompanying letter, which I found amongst the papers of my brother, the late Dr. Nicholas Williams, of Crookstown, Co. Cork.

I am, &c. JOHN WILLIAMS, L.K. and Q.C.P.I.

16, Charlotte-quay, Cork, March 16, 1865.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your number for January 7 a case of acute rheumatism is recorded, in which the treatment adopted was that of blistering; and this method, as if a novel one, is ascribed to Dr. Davies, of the London Hospital.

While a student at the Whitworth and Hardwicke Hospitals, Dublin, now seven years ago, I saw dozens of such cases treated in this manner by the talented Medical staff of those institutions, "an opiate at night," when necessary, being the only additional treatment. I had, likewise, many opportunities afforded of noticing the morbidly fibrinous vesicles produced by the blisters. Although it may be correct to ascribe to Dr. Davies the theory which asserts that "the poison locates itself in the inflamed joints," still, in justice to Ireland, I must say I have seen the treatment of acute rheumatism by blistering practised extensively.

I am, &c. NICHOLAS WILLIAMS, M.D.

Bride Cottage, Crookstown, Co. Cork, January 11, 1865.

Advice Gratis to Young Men.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—If you do not think the enclosed instructions to young men, as to the necessity for washing the glands and prepuce, will interest some of your readers who have not forgotten their Latin grammar, it may at least amuse them. I am, &c. CHREMES.

Ad Adolescentes.

Quâ morbus ille, tot malorum auctor malus,
Valdè timendus, arte sit vitabilis,
Sermone juvenem in hôc brevi senex docet.

Loquuntur: PAMPHILUS juvenis et CHREMES senex.

P.—Salvere Chremêtem plurimum jubeo.

C.—Salve Pamphili: quid tu? rectin atque ut vis vales? cœnastin? age; poculum exple: ecce Falernum præstantissimum: sume: me ipse quidem sentio jam vino benevolentiâque abundantem. Quid vis amicissime? die quomodo benè de te mereri possim.

P.—Gratias ago: de valetudine meâ magnoperè cupio tecum confabulari.

C.—Ædepol! Tu florentis ætatis juvenis, tanquam heri modo togate, virtute et viribus prædite; de valetudine tuâ mecum consulere!

P.—Imo amice. Ita Dii te ament, ut mihi exponas quâ ratione ille morbus, quo tot amicorum affectos video (quod ad nos viros pertineat) evitandus sit.

C.—Hem! rogas? Sum animi dubius: nescio an arcanum tanti pretii liceat mihi enunciatum facere.

P.—Cur hôc? an lucri causâ vulgatum non-vis? Verere ne æra perdas? nonne ita est? Vah!

C.—Certissimè: satis video te, licet adhuc adolescens sis, et Thermas et Forum frequentare. Ita Dii me adjuvent, si is modus quem equidem mihi cognitum habeo, omnibus divulgatus fiat, morbus ipse perpaucos afficiat.

P.—Amice, amicissime, validissimam rationem *mihi* protulisti, quare id, quod ad salutem publicam tantoperè pertineat, universè cognitum esse debeat, nec tantum medicis sed etiam omnibus: nonne officii tui est hoc vulgare?

C.—Certè quidem officii est, sed meâ interest potius celatum habere. De œre suprà dixisti: mehucule, si mali origo abscindatur, lucri fons abundans exsiccus erit.

P.—Abscinde, abscinde. Video te nobis tam ex animo factum velle, ut hodie nihil mihi recusaturus sis.

C.—Hem! sentio me vino plenum: ain' tu "abscinde" an circumscinde. Hem! jam caput meum vertigine agitatur; cor palpitat. Ægrotatne *Passerculus* tuus?

P.—Bene habet, ut fit; vereor tamen ne, nidum petens, morbo afficiatur. Pater, si me amas, mihi aperi rationes, si quæ sint, per quas malum tantoperè timendum evitare possim. Oro, obsecro, ut hoc mihi pandas, optime hominum.

C.—Hei mihi! vitam longam egi, et plurima vidi quæ referre frigeat, vel etiam animadvertere; quæ mala, quo pauciora in hoc avo fiant; et propter amicitiam quam erga patrem tuum et teipsum, et amicos nostros habeo; et liberorum etiam qui futuri sint, causâ, id quod tu prudenter rogavisti, prædicabo. Tu te dictis præbeas volo; atque imprimis te præmoneo perfacile esse plerisque illum morbum evitare.

P.—Ab ore tuo totus pendeo: dic tandem.

C.—Inter Judæos et omnes alios, quibus abscisum præputium, hoc malum rarissimè invenies: nempe illis, cutis adeo indurata, ut abrasio non facile fiat qua propter morbus rarè concipitur; ergo illis ætas integra permanet: contra, cutis tenua Christianis multorum malorum causæ est.

P.—Hei mihi! vis omnes "Curtos Judæos"(a) imitemur?

C.—Forsitan paucos, verum non omnes circumcisionem pati debere puto. Altera est et multò facilior ratio, quæ pene parem immunitatem præbet. Vin' tibi explicem?

P.—Perge, perge, quæso.

C.—Et simplex et secura est: quotidie matutius tempore quum e lecto surrexeris, præputium retrahere, ac glandem nudare: itaque indurata cutis morbum rejiciet. Hoc munditiê perindè ac valetudinis causâ facere oportet. Permagni refert Pupillos, Milites, denique omnes adolescentes hoc scire et continuò exsequi; neque amplius eclari rem tante utilitatis. Abi fac certos omnes familiares tuos, ut tibi pro tanto beneficio gratias habeant.

P.—Tu, quantus, quantus, nihil nisi sapientia es. Dii me perdant ni tibi ex imo corde gratias habeo ob tantum meritum: et ipse utar, et amicos uti admonebo; quæ res bene vertat nobis!—*Vale!*

Exit PAMPHILUS exultans: dormit CHREMES.

The Action of Digitalis.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I fear that "Doctors disagree" on many subjects besides railway accidents. At all events, I am quite sure that I should disagree with Dr. Murray, of Newcastle-on-Tyne, if we were asked to give evidence in a court of justice upon a case of poisoning by digitalis. I have not had the good fortune to read Dr. Austie's work on "Stimulants and Narcotics," and am therefore unable to say how his arguments might affect me. In my present state of ignorance I am bound to confess that I regard digitalis as a contra-stimulant, sedative, depressant, and diuretic.

In the case of the lady adduced by Dr. Murray as a proof that digitalis "has given power to the heart when exceedingly weak and increased the rapidity of its action," I cannot help thinking that the favourable results arose from the secondary or indirect action of the digitalis as a diuretic, and that probably there might be dropsy of the pericardium as well as "a dropsy of the legs and belly," that "was making fast progress."

Again, Dr. Murray says, "I have alternated the use of digitalis with the strongest of our stimulants in some of these cases, and have been astonished at the superiority it possesses as a stimulant." This sentence I should alter thus:—I have alternated the use of digitalis with the strongest stimulants, and have been astonished at the superiority it possesses as a sedative and diuretic over any stimulant whatever in some of these cases.

(a) *Vide* Horatium, Sat., Lib. I., ix., 70.

In my opinion the physiological action of digitalis is that of a contra stimulant or sedative, lowering the nervous power and diminishing the heart's action and the respiration, and, if continued, producing dilatation of the pupil, vertigo, low delirium, vomiting and purging (often of blood), syncope, and death.

To my shame I confess that, not having been in the habit of keeping a record of cases, I am compelled to quote from memory.

When a student at Edinburgh, one of the Physicians to the Royal Infirmary prescribed digitalis for almost every patient that had any symptoms of heart disease, and in too many instances the results were unfavourable, which I attributed then, and still do, to the lowering effects of the digitalis upon the vital organism when incurable organic disease was present.

Afterwards, at University College, London, I well remember a fellow-student falling down in the dissecting-room in what was called a "fit." He was bled and digitalis was administered, with the very worst possible results short of death. It subsequently appeared that on the previous night he had indulged too freely in libations to Bacchus. Who can doubt that a glass of brandy and water would have restored him at once to a normal condition? In fact, he required "a hair of the dog that bit him."

A few years ago I was asked to see a youth at school, who had been afflicted with typhus fever for three or four weeks. Suffice it to say that he was in the last stage of debility, had low muttering delirium, very rapid and feeble pulse, extreme emaciation, and all the worst symptoms of this formidable disease. His Medical attendants were keeping him on low diet and giving digitalis. I at once discontinued the use of this drug, and ordered animal food and wine, the latter in considerable quantities. The delirium gradually subsided, the pulse fell and gained in strength, and from the very brink of the grave this young man was restored to health.

On another occasion digitalis was given to a gentleman in the prime of life affected with rheumatic fever. This eased the pain, lowered the pulse, and quieted the restlessness, which had previously been extreme, but, being continued, brought on vertigo, wandering of the ideas, dilated pupil, vomiting of blood, syncope, and death.

Yet one more case. A little boy, about eight years of age, had received a violent blow on the forehead, which in three or four days was followed by symptoms of inflammation of the brain. Ice was applied to the head, and leeches to the temples. To this treatment the symptoms yielded, but were not wholly removed. Another Surgeon was called in, who prescribed digitalis in repeated doses. This aggravated all the symptoms, inducing furious delirium, screaming and convulsions, which were only arrested by omitting the digitalis, and substituting ammonia, hyoscyamus, and camphor.

It is generally admitted by philosophers to be unwise to alter the meaning of a word that has been long in use and well understood, more especially if a directly opposite meaning to the customary one be substituted. If digitalis be a stimulant, so is prussic acid, and aconite. Then what are we to call alcohol, ammonia, and strychnine? I conceive that a classification of drugs should be founded upon their general results, and not upon their therapeutical effects in a few instances.

Sedatives or contra-stimulants directly depress the energy of the nervous system, and under this head I place digitalis, and must continue so to do in the present state of my physiological, pathological, and therapeutic knowledge, though I am quite willing to listen to any arguments in favour of its being a stimulant, excitant, or exalter of the nervous system.

Upper Clapton, March 20. I am, &c. J. Jones, M.R.C.P.

The Last Indian Medical Warrant.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Knowing the interest you have constantly taken in the Indian Medical Service, and, as a member of that Service, acknowledging gratefully that for many of the benefits conferred by Sir Charles Wood's recent despatch we are indebted to your advocacy of our cause, I venture to send you by the present mail a copy of a statement I have prepared, which will, I think, convince you that, although the recent order has done much to improve our position, it cannot justly be looked upon as a final settlement of all our grievances. In the sketch I have attempted to give of the service as it was and as it is, I have done my utmost to avoid all exaggeration. I have purposely understated rather than overstated our claims for further consideration; and, as a check upon any unconscious overstatement, I have appended to the document copies of the various Government orders which have authorised the different changes in the Department that have been introduced since the period of the mutiny. I have touched but slightly upon the general effects of Sir Charles Wood's last despatch, and I have purposely refrained from doing so because many of the orders which will affect the service as a whole have yet to be carried out, and much will necessarily depend upon the exact interpretation put upon them; there can be little doubt, however, that their tendency must be to lower the *prestige* and weaken the influence of the Indian Army Medical Department. The despatch expressly orders that all European charges are to be taken away from Indian Medical officers; that non-military appointments are, as far as possible, to be conferred for the future upon Professional men not in the regular Government employ; and that the number of officers in the administrative staff, the Inspectors-General and the Deputy-Inspectors-General, is to undergo material diminution. All these changes have a tendency to lower the status of the service, and to diminish each individual officer's chance of earning distinction; and the last especially will practically nullify the good effects of that portion of the despatch which confers upon Inspectors-General and Deputy-Inspectors-General an increased pension upon retirement, as the number of such appointments will be too small to render their attainment possible except to a very small minority.

You will readily understand that Sir Charles Wood's last despatch has accorded to regimental Medical officers an increase, though not in all cases an adequate increase, to their monthly emoluments; the salaries of non-regimental appointments, however, remain in *statu quo*. It is true that such salaries are ordered to be revised without delay, and to be fixed at a consolidated sum, but no provision is made for conferring retrospectively such increased remuneration as may be decided upon; and the consequence will be that the hardest worked members of the Service will continue for a year at least to draw their old rates of pay, whilst their more fortunate brethren in regimental employ are already enjoying the advantages of the recent order.

I trust the remarks I have made will induce you to concur with me in the opinions I have expressed. Should such be the case, I feel confident you will do your utmost to advocate our cause, and that we shall have as much reason to thank you in the future as we have to be grateful to you for the past. I am, &c.

Calcutta, February 8. A Surgeon of the Bengal Army.

ORIGINAL LECTURES.

LECTURES ON CHEMICAL AND MECHANICAL DISEASES AND THEIR RELATIONSHIP.

By H. BENCE JONES, A.M., M.D., F.R.S.

Lecture IV.

DISEASES OF SUBOXIDATION.—ON ACID GRAVEL.

(Continued from page 302.)

On the Consequences Produced by Gravel.

The tertiary diseases which arise from gravel or stone are chemical or mechanical. We will for clearness divide them according to their birthplaces.

1st. The kidney often becomes inflamed from the mechanical irritation of the pelvis. Pyelitis is set up; pus forms and escapes continually for years without pain, or if it have not a free exit it is passed intermittently, with more or less violent pain, sometimes almost causing as much suffering as a renal calculus makes when passing. In these cases the pressure on the pelvis of the kidney being the same as on the obstruction, the pyramids are changed into calices, and ultimately the whole kidney is absorbed, and becomes lost in the abscess.

J. C., aged 32, was admitted into St. George's Hospital in October, 1843, for acute double pleurisy, with effusion. He died comatose on February 11, 1844. The right kidney was healthy; the pelvis, infundibula, and calices of the left kidney were very much dilated, and filled with a thick fluid mixed with gravel and sand. The dilatation depended upon a stricture of the ureter, which existed two inches from the pelvis of the kidney. The ureter was still pervious, but a pig's bristle was the only thing that could be passed through the stricture, which was not more than two lines in length. The other portion of the ureter presented nothing remarkable beyond a slight discoloration. The parts in the neighbourhood of the stricture of the ureter were not thickened.

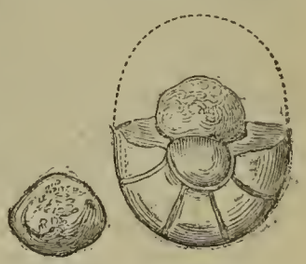
2nd. The stone or gravel lodges in the ureter, and there produces mechanical and then chemical symptoms.

A gentleman, aged 55, was seized with pain in the loin and vomiting on March 23, 1850. The urine was very scanty until the morning of the 26th, when he ceased to make any. The catheter was passed on the 27th, and no urine was found in the bladder. On the 28th he had some delirium, and much increased vomiting. On April 3 there was great drowsiness, with delirium hiccup; at 11 p.m. still no urine was in the bladder. On the 4th, at 4 a.m., after very great pain, he passed two pints of clear urine and a very small stone; it consisted of oxalate of lime, and did not weigh half one grain. For nine whole days no water whatever was passed, and for three days previously only a very small quantity of urine was made. On April 12 the patient was in his usual good health.

On November 23, 1844, I saw a gentleman, aged 54, with a renal attack of three weeks' duration. There was much pain in pressing over the region of the left kidney either before or behind, and there was more fulness in passing the hand over the left lumbar region than over the right. The urine was alkaline, and contained blood. In December the attack gradually went off, and on the 20th he passed a calculus consisting of phosphates and urates; it was the size of a small bean. In three days he appeared quite well. On the 24th he had some pain in the region of the left kidney. On the 27th, pulse 110, jerking; face flushed; skin cold; unable to sleep; tongue brown; urine thick from pus-globules and alkaline. 28th, pulse feeble, intermitting; tongue dry, brown; hiccup; distension of abdomen; very little urine secreted. He sank the following morning. There was general peritonitis, and a large abscess in the cellular tissue around the left kidney extended up to the diaphragm. On trying to remove the kidney with the ureter, it parted an inch and a half below the pelvis, though very little force was used. The ureter to this point was dilated so as to admit the little finger. The lower end of the ureter was not dilated. The pelvis and calices of the left kidney were much dilated, and contained gravel.

3rd. The stone may stop in the bladder, and there also produce mechanical and chemical symptoms. Slight rupture of vessels and hæmorrhage on motion, and pain in the glans when the stone is pressed on the neck of the bladder: these are the two chief signs of cystic calculus.

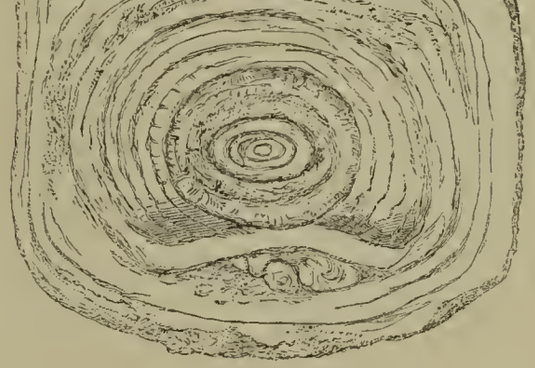
Sometimes the hæmorrhage is enormous. On December 29, 1850, I saw a gentleman, aged 68, who had passed large fragments of uric acid calculus from his bladder. Eight of these fragments, and a large piece the size of a pea, he had collected and put together, forming a stone nearly as large as the first joint of an ordinary thumb. Two or three fragments only were wanting to make the stone perfect. He began to pass a little blood without pain on the 28th; at 8 a.m. on the morning of the 29th he passed very bloody water. I saw him about twelve hours afterwards. The bladder was distended, forming a perceptible tumor in the abdomen. On the 30th there was a very little bloody discharge, but the tumor in the abdomen was less distinct. There were no urgent symptoms, and as he had on a previous occasion suffered in the same way, and no instrument was passed, I let him alone. On June 31, clots and urine came away, and the following day he made clear urine.



Nucleus. Whole Stone.

The following extreme case of mechanico-chemical disease occurred to Mr. Hewett:—

R. R., 17 years of age, was admitted into St. George's Hospital for gravel and irritation in the bladder, from which he had suffered as long as he could remember. The urine was alkaline and purulent; on examination by the rectum a large rough stone was felt pressing backwards, and on pushing it upwards it was felt in the abdomen. The stone was so large that it was proposed to dissolve off the phosphates by hydrochloric acid injections previous to any mechanical operation, but before anything was done, the patient after a week of fever died. Three externally phosphatic stones were found in the bladder: one weighed 120 grains, another 115 grains, and the third 5 ounces 120 grains. The drawing represents the size and appearance of the large stone.



The history of the case, as it was recorded on this stone, was very unusual. At first acidity caused a small stone to form in the kidney, where it remained increasing by different degress of acidity for some time, after which it was passed into the bladder. There the acidity continued very uniformly, for as long a time as the stone had been in the kidney. Then it set up inflammation of the bladder, and the stone by nearly one-fifth of its surface became adherent to the bladder, the urine became alkaline, and the phosphates were deposited wherever the stone was detached. This lasted for a considerable time, the phosphates being mixed with urates in variable quantities. Then the adherent part separated, and an irregular stone one-fifth depressed and four-fifths oval was free in the bladder. After this a more phosphatic state was produced, and when this had lasted for a short time two other small stones probably passed from the kidney, and lodged themselves in the depressed part of the large stone, and these were soon united by fresh phosphatic deposit, which went on increasing the calculus until the death of the patient, when the depression was entirely obliterated.

This stone by mechanical pressure had caused ulceration of the bladder, and a circumscribed abscess had been formed in the peritoneum the size of a cricket ball, which opened into the bladder; another ulcerated opening led into the cavity of the peritoneum, which was inflamed throughout, the intestines being glued together by purulent fluid. The bladder itself

was thickened, and the mucous membrane coated with phosphates.

4th. The urethra is the rarest birth-place for mechanical or chemical tertiary calculous disease. Occasionally a piece of gravel obstructs the passage, or inflammation of the bladder spreads to the urethra, and the angular fragments after lithotrity excite much inflammation, and have even been known mechanically to cut through the tube, and blocking up the natural passage, to cause extravasation of urine and death. But these are rare accidents, and belong more to the Surgeon than to the Physician; still, if time permitted, such cases would furnish me with the very best illustrations of the relationship that exists between mechanical and chemical diseases, showing how, out of the motion of masses of matter, molecular motions arise in consequence of that correlation of force in the body which constitutes the subject of these lectures.

On the Treatment of Acid Gravel.

In the treatment of every kind of gravel the first question is regarding its solvency. The solution of uric acid gravel in any alkaline fluid that can be borne in contact with the mucous membrane of the urinary organs is scarcely possible. It can hardly be doubted that uric acid in a fine state of division as powder could be dissolved, but the problem is to dissolve uric acid in a more or less massive state. The mechanical force of cohesion of the crystalline particles as well as the chemical insolubility of each crystal has to be overcome. And notwithstanding the appearance on the surface of some uric acid calculi, and notwithstanding the supposed disappearance of calculi that have been considered to be in the urinary organs, and notwithstanding I have made numberless experiments, in the body and out of the body, to find a solvent for the stone in the kidneys or in the bladder, yet at present the state of aggregation of masses of uric acid cannot be overcome chemically. Acid gravel has not been dissolved in the kidneys or bladder, though my friend Dr. Roberts, of Manchester, tells me he expects to do both.

Until the gravel comes away or is removed two chief indications for practice exist. Firstly, to prevent it from hurting the mucous membrane, and secondly to stop its enlargement.

Pain and blood are the evidences of hurt to the mucous membrane. Hence, any amount of exercise or of motion may be taken, provided it does not cause pain or blood. The amount of pain may be taken as the measure of the risk of inflammation, and the amount of blood may also be taken as the measure of the mechanical hurt to the kidney, and of the loss of strength which results from hæmorrhage. Both pain and blood may be prevented or temporarily removed by rest; but long-continued perfect rest would in most people soon injure the general health. So that the mean must be found by trials, the problem being to keep up the general health by exercise, but to avoid by rest inflammation or hæmorrhage—that is, chemical or mechanical injury.

The second indication is to stop the growth of the stone. In other words, to prevent fresh acidity; for thus the gravel is kept so small as to admit of perfect cure by the escape of the mechanical mass through the urinary organs. The means of preventing acidity have been already brought before you. Here I shall say only a few words on the good of dilution, which not only delays the precipitation of the uric acid, but helps to wash out the gravel or stone. The best diluent is some alkaline mineral water, as Vichy, or Fachingen, or Seltzer water, taken not only with the food, but two hours before each meal. When there is no acidity, soft spring water night and morning is the best diluent.

This brings me now to the treatment of the passage of gravel or stone from the kidneys or bladder. The chief objects to be obtained are, first, to relieve pain; and secondly, to promote the passage of the calculus.

The pain is most rapidly removed by chloroform or ether inhalation. This, with care, may be continued for hours. The slightest unconsciousness is all that is necessary; but this must be kept up, for on the return of consciousness the pain is again felt.

The second remedy is the hot-bath at the temperature of 100° F. continued for hours, unless it causes faintness. Four hours' bath and then two hours' warm blankets; then three and a-half hours' bath and three hours' warm blankets; continue in this manner, gradually prolonging the rest and shortening the bath. Nothing weakens like pain. Or any hot applications may be used when the bath cannot be taken.

The third remedy for pain is opium externally or internally. Externally, it may be used as a fomentation in any quantity; as laudanum or solution of morphia poured on a poultice, or with one-eighth to one-sixteenth of chloroform on spongio piline. Internally, half a grain of acetate of morphia in solution may be injected into the loin; within a few minutes it will act potently on the pain; or opium, or any of its preparations, may be given by mouth freely, and the severity of the pain renders the system tolerant of large doses; but the ill effects of the sedative in causing inaction of the liver and constipation are very evident when the pain ceases. Half a grain or even two-thirds of a grain of morphia may be given by the mouth, and repeated in four or six hours, if the pain lasts; or thirty drops of laudanum may be taken, and repeated in two or three hours. For the relief of the suffering it is best that no aperient should be taken at the same time as the opiates, the action of the aperient counterbalancing the action of the narcotic on the bowels. Calomel in full aperient doses, as it stops sickness, may be given with the opium if there is great constipation, or if there is great intolerance of narcotics.

Secondly, the passage of the calculus is probably made easier by all the means that relieve pain. When the spasm is relaxed by chloroform and opium, or by the warm bath, or fomentations, the escape of the calculus is made more easy. Still, the pressure of the urine behind the obstruction is the great motive power in the passage of the gravel or stone. This force comes into action only when the obstruction is more or less complete, and then the pressure of the fluid is the same on the structure of the kidney as on the obstruction; and thus the secretion of urine is lessened, and the pressure more and more slowly reaches its maximum. Diluents may early in the attack be of use in increasing the pressure; but after the symptoms of suppression of urine occur, they are of less use in this respect, and when urinous poisoning comes on vomiting and purging give relief by removing some of the poison. Usually, without emetics or aperients, sufficient, sometimes excessive, evacuation takes place; and if this tertiary chemical poisoning does not bring the heart to rest, the obstruction of the ureter may be removed by the continued pressure, and then, the circulation through the kidney being free, the blood is rapidly purified, and a chemical disease far more dangerous than the original chemical complaint (acidity) rapidly passes away.

When the obstruction cannot be removed, not only does the pressure of the secreted urine stop the purification of the blood by stopping secretion, but the urine that has been poured out must, by diffusion, pass back into the blood. When the blood is urinous, diffusion must carry the poison to every part of the textures, even into those parts where no vessels exist—the cornea, the crystalline lens, the cartilages, and, perhaps, even into the nails and the hair. The uric acid, oxalic acid, and urea poison the nerves, and muscles, and blood-vessels, and other textures, and render them incapable of carrying on the actions of nutrition and oxidation.

When the gravel passes into the bladder, usually little or no treatment is requisite. After a longer or shorter delay the stone is forced into the urethra, and ultimately is driven out; but whilst it remains the same objects are still to be kept in view—first, to promote the escape of the stone; secondly, to prevent its growth; and, thirdly, to keep the bladder from harm.

Free dilution and alkaline remedies best fulfil the first two objects; whilst the last is chiefly to be gained by rest. Inasmuch as the bladder is nearer the external orifice than the kidney, two or three other remedies are possible.

First. There is great Surgical authority for occasionally passing a catheter when a small stone is suspected to be in the bladder. If there be no stricture, it is not easy to see how this should help the passage of the stone more than passing a probang before food would make swallowing easier.

A gentleman came to me one morning, and from the microscopic blood in the urine and the pain in making it, whilst his general health was robust, I considered a stone had formed in the bladder. I went with him to a Surgeon, who sounded him, and said "There may be a stone, but I cannot find it." The following morning the patient brought me the stone, which he had voided in the night. To him, and to his Surgeon, it was beyond all doubt that the passing the sound made the stone come away.

Secondly. The Astley Cooper forceps, by which a small stone may be removed whole through the urethra; and the lithotrite, by which a stone may be removed in pieces; and, still more, lithotomy, by which the foreign body is removed whole through an artificial opening, are mechanical proceedings belonging to the Surgeon and not to the Physician.

Thirdly. There is yet another method of cure, so far beyond all other methods in its philosophy, its safety, and its freedom from suffering, that success, though still postponed, must ultimately be attained. This is the dissolving the gravel in the bladder. There is no difficulty whatever, excepting want of patience and chemical knowledge, that hinders the solution of phosphates in dilute acid. A stream of diluted lactic or hydrochloric acid, made so weak as not to irritate the bladder, and passed at the temperature of 100° F., must dissolve any phosphatic gravel or stone or outer layer of stone, provided only that the current is continued long enough.

A warm stream of very diluted lithia or soda should dissolve any urates and attack uric acid. But gravel and stone vary very much in density, that is, in compactness of aggregation, and some uric acid gravel is so hard that it is vain to expect that any stream of water or of alkaline water will have any effect in any reasonable time.

Hence it becomes necessary for the solution of some uric acid stones, and for all oxalate of lime stones, to discover some way of exposing the gravel or calculi to the action of stronger agents than dilute lithia or soda.

In the *Philosophical Transactions* for 1852, p. 201, I have shown what can be done out of the body by disengaging nitric acid and potassa in contact with uric acid by the help of the voltaic battery. Although this is easy in glass vessels, it is very difficult to make a catheter that can cause this action to take place within the bladder, and after months spent in producing an instrument fulfilling all the electrical conditions for success, the equally essential Surgical conditions are by no means perfect. There is a want of firmness and fixedness of the blades which make the introduction of the litholitic instrument difficult. Still, when Surgeons skilled in electrical science, and possessed of sufficient time and patience, arrive, I have little doubt but that uric acid calculi will be dissolved in the bladder. Some more energetic substances may be liberated in contact with the stone, or some way may be found of rendering the stone more soluble. At present progress is stopped more by the mechanical than by the chemical difficulties of the problem.

Oxalate of lime gravel or calculi are so hard and so insoluble that as yet there is no prospect of obtaining any good results by any process of solution. But oxalate is so closely related to carbonate of lime, and this last is so rapidly soluble in any dilute acid, that hopes must be held firm that some day a process of oxidation may carried on in the bladder to compensate for the want of that oxidising action in the blood and organs which leads to the formation of this kind of stone.

ORIGINAL COMMUNICATIONS.

ON NUTRITION.

By LIONEL S. BEALE, M.B., F.R.S.,

Fellow of the Royal College of Physicians; Physician to King's College Hospital; Professor of Physiology and of Morbid Anatomy in King's College.

(Continued from page 277.)

DOES TISSUE EXHIBIT VITAL PROPERTIES?

In this paper I propose to adduce in a form as concise as possible some of the principal arguments which have led me to conclude that the *formed material* which results from the death of the germinal or living matter is destitute of VITAL properties or endowments.

All formed material is permeated by special fluids during life; but I do not think that these fluids *nourish* the formed material. They doubtless cause it to retain its physical properties. *Nutrition*, however, cannot take place unless, as has been already shown, germinal or living matter is present. Even if a fluid deposits certain of its constituents in the formed material, this process is not *nutrition*, for this simple reason—that the substance deposited existed in solution in the fluid. Nutrition involves much more than deposition of matter from a solution. There must be conversion—a complete separation from one another of the elements combined in the constituents of the pabulum and their re-arrangement.

The fluids which permeate the formed material cause it to retain its peculiar characters and properties perhaps somewhat in the same manner as certain preservative fluids prevent physical and chemical changes from taking place after death. It is true that the formed material of many tissues manifests certain peculiar properties, which it loses if immersed in any artificial fluid; but is it unreasonable to infer that if we could cause a fluid having the *same composition and properties* as that which traverses it during the life of the organism to which it belongs, to permeate it after death, it would still continue to exhibit the same phenomena? It seems to me that the formed material of many simple cells—as, for example, the epithelial cells of skin and mucous membranes, and those of hair, cuticle, and nails, or the formed material of which white and yellow fibrous tissue consists, or that of cartilage, bone, and teeth—is lifeless; but that its characteristics are preserved by the continual passage through it of fresh portions of fluid introduced by currents determined by the position of the masses of germinal matter which are so arranged as to ensure every portion of tissue being subjected to the influence of the currents produced.

Indeed, I think few will be disposed to maintain that the particular tissues above referred to manifest *vital properties* during the life of the organism. Their action seems passive, and as far as we know there is no difference between the properties and endowments of a piece of white or yellow fibrous tissue or a portion of the matrix of cartilage, or of cell wall generally, while it remains a part of the organism, and those manifested after it has been removed from the body. The supposed metabolic power or catalytic influence of such structures need not be considered, as it has been already shown that evidence of such power is wanting, while those who have assumed its existence have not attempted to adduce any fact in favour of the view. In truth, such a notion never had any foundation, and was probably only resorted to for want of some more plausible hypothesis.

Since, then, such textures as cell wall and intercellular substance generally exhibit no evidence of *vitality*, it is well to inquire if some of the substances deposited within cells—that is, in the substance of germinal matter—possess vital properties.(a)

Adipose tissue is continually altering in proportion during life, sometimes being deposited, sometimes being removed; but can the fat of adipose tissue be regarded as living? Surely all will admit that the fatty formed material is lifeless, is *dead?* The starch of the starch-cell is likewise *dead.* But it might be said starch and fat are secondary deposits, formed in the substance of germinal matter, and they cannot therefore be included in the same category as the formed material of which the cell wall, intercellular substance, etc., is composed. Both secondary deposits and cell wall, etc., are formed material, but the difference in composition seems to be dependent mainly upon the different conditions under which the death of the particles of germinal matter which took part in their production occurred. The production of cell wall, intercellular substance, etc., is a process very analogous, probably in its essential nature, to the production of secondary deposits within cells, for, as I have shown, the matrix of cartilage may be formed in the substance of the germinal matter of the cartilage cell and this matrix be perfectly continuous with that which surrounds it ("on the structure of the tissues"). In certain cells in the common potato which are devoid of starch granules, a considerable deposit of matter, closely allied to starch, has been deposited upon the interior of the so-called cell wall. These facts show how very closely the production of peculiar matter in the substance of germinal matter is allied to the production of formed material upon its surface. The latter as well as the former are formed material, and there seems no good reason for regarding one as dead and the other as living.

Thus I am compelled to accept the conclusion that all formed material is dead or that all formed material is living. Now, the latter view cannot, I think, be sustained for a moment. If so, the extremity of the hairs and nails, the oldest part of the dental tissues, the outermost part of the bark of trees which may have been formed centuries ago; the hard, dry tissues of which the stones of fruit are composed, etc., must be examples of *living formed material;* and as no essential change can be observed in many of these tissues after they have been preserved in our museums for centuries, we are, I think, logically compelled to consider them as still living, or to maintain that the difference between *dead* matter and *living* matter depends not upon any difference in the phenomena occurring in the matter itself, but simply upon the circumstance of its remaining still in connection with a living organism. In short, that a dried up leaf, in

(a) The question concerning the vitality of muscle and nerve will considered in the next paper.

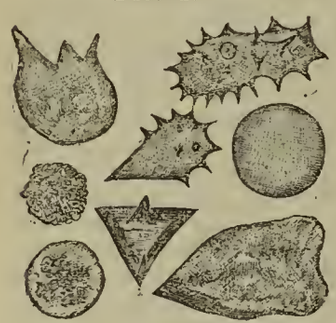
which every vital change has long since ceased, is *living* so long as it remains upon the living branch, but is *dead* the instant it falls from it. That is, a very slight change in the position of the matter alone determines its *living* or *dead* state. For these reasons, then, I am compelled to consider all formed material as matter in which life has entirely ceased; and I think that the *living state* is quite distinct from the *formed state*, that matter which manifests *life* does not exhibit *form*, and that *life* and *form* cannot co-exist in the same particles of matter at the same time. (b) *Life* prevents matter from assuming form for the time being, but so disposes the elements of matter as to compel them to assume a definite arrangement when the matter ceases to live.

But it may be asked, "Is the red matter of the red blood corpuseles—which is undoubtedly formed material, as the changes occurring in the frog's blood corpusele abundantly testify—lifeless?"

It has often been said that the red blood corpuscles are living cells which *distribute life* and nutrition to all the tissues of the body, and it is now generally supposed that the red blood corpuscles exhibit *vital phenomena*. Yet when we come to inquire into the history of the formation of the red blood corpuseles and study the changes which occur in the fully formed corpusele under certain conditions, we seem forced to a very different conclusion, and the red blood corpuscle, instead of being a living cell possessing wonderful vital powers, would rather seem to be a small mass of soft, lifeless matter, the very form of which (circular or oval) is probably due in great measure to the size of the tube through which it is forced, the rate at which it is made to pass through it, and the influence of fluids of different density to which it becomes exposed in different parts of its course.

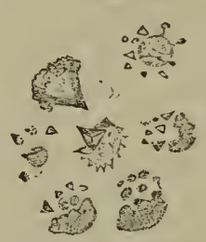
Wonderful powers have been attributed to the cell-wall of the red blood corpuscle, and it has been supposed that it may burst and thus the contents become set free. Careful observation of the changes occurring in the red blood corpuscles of the guinea-pig soon after its removal from the body, prove conclusively, I think—1, That there is no cell-wall distinct from the contents; and 2, that the whole corpuscle consists of viscid matter, which very readily becomes crystalline. (c)

Fig. 1.



Changes in form of red blood corpuseles of guinea-pig after removal from the body, × 1800.

Fig. 2.

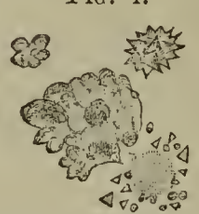


Disintegration of red blood corpuscles of guinea-pig's blood, each corpuscle breaking up to form many minute tetrahedral crystals.

Fig. 3.

Perfect tetrahedral crystals formed from guinea-pig's blood. In many cases one corpuscle became one crystal.

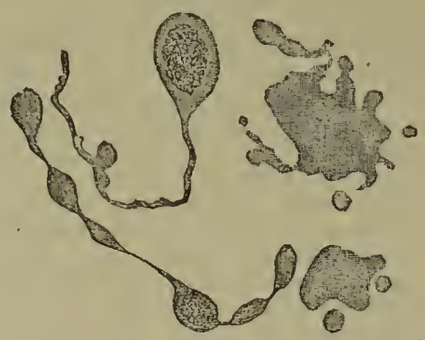
Fig. 4.



Disintegration of the red blood corpuseles of the guinea-pig resulting from heat. Some have separated into several small particles, each of which has assumed the crystalline form, × 700.

Portions of the viscid matter may be detached from the general mass, as shown in Fig. 5. These facts are surely strongly opposed to, if not incompatible with, the view generally entertained with reference to the nature of the red blood-corpuscle.

Fig. 5.



Curious spontaneous changes in form of red corpuscles of the frog, × 700.

The mode of formation of the red coloured matter (lifeless formed material) of the red blood-corpuscle can be studied in the large corpuscles of the frog, and will be readily understood by the following figures, which explain themselves (d):—

Red Blood-Corpuscles—Frog.

Fig. 6.

Young corpuscle, frog, not yet coloured, × 1800.

Fig. 7.

Young red corpuscle, frog. Formation of coloured portion × 1800.

Fig. 8.

Young red corpuscle, frog. A part of coloured portion fully formed, × 1800.

Fig. 9.

Young red corpuscle, frog. Coloured portion and nucleus, × 700.

Figs. 10 and 11 represent old blood-corpuscles the germinal matter of which has been almost entirely converted into formed material:—

Fig. 10.

Fig. 11.

Old red corpuscles. Nearly the whole of the colourless germinal matter has been converted into coloured formed material, × 700.

The coloured matter of the red blood-corpuscle is, therefore, composed of lifeless matter, and, so far from exhibiting vital properties, in some instances assumes the crystalline form almost as soon as it ceases to be urged in rapid motion through the blood-vessels.

In discussing the complex phenomena of living beings, and more especially the changes occurring in disease, it is most important that we should determine what matters of the body are *dead*, and what *living*,—what *have been formed*, what are to be formed,—what matters are the seat of vital, and what the seat of physical and chemical changes only.

Next, I must consider if the contractile tissue of muscle and the axis cylinder of a nerve fibre are to be regarded as *living*, or if these, like the other kinds of formed material alluded to in this paper, *have ceased to live*.

(To be continued.)

(b) Perhaps I should rather say "except the spherical form," for particles of *every kind* of living matter assume the spherical form. Living matter never exhibits any other *form*.

(c) I hope the Figures 1 to 11 and the explanations under them will enable the reader to see the force of the main points in the argument without trouble or loss of time. Those who desire a more detailed statement of the facts are referred to a paper published in the *Transactions* of the Microscopical Society for 1864, from which these drawings have been selected.

(d) In the figures, the coloured matter or formed material which is external is represented by the smooth tint—the germinal matter by the dark granular shading.

CASE OF

ANEURISM OF THE FIRST PORTION OF THE FEMORAL ARTERY TREATED BY COMPRESSION—DEATH AND AUTOPSY.

By R. COOPER TODD,
Surgeon 60th Rifles.

Private James M'Namara, aged 25, was admitted May 9, 1864, with a tumour in the left groin.

A fortnight previous to admission he had been jumping, and he felt "something give way" in his left groin. About

six or seven days afterwards a small tumour appeared in the seat of the injury, and as it seemed daily to increase he reported himself sick.

The tumour lay close beneath Poupart's ligament. The pulsation was very forcible and expansive in its character; pressure on the artery with the thumb against the pubis in a direction downwards and slightly forwards commanded the pulsation.

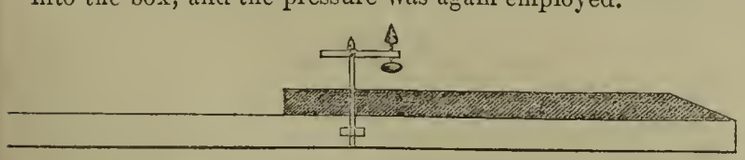
The nature of the tumour was clearly aneurismal; but, while the apparently healthy constitution of the patient, his youth, and the recent date of the injury gave promise of a cure by compression, the trifling cause of the complaint in one so young, free from syphilitic or rheumatic taint, and, as far as was known, steady in habits, pointed to general arterial deterioration and an unfavourable prognosis under any line of treatment.

An aneurismal compressor suitable to the case could not be found in the whole command. An ordinary tourniquet was, therefore, contrived to suit the purpose; but it could not be so fixed as to act steadily. The patient himself, also, rather opposed than aided the measures adopted. He believed the disease to be a trifle curable by a liniment, and that we were putting him and ourselves to very unnecessary trouble. The exact nature of the disease was explained to him fully, and the danger to his life pointed out, but without enlightening him in the least degree. To the very end he exhibited the same dogged indifference and scepticism.

Through the kindness of the Surgeon of the Civil Hospital, I was fortunate enough the next day to borrow Carte's instrument. It was so applied as to check the pulsation, while the slightest pressure of the finger on the instrument perfectly commanded it. The complete cessation of the pulsation was not deemed desirable, but merely its reduction to the minimum power practicable, and the patient was put under the influence of tartarised antimony and opium.

This line of treatment was continued for some days, but without any apparent benefit. The patient was instructed how to use the instrument, but his interest could not be enlisted in his own case. Everything seemed favourable. He had no pain from the pressure; the integument remained firm and healthy, and he could adjust the instrument, and even command the pulsation at will, without any inconvenience. He got morphine draughts occasionally, tinct. ferri. sesquichlor., tinct. digitalis, potass. iod. in large doses, yet without benefit, for the moment he got a chance he did everything in his power to thwart our endeavours.

On the 3rd of the following month my coadjutor, Dr. Oliver, got a box made, to the outside of which the compressor of Carte's instrument was attached. This apparatus contained the whole leg. It had a footboard moveable on a pivot. Its outer side was long and extended to the armpit, to prevent the patient slipping down in the bed. Its inner side was short, and reached the middle third of the thigh, while the posterior side expanded out behind the sacrum, so as to render it more comfortable to lie upon. The whole was then well padded. The limb was carefully bandaged and bound into the box, and the pressure was again employed.



A steady and uniform pressure was now carefully kept up for some days. A more generous diet was allowed, and even porter was given. Great attention was paid to the case, and certainly, if pressure could have cured, it must now have succeeded. No sign of consolidation, however followed, and, as the last resource, ligature of the external iliac was proposed, but the patient positively refused to submit.

On June 13 the tumour had greatly enlarged, but its contents were still fluid. There was, however, a very distinct purr felt not only in the tumour but in the radial artery, and then for the first time was detected a bruit with the first sound of the heart. "It was most distinctly heard over the region of the aortic valves (so runs the morning report), and for an inch above their usual situation."

On the following day this bruit had a double character, but its situation was unchanged. Now to this bruit I would call attention, because in the first place it had not been audible at the outset, and in the second place its source proved after death to be remarkable. It is true that the presence of atheromatous deposits was suspected, but the true nature of the aortic disease had not been diagnosed nor suspected during life. The bruit itself was peculiar. It was sometimes single and sometimes double. It was sometimes absent, at least not audible by the stethoscope. It was palpably organic, yet sometimes it presented characters which led one to hope that it was functional.

It would be useless to follow this long case through all its stages and symptoms. Suffice it to say that the tumour enlarged, became diffused, and threatened to eat its way through the integument; that the patient suffered from hectic fever, differing in its intensity from time to time; and at last died from exhaustion, seven months after the receipt of the injury.

Autopsy Eighteen Hours after Death.—This was carefully made by Dr. Oliver, from whose notes I have compiled the following:—The body was greatly emaciated. The left foot and ankle were swollen and œdematous, the thigh and leg semiflexed on the abdomen and everted. Their wasted condition formed a very marked contrast with the gigantic size of the tumour, occupying as it did the anterior and upper half of the femoral, and extending into the iliac, until lost in the umbilical regions. The tumour was solid to the feel, and in the upper part of the thigh measured thirty inches, and was capped with a circular granular ulcer, which measured one and a-half inches in diameter. The head was not examined. The lungs were sound. The heart was enlarged, and its left cavities hypertrophied. Atheromatous deposits were found on the aorta in the sinus corresponding with the right anterior semilunar valve. In this part also the vessel was thin and dilated, forming a projection to the right of the infundibulum of the pulmonary artery, and plainly visible as it bulged out behind this vessel. The cavity of this aneurismal dilatation contained a small clot about the size of a walnut, which was probably post-mortem. No abnormality was detected in the rest of the vessels of this region. That this aortic lesion was the cause of the bruit heard during life cannot be doubted, but I must leave it to your readers to account for the various changes in the character of that sound. The atheromatous deposits probably produced the sound, and the changes in the condition of such a dilatation so close to the aortic valves would certainly affect their action and vary the character of the bruit. The tumour was exposed by opening the abdomen and dissecting off the integuments from the anterior surface of the thigh. It measured *in situ* one and a-half feet from above downwards, and one foot transversely. In the pelvis it presented an immense elastic swelling, which filled the whole iliac fossa. The fascia of the region prevented its growth superiorly and externally, and limited its encroachment on the true pelvis. Poupart's ligament was torn away from its bony attachment, and lay flattened across the centre of the tumour. Internally, was the spermatic cord, uninjured; and superiorly the cribriform fascia and fascia lata of the thigh bound it in its place. The colon was much contracted, and loaded with scybala. It adhered closely to the tumour superiorly, and internally for about three inches, forming an agglutinated mass, with the left ureter and corresponding kidney. At its point of contact with the aneurism it was highly inflamed, and contracted in calibre, although permeable. The ureter and kidney participated in the inflamed condition of the intestine. The external iliac artery and veins were also discoloured, but in other respects seemingly healthy. The aorta and common iliacs presented nothing abnormal, but the internal iliac was enlarged. The psoas and iliac muscles, flattened and expanded over the mass, were seen through the fascia enclosing the anterior crural nerve. The external iliac, accompanied by its vein and some branches of the genito-crural nerve, passed internally. The vein was pervious, and continuous with the internal saphena vein, but the artery was greatly diminished in size, and its branches were quite obliterated. In the femoral region the vessel became amalgamated with, and lost in, the tumour, and about two inches below Poupart's ligament had been torn in two, the ruptured ends lying about two inches apart. In tracing the vessels upwards from the opening in the great adductor, the vein soon became impervious, and the artery presented the torn appearance already mentioned. It was impossible to demonstrate accurately the channels which supplied the circulation of the limb. Even if the whole body had been artistically injected, which army Medical officers have no means of doing, I doubt if much information could have been gained; but the increased size of the internal iliac showed that it must have been highly instrumental to this end. When the tumour was laid open no trace of the profunda could be seen. The tumour seemed composed of a

mass of fibrine, containing in folds or sinuses about two pints of recently coagulated blood. The evidence of sacculation was by no means distinct. There was, however, one part of the mass which looked like the original sac of the aneurism; it lay above in the iliac fossa, far removed from the seat of rupture in the femoral. It probably had been detached and pushed out of its place by renewed depositions. The whole of this fibrinous mass could be easily peeled, lamina after lamina, and was so firm as to be readily removed and replaced. The tumour had exercised a very destructive influence over the neighbouring bones. The anterior spinous processes of the ilium were absent. Two-thirds of that portion which goes to form the iliac fossa were corroded nearly half-way through. The pubis was nearly eaten through into the foramen. The capsular ligament and anterior third of the acetabulum were destroyed, and the joint opened. The neck, lesser trochanter, and upper anterior third of the femur were likewise injured. The trochanter suffered most. All the muscles of the region participated in the injury caused by the tumour. The weight was six pounds. The ulcer which occupied the apex of the tumour had eaten through the fibres of the sartorius, which lay across the tumour flattened and detached.

A case of aneurism, similar in every respect excepting in its issue, came under my care in the General Hospital, Dublin, in 1863. The patient was a soldier in the 36th Regiment. The aneurism was caused by his lifting a heavy box; it was in the same leg and same position as in the present case. Compression was used, and the aneurism cured. I have heard that the man was subsequently discharged the service for atrophy of the muscles of the leg.

ACTION OF WATER, CONTAINING NITRITES AND NITRATES, ON IRON, LEAD, AND ZINC.

CARE TO BE TAKEN IN ADOPTING IRON WATER-PIPES WITHOUT BEING ENAMELLED.—NITROUS ACID IN WATER, AND SUSPECTED COMBINATION WITH AN ORGANIC BASE.

By HENRY OSBORN, M.R.C.P. Lond.,
Consulting Physician to the Southampton Dispensary.

In my early investigations of the "action of water on lead" so many cases of poisoning by that metal occurred that it was absolutely necessary to find a substitute for leaden pipes for raising and transmitting water from wells in dwelling-houses. Iron, being considered the safest of all metals, began to be very generally adopted for that purpose; but the ferruginous corrosion was so great in many places that the water could not be used for domestic purposes. A gentleman having gone to a great expense by removing the leaden pipes and substituting those of iron, and finding that the water could not be used owing to its being so strongly impregnated with that metal, resolved to dig a new well, to which a tube of gutta percha was attached.

A gentleman being paralysed by lead water was advised to substitute tubes of tinned copper for lead; but they failed to answer the purpose. I proved the presence of lead in this water, and the rapidity with which it was taken up in solution; but I did not examine it for copper, though I have frequently detected that metal in solution, resulting from the contact of water with a brass or copper pump, taps, etc. I am, however, not prepared to say whether the existence of copper may not be due to galvanic action or to the oil or grease which is used to lubricate the piston-rod, etc.

Water, containing nitrates and chlorides, was put into five test-glasses, with a rod of iron, lead, zinc, copper, and tin in each; the three first were rapidly corroded, but the two latter were not acted upon, even after a period of forty-eight hours. An experiment, however, on a small scale and in open vessels must not be trusted.

The presence of copper in water may be detected by adding a few drops of a solution of ferro-cyanide of potassium to a large test-glass of the suspected water, when a reddish tint may be discerned, and on standing a precipitate of a red colour will collect at the bottom of the vessel;

By way of further showing that iron cannot be depended on for the purposes under consideration, I may mention that another gentleman took a house, some years since, about four miles from Southampton, and, knowing that cases of lead poisoning had occurred in the neighbourhood, requested me to examine the water in the house which he had just taken. Finding so much lead existing in the water, I advised him to take up all the leaden pipes, extending even to the stable-yard pump, and to replace them by iron; but so great was the corrosion of the latter metal that the water could not be used even for washing purposes, and the horses refused to drink it. This water contained nitrates.

In order to prevent the oxidation of iron, zinced iron pipes (galvanised iron) were introduced, and zinc in solution was the result, thus getting rid of one evil by substituting another.

Water pipes of grain and block tin were also introduced about the same time as the zinced iron, and the first place in which I heard of their being used was at Osborne House, in the Isle of Wight. Tin has been adopted by many persons in this locality, and no injurious corrosion of that metal by water appears to take place, but further investigations are required in various localities. I have been informed that there is a cheaper sort of tin pipe now sold, but owing to its being a mixed metal it is rapidly acted upon by water, and some of those who incurred the expense of laying down the so-called tin pipes were compelled to take them up again.

Immediately after the ceremony of laying the foundation-stone of the Military Hospital at Netley, Dr. Andrew Smith (Sir A. Smith) called on me to make inquiry respecting the action of water on lead in the suburbs of Southampton, when I pointed out to him the risk that would be incurred by using either lead or iron for conducting the water, and suggested that tin would be preferable for that purpose. Dr. Richardson's communication in the *Medical Times and Gazette*, October 29, 1864, informs us that the cost of the tin pipes in the Netley Hospital amounted to £9000. I may add that the money has been judiciously expended provided good block tin was selected and some precautions taken hereafter to be mentioned.

The well at the Netley Hospital being of considerable depth, the water in it would be less liable to attack either lead or iron than ordinary well water in the neighbourhood. Still, however, the risk would have been too great for such an establishment. Iron pipes enamelled are, perhaps, next to tin in point of durability, and, being far more economical, would meet all classes of the community. I speak, of course, of those localities where lead cannot be used without the risk of saturnine impregnation.

Notwithstanding the presence of nitrites and nitrates of lime and magnesia in water, constituting the most powerful oxidising agents of iron, lead, and zinc, I have met with nitrous acid, which is a still more powerful oxidising agent of these metals. Prior to my proving that the oxygen salts were the most active agents in producing the continuous formation of oxide of iron in water, I entertained the opinion that atmospheric oxygen was the chief oxidising constituent; but having found on one occasion the presence of nitrogen without a trace of oxygen, and the interior of the leaden pipe, when removed from the well, being thickly covered with flocculent carbonate of lead, I looked to another source for oxygen. I must not omit to state that chlorides play an active part in the action of water on metals; but when chlorides without nitrates are present, the corrosion is generally arrested after a few months or a year.

I have made but few examinations of the gaseous constituents of water, but I believe free nitrogen is seldom met with, and in most cases it is associated with oxygen, while carbonic acid exists in a free state, or contains but a small quantity of carbonate of lime; hence it is that the oxide of lead is rendered soluble until the water is exposed to the air, when the carbonate of oxide of lead is precipitated or suspended by the water. In like manner oxide of iron is rendered soluble by carbonic acid, but there is a considerable excess of the peroxide and protoxide of iron.

I have stated above that some precautions are necessary to be taken in the preservation of tin pipes, and the information which I have received from a plumber in this town (Mr. Brumfield) I think of sufficient importance to mention. He stated that he had never found either grain or block tin pipes corroded by water, but that they are liable to be acted upon by the soil in which they are imbedded, and the kind of soil which corrodes the most is that of clay-earth rather than chalk. Mr. Brumfield produced a piece of block tin pipe, the external part of which had been corroded into holes, and the interior was oxidised by water; but I had no opportunity of proving whether the oxide was soluble in that fluid prior to its becoming dry. I need scarcely state that it is requisite, by way of economy, to protect all tin pipes by drain-tiles or some other material in order to prevent contact with the earth.

In conclusion, I would revert to a communication of mine in the *Medical Times and Gazette*, May 28, 1864, on the Existence of Free Hydrochloric Acid in Spring-water, contained in a well, situate within three miles of Netley Hospital. The acid, as stated, was obtained by simply reducing the water by evaporation and distilling over the latter portion in a water bath; but the quantity of acid obtained being very small, I did not determine the presence of nitrous acid, which I also suspected to exist in a free state. On procuring a fresh supply of the water,(a) and reducing two gallons by evaporation, I obtained by distillation a sufficient quantity to prove the existence of free nitrous acid in addition to the hydrochloric. The last drachm of the distillate contained the acids in a dilute state, but care was taken not to allow the whole of the acids to come over in order that no decomposition of the nitrate, nitrite, and chloride of lime and magnesia might take place.

When a solution of chloride of magnesium or nitrate of magnesia is evaporated, there is a liability of decomposition taking place, the acid escaping while magnesia is deposited, but no such decomposition took place in the water under consideration. It may be said that although hydrochloric acid is present in water after evaporation, it does not necessarily follow that it exists in an uncombined state prior to evaporation if another mineral acid is present. There is just this possibility, however, that nitrous acid may pass into nitric and displace chlorine from calcium,(b) and by taking hydrogen from water forms hydrochloric acid.

When I first discovered hydrochloric acid in water I made a quantitative analysis, after evaporation, by estimating the amount of combined and uncombined acid, but I have never ventured upon a quantitative analysis previous to evaporation, as the acid exists in so small a quantity, and cannot be detected without introducing a strip of blue litmus paper for a short time in a glass of the water. With this reagent a little precaution is necessary; the litmus must not wash out of the paper, and the water should be exposed in an open vessel in a warm room for about twenty-four hours to allow the carbonic acid to escape; it is also requisite to procure water from some other source and test it in the same manner, by way of comparison.

I endeavoured to prove the presence of free hydrochloric acid, without distillation, by treating the reduced water with nitric acid and gold leaf; but although a small portion of the gold was dissolved, there was no proof of the acid existing in a free state, because nitric acid displaces chlorine from calcium, and thus prevents a satisfactory result. Water containing nitrates and chlorides dissolves gold leaf when the residue which is left, after evaporating the water nearly to dryness, is treated with sulphuric acid; but the quantity of gold dissolved by the nitro-hydrochloric, which is set free, may be so small as not to be observable to the eye; in that case, the solution must be filtered and tested for gold with protochloride of tin. Nitrates in water may be readily detected by the ordinary test—sulphuric acid and protosulphate of iron—but it is sometimes requisite to reduce the water by evaporation before applying the test.

The argument against the existence of an uncombined acid in water being so great, I have endeavoured to account for its presence by displacement, as already described; but free nitrous acid may be also doubled, especially as nitric acid is its solvent, and when mixed with water it passes into nitric acid. But when we bear in mind that hyponitric acid has a feeble affinity for inorganic bases, and does not combine with them directly, but that it has a strong affinity for organic bases, with which it readily unites, such a compound may, perhaps, exist in water naturally as well as artificially. Gun cotton (pyroxyline) is a compound of nitrous acid, insoluble in water, but there is another compound of the same acid, and organic base (c) soluble in water; hence it is possible that the latter may exist as a natural product. If this hypothesis be correct, the nitrous acid having an organic base cannot be said to exist in a free state previous to evaporation; but it may be an unstable compound formed by the acid in its nascent state from nitrogenous matter, and lastly passing into inorganic nitrites and nitrates. It may be as well to state that vegetable matter having a gelatinous appearance was found in the water after being kept for a few weeks in a stone bottle, and when placed on a glass slide and permitted to dry, it presented under the microscope the appearance of oscillatoriæ and nostoes; but whether such vegetable matter is capable of playing the part of a base I am not prepared to state; the subject, however, is of great interest, and requires further investigation. Lastly, I may add that the properties of such water, in a Medical point of view, is unknown to us, but the idea suggests itself that its continuous use might prove beneficial in certain cases of renal or vesical calculi.

Southampton.

(a) The first supply of water was procured in dry weather, and the second after a heavy fall of rain. I had an opportunity of proving, on one occasion, that water containing the hydrochloric acid came from a spring or springs twenty-five to thirty feet below the surface.

(b) The first water in which I found the acid (in a well in the New Forest) possessed a slight bleaching property before evaporation.

(c) See Brande and Taylor's "Chemistry," p. 186.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ST. BARTHOLOMEW'S HOSPITAL.

THE BLISTER TREATMENT OF RHEUMATIC FEVER.

(Cases under the care of Dr. JEAFFRESON.)

The following abstract of five cases of acute rheumatism, treated by Dr. Jeaffreson on the plan recommended by Dr. Herbert Davies, of the London Hospital, has been made, by the kind permission of Dr. Warter, from his Clinical Case-book. The cases were of marked severity, the relief afforded was speedy and permanent, the temperature of the body fell rapidly, and in those cases which came into the Hospital free from heart complication no cardiac mischief was developed. The safety of the heart is undoubtedly the main point at which every treatment must be directed; and in this particular more especially does the Blister Treatment exhibit its peculiar value. In a communication read Wednesday, March 22, by Dr. Davies at the Hunterian Society, he stated that of 50 cases which had been admitted under his care at the London Hospital 27 had hearts already damaged by recent or old inflammatory mischief, and 23 were free from cardiac complication. The results of the blister treatment in these fifty cases showed that as many as twenty-five, when discharged from the Hospital, were totally free from any endo- or peri-cardiac disease; or, in other words, that while every heart was saved which came in sound, two recent cases of endocarditis were apparently cured by the alteration effected, as he believed, in the alkalinity of the blood by the free discharge of serum from the neighbourhood of the inflamed joints. Dr. Davies also states that those cases answer best to the treatment in which a great number of joints are simultaneously affected, and when, by setting up a large amount of discharging surface in the proximity of the inflamed parts, a large proportion of the *materies morbi* may be evacuated at one *coup*. Cases where the poison would appear to crop up to the surface by instalments, attacking the various joints at intervals of days, do not afford such striking examples of the efficacy of the treatment. The first case, where an unexampled amount of blister was applied in an extremely acute case, and where the patient was discharged cured in thirteen days, will well illustrate Dr. Davies' position. That this treatment is not simply local in its action was also shown in the alteration produced in the urine in the majority of the cases cited; for in 11 the urine remained acid, but generally diminished in acidity during the whole period of the case; in 22 it became neutral shortly after the serum was discharged; in 10 it exhibited an absolute alkaline reaction; while in 7 no notes were taken.

Case 1.—William S., aged 32, a working silversmith, and exposed to great variations of temperature, was admitted into the Hospital on December 2, the seventh day of his illness, and was discharged cured on December 15, thirteen days after he came under treatment. Eleven blisters, amounting to 482 square inches, were applied simultaneously, and with almost immediate relief. As the patient said, "the rheumatic pains left me as soon as the blisters drew;" and on the third day from admission all pain had disappeared. The pulse fell from 105 to 95 per minute; the temperature from 101·4 to 99·6 and 98·8; no cardiac mischief was developed. The urine, scanty and acid on admission, was rendered slightly albuminous from the presence in it of a small quantity of blood. The slight strangury and albumen, however, disappeared in forty-eight hours. He had slept very badly from the commencement of his illness, but as soon as the poultices were applied to the blistered surfaces sleep returned,

and was "good" every night during the time he remained in the Hospital. His appetite, bad on admission, was good on the third day; and his thirst, which was slight when he came under treatment, was not increased by the blisters, is reported to be absent on the fourth day. The heart was sound when he came under treatment, and free from disease when he left the Hospital.

Case 2.—Wm. P., aged 22, bootmaker, was attacked, for the first time, with rheumatic fever on November 29. He was admitted into the Hospital on December 6, the seventh day of his illness, and was discharged on January 2, 1865. Seven blisters, equal to 133⅜ square inches, were applied on December 9, and the pain, which was severe previous to their application, had disappeared as soon as the surfaces had been dressed. The following day the clinical report states:—"There is no pain anywhere, and, with the exception of a little uneasiness on the right shoulder on December 17, he was quite easy and comfortable until the day of his discharge." The pulse fell from 110 on admission to 90 per minute on the third day. The temperature from 101·4 to 98·6. The heart presented a systolic murmur, distinct at admission over base and apex, and was unchanged at the time of the patient's leaving the Hospital. His sleep, which was stated to be bad before the blister application, was improved on the second, good on the third night, and remained satisfactory until he was discharged. The urine presented a slight trace of albumen as the result of the treatment, but was normal and free from that substance forty-eight hours after the blisters had been applied. The appetite, which was indifferent on admission, is reported to have been "good" on the fourth day, while the thirst was absent at first, and continued so, unaffected by the local irritation set up by the blisters.

Case 3.—John B., aged 19, was admitted on December 8, 1864, the seventh day of his disease, and discharged January 30, 1865. He had, however, been up and dressed from January 11, 1865. Eight blisters were applied on December 9, three on the 12th, one on the 13th, one on the 14th, one on the 21st, making in all 603½ square inches of empl. lyttæ. The day succeeding the application of the eight blisters the report states that all pain had disappeared. On the fourth day from that date, the patient has "now a little pain in the right shoulder, and says he wants another blister for it," which is applied and followed by great relief. The clinical account says:—"December 14.—The patient has no pain anywhere. December 18.—The same. December 19.—Had pain in the left knee yesterday, I think he caught cold from going to the closet yesterday. And December 20.—The left ankle and knee were swollen. The application of the blister removed all pain and swelling, and never returned during the time he continued under treatment. The pulse fell from 108 to 86, and varied from time to time, with the appearance of the affection in different joints. The temperature fell from 100·8 to 99·4, and also varied with the pulse. The heart presented before the application a systolic murmur at the apex, which remained unaltered at the time of his leaving the ward. His sleep, which has been bad since December 2, was pretty good on the night after the blisters had been dressed; moderate on the fourth; good on the fifth; disturbed considerably by a blister on the 6th; good on the following and every succeeding night. The urine.—Its reaction before the blister application was not noted, but the treatment induced some strangury and traces of albumen, and its condition varied from time to time with the variable condition of the joints. Appetite is stated to have been bad on admission; a little better on the second day from the application of the blisters; improving and gradually becoming good from the fifth day of the treatment. The thirst was slight when the patient entered the Hospital. It appears, however, to have been considerably increased after the application of the blisters, but the symptoms vanished in a few days.

Case 4.—Charles P., aged 20, butcher, already previously the subject of acute rheumatism, was admitted on December 8, 1864, the fourteenth day of his illness, and discharged on January 18, 1865. Four blisters, equal to 118⅜ square inches, were applied simultaneously, and with such relief that on the day succeeding the application all pain had disappeared, and his sleep, which for fourteen days had been wretched and without benefit to him, is reported as being good, and continuing satisfactory for the remainder of the time he was under observation. The pulse, which was 80 and 66 respectively on the two days before blistering, became 72, 68, 63, and ultimately 60. The temperature, 100·4° and 98·8° before blistering, became 98·8°, 99·2°, 98°, and ultimately, on cure, 98·4°. The heart was free from disease on admission, and continued the same during the entire period. The urine presented after the blistering a very slight trace of albumen. The appetite, which had been bad since November 25, was very much improved on the day after the blisters had been applied. The report says, "he eats everything before him;" and it continued excellent from that date. The thirst was great on admission, only slight after the blisters were applied, and stated to be *nil* on the following day.

Case 5.—Susan J., aged 22, needlewoman, of fair complexion and sanguine temperament, and who had had three previous attacks, was admitted with acute rheumatism on December 12, the fourth day of her illness, and discharged on February 2, 1865. Six blisters were applied: four on December 12, and two on December 14, equal to 328 square inches. On the day succeeding the first application the report states:—"There is no pain now in the hands and ankles, but pain came on in the night in both shoulders, and she has had a very slight pain in passing urine." After the second application the report continues:—"Feels much better; no pain anywhere; got out of bed this morning; wrist still swollen and red, but soft, moveable, and not tender to pressure." On the following day report states:—"She cannot even invent a pain anywhere; looks well, and is only weak. The pulse fell in this case from 114 to 100, 90, and 70, and was 84 at the time she left the Hospital. The temperature fell from 101·7° to 99·7°, or two degrees. The heart was diseased on admission, and the systolic murmur at base and apex remained unchanged. The urine, at first acid, and containing a slight trace of albumen from the blisters, became alkaline on the second day from the time of the local application, and normal speedily after this date. Her sleep, which had been almost absent from December 8, is stated to have somewhat returned after the blisters were removed, to be much better on the fourth, and very good on the fifth night, and to have continued satisfactory until the time she was discharged. Her appetite, none on admission, was improved immediately after the application of the second set of blisters, and pronounced good on the fifth day after the last-named application. The thirst was very great on admission, unaltered the day after the blistering process, much less in amount on the following day, and none on the succeeding days.

THE LONDON HOSPITAL.

CASE OF RHEUMATIC FEVER QUICKLY CURED BY BLISTERS.

(Under the care of Dr. DAVIES.)

A CASE at present under the care of Dr. Davies affords an excellent example of the safe and rapid results of the treatment. The patient was brought into The London Hospital on Friday night completely crippled from acute rheumatism, and presenting the usual symptoms of that disease. He described his agony as very intense. Ten blisters were at once applied, and a grain of morphia was administered internally.

On the Saturday evening he was free from all pain.

On the Sunday he declared himself to be comfortable, and his joints to be moveable.

On Monday morning he sat up and washed himself, and in the evening was able to walk down the ward to the closet.

On Tuesday he was perfectly easy, with appetite returned, and thirst absent; and was ordered to have a chop and a pint of Bass's ale, as he had been accustomed to live rather freely. The urine in this case was found to be strongly alkaline on reaction, and perfectly free from any trace of albumen as tested by heat and nitric acid. He had had no strangury. On being questioned as to the pain induced by the blisters, he said that he would gladly have them repeated were he unfortunate enough to have another attack of rheumatism. No cardiac mischief was developed. No medicine beyond the morphia already mentioned had been administered.

UNIVERSITY COLLEGE HOSPITAL.

A CASE OF TRUE LEPROSY (ELEPHANTIASIS GRÆCORUM)—ERYSIPELAS—DEATH.

(Under the care of Dr. HILLIER.)

J. F., aged 58 years, a native of Limerick, in Ireland. His father and grandfather were very strong men, and lived to a good old age. He knew nothing of the rest of his family.

He spent seventeen years in India as an engineer; he came home two years ago. Whilst in India he lived usually at Bombay, in very damp quarters. He always had enough to eat; at one period of his life drank freely. His general health had been very good till lately. About eighteen years ago he had venereal disease, for which he was treated with pills which made his mouth sore. There is still a depressed scar on the glans penis, not indurated; he says this has been there eighteen years. After his return from India an eruption appeared on his skin. He first observed on his arms, legs, and thighs pimples of the size of pins' heads, nearly of the normal skin colour. There was no itching or unusual sensation in them. Since then they had increased in number and size. He stated that he had lately felt very low-spirited and unusually weak. Had lost all sexual desire for twelve months.

When admitted to University College Hospital, in May, the following notes were taken of his condition:—A very strongly-built man, much disfigured by an eruption on his face and elsewhere. His eyes are suffused; his voice hoarse. Pulse between 80 and 90, weak. His face is studded with numerous round, hard elevations, varying in size from pins' heads to large peas, either of the skin colour or paler. They are to be seen on the forehead, cheeks, chin, nose, and ears. A few of the tubercular swellings are soft and fluctuating, and on section a purulent fluid escapes. The harder ones have a solid, opaque, white section. The eyelids are thickened and knotty; there is no hair on the outer half of either eyebrow. (Attention has been specially called to this as a characteristic symptom of leprosy, as seen in Madagascar by Dr. Davidson.) There are also on the face several crusts of a darkish grey or brown colour, something like rupial scabs; beneath the crust a sharply-cut circular ulcer is found. The sclerotics have a muddy aspect, and the conjunctivæ are injected. There is but little hair on his head, and the scalp has a peculiar olive-brown discoloration in patches, which are elevated, and present in some cases a little desquamation. The external ears are hypertrophied and knobby, with a little scabbing. On the thorax are twenty or thirty tubercles similar to those on the face, but less prominent, as well as one or two crusts. The skin of the abdomen is mottled, of a brownish colour. On the thighs are also tubercles and numerous crusts, which leave round, unhealthy-looking ulcers when removed. On the arms there are patches of brown discoloration, and the skin feels generally thickened and studded with tubercles, mostly of the colour of the skin, but some of a livid purple tint. The backs of the hands are like the arms, but more livid, and have many crusts. A few of the tubercles have softened, and contain unhealthy sanious pus. The palms of the hands are very dry, but not peeling or tubercular. At the nape are clusters of tubercles which are almost confluent; and on the back are also some tubercles, and much brown discoloration.

It was thought that possibly it might be a syphilide modified by long residence in a tropical climate. He was accordingly treated by mercurial vapour-baths twice a-week, and five grains of blue pill every night. He very soon became salivated under this treatment. He stated, however, that he felt much stronger and in better spirits than he had done for months. Some of the tubercles were absorbed, and most of the scabs separated, and the ulcers healed, leaving in many cases an irregular warty surface, of a darkish colour. The discoloration of the skin of the scalp, as well as of the trunk, rather increased than diminished. There was no albumen in his urine. He suffered usually from a cough, with copious expectoration; and on examination of the chest the lungs were found to be emphysematous.

The patient stated that he had, since childhood, had a feeling of numbness in the little finger of his right hand, which had increased lately. On pinching the little finger he felt a darting pain in the course of the ulnar nerve up to the elbow. There was also some numbness on the inner side of the right foot; sensation was decidedly less than on the corresponding part of the left foot, where it appeared to be exaggerated. Examined with the compasses, there was a decided loss of sensibility both in the feet and hands. On the dorsum of the foot he could not distinguish the two points of a pair of compasses until they were four inches apart, instead of at a distance of less than half-an-inch, as in two ordinary patients tested at the time; and on the dorsum of the hand a distance of two and a-half inches was reached before he recognised the two points. In one or two spots on the thighs, near tubercular elevations, there was decided hyperæsthesia. It could not be determined that there was either more or less sensation in the tubercles on the discoloured patches than in other parts.

He constantly affirmed from time to time that he felt better; he certainly had more energy, and was in better spirits. His voice continued husky, his cough troublesome, and the discoloration of the skin was on the increase. No fresh tubercles appeared. There were noticed, soon after he came into the Hospital, several ulcers on the soft palate, with raised, thickened edges.

He continued in this condition until September 1, when he was attacked with rigors and general pyrexia.

On the 3rd an erysipelatous rash appeared. Typhoid symptoms rapidly supervened and signs of pulmonary mischief. He refused nourishment, and on the 11th he died.

On post-mortem examination there was found to be pneumonia of both lungs. The larynx was finely injected, as well as the trachea. There were large ulcers in the pharynx and the anterior pillars of the fauces; the ulcers were surrounded by raised borders, and sharply cut; the kidneys were congested, but appeared healthy; a portion of skin from the arm exhibited no change in the cuticle, but the cutis was thickened and here and there raised into tubercular elevations, some of which were suppurating. On section the skin was harder and more opaque than usual. Under the microscope were seen numerous granules, and round and oval nuclei infiltrating the fibrous stroma. Owing to my absence from town at the time of his death, the examination of his skin was incomplete, whilst the nerves and spinal cord were, unfortunately, not examined.

Remarks by Dr. Hillier.—The case was seen during life by Dr. Webster and Dr. G. Milroy, both of whom have paid considerable attention to leprosy; they expressed their full conviction that it was a case of true leprosy. The disease is not often seen in this country in a well-marked form. Some cases, quoted by Mr. Hutchinson and others, make it probable that the disease, in a modified form, sometimes occurs and is not recognised. This case may be regarded as an example of the variety called by Danielssen and Boeck *Lepra tuberculosa*, although it exhibited some of that loss of sensation which is the most striking feature in the variety called *Lepra anæsthetica*. The two varieties no doubt frequently run into each other.

GUY'S HOSPITAL.

HERPES ZOSTER AFFECTING BOTH SIDES OF THE BODY.

(Under the care of Mr. THOMAS BRYANT.)

The most striking peculiarity of herpes zoster is that it affects but one side of the body. Except the following case (Case 2) we have never seen it on both sides. A few years ago we heard Dr. Jenner say that he had once seen the eruption pass quite round the body. Now, we sometimes hear of cases of this kind, but we are fortunate to be able to state that they do occur on the authority of such good observers as Dr. Jenner and Mr. Bryant. We must still keep in mind that neither of them have seen more than an exceptional case. Mr. Hutchinson, who collected a great many cases for a paper read two years ago before the Hunterian Society, stated that he had never met with such a case.

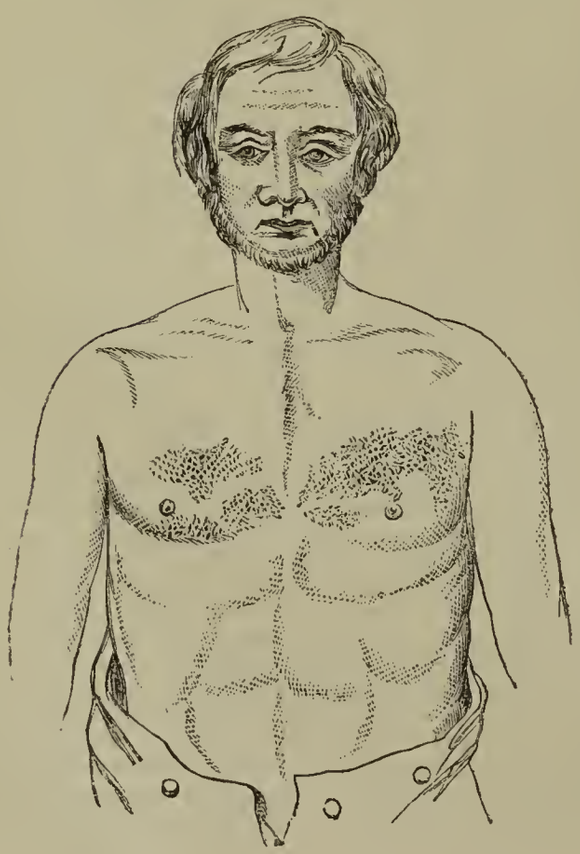
Very careful coloured drawings have been made by Mr. Hurst of the eruption in Mr. Bryant's case, and from them the following diagrams have been taken. The original can be seen at Guy's Hospital.

Case 1 is rare, in that the eruption passed the middle for six inches. Not unfrequently it oversteps the middle line for an inch or so, but six inches is decidedly exceptional. Case 3 is unusual in the position of the eruption. As a rule, the vesicles are found in the course of a dorsal intercostal nerve; but in case 3 nearly every branch of the cervical plexus has been marked out by the eruption. In a case we saw a few years ago, under the care of Mr. Startin, every one of the cutaneous branches of the plexus was marked out; the limited region of the face supplied by the auriculares magnus, the back of the head supplied by occipital, and the front of the chest and back of the shoulders by clavicular and anæmial branches. We have seen it affecting the frontal branch of the fifth; and the New Sydenham Society has published a plate in which the eruption followed the course of the frontal and trochlear branches only. This latter case occurred in the practice of Mr. Hutchinson. In Fig. 3 the eruption is represented as going as low as the wrist. Had it stopped at the

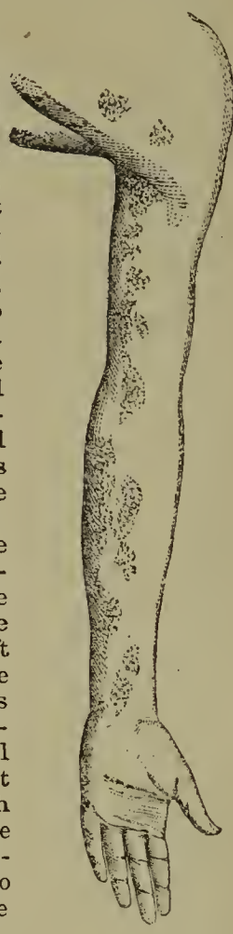
elbow, as it generally does, we should say that it was still limited to branches of a dorsal nerve, as the second intercostal sends branches to the arm as low as the elbow. In a discussion on herpes zostes at the Hunterian Society, Mr. Durham said he had, by careful dissection, traced the humeral branch as low as the wrist.

Herpes zoster is one of the most interesting diseases, in showing most prominently the nervous link in nutrition; but this part of the subject requires to be discussed from a far wider basis than the following cases (which are interesting chiefly from their position) can supply.

Case 1.—Eliza T., aged 27, a single woman, came under Mr. Bryant's care at Guy's Hospital on September 11, 1861, with an attack of herpes zoster, which circled the left side of the body from the spine to the sternum, passing beneath the mamma. The eruption extended posteriorly across the median line for two inches, and anteriorly for six.



Case 2.—Daniel F., aged 49, a labourer, applied to Mr. Bryant at Guy's on March 19, 1863, with herpes zoster occupying both sides of the body and one arm. On the *right* side it began opposite the spinous processes of the 4th, 5th, 6th, 7th, and 8th dorsal vertebræ, and passed across the breast to the sternum, where it joined the eruption of the left side of the body. On the *left* side the eruption commenced opposite the spinous processes of the 4th or 5th dorsal vertebra, circling the chest beneath the axilla to the sternum, and joining the right ring. From the axilla it passed down the anterior and inner surface of the arm and forearm as far as the wrist; and posteriorly it followed the line of the deltoid muscle. The unusual course of this eruption is accurately displayed in the accompanying woodcuts.



Case 3.—Martha S., aged 17, came under Mr. Bryant's care at Guy's Hospital on November 7, 1864, with a severe attack of herpes zoster, occupying the nape of the neck. It began on the left side of the spinous processes of the cervical vertebræ, and passed forwards beneath the ear to the left cheek, following an imaginary line passing level with the meatus of the nostril. It covered the cheek below this line, with the lower jaw and anterior portion of the neck as low as the clavicle, and posteriorly it passed over the shoulder to just below the level of the spine of the scapula.

MIDDLESEX HOSPITAL.

CASES OF ARRESTED TRANSIT OF THE TESTIS—CLINICAL REMARKS.

(Under the care of Mr. HULKE.)

It is a generally accepted fact that testes which have not completed their transit from the loins to the scrotum are very liable to disease, more so when they are arrested in the groin than when they remain within the belly. Their greater liability in the groin evidently proceeds from their greater exposure to injury, which their fixity in this situation does not allow them to evade; but the occurrence of cancer and inflammation in testes lying inside the belly, out of reach of external violence, points to the existence of predisposing causes, one of which may probably be the imperfect development of the organ, which post-mortem examination has verified with scarcely an exception. In the following cases the patients were not aware of the faulty position of the testis till it became inflamed and the gland had been mistaken for a rupture, a mistake which a very moderate amount of care would have made impossible.

Case 1.—A well-grown lad, aged 15, had a swelling in the left groin, which did not occasion any trouble till one day it enlarged and became very painful after unusually hard work. A Surgeon pronounced him ruptured, and ordered him a truss, the use of which increased the pain and produced still more swelling. After a fortnight of great suffering he came to the Hospital for further advice. The left side of his scrotum was empty, and there was a swelling the size of a hen's egg in the left groin. It consisted of a solid oval body overlaid by a stratum of fluid. Its size was not influenced by posture, and it did not receive any impulse when he coughed. It was manifestly the undescended testis.

Case 2.—An apprentice, aged 15, was brought to the Hospital for advice about a truss, which caused so much pain that he was unable to work while wearing it. He had a swelling in his right groin which had not given any trouble during childhood, but had lately, on several occasions, been painful and temporarily enlarged. This led his father to take him to a Surgeon, who pronounced him ruptured, and ordered him to wear a truss. On stripping him, the emptiness of the left side of the scrotum was at once evident, and on taking off his truss a solid body of the figure and size of a small testis

was found protruding from the inguinal canal at the external abdominal ring, through which, however, it could not be pushed. It was clearly the testis, and there were no signs of hernia.

Case 3.—A porter, aged 25, slipped while carrying a heavy load, and immediately felt a severe pain in his groin. He supposed he had sprained himself, but two days afterwards a very tender swelling appeared in the groin, which prevented complete extension of the thigh, and he went to a Physician, who thought it a rupture. Mr. Hulke found the right side of the scrotum empty, and the testis blocking up the external abdominal ring. The right testis exceeded the average size.

SATURDAY, APRIL 1.

MR. SOLLY AND THE GOVERNORS OF ST. THOMAS'S HOSPITAL.

"Summum jus, summa injuria," says the old maxim—strict interpretation of law is often fraught with the grossest injustice. A good illustration of this text is now likely to occur at St. Thomas's Hospital. It will be within the recollection of some readers, that in the year 1858 the Grand Committee of that institution reported at a General Court, held on May 25,

"That a rule should be made, limiting the period of service of each Physician and Surgeon to the age of 60, or to a service of twenty years (not including the period during which he shall have been Assistant-Physician or Assistant-Surgeon), whichever event may first happen, but this rule should not come into operation with the present staff before July 1, 1863."

After some discussion it was resolved—

"That the Report of the Grand Committee now read be received and adopted (with this addition to the rule for limiting service as it respects the present staff—viz., that it shall not come into operation until the officer be 60 years of age), and that it be referred back to the same Committee to carry their recommendations into effect at such times and in such manner as the said Committee may deem best, having regard to the best interests of the Hospital, and to report from time to time to this Court."

In pursuance of this Rule, we understand it is now proposed to insist on the retirement of Mr. Samuel Solly, Senior Surgeon to the Hospital, who attains the age of 60 in the month of May next.

It is not our present object to enter into the general question of enforced resignation at definite ages; much has to be said on both sides of the question. In the present instance, however, Mr. Solly appeals against the proceeding, and, as we think, with justice. He points out that his position as full Surgeon to the Hospital has fallen considerably short of twenty years' duration, while it was preceded by twenty years of almost gratuitous service in the minor offices of Demonstrator, Lecturer on Practical Anatomy, and Assistant-Surgeon, appointments which now have salaries attached to them. He refers to the license already allowed to his seniors in office—Mr. South and Mr. Mackmurdo; to the fact that in every other Hospital but one where a limit to service has been made, the age fixed is 65, and not 60; and also that the rule has in no instance been made retrospective, or applicable to the existing staff.

It may be well, at the outset, to state categorically what must be obvious to many, that this is no question of inefficiency. The treasurer and governors themselves would be as ready as any to disclaim such a supposition. They would, beyond a doubt, join willingly in the testimony of many former pupils, now attached friends of Mr. Solly, in acknowledging that he has faithfully and usefully served the Hospital for many years, and that he is now as equal, in every respect, to his duties as he has ever been: they might add that his energy and activity are borne witness to by that "*ultima ratio medicorum*" a large and successful private practice. The authorities appear to be acting entirely on general principles, and on grounds of economy; indeed, they have on other occasions intimated their wish to reduce the number of the staff to what they consider a fitter proportion with the present diminished size of the Hospital. It is to be hoped the latter argument is one of only temporary cogency, even at the very leisurely rate with which the proceedings relative to reconstruction seem to move. Giving the governors, however, every credit for good intentions, there can be little doubt that they are committing an error and an injustice; it is an error, because the attempt to remove a senior Surgeon still active and vigorous, whose name is known to the public as a good Practitioner, and to scientific men by his writings, would, if successful, deprive the institution of far more *prestige* and reputation than could be made up by the paltry economy so secured. Surgeons of high standing are not like hands in a mill or clerks in an office, to be taken on and dismissed according to the supply of raw material, but scarce and precious functionaries, who confer on their Hospital and school at least as much credit as they derive from it. In the early years of Professional life, indeed, an old foundation, to a great extent, stands guarantee for its junior officers; but at the other extreme of the scale the case is reversed, and the senior members of the staff give tone and character to the institution. To cast off, then, a tried servant at a period when he is most experienced and in popular repute is, even in a mercantile point of view, inexpedient.

It is also an injustice, for it is the virtual violation of a contract implied, if not actually expressed, at the very beginning of the connexion. There may even be some doubt whether a Surgeon appointed to his post without limit of time can legally be removed, except for distinct neglect of duty or misconduct; but, however this may be, the governors must be prepared to show good and sufficient cause for altering the terms on which all their officers have hitherto stood, and those who were elected before the rule passed in 1858 were clearly not parties to any stipulation of retirement at a stated age. We entertain no doubt they will see the matter in this light, and bring it to an amicable settlement by a concession which the opinion of the public at large, as well as that of our Profession, will fully understand and justify.

MODERN DERMATOLOGY.—No. II.

Mr. Wilson observes, "The aims of classification are twofold,—namely, in the first place to lay down a plan by which a knowledge of diagnosis may be most easily acquired; and, secondly, to arrange a number of diseases according to a method that will facilitate the comprehension of their nature and phenomena, and conduce to their treatment with successful results. The first of these objects is amply fulfilled by the classification of Willan . . . . ; while the second has been attempted by a number of authors, with varied success, under the name of practical or natural classications; the most recent of these essays being the 'Clinical Classification.'" This classification is, in truth, one of a

mixed character, some of the groups being based on the pathological appearances, as the eczematous affections, the erythematous, the bullous, and so on; and some on causation, as the strumous affections, the zymotic, the syphilitic, and the like. It appears to us to possess the great merit of simplicity, and to be, as we have already observed, practical; but some of its weak points and faults are, we think, very patent. For instants, scabies is classed as an eczema; now it may be very true that the eruption, *par excellence*, caused by the acarus scabiei is eczema, but we must take leave to doubt whether classifying it with eczematous affections will "facilitate the comprehension of its nature and phenomena, and conduce to its treatment with successful results," for the special local cause to which it owes its existence requires a treatment different from that which will cure any other of the eczematous affections; it can be cured by only local treatment, and it cannot be cured without local treatment; arising from a specific local cause, it requires a specific local treatment. Were the classification a purely anatomical one, we could very well understand why scabies should be classed according to the eruption the acarus gives rise to; but as some of the skin diseases are grouped according to their causes, why should not scabies have been classed as a parasitic affection? Mr. Wilson does not dispute its parasitic nature, as he does that of the eruptions generally attributed to vegetable parasites. The majority of English dermatologists will also, we suspect, take exception to psoriaris and pityriasis being classed as not merely "eczematous affections," but as varieties of eczema. Mr. Wilson considers them to be forms of "eczema squamosum or chronic eczema;" pityriasis, he says, is squamous eczema of the scalp, psoriasis in its varieties, squamous eczema of the rest of the body; pityriasis nigra he considers to be an "eczema erythematosum of children born in India and brought to this country;" pityriasis versicolor he classes under the name of chloasma, among the "discolorations of the skin." Lichen and impetigo he also includes among the "eczematous affections." This is, to a great extent, following Hardy, who places all these diseases of the skin in the class of "dartrous affections," and they are certainly so closely allied, pathologically and therapeutically, that we are strongly disposed to accept Mr. Wilson's classification of them. One other point we must notice as very questionable, namely, that erysipelas is placed among the "erythematous affections." In speaking of this disease, Mr. Wilson observes that it "generally runs a course of ten days to a fortnight or three weeks; the local inflammation commonly makes its appearance on the second or third day of the constitutional disturbance;" . . . "the constitutional symptoms are those of invasion, course, and decline," and that in some cases it "seems to be referable to malaria, and sometimes to infection and contagion, and it is apt to prevail epidemically." Surely these characters show that it is much more nearly allied to the "zymotic affections," which, Mr. Wilson says, "are the diseases or fevers originating in a poisonous ferment, and attended with exanthema of the skin," than with erythema?

These appear to us to be some of the weak points in the "Clinical Classification," but it cannot be fully considered or fairly judged at present, for Part I. of Mr. Wilson's new work, all that is as yet published, includes only the first eleven of the groups under which he classes skin diseases. But whether the "Clinical Classification" be generally accepted or not, we are certain that the "Student's Book of Cutaneous Medicine" will be regarded as a valuable boon. It is written with an ease and simplicity, a fulness of detail, and at the same time a clearness and precision, that show the master, and it will be accepted as a standard guide not by the student only, but by the Profession at large. We shall have to refer to it frequently when speaking of the causation and the treatment of skin diseases, and we will add that we trust the remainder of the work will speedily appear.

Dr. Tilbury Fox calls his work "A collective account" of "the present knowledge in regard to skin diseases." His "own peculiar views have been obtruded as little as possible; general principles of treatment rather than empirical data have been indicated; while the views of others, especially those of the leading French and German authorities, have been fairly stated." He has carried out these objects well and ably, and produced a clear and good *resumé* of what is at present known and taught on the pathology and treatment of diseases of the skin; but his work is, we think, more suited for a book of reference for the Practitioner than for the student. The "mixed classification" of diseases of the skin given by Dr. Fox is "suggested by the joint consideration of anatomical characters, and the nature of the causation (as far as this is known). The kind and extent of the structures involved should first be clearly defined, then the prevailing character of the outward evidences (eruption), and subdivisions made in detail, according to the general nature of the disease." He begins by making "two grand divisions"—parasitic and non-parasitic,—then these latter are arranged in "two primary groups anatomically"—diseases of the epidermis and of the derma; and then "the details are dissected out by a process of exclusion," so as to "define the *limits* of disease precisely, and the exact *extent* and *character* of the structure involved." "Thus," he says, "you see in a glance the nature, extent, and cause of any given disease, as far as science has taught us. Take an example, *acne:* the Tabular View tells us that it is an *inflammatory condition* with *retention* of secretion of a *sebiparous* gland (one of the *special* structures of the *derma*). Rubeola rash is an eruption of an *acute specific blood* disease, *erythematous* in nature, and in *which the structures generally of the derma* are affected," etc. This "classification" is ingenious, but it appears to us to attempt too much, and though we fully agree with its author when he says that it "is at first sight rather puzzling," we are not able to go along with him in his belief that "a little careful scrutiny will show that its simplicity and truthfulness are its greatest recommendations, and that in the present state of science it is, perhaps, the most useful."

Dr. Hillier's "Classification of Skin Diseases" is simple enough; he makes four main divisions—Acute specific infectious diseases, Parasitic diseases, Syphilides, and *Other* diseases; and the "syphilides" and "other diseases" he "distributes mainly on Willan's principles," adding a few new orders, as the "pustulo-crustaceous," the "ulcerating," and the "vegetating" (including mucous tubercles and condylamata), among the "syphilides," and "hæmorrhagiæ," "diseases of the sebaceous glands," and two or three others among the "other diseases." Both he and Dr. Fox place erysipelas among the acute specific diseases, and scabies, of course, among the parasitic. In one respect his book forms a curious and rather amusing contrast to Dr. Fox's. The latter Physician's work contains comparatively little of his own opinions or practice, and he dedicates it to Mr. Wilson in graceful acknowledgment of that gentleman's labours. "For a life time," he writes, addressing Mr. Wilson, "you have fought almost singlehanded the battle of British cutaneous medicine, and I am proud to confess how much I owe to your writings and researches." Dr. Hillier's Hand-book is almost pure and unadulterated Dr. Hillier; the labours of foreign, and especially of the French, dermatologists are indeed acknowledged and made use of in the work itself, and in the preface he says, "I have availed myself largely of the works of Professor Hardy, of Paris, whose descriptions of disease are generally very vivid and truthful, and I have also to acknowledge my obligation to Professor Hebra, of Vienna, from whose writings I have derived many valuable hints;" but one could hardly gather from him that such a thing as "British Cutaneous Medicine" exists. He has "obtained information from Dr. Jenner's lectures, and from Dr. Thompson's treatise edited by Dr. Parkes," and Mr. Wilson is referred to some four or five times in all, not in a very complimentary manner; he could find no English book on skin diseases to recommend to students—"the existing books were

either out of date, diffuse, inaccurate, or incomplete"! So he "determined to try and write a book such as he could recommend to the student." We hope for the sake of both that the student will think as well of Dr. Hillier's attempt as its author, no doubt, does; and, indeed, we can conscientiously "recommend it to the student;" the style is clear and pleasant to read, the matter is good, and the descriptions of disease, with the modes of treatment recommended, are frequently illustrated by well-recorded cases.

Mr. Wilkins Williams, in his work on "Skin Diseases of Constitutional Origin," recognises the dartrous diathesis of M. Hardy, and, adopting partly M. Bazin's sub-classes, arranges the diseases of which he treats under the four heads of Dartrous, Arthritic, Syphilitic, and Scrofulous Eruptions; for his sub-orders, groups, or varieties, he, like all other dermatologists, is obliged to have recourse to Willan's system and nomenclature. His "Dartrous" sub-class contains "three main groups—viz., eczema, pityriasis, psoriasis." "Other skin diseases exist," he says, "(lichen and impetigo, for instance) which, although of the dartrous type, are not of sufficiently distinctive importance to entitle them to a separate division, inasmuch as they are merely modifications of the largest and most important division—eczema." It will be observed that the Dartrous class thus very closely corresponds to Mr. Wilson's group of "Eczematous Affections;" but the terms "dartrous" or "herpetic," and "eczematous" must not be supposed to be interchangeable, for we do not understand Mr. Wilson to affirm that there is an "eczematous diathesis," which is the real cause of all the diseases which he groups together as eczematous. They are allied by their anatomical elements and pathological appearances rather than etiologically. While the "Dartres" are allied etiologically, they originate in a special constitutional defect, called the "Dartrous diathesis." The existence of this diathesis is not generally recognised by English dermatologists; and, indeed, Mr. Williams admits that the existence of both the dartrous and the arthritic diathesis "is a questionable hypothesis rather than an undisputed fact." He accepts them, with other speculations of the French dermatologists, "not as arrows shot home to the mark, but simply as arrows aimed in the right direction." His work is well worth a perusal; it is much better than could have been expected from the *ad captandum* first title of it—"A Clean Skin: How to Get it and How to Keep it." We strongly recommend Mr. Williams to discard this title in future, and to retain only his second title—"Skin Diseases of Constitutional Origin: their Etiology, Pathology, and Treatment." By that change, and a little closer attention to soberness and exactness of expression here and there, he will do much more justice to the amount of information and good work that his treatise really contains.

THE WEEK.

THE COMING DISTRIBUTION OF STATE HONOURS—CREATION OF NEW PEERAGES.

A STATEMENT has been going the round of the papers lately to the effect that several new peers are to be created before the dissolution of Parliament; and rumour even goes so far as to name some of the individuals who are likely to receive this mark of distinction. If new peerages are to be created, it is not improbable that some baronetcies may be conferred at the same time. If such is the case, we trust that the claims of the Medical Profession will not be overlooked. It is now eight years since any member of our Profession was raised to the rank of a baronet; and in the mean time our scientific and practical knowledge has been making great and rapid progress. There are men, both among our Surgeons and Physicians, who well deserve a baronetcy, and who could worthily uphold the dignity. If the Premier wishes to do a graceful act, and at the same time make himself popular with the Medical Profession, he could not do better than recommend one of our leading Surgeons and one of our leading Physicians to the special favour of the Sovereign.

THE REWARD OF MERIT.

THE late Director-General of the Army Medical Department, after a life devoted to the army, distinguished services in the field, and a constancy to the cause and honour of the Profession to which he belonged, died as plain Mr. Alexander. His successor is more fortunate. The high Professional attainments, administrative talents, and, above all, the important services he has rendered to his Profession and his Department in doing everything that he could to preserve the dignity and elevate the position of the army Medical officer, have not been without their effect upon the powers that be. Dr. Gibson is about to be made a K.C.B. We feel quite certain that the great popularity of the present head of the Medical Department with all his subordinates is such that he will be overwhelmed with congratulations. Our prophecy has been fulfilled. We said long ago that Dr. Gibson was anxiously waiting for the letter K to be added to his C.B.

THE NEW BILL OF THE PHARMACEUTICAL SOCIETY.

WE expressed our opinion on this Bill last year, and see no reason to alter it. It is, no doubt, a very laudable thing to encourage young men who propose to carry on the business of chemists to educate themselves well, both generally in literature and specially in the sciences of chemistry and pharmacology. But there is no reason why this should not be voluntary, nor why the Pharmaceutical Society should claim exclusive privileges. In the first place, there is no adequate cause shown. They say the public require protection. From whom? Where are the cases of mischief arising from mere ignorance? But if the masters are to be registered compulsorily, will the assistants and apprentices be debarred from making up a black draught till they are registered also? Will they tell us whether more mistakes do not arise from negligence or from thinking of two things at one time than from ignorance, and whether any registration is a safeguard against absence of mind? It seems to us highly probable that the new Bill, if its provisions be stringent, may create a new class of offence and set up monopolies, which, as Lord Elcho pointed out, might be very inconvenient to the public. As for its being an "anomaly" that England should be the only country where the dispensing of medicines is carried on by any but experts, we must remind Dr. Brady that England is the most "anomalous" country in the world, and we hope will long remain so, in its freedom from police restrictions. We quote the following passage from the *Pall-Mall Gazette*, with every word of which we agree; and meanwhile say only, that if we criticise the Bill it is in the interests of the younger and "less fortunate" members of our Profession, whose incomes are diminished through the counter practice of chemists, to which counter practice this Bill will confer something of the sanction of law:—

"Although we desire to give our support to the Pharmaceutical Society, which has now for a quarter of a century been fighting a good fight in the cause of education, we cannot say that we entirely approve of all the details of the measure they bring forward. These, no doubt, will be altered in committee. It is too much to expect, for example, that after the passing of their Act, no one in the kingdom but a member or an associate of the Pharmaceutical Society shall be allowed to make up prescriptions and to compound medicines. That is an interference with free trade which in this country will never be tolerated. It is something like what the doctors tried to get passed some years ago in the Medical Act. They got it passed that no one should call himself a Physician, a Surgeon, or a doctor, unless he were duly qualified and registered; but they also tried to bring it about that nobody should consult the so-called quacks. Why should we not consult quacks if we like? and why should not quacks give us advice if they make no claim to the possession of false titles? And so of pharmaceutical chemists, of chemists and druggists. We cannot ask more than that the public should have a complete understanding as to the meaning of their titles. But if, knowing that those with certain

titles are alone duly qualified, we yet choose to get a prescription prepared by one who obviously is not on the register, what harm do we commit except against ourselves? The Government undertakes that by the title of the chemist's shop we shall know whether it is a good one or not—at least whether the chemist has passed his examination or not: but what can the Government do more? If we choose to patronise a bad shop, who is to prevent us? and why should we be prevented? This provision is a blot on the measure of the Pharmaceutical Society; but their general principle is sound."

SLEEPLESS BABES.

The experience of all Physicians has pointed out the extreme suseeptibility of young children to opium in every form, and the fatal results of very small doses. Nevertheless, an anonymous philosopher writes thus in the *Household Monthly Magazine*, and is quoted without eondemnation in *Public Opinion* for March 25, 1865:—

"New Notes on Nursing.—In the first place I would observe that people have, of late years, been making a very pedantie and absurd outcry about the use of laudanum in the bringing-up of babies. No doubt, much harm is done by the indiscreet use of cordials and sleeping mixtures; but I stoutly maintain that *it is, in the majority of cases, all but impossible to bring up a baby without having occasional recourse to sedatives*. A sedative is, of course, an evil; but it is sometimes the less of *two* evils. That is the case with grown people; and it is the case with babies, too. There are times when the restlessness of an infant is so extreme as to be capable of wearing out the strength of three grown people. 'Then,' say the wiseacres, 'the child is ill; and you ought to have a Doctor in to it.' But, I answer, the child is *not* ill. It is only too well—provokingly well. It does not cry; but it wants sleep—or, again, perhaps, it *does* cry. Then if a little present harm is done to the child by a sedative, it may be a gain to the household. For it may be ten times worse for the child to have a worn-out mother who has not got a refreshed brain and body at its service during the day, than to have a little torpor put into it at night for onee and away. If the mother is so very tired as it is in the power of a quite healthy baby to make her, she is not in a fit state to take care of it between morning and evening. When is it that a baby catches the dangerous cold, or gets the bad fall, or the bad scald, or falls into some other trouble? I answer, it is when the poor mother is over fatigued—when she is not alert, energetic, up to the mark, and capable of that intense and all-seeing watchfulness which the child requires for its protection. To talk of sending for the Doctor is nonsense. You cannot be always having the Doctor. Neither can you be always giving syrup of rhubarb, on the hypothesis that the child wants medicine of that kind every time it is restless. In truth, it does not. Like an adult, an infant becomes overexcited now and then, and is benefited, not injured, by a mild sedative judiciously given. At such times—which must be made as seldom as possible—I do boldly assert, in the face of all the Doctors in the world, that from five to ten drops of laudanum, in peppermint water diluted and sweetened, is a proper and necessary thing for a baby. What is more, no intelligent and conscientious Doctor will contradict me—if he be a father."

The force of bold assertion cannot go much further than this, in the face of the fact that thirteen minims of laudanum, or 26 drops, are equal to one grain of opium; and that one-tenth of a grain of opium = 2·6 drops has killed a child four months old. We would humbly suggest that if good food, air, light, exercise, and baths do not produce healthy sleep, the "father" had better send for the Doctor before giving 5 to 10 drops of laudanum to a baby. We can assure him that the cry for "sleeping stuff" is too often, not always, the fruit of sour pap, chafed skins, and want of a warm bath; and that we should feel very ashamed of our own management if babies could not be brought up without occasional recourse to "sedatives."

FROM ABROAD.—LECTURES ON MEDICAL HISTORY AT THE PARIS FACULTY—HOMŒOPATHY AT MADRID—THE HYDROSTATIC MATTRESS.

At the present time there is a *furore* prevailing in Paris and other large French towns for the delivery of public scientific lectures, termed sometimes "conferences,"—why, it would be difficult to say, seeing that no conference takes place. Some of the most gifted men have taken part in these, and the appetite for them, judging by the rush for tickets, is still on the increase: so that the Friday evening lectures at our Royal Institution, which first gave the idea of these, are now much surpassed in point of number, variety, and general accessibility. Some of the more interesting have been fully reported in a new journal, which we can cordially recommend to the notice of our readers, the *Revue des Cours Scientifiques*, instituted in order to furnish accurate reports of the various scientific lectures delivered in Paris, several of which, as those of M. Claude Bernard, at the College de France, are intimately connected with our own pursuits. The Faculty of Medicine has just determined to have its "conferences" also, and at the suggestion of M. Verneuil, M. Tardieu, the Dean, has appointed thirteen of the *agregés* of the Faculty to deliver in succession weekly lectures on the biographical history of Medicine. M. Verneuil himself opened the course, with a crowded audience, composed of both pupils and Practitioners, and will be followed by MM. Follin, Broca, Trélat, Lefort, and other of the well-known names among the rising French Medical *savants*. M. Verneuil, in his lectures on "Erudite Surgeons," laid open with a bold hand the shortcomings of the present race of Medical students with respect to their knowledge of the history of their Profession, and of the great men who have adorned it, the very dates of the most important steps in the progress which has been achieved being unknown to most of them. He dwelt upon the vast importance of science and erudition for the due comprehension and satisfactory practice of the art of Surgery; and maintained that the history of Surgery showed that where they were not held in due consideration its practical value declined in excellence in a corresponding degree. In pursuance of this theme, he gave a rapid sketch of the history of Surgery from the time of Hippocrates to that of the French Academy of Surgery, with Anthony Louis for its Secretary. This he regards as the culminating point of French scientific and erudite Surgery.

"What, in fact," he exclaims, "is erudition? In my opinion it consists in a compilation, having some object in view, or some doctrine to elucidate. I do not call the mere collators of texts erudite. For erudition, scientific knowledge, critical acumen, and practical experience, are alike requisite. Louis possessed all these, and this is why he has so much contributed, together with Quesnay and other eminent members of the Academy of Surgery, to the glory and renown of French Surgery in the eighteenth century. Since that epoch things have undergone great changes; political troubles, the great wars of the Republic and the Empire, dried up the sources of French erudition, the level of science and art sinking in the same degree, has never yet regained its elevation. With some rare exceptions, which are, so to speak, but accidents in the history of contemporary Surgery, France has produced no great Surgeon. She has allowed herself to be surpassed abroad, and will only regain her place in the first rank when a numerous pleiad of Surgeons and Physicians shall have become constituted who, following the traces of Littré, Daremberg, and Malgaigne, resolutely enter upon the course so brilliantly pursued by the great erudite Practitioners of the eighteenth century, and open a new era to French Medicine and Surgery."

We confess that we think M. Verneuil has somewhat exaggerated the circumstances of the case, and that, while bearing unfairly upon modern French Surgery in his estimate of the position it has attained, he anticipates from critical erudition an impulse which it is powerless to impart. MM. Malgaigne, Littré, and Daremburg are, indeed, consummate scholars and masters in erudition, but we doubt the propriety of setting them up as models of imitation for students to the derogation of the practical teachings of Dupuytren, Velpeau, Nélaton, and many others of whom the French Surgical school may well be proud.

However pleased the Paris students may feel at the Dean of the Faculty having instituted this course of lectures, we

doubt if they will admire the issue of another of his projects. Some time since he suggested that the students should form among themselves a kind of benevolent society for the succour of those in distress. This was warmly responded to, and it was resolved to form a "Fraternal Society of Paris Students," and a committee of their number was appointed to draw up the rules for its management. As this body, however, contemplated embracing other matters within its scope than merely relieving the necessitous, the Dean became alarmed at his own creation, and refused his sanction to the project, declaring that hereafter he would draw up such regulations as he deemed suitable. On application being made to the Préfet of Police for permission to hold a public meeting of the students to which the rules proposed by the committee should be submitted, this was peremptorily refused, and thus at present the matter ends.

Exploded in almost every other part of Europe, Homœopathy seems to be in high favour at the Spanish Court, under the immediate patronage of the Queen. Some time since a "Homœopathic Academy" was founded, and its president received letters of nobility; and now we learn that the Government has ventured upon the establishment of a professorship and clinic, under the specious pretence of examining into, under suitable inspection, the practical value of the Homœopathic doctrines. Believing this to have been effectually tested, the Faculties of Medicine of Madrid and other cities, as well as the body of the Medical Profession at large, have entered so vigorous and universal a protest against further tampering with truth and with the lives of patients that great hopes may be entertained that the obnoxious decree will be withdrawn.

M. Cosmao-Dumenez, in a recent communication to the *Gazette Médicale*, gives an account of the great advantages derived by M. Demarquay from the employment of the hydrostatic mattress during the last five years. It is made of vulcanised caoutchouc by Galante, of Paris, and measures 80 centimetres in length by 70 broad, and when suitably distended with from 26 to 29 litres of water, it is about 1 decimetre in thickness. Its weight does not exceed from 28 to 30 kilogrammes. This is a far more convenient, effectual, and economical apparatus than Arnott's bed, which by reason of the rigidity of its parietes prevents any lateral displacement of the water, and the patient becomes buried in a hole, formed by the elevation of the water on each side of him. In the mattress, all its walls are elastic, and the water displaced by the weight of the body, instead of being only directed towards the upper part of the apparatus, is uniformly dispersed in every direction. The bed, too, is large, cumbersome, and expensive, requiring a great quantity of water, and only moved with difficulty. The mattress has been employed with eminent success in the treatment of bed sores, and in fractures of the cervix femoris and pelvis, and it would form an admirable means for the transport of the wounded, either in a railway or ordinary carriage. The water, too, with which it is filled may become a convenient means of applying either caloric or cold, as the case requires. Thus in the aged or debilitated, and in children of weakly powers, warmth may be thus readily applied and long retained, while in inflammatory affections the temperature may be easily lowered. A few minutes suffices to discharge and replace the water.

PARLIAMENTARY.—FLOGGING IN ENGLAND AND WALES—CASE OF ALLEGED WRONGFUL CONFINEMENT IN A LUNATIC ASYLUM — VOTE FOR THE PREVENTION OF CONTAGIOUS DISEASES AT NAVAL AND MILITARY STATIONS—EXCLUSION OF MEDICAL OFFICERS FROM THE BENEFITS OF THE UNION OFFICERS' (IRELAND) SUPERANNUATION BILL—THE UNION CHARGEABILITY BILL, MR. CEELY, OF AYLESBURY, ON ONE OF THE EFFECTS OF PAROCHIAL RATING—LEGISLATION FOR CHEMISTS AND DRUGGISTS: SIR FITZROY KELLY'S AND SIR J. SHELLEY'S BILLS.

On Thursday, March 23, in the House of Commons, Mr. Scully called the attention of the Home Secretary to the returns lately presented to the House showing that more than 1100 persons, exclusive of soldiers and sailors, had lately been flogged in England and Wales, many of them by the order of only one magistrate, some of them young children and persons advanced in life, and a large number for very trivial offences. He particularly called Sir G. Grey's attention to three cases, requesting an explanation of them:—

1. The case of a person, aged 63 years, who received twelve cuts of a cat for "refusing to work" in the House of Correction at Falkingham. 2. The case of a child, aged 6 years, who received twelve lashes at Knutsford on June 6, 1864, besides seven days' hard labour, for "stealing one pocket-knife." 3. The case of a child, aged 12 years, sentenced on November 3, 1863, by the Rev. Algernon Peyton and Mr. Thomas Richardson, for "stealing three gingerbread cakes," to fourteen days' hard labour, and to receive twelve strokes with a birch-rod, which were inflicted on November 11, 1863, in the House of Correction at Wisbeach up to the eighth stroke, when the punishment was stopped by the Surgeon in attendance.

Sir G. Grey stated that he could give no explanation of these cases. He specified the various enactments under which the punishment of flogging was inflicted. By an Act introduced by the hon. member for Sheffield it was provided that the sentence must in every case specify the number of lashes to be inflicted, and the instrument with which it was inflicted, and in the case of boys under 14 the number of stripes was limited to twelve, and they were only to be administered with a birch-rod. By far the greater part of these cases were dealt with by the magistrates under that Act. There was also a general provision that a sentence by one police magistrate should have the force of a sentence by two other magistrates. He promised that the second case specified by Mr. Scully should be made the subject of inquiry.

On Friday, in the House of Lords,

Lord Malmesbury moved for a return of the correspondence relating to the illegal detention of a Mr. Docknall in a lunatic asylum at Sedgefield. In giving a narrative of the case, his lordship stated that Mr. Docknall was a bookseller, at Chester-le-street, in the county of Durham, who, in October, 1863, was confined in the lunatic asylum at Sedgefield for five days, on an order from Colonel Johnson, a magistrate of the county. This order Colonel Johnson signed on the evidence of one Medical man only, whereas the law requires the testimony of two. The magistrate also declared by the order that he had himself seen the patient, when he had not done so. Mr. Docknall was advised by his friends to bring an action against Colonel Johnson for false imprisonment. This action was to have been tried last summer at the Durham Assizes, but in consequence of a press of business it could not be brought on. All the attempts made by Mr. Docknall to obtain redress from the Home Office had also failed, and these anxieties so affected Mr. Docknall that in October last the unfortunate man committed suicide. He read various letters and affidavits connected with the case, and contended that the facts disclosed imperatively demanded an inquiry.

Lord Granville was not prepared to defend the conduct of Colonel Johnson, but on his behalf it might be stated that Mr. Docknall had twice before been confined in a lunatic asylum. Under all the circumstances of the case the Home Office could not interfere in the matter.

Lord Shaftesbury thought if misconduct like that of Colonel Johnson's were overlooked it was of very little use for the Government to appoint Commissioners in Lunacy or visitors of asylums to protect the patients. In this case the law had been completely evaded, and some opinion ought to be expressed on it.

After a short discussion, the motion was agreed to.

In the House of Commons, in Committee of Supply on the Army Estimates, on the vote of £107,700 for miscellaneous services,

Mr. Ayrton called attention to an item of £5000 for expenses attending the carrying out of the Act of the 27th and 28th of Victoria, cap. 85, for the prevention of contagious diseases at naval and military stations. He characterised the vote as one which would have the effect of ministering to the vices of the soldier. He wished to know how the money was to be appropriated.

Mr. Locke, as a member of the committee who sat upon the bill which had now become law, and on which this vote was based, protested against the extraordinary description

which the hon. member for the Tower Hamlets had given of the measure. It was wholly incorrect to talk of that £5000 as being intended for the purpose of catering to the vices of the soldiers. It was simply intended for their protection; and if a similar measure could be carried out throughout the whole country it would be a very great advantage. The object of the Act was that where a woman was proved to be a common prostitute—a term well known to the law of England—she should be taken care of, and not allowed to be the source of mischief to other people.

The Marquis of Hartington: With regard to the item of £5000 it was proposed to extend it in the hire of certain lock wards in different places, and, although it was not quite decided, yet it was contemplated to commence a Hospital in one or two places where no such wards could be procured. The proportion of the grant to Aldershott would be expended either there or in London, to which those persons would be removed.

Dr. Brady remarked that there was no city of Europe in which public Hospitals were not open to this class of patients.

The vote was agreed to.

The House went into committee on the Union Officers' (Ireland) Superannuation Bill.

Mr. Hennessy moved an amendment, including the Medical officers and the clerks of the Unions in the list of those to whom the benefits of the bill should be extended.

Sir R. Peel said that he could not conscientiously proceed with the bill if the amendment of the hon. member for King's County were carried, because he never would be a party to the imposition upon the rate payers of Ireland of the taxation which it would render necessary.

After a short conversation, the Committee divided, when the numbers were:—

Ayes	11
Noes	42
Majority against the amendment .	—31

We cannot conceive on what principle of justice the tax payers of Ireland are to be made to pay superannuation pensions to one class of union officers but not to another. If it would not be right to impose taxation for the support of the worn-out Doctor of the Union, it must be equally wrong to do so in the case of the worn-out Master. The result of the division on Mr. Hennessy's amendment is only another proof of the indifference of the Government to the requirements and interests of the Medical Profession, and of the necessity which exists for a Medical organisation that shall make itself felt in the House of Commons.

On Monday, in the House of Commons, the Union Chargeability Bill, after a full debate, was read a second time.

The evils which this Bill, by substituting union for parochial rating, is intended to remove are the gradual removal or expulsion of the poor by the landlords from some parishes, and the resulting over-crowded condition of others, together with the consequent inequality of rating. Mr. Villiers, the mover of the Bill, gave the following sketch of the working of the present system:—

"The object of the parishes after the new poor-law was established was to keep down their poor, in order that they might have to pay as little as possible. Although the guardians administered the relief, yet the parishes paid for it, and were anxious to keep the charge as low as they could. The great source of settlement and charge in parishes is the residence of the poor. The poor obtain a settlement by residence, and their families derive their settlement from them. Therefore, the great object, in order to keep down the poor, is to prevent them residing in parishes; and for that purpose their dwellings are pulled down, and no new cottages are built. This is one way of what is called managing the parishes. But where poor residents have got into a parish, the next best thing is to get them out, and thus shift the burden to a neighbouring parish. That used to be the practice under the former law, and it was also the mistake of retaining the parochial liability under the new system that the officers of the parish still had the opportunity of exercising their zeal and discretion in keeping down the poor as they had always done before. That accounts for many of the complaints heard of the working of the new poor-law, many people observing that the labouring poor still live in wretched dwellings, and sometimes far from the place at which they work, and that a struggle still goes on in different parishes, varying with the peculiar circumstances of each. Parishes, it is well known, vary almost in the same proportion as their number, and according to their size or the character of those who reside in them. A parish with one, two, or three proprietors may seek to get rid of its poor in the way I have described, and an adjacent parish may be in such a position that it cannot help receiving the outcasts from the proprietary parish. Hence the great complaints raised during the last twenty-five years as to the manner in which the poor have been dealt with, and the vicious and unjust distribution of the burden of their maintenance, some parishes being compelled to pay far more than they ought, while others are pretty nearly exempt."

In the course of the debate Mr. T. Bernard quoted the following extract of a letter from Mr. Ceely, of Aylesbury, on the effect which residence in another parish at a distance from his work has on the health of the labourer:—

"In the course of more than forty years' Professional observation I have very often had to deplore the effects of the additional toil imposed upon agricultural labourers who have to travel two, three, and four miles night and morning to and from the seat of their employment. I have witnessed many cases of severe and protracted illness, premature infirmity, and even death induced by this cause. There can be no doubt but that a labourer's services are more valuable and his health better preserved when he resides within the precincts of his labour. I should advocate union rating on this very ground."

On Wednesday, Sir F. Kelly, in moving the second reading of the Chemists and Druggists Bill, said that as the law now stood the trade of chemists and druggists, and consequently the making up of Medical prescriptions, might be carried on by persons altogether ignorant and incompetent. It could scarcely be disputed that some protection was required by the public in that respect; and the defective state of the law had been pressed on the attention of the Secretary of State for the Home Department, who was urged to bring in a Bill on the subject. It was not for him to arraign the Government; he had no doubt they had very good reasons for not introducing a measure. At all events, nothing had been done; and he was therefore induced to submit to the consideration of the House the present Bill. There was no qualification required; no licence need be taken by those who carried on the trade of chemists and druggists; they might be totally ignorant and incompetent, and the remedy proposed was that a proper examination should take place, certificates being given to those found duly qualified, who would thereupon be registered as chemists and druggists under the Act. The only question was what the examination should be, and by whom it should be conducted. There existed all the means necessary for the purpose in the machinery of the Pharmacy Act. Examiners were appointed who conducted an examination in botany, in chemistry, Materia Medica, and in the Latin language, and those who passed that examination were qualified to become associates of the Pharmaceutical Society. The whole substance of this Bill was comprised in a single sentence. Persons seeking to carry on the business of chemists and druggists, and make up Medical prescriptions, should submit themselves to examination by that Board, and if found qualified they would receive a certificate of fitness from the examiners, and be registered on payment of a small fee to the Pharmaceutical Society. He was quite content to leave the question of fees and any other detail to the approval of one of the Secretaries of State. The main object of the Bill was the examination, and that, he thought, would give all the security that was required for the public. It was impossible to speak too confidently as to the results of examination by this Board. It had existed for twenty years; it had been confirmed by Act of Parliament; and, above all, it had received the sanction of the Government. The Medical Board charged with the well-being of the army had stamped their approval on the examination and whole proceedings of the Society by a resolution which had been in force for many years; and no one could be an army dispenser without producing their certificate. An exception was made by the Bill in favour of those who had carried on this business for a certain period, and there were some thousands who might have carried it on for a great length of time; but it would be necessary for them to produce the certificate of a Medical Practitioner that they had actually and *bona fide* carried on the business of a chemist and druggist before this Bill came into operation, and on that certificate

they would be entitled, without further qualification, to be registered and to carry on the business hereafter. The Bill of the hon. Baronet the Member for Westminster had two objects—the first identical with the present measure, and the other prescribing the terms and conditions on which the sale of drugs and chemicals should be carried on. This latter branch of the subject was far too complicated, delicate, and difficult to be undertaken by any private member. It required all the knowledge and experience of the Government. Both Bills admitted the necessity of affording some protection against incompetent persons carrying on the business of chemists and druggists; they agreed in requiring some examination, and the only question as between the Bill was who should conduct it—whether a body that now existed, recognised and sanctioned by law, approved by the trade, by the general public, and especially by an important Government board, or a new corporate body of a speculative character, and of whose qualifications they must be in utter ignorance. He begged to move the second reading of the Bill.

Sir J. Shelley pointed out the distinctions between the two measures, and urged the greater advantage of placing the examination under the United Chemists' Society, instead of the Pharmaceutical Society, as regarded the interests of the trade, as well as those of the public. He suggested that both Bills should be read the second time, and referred to the same Select Committee.

Dr. Brady supported the present Bill, panegyrising the Pharmaceutical Society, and placing its pretensions in very favourable contrast with those of the Chemists' Society.

Mr. Kinglake remarked that the Pharmaceutical Society had already a machinery for conducting examinations, whereas the Chemists' Society had none, and must create one.

Mr. Roebuck observed that the question was one of great public importance, and wished to hear the opinion of the Government.

Sir G. Grey observed that both Bills contained provisions entitled to the consideration of the House, and recommended that both be read the second time and referred to a Select Committee.

Lord Elcho said he had some objections to the Bill proposed by the hon. and learned member (Sir F. Kelly). When the representatives of the Pharmaceutical Society came to him with this Bill, he told them they went a little too far in one respect, and an injustice would be inflicted. He contended that it was necessary to allow certain persons in country villages to dispense medicines, and even to make up prescriptions, although it could not be expected that those people should undergo examinations. Having met with an accident during the present year he had had occasion himself to get a prescription made up in one of these country villages. He had to go for this purpose to the post-office of the village, which he found to be a store for the sale of almost every article, from fiddles to hobnails. His prescription, however, was made up, and did him great benefit. He should support the Bill brought in by his hon. and learned friend in preference to the one introduced by the hon. baronet, because, of the two, he believed it to be the more liberal. He regretted, however, that the Government had not taken charge of the Bill, instead of recommending its submission to the Select Committee.

Ultimately the Bill was read a second time, and ordered to be referred to a Select Committee.

Sir J. Shelley then moved the second reading of his Bill, a motion which was agreed to, and the Bill was ordered to be referred to the same Committee.

In another column we have expressed our opinion on the subject of one of these Bills. We are opposed to any scheme by which chemists and druggists will be constituted a privileged class to be the rivals of the General Practitioner of Medicine; and we feel convinced that no corresponding benefit can be secured to the public by such a measure. To enact that a qualification should be required from every dispenser of medicine, whilst there is no law to prevent any one who may choose prescribing, is such a palpable absurdity that we really wonder it did not strike any speaker in Wednesday's debate. As the matter has been referred to a Select Committee, however, we may hope that the measures in question will be thoroughly canvassed and discussed before Parliament is called on to assent to them.

REPORT ON CHEAP WINE.—NO. XV.

(By our Special Empirical Commissioner.)

Sherry—Rise of Price and Deterioration of Quality—Increased Consumption—No Pure Sherry Imported—"Amontillado:" how Produced—Old Sherry and New—University Wine and Drinking Customs—Rites of Hospitality: Wine for One's-self and Wine for One's Friends—Hambro' Sherry—Substitutes for Port and Sherry: Marsala.

The account given at present of sherry by all wine merchants is the same as that of port—largely increased price and deteriorated quality. My own experience is, that the pure light wine which we got ten or twelve years ago at from 30s. to 40s. per dozen is now not to be had at all. Cheap sherry now tastes as if intensely fortified with coarse brandy, whilst the price of an old, soft wine has risen to 60s. at the least. Wine merchant A tells me, "I really often think of giving up the trade in sherry; it is so difficult to supply people with creditable wine at reasonable price." Wine merchant B says that "within the last ten years many common and low priced, but pure and most useful, varieties of wine have disappeared from the market; customers must pay at least 30 per cent. more than they did, and even then will get a wine not only 10 per cent. worse, but of different quality." Mr. T. G. Shaw tells us (a) that a more agreeable wine could be met with at £20 before the vine disease broke out in 1852 than can now be easily met with at £40. The price, too, is rising still, though the grape disease has passed off and produce is increasing, for more wine is made and the last vintage was a good one.

The cause of this state of things is, first, the vine disease, which checked production and tempted the shippers to part with much of their old stock, and to send young, immature, brandied wine at the high prices ruling; but secondly and chiefly, the enormously increased consumption.

In 1850, according to the tables in Mr. Shaw's book, sherry ranged from £28 to £70 per butt at Cadiz, and the quantity shipped to Great Britain was 35,433 butts, which at 108 gallons per butt, equal 3,826,764 gallons. In 1864 7,081,033 gallons were imported into England, of which 4,551,949(b) were retained for home consumption; and that consumption has been increasing steadily at the rate of about 12 per cent. per annum.

Respecting the real nature of sherry, there is no doubt whatever that after the young wine has undergone a certain amount of fermentation it receives an addition of spirit, said to be six gallons per butt, and another four on being shipped. Moreover, we never get sherry in a pure, unmixed state. Flavour, softness, colour, richness, and piquancy are the product of various ingredients. For the true sherry flavour and softness old wine must be used. For richness and dark colour, a stuff called the "Doctor," composed of wine made from juice concentrated by boiling. For piquancy, an admixture either of the thin, dry, light, pure wines, known as Montilla and Manzanilla, or of sherry which has undergone a certain change which converts it into "Amontillado."—See Shaw, *Op. cit.*

The best account of sherry is that given before the Committee of the House of Commons on the Import Duties on Wines in 1852, by Dr. Gorman, Physician to the late British factory at Cadiz, a long resident in Spain. He says that no natural sherry comes to this country. It is all mixed and brandied. The quantity of proof spirit which good pure sherry contains by nature is 24 per cent., possibly 30. The less mature and less perfectly fermented the wine, the more brandy is there added to it to preserve it. "*It is not necessary to infuse brandy into any well-made sherry wine; if the fermentation is perfect, it produces alcohol sufficient to preserve the wine for a century in any country.*"(c)

Dr. Gorman was the first who introduced Manzanilla into this country; a pale wine of peculiarly thin, bitter flavour, not brandied, and used of late years for gouty, dyspeptic, and rheumatic patients. Montilla is a wine of similar character, thin, and very dry. "Amontillado" is the name of certain sherry which has undergone a peculiar transformation in cask. There is no doubt, says Mr. Shaw, but that out of a given

(a) "Wine, the Vine, and the Cellar." P. 154.
(b) Ridley's "Monthly Wine Circular," March, 1865.
(c) Minutes of Evidence, part 2, question 5776.

number of casks some become an entirely different wine; this is stated to be the case with the well-known "Amontillado," which name signifies *à la Montilla*, like the mountain wine grown on the hills about Montilla, near Cordova. These wines, as Mr. Shaw says, are "invaluable for giving character to sherries that require some of their heaviness knocked off."

One or two practical questions arise here. First, the extraordinary development of that peculiar flavour which is known as "amontillado" in some casks of wine. As to the nature of it, it is doubtless an ether, and it has such a resemblance to sweet spirits of nitre, or nitrous ether, that more than one friend and œnological fellow-student of mine, during a practical exercitation, has declared that the wine has been artificially flavoured with that ether. The flavour is the same in the manzanilla, the montilla, and the amontillado, and in all I have known some persons detect it immediately, and denounce it as odiously physicky; one great œnologue declares it is a disease in sherry. The curious thing is, that I have known this same flavour developed in a stray half-bottle of white Mount Hymettus that had been standing about forgotten and half-corked for some months. The power of amontillado to brighten up and give character to common wine is quite marvellous.

Sherry as it used to be was a most valuable wine. I am no fanatic, who desire to run down one thing and unduly exalt another, and though an apostle of light wine, declare that the stronger alcoholic liquors have marvellous uses for stimulating the heart and brain, and for making a feeble stomach agree with a refractory mass of aliment. Sherry was such an alcoholic drink, tempered by a certain dry vinosity; an excellent medicine and substitute for spirits in nineteen cases out of twenty. Ten years ago Physicians prescribed sherry with confidence to the dyspeptic and to those troubled with acid diseases, as gout and rheumatism. But the sherry of to-day is quite a different thing, even if all considerations of price be set aside. It is newer, less mature, never soft, more brandied, and instead of being a preservative against acidity is a promoter thereof.

We are, therefore, driven from sherry, in very many cases, as a wine for invalids, and made to seek some substitute; which substitute I find, in nine cases out of ten, in the pure and well-fermented wines of France. But as for persons in good health, why should they drink a brandied wine? If the stomach be old, or feeble, or diseased that is one thing; but what possible excuse can there be for a child, or for a young man in health and strength, or for a blooming girl to take a glass of brandied sherry whilst all the light and innocent wines of Hungary, Greece, Germany, and France are to be had so easily?

The greatest patrons of heavy brandied wines are, I am sorry to say, the ladies and the clergy. Their reason is most meritorious, for they have never been taught the difference in nature, flavour, and effects between wine and spirits; highly sensitive and gifted as women are with perceptivity of odours, they have never been taught to look for the juice of the grape and its admirable bouquet; they know only the effects of alcohol, and as it would be considered a scandal to drink many glasses of alcoholised wine, and as some houses have only the miserable little wine-glasses adapted for those wines, and as such a glassful of "claret" would be cold and flat, so they prefer something stronger. When Monsieur Assolant visited England at the time of the International Exhibition, 1862, he caused wondrous offence by describing the English "Miss" as fond of brandy. The fact is, that our sherry would be called brandy by a Frenchman. The clergy, again, have never been taught the advantages of real wine. Desirous of knowing what sort of wine the future clergy get at the Universities, I procured specimens from one of the two great English Universities, and some information withal as to the drinking customs of the place. I am glad to learn that a wholesomer taste is beginning to prevail. "Claret," says my informant, "is much drunk when friends meet after dinner; more so now than port or sherry. An average price I should say is 2s. the bottle. It is rough, but pure and wholesome." My friend tells me that very little positively bad wine is bought, except by young men who are in debt with the local wine merchant; most of the wine, however, is described as indifferent. There is one occasion, however, when bad wine is much in request. "It is very common," says my informant, "when a student gives a large miscellaneous wine party (as, for instance, his terminal 'college wine'), to buy for the occasion a cheaper quality of wine than he keeps for his ordinary daily use. At my old college I remember it was only at these sort of parties that one met with any stuff which was undrinkably bad." Marvellous are the varieties of what are called the rites of hospitality! In some countries the stranger is clubbed and devoured; in some, the house, wives, meat, drink, and whole property of his entertainer, are put at his disposition. To drug a guest with cheap bad wine argues no very great advance in the scale of civilisation; and I would not give much for a friendship cemented by such liquor. If one were tied to port and sherry, such conduct would be excusable; but not now.

My notes of four specimens of wine, sent me from one of the great Universities (I asked for such wine as undergraduates would be likely to buy), are these:—

1. *Port.* Messrs. A. Price 40s. Alcoholic strength, 33. No smell of port wine. Tastes and smells of spirits, and some sweet matter.

2. *Port.* Messrs. B. Price 48s. Alcoholic strength, 35. Very pale; no crust, nor tinge of cork; sweetish; smells a little of port.

3. *Sherry.* Messrs. A. 36s. Alcoholic strength, 36. Pale; some taste of wine; very hot.

4. *Sherry.* Messrs. C. 40s. Alcoholic strength, 35. Pale; some taste of wine; not quite clean; hot and spirituous.

These are about the same kind of wine, and not much above the same price, as would be procured at most retail places in London. They are examples of the low-priced port and sherry of the day.

There are many liquids which do duty as sherry which are much worse than these. There is British sherry at 1s. 6d. per bottle, and other imported liquids of low price. A wine merchant told me that he remonstrated with a customer who asked him for sherry at 20s. per dozen, and told him it was not good to drink. "Oh! it is not for myself," said the considerate purchaser; "but we like to have some in the house for our *friends*."

Amongst these, I am bound to notice the Hambro' sherries, which I denounced in an earlier number of these papers; for Mr. Chaplin, whose firm is engaged in the manufacture, was obliging and frank enough to send me two sample bottles, on which I feel it my duty to offer a fair criticism.

One specimen of this sherry, labelled "E C," and which costs £11 per butt, free in the Thames, is of alcoholic strength about 32. The other, labelled "M M," is at £14 per butt in the river, and 18s. per dozen retail; alcoholic strength about 35. The predominant taste of each is alcohol; and the predominant effect on me is, that heat of throat which spirit causes, and which natural wine does not cause. There seems a little wine taste in each, but no wine flavour, and a sweetness which makes them not clean on the tongue. I gave a glass of one to a wine merchant, telling him it was fine sherry; but he gave it its right name in a moment. A second person to whom I gave some said, "This is nice; but it is not sherry." A third said, "One glass of this would give me heartburn all day." A fourth, butler to a nobleman, said, "I would not give this to my lord; it is hot and sickly sweet." He also said, "We give 80s. per dozen to Tod Heatly for our ordinary sherry this year; last year it was 72s." These were persons simply invited to taste. Mixed with hot water, it gives more of the nice smell of negus; but I confess "M M" so treated has more of wine *taste* than I expected.

They show so forcibly the great chemical and manipulative skill employed in their fabrication as to make one wish that such talents were devoted to some worthier product. I beg meanwhile to add that I am informed on good authority that there is *some* wine in them, else they would not be admitted by the Customs at all; and that the liquids which are stopped and charged as sweetened spirits 14s. per gallon have no wine in them. Moreover, the fact that wine may come direct from Spain is no proof that it is any better than Hambro' wine; for lo! Hambro' wine has been shipped from London to Cadiz and back—an operation which, as we are told, costs 30s. per butt, but enhances the nominal value of the wine 100 per cent.

It appears from "Ridley's Circular" that 2416 butts of Hambro' wine were taken for home consumption in 1864, against 2594 in 1863.

Of *port for Hospital use*, I may say that the Physician should consider what he wants; is it the powerful stimulation of alcohol or the nutritive virtues of wine? If the former, he may just as well give Rickards' British brandy, at 18s. per gallon; that is, three shillings a bottle, and each bottle will make, when mixed with two of water, a liquid equal in alcoholic strength to most sherry. If *wine* be really needed,

then there are the various sorts which I have enumerated before, of which I find that the Red Hymettus, Santorin, Ofner, Carlowitz, and Voeslauer are readily taken by uneducated people. If there should still be a prejudice in favour of "port"—*i.e.*, a liquid hot, strong, and sweet—and if the Hospital Committee object to give 42s. per dozen for some of Thompson and Croft's or Sandeman's new wine, then there is a choice of red South African; of Tarragona, and other kinds of Spanish red; of Como, Roussillon, Château Neuf du Cape; and last, not least, Masdeu. The South African may be not unpleasant to taste, but hot and flavourless; the Tarragona intensely strong, coarse, grapy, sweet, and very astringent; the Como of natural strength, very grapy, requires development; the South of France wines usually spoiled by coarse fabrication and added alcohol. The nicest of the lot is Masdeu. I have tasted some that had been some years in bottle, delicious, from Durand, Selby, and Co. It will be a good move when Hospital Committees inquire into these things systematically. The average price of Masdeu, Tarragona, etc., is £1 1s. a dozen.

Of substitutes for sherry I have no doubt that some will be found amongst the more perfect and dry Hungarian vines, as the Szamarodny, and amongst the Greek. I have had a sample of old St. Elie, which was pronounced fine sherry. *Bucellas* was a most useful wine, of high vinous character, ten years ago; now I never meet with any worth drinking. The best substitute for cheap sherry is Marsala, which is what it pretends to be, and nothing else. New Marsala is intensely strong and brandied; when old, although it preserves a coarse, earthy *taste*, it acquires *bottle flavour* so much as to astonish persons who taste some forgotten bottle of it that may have been laying for years in the cellar. I have to acknowledge the receipt, through the *Medical Times and Gazette* office, of a very satisfactory specimen of Marsala from Messrs. Watson, of 73, Great Russell-street; clean, with a smack of flavour, and cheap at 21s. per dozen. If a man will drink strong wine, or if he desires to have a serviceable wine of the sort in his house, let him lay down Marsala instead of cheap sherry.

(To be concluded in our next.)

REVIEWS.

The Successful Treatment of Internal Aneurism, illustrated by Cases in Hospital and Private Practice. By Jolliffe Tufnell, F.R.C.S.I., M.R.I.A. London: Churchill and Sons. Dublin: Fannin and Co. 1864. Pp. 34.

We are inclined to think that this unpretending pamphlet will prove a more valuable addition to Medical literature than one-half, at least, of the portly octavos which the current of the past year stranded on our book-shelves. Our readers are aware that various proposals for the treatment of aortic aneurism have been of late years brought before the Profession, and that more than one successful and several encouraging cases have been recorded. Thus, Dr. Blakiston's treatment by the application of cold, a measure which had previously formed part of Guerin and Pelletin's plan, has been found productive of marked benefit in, at least, one case. Dr. Murray, of Newcastle, again, has treated a case successfully by pressure. Then, also, the plan of filling the cavity of the aneurism with a coil of fine wire, and that of endeavouring to produce coagulation by the galvanic current, have each found supporters. Yet we know of no mode of treatment which has been supported by such a weight of evidence as that advanced by Mr. Tufnell. The author gives the details of six cases, four of abdominal and two of thoracic aneurism. Five of these cases were ostensibly cured, the patients resuming their usual occupations, and suffering no further inconvenience; the sixth was greatly relieved by the treatment, but subsequently discontinued it, and, although warned of the danger, returned to a life of hunting and other athletic exercise, and ultimately died from the bursting of the aneurism. We do not give the details of these cases, as we hope that our readers will study carefully Mr. Tufnell's pamphlet for themselves; neither do we reproduce his very valuable practical remarks on the diagnosis of internal aneurism; we confine ourselves to an account of the treatment which has been in his hands so successful. It was originally excogitated by Dr. Bellingham and himself, and was being tested by the former in conjunction with the author at the time of Dr. Bellingham's death. Since that event Mr. Tufnell has continued the experiments alone. The ends which all treatment of internal aneurism must have in view are two: first, to contend successfully against "the distensile action of the heart, the forcible flow of the blood from which has the effect of thinning and destroying the sac;" the other is to promote fibrinisation. For the latter purpose it is necessary that the health of the patient should be preserved, and his blood kept in a highly-fibrinised state. Valsalva's treatment failed most conspicuously in fulfilling the latter object. His frequent bleedings rendered the blood watery, and deficient in the very element which is most needed for the cure of the disease. The main point in Mr. Tufnell's plan is the enforcement of the recumbent position for a considerable time—from two to three months. The powerful effect of this measure in lowering the rapidity of the heart's action is best exemplified by one of his own cases. The patient when first seen had a full jerking pulse of 104. After a few days it fell to 96, but when standing or taking ordinary exercise it never sank below this. By placing the patient horizontally, however, for forty minutes, the pulse fell to 66. The full amount of retardation thus gained he shows by the following calculation:—

The pulse when standing and in ordinary exercise . . .	96 per minute.
The pulse after lying horizontally for a while	66 „
Difference of pulse caused by position	30 beats per minute.
Multiplying 30 beats by 60 minutes	60
	30
Gives	1,800 beats per hour.
And multiplying 1800 beats by 24 .	24
	7,200
	3,600
Gives no less than . .	43,200 beats per diem.

In a word, when in the recumbent position, the aneurismal sac was distended 43,200 pulsations less frequently per diem than when the patient was erect. Mr. Tufnell may well ask "What remedial agent in the Pharmacopœia will, without prejudice to the constitution of the patient, produce this result? and his answer—"There is none"—is one which assuredly none will gainsay. As the measures by which he has been enabled to keep his patients lying for so long a time are, though very simple, of the highest practical importance, we transcribe the passage in which he describes them:—

"Recumbence is the secret of cure, but this recumbence must be regularly and steadily maintained. I have mentioned 'a considerable length of time.' I mean by this expression two months, or ten weeks at least, and this period to be passed without the patient, if possible, sitting even once erect. In carrying out the treatment we require, therefore, a light, cheerful, and airy room, where by day the patient shall have an opportunity of seeing what is going on; and especial care must be taken that it has a southern aspect, for nothing is more depressing to the spirits of a patient than being immured in a chamber upon which the sun never shines. The next point to be attended to is the bed. It must be of camp form, so that the bowels, when acting, can be easily relieved by an assistant with the pan, or (if not acting) by the administration of an enema without disturbing the patient. Yet it must not be too narrow, as the sufferer would otherwise feel cramped and confined, and not sufficiently at ease. Upon the bedstead must be placed two hair mattresses, one upon the other, both full and elastic. Upon these (in proper site to receive the sacrum and hips) a large water cushion properly, but not over, filled. Upon this a double blanket, sewn at the corners and sides to the lower mattress, and upon the blanket a fine linen sheet similarly attached—this being done to prevent all wrinkling in the bed and disturbance of the sheet on which the patient's legs and body lie—another linen sheet (folded as after a lithotomy operation) being laid transversely to receive the buttocks, and to be drawn from beneath from time to time. Three or four good feather pillows to prop the shoulders and receive the head, together with the over clothes, complete the bed, on which, when once comfortably settled, the individual must be content to lie without changing his position further than to turn from side to side, or occasionally round upon his face, should such movement give relief to the dorsal pain, as it sometimes will. A urinal and bed-pan must be at hand, and an attendant always ready to offer such aid as the patient may require: to read to, converse with, or amuse him."—Pp. 29, 30.

Next in importance to the recumbent position is a restricted diet and the allowance of a minimum amount of fluid. The following is Mr. Tufnell's diet scale:—For breakfast, two ounces of white bread and butter, with two ounces of cocoa or milk. For dinner, three ounces of broiled or boiled meat, with three ounces of potatoes or bread, and four ounces of water or light claret. For supper, two ounces of bread and butter, and two ounces of milk or tea, making in the aggregate ten ounces of solid and eight ounces of fluid food in the twenty-four hours, *and no more.*" Thirst if urgent is to be relieved by sucking a pebble or an occasional bit of ice. If the restriction in diet render the patient restless and intolerant, it may be raised sufficiently to insure tranquillity, but no higher. With regard to medicines—the third point in Mr. Tufnell's plan—he recommends sedatives, especially lactucarium, henbane, and where necessary black drop to relieve pain and procure sleep, and aperients such as compound jalap powder, compound colocynth, and compound rhubarb pill, the first especially on account of its action in withdrawing fluid from the blood, but he especially warns against unnecessary and irritating purgation. Other remedies, such as iron, quinine, and iodide of potassium, are mentioned incidentally, but they do not form a special feature in the treatment.

It is clear that it is only in cases where pressure on vital organs or irreparable injury to important structures have not yet taken place that this or any other plan of treatment can be expected to succeed. Even in the best selected cases cure must depend no less upon the fortitude and confidence of the patient than on the strong will and sagacity of the Physician. We shall expect, therefore, to hear of many failures. But if anything like the amount of success which he has met with attend in other hands Mr. Tufnell's treatment of this well-nigh hopeless disease, he will have established no small claim on the gratitude and remembrance of the present and all future generations.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

March 25, 1865.

In the first place, I will allude to the report of the health of our town during the year 1864, drawn up by the Medical Officer, Dr. Trench, and which, I need hardly say, contains much interesting matter. I find that during the year 1864 the deaths in the borough amounted to 16,836, or to 1626 above the corrected average of the preceding ten years, making the death-rate equal to 36 in every 1000 of the inhabitants—that of the parish being 39·4, and of the out townships 30·9, in the 1000. Many diseases combined to cause this high mortality, but the most important were zymotic and pulmonary complaints. The zymotics account for 4870, or 28·9 per cent., of the deaths from all causes—the most fatal form being typhus, which began to spread towards the end of 1861, and has steadily increased until it has now assumed the form of a destructive epidemic. We find, on looking at the report, that 390 deaths occurred from typhus during the year 1860, whilst in 1864 the number reached 1774. Dr. Trench then treats of the various conditions that are generally regarded as conducive to the spread of typhus—viz., contagion, poverty, overcrowding, and filth. Under each of these heads we find much valuable information. On the question as to the cause of epidemic diseases Dr. Trench offers the following remarks:—"It is not possible to arrive, by the deduction of uncertain and speculative science, at absolute demonstrable and exact truth on a question so recondite as that of the causation of epidemic disease; but the following corollaries follow from the premises which have been detailed, and lead, with every appearance of high probability, to the conclusion that destitution was the cause of the epidemic:—

"1stly. Great distress in the labourer's class, accompanied by an enormous increase of parochial pauperism, existed previously to the winter of 1861 and spring of 1862, when the typhus began to be in permanent excess.

"2ndly. The distress and prevailing fever were both so simultaneously increased during 1862 as to indicate the parallelism of cause and effect.

3rdly. The number of recipients of workhouse relief in 1863, though reduced by 186 out of 16,003 in 1862, showed that, in spite of a partial revival of trade, the want was exceptionally great as compared with the ten years before 1861.

4thly. The transactions of the Central Relief Society, and the condition of the fever patients of the Workhouse Hospital in 1864, demonstrate that whatever might be the bettered circumstances in trade or commerce, the distress was not alleviated among the persons immediately above the rank of habitual pauperism.

5thly. It was of necessity and by reason—*firstly*, of want of employment; and *secondly*, especially in 1864, by the losses sustained by sickness in their homes, that so many individuals of the working classes ceased to contribute their deposits in the District Provident Society.

And 6thly. The pressure which prevented the better-off from exercising a prudent saving, threw the more necessitous into abject want."

Dr. Trench goes on to say: "It may surprise many to have it even hinted at that want and destitution prevailed so widely among the people as to be the chief cause of this, as of every preceeding epidemic of typhus known to Medical history; for during the years of which I write our fashionable streets bore evidence, by the great increase of splendid equipages and the accumulation of treasures of art and luxury, that much prosperity was not only co-existent with the want which I have described, but also co-dependent on the same causes. Fortunes of large amount are said to have been realised by speculators on the very cotton famine which threw thousands of labourers out of work; while shipowners, to whom the American internecine war had given almost a monopoly of the carrying trade, obtained such advantageous freights as to more than counterbalance the losses sustained by the reduction of cotton imports."

Small-pox I find almost absent from the death registry during the years 1860, 61, and 62, but in 1863 I find 100 deaths placed to its account, whilst in 1864 482 deaths occurred, being 369 above the corrected average of the preceding ten years. 182 deaths occurred in persons over five years of age. If this large mortality is in any way owing to the public not attaching of late sufficient importance to vaccination, we ought to be free at all events for the next few years, a vaccination mania at present pervading all grades of society, both young and old, and lymph in the form of points, tubes, etc., is eagerly sought after. As I am anxious to touch upon one or two other topics, I will postpone further allusion and quotation from Dr. Trench's interesting report to another occasion.

At the Royal Infirmary, Mr. Bickersteth has lately successfully removed with the whip-cord écraseur a polypoid growth, about the size of a walnut, growing from the anterior wall of the bladder. The patient, a young woman, had suffered most distressing symptoms of vesical disease for some time past. Twelve months previously a fibrous polypus, the size of a hen's egg, had spontaneously been expelled from the bladder into the urethra, where it was visible, being attached by a pedicle to the wall of the bladder from whence it was removed, I believe, by Dr. Grimsdale. She remained well for some weeks after its removal, and it was only recently that symptoms of the formation of another growth manifested themselves. She quickly again recovered from the effects of the operation. An interesting abnormal arrangement of the peritoneum was observed the other day in the post-mortem room at the Infirmary: the small intestines, with the exception of the duodenum, were all found lying in a cyst formed by reflections of the peritoneum, the large intestines being alone visible, and occupying their natural position. A full description will, I believe, shortly appear.

In the Northern Hospital at the present time there is a case of embolism of the brachial artery under the care of Dr. Waters. It occurred suddenly a few days ago in a patient under treatment for phthisis. No pulsation can be detected either in the radial or ulnar arteries; he complains of numbness and loss of sensation in his hand and wrist, and the difference of temperature in the two hands is very obvious. There is no evidence of cardiac disease.

At the last meeting of the Medical Society, Dr. Grimsdale concluded the narrative of his ovariotomy cases. He has performed the operation ten times, and seven with perfect success. A full account will, doubtless, appear amongst the proceedings of the Society.

There is a step in the right direction in the manner of conducting the anatomical examinations for prizes and honorary distinctions, introduced for the first time at our Medical school. Each candidate has to undergo a practical examination on the dead subject, in addition to the usual written questions; this will give the practical student a better chance

of distinguishing himself than his "grinding" opponent, and consequently tends to encourage practical work amongst the junior members of our Profession.

GENERAL CORRESPONDENCE.

THE THEORY OF MOLECULES IN RELATION TO THE MEDICINAL VALUE OF WINE.

Letter from Dr. Macvicar.

[To the Editor of the Medical Times and Gazette.]

Sir,—In the hope that you may be disposed to follow up the interesting information of your Empirical Commissioner on wines and their medicinal worth or worthlessness by a scientific treatment of the subject, I beg to forward to you the physiological bearings of the question in so far as alcohol and water are concerned in the light of the most advanced theory of molecules—I mean that which maintains that the phenomena equally of nature and the laboratory may be fully explained if we assume that the molecules of bodies in general, whether liquid or solid, are constructed like the regular polyhedra of geometry; but so that almost all those that have as yet been discovered in our planet are either dodecahedral or icosahedral, or both—that is, consist of either 12, or 20, or 32 (aeriform) elements, and all occupy equal volumes, or volumes in simple ratio like aeriforms. (See *Trans.* Roy. Soc. Edin. for 1864, p. 581.)

That we may be able to deduce specific gravities *à priori*, it is only necessary to premise that the liquid particle of water in this theory is a dodecatom, each of the 12 elements of which consists of 3HO or 3aq, as commonly written, but which, in this theory, is an unity consisting of an atom of HO in each pole of an atom of aq, and which, when written symmetrically on both sides of the centre, gives OHaqHO. The particle or molecule of water, therefore, which gives unity for specific gravities is in this theory

$$(OHaqHO)^{12} = 36aq = AQ = 36 \times 9 = 324.$$

Using the old English atomic weights of C and H and O, we similarly obtain for alcohol—

$$(C_4H_6O_2)^{12} = 12(C_2H_6O_2) = \text{Alcohol} = 12 \times 46 = 552.$$

It is well known that molecules, in order to be fit to take their place in the course of life, must be very highly hydrated. It appears, according to the theory of which I have stated the principles, that each element of the chemical anhydrous molecule receives a particle of AQ on its peripheral summit, so that the dodecatomic molecule of the substance is encased in 12 particles of water. To this there is added one more on each pole when the water is still abundant. This I may illustrate in reference to the plastic molecule of which tissue is ultimately composed. When reduced to its lowest terms, as has been done by C. Schmidt, this molecule has for its element $C_8H_6NO_3$. Of this the atomic weight is 92, that of the dodecatom, of course, twelve times as much. And this $(C_8H_6NO_3)^{12}$ we may call Plastic $= 12 \times 92 = 1104$.

Now, applying to each of the 12 elements of plastic matter an AQ, we obtain plastic matter : water : : 92 : 324, or $12 \times 92 : : 12 \times 324 = 22{\cdot}8 : 77{\cdot}2$ water per cent. Now, the last number is just the percentage of water proper to flesh, etc. We thus obtain as the form of the plastic molecule when constituting tissue

$$\begin{matrix} AQ^6 \\ \text{Plastic} \\ AQ_6 \end{matrix}$$

But when water abounds, as when the plastic matter is still in the state of blood, it has been stated that 2AQ additional may be expected, one aq on each pole. Supposing the axis of the molecule horizontal, we thus obtain

$$\begin{matrix} AQ^6 \\ AQ, \text{Plastic}, AQ \\ AQ_6 \end{matrix}$$

And in this the percentage of water must obviously be $\frac{2}{12}$ths more than in the solid. Now, 77·2 increased by $\frac{2}{12}$ths gives 80, and this is just the percentage of water, in so far as integers are concerned, that is found in good healthy blood.

It may be shown that hydrous molecules of the same structure tend to form in inorganic nature. Thus, taking $ClNa^2Cl = 2NaCl$ as the smallest element of table salt that is symmetrical and soluble or capable of isolation; and supplying it now with AQ^{12}, and now with $AQAQ^{12}AQ$, we obtain as percentages of salt 2·56 and 2·99. Now, these limits define those of chloride of sodium in the waters of the ocean. Looked at in relation to the same theory, much light may be thrown on the normal structure of urine, also on such hydrates as may be alternately liquid and colloidal. (See Mr. Graham's Researches.)

But to come to wine, that which we are to look for as the normal hydrous molecule of alcohol, which nature will tend to develope when an adequate amount of saccharine matter and a ferment are supplied, and which will be most suitable for entering into the circle of life, will be one or other of the two aqueous dodecatoms defined above. And we may expect that the percentage of alcohol in the best wines will be defined by the proportion of alcohol that they give. Now, of a single element of alcohol the atomic weight is 46, and that of AQ 324, we have $324 : 46 = 87{\cdot}57 : 12{\cdot}43$, the last number being the absolute alcohol per cent. And diminishing it to correspond to an increase of $\frac{2}{12}$ths in the water, by the construction of the more aqueous molecule we obtain 10·85 per cent. of alcohol. Now, doubling these percentages of alcohol to reduce them to proof spirit, we obtain in a true wine—that is, a liquid in which there is neither any free water nor any free alcohol—from 21·7 to 24·8 per cent. of proof spirit. No result could accord better with the best analyses of the best sorts of wine than this.

But this is not the only verification of the theory which I illustrate, nor the main one. That arises from the power which it gives the chemist to calculate specific gravities all independently of the intricate and questionable doctrine of atomic volumes, and simply by the application of the ordinary method to molecular weights. Thus, allowing to the molecule of alcohol, which is larger and heavier than the molecule of water, two normal or aqueous volumes, the specific gravity of alcohol as developed in a natural hydrate, *i.e.*, in wine ought to be :—

$$AQ^6$$

Warm wine—Alcohol, sp. gr. = ·9788, = spirit 24·8 per cent.

$$AQ_6$$

$$AQ^6$$

Cool wine—Alcohol, sp. gr. = ·9815 = spirit 21·7 per cent.

$$AQ_6$$

Unhappily the hydrous alcohol of wine cannot be obtained till after its molecular structure has been destroyed by distillation. And that the re-construction, when water is added to alcohol to reduce it, is incomplete, fully appears from the loss of volume that ensues. To this happily, however, there is a limit—viz., as is well known when 6 aq have been added to one atom of alcohol. Now, here we at once see the axis of our wine molecule laid. For multiplying both by 12 we obtain 72 aq = 2 AQ and $(C_4H_6O_2)^{12}$, which, written symmetrically, give—

AQ. Alcohol. AQ

And here we may expect the theoretical specific gravity to be responded to by the hydrometer. Now, allowing (as has been said, 2 volumes to the molecule of alcohol) that is, 4 volumes to the hydrous alcohol molecule, we obtain—

$$G = \frac{324 + (12 \times 46) + 324}{4 \times 324} = ·926.$$ Experiment at 60° F. ·927!

By adding water until the mixture is reduced to our wine strength, instead of ·9815 which is the theoretical specific gravity of the cool wine, we obtain from the tables (they all differ) about ·9826, not very different, and identical at a certain temperature. And for the warm wine instead of ·9788 we obtain about ·9805.

The theory of the phenomenon which takes place during the addition of water to alcohol appears to be this. In absolute alcohol, which is a wholly unnatural and impatient substance, the molecules are alternately dodecatoms and icosatoms, differentiating each other, and thus securing a greater degree of stability or electrical neutrality than could exist if they were all of one kind. When water is added, the dodecatoms, which are the most stable of the two, gain upon the icosatoms: three of the latter resolve themselves into five of the former.

Supposing absolute alcohol to consist, as I have said, of these two kinds of molecules in equal numbers. And as the icosatom is nearly double the mass of the dodecatom, allowing to the former a double volume, we obtain for the specific gravity of absolute alcohol :—

$$\text{Alcohol } G = \begin{cases} \frac{(C_4H_6O_2)^{12}}{2AQ} = \frac{12 \times 46}{2 \times 324} = ·882 \\ \frac{(C_4H_6O_2)^{20}}{4AQ} = \frac{20 \times 46}{4 \times 324} = ·741 \end{cases}$$

Mean, 796; experiment, 795!

This spontaneous differentiation of liquids in order to a more stable condition is, in the theory on which these remarks proceed, a very frequent phenomenon wherever H or S occurs in the formula of the substance along with C or O or N.

The ideal of distillation as a rectification in which there would be no waste would be when the mixture submitted to treatment gave

$$\text{In the still}—\text{AQ.}\ \text{ALCOHOL.}\ \text{AQ.}^{6} = \text{Wine, Toddy, Punch.}$$

$$\text{In the receiver}—\text{AQ}\ \frac{\text{ALCOHOL}^{6}}{\text{ALCOHOL}_{6}}\ \text{AQ}_{5} = \text{Spirit as strong as can be distilled.}$$

In ultimate distillation every aëriform element seems to consist of a couple of alcoholic elements united by an atom of aq., which insists on going over along with the alcohol. This gives 8·8 per cent. of water. And when constructed into a molecule (which it probably never is in point of fact), gives the last molecule represented above. It is the inverse of the wine molecule, its body being alcohol instead of water.

I am, &c. JOHN G. MACVICAR.

JERKED BEEF.

LETTER FROM DR. H. BUSS.

[To the Editor of the Medical Times and Gazette.]

SIR,—It being in every way desirable that the Profession should encourage the importation of cheap meat, provided such meat be wholesome, my experience of the above may at this time be acceptable.

A week ago I purchased 7 lbs. of charqui or jerked beef from Mr. Madden, 3, Leadenhall-street. It was in appearance and smell exactly as has been described in your columns by Dr. Ballard and others.

My wife was certainly not prejudiced in its favour. It was soaked in cold water all night. It was now placed for three or four minutes in boiling water, and then beaten with a rolling pin. This water was rejected. This stage is very important, because it removes the sickly and offensive taint of such decomposition as had been going on. Now it is put into fresh water for soup, or hashes, or stews, seasoning and vegetables having been added according to taste. When it came to table as strong soup there was nothing objectionable in its flavour. I believe that all my family had they not known previously that it had been made from charqui would have given their verdict in its favour.

I am, &c. H. BUSS, M.D.

56, High-street, Shoreditch, March 23.

COMPULSORY REGISTRATION.

LETTER FROM MR. EDWIN LEE.

[To the Editor of the Medical Times and Gazette.]

SIR,—Perceiving that it is a question to make registration compulsory on all Practitioners of Medicine and Surgery, I presume that any amendment of the Medical Act to that effect would not have a retrospective action affecting many who, like myself, objected on principle to the payment of an unnecessarily large fee for merely enrolling their names in a list of Practitioners, who are thereby enabled to sue at law for compensation for Professional services refused or contested, and to compete for appointments to charitable or public institutions, without its conferring any other advantage; for as to its affording any protection to the Profession against illegal Practitioners, registration (as it has been conducted) is confessedly a failure.

Soon after the passing of the Medical Act, I publicly expressed my opinion that a chief object of its framers was to obtain from the Profession a large sum of money, of which no satisfactory account would be rendered. I did not, therefore, register, and the statement of the receipts and expenditure have, I think, fully confirmed my opinion, for it is pretty generally admitted that very little serviceable to the Profession has hitherto been effected in return for the large sum that has been derived from the registration fees.

To take, as a sample, the last year's account, we see that the receipts have been £5281, and that the expenditure for fees, salaries, and expenses of meeting has exceeded that amount, viz., £5657, upwards of £2000 of this sum having been paid for councillors' fees and expenses. Had there been any guarantee that the money obtained under the plea of registration was to be applied to Professional purposes, no one would have objected to register, nor would there have been so many complaints from those who have registered as to the uselessness of registration to them. I am, &c.

Cannes, March 22. EDWIN LEE.

EXAMINATION AT THE

CLOSE OF THE NINTH SESSION OF THE ARMY MEDICAL SCHOOL, ROYAL VICTORIA HOSPITAL, NETLEY,

BETWEEN JANUARY 30 AND FEBRUARY 4, 1865.

A.—WRITTEN QUESTIONS.

I. Military Hygiene (Professor E. A. Parkes, M.D., F.R.S.).

1. If you were called upon to give your opinion as to the desirability of a certain water supply which it is proposed to use for a garrison of 5000 men, what points would lead you to an opinion—firstly, as to the sufficiency of the supply; secondly, as to the purity of the water?

2. If an outbreak of diarrhœa affected suddenly a number of persons in a limited area, what would be the most probable causes, and how would you ascertain the existence of those causes?

3. What are the principal causes which produce movement of air in rooms, and at what rate does movement become perceptible? What are the regulations as regards cubic space per head at home and abroad, and what are the recommendations of the Barrack Commissioners in respect of the quantity of air which should be given per head per hour in barracks?

4. What are the chief diseases which at present cause mortality in the West Indies and the Mauritius, and what are the chief rules of prevention?

II. Military Medicine (Professor W. C. Maclean, M.D., Deputy-Inspector-General).

1. Give as complete an account as you can of the causes which produce—(*a*) typhus, (*b*) dysentery, and (*c*) phthisis in armies.

2. Describe the general and special indications of the treatment in the typhus of armies.

3. Give the causes, symptoms, diagnosis, consequences, and treatment of enlarged spleen.

III. Military Surgery (Professor T. Longmore, Deputy-Inspector-General).

1. Describe the treatment you would adopt on being called to a recent case of gun-shot wound of the abdomen under each of the following six conditions:—(1.) One opening, without direct evidence whether the projectile has or has not penetrated the cavity of the abdomen; (2.) One opening, the cavity being evidently opened, but no complication being visible; (3.) Wound penetrating the cavity, complicated with hæmorrhage externally; (4.) Wound with protrusion of the intestine, the intestine itself being unopened; (5.) The same, but with intestine opened; and (6.) Two penetrating wounds without visible complications.

2. Explain the way in which the eye is enabled to see objects at different distances, and the method by which the range between the nearest and the most distant points of distinct vision may be determined and expressed. Show also how, when presbyopia exists, its degree and the means of correcting it can be ascertained.

3. Give an outline of the Surgical duties and of the general arrangements for the care of the sick and wounded under the ordinary circumstances of troops on the march in time of war.

IV. Pathology (Professor W. Aitken, M.D.).

1. Define what is understood by syphilis. Describe the characters, probable periods of incubation, duration, and consequences of the various primary venereal sores, and state what kinds of eruptions or sores on the organs of generation may be confounded with venereal sores.

2. Define what is understood by pyæmia and Hospital gangrene. Describe the circumstances which tend to induce and propagate the morbid states which these terms comprehend.

3. Describe and interpret the prominent lesions seen in the post-mortem examination of ———, who died, aged 23, of chronic dysentery, and was dissected on January 6, 1865. The points to be attended to in your accounts are as follows:—(1.) What were the anatomical signs in the small intestine which pointed to the nature of the common continued fever which he was said to have had in Hong Kong? State the name of the common continued fever it is probable he had.

(2.) What were the conditions of the colon and rectum; (3.) Of the liver; and (4.) Of the lungs?

B.—Practical Examination.

I. and II. Examination, historical account, statement of diagnosis, prognosis, effects of proposed treatment, etc., of one Surgical and one Medical case.

III. Hygiene.

Examination of various specimens of water for chlor. sod., for organic matter, and for total hardness.

Examination and analysis of specimens of milk and of beer.

Microscopic examination of samples of coffee and flour.

IV. Pathology.

Demonstration of the urinary tubuli and cortical portion of a microscopic preparation of a kidney.

Descriptions of various preparations of Morbid Anatomy.

Examination of secretions.

MEDICAL NEWS.

Apothecaries' Hall. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, March 23, 1865:—

James Vince Worthington, Ulverstone, Lancashire; Thomas Griffiths Merthyr Tydfil; Griffith Griffith, Edeyrn, Pwllheli, N. Wales; George Hunt Orton, Narborough Hall, Leicestershire.

The following gentlemen, also on the same day, passed their first Examination:—

William Henry Ellis, John Quick, and William Barnett Burn, St. Bartholomew's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Armstrong, Alexander, M.D., R.N., Deputy-Inspector-General of Hospitals, has been appointed to Haslar Hospital.

Blasson, William, M.R.C.S. Eng., has been appointed Medical Officer for the Redhill Workhouse of the Hendon Union.

Duckworth, Dyce, M.D., Edin., has been elected Assistant-Physician to the Royal General Dispensary, Bartholomew-close.

Ensor, A., M.R.C.S. Eng., has been elected House-Surgeon and Secretary to the Dorset County Hospital, Dorchester.

Forbes, D. M., M.D., has been appointed House-Surgeon to the Leith Hospital and Dispensary.

Jones, Robert, M.R.C.S. Eng., has been appointed Surgeon-in-Ordinary to the Chorlton-upon-Medlock Dispensary, Manchester.

Lyle, Thomas, L.R.C.P. Lond., has been appointed Medical Superintendent of St. Thomas's Hospital, Exeter.

Mahon, George A. D., M.R.C.S. Eng., has been appointed Resident Registrar to St. Mary's Hospital.

Muscroft, Henry, L.R.C.P. Lond., has been appointed Medical Officer for the Union Workhouse, Pontefract, Yorkshire.

DEATHS.

Brown, Robert, M.D. St. And., at Strood, near Rochester, Kent, on March 25, aged 84. He was a Staff-Surgeon in the Army, and Medical Superintendent of Quarantine at Standgate Creek. His full-pay service extended over sixty-two years.

Bullen, Robert, Surgeon, at Bampton, Oxfordshire, on March 12, aged 84.

Foster, Joseph, Surgeon, in London, on March 23, aged 63, late of Heywood, Lancashire.

James, William Withall, F.R.C.S. Eng., at Exmouth, on March 17, aged 41, Surgeon to the Devon and Exeter Hospital.

Jencken, Dr. Ferdinand I., at 11, Royal-terrace, Kingstown, Dublin, on March 22, aged 79.

Kennedy, George A., M.D., Dub., at Mountjoy-place, Dublin, on March 24, aged 73.

Lockhead, James L., M.D. Glasg., at Regent-street, Greenock, on March 17.

Lord, James, M.R.C.S. Eng., at Fleetwood, Lancashire, on March 16, aged 45.

Maxwell, Robert G., L.F.P.S. Glasg., at Killbourne-place, Millport, Islo of Cumbræ, on March 19.

Morrison, Charles H., M.R.C.S. Eng., at Rockcastle Mills, Dunmanway, Co. Cork, on March 14.

Murphy, Dr. John, at Holles-street, Dublin, on March 13.

Ribton, G., M.D., at Tivoli-place, Kingstown, Dublin, on March 17.

Simpson, T., M.D., at Old Calabar, Western Africa, on January 4, formerly of Kilbirnie, Ayrshire.

Willey, Thomas, M.R.C.S. Eng., at Littlethorpe, Leicestershire, on March 10, aged 44.

Chemists and Druggists.—Sir John Shelley's Bill, now before Parliament, proposes to commit the examination and registration of this class of persons to a council of chemists and druggists, elected from the general body, with power to appoint local examiners.

Medical Knighthoods.— The *Gazette* of Tuesday announces that the Director-General of the Army Medical Department, Dr. Gibson, C.B., and Inspector-General of Hospitals, Dr. Lenton, C.B., have been appointed Ordinary Members of the Military Division of the Second Class, or Knights Commanders of the Most Honourable Order of the Bath.

Medical Benevolent Fund.—At a meeting of the committee, held in New Burlington-street, on Tuesday, the 28th inst., the Treasurer, Mr. Toynbee, made the gratifying announcement that he had received from the executors of the late Mr. Hine, of Budleigh Salterton, the munificent sum of £2635, being the amount realised from the testator's residuary estate, in addition to £3000 previously paid to the Society. The committee decided at once to elect five additional annuitants.

The Alleged Cases of Poisoning in Glasgow.—The Glasgow authorities have received communications from Professor Maclagan, of Edinburgh, giving the result of the chemical analysis. Antimony has been abundantly found in the liver, spleen, intestines, and blood of the late Mrs. Pritchard. The quantitative analysis is not yet completed. A warrant has been issued for the examination of the body of the late Mrs. Taylor. That lady, it may be remembered, died suddenly in the house of Dr. Pritchard about three weeks before the death of her daughter, Mrs. Pritchard. She had, it is alleged, been in the habit of using a preparation of opium; but there are some suspicious circumstances connected with her death. The Medical man who was called in, and who only saw her *in articulo mortis*, declined, when applied to by the district registrar, to give a certificate, and at the same time intimated his opinion that the death was mysterious. Under these circumstances Dr. Pritchard himself certified the death as having taken place after twelve hours of paralysis and one hour of apoplexy, whereas it is alleged that the lady died after only four hours' illness. With regard to the death of Mrs. Pritchard, it is stated that the servants of the house were made sick and ill by eating the remains of certain articles of food which had been administered to her. There was, however, no intelligible motive for foul play on Dr. Pritchard's part.

Never too Late to Mend.—At a late meeting the Board of the Carlisle Workhouse increased the salary of Mr. C. S. Hall, the non-resident Medical officer, from £49 to £100 per annum. The former sum was made up of £40 salary and midwifery fees, which during the past year had amounted to £9. For this Mr. Hall had seen, prescribed, and supplied medicines for from sixty to eighty patients a day, and there was abundant evidence that he had done it with the most praiseworthy and conscientious attention. That such a state of things could exist for a whole twelvemonth in Carlisle is sufficient disgrace to the parochial authorities; but we are glad to add that the Board showed themselves fully alive to their position and anxious to escape from it—which they did by voting Mr. Hall the increased salary above stated.

The Treasurer of Guy's Hospital held a *conversazione* on the evening of the 28th instant, at which a large number of persons eminent in the literary and scientific world were present. Among the distinguished visitors were the President of the Hospital, Sir Lawrence Peel, the Earl of Harrowby, Lord Sandon, Lord Kirkaldie, Sir William Page Wood, Archdeacon Hale, and many of the Governors and Medical officers of the Hospital. Several of the large rooms in the new wing were thrown open and filled with numerous and well-selected objects of interest. The magnesium light was shown at intervals at different parts of the room; and a photograph of the Assembly was taken by its assistance in the course of the evening. A large collection of microscopes and scientific instruments were exhibited by Messrs. Smith and Beck, Casella, Highly, How, Browning, Marratt and Short, Novra, Baker, Horne and Thornwaite, Powell and Lealand. Some magnificent jewellery, and the well-known original piping bullfinch, now 200 years old, were sent by Mr. Emanuel, and some splendid electroplate by Elkington. One room was filled with the celebrated anatomical models made for the Hospital by Mr. Towne. A large number of most brilliant electrical experiments were shown by Mr. Atkinson, and also by Mr. Browning. The photomicrographs of Dr. Maddox were exhibited on a screen by Mr. How, and the process of photomicrography by the magnesium light was practically illustrated. On the walls were some splendid horns, antlers, and stuffed animals, exhibited by Mr. Leadbeater and Mr.

Sowerby, and many pictures and some beautiful photographs by Mr. Francis Bedford. About 1500 persons were present, including many ladies and most of the students, altogether the *soirée* was a most interesting one, and went off with the greatest *éclat*.

A MYSTERIOUS affair, which recalls to mind both the execution of Dr. La Pommeraye and the trial of Trumpy-Demme at Berne, at present occupies the attention of all the inhabitants of a small town in Normandy. A Physician is said to have committed a triple murder. The Doctor is accused of having murdered the husband of a young woman of whom he was passionately fond. He is said further to have insured the life of his own wife for a large sum and then poisoned her. An unfortunate young woman is said to be the third victim, likewise poisoned in consequence of having several times drunk potions intended for her master. It appears that the grave had scarcely closed on the three victims when the Doctor and his accomplice caused their banns to be published, and suspicions having been roused by their marriage, the judicial authorities caused an inquiry to be instituted, which it is believed will bring the accused to trial. —*Times' Paris Correspondent, March* 27.

PROSECUTION UNDER THE HEALTH OF TOWNS ACT.—On March 24, at the Thames Police-office, Mr. Charles Owen, a junior partner in the firm of Owen and Mertens, of the chemical manufactory on the west side of the West Ferry-road, Millwall, appeared before Mr. Partridge, to answer the complaint of Mr. E. Fulcher, sanitary inspector of the Poplar Board of Works, who charged them with a nuisance in the manufacture of sulphate of ammonia. Mr. S. K. Ellison, Medical officer of health for the south district, Poplar, made an inspection of Owen and Mertens' works on the 11th of February last. During the process of manufacturing sulphate of ammonia large volumes of sulphuretted hydrogen gas were given off from the evaporating tanks and were diffused into the surrounding atmosphere, causing a nuisance injurious to the health of the inhabitants of the neighbourhood. The best practicable means to prevent the escape of sulphuretted hydrogen were not adopted. Mr. Ellison then produced test papers of a dirty brown hue, and which were originally quite white, and said the discoloration was caused by the sulphuretted hydrogen. He applied the papers to the outside of the covered tanks containing the noxious liquors. The discoloration of the papers was instantaneous. The effect on the constitutions of the people in the locality was very prejudicial. The neighbourhood would be affected by the nuisance to the extent of 200 or 300 yards. On the 1st of the present month he made another survey of the premises. Sulphuretted hydrogen was escaping from the tanks in a similar way while he was walking round the building. The test papers were again applied, and discoloured as before. The paper was discoloured twelve or fourteen yards from the saturating boxes. A joint report by Dr. Letheby and Mr. Ellison was read, which detailed the process of manufacturing sulphate of ammonia, and described the mode in which offensive gases were produced. Evidence was given that the sulphuretted hydrogen evolved had injured property in the neighbourhood, and had produced an injurious effect on the health of individuals. Mr. Partridge convicted the defendant, and inflicted the full penalty of £5, with £2 4s. for costs.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Dr. Pavy's Lecture is in type, and will appear in our next number.

M.R.C.S., Eng.—He certainly has no heraldic right to use them.

Old Kilpatrick.—We cannot decide on the relative merits of Operating Surgeons. Any Loudon Hospital Surgeon is competent to perform such an operation.

Nothing New under the Sun.—The admiuistration of lead in aneurism is a very old remedy, and many cases are on record of its efficacy.

E.B.—Parents must be firm, and must insist on at least two meals of meat daily, and should offer to pay for it. There really ought to be an association for distributing Mr. Erasmus Wilson's admirable pamphlet ou Food amongst schoolmistresses aud mothers of families.

M. D.—1. We do not know whether M. D., in his question as to the Erlangen degree, means 1846 or 1864, as he first writes the former, aud then the latter year. What we know is, that in 1864, and for several years back, that degree has not been given without examination. 2. We do not think that the Apothecaries' Company could legally interfere with one of its Licentiates so practising.

The Dirty Quacks.—We know that the proceedings of these persons are under the consideration of eminent legal M.P.s; but the difficulty of checking them is in proportion to the audacity of their present movements. We have heard that a copy of an obscene pamphlet was lately sent to every house in Erith. But this is a matter which affects all society, not the Medical Profession only. If "A Lawyer" is aggrieved, will he tell us whether the existing law affords a remedy?

Dr. Messenger Monsey.—In the memoirs of this eccentric Physician, it is stated that he often, and strenuously, recommended the opening the bodies of patients who had died of remarkable complaints —a conduct for which he had been grossly abused by the ignorant. He had, therefore, always determined to convince his enemies that what he had so frequently advised for his patients he was very willing to have performed on himself. In verification of this, a letter is preserved in the library of the Royal College of Surgeons, of which the following is a copy, as well as the bad writing and mutilated condition of the letter will allow, viz. :—"Ch(elsea) College, May 12, 87. —Dear Sir,—Mr. Foster, a Surgeon in Union-court, ———, has been so good as to promise to open my carcass and see what is the matter with my Heart, Arteries, etc., and Kidnies, etc. He is gone to Norwich, and may not return before ———. Will you be so good as to let me send it to you, or if he comes will you like to be present at the Dissection? Nichols told me seven years ago there was no mischief in the Breast, Aorta, etc., besides I make and have made blody (*sic*) uryne. Would you be so good as to let me see you to-morrow between 11 and 1, or 2, or any day. I am now very ill, and hardly see to scrawl this and feel as if I should live two days, the sooner the better.—I am tho' unknown to you, your respectful humble Servant, MESSR. MONSEY."

Fossil Remains of the Elephant of Malta.—The explorations of Dr. Adams among the cave deposits and alluvial soil of these islands have been lately crowned with such signal success that we think the public would be glad to be made acquainted with the leading facts. It will be remembered that Captain Spratt, the indefatigable and learned hydrographer of the Mediterranean, was the first to bring to light the remains of the remarkable fossil elephant of Malta (*elephas melitensis*) by his explorations in the Zebbug Cave, in 1859. Since that time Dr. Adams has been unremitting in his exertions to discover more traces of this extinct species, and has been fortunate enough to find them in many new localities in Malta. He has just met with its teeth in great quantities in a cavern near Crendi. In another gap, evidently at one time the bed of a torrent, he has found the teeth and bones of thirty more individuals. These skeletons of old and young elephants are met with jammed between large blocks of stone in a way that clearly shows that the carcases must have been hurled into their present situation by violent floods or freshes. He has now brought together almost the complete skeleton of this wonderful little representative of an order of quadrupeds, to which we had, until the fossil Maltese elephant appeared, applied the word gigantic. There can be no doubt, however, that it scarcely exceeded a small pony in height. We hope that Dr. Adams will give a detailed account of his highly interesting discoveries to the scientific world.—*Malta Times*, March 16.

Erratum.—In the list of Medical men at Her Majesty's levée given in our last number, p. 313, *for* and Thomas Watson Lavies, *read* Thomas Watson and Lavies.

GRIFFIN TESTIMONIAL FUND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The following subscriptions have been further received on behalf of the above fund:—C. Spurgin, Esq., Stratford St. Mary, 10s. R. Sleman, Esq., Tavistock, 5s.; H. T. Wood, Esq., do., 5s.; J. Pearse, Esq., do., 5s.; W. C. Northey, Esq., do., 5s.; R. Willis, Esq., do., 5s.; J. G. Doidge, Esq., do., 5s.; J. H. Willis, Esq., do., 5s., per R. Sleman, Esq., Tavistock. From Lower Norwood, 5s. Amount previously announced, £118 16s. Received at "Lancet" Office, £7 17s. 6d. I am, &c.,

ROBERT FOWLER, M.D., Treasurer and Hon. Sec.

145, Bishopsgate-street Without, March 29, 1865.

WINE QUERIES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Permit me to reply to one correspondent, that if the Voeslauer wines made the circuit of the globe in the *Novara* frigate, their stability could have no better test. I have tasted samples of 1862 and 1863 wine, and both appeared to me firm and likely to keep.

I have no knowledge of any unnatural colouration of the face produced by Bordeaux wine. Red noses may be tinted by acidity, but I suppose that is quite a different thing. Neither have I any knowledge that such wine is adulterated by iron. I should be glad to learn any facts from your correspondents. I am, &c.

THE AUTHOR OF THE REPORTS ON WINE.

SOUTH AMERICAN BEEF.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Amidst the somewhat angry discussion now being carried on concerning the merits or demerits of the South American beef, I am pleased to see you have taken up the subject on its real merits. If it be a meat fit for food, and acceptable generally, it will be sure to have a large sale here; if, on the other hand, it be found unpalatable or injurious to health, all the pushing and puffing of interested parties will not avail. While you, sir, ask for the testimony of Medical men all over the country as to its acceptability with the labouring classes, would it not be as well to inquire if any results have come under their notice touching upon its effect on the health of the recipients; for example, the fat in most specimens I have seen has certainly undergone some change towards the formation of those fatty acids which are known to be prejudicial. Have any of your readers seen cases of diarrhœa, vomiting, fever, clearly adducible to, and caused by, the ingestion of the charqui food?

I am, &c. SPECTATOR.

Consanguinous Marriages.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I am sure "X.," like myself, was pleased to see the letter of "T. J." in your journal of to-day. Like him, my interest was excited on this subject by the disturbance caused in the family by my sister marrying her first cousin; and as the union entirely took place through my backing her through "thick and thin," I resolved to try and work out this problem, and ascertain if the popular prejudices are well or ill founded.

"T. J." brings to bear on his inquiries what I cannot—viz, the experience of a number of years and observations on the lower animals; these latter are of course impossible to those living in a city. I drew my rough conclusions that these marriages were not hurtful or injurious—

1st. Because all the evils attendant on these unions are just as liable to be attendant on mixed marriages; of which I have seen ample proofs.

2nd. I know of no instance where the children of cousins show any taint differing in degree or intensity from the offspring of mixed parents.

3rd. A mixture of bad bloods between strangers is as productive of as much evil as if the parties were related.

4th. That the prejudice against these unions has resulted more from theory than actual facts, or facts viewed from one side only.

5th. That in these inquiries, if you find anything to put into one scale, you are sure to find something to put into the other.

"T. J." says there is some truth in all the propositions he was educated in; but cannot these apply to ill-assorted unions of any kind? He says, also, that he never saw a single cousin couple who have a healthy set of children. I can point to such a couple, who have produced nine healthy children, all grown up except one, who died of fever about the age of 18. They are a remarkably handsome family; their mother was one of a family of six healthy children, also the offspring of first cousins. This may be an exceptional case; but I have no doubt there are plenty more like it.

Lastly, in conclusion, "T. J." puts his moral in few and simple words, quite to the point. It is what I have always felt myself, and which I feel every one must who has thought on the subject; or I may go a little further, and quote the words of Dr. Child, from his paper read before the British Association in 1862:—"If there be vigour and health, and no taint of blood, the offspring of parents however nearly allied need not be degenerate." But the above moral would be good advice for all proposed unions; therefore I think I may repeat my former words, that "these marriages are not hurtful or injurious."

I am, &c.

A. R.

March 25, 1865.

On Catarrh.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Both patient and Physician seem to have an understanding that little or nothing should be done for the relief of this complaint; for whilst the former dismisses it with the remark, "It is only a cold," the latter seldom attempts to interfere with its progress. Such indifference is, perhaps, owing to the difficulty of cutting it short even more than to its usually happy prognosis. But as catarrh often leads to bronchitis, and not unfrequently hastens the symptoms of phthisis in cases otherwise hopeful, surely it deserves more attention than has hitherto been given to it. There are, moreover, many persons who suffer much from an uncomplicated attack of the disorder. I refer to those who, with well-developed frontal sinuses, have an unusually large surface of mucous membrane for its location. In such patients, especially if they be of the sanguine temperament, the febrile symptoms are often severe; the excessive headache, and the discharge from so great an extent of membrane, produce a wretchedness which no one can understand who has not suffered from the complaint in this exaggerated form. Such has been my misfortune very frequently, and I attribute the severity of the attacks to my having a well-developed frontal region. By the way, I may remark how much freer I am from them during those winters which follow a sojourn at the sea-side.

My own experience has taught me that the treatment of our text-books is of no value whatever: but more than once Nature has effected a speedy cure for me by a kindly bleeding from the nose. Believing the hint to be a good one, I have, on two occasions since then, applied a leech within the nares, and each time with perfect success; but in the last attack I found it necessary to employ two leeches. When the dryness of the first stage, and the flow of mucus of the second, are confined to one nostril, the symptoms are less severe than when both nasal passages are affected. My plan has therefore been to leech only one or both nostrils, according to the extent of the disorder. The wounds generally bleed very freely; it is, therefore, well not to allow the leeches to travel too high up the nostrils, and by means of a glass they are perfectly under control. On one occasion I was called from home soon after the leech had dropped off, and, in spite of all the means I could think of, one of the bites bled for five hours; this arose, however, from the effort of walking, and from the leech having bitten too high within the nares. When the leeches first take hold, they cause a great disposition to sneeze,—an effort which would at once dislodge them unless they were properly supported during its occurrence. If they be applied during the first stage of the complaint, they seem to stop it at once and completely; but when the second stage has become well established the relief is neither so signal nor so prompt; still, however, the discharge is reduced to a minimum, and it takes the bland form of thickened mucus or muco-pus. In both cases the constitutional symptoms scarcely survive the flow of blood.

Whilst recommending a remedy which I consider almost specific and of great value, I must not omit to mention the difficulty which will arise in many cases from the patient's dislike to its adoption. I have, however, met with some who thankfully employ it. Two cases I remember at this moment:—A woman had suffered from chronic nasal catarrh for some time, which yielded at once to a single leech and a few doses of quinine. Another one had long-continued headache following coryza, though the discharge had left; and nothing relieved her until a leech was placed within the nostril.

But of all persons none have so much reason to dread an attack of catarrh as tuberculised patients; and if the peril attending its continuance were properly explained, perhaps none of them would object to the remedy. Still, I must own that to discover a less objectionable and equally good place for the application of the leech would be much better; and I think it very probable that the old-fashioned plan of local bleeding just within the lower lip may possess both recommendations.

I am, &c.

Collingham, March 14. Alpha.

APPOINTMENTS FOR THE WEEK.

April 1. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m. Royal Free Hospital, 1½ p.m.

3. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

Medical Society of London, 8½ p.m. Mr. Walter J. Coulson, "On Lithotrity." Dr. E. Day, "On Menstruation during Pregnancy."

4. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

Anthropological Society of London, 8 p.m. Meeting.

Pathological Society, 8 p.m. Meeting.

5. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

Hunterian Society (Council, 7½ p.m.), 8 p.m. Mr. Hutchinson, "The Medical Aspects of Constitutional Syphilis."

Obstetrical Society of London (Council, 7 p.m.), 8 p.m. Dr. Meadows, "Case of Monstrosity." Mr. Freeman, "Extra-uterine Fœtation." And other Papers.

6. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Harveian Society of London, 8 p.m. Dr. Camps, "In what Class of Cases and under what Circumstances may we reasonably hope for Cure in Epilepsy?"

7. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

Western Medical and Surgical Society, 8 p.m. Practical Evening, for the Narration of Cases and the Exhibition of Specimens.

ORIGINAL LECTURES.

ON THE ASSIMILATION OF SUGAR BY THE LIVER.

FROM

THE LECTURES ON PHYSIOLOGY,

DELIVERED AT

Guy's Hospital.

By F. W. PAVY, M.D., F.R.S.,
Assistant-Physician to the Hospital.

I PROPOSE to-day, gentlemen, to direct your attention to an investigation of the bearings of sugar in connection with animal life. As you are doubtless aware, this is a matter to which I have devoted a considerable amount of attention. For many years I have been closely studying the subject, and my experimental results have forced me to entertain conclusions adverse to those which prevailed when I originally started out. I must begin at the commencement, and first of all make you acquainted with the tenets of the doctrine of animal glycogenesis. I will then place before you my own views; show you the experimental results upon which they are based; and afterwards criticise the objections that have been raised to them.

In 1848 Bernard, of Paris, came down in an unexpected manner upon the discovery that sugar could be produced by the animal system, for he had recognised it in the blood, although it had been excluded from the food. In the course of a series of experiments to ascertain what became of sugar when ingested with the food, Bernard traced it from the alimentary canal into the portal system, and through the liver to the right side of the heart, but no further. It therefore seemed that the sugar consumed with the food underwent destruction in the lungs. It was necessary, however, Bernard thought, to make a counterproof experiment, and see that no sugar was contained in the blood of the right side of the heart when it had been excluded from the food. For this he operated on a dog that had been restricted for some time to animal food, and to his surprise still found sugar in the contents of the right heart. Thus was laid the foundation of the doctrine of animal glycogenesis. Previously the production of sugar had been regarded as a phenomenon, occurring only in the vegetable world; but now it became evident that such a limitation could no longer be upheld.

Continuing his experiments, Bernard came to the conclusion that the sugar he had met with in the blood, when sugar had been excluded from the diet, was derived from the liver. He now gave to the liver a glycogenic or sugar-forming function, and stated, in support of his view, that with an animal restricted to a purely animal diet, the blood going to the liver was to be found free from sugar, whilst that flowing from it was highly charged with sugar, and that the liver itself, differently to all other organs of the body, was strongly charged with the saccharine principle. The evidence advanced seemed so conclusive and simple, and, moreover, was so easy of corroboration by others, that the glycogenic function of the liver soon became looked upon as having an established existence. It was admitted into our text-books, and became engrafted, indeed, upon us as one of those truths which we accept without pausing for an instant to raise a doubt about. The amount of sugar said to exist in the blood of the hepatic veins was about 1 per cent. during fasting, and 1½ or even 2 per cent. at a period of full digestion; whilst the mean amount of sugar in the liver was put down at from 1½ to 2 per cent. The process of sugar-formation, therefore, appeared to be carried on upon a large scale, and to constitute a function of importance in the economy of animal life.

As the blood removed from the arterial system gave signs of being charged with scarcely any sugar, the lungs were supposed to form the seat of its destruction in the system.

After returning to England from studying under Bernard in Paris, I commenced a series of experiments with the view of ascertaining the precise conditions required for this supposed destruction of sugar in the lungs. I injected fibrinated and defibrinated blood through the capillaries of artificially inflated dead lungs, and I thought I discovered that in the fibrinated blood a disappearance of sugar had taken place. I was working under the notion, which prevailed then, that the contents of the right heart were naturally charged with a considerable amount of sugar. It was not known but that the condition of the blood collected in an ordinary way after death formed a representation of its natural state. For my experiments with the defibrinated blood, in order to have it in a fluid state, I was obliged to be very expeditious in collecting it from the heart after death had been produced. I injected my syringeful through the prepared lungs, and, examining what had flowed, found that it contained scarcely any sugar—no more than was to be met with in ordinary arterial blood. I did not give it a thought but what I had been operating upon strongly saccharine blood; and I thought this sufficiently proved by finding that the blood I obtained afterwards from the animal gave the ordinary strong reaction of sugar that had been looked upon as naturally belonging to right-ventricular blood. I therefore concluded that in blood containing fibrine, or in the condition belonging to life, sugar underwent destruction on being injected through the capillaries of the artificially-inflated dead lungs; and that the presence of fibrine was a necessary condition for this, for my specimens of defibrinated blood (these having been collected from the ventricle without any particular haste) showed signs of strong impregnation with sugar after injection through the lungs.

A further prosecution of my researches taught me that the conclusion I had arrived at was erroneous, and that the error resulted from my having taken the blood procured from the right ventricle instantly after death to be saccharine, like that collected a little later. It was at the very onset of my career that this erroneous conclusion was arrived at, and when I was under the firm conviction, in accordance with what I had been taught, that the blood of the right side of the heart was naturally strongly charged with sugar, in conformity with the doctrines laid down under the glycogenic theory.

I was still making some experiments on the presumed destruction of sugar in the lungs, and was collecting blood for injection, by means of a catheter, from the right ventricle during life, when I discovered that the ante-mortem and post-mortem states did not coincide. For the glycogenic theory the state of the blood on the right side of the heart had been judged of from an examination of that which was collected from it in an ordinary manner after death. Now, under such circumstances there is a copious orange-yellow or orange-red precipitate thrown down on boiling the prepared liquid with the copper test; and the amount of sugar in five analyses that I made showed itself to the extent of from 5-10ths to 94-100ths of a grain per cent. From these animals blood had been removed by catheterism from the right ventricle just previously during life, and gave only the merest trace of saccharine reaction—no more than was recognised as belonging to the contents of the arterial system. Subsequently, in a quantitative determination of three specimens of blood removed by a catheter from the right heart during life, I obtained respectively 47-1000ths, 58-1000ths, and 73-1000ths of a grain per cent. as an expression of the amount of sugar present.

By expeditiously opening the chest of an animal instantly after death, and collecting the contents of the right ventricle, I obtained the same behaviour as regards sugar as with the blood removed during life; while that which flowed later gave evidence of strong impregnation with sugar.

It thus became evident that it was erroneous to take the saccharine state, in which the blood removed from the right heart in an ordinary way after death is found, as a representation of its natural condition. The blood of the right side of the heart, as far as I can discover, is not appreciably more saccharine, under physiological circumstances, than that of the arterial and general venous systems; and even the blood of the portal vein agrees with it. In experiments on three successive dogs in which I carefully compared right ventricular with portal blood, I could recognise no difference of behaviour with the copper test between the two. In preparing for testing, the specimens had been scrupulously treated precisely alike.

Violent muscular efforts and interference with the breathing determine a considerable increase in the amount of sugar in the circulation, so that to obtain a representation of the natural state, natural circumstances must prevail when the blood is collected. Simply through interfering with the breathing, and thereby producing congestion of the blood-vessels, I have occasioned such an appearance of sugar in the circulation as to render the urine strongly saccharine in the course of an hour.

In order, gentlemen, that you may have an opportunity of actually seeing for yourselves if what I have been telling you with regard to the blood is correct, I will test the liquids before me, which came from an experiment I conducted for

the purpose two days ago. Mr. Salzmann, a pupil amongst you, who has been assiduously assisting me for some time past in my laboratory, was present, and helped me with the experiments, and will be able to check me if I am incorrect in the account I am about to give you of the steps that were adopted.

A good strong dog was taken, and the jugular vein on the right side cut down upon. A ligature being placed upon it, about a couple of ounces of blood were collected from it, and stirred to defibrinate. A suitable shaped catheter was then passed down the jugular and superior cava into the right ventricle of the heart. There was no difficulty in seeing by the movement given to the instrument that it was properly in the ventricle, but to remove any possibility of doubt on this point the catheter was ligatured in the vein after the withdrawal of about two ounces of blood had been effected, and its position was verified by examination after death. The right-ventricular blood was stirred to defibrinate like the other. Next, the life of the animal was destroyed by pithing, and, making an incision through the right side of the abdomen, a ligature was placed around the portal vein. Blood was collected from this vessel below the ligature, and, like the other specimens, stirred to defibrinate. Lastly, blood was collected from the inferior cava above the entrance of the hepatic veins, and likewise defibrinated.

The same quantity of each specimen of blood was now taken and treated with the same amount of crystals of sulphate of soda, and heated and filtered. The sulphate of soda causes the precipitation of all the colouring and albuminous matters of the blood; and, as you observe, we get a liquid as colourless and limpid as water to test.

Let us place equal quantities of these specimens into test-tubes, and treat them with the same amount of our copper liquid respectively. The specimen derived from the inferior cava blood collected after death gives, upon boiling, an orange-red reduction. The quantity of sugar present is so large that the whole of the copper is thrown down in the form of sub-oxide. The other three specimens behave, as you perceive, as near as possible alike. It may appear to those at a distance that there is no reaction at all, but I can see that some amount of reduction has occurred,—that there are particles of sub-oxide suspended through the contents of the test-tube, giving what I describe as a shot-silk appearance. On comparing them together, it is true there is just a shade of difference to be discerned between the behaviour of the specimen derived from the jugular and the other two. The jugular blood shows signs of being in a trifling degree more saccharine than the right ventricular and the portal. This is contrary to what would be looked for; but I consider it to be accounted for by the efforts of resistance that were experienced during the exposure of the jugular vein for the withdrawal of its blood.

After discovering the fallacy of taking the condition of the blood, collected in an ordinary manner, from the right ventricle after death, as a representation of its natural or physiological state, I still regarded the liver in the same light as before. It did not at first occur to me that a similar fallacy might exist here; and I undertook some experiments on injecting blood through the liver at different pressures with the view of finding out why such an escape of sugar took place from the organ after death, and not during life. Failing to meet with anything satisfactory, I began to think that possibly the liver, like the blood flowing from it, might not be in the saccharine state during life as had been inferred from previously-conducted post-mortem examinations. Without the slightest anticipation of finding this to be true, I started out upon experiments directed towards displaying the condition of the liver actually existing during life.

I knew that the liver contained a substance which enjoyed the property of being exceedingly susceptible of undergoing transformation into sugar. This substance was discovered by Bernard, and called by him glycogenic matter on account of its being presumed to form the source of the sugar produced under his glycogenic theory. I shall speak of it to you under the name of amyloid substance—a name which has the advantage of implying nothing as regards its destination. There is this misfortune, however, that amyloid matter is a name also given to a totally different material, a product of disease, which seems to contain nitrogen, and to have no real claim to the title. You must not, therefore, confuse the two together. The amyloid substance of physiology is composed of carbon, hydrogen, and oxygen, united, according to Pelouze, in the proportion of $C_{12}H_{12}O_{12}$. You see it here in the form of an amorphous white powder, and it cannot be obtained in a crystalline form.

Its solution in water is lactescent. With iodine it behaves like dextrine, and produces a deep wine-red coloration. Alcohol throws it down as a dense white precipitate from its aqueous solution, and it is also precipitable by glacial acetic acid. In contact with saliva, pancreatic juice, blood, etc., it undergoes, like starch and dextrine, metamorphosis into sugar. I will treat some of this solution of amyloid substance with saliva and apply gentle warmth; and it is astonishing, as you perceive, the rapidity with which the change is effected; for I can see now, at the end of not very many seconds, from the loss of lactescence, that transformation into sugar has taken place. The amyloid substance gives no reaction with the blue liquid, but with the contents of our test tube we get a copious reduction, showing that sugar in reality has been produced.

I say, I knew that this substance, so susceptible of transformation into sugar in contact with a ferment, existed in the liver, and that a ferment existed there also, for it had been shown that a liver deprived of its sugar by passing a stream of water through its vessels would soon become re-charged with sugar. I, therefore, looked out for an agent that would hold the transformation in check without exerting a destructive influence upon the materials concerned. Seeing that potash answered the purpose, I first tried the effect of injecting the liver from the portal vein instantly after death with a solution of this agent; and, to my astonishment, for I had by no means anticipated anything from the experiment, failed to recognise the ordinary presence of sugar. By afterwards injecting only a portion of a liver, I proved I was dealing with an organ susceptible of becoming saccharine on being left alone; and by injecting a liver that had been allowed to remain for a short time after death, and finding abundance of sugar, I satisfied myself that the result was not attributable to a destruction of sugar having been effected by the potash.

Acids, like alkalies, check the action of ferments upon the amyloid substance; and I afterwards found that the injection of a strong solution of citric acid into the liver produced the same result as the injection of potash.

I discard now the employment of these chemical agents for displaying the condition of the liver actually existing during life. Seeing how processes of the nature of fermentation are influenced by temperature, I looked to the effect of a sudden alteration of the temperature of the liver at the instant of death, and found that it supplied me with the same information as that afforded by injection. By plunging a piece of liver into a freezing mixture at the instant of death post-mortem change is prevented and the condition belonging to life represented.

I do not ask you simply to listen to what I have to say, but shall give you the opportunity of seeing the result and judging for yourselves. Immediately before lecture I experimented upon this rabbit in the manner I will point out to you. By the process of pithing the life of the animal was in an instantaneous manner destroyed, and instantly afterwards the abdomen was laid open and a piece of the liver excised and plunged into a freezing mixture of ice and salt that had previously been got ready. It was necessary that the ice and salt should have been mixed a little time in order that its cooling influence might be at the utmost. In a few seconds, by stirring about, the liver had become frozen quite hard. It was then taken out, cut up into slices, reduced to a pulp in a mortar, and immersed, a small quantity at a time, into about three parts of an ounce of water kept boiling in a porcelain capsule all the while. You must bear in mind that in the frozen liver we have amyloid substance in contact with a ferment, and it is necessary in preparing a liquid for testing that no transformation should be allowed to occur during the process. This is the reason for treating the liver as I did. The ferment must be suddenly coagulated and destroyed. A gradual rise of temperature would give it the opportunity for a time to act, and sugar would be formed. The contents of the capsule were then thrown on to a filter, and this highly-milky liquid has run through. It is the presence of amyloid substance which constitutes the cause of the milkiness we here observe. The liver allowed to remain behind in the animal was next removed, and a portion of it pounded in a mortar and treated with water and boiled. The filtered liquid is likewise milky from the presence of amyloid substance, though not quite to the same extent as the other.

We have, then, before us two decoctions of the same rabbit's liver. The one has been derived from the specimen placed in a condition to prevent any post-mortem change taking place; the other, from a specimen with which no such precaution

was observed. You know as much about the actual condition of these liquids as I do myself; for I have not as yet tested either of them for sugar. I do not hesitate thus boldly to proceed; and I should not shrink—I have not shrunk at any time, or before any number of persons—from performing the whole of the experiment from beginning to end. It is only with the view of economising our time that I had these decoctions prepared before lecture. Let us place equal portions of the decoctions into test-tubes, and treat them respectively with an equal amount of our copper liquid. On boiling that derived from the liver taken in an ordinary manner after death, we instantly get a copious orange-yellow reduction. This is what was formerly supposed to represent the natural or physiological state of the organ. On boiling the other, however, you do not notice that any change is observable. We continue boiling, and still the contents of the test-tube retain their blue colour. I expect after a time that a trace of reaction will be apparent, but at present this is certainly not the case; and with some specimens of liver that I have thus tested there has been such an almost absolute freedom from sugar that at the end of half an hour's repose of the test-tube the amount of deposit of red oxide accumulated has only been just perceptible to the eye. Speaking of what ordinarily occurs, on looking at the first behaviour of the test, you would say there is no sugar; but giving it a prolonged attention, a traceable indication is to be discovered. Seeing what susceptibility the amyloid substance possesses of transformation into sugar, it is fairly presumable that even this traceable indication may be due to post-mortem metamorphosis. A few moments must elapse before the centre of the piece of liver is reached by the influence of the freezing mixture; and in making the decoction, the destruction of the ferment, although nearly, is not absolutely instantaneous.

I did not resort to it in this case; but plunging a piece of liver instantly after death into a quantity of boiling water has the same effect as submitting it to the influence of cold.

I think that what I have shown you is sufficiently convincing that the liver is not in the saccharine condition during life, like it used to be supposed before my experiments were instituted. I will now take into consideration and criticise the objections that have been raised to my experiments and conclusions.

(To be continued.)

ORIGINAL COMMUNICATIONS.

SIX CASES OF OVARIOTOMY IN PRIVATE PRACTICE.

By T. SPENCER WELLS, F.R.C.S.,
Surgeon to Her Majesty's Household and to the Samaritan Hospital.

(Continued from page 304.)

Case 4.—On January 24, 1865, an unmarried German lady, 19 years of age, came to me with an introduction from Professor Crédé, of Leipsic. She gave me the following history:—She was born at Roslau, on the Elbe. Her parents and all her blood relations were healthy. She had lived most of her life at Zerbat, in Anhalt Dessau, and had always enjoyed very good health up to the preceding May. She had first menstruated when 16, and was always rather irregular, there being often a somewhat profuse discharge of blood recurring at fourteen days' interval. In May, 1864, pain was felt all along the inside of the thigh, running down from the hip to the knee-joint. At first it was confined to the left thigh, but afterwards both sides were affected. Pain soon began to be felt on the left side of the abdomen very low down; the patient became alarmed, and consulted Hofrath Hemming, who in August, 1864, discovered a tumour as large as an infant's head in the right hypogastrium, and diagnosed encysted dropsy. The tumour rapidly increased in size, but the symptoms, instead of becoming aggravated, rather diminished in severity. The patient went to Leipsic to consult the well-known Professor Crédé, who confirmed Dr. Hemming's diagnosis, and on October 1, 1864, tapped, drawing off about eight pints of dark yellow thick fluid. The tumour soon regained its former size, and on January 13, 1865, Dr. Crédé tapped again. He made on this occasion two punctures, as by the first only a few drops of blood were to be obtained. By the second he evacuated about nine pounds of thin watery fluid. The patient on arrival in England was much emaciated, and very anæmic looking, her pale cheeks having almost a greenish hue. There was no œdema of the extremities. The digestive organs were in good order. There was a slight cough, and inconsiderable yellow expectoration. The base of the right lung was evidently compressed; but, with that exception, the respiratory organs seemed healthy. The patient slept best on the right side. Her pulse was 88, very feeble; the sounds of the heart were normal, but there was a distinct anæmic murmur over the vessels on each side of the neck. The girth at the umbilical level was $33\frac{1}{2}$ inches, the distance from the umbilicus to the ensiform cartilage 7 inches, to the symphisis pubis 9 inches, and to either ilium $8\frac{1}{2}$ inches. The abdomen was occupied by a partially fluctuating tumour, about the size of the gravid uterus at the eighth month; it extended rather higher on the left than on the right side. Its consistence was unequal; in some parts it evidently had fluid contents, while below and to the left of the umbilicus there was a hard, resisting lump, about the size of a cricket-ball. The abdominal parietes were normal; there was no tenderness, nor were there any dilated veins. The vagina was in every respect virginal; the uterus was central and small; the os uteri was normal and virginal. In front of the uterus the tumour was to be felt, but it appeared to be moveable. My diagnosis was, "multilocular ovarian cyst, adhering anteriorly; no important pelvic attachments." As there was a clear week before the approaching catamenial period, and the patient, in the prospect of marriage, was very desirous to avoid unnecessary delay, I performed ovariotomy on January 27, with the assistance of Dr. Dehn, of Hamburg, Dr. Bowen, Dr. Ritchie, and Dr. Wright. Dr. Parson gave chloroform. The incision was six inches long. There were extensive parietal adhesions anteriorly; they were somewhat vascular and firm, though they yielded readily to the hand. One large cyst was tapped and emptied. The tumour, including another large cyst, was then drawn through the wound, and a long strip of omentum was separated from the cyst. The pedicle was as thick as two fingers, was from three to four inches long, and sprang from the left side of the uterus. It was secured in the smallest size of clamp, and kept outside without producing any traction. There was no serious hæmorrhage. The right ovary appeared healthy. The wound was closed by five deep and two superficial sutures above the clamp and one superficial suture below it. The patient rallied very well. For the first few hours there was pain, which was relieved by opium. On the first day cramp in the right thigh and a tickling cough were rather troublesome. There was a good deal of sthenic reaction, and for the first four days little was given except cold water. On the third day I removed all the stitches except the one below the clamp. On the fifth day there was a strong animal smell in the urine, similar to that occasionally perceived in the axillæ of young women when they perspire freely. On the sixth day I removed the last stitch. After that time recovery was uninterrupted. On the thirteenth day the clamp came away. The patient gradually gained strength. She called on me on February 18, three weeks after operation; went out daily afterwards; left for Germany, *viâ* Antwerp, on February 23, twenty-four days after operation; and I have heard that she bore the journey perfectly well, and joined her family in excellent health. The cyst removed was a fat cyst, containing true skin, bone, hair, and other structures. I gave it to Dr. Ritchie, who has not yet finished its careful examination.

Case 5.—On January 21, 1865, a married lady, 54 years of age, called upon me with a letter from Dr. Evans, of Hertford. She had had seven children, the youngest of whom was 11 years old, and she had miscarried several times, the last abortion having been in 1856. She was rather pale; her appetite was good; she slept well; and her chest was healthy. The urine was free from albumen, but occasionally deposited lithates. There was some difficulty in passing water, and a frequent desire to pass it. The girth at the umbilical level was $48\frac{1}{2}$ inches; the distance from the umbilicus to the ensiform cartilage, $15\frac{1}{2}$ inches; to the pubic symphisis, 12 inches; to the right ilium, 14 inches; and to the left, 16 inches. The entire abdomen was filled by a tumour which rose as high as the sternum, and passed under the ribs on each side, although to a greater extent on the left than on the right. Fluctuation was very perceptible above the umbilical level; not so beneath it. The tumour swayed freely from side to side. The abdominal parietes were thick and œdematous. There were numerous lineæ albicantes. There was no crepitus nor tenderness. Since her last miscarriage the patient had never menstruated regularly. In the spring of 1863 a bloody discharge from the vagina was the sequence of a fall. It continued for

several weeks. It then ceased, but in August, 1863, reappeared, and had never afterwards completely ceased. The uterus was central, normal, and pretty freely moveable. The os was soft and the cervicle mucous membrane velvety. The vagina was normal, and the tumour could not be felt through it. The patient's family history was excellent. In 1849 a severe blow on the left groin during pregnancy was followed by adherent placenta. Ever since the year 1848 she had been becoming gradually fatter; but she had observed no disproportionate size of abdomen till the spring of 1863. After this, and simultaneously with the re-appearance of the uterine discharge, there was an increase in the size of the abdomen, although a bandage was constantly worn. In the spring of 1863 something hard was to be felt on the left side of the abdomen lower down. Dr. Evans saw her in August, 1863. In September, 1863, Dr. Farre thought that the enlargement was general only, and that there was a congested condition of the womb. He confirmed this in October, and again in November, 1863. In November, 1863, the patient began to suffer from nausea and dyspepsia, and her size lessened. There was no increase until September, 1864; from that time her girth increased steadily. On December 3, 1864, eleven quarts of a fluid having all the appearance of linseed tea were drawn off. Dr. Gream was present at the tapping and said that the womb was healthy. The vaginal discharge ceased immediately after the tapping, and did not reappear till December 18. Since that time the girth had steadily increased, and the discharge had been continuous. My diagnosis was:—"Multilocular cyst of left ovary; no adhesions, abdominal or pelvic, to make ovariotomy unusually hazardous." I performed ovariotomy at the patient's home, in Hertfordshire, on January 28, 1865, with the assistance of Dr. Evans, Dr. Drage (of Hatfield), and Mr. Webb (of Welwyn). Dr. Parson gave chloroform. The incision was begun one inch below the umbilicus, and extended downwards seven inches, through a very thick œdematous abdominal wall; but before I made it I emptied one large cyst by puncture two inches above the umbilicus with an ordinary trocar. At the first incision I opened the adherent cyst. I sponged it out, and, having with some difficulty found its edge, I separated its firm parietal adhesions, and detached it from a piece of omentum which adhered to it. One small patch of cyst-wall remained adherent near the umbilicus, and was carefully separated after the rest of the cyst had been cut away. The pedicle was of the thickness of two fingers, and from three to four inches from the left side of the uterus. It was compressed in a medium sized clamp, and was fixed outside without any traction. During the operation a good deal of bloody serum oozed from the parietes of the abdomen, but there was no hæmorrhage of consequence. The right ovary was healthy or atrophied. The wound was closed with six deep and two superficial sutures above the clamp, and one superficial suture below it. The peculiarities of the operation were—(1) the preliminary tapping, (2) the closeness of the parietal adhesions, (3) the œdema of the abdominal wall. The quantity of fluid removed at the operation was thirty-nine and a-half pints; the cyst-walls and cysts removed entire weighed seven pounds. There was so little pain after this operation that no opium was given. The pulse being rather low, a teaspoonful of brandy was given every hour. The uterine discharge continued till night, and then ceased. I left early on the day after operation, and I am indebted to Dr. Evans, to whose care the patient was left, for the notes of the after treatment and progress. During the first few days there was a good deal of flatulence, but from that the patient had been a sufferer for some years. Dr. Evans removed the stitches on the fifth day. On the eighth day the bowels were moved; there was a good deal of prostration afterwards, and a profuse discharge from the wound. The clamp came off in the evening. On the tenth day the bowels were again freely moved several times. There was a very free discharge from the wound, and stimulants were plentifully supplied. The discharge gradually ceased, and the patient recovered her strength; and I have received an excellent report of her recently.

Case 6.—On January 10, 1865, I met Mr. Wright, of Nottingham, in consultation on the case of a single lady, 27 years of age, the subject of ovarian disease. She came of a consumptive family, but she herself had, till lately, enjoyed good health. She began to menstruate at the age of 15, and the periods had habitually returned at the end of three weeks, and had lasted five days. Lately, the catamenia had appeared every fortnight. In the autumn of 1863 the patient had begun to lose flesh, and she noticed that her body was increasing in size. The earliest symptoms were indigestion and headache. In the spring of 1864, Mr. Wright found a tumour in the left iliac and right hypochondriac regions. This tumour had gradually got larger, the increase latterly having been very rapid. On January 6, 1865, Mr. Wright, having diagnosed ovarian dropsy, tapped, and drew off twenty pints of thick viscid fluid, like linseed tea. I found the patient (who was of a cheerful disposition) with a bronzed look, which seemed to depend upon the ovarian mischief, as no other disease could be detected. The tumour, which was evidently ovarian, reached several inches above the umbilicus. My diagnosis was, "Multilocular ovarian cyst, probably rather closely connected with the uterus." If she were left alone, I thought that the patient could not live two years, and Mr. Wright and I agreed that she should come up to town and have ovariotomy performed before another tapping became necessary. On January 29 Mr. Wright wrote:—"The cyst is filling rather rapidly. She has just got over her menstrual period. She has had sympathetic pains in the right foot, right shoulder, and right scapula. Two or three days in bed, with a dose of physic, have quite relieved her." The patient came to town on February 4. She was in excellent spirits, and it was resolved to operate on the 7th. Just before the operation the girth at the umbilical level was forty-four inches, the distance from the umbilicus to the ensiform cartilage thirteen inches, and to the pubie symphisis ten inches. The tumour filled the whole of the abdomen, reaching into the epigastrium and both hypochondria. Fluctuation was very distinct in it. Just above the pubes a pyriform nodosity could be felt, and was supposed to be the uterus. The abdominal parietes appeared rather thick. Neither lineæ albicantes nor dilated veins were seen. There were no crepitus nor tenderness to touch. The uterus was pushed a little forward, but was tolerably moveable; the tumour could be reached just in front of the cervix. At the operation I was assisted by the Messrs. Wright, senior and junior, of Nottingham, by Dr. Ritchie, and Dr. Wright. Dr. Parson gave chloroform. The incision was commenced an inch below the umbilicus, and continued downwards seven inches. Adhesions were very intimate all over the front and sides of the abdominal wall; there were no adhesions behind, nor to the omentum. I broke them down readily with my hand, tapped first a large cyst, and then a smaller one, and then having largely opened the chief cyst inserted my hand and broke down a number of smaller ones, and then withdrew the whole mass, including some semi-solid matter. The pedicle was very broad and short, its shortness depending not so much on the Fallopian tube as on the fold of broad ligament running to the left side of the brim of the pelvis. The pedicle was secured in a medium sized clamp. It was kept outside with considerable traction, depressing the flaccid abdominal wall almost to the sacrum, and keeping the left side of the uterus within an inch of the abdominal wall. There was no hæmorrhage of any consequence, but a little oozing from the torn adhesions led to the necessity of sponging out the pelvis. The right ovary was healthy. The wound was closed with one deep and one superficial silk suture below, and five deep and one superficial above the clamp. The patient rallied well. About an hour after operation one-fifth of a grain of morphia was injected under the skin. Within the next three hours there was a good deal of pain and of cramp, which was relieved by forty drops of laudanum; twenty being given by the mouth and twenty shortly afterwards by the rectum. At nine o'clock the patient was very well. A quart of clear urine had been drawn off. She was perspiring; her pulse was 104. There was but little pain and no vomiting. The patient passed a good night, had no opium and scarcely any pain; in the morning the pulse was 112. At half-past two on the first day she was equally well, perspiring freely. The urine was abundant, but pain began to be complained of when the catheter was passed. A little uterine epistaxis was noticed. Thirty-six hours after the operation the patient was allowed to pass water naturally. On the second day water was passed frequently; it was somewhat ammoniacal; otherwise everything was going on well. On the third morning there was a little bloody discharge from the pedicle, evidently catamenial. In the afternoon I found the clamp loose, and removed it, tying a small piece of slough. I also removed the stitches, and as I found a pint of ammoniacal urine in the bladder, I directed the catheter to be used regularly. On the fourth day the pulse and appetite were good; there was considerable vesical tenesmus. On the fifth day, the urine being still ammoniacal, the bladder was ordered to be washed out twice daily with tepid

water. Uterine epistaxis still continued. There was a free fœtid discharge from the wound, and, to avoid as far as possible the chance of its absorption, strips of blotting-paper were arranged all round the stump. Some flatulent pain was relieved by cajuput oil. On the tenth day the urine was no longer ammoniacal; there was still a good deal of fœtid discharge from the wound. The stump had sunk slightly on the left side, but still adhered to the right lip of the wound. The general state was very satisfactory. On the eleventh day the bowels acted after the use of an enema, which was given on account of a feeling of discomfort about the rectum. In the afternoon the patient had a dark, jaundiced look, but was otherwise well. On the morning of the twelfth day a second enema was given and acted well, bringing away a large quantity of fæces. The pulse was 90; the urine quite clear; the nurse observed a fœtid discharge from the vagina. During the day the patient felt hot, feverish, and faint, requiring a great deal of wine. At night her pulse was 130, and her skin suffused with perspiration. During the night the bowels acted spontaneously. Next morning we had the patient moved into another room. She complained of no pain; her pulse was 132; her skin dry and hot; her tongue loaded; there was still some fœtid vaginal discharge. The vagina was hot; the os uteri somewhat open; there was no fluid in Douglas' space, but the rectum was felt to contain fluid fæces. During the day the patient could eat nothing, but dosed continually, although she had no opium. At 10 p.m. the pulse was 120; there was free perspiration; urine was plentiful and clear. There were now two distinct varieties of discharge from the wound. First, a superficial layer of pus coating the granulations; and second, a fœtid, clear, bloody serum, which welled up from the bottom of the cavity, where the pedicle was, and where the right lip of the wound was still deeply retracted. On the fourteenth day there was no great change; the pulse was 120, the patient felt well, but towards night became sick without actually vomiting. On the fifteenth day I pushed some small pieces of drainage tube down to the bottom of the wound. They sank deeply, but no discharge followed. On the sixteenth morning the patient had a rigor, which lasted ten minutes, and was followed by profuse sweating. In the afternoon she was pretty well, with a pulse of 120. Another rigor came on in the evening. During the day three fluid motions were passed. On the seventeenth day she was better; the pulse 116; there was a slight fœtid discharge coming away by the drainage tube. I again examined the pelvis carefully. The uterus felt too far back, but no fluid collection was to be discovered. A grain of quinine was ordered to be taken thrice daily. Next day there was another rigor; the pulse was 120. The quinine was increased until she took two grains every three hours. I again changed the patient's room, and as her nurse was fatigued we got a fresh one. On the nineteenth day I removed a small piece of black slough from the bottom of the wound. The discharge was rather free. Two grains of quinine were ordered to be taken every four hours. From this to the twenty-fourth day there was gradual and steady improvement. The pulse sank to 104 (at the rate of four beats per diem), the urine became more copious, the perspiration less, the quinine was steadily continued, and the drainage still kept up. On the twenty-fifth day the catamenia came on; it was the proper period. Some menstrual discharge made its way through the wound. Next day the catamenia ceased; there was still a little fœtid discharge at the bottom of the pedicle opening. The general condition of the patient was now tolerably satisfactory. Her appetite was very good, and she felt well. She still required a large quantity of stimulant, but her strength was gradually returning. She was able to sit up by the fire in an arm chair, and as I thought that the country air might benefit her, she started for Nottingham on the thirtieth day after the operation. She arrived safely at home, and I have since heard from Mr. Wright that she is very well and rapidly gaining strength. This was clearly a case in which absorption of some of the fœtid fluid about the pedicle produced septicæmia, and in which quinine given in two-grain doses every three hours appeared to be of great use. The patient quite craved for it. She also took wine very freely, and without the slightest intoxicating effect.

M. Broca.—The numerous scientific friends of M. Broca in this country will hear with regret that his health has become seriously affected by overwork, and that he has been obliged to leave Paris for the south of France, with a view to its restoration.

ANEURISM OF ANTERIOR COMMUNICATING OF CIRCLE OF WILLIS.

By T. W. W. WATSON.

Susan S., aged 49 years, died very suddenly on the night of March 5, 1865, had been a healthy woman all her life, but had varicose veins in both legs, and for the last three months suffered from a varicose ulcer about an inch above the outer malleolus on right side; had complained frequently of headache, and occasionally of an acute pain in her head; was in her usual health on retiring to rest on the night mentioned; but about 2 a.m. awoke her daughter, and asked for a shawl, as she felt such a "dreadful shivering;" but before the girl could procure it the mother appeared to "faint," and upon my arrival at 2·15 I found her quite dead.

Autopsy, made by Order of the Coroner about Forty-nine Hours after Death.—Externally the body was well developed, with no mark of violence upon it; varicose ulcer on right leg; rigor mortis slight; thorax, heart healthy; old adhesions at apices of both lungs; tubercles in both, more especially in right; abdomen, stomach, and intestines loaded with adipose tissue; the stomach contained about two ounces of digested food; intestines, spleen, kidneys, and other viscera normal. Head: On removing the calvarium, I at once diagnosed the cause of death from the immense quantity of blood effused beneath the dura mater; but on dissecting out the brain I found an aneurism of the anterior communicating artery of the circle of Willis, about the size of annexed sketch, the dark line in the centre denoting the site of the rupture of the sac from which the effused blood had escaped; other arteries healthy; the small ends of the one mentioned (the aneurism intervening) were much enlarged.

PAPERS ON

THE THERAPEUTIC AND PHYSIOLOGICAL ACTION OF REMEDIES.

By WM. MURRAY, M.D., M.R.C.P. Lond.

Physician to the Dispensary, and Lecturer on Physiology in the College of Medicine, Newcastle-on-Tyne.

No. 2.—On Chloroform in Epilepsy.

Dr. Russell Reynolds has detailed in his classical work on epilepsy the effects produced on that disease by the inhalation of chloroform till the patient is fully under its influence. He uses the chloroform thus when an attack is threatening, and at certain intervals afterwards, and concludes that when administered in this way "it may delay the attacks for a time, but it exerts no permanently good influence." The plan of treatment I have adopted (the results of which are about to be detailed) differs from the above in some important particulars, although the principle on which it is administered seems to be the same.

1st. The chloroform is inhaled in quantities so small as to stop short of inducing unconsciousness, except of the most trifling nature.

2nd. It is administered two or three times daily for a period of two or three months at least.

3rd. It is given regardless of the fits, never being given to ward them off, and never omitted because of their occurrence.

The principle on which it is administered is that of paralysing the upper ganglia of the sympathetic, to induce conditions (hyperæmia) tending to unconsciousness, the very opposite of those which occur at the onset of an epileptic attack. Thus the primary influence of the drug as a stimulant to the brain, by inducing hyperæmia thereof, is brought to bear upon that organ thrice daily for a long period of time, and it is believed that there are cases of epilepsy in which this treatment must and does prove beneficial.

I should have used the nitrite of amyle instead of chloroform in some of these cases had the agent been less dangerous; for it seems to be the most powerful means we possess of exciting the heart's action and producing results similar to those which follow paralysis of the sympathetic in the neck. When a few drops of the nitrite of amyle are inhaled, the heart's action increases by forty beats per minute, and the

head, face, and neck become suffused by an intense hyperæmia; at the same time cerebral symptoms, such as throbbing and a sense of fulness of the head, indicate corresponding hyperæmia in the cranial cavity and its contents.

The following is a continued report of the patient Bryce, whose case was given in full in the *Medical Times and Gazette*, June 4, 1864. The attacks up to that date had been postponed in a very striking manner. The disease had lasted thirty years. During the last four years the attacks had occurred twice a week, and in the intervals he was almost helpless from losses of consciousness, vertigo, failure of memory, apathy, etc. By the use of chloroform the attacks at once became postponed for one month; the next interval was of nearly five weeks duration; the next seven weeks. He then left off the chloroform, and an interval of eleven weeks was followed by several severe attacks, upon which he recommenced the chloroform for about five weeks. The interval now reached three months, when a severe fit occurred during exhaustion from great bodily exertion. Since that attack, which occurred in September last, he has had no grave fit and only two slight ones, which occurred last week, so that the interval has now reached five months. The attacks have become forty times less frequent, and much less severe.

Case 2.—A young woman, who had an attack of fever four years ago, has since suffered from epileptic seizures. At the time when I first saw her she was seized daily. The fits were very severe. Her memory and other mental faculties were fast failing, and her physique was very feeble. Other treatment having failed to relieve, I advised the use of chloroform, of which she was very susceptible, and for seventeen days no fit occurred. After the attack which then occurred she again resumed the chloroform, and was without a fit for eighteen days. After reaching this interval, as several severe fits occurred, the chloroform was omitted, and the disease became worse. She has again commenced the chloroform, and sixteen days have now elapsed since an attack. In this case decided, but so far only temporary, benefit has been derived.

Case 3.—A young lady has had fits for three or four years. In October, when first I saw her, she was having them twice a week. They were unusually severe at the time of the monthly period, nevertheless all treatment directed to that source failed. The mental faculties were becoming obtuse and the memory was failing. In this case the chloroform was tried for three months, and in some respects good was done. The fits were at one period of the treatment postponed for two weeks and once for a month, but they occur with as much severity as before, and the mental faculties are still impaired.

Case 4.—This was an imbecile girl of 15 years, a congenital idiot, who suffered severely from the disease. In her case the fits became reduced to one-fourth their usual number, and the removal of the treatment was followed by a recurrence of these fits in their usual frequency. No permanent good was effected in this case; but very decided temporary relief was afforded.

In each of these cases it will be observed there was loss of mental activity and force. I shall now quote a case where the disease was accompanied by marvellous activity of the mental faculties and great excitability of temperament.

L. H. has had fits for about fifteen years, and they have increased in frequency during the last two years. At present they occur once a month. He is of a very active turn of mind, and he has great mental powers, which have been in no way impaired. The chloroform was tried on him for one week, and in a few days his symptoms became worse, he talked violently in his sleep, never slept without dreaming, great excitement prevailed, and some very severe attacks followed.

The remedy has also been tried in the following cases *without any apparent effect*:—

In a young Surgeon, for about three months, who has suffered long and severely, but has no prominent mental characteristics or bodily peculiarity.

Also a young lady, who is of an even, cheerful habit of mind, and moderately intelligent, whose fits have slowly increased in number during the last two years.

From all this it appears that in accordance with the view taken of the physiological action of chloroform administered in this way, its therapeutic properties are to be relied on in cases of epilepsy where there is manifest loss of brain power. In such cases it seems to lead to increased vascularity of the head and consequent stimulation of the brain, accompanied by that excitement of the system which occurs in the very first stage of chloroformosis. It seems to do positive harm in cases where the brain is active and excitable, and in cases where the mental faculties are of average power and unimpaired no appreciable effect is produced on the disease.

In none of the cases in which the remedy was tried for a lengthened period has its use been followed by injury to the mental faculties.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

MIDDLESEX HOSPITAL.

LIGATURE OF THE RIGHT COMMON CAROTID ARTERY FOR HÆMORRHAGE FROM THE RIGHT INTERNAL CAROTID — DEATH — AUTOPSY — ATHEROMATOUS DEPOSIT ON SURFACE OF INNER COAT OF THE ARTERY AND ULCERATION OF PHARYNX IN THE REGION OF THE TONSIL.

(Under the care of Mr. DE MORGAN.)

For the notes of this case we are indebted to Mr. J. Ablewhite Smith, the House-Surgeon. We have lately given several cases of ligature of the common carotid artery for hæmorrhage from malignant tumours which this artery or its branches has supplied. The following case is interesting as illustrating the spontaneous giving way of the coats of an artery at the site of some atheromatous deposit, and apparently also from external ulceration commencing in the pharynx. This case also illustrates well the difficulty often met with in determining the exact source of hæmorrhage when it occurs in affections of the throat. It was evident that a large artery had been opened, and the result of pressure on the carotids and complete cessation of the hæmorrhage after ligature of the right artery led to the inference that the lesion had taken place in one of the main branches of that vessel, yet after death a large opening was found in the internal carotid of the left side. The only way in which the right artery could share in supplying the blood which escaped was by means of the free communication which exists between the arteries of the two sides at the base of the brain. Had the patient lived long enough for the full restoration of strong circulation the hæmorrhage would have returned, and it would have been necessary to tie the remaining carotid artery.

H. D., a strumous-looking boy, aged 18, was admitted into the Hospital December 27 last with enlargement and open suppuration of glands beneath the right angle of the lower jaw. The disease had existed five months. The patient had always been delicate, but there was no history of phthisis or struma in his family. Under a course of tonic remedies his health improved a little, and the enlargement of the glands began to subside. On February 1 he complained of soreness of the throat, and the right tonsil was found to be enlarged. On the 3rd the left tonsil also became enlarged, and the surface of both tonsils was dotted with yellowish spots. There was swelling under the lower jaw on both sides and great difficulty in swallowing. The patient complained also of intense frontal headache. The enlargement of the glands beneath the jaw increased, and on the 4th a small patch of ulceration was seen on the back of the pharynx. On the 6th the patient seemed better; he swallowed with less difficulty, and there was a diminution of the swelling beneath the jaw. On the 9th the ulceration of the pharynx seemed to be extending towards the left side. On the 10th patient felt and appeared better, but about midnight, while coughing, he was suddenly seized with profuse hæmorrhage from the throat. The House-Surgeon (Mr. Smith) was immediately called, and found the patient kneeling in the bed with blood flowing in large gushes from his mouth. Compression was at once made over the carotids. Pressure on the left artery did not check the bleeding, but when the right was compressed and the left released the bleeding soon ceased. The patient was very faint, his extremities were cold, and his pulse very feeble. He had lost about three pints of blood.

February 11, 12.15 a.m.—Mr. Smith tied the right common carotid immediately above the omo hyoid muscle. After the operation the colour began to return to his lips. The pulse was very feeble and rapid—160. He muttered frequently to himself and seemed restless. Pulsation of the left temporal

artery distinct. 1.15 a.m.—Surface warmer; right pulse fuller, left still small and feeble; breathing calm; restlessness continued. Subcutaneous injection of $\frac{1}{6}$ grain of morphia. A little brandy was given, but it brought on coughing, and patient spat a few drachms of dark blood, apparently not recent. 1.40 a.m.—Sleeping calmly; pulse 122, fuller; occasional twitching of the facial muscles of the left side. Vomited a quantity of dark blood. No return of hæmorrhage. Enema of an ounce of brandy administered. 2 a.m.—Breathing rather laboured; pulse weaker; surface warm. Sponge was pressed down to fauces, and some thick mucus removed. This was repeated at times, and relieved the difficulty in breathing. 3 a.m.—Breathing more laboured, as from an accumulation in the trachea; pulse weaker; no fresh bleeding. An enema of 1 oz. of turpentine was given, and hot flannels sprinkled with turpentine were held under patient's nose. Gradually the breathing became more embarrassed, and the patient died at 5.15 a.m.

Post-mortem examination, made by Dr. Cayley.—Body well nourished; rigor mortis well marked; surface extremely pallid. There were some very large glands at the angle of the jaw on the right side, which extended down the side of the neck; the glands on the left side of the neck were also enlarged, but to a less extent. There was a recent incision, exposing the right common carotid artery; and this vessel was ligatured immediately above the omo-hyoid muscle. The fauces contained a quantity of coagulated blood. The right tonsil was much enlarged, and its follicles much dilated; the left tonsil was also considerably enlarged; there was no ulceration of either. In the posterior wall of the pharynx in the middle line, above the level of the soft palate, was a small ragged opening, leading into an irregular cavity situated behind and rather to the left of the pharynx. This was two or three inches in diameter, and contained a very little loose black clot. There was no distinct lining membrane to this cavity, which was bounded by the surrounding muscles and cellular tissue, and there was no pus either in it or near it. When water was injected into the *left* internal carotid it escaped in a full stream through the opening leading into the pharynx. In the left internal carotid, less than half an inch from its entrance into the carotid canal in the temporal bone, was a perforation forming an oval opening, the long diameter of which was about three lines; its edges were somewhat thickened and everted, and were smoothly rounded off. In the artery below this, and also in the common carotid, were a few small yellowish atheromatous deposits beneath the lining membrane. There were two or three similar deposits in the right carotid, which, with its main branches, was otherwise normal; the inner coat was cleanly divided by the ligature. In the arch of the aorta were several small atheromatous deposits. All the cavities of the heart contained some fibrinous clots; the right cavities contained also dark fluid blood. The heart itself was normal. The bronchial tubes contained throughout small quantities of loose black clots, and some frothy blood. In both lungs, principally towards the posterior parts, were scattered numerous small patches of pulmonary apoplexy. In other respects the lungs were normal. The abdominal organs were normal, and not particularly anæmic. The stomach and upper part of the small intestines contained some blackened and altered blood. The abdominal, aortic, and iliac arteries were normal. The brain was normal, but anæmic; the arteries in its base were normal.

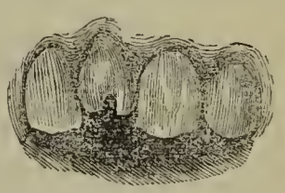
THE METROPOLITAN FREE HOSPITAL.

DISEASE OF THE LIVER AND ASCITES IN CONNEXION WITH INHERITED SYPHILIS.

(Under the care of Mr. HUTCHINSON.)

The following case is one of especial interest as regards the visceral lesions which are now well known to be not infrequent in the later stages of constitutional syphilis. The case also shows in a remarkable manner the value of the malformations of the teeth as a sign of inherited taint. The malformation differed from what is usual in that it was not symmetrical. Only one tooth was affected; but it fortunately was quite typical. The condition of this tooth was the single symptom which led to a correct conjecture as to the nature of the disease. Mr. Hutchinson stated that to any one inclined to be incredulous as to the correctness of the diagnosis, he should cite four mutually corroborative facts—first, the very peculiar tooth; second, the history of keratitis in childhood; third, the existence of liver disease (both keratitis and liver disease being well known to be often syphilitic); and fourth, the beneficial effects of specific treatment. To these might be added the pale, earthy complexion of the patient. The following are the notes of the case. We may add that the patient herself was brought before a meeting of the Hunterian Society, on which occasion Mr. Hutchinson mentioned two other cases which had come under his notice in which hepatic disease and ascites occurred in connexion with inherited syphilis:—

Mrs. H., aged 34, was admitted about three months ago, and is still in the Hospital. She is the oldest born of her family, has two sisters and four brothers living. The next to her is four years younger. Mrs. H. was sent up from Sheerness by Mr. E. Swales on account of ascites, which had lasted for three years. Paracentesis had been performed thirteen times. At one time she suffered much from œdema of her legs—so much so that punctures were made in them. This was in June, 1863. During the last twelve months she has been tapped eight times. When first the dropsical symptoms commenced she was very ill, and was for some time confined to bed. The ascites commenced three months before the legs began to swell. During the last three months she had required paracentesis with increasing frequency, and her general health had much failed. Her aspect on admission was pale and sallow, but not jaundiced. Her physiognomy was not peculiar, if we except a somewhat earthy pallor of face. Her left upper central incisor displayed, however, the most characteristic notch. Her other teeth were normal in shape. The abdomen was distended to an extreme degree, and both legs were somewhat œdematous.



After she had been in the Hospital about three weeks, Mr. Hutchinson performed paracentesis, and drew off two pails full of yellow fluid. When the abdomen was emptied, the edge of the liver could be easily felt. It was rounded, very firm, and presenting large nodular irregularities. The whole organ was evidently much contracted. She recovered well after the paracentesis, and she afterwards continued the steady administration of the iodide of potassium. Under this she has greatly improved in health, and no further operation has been needed. Mrs. H. states that she has always had delicate health, and that in childhood she was considered to suffer from her liver. Eight years ago she had an attack of jaundice, and was for a time very ill. She had a second slight attack of jaundice after the second tapping. She recollects that at the age of 9 or 10 she had inflammation of both eyes, which lasted for some months, and was so severe that for a few weeks she was quite blind. The cornea do not now show any superficial scars; but there is a very slight degree of haze as if from interstitial keratitis. Her urine is not albuminous, and there is no evidence of cardiac mischief. She does not appear to have ever suffered from periostitis nor from any form of skin disease.

CENTRAL LONDON OPHTHALMIC HOSPITAL.

REPORTS FROM CASES OF CATARACT.—CLINICAL REMARKS.

(Under the care of Mr. HAYNES WALTON.)

In the course of remarks on several patients with cataract who were in attendance, Mr. Walton drew attention to the formation of cataract, the mode of its progression, and the proper period for an operation. He rebutted the idea that the first symptom of cataract, that by which the disease could be first recognised, was to be detected by impaired vision, and showed that, although to the person afflicted this subjective evidence must be the first, the loss of the transparency of the lens whenever it occurred in striæ, or dots or patches of any kind, might be seen with the ophthalmoscope before there were any appreciable deterioration of sight. He had proved this many times. The power of such recognition cleared away much of the difficulty of distinguishing between the causes of the commencement of impaired vision, which was so very perplexing up to a recent period, and enabled us to say whether the visual disturbance was or was not due to cataract.

The rate of the progress of cataract was commented on, and the advantage of prognosis, if it could be made out, especially

to the patient, as it usually involved one of the very anxious subjects surrounding him, and the Surgeon seldom escaped the question, "How long will it be before I am blind?"

He had for many years watched cases with the view of solving the question, and these were his conclusions. There were no marks or signs by which it could be told in any individual case what would be the ratio of increase, and, therefore, when vision would be lost; and this would be more difficult in proportion as the attack was more recent. The reason of this is simply because there is not only no uniform rate of progress, but because exceptionally there may actually be an arrest of increase for months or years. All he could say was only in the way of generalisation and to the effect that cataract progresses much more quickly in early life than in old age, and that at all periods of life it is more quickly developed when the lens has been uniformly pervaded by haze or opacity than when striæ or spots appear. Illustrations were mentioned to confirm these statements. In some, after the lapse of from ten to fifteen years, the cataract had not sensibly increased, or but just perceptibly augmented. As still more sure evidence of the fact that cataract may go to a certain limit and not increase, was adduced the partial implication of the lens in some of the forms of congenital cataract, and the persistency of this state during a long life.

The state of vision, according to the degree of cataract present, was next examined, some curious results mentioned, and some circumstances difficult to be explained were adduced. It would seem from what we could gather that it would be impossible to tell from a mere inspection of a cataractous eye, supposing always the rest of the eye to be sound, what is the degree and quality of the sight. In almost every case, with even very partial opacity, the distant vision is impaired, but not necessarily the near sight; and in many old and elderly people the near vision is very much improved, and short-sightedness is supposed to have come on. Those who have worn spectacles for years are now able to read the smallest print without them, and altogether throw them aside.

Mr. Walton said, that conversant as he was with this condition of things, he had been from time to time puzzled with cases that were in extreme. Now and then, when for the first time he looked at a case, he would think there could be no definite sight, and a trial has astonished him; but he was quite amazed with the following example:—A gentleman, aged 55, who had had remarkably good far sight, and good near sight with common spectacles, applied to him for an explanation of certain optical changes. He examined his eyes, told him that cataract was present, and advised an operation on the right, that in which the lens was most opaque. The gentleman asked for a book in fine print, and read it readily with either eye without his glasses. For two years he had put these appendages aside, as he did not need them for any minute objects. His distant sight only was affected, and he could not recognise his friends across the street. He laughed at the idea of an operation. The gentleman kindly consented to allow some of Mr. Walton's friends conversant with eye disease to examine him; and all were deceived in their diagnosis about the sight, not only on account of the density of the opacity that occupied the pupil, but the impossibility of illuminating with the opthalmoscope the right eye in any degree, and the very slight amount of light that entered the second. No one could solve the riddle.

Mr. Walton begged his hearers to note that among the practical lessons to be drawn from the several topics that had been brought forward was the important one of not operating in any case of cataract by anticipation; that is, before the patient had lost all useful vision—not before his avocations in life were interfered with, or the interruption to sight was sufficient to produce positive discomfort. He based the rule on the well-known fact that however large may be the percentage of successful operations, that failures do, and must occur. It would be otherwise if by an operation the eye could be restored to perfect integrity. He mentioned an instance in which, just twelve years ago, he prevented one of these operations; and the gentleman about to be operated on is still attending to his Professional duties.

We must not omit to notice what was said about the artificial dilatation of the pupil by the use of some of the preparations of belladonna. The improvement to vision that may ensue by the widened pupil in some cases of cataract has been long known. But it is not always possible beforehand to tell when it will be beneficial, as under apparently the same conditions it may or may not be useful. Mr. Walton gave the particulars of several cases—some of them congenital—in which, without the dilatation, there was no useful vision, but with it the smallest type of a newspaper could be read. A trial only could decide the matter, and a trial should be made, for nothing was easier or less hurtful. He knew persons who have applied the belladonna twice a week for several years, and by it are enabled to pursue their avocations. It is well to use the least strength that will answer, that the adjusting power of the eye, which is a little influenced while the belladonna is acting, may be affected as little as possible. It is strange that the iris is affected by the belladonna in the same manner, by the same strength for any time, and that it quite recovers its natural state whenever it may be left off.

Medical Times and Gazette.

SATURDAY, APRIL 8.

THE PHARMACEUTICAL, AND THE CHEMISTS' AND DRUGGISTS' BILLS.

We will venture to repeat here the objections which we have felt it our duty, on behalf of the English general Practitioner, to make to these bills. The existence of a grievance or of danger to the public from incompetent dispensers is not proved nor probable. Even if it were proved, it could not be remedied by Act of Parliament. The good objects of the Bills can all be better obtained by voluntary effort without a bill. The exclusive privileges it is proposed to confer may be highly inconvenient to the public. The restriction to certain persons of the right of "compounding the prescriptions of duly qualified Medical Practitioners," makes the whole affair seem ironical, so far as public safety is concerned, because it clearly leaves the field open, and gives virtually legal sanction to unduly qualified Medical men who shall prescribe, and unqualified personages who shall dispense, their prescriptions. Literally it will come to this, that a man who on an emergency shall make up a box of colocynth pills from a Physician's prescription shall be fined £5, whilst he may compound a drink from the receipt of a "botanist" or sell a box of Morrison's pills with the sanction and approbation of the law. Lastly, the habit of counter practice, and of consultations and prescriptions of chemists in their back parlours will increase and multiply, and the regular Practitioner be starved, all for the "safety of the public."

There are, in London alone, hundreds of M.R.C.S. and L.A.C.'s, whose daily income is affected by this bill. If any of them think about it as we do, we ask them to forward their names at once to the *Medical Times and Gazette* Office, stating whether they are willing to wait on the framers of these bills to discuss the matter. They must bear in mind that Sir F. Kelly and Sir John Shelley are well disposed to the Medical Profession, but take their tone in the present matter from the very able, energetic men who—small blame to them—desire to aggrandise the Pharmaceutical Society or the United Society of Chemists and Druggists, and to substitute the pharmaceutical chemist for the general Practitioner. But if our Medical brethren are silent now, it will be in vain to grumble hereafter.

ARMY MEDICAL DEPARTMENT.

Amid the discussions on armour-plated and turret ships, the wordy clamours of rival artillerists, and the self-laudation of one noble peer because he was in power when the Royal Victoria Hospital was built, no one thought fit to vouchsafe a word upon the condition of our army Medical brethren. They never have, and they probably never will, receive any attention, unless the fortunes of war should carry a wounded aristocrat within the province of some third-class man, whose scientific attainments should prove too much for his patient. Even when any question of Professional interest is discussed in the House, the opinions and labours of civilians are quoted, as if there were no Medical Departments, or as if the members thereof were so many mummies. We do not desire to depreciate the value of the services which civilians of our Profession have rendered to the army; but we hold it to be unjust and ungenerous to exalt them at the expense of their less fortunate military brethren. It is as well known as any fact can be, that the reams of official complaints and sanitary suggestions made by military doctors would be sufficient to cover acres of ground, or to make fools'-caps for present and future Government dunces for years to come. It is rather too much to expect men to maintain an everlasting chorus of complaint, and to iterate and reiterate their opinions on the sanitary defects of military life before men who care nothing for importunity and still less for Medical science. It was only when the gigantic disasters and mismanagement of the Crimean war had dissipated every atom of the characteristic lethargy and good nature of John Bull that the Government had any ears to hear. To preserve place and lull the irritation which was general over the British isles, the Government was ready to do anything. Civilians of eminence were sent out to the East, and things were found to be as bad as they could be. The general impression was, and still is, apparently, that no Army Doctor is possessed of the commonest observation or the smallest amount of conscience in the discharge of his duties.

Our Profession, as a body, is possessed of very little political influence. A man who proposed to make a turret-ship to fire at the moon would be listened to with more show of attention and complacency than one speaking of the unfortunate Medical Department. Because, forsooth, it is a humane Profession, and the men who practise it cannot neglect their duties without being guilty of a cruelty and moral culpability which few have the hardihood to incur, we are to shiver in the cold shade of Government neglect and national ingratitude. We had extracted this lesson from the very chronic disorder under which the Army Medical Officers are labouring, and we had learned to trust to time and the steady diminution of candidates to work a change. When that supply was at zero, the Horse Guards and War Office began to perceive that they might have a Director-General without any Department to direct—in short, a Doctorless army. In January, 1862, in conformity with the prayer of a memorial presented to Sir George Lewis, a committee was appointed to inquire into the condition of the Army Medical Department. That committee presented its report in the summer following, and it was soon known that they recommended that the chief grievances complained of should be redressed. The Secretary for War declined, however, to lay the Committee's report on the table of the House, because it was intended only for the information and guidance of the War Office; as if that bureau was not perfectly aware of all that any committee could discover. A promise was afterwards given that "arrangements were in progress"—arrangements which have continued to progress ever since, we suppose, whilst the Department has been continuing to deteriorate. These promises have turned out as delusive as the rest. Nothing has been done, and almost all the evils remain just where they did. This has not surprised the Medical officers, for they receive all statements made by ministers of state with incredulity. When, however, the Department was dying of inanition the War Office began to urge concessions upon the Horse Guards, which the latter refused to yield as steadily as the former refused to give a greater pecuniary bait. Still, things had come to such a pass that the authorities were at their wits' end, and radical changes were imminent and certain. Even that warm friend of the army Medical officer—*The Army and Navy Gazette*—had gauged the merits of their case clearly enough to perceive this, for it commenced to damn them with faint praise, and to advocate their cause with an ill-concealed irony and enmity. What happened? A rush of candidates of the third class, and chiefly composed of one national element, appeared; they rallied round their chief; stood to the pumps of the sinking ship; and it was mainly by their efforts that the water-logged vessel was preserved. Horse Guards goes down in due time to Netley to thank the noble salvors of a derelict department, and that night the Director-General sipped right royal wine, received the approving smile of his patron and benefactor, and beheld the near approach of that honourable distinction which has since been added to his name. Our readers have been furnished with a list of the passed candidates from Netley Hospital, with the number of marks each one obtained at his examinations there; but they have not been informed of another result at which these candidates appear to have arrived from their own examination into their present and future position as Army Medical Officers. They were so little impressed with the value of their newly acquired privileges and prospects, as to have forwarded a memorial to the War Minister some months ago, in which they expressed their regret at having entered the service, and ventured a hope that no injury might arise therefrom to their Professional brethren. If this be a fact—and we believe it to be so,—it ought to be a sufficient answer to those who declare that satisfaction now reigns triumphant in the Medical branch of the service. What answer was returned to this memorial we know not. The War Office must have felt very much as the fowler did, in regard to the unwary geese which had been caught in the net he had spread for storks. If we remember the fable aright, the geese appealed for mercy on the ground that they were not storks, with as little effect as logic. The late ill-timed accession of Medical candidates for the army has robbed the Profession and the Department of every grain of corn when the harvest was ready to the sickle.

Now, Army Surgeons—and none more loudly than Irish Army Surgeons—complain of being subjected to a constant repetition of petty annoyances, for which no amount of material advantages can compensate. But what are these material advantages? Let any one take up an Army List and he will see. Many Medical officers have left, and many are still leaving, the service in disgust. Only a week or so ago we read of an Assistant-Surgeon of 1854 contesting the coronership of some place in Ireland. By the way, we do not remember to have seen any *official notification* of this officer's resignation yet. Spite of all this, which is a plain statement of facts, we find some journals advocating the army for its pecuniary advantages. Yes, ten shillings a-day is a good beginning for a man, young and inexperienced; but thirteen shillings, the rank, title, duties, and discomfort of an Assistant-Surgeon, with grey hairs and a big liver, presents another, and an equally certain, aspect of the question. Ask any old Medical officer, or any of our leading Physicians or Surgeons, and the verdict is clear and unanimous. The army presents a wretched opening for a young man of ability—for any one who is animated by a sincere love of his Profession and a desire to succeed in and by it. If a young Surgeon, endowed with the capacities of a Hunter or a Paget, entered the service to-morrow, it would be little short of a miracle if he were again heard of. No amount of *Professional* attainments

would enable a man to achieve reputation in the public services. The large number of unnecessary and uncongenial duties he is called upon to perform, the absence of emulation, the nature of a military life, are such that it requires uncommon zeal to prevent a man's becoming merged in a prevailing dead level mediocrity. It is believed that Dr. Gibson prefers the third-class candidate, because he finds those of the first rank to be the most troublesome and the least amenable to the red-tape discipline and monotonous functions of his Department. After a man has served some time as a Medical officer he becomes more and more unfitted for civil life, and is more and more bound—body and soul—to his salt. After long years he is promoted perhaps, shunted off to India, and eventually retires a Surgeon-Major. There are none of the staff appointments, special services, or snug berths for the Medical Department which exist for officers of the Royal Engineers or Artillery. No prizes are open to the old Medical officer, such as is the colonelcy of a regiment, for instance, for the old combatant officer. During the gigantic war which has been going on in America, amid the most ingenious and practical people in the world, in what have the Medical officers of our army benefited? Had there been very important questions of artillery or military science, officers would have been sent by our Government, but "matters Medical" are beneath their notice.

We wish the Director-General and Horse Guards all joy. They have their hearts' desire, which is "Candidates, but of no high order." The time must come one day when they will rue their gross unfairness to the Medical Profession. We are diminishing in numbers as rapidly as we are increasing in all that claims the respect of mankind—viz., in scholarly and scientific attainments,—and the day must come when this will be no longer tolerated by the rising generation of Medical men. At present we see no chance of improvement. The supply of candidates has settled the matter. The Horse Guards are chuckling over the victory; and the young aspirants for money and station will yet be left to behold the Dead Sea apples crumbling to ashes in their hands.

THE RUSSIAN PESTILENCE.

The latest accounts from abroad tend somewhat to diminish the alarm naturally felt at the intelligence of the depopulation of whole villages by a fatal and hitherto unknown disease, of whose origin and nature the most opposite reports prevailed, and which our reminiscences of Defoe's vivid history of the Great Plague did not tend to counteract. The mist, however, that magnified the proportions and obscured the lineaments of the spectre, is at length rising, and reveals to us the face—not of the supposed spectre—but of an old foe, which, though already contended with not unsuccessfully, has risen from time to time in a Protean shape, at once a stimulant to increased sanitary vigilance, and a warning of what might occur should that vigilance be relaxed. From the minute and excellent report of Dr. Tillner, Physician to the Grand Duchess Maria, of Russia, published in *The Times* of April 5, it is highly probable that this disease is a modified form of the famine fever, which, according to Dr. Murchison, first appeared in Ireland in 1739, and which has since visited the British Isles again and again, having been especially fatal in Scotland and Ireland. Dr. Murchison, whose accuracy no one can impeach, states, in his "Treatise on Continued Fevers," that it was observed in North America in 1847 and 1848. Should the two be identical, the cause of its non-recognition by our Russian friends on its recent appearance among them is found in the following sentence from Dr. Murchison:—"In 1847 an epidemic of relapsing fever, identical with that observed in Britain prevailed in the Silesian provinces of Prussia and Austria; and in the summer of 1855, after the hardships and privations of the preceding winter, it is said to have been 'pretty common among the British troops in the Crimea.' With these exceptions I am not aware that relapsing fever has ever been met with in any other part of the Continent of Europe." The symptoms of relapsing fever and of the Russian disease described by Dr. Tillner closely correspond. The access of each commences with shivering, followed by increased heat and sweating. The pulse in relapsing fever beats from 120 to 150, being often as high as 140 on the second day. In the Russian disease it is usually 130. The temperature is elevated to 104° F. in the Russian fever, and in relapsing fever varies from 102° to 107° F. In the Russian plague the skin is yellow; in famine fever "there is never any characteristic eruption, but a large proportion of cases are jaundiced." There is a marked crisis in both diseases on the seventh day, followed by an interval of almost perfect health—languor being the only symptom complained of. The amelioration in both cases is ushered in by profuse perspiration, and seven days later a second relapse occurs, followed by an interval as before. The mind is generally unaffected in each disease. The rate of mortality in the Russian disease is, according to Dr. Tillner, 8 per cent.; in relapsing fever from 2 to 4 per cent., according to Dr. Murchison. Death in relapsing fever sometimes occurs by sudden and profound collapse, the face and extremities becoming livid. "Sometimes a fatal termination occurs in this way a few hours after there had been any evidence of danger." Hence, perhaps, the supposed resemblance of the Russian fever to cholera. At other times death occurs by coma and convulsions. Death in the Russian fever occurs by great prostration and a kind of general paralysis. Moreover, the causes which produce relapsing fever have been at work in St. Petersburgh, and have also modified the disease. According to Dr. Tillner there is an excess in the capital of 43,000 workmen above the usual number, and these have been obliged to forego animal food and live almost entirely on black bread containing 1 per cent. of ergot of rye, and to live in unhealthy localities. Poisoning by ergot has thus been, no doubt, superadded to fever caused by famine, overcrowding, and destitution. Further details will no doubt prove the identity of the two diseases, and by robbing the disorder of the mystery that now hangs about it increase our confidence in the remedial means to be employed should we be visited by the scourge.

THE WEEK.

THE GENERAL MEDICAL COUNCIL.

We must reserve till next week any comment on the proceedings of this body. It will be seen that compulsory interference with education is virtually abandoned; but that an attempt will be made to induce Parliament to amend Clause 40 of the Medical Act and to punish persons who falsely pretend to possess Medical qualifications. The form of amendment agreed to by the Council, if it become law, will render registration compulsory on all Practitioners.

A RECENT RAILWAY CASE.

We ventured in a late number to call attention to the gladiatorial displays of Medical witnesses in those cases of action for compensation by railway companies which seem to have become one of the recognised institutions of the age. We have no doubt that these performances afford considerable amusement to the briefless barristers in the back row of the assize court, that they possess great interest for the attorneys and their respective clients who inaugurate the show and pay the performers, and that they arouse sufficient of the combative instinct to give a not unpleasurable stimulus and excitement to the Medical athletes who are the combatants. For ourselves, looking at them in the interests of the Profession, neither merely as unconcerned spectators nor as personally affected by the questions at issue, we regard them as simply deplorable exhibitions which damage our calling in the eyes of the public, rob it of its claim to be the exponent and dispenser of scientific truth, and detract very much from our pretensions to Professional feeling. Since we wrote another

case has occurred which, although not so gross an instance of irreconcileable difference of opinion on the part of the Medical witnesses, is no less to be regretted on account of the high Professional and scientific rank of the opposed forces. The case was that of a gentleman, a clerk in a Government office, who had been seriously injured in the terrible accident at Blackheath on December 17, 1864. He had previously been in robust health, was addicted to literary pursuits, and added to his income by employing his spare time as author and private tutor. By the collision this person was thrown violently forward against the partition of the carriage in which he was; he pitched upon the top of his head, and the blow was of such force as to be described as "doubling the head up in the neck," and forcing it back on the vertebral column. The result was paralysis—on this both sides were agreed—and disturbance or diminution of mental power. The latter was proved by the evidence of a clergyman, who detailed a conversation he had had with the patient. Four or five of the leading Hospital Physicians and Surgeons in this metropolis gave evidence that the man had suffered a "lesion" of the brain and spinal cord, from which it was improbable he would ever recover. On the other side four or five equally eminent Hospital Physicians and Surgeons were called, who acknowledging that the man was injured, admitting the existence of some paralysis, still were unanimous in stating that the whole of the symptoms were the result of "shock," or "concussion," that there was no organic injury, and that in all probability the patient would get quite well. Now, we, of course, can give no opinion on which side truth preponderated, we are quite ready to admit the enormous difficulties attending prognosis and diagnosis in such cases, and we are most willing to suppose that this case presented special points of doubt. We might ask the gentlemen who opposed the opinion of the plaintiff's Medical attendants if they will be good enough to define "concussion" and "lesion," or at least to tell us where "concussion" ends and where "organic lesion" begins, and whether it is possible to conceive of shock sufficient to produce paralysis without associating the effect with some alteration of nervous structure? But we have no wish to enter here on the scientific points of the conflict, we divest ourselves of our Professional habits of thought, and take the place of a layman, and what do we observe? 1st. That the Medical witnesses agree with others on their own side, with remarkable unanimity, on a debateable Medical point; 2nd. That the witnesses on each side, although agreeing amongst themselves, differ in opinion as remarkably and as entirely from the witnesses on the opposite side; 3rd. That the opinion of the Medical men on the side of the plaintiff happens to coincide with the pecuniary interests of the plaintiff; 4th. That the opinion of the Medical men on the side of the defendants happens as remarkably to coincide with the pecuniary interests of the defendants; 5th. That the Medical witnesses on each side receive remuneration from the side on which they are employed. We draw no conclusion from these facts, but we very well know what the world says.

PARLIAMENTARY.—MORTALITY OF MINERS—THE POLICE AND UNION INFIRMARIES—DEMOLITION OF THE DWELLINGS OF THE POOR—PAROCHIAL MEDICAL RELIEF—MORTALITY IN EMNETH—THE EPIDEMIC IN RUSSIA.

In the House of Lords on Thursday, March 30,

Lord Kinnaird, in moving the first reading of the Metalliferous Mines Bill, said: In 1862 a Royal Commission was appointed to inquire and to report as to the health and safety of those employed in the lead, copper, tin, and ironstone mines. The result was a report, which was presented to Parliament at the end of last Session. The inquiry brought to light a most fearful state of mortality among the men. On comparing the mortality among the miners with that among other classes in the same districts, it was found that double the number of miners died. It was also ascertained that that was not the immediate effect of working underground, because it was found, on a comparison of the returns of the Registrar-General, that the colliers in the North of England were, notwithstanding the numerous accidents which occurred, the healthiest and longest lived of any of the working classes in that country. It was true the colliers were better fed than the metal miners, but it was clearly proved that the difference was owing to the better system of ventilation which was in practice in the collieries. In the metal mines there was no such danger of explosion as in the collieries, and therefore their ventilation was entirely neglected. The Commission had upwards of 300 specimens of air taken from different mines and submitted to the analysis of scientific men, and it was found that the air was unfit for men to work in. They had also caused many miners to be examined by Medical men, who all agreed that the sufferings of the miners from disease were owing to want of ventilation. It might be imagined that the miners were all strong and muscular; but the contrary was the fact, for there were none to be seen among them, even when they had not reached middle age, but pale, emaciated men. It was a common expression that a man of 50 among the miners was an old man. There were other causes also which tended to produce this melancholy state of things. In collieries the men on returning from work were lifted by a hoist, but the metal miners had to climb 1200 or 1600 feet after the fatigues of an exhausting labour. When they got to the top they were in a state of such profuse perspiration that they easily took cold, and much sickness and many deaths were thereby occasioned. The Commissioners did not think it desirable to point out how these evils were to be remedied, but the necessity for legislation was clearly established. It was, he admitted, a difficult subject to deal with, but having given much attention to it, and having lived among the miners for two months, during which time he was constantly underground, he was prepared to show that the evils under which these men laboured might be remedied. The working of the Act might be intrusted to a Board or Department under the Board of Trade, similar to the Railway Department, and there was in the Mining Record Office an admirable nucleus for carrying out the provisions of the Bill. He believed that such a Board would meet with the concurrence of the mining interest. He proposed that this Board should inquire into the state of the different mines, and enforce the provisions necessary for the health of the men, which were all pointed out in the Report.

The Bill was then read a first time.

In the House of Commons,

Sir J. Shelley asked the Secretary of State for the Home Department whether his attention had been directed to the report of an inquest held at the Strand Union on the body of a gentleman, from which report it appeared that the gentleman, in an apoplectic condition, was taken there by the police, supposed by them to be of unsound mind from drink, and left without any information by what means he came into their hands; and whether he would cause a communication to be forwarded to the police authorities requiring that in future, when any sick person, incapable of giving any explanation of his or her condition, was taken to a Union Infirmary, all the facts bearing on the case which the police could furnish should be forwarded in writing with the patient for the guidance and information of the Medical officer.

Sir G. Grey was understood to say that he would communicate with the magistrates on the subject.

In the Upper House on Friday, Lord Shaftesbury called attention to the want of house accommodation for the persons driven from their homes by new railway works in the metropolis. The demand for lodgings thus created could not find the immediate supply it required, and the consequence was a dangerous overcrowding in the districts to which the displaced population was driven. The consequences of this uprooting were disastrous to the classes who suffered from it. Within the last twenty years there had been a great improvement in their moral condition by means of schools, working men's clubs, and reading-rooms; but with the dwellings of the poor all their institutions were also swept away. The enormous evils thus created could not be adequately met either by model lodging-houses or cheap railway trains, which could be of little use till suitable houses were built to run them to. To lessen the inconvenience caused to the working classes by such sudden removal, he moved that the standing order No. 191 be so amended as to secure to the Legislature full information of the number and description of the houses to be taken under the power of any railway bill, and to the inhabitants eight weeks' notice to quit.

After some discussion, Lord Shaftesbury withdrew his

*

motion, with the understanding that it was to be brought on again in an amended form.

In the House of Commons,

Sir J. Shelley asked the President of the Poor-law Board whether the Poor-law Board intended in this Session to take any, and if any what, steps to carry out the recommendation of the Select Committee on Poor Relief, that in future cod-liver oil, quinine, and other expensive medicines should be provided at the expense of the guardians, and not as heretofore by the parochial Medical officers?

Mr. Villiers said the subject referred to was one to which the Board had given much consideration, and on which they had communicated much with guardians in different parts of the country, and they did not despair of inducing them very generally to adopt the recommendation of the committee in question. There were difficulties in the way, however, owing to the existing contracts with the Medical men, which were made on the other system. These contracts usually were made for life, and there had sometimes been an unwillingness to revise them; but in certain cases the Doctors did not live in the union, and were then selected annually, and in all these cases there was reason to hope that the recommendation would be adopted. The Poor-law Board in such cases would use all its authority to induce the guardians to adopt it. (Hear.)

Dr. Brady asked the Secretary of State for the Home Department if his attention had been directed to a statement made by the coroner at an inquest held at Emneth, in the county of Norfolk, last week, directing attention to the extraordinary mortality among children in Emneth, amounting to 80 per cent. of the population, which the parish Surgeon attributed to gross and culpable neglect, the children dying from starvation.

Sir G. Grey said he had received a letter from the coroner, stating his belief that the great mortality among the children was attributable to the neglect of the mothers. The letter had been forwarded to the High Constable of the county, who would inquire into the facts.

In the House of Lords, on Tuesday, the Bishop of Oxford asked whether the attention of the Government had been called to a report which had appeared in the public papers, and which had created considerable excitement in the public mind, as to an epidemic which seemed to be rapidly advancing towards this country from Russia. The statement was that it was one of those mysterious diseases resembling the cholera; that the plague had passed the Ural Mountains, and had reached St. Petersburg, where its ravages were so great the number of deaths was no longer officially stated, and had broken out in some parts of Prussia.

Earl Granville said that his noble friend the Foreign Secretary had already given orders to the consuls and our ambassador in Russia to furnish all the information they could procure on the subject; and on that very day he had sent suggested questions to the Foreign Office in order that they might be telegraphed to our representatives not only in Russia, but in the Baltic ports, and that replies might be received as soon as possible.

FROM ABROAD.—HORSE- AND ASS-EATING IN PARIS—PRIZE QUESTION OF THE BELGIAN ACADEMY OF MEDICINE—THE ENGLISH AND FRENCH IN THE CRIMEAN WAR.

Hippophagism is still making progress in Paris. The Prefet of Police has authorised two establishments for the sale of horseflesh. These are to be inaugurated by a great popular banquet, to which the wives of *chefs d'atélier* and of workmen alone are to be invited, it being naturally understood that the only chance of introducing this substance into the domestic dictary must be through the instrumentality of the female portion of the community. But alas! how unstable is greatness and success; when all seems smiling in the prospect of the acquisition of this new viand, it is threatened to be displaced, almost before it has acquired its footing, by the discovery of another long-neglected variety of animal food, not in the shape of the unmanageable *charqui*, but of the muscles of that patient, ill-treated, serviceable beast of burden, the common ass. At a banquet given by an academician, having MM. Velpeau, Tardieu, Latour, and other notabilities as his guests, the "bifsticks" and "filets" prepared from the flesh of an old she ass were unanimously pronounced as more tender, succulent, and delicate than similar *plats* prepared for comparison from the horse. A little nonsensical qualmishness was at first betrayed by some of the guests; but on the whole this asinine triumph was complete.

The Belgian Academy of Medicine has published the programme of its Prize Questions:—1. A medal of 300 francs for the best essay on the "Effects of the Use and Abuse of Tobacco in a state of health, demonstrated by cases and experiments." (Essays to be forwarded by July 1, 1865.) 2. A medal of 500 francs, "The character of the disease which attacks domestic animals, known as 'Carbuncular Typhus,' indicating its causes, and the therapeutical procedures requisite for its cure, and the means of preventing its development." (April 1, 1866.) 3. A medal of 500 francs, "The Chemical History of Digitaline, establishing clearly by new experiments its destructive characteristics and composition." A simple process for obtaining it as a constant and definite product is to be given, and a sample of such product is to be forwarded. (April 1, 1866.) 4. A medal of 1200 francs, "The Life and Writings of J. B. Van Helmont, expounding his Medical doctrines, criticising their value, and clearly establishing the influence which they have exercised on the science and practice of Medicine." (April 1, 1866.) 5. A medal of 1200 francs, "Cancers which are termed Surgical, considered especially with regard to their treatment." (April 1, 1867.) 6. A medal of 500 francs, "The Chemical and Pharmaceutical Examination of *Tanaisie (tanacetum vulgare)*." (April 1, 1867.) 7. A medal of 1500 francs, "An Examination into the functions dependent upon the various portions of the Encephalon, experiments on living animals, clinical and microscopical observations, as well as the facts furnished by histology and comparative anatomy constituting the bases of the investigation." (April 1, 1868.) The essays, written in Latin, French, or Flemish, must be forwarded to the Secretary of the Academy before the dates we have specified.

At an early stage of the Crimean warfare, the numerous shortcomings in the provision for the necessities and comfort of our army aroused public indignation in an extraordinary degree, and the great superiority of the French in this respect was loudly proclaimed. This difference, however, only characterised the commencement of the war, and arose from the army of the one country being kept on a constant war footing and the other being caught somewhat unprepared. But no sooner had public opinion become thoroughly aroused to the importance of the emergency and the unlimited resources which we have at our disposal entrusted to duly responsible agents, than a mighty change came over the scene. The troops encamped on a foreign shore furnished a smaller mortality than they had done at home, and effectual sanitary inspection became a recognised portion of military organisation. While as the campaign progressed our arrangements became more and more matured, and our soldiers better and better provided for, with the natural result upon their health, our allies, the first impulse having passed away, and the provisions made, sufficient in the case of immediate success, proving inadequate when exertions had to be prolonged, found their army daily diminishing in effective force, though the insufficiency of supplies and attendance and the consequent ravages of disease. When, chiefly on this account, the campaign was abruptly ended, we were in point of fact in a better condition for continuing the war than the French had been for commencing it.

The truth of the above statement has been vouched for by all the French Medical officers who have written upon this campaign, and now we have another witness to the same effect in M. Chenu, who has just published the most elaborate report on the Medico-Chirurgical service of the Crimean war that has yet appeared. It is a work of immense labour, in which he has entered into an elaborate comparison of the condition of the French, Piedmontese, and English armies. To confine ourselves at present to the general results, M. Chenu finds that while in the French army of 309,268 soldiers there occurred 95,615 deaths, in the English army of 97,864

there occurred but 22,182 deaths. This return comprises, it is true, deaths from all causes, whether wounds or diseases; but when any of the categories are separately examined the same comparative results are brought out.

Although not connected with our present subject, we may transcribe some interesting observations made by M. Chenu upon another topic also of great interest to ourselves—viz., the Medical officer considered as a non-combatant:—

"What is the position of the military Medical officer? He is looked down upon by the soldier because he is a non-combatant, and yet his true value is only comprehended on the field of battle, in the ambulance, and surrounded by contagion in the Hospital. In the hour of danger he is, indeed, well spoken of. 'The Surgeon who succumbs in the performance of his holy duty,' says the *Moniteur de l'Armée*, 'deserves as well of the army of his country and of his sovereign as does the soldier who falls in battle.' But danger once passed, these benevolent reflections are soon forgotten; and yet in what does he differ from the combatant officer? He marches with his regiment or his ambulance to the field of battle, and he is in no wise secured from wounds or even death, his sole distinction there being that he cannot return the blows he receives, since his special functions compel his attention to the wounded who are falling around him. But does he contribute less to the general end all have in view? In the Hospital his position is still more perilous, and there the danger to which he is incessantly exposed has no brilliancy wherewith to stimulate his courage. His energy is expended in obscure struggles, and he is not supported, excited, or intoxicated, either with the ardour of the combat, the incense of the powder, or the exhilarating sound of the trumpet. The enemy which surrounds him is invisible, and he has no means of defence, and is more and more exposed to attacks every day. In the midst of an infected Hospital he must brave the danger of contagion in order to fulfil a sacred duty, and he must regard the prospect of death itself with calmness in order to retain his Medical lucidity. It is a dangerous field of battle upon which he falls defenceless, succumbing bravely and humbly amidst those whom he has sought to save."

These words are amply justified by the figures which follow. 1. In an effective of 5852 officers of all grades, there were killed or died from their wounds 779, or 17 per cent. 2. Of officers of all grades in the entire army, comprising intendants, almoners, and various administrators, there died of various diseases 402, or 7·30 per cent. 3. Of an effective mean of 450 Medical officers, 82, or 18·22 per cent., died of various diseases. 4. Of officers of all grades there died of typhus 26, or 0·17 per cent. 5. Of army Medical officers there died of typhus 58, or 12·88 per cent.

REPORT ON CHEAP WINE.—NO. XVI.

(*By our Special Empirical Commissioner.*)

German Wines: their Uses—Wine Clubs—Red Hock—Sparkling Wines—Characters of Good Champagne—Cause of Unwholesomeness in Wines—Mixing Wines—Real Elements of Cost in Wine—Wine Duties and their Moral Purport—Conclusion.

I AM unwilling to finish these papers without at least a respectful mention of those noble vintages of the Rhine which afford such models of what wine ought to be. Of light alcoholic strength, and yet almost imperishable through their purity, and with marked fragrance of the true vinous character, the Rhenish wines are the wines for intellectual gaiety. They increase appetite, they exhilarate without producing heaviness and languor afterwards, and they purify the blood. But they are not *cheap* as a rule. There are some wine merchants who have specimens of moderate price; for instance, there is a "Rheinwein" sold by Fearon's, at £1 per dozen, which I have prescribed in dropsy from liver disease; in just the class of case in which we should give nitro-muriatic acid. There is a thin, sub-fragrant, sub-acid Moselle (Zeltinger), of which I have had a specimen from Mr. Andres, of very moderate price. The higher class of Rhenish (all of which are called *Oc* by our man-servants) differ remarkably in their flavours, but as a rule are all very useful in cases in which we want to support the nervous system, clean the tongue, quench thirst, and oxidate the blood. How I have seen a poor fellow with pleurisy—his face just dusky, turn from sherry and grasp at a goblet of Rudesheimer! These wines are the reverse of cheap, and should be reserved for the rites of hospitality or for serious illness; but if any rational persons desire to have specimens of these and of other first-class wines at moderate cost, they should form *wine clubs*,—just as the English in India form mutton clubs—and order a cask from such a firm as Mayer, of Mayence, and have it bottled there and put on board. I venture to say that it will be a sign of a true advance in the Healing Art when these wines are more frequently prescribed.

There are Red Hocks, the finest of which is the *Assmanshauser*, a wine of great body, powerful peculiar aroma, and high price. It comes, whether in conviviality or in illness, with the higher class of Burgundies. There are some middling red hocks, as the *Affenthaler*, which are often passed off as Assmanshauser, and some very indifferent ones which I have bought in London, and consigned to the nearest gutter. A sense of charity induces me to mention a stuff called *Walpotsheim*, of which I unluckily got a specimen at 24s., and of which I noted that it was "wretched stuff; cork dyed; wine probably a poor white wine coloured by logwood; slightly turbid." I have had good middling wine of these sorts at about 35s. per dozen, but it is too dear for an ordinary wine, and not good enough for an extraordinary. Moreover, some of these red hocks have had a want of care in their manufacture, so that they do not keep well.

Sparkling Wines must not be passed over without one word of notice, because of their very great medicinal virtues. When, on an emergency, we want a true stimulant to mind and body, rapid, volatile, transitory, and harmless, then we fly to champagne. But champagne, to be good, requires such care and skill, and is subject to so much loss in its manufacture; it is so truly a child of art, that it cannot be cheap. The properties of good champagne are firmness and cleanness, with high grapy and sometimes true vinous bouquet and flavour, which must be appreciated when the effervescence has passed off, and for this purpose the wine must be judged of when it has been open three days. It may be sweet, or may be dry, but must be *clean*.

It must have these high qualities, spite of the fact that its fermentation has been checked, and that it has been subjected to dosage with brandy and sugar. The process of *racking*, so as to get rid of sediment—*i.e.*, of decomposable vegetable matter—is performed by opening each bottle more than once. Bad *dry* champagne tastes of bad wine and bad brandy, in about equal proportions; and to these, bad *sweet* champagne superadds the flavour of brown sugar-candy. There is nothing more dangerous for a patient subject to acid dyspepsia. Amongst the maladies which are benefited by good champagne is the true *neuralgia*: intermitting fits of excruciating pain running along certain nerves, without inflammation of the principal part—often a consequence of malaria, or of some other bad and exhausting causes. But there is another neuralgia, which is really a true rheumatic inflammation of some nerve, especially the sciatic, and attended with all the gastric and assimilative disturbance characteristic of rheumatism, and I can conceive of nothing more mischievous than the administration of bad champagne in such a condition. Yet I have known it done.

Even amongst highly priced *dry* champagnes, some are too heavily brandied and coarse; whilst the true connoisseur looks for lightness and fragrance. So far as effervescence is concerned, the perfection of the wine is to have the carbonic acid so intimately dissolved that it escapes creamily, so that when the cork is drawn it does not blow half of the wine out of the bottle. As for sparkling wines in general, they are looked upon by the true œnologist with much the same favour with which the philosophic botanist regards some of the monstrosities of flowers which adorn the ladies' boudoirs—pretty playthings, but not to be despised on that account. *Dulce est desipere in loco.* They have, nevertheless, far too great a vogue amongst those rich people who think themselves Mæcenas, whilst at the best they are but Trimalchio, and who conceive that a profusion of costly sparkling wine gives brilliancy to an entertainment, and supplies the place of good taste and true hospitality. Vast quantities of spurious wine are sold as champagne, and this must be the case until the public learn to discriminate good wine from bad, and dare to introduce new wines at their tables, trusting more to merit than to name. The man who can afford to give

sparkling wine freely should try the sparkling St. Jeray (Burgundy), the sparkling Voeslau (Austrian), sparkling Scharzhofberger (Moselle), sparkling Hock, sparkling Tokay, etc. The perceptive and reflective faculties should be duly exercised, even at a wedding breakfast.

There is one method of producing these wines by art which almost surpasses that of nature. Instead of trusting to evolution of carbonic acid for the last stages of fermentation, it is better to choose sound wine and charge it with carbonic acid gas, as soda water is made. We are much more sure of getting a wholesome wine; and as for the gas, it produces its fillip and flies off without leaving an unwholesome fermenting substance in the stomach. I have tasted a *Vino d'Asti*, at 2s. per bottle, aerated in this way, which is far above bad champagne, as it does taste of wine.

I have now finished my Report on Cheap Wines, into which I have ventured to introduce such observations as came to hand upon wine in general. These are the results of experience, and I hope will be accepted as such by my Medical brethren. There are a very few remarks which I beg to offer in conclusion.

What is it that makes some wines and other fermented and distilled liquors unwholesome? Why after drinking a very small quantity of some do we feel next day headache, languor, nausea, and oppression at the stomach, whilst after others we feel light and vigorous? Certainly it cannot be alcohol *per se*, for the more we see of the use of wine in health and sickness the more we see how innocuous the true alcohol of wine is in moderate quantity. I believe it to be the undefined oily matters, of the *fusel oil* or *feints* kind, which are generated in some fermentations, and more especially of grain. Some kinds of new beer are terribly brutalising and stupifying; I hear of some whiskies in Ireland which soon make men drop dead drunk. Some new wines probably have similar oils in their composition, and others have them in the shape of added spirits. Luckily *time* seems to destroy them.

Is it unwholesome to mix? i.e. to take different liquors at one sitting? If each is good, the whole will not disagree; I never could trace any substantial ground for the prejudice that they do harm. On the other hand, a very small quantity of bad wine will disagree, whether "mixed" or not. It is the question of consanguineous marriages in another shape.

Is pure wine really cheap? Some of my friends tell me that I delude them; that pure wine is cheap in name, but dear in fact, because they can drink so much of it; whereas really they can't drink and don't want more than a very little of port or other brandied wine. I really am not advocating extravagance; but then I consider nothing extravagant which conduces to the health and innocent refreshment of mind and body. Neither do I reckon a thing cheap which can't be used, just as bread a week old is used in some ghastly girls' schools, in order that the children may not devour too much of it. Uneatability and undrinkability are queer recommendations for meat and drink. But let us come to figures, and we shall see that port wine is not so cheap as it seems, and that if people who buy a dozen of port would calculate how much they give for the wine, and how much for the added spirits, they would find that the cost of very bad port is, at least, equal to that of very good Burgundy.

For, as is known perfectly well, port wine fortified up to 40° per cent.—the dry tawney, throttling, old-in-the-wood stuff, so much admired by some personages—consists partly of wine, partly of added grain or potato spirit, the price of which last, German or English, is 1s. 3d. to 1s. 7d. per gallon. Now, as I showed in my last, a pipe of port wine consists of 39 *liquid* gallons=50 *proof* gallons of spirit, to 76 of wine, making 115 gallons, which equal one pipe. Suppose, then, a pipe of port to cost £40 in bond; we may distribute that cost thus:—

	£	s.	d.
39 liquid gallons spirits, equal 51 proof gallons at 1s. 6d. per proof gallon	3	16	6
76 gallons of wine	36	3	6
115 gallons.	£40	0	0

Or, supposing a man has given 5s. for a bottle of port, the cost will be distributed thus—

	£	s.	d.
Bottle, bottling, cork, etc., say	0	0	5
Duty, at 2s. 6d.	0	0	5
One-third of a bottle of proof spirit, at 1s. 6d. per gal.	0	0	1
Two-thirds of a bottle of port wine, say 18 fluid ounces	0	4	1
	£0	5	0

But if two-thirds of a bottle of port cost 4s. 1d., it is clear that a bottle costs 6s. 3d., and that, in buying port wine, we are really robbing ourselves of one-third of our wine, and paying wine price for a third of miserable proof spirit, which (duty apart) is only worth 1s. 6d. a gallon, or 3d. a bottle.

Whoever would make a fair experiment on a matter so important to health, morals, taste, soundness of mind, and domestic economy, let him drink any bottle of port he can get for 6s., 7s., 8s., or 10s. 6d., side by side with a bottle of Burgundy, which he can get at such a place as Ward's, in Mayfair, or Hedges and Butler's, in Regent-street, for 4s., 5s., 6s., or 7s. (I mention these two places because I have patients now who are drinking their Burgundies with benefit.) At any rate, let the Burgundy cost 2s. or 3s. less than the port, and then, as they are sipped side by side, let any impartial man say which is the better, which has the more wine in it, which is the cleaner, firmer, purer, and better flavoured? The first will taste sickly, vapid, and dead, side by side with the glorious Burgundy. And then to think that we pay such a price for stuff, one-third of which is that mere spirit of wine, which, with a little sweetness and flavour, makes gin! Further, let any one try the same experiment with the White Hymettus, the St. Elie, Szamarodny, or Dry Ruszte side by side with any sample of sherry which shall cost at least 2s. per bottle more. Let them be tried with water and without, and be judged of by wine body and wine flavour. Of course, the port and sherry bigot will complain that they don't heat his throat nor "warm his backbone" as the brandied wine does; but, thank Heaven, there are a good number of us who have warmth enough in our backbones without seeking it from a distillery.

Who should Drink Brandied Wine, and who Pure Wine?—They should drink brandied wine who really require strong alcohol, such as persons in serious and critical states of debility, flooding, fever, etc.; the very aged and others who cannot digest wine, and any one in great fatigue who really is forced to goad the stomach by a concentrated stimulant. (I may observe that many people think pure sherry as bad as claret.) The persons who should drink pure wine are the healthy population in general, and especially the young and vigorous, if they drink any—for why should innocent young children and girls drink brandy?—the thousands of persons who complain of irritable throats and bronchitis; those who are liable to boils, scrofula, skin diseases, chlorosis, or other cachexies; the gouty and rheumatic and phthisical, above all others, and those who are in want of good pure blood.

Wine Duties.—One word in conclusion on the wine duties. I may recall to my readers' recollection that natural unbrandied wine contains alcohol equal to from about 14 to 24 per cent. of proof spirit; that wine containing less than 26° pays 1s. per gallon; from 26° to 42°, 2s. 6d. per gallon; and 3d. for every degree of strength above 42°. On the whole, this rate of duty is beneficial and equitable, and it carries the important moral lesson into every household of the natural strength of wine. Occasional hardships there are, no doubt; for instance, if a natural wine, or a wine which has concentrated in cask, comes over with 27°, it is a hardship that the duty should jump to 2s. 6d. per gallon for one degree of extra strength. Again, some authorities, such as Mr. Shaw, demand that all wine, no matter how fortified, shall come in at 1s., on the plea that the revenue would be increased, and the consumption of heavy wines be largely increased, and that heavy wines are the only ones people care to drink.

For my own part, looking upon taxation not only as a means of raising money, but as an instrument for modifying habits and tastes, I would most respectfully urge the Chancellor of the Exchequer to show every favour to pure wine. This must react in time on the manufacturers, who will supply us with a better fermented and more wholesome liquor, not requiring brandy to keep it. The wine-makers would have no temptation to brandy their wine, if it would keep. In the next place, it would be a gross injustice to the "lower orders" to tax their spirit which they drink as gin, 10s. 6d. per gallon, and let in the same spirit, in the shape of fortified wine, for their "betters" really duty free; for if fortified wine pay no more than pure wine, the added spirit is let in free.

That which is demanded by many is a sort of sliding scale, so that every degree above 26° shall be charged 2d. With the admirable arrangements at the Custom-house this could be easily done; for the determination of the alcoholic strength of wines is made with marvellous precision and rapidity. Thus a wine at 26° would be 1s.; at 27°, 1s. 2d.; at 30°, 1s. 8d., and so on. All the natural wines and finest sherries

would thus come in at an easy rate, whilst the ill-made and fermentescible stuff which will not keep without added spirit would be trounced as it deserves.

Here I stop. Looking on my Professional brethren as missionaries of health, philosophy, and morals to the bulk of the people, I ardently desire their approbation of this humble attempt to promote the use of good wine; and I cannot forbear transcribing a portion of a letter from a well-known Physician, which I honestly confess gave me extreme satisfaction, not merely because praise is dear to me, but because it justifies me for having ventured to bring the subject before the Medical Profession. "I am glad to find White Keffesia so cheap. It suited my palate and stomach better than any wine I remember to have tasted. . . . I have read all your papers, and feel not a little indebted for the immense amount of information they have given me, in a form concise, pleasant, and easy to remember. . . . I firmly believe that the great majority of my brother Doctors would say the same. . . . I only hope others have got as many hints, both for their own and their patients' benefit, as I have out of these papers."

GENERAL MEDICAL COUNCIL.

The General Medical Council commenced its annual sittings at the Royal College of Physicians on Tuesday, April 4.

The following is the list of members present at the sittings :—

Dr. Burrows (President),
Dr. Alderson,
Mr. Arnott,
Mr. Cooper,
Dr. Acland,
Dr. Paget,
Dr. Embleton,
Dr. Storrar,
Dr. Andrew Wood,
Dr. Fleming,
Mr. Syme,
Dr. Thomson,
Dr. Smith,
Mr. Hargrave,
Dr. Leet,
Dr. Apjohn,
Dr. Corrigan,
Dr. Sharpey,
Dr. Parkes,
Dr. Quain,
Mr. Rumsey,
Dr. Christison,
Dr. Stokes, and
(Dr. Francis Hawkins, Registrar.)

The President, in opening the proceedings, said that the very peculiar nature of the business to be transacted this year required the Council to meet at an earlier period than usual; and he much regretted to learn that the period which he had been called upon to fix was not altogether in accordance with the wishes of many of the members, and no doubt had led to the inconvenience of others. When, however, he looked round and observed the chairs all occupied by distinguished men, some holding most important offices as Medical teachers at our universities, and others holding prominent positions in various localities, he believed it quite impossible to fix any time for the assembling of the Council which would not be attended with more or less inconvenience to its members. Of all the duties which devolved upon him as President, the least agreeable was that of deciding the time for the meeting of the Council. Appeals of a conflicting character were very naturally made to him from different quarters as to the time of meeting, and it was very painful not to be able to respond to them; and therefore it was with peculiar pleasure that he had observed that the Irish Branch Council had taken the subject into their consideration, and would probably propose some modification of the standing orders relieving the President from the responsibility of fixing the time of meeting. He feared, however, that the proposition of the Irish Branch Council, as far as he understood it, would hardly accomplish the desired object. In the month of January the Scotch Branch Council passed a resolution from which it might be inferred that they deemed it important that there should be a very early meeting of the Council this year, and in the latter part of the same month he called the attention of the English Branch Council to that resolution. After due deliberation, the English Branch generally agreed that the meeting this year should be earlier than usual, and that the time at which they were now assembled would probably be the most convenient, and give an opportunity for the accomplishment of one object which they had in view. At a later period he learned that the Irish Branch Council were not of the same opinion, and that they believed delay would be advantageous, and that the deferring of the meeting till after the Easter recess would be more likely to conduce to the attainment of the objects of the Council with respect to fresh legislation. That opinion might be quite correct, but he feared that their proposal that the President should appeal to the three Branch Councils before fixing the time for the meeting would not exonerate him from the responsibility of deciding. He assured them that in giving his decision he had not been actuated by any consideration of personal convenience, but he had endeavoured to the best of his ability to suit the time to the nature of the business to be transacted, and after obtaining information from Parliamentary agents and other sources he had assumed the responsibility of summoning the Council for the present time. Whatever might be the opinions of the members of the Council as to the time of meeting, he felt confident that now they had assembled they would all earnestly and cordially co-operate in an effort to expedite public business and grapple with those questions that pressed for solution and decision. Those questions were, first, the amendment of the Medical Act; and, second, the question of Medical registration and education, the consideration of which had been temporarily suspended through the rising of the Council last year. Looking back with a pleasurable remembrance on the year during which he had filled the office of President, he felt assured that he could reckon upon the loyal and generous support of all the members to enable him to conduct their deliberations with that regularity, order, calmness, and dignity which ought to characterise the proceedings of the General Medical Council, and which were essential to the proper protection of the public and Professional interests with which they were entrusted.

The following were appointed as a Committee for the transaction of the business of the Council during the present session :—Dr. Andrew Wood, Dr. Acland, Mr. Rumsey, and Dr. Alderson.

The following were appointed as a Finance Committee :—Dr. Sharpey, Mr. Arnott, Dr. Fleming, Dr. Aquilla Smith, and Dr. Quain.

Dr. Andrew Wood moved—"That the consideration of the question of the amendment of the Medical Acts shall take precedence of all other business." He said that he did not think the motion would require much enforcing. Whatever had been the opinion of the Council on the subject in previous years, it was now absolutely necessary for the Council to take action in the matter, unless they wished to be superseded by another body. The excuse had been formerly made that the matter had been brought forward so late in the session that it was impossible for the Council to deal with it. He had therefore resolved to do away with that excuse by bringing it forward as early as possible. With regard to the time of the meeting of the Council, he had listened with much satisfaction to the explanation of the President, but he much regretted that the meeting was not fixed for an earlier date. He then called attention to the position in which the subject was left at the rising of the Council last year, and said that what was actually carried was that it be committed to the Branch Councils to consider the needed amendments in the Medical Act, and communicate the result of their deliberations to the General Council. The Branch Councils had acted in accordance with that resolution, and the present Council had the result before them. It would now be their duty to consider what amendments they should adopt, get them drafted by a Parliamentary solicitor, and put the bill into the hands of the Secretary of State. He believed that unless the bill were taken up by the Government, there would be no chance of improvement in the legislation.

Dr. Corrigan said he believed nothing could be done at present in the matter, but he should, under the circumstances, support the resolution. The Irish Branch Council had been charged in the press and elsewhere with being obstructive in the matter, and he wished now to openly rebut that charge. He was glad to see the press now represented, although he had refrained from entering the arena outside the Council, and answering the attacks which had been made by anonymous writers. He stated that the first proposal for the amendmend of the Medical Act originated with him after consultation with his colleagues on the Irish Branch Council. They repeated their proposal year after year, and in the year 1864 the English Branch Council passed a resolution to the effect that it would be inexpedient to interfere with the existing legislation. Who had been the obstructives time after time? It was neither the Irish Branch Council nor the Scotch Branch Council, but the obstruction took place with the General Council, and it was no use to disguise the fact.

Mr. Arnott said he should neither vote for nor against the motion, but he was not satisfied that the time had come for

new legislation. He contended that the powers now possessed by the Council had never been fairly tried, and therefore any alteration would be premature. The question might arise whether the Council was so constituted as best to promote and protect the interests of the public on the one hand and the Profession on the other. He for one believed that the Council was too numerous, and he was not at all satisfied that it was well constituted for effecting the purposes it had in view. He contended, however, that it had the power to lay down a scheme of Professional education, and he should hesitate to go to Parliament for further enactments until those now existing had been properly applied.

Mr. Hargrave said the Council had, at all events, whether it was or was not constituted in the best way, done much good in bringing into the Profession a class of very highly-educated men, and publishing a valuable Pharmacopœia.

Dr. Aquilla Smith said that the fixing of the meeting of the Council for the present time was due to the English Branch Council. With regard to the remarks of Mr. Arnott as to the powers of the Council not having been fully tried, he believed that they had tried all the powers they had, and the result proved that they had really no powers at all.

Dr. Paget rose to ask the Council whether there was any objection, as a mere formal matter, to receive the communications to the Council, so that they might be placed in the hands of the printer rather than be delayed perhaps three or four days during the discussion of the Medical Act. As to the time of the meeting, he believed the English Branch Council had merely meant to express an opinion that if the meeting were delayed, legislation in the present session of Parliament would be more difficult, and that opinion was founded on the representation which had been made to them that the Bill would probably have to remain in the hands of the Secretary of State before anything were done.

Dr. Andrew Wood, in reply to Mr. Arnott, said that that gentleman seemed to consider they should not go to Parliament lest Parliament should say the Council was not qualified for its duty, and that it ought to be abolished. That, however, was one of the strongest reasons why they should go to the Legislature at once, for if the Council were inapt or unqualified for its work, let it be superseded by some other body better adapted for the attainment of the end in view. As to the powers of the Council not having been fully tried, he contended that they had been tried to their greatest extent, and found wanting. The Council would not be true to itself, to the public, and to the Profession, unless it endeavoured to remedy the defects which now existed.

The motion was then put, and carried *nem. con.*

Dr. Andrew Wood moved that the names should be taken down of those who voted and those who did not.

Dr. Aquilla Smith seconded the motion.

The President said the resolution had been carried without a dissentient voice. Very possibly some had not held up their hands because they thought the motion would not be opposed. The standing order was that when there was a division the names might be taken, but there had been no division in this instance.

After some little discussion, the motion relative to the consideration of the Medical Act was again put, and there appeared, for it 18, and against it none, two or three of the Council declining to vote.

Drs. Wood and Smith pressed their request to have the names taken down.

Mr. Hargrave said he should like the names taken down, in order that those who had voted might be defended from the attacks of those outside the Council.

Dr. Paget moved, and Mr. Rumsey seconded, that certain communications to the Council should be printed.

Dr. Corrigan objected to the printing of communications of the contents of which the Council knew nothing.

Dr. Paget said he did not propose to have them entered on the minutes, but merely to print them that they might be placed in the hands of the members.

Dr. Andrew Wood said that the motion for the consideration of the Medical Act precluded any other business till that had been disposed of. He therefore moved that the communications which had been received relative to the amendment of the Medical Act should be referred to a Committee to be reported on.

The motion was seconded by Mr. Hargrave, and carried unanimously.

Dr. Wood moved, "That the Committee consist of Dr. Embleton (chairman), Dr. Acland, Dr. Paget, Dr. Fleming, and Dr. Aquilla Smith."

The motion was seconded and agreed to.

Dr. Wood moved, and Dr. Embleton seconded, "That the communications of the various Branch Councils relative to the amendment of the Medical Act be read, and used as the basis of the proceedings of the present Council."

The clauses in the Act in which amendments were proposed were 20, 31, and 40.

The communications of the Branch Councils relative to clause 20 were then read by the Registrar.

Dr. Andrew Wood suggested that the Council should then proceed to discuss that clause before the communications as to the other clauses were laid before the meeting.

Dr. Paget said it would perhaps be better to discuss first that clause on which there was least diversity of opinion, namely, clause 40.

Dr. Andrew Wood thought it would be better to adhere to the natural order.

Dr. Corrigan thought the whole of the Act should be discussed. The Council were not unanimous as to the other parts of the Act; and it would be a piece of patchwork to repair three clauses when the whole Bill needed to be re-considered. The more common-sense way of dealing with the subject was to go through the Act clause by clause. When the Amendment Bill was laid before the Secretary of State he would be deluged with communications on the subject of the whole Act, and he would naturally say, "I cannot do anything with this Amendment Bill, for the Medical Council, who should have considered the whole Act, have given their attention to only three clauses of it."

Dr. Andrew Wood said that what occurred last year was a sufficient reason for proceeding with the three clauses in question.

Mr. Arnott said that he thought Dr. Wood would do the question more justice by allowing the discussion to be deferred till to-morrow. The members of the Council would then be better prepared for the consideration of the subject.

The President said it would probably be desirable to act on the resolution requiring the communications from the Branch Councils to be read.

The communications on the remaining clauses (31 and 40) were then read by the Registrar.

The President suggested that the resolutions of the three Branch Councils should be printed on the minutes for easy reference.

The suggestion was agreed to.

Dr. Andrew Wood moved "That the Council now proceed to consider the expediency of amending Clause xx. of the Medical Act, and that the following resolution be adopted:—'That the amended Bill should contain clauses conferring on the Medical Council definite powers to issue to the various licensing bodies regulations on the subject of preliminary and Professional education and examination; and that, in order to carry out that object, clauses to the following effect be adopted, viz.:—'That it shall be lawful for the General Medical Council from time to time to issue to the various licensing bodies such regulations respecting the Preliminary and Professional education and examination of persons desirous of obtaining any of the qualifications mentioned in Schedule (A) to the Medical Act, as may appear to the Council fitted to secure, on the part of such persons, the requisite knowledge and skill for the efficient practice of their Profession. That all such regulations as shall have been passed by a majority of two-thirds of the General Council shall be obligatory on all Universities, Colleges, and other Bodies enumerated in Schedule (A) to the Medical Act of 1858. That, in the event of any of the said bodies not conforming to such regulations, it shall be lawful for the General Council, if they see fit, to intimate to the said body that it has not conformed to such regulations, and to direct that, in the event of the said body not conforming within six months after such intimation, the qualification granted by such body, after the lapse of the said period of six months, shall not be registered. That it shall be lawful for any body in regard to which such directions shall have been given to appeal to the Privy Council, who shall have power, if they see cause, to disallow the direction of the Medical Council. That it shall be lawful for the General Council to restore any right to registration which may have been suspended by them, when they shall be satisfied that their regulations have been conformed to.'" He said that the reason for taking legislative action in this matter was, that the Council might recommend to the various educating

licensing bodies the course they considered desirable; but those bodies might, if they chose, entirely disregard those recommendations. It was true that the recommendations might be enforced by an appeal to the Privy Council, and that that course had not been taken; but it was most desirable that the Council should have the power of initiating and enforcing regulations, and of suspending any licensing body which did not conform to them. In order, however, to check any arbitrary exercise of power by the Council, the resolution provided that no recommendation should be enforced which had not received the sanction of two-thirds of the Council. The resolution was in the terms of the recommendation of the Scotch Branch Council.

Professor Syme seconded the motion, and, in doing so, remarked that moral suasion, which was advocated by some, had not, of itself, been found effectual. In one instance he had tried to induce the Council to report a certain body to the Privy Council, but after a lengthy consideration of the circumstances, they came to the conclusion that it would not be expedient to take that step. Moral suasion had been much applauded among them, but, with all his admiration for it, he did not deem it adequate to meet the case they had before them.

Mr. Arnott said he did not think that the Council would agree to the resolution. In England, at least, the influence of moral suasion had been effective, and the requirements of the Council as to preliminary education had been complied with, and he believed it would continue to be effective if no imperative powers were conferred on the Council. There was, however, great doubt as to what the Council really required in respect to preliminary education. As to Professional education, he did not consider that the Council should be entrusted with the imperative power of saying that no man should commence his Professional career until he had had a certain amount of instruction at a Medical School. He did not believe that such a power would be conferred by the Legislature.

Mr. Hargreave said that in the resolution before the Council they were beginning at the wrong end of the question. They were seeking amended legislation and further powers when they ought to be dealing with the questions of education and registration. As regarded compulsory powers, he did not think the constitution of the Council was such that they ought to be entrusted with them. There were only two pure Surgeons in the whole body. ("Oh.")

Dr. Corrigan proposed as an amendment,—"That the whole Medical Act should be taken into consideration, clause by clause, for approval or amendment, as the taking into consideration of only three clauses must lead to an imperfectly considered Bill, which would not command the attention of the Legislature." He said the essential difference between the Scotch and Irish Branch Councils was that the latter had recorded their opinion that the Council should not have power to enforce regulations before they had received the sanction of the Legislature, while the Scotch Branch Council proposed that the General Council should have the power of making and enforcing regulations without first submitting them to the Privy Council, but reserved to the licensing bodies the right of appeal to the Privy Council. Mr. Hargreave was in error in saying that the College of Surgeons were ready to comply with the requirements of this Council. On the contrary, there was in Churchill's "Medical Directory" a resolution of the College of Surgeons to the effect that they would not comply, because other bodies had not done so. (Hear, hear.)

Dr. Sharpey said he entirely concurred with the resolutions of the English Branch Council, and he believed that those resolutions were in accordance with the spirit of the amendment proposed by Dr. Corrigan. With regard to the general subject of new legislation, he was of opinion that there had been a large amount of compliance in England with the requirements of the Medical Council, and he wished the Scotch Branch Council could devise some means for securing an equal amount of compliance in Scotland. He felt sure, however, that any attempt to bring about a general assimilation in all points would fail, especially with regard to the subjects of study in preliminary education. There was a general agreement as to what those subjects should be, but any attempt to secure more than that would not be attended with good results. As to the respective merits of the suggestions of the English and Scotch Branch Councils with regard to the appeal to the Privy Council, he thought it better for the Medical Council to submit their regulations to the Privy Council before endeavouring to enforce them than to frame them independently of the Privy Council and reserve the right of appeal. It would be less inconvenient for the Medical Council to obtain the preliminary sanction of the Privy Council than to have their regulations disallowed. He should second the amendment of Dr. Corrigan.

Dr. Christison supported Dr. Corrigan's view as to the desirability of reconsidering the whole of the Medical Act before going to the Legislature. He was also of opinion that the application to the Privy Council should take place before the Medical Council attempted to enforce their regulations.

Dr. Andrew Wood said he wished to withdraw his motion.

Dr. Corrigan said he could not agree to that course, as the motion was the theme on which the amendment was based.

Dr. Paget said he considered it would be very inconvenient for the Medical Council to submit their regulations to the Privy Council before they had the right to enforce them, and such a practice would stand in the way of any modifications of the regulations which might from time to time appear desirable.

Dr. Storrar said that the impression which would be conveyed by the recommendations passed in previous years was, that the Medical Council either thought themselves wrong in taking the subject in hand, or that they had not the courage to go forward. He did not think them wrong, but he believed they had not the courage to go forward. The new powers proposed by the motion might prove a very dangerous weapon in the hands of the Council, and he considered the Council wholly incompetent to lay down a universal scheme for preliminary education for the nineteen bodies represented at the Council. They had not as yet exercised the powers which they had, and therefore they had no case for seeking new ones.

Dr. Quain said he thought the amendment objectionable. It would be better to take the three important clauses first, and then the other part of the Bill could be taken clause by clause.

The amendment and motion were then put to the meeting. The numbers were—For the amendment 7, and for the original motion 11.

The original motion was then put separately, when there appeared—For it 3, and against it 14.

Dr. Andrew Wood gave notice that he should bring forward another motion with reference to Clause 20 on the following day.

The Council then adjourned.

WEDNESDAY, APRIL 5.

(SECOND DAY.)

The Council re-assembled at 2 o'clock. The roll was called, and the minutes of yesterday's meeting were read and confirmed.

Dr. Corrigan asked whether there was an official shorthand writer in attendance as last year?

The Registrar said there was not.

Mr. Syme said when it was resolved that a special reporter should attend last year, it was not known that the press would be represented. The reports in the public papers last year answered every purpose.

The Registrar read the minute of last year's proceedings relating to the special reporter.

Dr. Corrigan said he only wanted to bring out the fact that the absence of a special reporter was not an infraction of the resolution of last year.

The President said the subject had not been lost sight of, and that it was under consideration yesterday.

Dr. Andrew Wood rose to bring forward a motion of which he had given notice yesterday in relation to the amendment of clause 20 of the Medical Act. He said the rejection of the resolutions of the Scotch Branch Council yesterday left the General Council only two courses open to them, instead of three. These were the adoption of the resolutions either of the English Branch or Irish Branch. The adoption of the English Branch Council's resolutions would be practically the adoption of nothing at all, for they recommended that the legislation should remain *in statu quo*. He repudiated the idea of the regulations of the Medical Council being left simply to moral suasion to be enforced. As the Council had rejected the Scotch dose as too strong for them, he had now to present to them the Irish dose, which was milder, and would possibly be accepted by them. The proposal was that it should be enacted that the regulations framed by the Council should be submitted to the Privy Council for endorsement, and that they should then be capable of enforcement

on the educational bodies, the right of appeal to the Privy Council being reserved to such bodies as might not comply with them. He doubted very much whether, after regulations had been carefully framed by the Medical Council, whose special business it was to consider such matters, and been endorsed by the Privy Council, the Privy Council would give any aid to recalcitrant Medical bodies. He believed that practically the recommendation of the Irish Branch Council would be effective. He should, therefore, move—"That the following be adopted as an amendment of Clause 20 of the Medical Act:—'It shall be lawful for the General Council from time to time to lay down such regulations respecting the education and examination of Practitioners in Medicine and Surgery as may appear to them fitted to ensure adequate knowledge and skill in the practice of their Profession. And the said General Council shall submit said regulations to Her Majesty's most honourable Privy Council. And the said regulations, if sanctioned by the said Privy Council, shall then be obligatory upon all Universities, Colleges, and other bodies enumerated in the Act. And it shall be lawful for the Privy Council, upon its being represented to them that any University, College, or other body enumerated in the Act does not comply with such regulations, to declare that any qualification granted by such University, College, or body shall not confer any right to be registered under the Act. Provided always that it shall be lawful for Her Majesty, with the advice of her Privy Council, when it is made to appear to her, upon further representation from the General Council or otherwise, that such College or body has made effectual provision, to the satisfaction of such General Council, for the improvement of its course of study or examinations, or the mode of conducting its examinations, to revoke any such order.'"

Dr. Corrigan rose to order. He said the motion could not be entertained, though if it could he should vote in its favour. A motion and amendment on the subject having been made and negatived already this session, the standing orders precluded another motion on the same subject.

The President, after some discussion, ruled that the motion was in order.

Dr. Lee seconded the motion.

Professor Syme moved the following amendment:—"That Clause 20 of the Medical Act stand as it is at present, and that if any of the bodies mentioned in Schedule (A) should decline or neglect to comply with the recommendations of the Council with regard to education, whether preliminary or Professional, the Council shall express their disapprobation."

Mr. Hargrave seconded the amendment. He said it would be the effect of pouring oil on the troubled water.

Dr. Corrigan said he should support the motion of Dr. Wood. He could not agree with the amendment of Professor Syme, which was in favour of moral suasion. He was beginning to get a perception of what moral suasion was. It was the principle that in the event of any body not complying with the regulations of the Council as to education, the Council should express its disapprobation. It was remarkable that the amendment for the expression of disapprobation should be moved and seconded by the representatives of two recalcitrant bodies—the University of Edinburgh and the College of Surgeons of London.

Dr. Christison said that the University of Edinburgh were much more blameless than Dr. Corrigan thought. They had refused to comply with a certain regulation of the Council, but they did so because they discovered that in making that regulation the Council had exceeded its powers. There was another point with which they had not complied, because it was thought unadvisable; but although there had been an appearance of misconduct on their part, there was really no wish to act contrary to the Council.

The amendment and motion were then put. The numbers were,—for the amendment, 10; against it, 11.

Dr. Embleton moved,—"That Clause 20 of the Medical Act of 1858 stand as it is at present." He considered that the powers conferred by it were quite sufficient, but the Council had not made use of them. The age of moral suasion seemed to be returning, and he thought the Council would now have a worse case for compulsory powers than they had before.

Mr. Rumsey seconded the amendment, and said that the Council should use the powers they had before they asked for more. If any Medical body did not comply with the regulations of the Council, did they take means to carry them into effect?

Dr. Fleming said he considered that it was intended by the Legislature that the Medical Council should have compulsory powers of regulating the practice of educational and licensing bodies. They were well qualified to decide on questions of education and registration, and if an application were made to the Legislature for an alteration of the Act, he should not fear the result. He did not approve of the regulations of the Council being submitted to the Privy Council for endorsement. The Privy Council was composed of noblemen and gentlemen not acquainted with Medical subjects. They would probably confer with some Medical man unknown to the Medical Council, and he would practically be the person who decided the whole question.

Dr. Corrigan, in reference to the statement that the powers of the Council had never been tried, said that that was quite true, and they never would be. There were different bodies who had neglected to comply with the regulations of the Council, and the powers could be tried within two days. He maintained that they dared not appeal to the Privy Council in reference to the bodies he alluded to, and he wished to know when the occasion was to arise. As long as the Act remained as it was, the standard of education would never be improved.

Mr. Arnott said it was contrary to the whole spirit of English legislation for a body like the Medical Council to be raised up, and to seek the sweeping powers which were contemplated by the motion. It was not desirable to interfere with the different educating bodies for the purpose of securing a uniform system of education. There was no uniform way of educating a clergyman or a lawyer, and the attempt should not be made in the present case to lay down a uniform plan of education for Medical Schools.

The amendment was then put. There appeared, for it 11, against it 9.

It then assumed, according to the standing orders, the form of a substantive motion.

Dr. Parkes said he did not approve of the resolutions of the Branch Council for England, which was that no alteration should be made in the legislation; and, with regard to those of the Irish Branch, he could not approve of the proposal for the regulations being submitted to the Privy Council for endorsement before they were promulgated. The Privy Council would naturally consult some other Professional persons, who would really be a higher authority than the Medical Council, and possibly override their decisions. He should, therefore, move as an amendment the substance of Dr. Wood's motion of yesterday on the subject, with some slight alterations in the latter part:—"That, with reference to amending Clause 20 of the Medical Act, the following resolution be adopted:—That the amended Bill should contain clauses conferring on the Medical Council definite powers to issue to the various licensing bodies regulations on the subject of preliminary and professional education and examination, and that, in order to carry out that object, clauses to the following effect be adopted—viz., 'That it shall be lawful for the General Medical Council from time to time to issue to the various licensing bodies such regulations respecting the preliminary and professional education and examination of persons desirous of obtaining any of the qualifications mentioned in Schedule (A) to the Medical Act as may appear to the Council fitted to secure, on the part of such persons, the requisite knowledge and skill for the efficient practice of their Profession. That all such regulations as shall have been passed by a majority of three-fourths of the General Council shall be obligatory on all Universities, Colleges, and other bodies enumerated in Schedule (A) to the Medical Act of 1858. That, in the event of any of the said bodies not conforming to such regulations, it shall be lawful for the General Council, if they see fit, to intimate to the said body that it has not conformed to such regulations; and that, in the event of the said body not conforming within six months after such intimation, a representation be made to the Privy Council to authorise the suspension of the registrations, decrees, or licenses of such bodies. That it shall be lawful for any body in regard to which such an intimation shall have been given to appeal to the Privy Council, who shall have power, if they see cause, to disallow the direction of the Medical Council. That it shall be lawful for the General Council to recommend the restoration of any right to registration which may have been suspended by the Privy Council when they shall be satisfied that their regulations have been conformed to.'"

Dr. Fleming seconded the amendment.

Dr. Corrigan said he did not think the amendment would

confer any additional power on the Council. It provided for an application to the Privy Council to have the registering and licensing powers of recalcitrant bodies suspended. That power was conferred by the existing Act.

Dr. Andrew Wood supported the amendment.

Mr. Rumsey said it seemed that Dr. Parkes had overlooked clause 21 of the Act. That really contained the provisions suggested by the amendment before the meeting.

The amendment was put; the numbers were—For it, 5; against it, 12.

The motion of Dr. Embleton, for the legislation to remain as at present, was then put:—For, 12; against, 8.

The motion was therefore carried.

The resolutions of the three Branch Councils relative to section 31 of the Medical Act were read by the Registrar.

The President observed that the suggestions of the English and Scotch Branch Councils as to Clause 31 very much coincided, and they did not recommend any alteration. The Irish Branch Council, however, proposed an important modification.

Dr. Quain moved that Clause 31 remain unaltered.

Dr. Alderson seconded the motion.

Dr. Embleton recommended the postponement of the discussion of the question, as there was a Bill before Parliament with reference to Pharmacy. He moved a resolution to that effect.

Dr. Parkes asked whether the English Branch Council thought Clause 31 threw some obstacles in the way of that union of Medical bodies which Clause 19 contemplated.

Dr. Storrar stated that they were not of that opinion.

Dr. Paget seconded the amendment.

On a vote being taken, there were for the amendment 11, and against it 7.

The amendment was therefore taken as a substantive motion, and put accordingly. There were for it 11, and against it 5.

The recommendations of the three Branch Councils as to Clause 40 of the Medical Act were then read.

Dr. Quain said the object of the clause was to enable the public to distinguish between qualified and unqualified Practitioners, but in that respect it had been an entire failure. It was necessary that some alteration in the law should be made to protect the public, and to guard the Profession against having attributed to them the misconduct of unqualified persons calling themselves Doctors or Surgeons. He did not, however, think that registration should be made compulsory before a person was allowed to practise; but he considered that, as recommended by the English Branch, persons practising without the qualification specified by the Act should be subject to a penalty. He should therefore move the following clause in amendment of the 40th clause of the Act:—"Any person practising Medicine or Surgery, or being engaged in the treatment of diseases or injuries, not being registered under this Act, nor being able to give evidence of being qualified to be registered under this Act, who shall take or make use of any of the titles or designations enumerated in Schedule (A) to this Act, or that of Physician, Surgeon, Doctor, Professor of Medicine, Professor of Surgery, or any Professional title, name, or distinction commonly used by, or used to distinguish, duly educated or qualified Practitioners in Medicine or Surgery, shall upon a summary conviction, be liable to a penalty not exceeding £20 for each offence." That was the resolution of the English Branch Council, with the omission of the words "for gain."

Dr. Paget seconded the motion.

Dr. Andrew Wood moved, as an amendment, the adoption of the following clause:—"Any person practising Medicine or Surgery, or being engaged in the treatment of diseases or injuries, not being registered under this Act, who shall take or make use of any of the titles or designations enumerated in Schedule (A) to this Act, or that of Physician, Surgeon, Doctor, Professor of Medicine, Professor of Surgery, or any title, name, or distinction used by, or used to distinguish, duly educated or qualified Practitioners in Medicine or Surgery, shall, upon a summary conviction, be liable to a penalty not exceeding £20 for each offence." He said that the clause should be framed so that a very small amount of evidence would be required in a court of law to prove the offence of practising without due qualification. Nothing could be simpler than the proposal he had submitted, which was that persons should not practise unless they were registered. The words, as proposed in the original motion, "not being able to give evidence of being qualified to be registered," would very much complicate the matter. The past year had been prolific of instances of the necessity of protecting the public against the extortions of unqualified men. He wished it to be distinctly understood by the public that, in attempting to improve legislation in this respect, they were doing it for the protection of the public, and not for their own benefit. There was an impression among some Parliamentary men that Doctors wished to have a monopoly. It was important to correct that mistake. The subject was really more important to the public than to Medical men. He did not wish to prevent duly-qualified persons from practising if they were not registered, and he would never attempt to do so.

Dr. Christison seconded the amendment.

Dr. Acland said that as he understood the amendment it would have the effect of compelling persons who practised to be registered. He thought that compulsory power was proper; but there were difficulties in enforcing it. Some duly qualified persons, from eccentricity or other reasons, objected to be on the register. He considered, however, that it would be no grievance to compel them, for the general weal, to appear on the register if they practised.

Mr. Rumsey said that the list of titles enumerated in the amendment was not complete. The list should either be complete or entirely omitted. He was in favour of its omission, as the ingenuity of quacks would devise designations, however long the list in the Act of Parliament might be.

Dr. Wood agreed to substitute the words "or any other title, name, or designation used by" for "or any Professional title, name, or distinction commonly used by," as the amendment originally stood.

Dr. Quain said that nobody was more in favour of compulsory registration than he was; but he did not think it could be obtained. Monopoly was always charged upon them whenever they agitated the question.

The amendment was put. There were in favour of it, 14; against it, 4. It was then taken as a substantive motion.

Dr. Corrigan rose to move an amendment. He said they all had one object in view; but there was a difference of opinion as to how it should be secured. He should move the adoption of the alteration proposed by the Irish Branch Council, which was, "That on and after the day of it shall not be lawful for any person, unless registered under the Act, to pretend to be or take or use the name or title of Physician, Doctor of Medicine, Licentiate in Medicine or Surgery, Master in Surgery, Bachelor of Medicine, Doctor, Surgeon, Medical or General Practitioner, or Surgeon, or Apothecary, or Accoucheur, or Licentiate or Practitioner in Midwifery, or any other Medical or Surgical name or title; and any unregistered person so offending shall forfeit and pay a sum not exceeding £20, to be recovered in a summary way before the justices of the peace." There was very little difference between this and the motion of Dr. Wood. The difference was that by the alteration proposed by Dr. Wood it would be necessary to prove that a man not only improperly assumed a Medical or Surgical title, but that he also practised; whereas, the suggestion of the Irish Council would make it penal to assume the title, whether he practised or not. He regarded the necessity to prove both the assumption of the title and the fact of practising as fatal to the operation of the clause.

Dr. Stokes seconded the amendment.

Dr. Paget objected to the amendment. He said that the Act was one to regulate "Practitioners in Medicine and Surgery," and he thought it utterly impossible that Parliament would sanction a penal clause against persons who did not practise.

Dr. Quain said there were 10 per cent. of qualified persons who were not registered. If registration were made compulsory, it would exclude from practice persons holding the degree of Bachelor of Medicine, who were qualified to practise, though not registered.

The President said that Dr. Storrar had given notice of a motion on that subject.

The amendment and motion were put by the President. There appeared—for the amendment, 3; against it, 15.

The motion of Dr. Wood was then put and carried *nem. con.*

Dr. Wood said that now the Council had decided that an alteration should be made in the Act, protecting the public against unqualified Practitioners, it was necessary to take action in the matter. It was desirable that an arrangement should be made for ensuring prosecutions, and he should probably himself bring forward a motion on the subject in the morning. He should now move that a Committee be appointed to draw up a memorial to the Home Secretary in reference to the amendment of the Medical Act, and to report to the Council."

Dr. Paget seconded the motion.

Dr. Paget moved "That the communications from the Directors-General of the army and navy Medical Departments, relative to the examinations of the candidates for Medical commissions, be referred to a committee to report thereon."

Dr. Andrew Wood said the communications should be read before they were referred to a committee. They were addressed to the Council, and should be fully laid before them.

After some discussion,

Dr. Paget moved, and Dr. Arjohn seconded, "That the communications be printed entire for the use of the Council."

Dr. Storrar moved as an amendment that the papers should be first read. They might contain confidential matter.

Dr. Corrigan seconded the amendment.

The amendment was carried.

The Council rose at 6 o'clock.

REVIEWS.

A Manual of Practical Therapeutics, considered chiefly with reference to Articles of the Materia Medica. By E. J. Waring, F.R.C.S., etc. Second Edition. Pp. 956. London: John Churchill and Sons.

Both student and Practitioner must find, we feel assured, in Mr. Waring's work a very useful volume. We have already noticed it (*Med. Times and Gaz.*, September 30, 1854), when in its first edition, eleven years ago, and then saw reason to commend it.

The publication of this, its second, edition has, like that of the last editions of several other works on Therapeutics and Materia Medica, been delayed, as the author states, for the appearance of the British Pharmacopœia. Besides alterations to bring it in accordance with this, notices of medicines introduced since its first edition have been added, and existing articles modified to suit the present state of opinion on their subject matter. In the preface to this edition the author remarks in explanation of some of these modifications,—

"Since the publication of the first edition of this work the treatment of inflammatory and febrile affections has been in a transition state, diffusible stimulants having, in a great measure, replaced blood-letting and other antiphlogistic remedies formerly in vogue. Although I have been unable fully to recognise the great asserted superiority of the new mode of treatment, to the total exclusion of other measures, which centuries of experience have proved to exercise valuable remedial powers, yet my own more extended experience, as well as the recorded cases of others, has conclusively shown that the old mode of treatment was capable of great improvement, and that we may have recourse, with manifest advantage, to stimulants at an earlier period and in larger quantities than was formerly considered either advisable or safe. A similar remark applies with equal force to the employment of quinine in the treatment of paroxysmal fevers, in which depletion and calomel are, in a great measure, replaced by the preparations of cinchona."

Improved as this edition is, and brought now more immediately under the notice of the English student, we shall give a short summary of its plan and contents, although we have already briefly noticed it on its first appearance, more especially as this appearance was eleven years ago, and that the first edition has been for some time out of print.

Its object, we may remind our readers in the author's words, formerly quoted by us, is to give collected, and brought "within a small compass, the opinions and experience of the most eminent writers of modern times, as to the real value of the articles of the materia medica in the treatment of disease;" and honestly, and with discrimination, we may add, has this object been accomplished. After a short introduction, follow —Part I., on "Articles of the Materia Medica;" Part II., on "Medicinal Agents and Classes of Medicines;" an Index of Diseases; and, lastly, a general index. An alphabetical arrangement is followed throughout the volume. Part I., forming the great bulk of the book, gives under each medicine critical accounts, generally excellent, of its value in different diseases, with copious references to authorities, and the modes of administration they recommend added. These accounts are preceded by the usual definitions of each medicine both as a drug and natural object, its source, and a brief notice, in finer type, of its medicinal properties and action. In Part II. we also find much valuable matter, although in "Medicinal Agents and Classes of Medicines" we find a somewhat heterogeneous collection of subjects. The author gives no classification of medicines, but notices most of the classes familiar to English readers. Nor has he evidently yielded to any temptation his subject may have offered to leave "practical" for "theoretical" therapeutics in his remarks on these (alphabetically arranged) classes. Many, we dare say, will commend him for this course. In this part we find fifteen pages devoted to the therapeutic value of *blood-letting*, six additional to *leeches*, eight to *baths*, five to *ice*, seven to *water*, and nearly nine to *electricity*. On the last subject we wish that A. Becquerel's "*Traité des Applications de l'Electricité à la Thérapeutique*" had been in our author's hands, as likely to have increased the value of his useful summary. The Index of Diseases, which extends over almost sixty pages, gives after each disease references to the paragraphs treating of the value of any medicine in it. This part of the volume, although it must enhance its value on the score of convenience, is, perhaps, open to some objection, as being liable to encourage an irrational empiricism in the practice of those who use it. However, we think this objection has not much foundation if the passages indicated are only carefully considered by the reader. To produce such an undesirable result for the sake of the supposed convenience of the Practitioner is plainly far from Mr. Waring's intention, for he says (p. 3):—"The practice of treating a disease according to its name, without minutely examining into each particular case, and adapting the appropriate remedies to the several indications which present themselves, cannot be too strongly reprobated." And, as far as is practicable in a work of the kind, he points out in the several paragraphs these indications. Our readers are, no doubt, aware that Dr. Stillé also includes a similar index of diseases in his splendid work on Therapeutics and Materia Medica.

We have little to say of the author's execution of the plan he set before himself to qualify our approbation other than to note some few imperfections of diction apparent here and there, the consequence, however, rather of hasty compilation of what is really an extensive treatise, despite the small compass into which it has been packed, than to any more serious fault.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, March 28.

Dr. Alderson, F.R.S., President.

An experimental and clinical inquiry, by Dr. Roberts, (communicated by Dr. Bence Jones) was read

ON THE SOLVENT TREATMENT OF URINARY CALCULI.

This paper is divided into two parts. The first part is devoted to experiments and observations relating to the solvent treatment of uric acid calculi by alkalising the urine by internal medicines. The inquiry starts from two known data—namely: first, that uric acid is dissolved by solutions of the alkaline carbonates of a certain strength; and secondly, that alkaline carbonates can be introduced into the urine, so as to render it alkaline, by the administration of certain salts by the mouth. The practicability of dissolving renal and vesical calculi, composed of uric acid, by alkalising the urine, is inquired into under ten headings or sections as follows:— Section 1. Comparison of solutions of carbonate of potash and carbonate of soda: in which it is shown that solutions of carbonate of potash are better solvents for uric acid than solutions of carbonate of soda. Section 2. Comparison of solutions of different strength: in which it is shown that the greatest solvent power (for uric acid) lies in solutions containing from forty to sixty grains of carbonate to the imperial pint. Above this strength dissolution is soon prevented by the formation of a crust of biurate which invests the stone. Below this strength the solvent power gradually declines. Section 3. Comparison of the effects of varying volumes of solutions of constant strength.—It is shown that the quantity of the solution permitted to pass over the stone, between the limits necessarily imposed by the capacity of the kidneys to separate aqueous fluids, is of slight importance. A flow of three or six pints during twenty-four hours was found nearly as effective as a flow of eight or fifteen pints. Section 4. Absolute rate of dissolution of uric-acid calculi in

solutions of the alkaline carbonates.—It is shown that solutions of carbonate of potash, of the maximum solvent power, when passed at the rate of from three to eight pints in the twenty-four hours over uric calculi, at the temperature of the body, dissolve from ten to twenty per cent. of the weight of the stone each day. Section 5. The most convenient way of alkalising the urine, the degree of alkalescence which can be communicated to it, and the doses required to produce the desired effect.—The bicarbonate, acetate, and citrate of potash are found the most effective substances to alkalise the urine. Of the three the citrate is preferred. It is found that forty grains of citrate of potash dissolved in five ounces of water taken every two hours alkalises the urine to a mean degree corresponding with the maximum solvent power of solutions of carbonate of potash. Section 7. The effect of alkalised urine on uric acid calculi.—The urine of a person taking full doses of citrate of potash, as recommended in Section 5, is passed over a uric acid calculus at blood heat. The stone (weighing 180 grains) loses weight at the rate of twelve grains and a-half in the twenty-four hours. In the performance of experiments on this point it came out that if the urine became ammoniacal (from decomposition of urea) it ceased to dissolve the uric acid, and the stone became invested with a crust of precipitated phosphates. Whence the important deduction is drawn that ammoniacal decomposition of the urine in cases of vesical calculi puts an absolute bar to the effectiveness of the solvent treatment by alkaline carbonates. Section 7. Illustrations of the application of the solvent treatment in practice; first in renal calculi, secondly in vesical calculi.—Two cases of complete dissolution of uric acid calculi in the bladder are quoted from other authors. The author relates three cases which occurred in his own practice. In none of the latter did complete dissolution occur. One of the cases proved to be an example of mulberry calculus; another, an alternating calculus of uric acid and oxalate of lime. This second specimen offers peculiarities of surface which indicate with certainty that dissolution of the uric acid had taken place: these peculiarities are explained by the aid of drawings of the stone after extraction. The third case proved abortive apparently because the treatment was not carried on sufficiently long. In neither of the cases was the treatment carried out as effectively (as the later experience of the author showed) as it might have been. The principal instruction from the cases is, the proof they offered that alkalising the urine does not cause the stone to be encrusted with a phosphatic deposit, so long as ammoniacal decomposition of the urine does not take place. Section 8. Discrimination of the cases in which the solvent treatment is and is not applicable.—The conclusions come to are:—That the solvent treatment is inapplicable in all cases where the urine is ammoniacal. When the urine is acid (before treatment) the case is *primâ facie* suitable for the alkaline solvent treatment; but exceptions must be made of cases where it is known or strongly suspected that the stone is composed of oxalate of lime, also where the stone is large. In cases where the urine is acid, and there is no indication of the nature of the stone, it may be either uric acid or oxalate of lime, or an alternating calculus composed of these two substances. Such cases deserve a trial of the solvent treatment for a limited period of a month or six weeks. The cases which are especially suitable for the solvent treatment are those in which (the urine being preliminarily acid) it is known or strongly suspected that the stone is composed of uric acid, and has not yet reached any large size. Section 9. Directions for carrying out the solvent treatment effectually.—The urine must be kept continuously alkaline, and alkaline to a mean degree corresponding with the maximum solvent powers of solutions of carbonate of potash. The treatment must be given up immediately if the urine become ammoniacal. Section 10. An examination of some of the objections which have been urged against the principles of the solvent treatment. The appendix to the first part contains some experiments showing that cystine is even more amenable to the alkaline solvent treatment than uric acid. The second part of the paper contains three sections. Section 1 contains experiments on the solvent treatment of uric acid calculi by injections into the bladder. Solutions of the following substances were tried in a manner to imitate injections into the living bladder:—Bicarbonate and carbonate of potash, common phosphate of soda, basic phosphate of soda, borax, borax with liquor sodæ, potash soap, carbonate of lithia, liquor potassæ, and liquor sodæ. The results obtained demonstrated conclusively that their operation was so slow that no practical advantage could be obtained from their use. Section 2 records some experiments on the effects of a solution of carbonate of potash and dilute nitric acid on oxalate of lime calculi: neither solvent promised any useful result. Section 3 shows the unsusceptibility of phosphatic calculi to solutions of the alkaline carbonates. Brodie's method of injecting dilute nitric acid into the bladder was imitated in one experiment, with results confirmatory of his statement respecting the use of this treatment in phosphatic concretions.

Dr. Harley had derived pleasure and benefit from the reading of the paper. It was valuable, as it combined chemical research with clinical instruction. Upon these two all improvements in Medicine must be based. A want of the knowledge of the chemical constitution of calculi formed the real obstacle to this mode of treatment in its earliest history. We now know that the uric-acid and phosphatic calculi require different chemical agents for their solution. That which was the antidote to the one was the bane to the other—one requiring the treatment by acids, and the other by alkalies. It was in cases of renal calculi, which he believed were more common than vesical, and in which no operation could be performed, that the plan advocated by Dr. Roberts was most valuable. Renal calculi were more easily dissolved by means of chemical agents than vesical, in consequence of the constant flow of urine over them. By a judicious regulation of tests, and a careful examination of the urine at short intervals, the nature of the calculus might be determined, and he believed in many cases might be successfully treated by chemical agents.

Mr. Moore referred to a difficulty which might arise where there were two calculi in the bladder of different chemical constituents; where, for instance, one had a coating of urate of ammonia, and the other was a fusible calculus.

Dr. Roberts having briefly replied, the Society adjourned.

THE PATHOLOGICAL SOCIETY.

Tuesday, March 21.

Dr. Peacock, President.

Mr. Partridge showed specimens taken from the body of a child who had had

MALFORMATION OF THE GENITALS.

The patient had been considered a girl by his parents, as the external parts somewhat resemble those of a female. In what appeared to be the labiæ, however, were bodies which Mr. Partridge conceived to be testes. Mr. Partridge had shown the child to the Society when living, and then one of the members suggested that the bodies were ovaries, and not testes. On dissection after death, however, they were found to be testes.

Mr. Partridge next showed a specimen of

GANGRENE OF THE PENIS.

A man, 45 years of age, who had been sober, and who had never had venereal disease, went to bed ill, and became delirious and unconscious. Eight days later he was seen by a Medical man, who found the penis cold and colourless, and eventually it became gangrenous from root to extremity, and finally separated. The patient rallied under bark, acids, and wine, and good diet. Mr. Partridge supposed that the gangrene followed low fever.

Dr. Murchison said that gangrene of the penis was not very uncommon after fever. He had seen six or seven cases during the recent epidemic.

Mr. Nunn said that he had rarely seen gangrene of the male genitals, although gangrene of the female genitals was not so rare. He had seen one case of gangrene of the penis in the Middlesex Hospital. The patient had not been a sober man.

Dr. Murchison said that in two of six cases he had recently seen there had been gonorrhœa. In one of the six cases there had been gangrene of the nose as well as of the penis.

Dr. Murchison showed specimens of

DISEASED MUSCLE FROM CASES OF TYPHOID FEVER.

He said he had frequently met with hæmorrhage and abscess in muscle after typhoid fever, and in none more frequently than in the rectus abdominis. Zenker, who had described similar conditions, attributed the rupture of the fibre to degenerations of either a granular or a waxy character. No

doubt, in some cases, degeneration of the fibres was seen, but in some it was not to be found. In the specimen which he exhibited he could not satisfy himself that the fibres were much diseased. There was a cavity containing oily and granular matter and corpuscles like pus cells. The patient had died of typhoid, the immediate cause of death being hæmorrhage from the bowels; the whole of the coils of intestine at the lower part of the ileum had sloughed out.

Dr. Murchison then brought forward the

ATROPHIED BRAIN OF AN IDIOT,

from a boy, 17 years of age, who had died of fever in the Fever Hospital. He had the manner and appearance of an idiot, and had always been idiotic. The brain was very small, and the chief bulk of the cranial cavity was occupied by fluid both externally and in the ventricles. It had unfortunately not been weighed at once, but, after having been three or four days in spirit, it weighed twenty-five ounces.

The President said that the brain, though atrophied, was apparently much larger than in other cases on record. The weight of the brain after maceration in spirit could not be compared with other observations, as the organ diminished very much in weight after having been in spirit even a short time.

Mr. Norton exhibited a specimen of

ABSCESS IN THE CEREBELLUM.

It occurred in a boy, 17 years of age, under the care of Dr. Sieveking, at St. Mary's Hospital. The symptoms he presented were extreme pain in the right ear; pain in the course of the right fifth nerve; dull, aching, throbbing pain in the head, extending down the spine, and much relieved on pressure. The pupils dilated; vision double; pulse 70, easily compressed. No delirium until a very late period of the disease, and then but little marked. At the post-mortem examination, the vessels of the dura mater were found much injected. An abscess extended through a large portion of the right hemisphere of the cerebellum. The seventh nerve was highly inflamed; but there was no pus near it. Lymph was deposited over the whole of the interpeduncular space. The anterior surface of the petrous portion of the temporal bone was somewhat softened in the position of the tympanum, and on passing a knife into this part thick yellow pus exuded. Mr. Hinton and Mr. Norton examined the internal ear, and found the membranous labyrinth of the cochlea somewhat thickened, but the semicircular canals apparently healthy.

Dr. Cayley exhibited a specimen of

RUPTURE OF THE CAROTID ARTERY.

The full details of this interesting case will be found in our Hospital Reports.

Dr. Cayley also exhibited a specimen of

TUMOUR OF THE SPINAL CORD.

A woman, 54 years of age, began to have pains in the left inguinal region, and loss of power in the left leg. Six months later both legs were paralysed and anæsthetic. There were occasional twitchings, but no reflex movements. At the autopsy a tumour, supposed to be of a myeloid nature, was found growing from the dura mater.

Dr. Morris Tonge exhibited, for Dr. Julius Pollock, a specimen of

COAGULUM IN THE PULMONARY ARTERY.

It was taken from one of Dr. Priestley's patients, aged 45, who was confined in the lying-in ward of King's College Hospital on the 31st of January last. She went on well till the fifth day after delivery, when she was noticed to be rather eccentric in manner, and on the twelfth day was quite maniacal. On the thirteenth day she was seized suddenly with severe collapse, resembling that of cholera; the face, lips, and extremities became blue, and she passed into a state of syncope, from which she was roused for a time by the administration of stimulants. She soon lapsed into a semi-conscious state, and died the same night. Shortly after the accession of the attack of collapse it was found that the left leg was œdematous and very painful and tender. On post-mortem examination it was found that there was recent and intense peritonitis. The left femoral vein and the veins of the left leg down to the foot were filled with large soft dark clots. The left ventricle contained fluid blood. The pulmonary artery contained a large firm almost colourless clot, which extended into the right ventricle on the one hand, and into the small ramifications of both branches of the pulmonary artery on the other. This clot had, no doubt, been the cause of the sudden attack of collapse, but in what manner was not very clear.

Dr. Robert Liveing then brought forward a specimen from

A CASE OF TRICHINÆ IN MUSCLE.

The following is Dr. Liveing's account of the case:—Chas. G., aged 68, a native of Jersey, was admitted as a "casual" patient into the Whitechapel workhouse on December 24, 1864. He complained of pains in his chest, with cough and expectoration. He walked with a peculiar shuffling gait, but nothing remarkable was noticed in his symptoms. His appetite was always good. Very little of his history is known previously to December 24, except that he had been several times to France. He was seized with a difficulty of breathing on March 7, and died on the following day, having been confined to his bed only thirty hours. On making a post-mortem examination of his body in the dissecting-room of the Middlesex Hospital, I found extensive pleurisy and pneumonia of the right side, sufficient to cause his death. On examining the muscles I found that they contained a large number of larvæ of the trichina spiralis, all enveloped in cysts which had become more or less calcareous, and thus very conspicuous to the naked eye. The muscular tissue itself was healthy, and of a bright colour. The muscles were well developed, and showed no signs of wasting. The muscles containing the largest number of the larvæ trichinæ were those of the neck, chest, and upper arm, particularly the pectoralis major, deltoid, and biceps. Those of the abdomen and thigh contained a much smaller number, while in the sole of the foot they were comparatively rare. The muscles of the abdomen, however, contained a large quantity of fat between the bundles of muscular fibre, which accounts for the small number of trichinæ found in this region. They abounded in the larynx and pharynx, also in the upper part of the œsophagus, but they could not be found in the lower half or in the heart, or any of the purely involuntary muscles, such as the stomach, etc. In spite of a copious injection of Burnett's fluid into the arteries of this subject, the trichinæ showed unequivocal signs of life when removed from their cysts. I think it probable that they existed in the muscles of this man at least some weeks (possibly months) before he was admitted into Whitechapel workhouse.

Dr. Cobbold remarked that although he had enjoyed fewer opportunities of investigating the natural history of this parasite than he had in the case of other human entozoa, yet not less than three instances of trichina in the human subject had now come under his personal observation. In all these cases similar features presented themselves, and two of them were dissecting-room subjects. From the condition of the cysts in Dr. Liveing's case, he believed that this man must have been attacked with trichinosis at least six months prior to his death, and notwithstanding that this person had entirely recovered from the immediate effects of the disease, he (Dr. Cobbold) was tolerably certain that they had indirectly promoted his decease. In cases of recovery from flesh-worm disease, the lungs were often left in a very weakened condition. Dr. Cobbold also remarked (in reply to a question by Dr. Murchison) that in trichinosis death ordinarily resulted from irritative fever superinduced by the almost innumerable wounds caused by the migrating larval brood. The injuries might even be classed as traumatic. Dr. Liveing had remarked upon the comparatively small number of trichinæ in the abdominal muscles. This was probably due to the abundance of fat in these muscles. Dr. Cobbold stated that he had fed various animals, such as the dog, rabbit, guinea pig, rat, mouse, donkey, fowl, sheep, etc., with the diseased flesh, but at present he had only killed two dogs. These gave a negative result, probably from having vomited the lumps of muscle given to them. No doubt this arose from the circumstance that the body had been injected with chloride of zinc.

Dr. Frederick Robinson exhibited a specimen of

MITRAL VALVE DISEASE.

The orifice was narrowed owing to bony deposit, so as only to admit of the passage of a large quill. The heart was much enlarged, occupying a position transversely across the chest, and weighing seventeen and a-half ounces. Left auricle much dilated, as well as the ventricle; the latter also hypertrophied. The subject of the disease was a delicate young man, aged 28, who never suffered from rheumatism. Whilst serving in the army in India, in 1860, he was attacked by pain in the cardiac region whilst running to the parade-ground. He dated the cough, bronchial affection, and dyspnœa which followed and continued at intervals ever since to this seizure. Dr. Robinson considered that this case strengthened the views of Dr. Peacock as to congenital and accidental

lesions of the valves being a more frequent source of organic disease than has generally been received.

CASE OF SPONTANEOUS CHELOID.

Dr. Hillier exhibited a man, 27 years of age, the subject of that somewhat rare disease of the skin the true cheloid of Alibert. The morbid appearances first presented themselves eleven years ago on the front of the chest, over the middle of the sternum, and were not preceded by any injury or scar. At first there was one hard shining tubercle, oval in shape, firmly set in the skin, of a red colour, and attended at intervals with darting pains. Since the commencement of the disease two other similar growths had appeared, one above and the other below that first formed. They varied in length from three-quarters of an inch to one inch and a-half, and were about three-quarters of an inch wide. The one which first appeared was undergoing absorption; it had lost its red colour, and exhibited a depression similar to that due to the scar from a deep wound. The one last formed was larger than an almond, was red, and small blood vessels were to be seen on its surface, with claw-like processes extending from it into the adjacent skin. The man's general health was good. No local treatment had been adopted; the experience of former cases discouraged the use of caustic or the knife.

Mr. Holmes (Hon. Sec.) exhibited, for Mr. Chas. Roberts, of York, a specimen of

HORNY GROWTH REMOVED FROM THE FACE.

Mr. Roberts' report was the following:—The horny growth which I enclose was removed by me from the face of an old woman, about 75 years of age, the wife of a blacksmith, residing in a small agricultural village a few miles from York. It was growing from the skin immediately over the edge of the lower jaw on the left side, at a point corresponding to the angle of the mouth. The patient stated that about three years ago a small wart (which she had had all her life) became irritable, and from frequent scratching bled freely. As the irritation subsided, a horn grew, and slowly increased in size for two years, when she broke it "short off." The enclosed horn has been the produce of the last twelve months, and has increased in diameter and length much more rapidly during the last three months. The soft, bulbous base was very vascular and painful, and the horn, by hanging down into the neck and catching the dress, was a source of great pain and inconvenience to the patient. In removing it, it was only necessary to divide the skin, as the tumour had no connexion with the deeper tissues.

Dr. Cruckshell showed a specimen of

RUPTURED ANEURISM OF THE AORTA.

The symptoms had been so obscure that aneurism had not been suspected. The patient, a woman, 34 years of age, had complained of pain in her chest, and had spat blood. She was getting up one morning, when profuse hæmorrhage occurred, and she died. The aneurism was of the descending part of the aorta, and had opened into the left bronchus.

MEDICAL NEWS.

Apothecaries' Hall. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, March 30, 1865:—

John Williams, University College; Hubert Wilson South Stirton, Trafalgar-road, Greenwich; Edwin Burrell, Westley, Bury St. Edmunds; Charles Claridge Brewer, City-road.

As an Assistant:—

John Lloyd, George-street, Cardiff.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Brodribb, William P., L.R.C.P. Edin., has been appointed Secretary to the Court of Examiners, Apothecaries' Hall.

Brown, Isaac Baker, Jun., M.R.C.S. Eng., has been appointed Assistant-Surgeon to the London Surgical Home.

Dalby, William T., M.D. Aberd., has been appointed to the Commission of the Peace for the County of Surrey.

Haines, R. W., M.R.C.S. Eng., has been elected Junior House-Surgeon to the Manchester Royal Infirmary and Dispensary.

Hood, William C., M.D. St. And., has been appointed to the Commission of the Peace for the County of Surrey.

Jackson, George, M.R.C.S. Eng., has been elected House-Surgeon to the West London Hospital, Hammersmith.

Scoresby-Jackson, R. E., M.D., F.R.C.P., has been appointed Physician to the Royal Infirmary of Edinburgh.

Smith, R. W., L.R.C.P. Lond., has been appointed Medical Officer for King's Norton Union, Worcestershire.

Smith, William, M.R.C.S. Eng., has been elected Junior House-Surgeon to the West London Hospital.

Snow, William, M.R.C.S. Eng., has been appointed House-Surgeon to the Kent County Ophthalmic Hospital, Maidstone.

Symes, William H., M.B. Dub., has been appointed Physician to the Carlow County Fever Hospital.

Walker, Henry G., M.R.C.S. Eng., has been elected House-Surgeon to the Hereford General Infirmary.

Watson, James D., L.R.C.S. Edin., has been elected Medical Officer for the Parish of Bothkennar, Stirlingshire.

DEATHS.

Kelly, William, M.D., Surgeon-Major Royal Artillery, at Bath, on April 4, aged 58.

Prater, William, M.R.C.S. Eng., of Fair-place, Okehampton, Devon, on March 18, aged 38.

Robinson, Charles S., M.D. St. And., at 23, Harewood-square, N.W., on April 1.

Rogers, Frederick J., M.R.C.S. Eng., at the Infirmary, Leicester, on March 29, aged 28.

At the Levée on Wednesday, the following presentations to the Prince of Wales, on behalf of the Queen, took place:—Dr. Th. Bernhardt, by the Lord Chamberlain. Assistant-Surgeon Henry Griesbach, M.D., Madras Army, by the Secretary of State for India. Dr. James Vaughan Hughes, by the Adjutant-General. Dr. Priestley, by Sir Charles Locock. Assistant-Surgeon T. Sharkey, Royal Artillery, on appointment, by Colonel G. Gambier. The following gentlemen attended the Levée:— Sir Charles Locock; Drs. Scott Alison, Gream, John T. Griffith, M'Cann, Ramsbotham, and Ruttledge; Messrs. Du Pasquier, Cæsar Hawkins, Joseph Toynbee, F.R.S., Haynes Walton, and Spencer Wells.

Summer Lectures at the Paris Faculty of Medicine.—These lectures, which commenced April 3, are to be delivered by the following Professors:—Medical Natural History, Baillou; Physiologie, Sée for Longet; Midwifery, Pajot; Therapeutics and Materia Medica, Trousseau; Legal Medicine, Tardieu; Pharmacology, Regnauld; Surgical Pathology, Gosselin; Pathological Anatomy, Empis for Cruveilhier; Medical Pathology, Béhier, Hygiene, Bouchardat; Medical Clinic, Bouillaud, Guillot, Grisolle, and Piorry; Surgical Clinic, Jobert, Laugier, Velpeau, and Nélaton; Midwifery Clinic, Depaul; Clinic of Diseases of Children, Roger; Clinic of Diseases of the Skin, Hardy; Ophthalmic Clinic, Follin.

Royal Institution of Great Britain.—The general monthly meeting was held on Monday, April 3; William Pole, Esq., M.A., F.R.S., Treasurer and Vice-President, in the chair. Walter Armstrong, Esq., R. M. Birkbeck, Esq., Henry Brandreth, Esq., M.A., James William Butler, Esq., the Rev. Tullie Cornthwaite, M.A., F.L.S., George Duppa, Esq., Mrs. Henry, Henry Mather Jackson, Esq., Major William Lyon, Sir Theophilus Metcalfe, Bart., Alexander McDonald, Esq., Colonel Robert Morrieson, were elected Members of the Royal Institution. The presents received since the last meeting were laid on the table, and the thanks of the members returned for the same.

The Main Drainage Works.—There are now about 1300 miles of sewers in London, and 82 miles of main intercepting sewers. 318,000,000 of bricks and 880,000 cubic yards of concrete have been consumed, and 3,500,000 cubic yards of earth have been excavated in the execution of these main drainage works. The total pumping power employed is 2380 nominal horse power; and if at full work night and day 44,000 tons of coal per annum would be consumed. The sewage on the north side of the Thames at present amounts to 10,000,000 cubic feet a day, and on the south side to 4,000,000 cubic feet per day; but provision is made for an anticipated increase up to 11½ millions on the north side, and 5¾ millions on the south side, in addition to 28½ million cubic feet of rainfall per diem on the north side, and 17¼ million cubic feet per diem on the south side, or a total of 63 million cubic feet per diem, which is equal to a lake of 482 acres, 3 feet deep, or fifteen times as large as the Serpentine in Hyde-park. All the works are now complete, save only the northern low level, which, as having to run under the Thames embankment, cannot, of course, be yet constructed.—*Times*, Friday.

Guy *v.* Staples.—Nisi Prius Court, Midland Circuit, April 1.—This was an action by a Surgeon to recover £66 for Medical visits which he had paid to an old man named Jupp, at the request, as he alleged, of the defendant. It was admitted that the defendant had written a letter, requesting the plaintiff to attend Jupp, who had a bad leg. The plaintiff did so, and continued his attendance for about fifteen months until Jupp died. With the exception of the letter, no communication on the subject had taken place between the plaintiff and the defendant. The plaintiff obtained a verdict for £40.

Bromide of Ammonium in Pertussis.—Dr. Küehenmeister states that additional experience confirms the favourable opinion he formerly expressed concerning the value of this medicine. He gives of a concentrated solution of the bromide from five to fifteen drops three times daily, according to the age of the child, proceeding to the larger quantity named only gradually.—*Zeitschrift für Mediein*, 1864, p. 410.

Death amongst the Parsees.—Physieians who attend Parsee patients are always charged (if the cases are likely to terminate fatally) to give timely warning to the friends of the sick man. When it is believed that he is drawing near his end, the attendance of the Physician is dispensed with; the dying man is given over to two Parsee attendants, who divest him entirely of clothing, and convey him to a chamber on the lowest floor, from which all the furniture has been removed, and in which there is nothing but two stones. The poor man is placed upon these stones, held up in a sitting attitude by one of the men, and his body is besmeared with cow's urine. If possible, he must be made to drink some of the same; this is regarded as of great importance, and, under the circumstances, of singular efficaey in fitting his spirit to appear before the Judge of all. After this a quantity of warm water is poured upon the poor man, one vesselful after another, and in the great majority of instances the vital spark is extinguished at this time. We have heard of a case where a Physician was summoned in all haste. Before he reached the house, however, the friends of the sick man thought him to be on the point of death, and, without waiting, removed him to the death-chamber. The Doctor arrived, and was told that the patient was dead. He asked to see him, but was denied access. He inquired regarding the symptoms, and on being informed of them, he declared his belief that that the man was not dead, and insisted on seeing him. But they would not allow him to approach the body; he might see it from a considerable distance. This ablution with the sacred element is regarded as a means of washing away their sin.—*The Times of India*, February 22, 1865.

The Metropolis Sewage and Essex Reclamation Bill.—The Select Committee appointed to inquire into the best means of disposing of the metropolitan sewage on the north side of the Thames have now issued their report. They say that the scheme brought before them by Messrs. Hope and Napier, and embodied in the Bill before the Lower House, fulfils the following requisitions:—"It provides, in the first place, for the complete removal from the River Thames of the whole of the ordinary sewage of the northern part of the metropolis, leaving only, on the occasion of heavy rains, a portion of the sewage still to run into the river, but so small and exceptional that it may, for all practical purposes, be left out of consideration. It provides, in the next place, for the irrigation by sewage, in whatever quantities may be found useful, of a considerable area particularly well adapted for such a purpose, inasmuch as the natural character of the soil is light and favourable. Moreover, the low level of the district enables the sewage to be applied with very little mechanical aid, and, in fact, mainly by gravitation. It may also be observed that an extension of this area might be made by pumping the sewage to a moderate elevation. Lastly, with respect to whatever portion of the sewage may not be disposed of in its course, the scheme proposes to apply it in the reclamation of a barren portion of land on the coast, in a manner recommended by experience." The combination of these different modes of using the sewage is, the Committee think, of great consequence in insuring at all times and seasons the beneficial application of the whole sewage, with the small exception above mentioned on the occasion of heavy rains. Upon this evidence the Committee are of opinion "that the scheme which has been submitted to them is a useful and profitable mode of applying the sewage of the northern portion of the metropolis, and they have no reason to suppose that any more useful or profitable scheme could be devised." The Committee consisted of Mr. Headlam (chairman), Mr. Ayrton, Mr. Knight, Dr. Brady, Mr. T. J. Miller, Colonel Smyth, Mr. Selater-Booth, Mr. Paget, Mr. Clay, and Mr. Charles Turner.

The Decision of the Guardians of the Holborn Union in the Late Official Inquiry.—We now learn to what extent the Guardians of the Holborn Union have accepted the official report, the conjoint work of Mr. Farrall and Dr. Carr, the Medical assessor, and which we hold as official, proceeding as it did from the Poor-law Board, being dated Whitehall, Jan. 20, 1865. It will be remembered that the latter gentleman, after commenting on the whole of the Medical evidence, the character and general relations of the Union Workhouse, suggested that for the future the drugs should be supplied by some respectable wholesale druggist, and paid for by the Guardians; 2ndly, that the salary of the Medical officer should be raised from £100 to £150; and 3rdly, that two properly educated nurses should be appointed and paid sufficient salaries to command a high elass character. In the face of these recommendations, emanating, be it remembered, from the Poor-law Board, and doubtless receiving the sanction of the Commissioners, it will scarcely be credited that the guardians have only in part accepted them! They cannot yet see that means calculated to expedite the recovery of the sick pauper will save their rates; that the employment of well-trained nurses can alone prove the only valuable auxiliary to their Medical officer; and that to offer an advaneed remuneration is not the surest way of commanding a proportionately advanced Medical *expert*. It is true the guardians have agreed to raise the salary of their Medical officer to £125 per annum, being an advance of £25; they have also determined on employing one paid nurse as an experiment; but they have wholly rejected the suggestion of paying for the drugs.

The Treatment of Aneurism by Compression on the Distal Side of the Sac.—(Extract from a clinical lecture on the Combination of Distal with Proximal Compression in Certain Cases of Aneurism. By J. M. O'Ferrall, F.R.C.S., L.K.Q.C.P.I., M.R.I.A., Chief Surgeon to St. Vincent's Hospital.)—I have long since been of opinion that compression of an artery on the distal side of an aneurismal sac should precede or accompany that on the cardiac side of the aneurism. Three cases have already been treated with success on this plan. I have often observed arrest of pulsation easily accomplished, attended at the same time with a flaccid state of the sac; but I have also remarked in such cases that the moment the pressure ceased the sac filled and throbbed as before. The formation of the coagulum is thus desirable as the first step to consolidation. A half-empty sac is the ready recipient for the slightest thready current that can follow the cessation of the compressing force on the cardiac side. It, therefore, appeared to me advisable to interrupt the current only when the sac was full of blood. These considerations, together with the knowledge of the fact that ligature of the artery on the distal side has sometimes cured an aneurism when the upper or cardiac portion of the vessel could not be reached, made me resolve to try this expedient whenever a fair amount of pressure was not followed by success. From what I have observed, I am inclined to think that cessation of pulse in a sac which suddenly diminishes in size and becomes flaceid is less likely to be followed by a permanent cure, whatever time may have been occupied in the compression; and that a sae which retains its volume, and is, moreover, full of coagulum, is less likely to be refilled, however short the duration of the compression force. When the supply is completely cut off by ligature of the trunk, I believe that the danger of relapse from refilling of the sac by collateral sources is more likely to occur when the sac collapses and becomes flaccid at the moment of deligation than when its dimensions are unchanged. This firmness of the parietes of the sac is always considered favourable to the success of the operation, as implying the presence of fibrinous deposits, whether we attribute them to stasis of the blood or to inflammatory exudation, as suggested by the researches of that distinguished Surgeon, the late Dr. Abraham Colles. I have no doubt, however, whether a sac be filled by fibrinous deposits of some duration, or by coagulum recently formed, that a full sac is very influential in preventing the ingress of blood from a compressed artery above, or collateral branches from below; the compression below the sac need not, in some cases, last more than a few minutes before the current above is stopped. If, on making the pressure above and arresting the pulsation, the sac remains full, the object is attained, and

time is merely required to allow the blood then liquid to coagulate in the sac. In other cases, it may be prudent to continue both compressions for a longer time.—*Dublin Medical Press*, Mareh 15.

THE CASE OF DR. PRITCHARD.—The *Scotsman* of Monday says :—"The particular stage at which the investigation in this complicated and exciting ease has arrived renders it impossible that any definite statement of results can be published for a few days. The chemical examination of Mrs. Pritchard's body is proeeeding, and will probably be completed in the course of this week ; but very special precautions have been taken to prevent any exposure of the first results obtained, and, as some time must elapse before any report will be made even to the authorities, it is not expected that public curiosity will be gratified for some days to come. We have grounds, however, for stating that the case against the prisoner has assumed a grave aspect from the result of the post-mortem examination alone of Mrs. Taylor's body. The condition and appearance of the organs denoted no serious or fatal illness of a natural character." The Glasgow *Morning Journal* of Saturday says :—"In the course of our inquiries yesterday, a fact or two came to our knowledge, the importance of which, in a painful investigation like the present, it would be difficult to over-estimate. Hitherto, little or no direct proof has been brought forward of the accused being in possession of antimonial preparations in any considerable quantity, or, indeed, of having them at all. The sale-books of the druggists with whom he was in the habit of dealing throw, it is understood, but little light on the matter ; and if the police officials have found the drug in any form in his surgery, this information has, of course, been studiously kept secret. There can be no doubt, however, after what we have learnt, that for several weeks past Dr. Pritchard was really in possession of tartarised antimony, and this, moreover, in unusually large quantities, purchased by himself at the establishment of a respectable wholesale druggist in town. We believe we are within the mark in stating that not less than two ounces of this medicine was thus procured by him within the space of two months. Another somewhat striking circumstance is that a few days before the death of Mrs. Taylor he was supplied from the same warehouse with a goodly quantity of 'Fleming's' tincture of aconite—a medicine possessed of virulently poisonous qualities when administered incautiously. It is quite true that both of the drugs mentioned are largely used in the healing art, but it is not easy to guess at first sight what need any Surgeon in private practice could have for great quantities of them, more especially of the tartar emetic. A very free use of antimony as an outward application might, perhaps, partially explain the necessity for purchases so unusually large, but we are led to understand that any such practice has been of late years almost completely laid aside by Medical Practitioners who keep pace with the pharmaceutical improvements of the day, as we may reasonably assume Dr. Pritchard to have done. A grave question, then, must now arise as to what has become of the powerful poisons which the aceused is known to have bought."

THORACENTESIS IN A CHILD.—M. Roger relates at some length the details of a case of purulent pleurisy occurring in a child 8½ years old, the treatment of which occupied nearly six months, during which the operation of thoracentesis was performed five times. Iodine injections were resorted to, and a canula was left within the wound to facilitate the discharge of the pus. From this case he derives the following considerations :—1. The importance and at the same time the difficulty in coming to a quick decision with regard to this operation in certain urgent and complicated cases of purulent pleurisy. (In this case it was complicated with bronchopneumonia of the opposite side.) 2. The advantage of making in children the puncture without preliminary incision of the walls of the thorax. 3. The necessity which almost always exists in empyema of repeating the operation several times. 4. The difficulty which exists, do what we will, in preventing the admission of air into the pleura. 5. The frequent innocuity of the presence of this air. 6. The manifestation as a consequence of its introduction of stethoscopic phenomena not always of easy interpretation, and which may be mistaken for perforation of the lung with consecutive hydropneumo thorax. The readiness with which lateral deformity of the spine, with concavity on the bad side occurs, and the rectification of this deformity which takes place sometimes rapidly after recovery.—*L' Union Méd.*, No. 82.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Mr. Dufour writes to ask the *Medical Times and Gazette* to recommend a dentist who will extract a decayed tooth skilfully. We strongly advise him to consult the Council of the Odontological Society, or any one of them—viz., Messrs. Saunders, Rogers, Cattlin, Imrie, Perkins, Ibbettson, Sheffield, Harrison, Fox, Kempton, Hulme, Tomes, Bigg, Owen, and Hill. If he cannot get his tooth drawn, perhaps he will write again.

Another Competitor.—The report of the Jacksonian Committee was only made to the Council on Thursday evening, when the award was made in favour of a metropolitan Surgeon, for the essay on Club-foot. We shall publish the result next week.

A Fellow by Examination.—From inquiries made, we are told that the election will take place in July, and should no death vacancy or resignation occur, the candidates going out of office are Messrs. Wormald (the senior Vice-President), Quain, and Shaw ; they are, however, eligible for re-election, and no doubt will offer themselves.

Errata.—The remarks on Mr. Bryant's case of Double Herpes-zoster were unfortunately printed from an uncorrected proof. Besides several obvious mistakes, *for* "anæmial," *read* "acromial."—In our last No., p. 349, under the heading "Medical Knighthoods," *for* "Dr. Lenton C.B.," *read* "Dr. Linton, C.B."

"CASTOR-OIL PILLS."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—So-called "castor-oil pills" are very much in vogue in my neighbourhood ; many patients in delicate health, some only just confined, use them, supposing that they are really what they profess to be. A patient of mine very nearly lost her life by taking two last week, under an impression that they were the same thing as castor-oil. Of course, castor-oil pills do not contain a particle of castor-oil. Will you have the kindness to warn the godfathers of these bastard productions that they are in danger of having a charge of manslaughter brought home to them ?

HYDROSTATIC MATTRESSES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your last week's issue you give an extract from a communication to the *Gazette Médicale*, by M. Cosmas-Dumenez, of the great advantages derived by M. Demarquay from the employment of the hydrostatic mattresses during the last five years.

As the hydrostatic mattresses referred to were invented and introduced to the Profession by myself, about twenty years ago, it is gratifying to find that, after such a lengthened period, the advantages derived from their use are sustained by the evidence of so high an authority, and that the opinions of English Practitioners are so favourably endorsed.

Since there are few members of the Medical Profession, either in the United Kingdom, our colonies, or in India, who have not had experience of their value in cases of fractures, sloughing, paralysis, etc., or the prevention of bed-sores, we may, perhaps, by remaining passive to the remarks of M. Cosmas-Dumenez, lead our Continental friends to believe that they are not of English introduction, and that we are behind the age in the production of such Surgical and invalid appliances.

I trust I may be pardoned in stating that the published accounts in our Medical journals, first by Mr. Cæsar Hawkins on my hydrostatic cushions, and more recently by other eminent Medical men on my hydrostatic mattresses, show nothing has certainly been done by any other manufacturer towards their development, and which is confirmed by the fact that only one award was made by the Jurors of the International Exhibition, which was a medal to myself.

Various forms of permanent elastic caoutchouc were exhibited by me, independently of the hydrostatic mattresses and cushions, especially forms for the local application of heat and cold, at any temperature, from that of zero to boiling water.

Mr. Seymour Haden directed my attention to the construction of elastic caoutchouc bags for the local application of cold by ice, and after some expense I succeeded in accomplishing the objects which were desired. A valuable communication by Dr. Esmarch, translated by Dr. Edmund Montgomery, and published by the New Sydenham Society, vol. xi., enters very minutely into the subject, and gives most useful results.

It is now somewhat surprising that attempts are being made to introduce the elastic caoutchouc bags as patented articles, and altogether ignoring my priority and manufacture.

I am, &c.

Pall-mall East, April 4. WILLIAM HOOPER.

WASTING OF THE TESTICLE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I shall feel obliged if any of your readers will give me the benefit of their experience in cases similar to the following :—

At the beginning of January, W. J., aged 24, stonemason, consulted me for "shrivelling of the testicle." He tells me that when 17 he practised masturbation daily for twelve months, but finding his health failing at the end of that time, he ceased to do so. Ever since he has been subject to nocturnal emissions. He has never had gonorrhœa or orchitis. Eighteen months he got a severe cold, had swelling of cervical glands, with dull aching pain in left testis, but no redness or swelling ; lancinating pain in groin and down thigh. After a week's rest in bed and the use of fomentations and purgatives the pain gradually subsided, but from this date he has observed a softening and gradual decrease in size of the left testis, with occasional darting pain. He has all the desire for intercourse, but is unable to effect his purpose, as the erection is imperfect and seminal emission so speedy and scanty, an oozing continuing for some hours subsequently. On examination, I found the genitals well formed, but left testis is only of size of hazel-nut, and very soft ; right testis not so firm and large as natural. Manipulation causes no pain in left and only slight in right. He has the appearance of a vigorous young man, with a plump, ruddy countenance, but is highly nervous and imaginative. He is of steady and temperate habits.

Viewing the impaired function as the result of excessive action and excitement during his youthful imprudence, and with the object of checking, if possible, the progressive atrophy of the testis, I have prescribed the tepid salt water douche, cod-liver oil, with tinct. ferri æther., chlor., and sol. strychniæ, ter die.; nourishing, unstimulating diet, and, above all, a strict avoidance of sexual excitement, but I cannot find any improvement. Syme and Ferguson do not refer to the subject; Druitt simply says "there is no cure." Have any of your readers had better success?

I am, &c.

ACTA NON VERBA.

A Parish Surgeon's Grievance.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The following case exposes another parish doctor's grievances, and one which I have never before heard mentioned:—

An imbecile old man, who lived with his wife and an unmarried son, and whose weekly family income consisted of 8s. from his club, 12s. from the son's labour, 2s. to 3s., with two to three days' keep, by old woman's work, and 2s. 6d. from the parish, was so negligently left that his clothes caught fire and he was dangerously burnt. I had visited the old man some three times during the past three months, in order to sign his club medical certificate; and this I did partly out of charity, partly from a promise by members of the club that I should be remunerated for so doing. I consequently knew the old man's state, and knew of how little avail my presence would be, and so, being tied by other cases in hand, and having sent opiates and given directions, I omitted, or (as was said) neglected, to visit him that evening. He died early in the morning. A few days after I received a note from the coroner, stating that there was a charge of neglect against me. I attended the inquest; and while the neglect that really caused the old man's death was only mentioned, half the coroner's papers were filled up with evidence of the Doctor's behaviour. While there was not a single expression of dissatisfaction, there was not the slightest evidence of omission or neglect having accelerated death or even increased suffering. Again, there was no evidence given that the old man was a parish patient, but to the contrary. Judge, then, my surprise when the next issue of the local papers charged me with "wilful neglect," and stated that I was to be reported to the Poor-law Board. I therefore wrote to the coroner, and found the newspaper report dwindled down to this, "that the jury, at the conclusion of the inquest, made observations upon my omission to visit, and requested him (the coroner) to report to the local board of guardians." I beg to add that the board of guardians decline to take up the matter.

Now, I know and attend upon, I may say, all the people concerned—jury and deceased's family; and I have subsequently made inquiries, and have not heard the slightest word of dissatisfaction. In fact, the whole inquest was got up by the local police-constable. He has a direct interest in the payment of expenses, an indirect interest in the matter of future promotion. He it is who opines he has enough to make an inquest; he alone tells the coroner; he chooses the witnesses; he chooses the jury; and in this case he it was who gave the local reporters to the newspapers the erroneous verdict containing the charge of "wilful neglect."

I may misunderstand the object of a coroner's inquiry, but if the carelessness of friends and relations is to be condoned, and an inquest into the cause of death to culminate into the mode the Medical man conducts his practice, the committors of crime will have a new mode of escape, The Medical Profession, too, is come to a poor state when the police-constable of the district is upheld as the constituted authority and judge of the performance of its duties.

I am, &c.

A COUNTRY PRACTITIONER.

Arbitrary Choice of Medical Witnesses by Coroners.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I seek advice under the following circumstances:—On Sunday, March 19, at 2 15 p.m., I was called up by a police-officer and requested to go to the police-station, where he said there was a child either dying or dead. I live close thereto, and am the police Surgeon. I went immediately and found a woman with an infant and a man, who with her had been drinking and rambling about the township and neighbourhood for several hours. The child, about eight weeks old, was robust, well-nourished, quite warm and flaccid, but dead. As a result of my examination, the man and woman were taken into custody on suspicion of causing the child's death. An inquest was entered upon the day following, but adjourned until Friday for a post-mortem. Not I but another gentleman was sent for by the coroner, and instructed to make the required examination. The result of this inquest was, the woman was committed to be tried at the assizes on a charge of manslaughter. The same Medical man was of course examined before the magistrates at the police-court, where he repeated his evidence, and was bound over to attend at the trial. I would probably have arrived at the same conclusion as to the cause of death (suffocation); but not for the reasons he assigned—viz., certain marks, which were not present on the recent body when I saw it, but which were, I apprehend, the result of position and post-mortem rigidity. It was also given in evidence that one lung was empty of air; which I cannot understand if it was healthy and used for respiration. Have I not cause to complain that I was not the Medical witness employed? and is it right the mother should lose the benefit of my observation of the body?

If this was the only case in which the coroner so acted, I would not ask for advice of you or my brethren in the Profession; but it is at least the third. The first was in the case of a new-born child found partially buried in the sand on the river shore. A young woman recently confined was suspected of destroying it. I, sent for by the police, saw and examined it carefully when found; but I was unnoticed by the coroner, and the Medical gentleman in the first instance sent for by him was the same individual employed by him last week in the case I have just described; but as he was not at home another gentleman was employed, although neither saw the infant previously, and both lived further from the place of the inquest than I did. This case also became an assize one, and resulted in a conviction for concealment of birth.

The third case was one of murder. In June, 1862, a man was waylaid and killed. I also was sent for, and examined the wounds, etc., and again passed over by the coroner, and the same gentleman sent for to make the post-mortem, etc.; but in this case the magistrates deemed my evidence essential, and I had to attend the assizes.

In each of the two cases I have last sketched I remonstrated with the coroner in a gentlemanly strain, and with the respect due to his judicial office, but I am sorry to state that on both occasions he replied in an angry way, asserting his legal right to call upon any Medical man he pleased, stating I had no right as police Surgeon to a monopoly of post-mortems; or that being so made me more competent (two ideas which I would simply be ridiculous for one moment to suppose or entertain); that my letters were "silly;" and as to his repudiation of monopoly, it is remarkable that, in each of the three cases I complain of, it was the same gentleman he sent for.

In conclusion, I assure my brethren in the Profession that I would consider it a degradation to seek a favour from the coroner or any other official, or to be employed if I had not a right, equitable, if not legal; neither do I for a moment wish it to be supposed I claim a preference because I am the police Surgeon, and I am sure I would not complain if it could be shown that any other gentleman had a prior or better claim. But being systematically passed over by the coroner, I conclude it is owing to some dislike or prejudice, which I cannot understand.

I am, &c.

Birkenhead, March 28. MATTW. JENNETT.

ORIGINAL LECTURES.

ON THE ASSIMILATION OF SUGAR BY THE LIVER.

FROM

THE LECTURES ON PHYSIOLOGY,

DELIVERED AT

Guy's Hospital.

By F. W. PAVY, M.D., F.R.S.,
Assistant-Physician to the Hospital.

Part II.

Let us first see what Dr. Thudichum has to say in an "Experimental Epicrisis of some late Researches on Liver-Sugar," contained in the *British Medical Journal* of March 17, 1860. I should not myself have thought it necessary, so extravagant are Dr. Thudichum's assertions, to have detained you with an answer to this communication; but as I find Dr. Thudichum's conclusions quoted by an authority like Dr. Beale, and have seen them, in a notice or review of Dr. Beale's work, specially picked out and put forward in the light of weighty evidence against me, it is requisite that I should show what Dr. Thudichum's communication in reality amounts to.

Dr. Thudichum's attack is upon my method of procedure. He first details three experiments of his own upon dogs in which portions of the liver immediately after death were pounded in a mortar with potash. In the first, sugar was found; in the other two, there was none. Dr. Thudichum, however, assumes that sugar was originally present in all three, but had become destroyed in the last two. He says, "No doubt, in the second and third experiment the proof of sugar having been originally present in the liver is wanting; but the first experiment made me so well acquainted with all the conditions which are essential for finding or missing any sugar in the liver, by employing potassa as a reagent, that I was quite satisfied of the correctness of the conclusion, which caused me at once to give up all further experiments on this subject as lost labour, namely, *that no experiment can be admitted as proving the absence of sugar from the liver, in which the contact of that organ with potash, air, and water, at the ordinary or any higher temperature, has not been avoided.*" The last passage, I must tell you, is printed in italics.

One experiment! gentlemen, suffices to teach Dr. Thudichum all the conditions that are essential for finding or missing sugar in the liver when potash is employed as a reagent; and he immediately frames a conclusion which tells us that my experiments with potash are not to be admitted as proving that for which I have advanced them. He elsewhere asserts that the potash-test having been the basis of my conclusions, and being now proved to be fallacious, the conclusions themselves, in so far as they are derived from the analysis with potash, are not any longer valid. Let us examine the matter closely, and see upon which side in reality the fallacy lies.

All the information supplied about the first experiment, from which Dr. Thudichum was taught so much, is that the liver was pounded with an equal amount of caustic potash without the addition of water, and afterwards submitted to filtration through asbestos. The filtrate which passed during the first hour gave evidence, with an alkaline solution of copper, of being charged with sugar, whilst that which passed afterwards gave none. A second piece of the same liver, after being exposed to the air for fifteen minutes and then treated like the first, is stated to have behaved in precisely the same manner. From this it is concluded that when a liver containing sugar is treated with caustic potash, the sugar under the influence of the alkali, the oxygen of the air, and water is rapidly destroyed. In the second experiment, as in the third, no evidence of the presence of sugar was obtained even in the first filtrate; but it is assumed that sugar was originally present in the liver and had undergone more rapid destruction on account, as it is stated, of there having been an elevation of temperature occasioned when the admixture with potash was effected. To one ounce of the mixture of liver and potash of his second experiment, Dr. Thudichum added ten grains of grape-sugar, and tells us that at the end of twenty-four hours the reaction with the copper solution was so slight that "the ten grains of sugar had so effectually been destroyed in the mixture, that certainly not one-thousandth part of them was left over."

Now, gentlemen, I have repeated Dr. Thudichum's experiment of adding sugar to the mixture of liver and potash. I took 200 grains of a specimen of liver that was free from sugar, and pounded it in a mortar with 200 grains of caustic potash. Ten grains of grape-sugar dissolved in a small quantity of water were added, and the contents of the mortar turned out into a glass measure, and made up with water, only a little being required for the purpose, to one ounce. This mixture was examined from day to day, *and at the end of five days, the last time it was tested, it gave a copious indication with the copper solution of the presence of sugar.* In another experiment, five grains, instead of ten, of grape-sugar were used. The mixture was placed aside for three days. It was then thrown into a funnel, the neck of which contained some asbestos. The clear liquid that ran through, on being boiled with the copper solution, changed to a lilac colour, but threw down no deposit. It behaved like liquids that I have often met with where albuminous or nitrogenised matter has been present in addition to the sugar. I took a portion of the mixture, and *after neutralising it with sulphuric acid to get rid of the nitrogenised matter that had been dissolved by the potash, now found that my copper solution gave an immediate and copious indication of the presence of sugar.*

Dr. Thudichum seems to have been unaware or unmindful of the fact that the presence of nitrogenised matter interferes with the reaction of the copper liquid in testing for sugar. It is to be inferred from what he says, that he took no steps to separate the nitrogenised matter which his potash solutions would contain; and on this account his negative results, whether for or against me, must be taken as standing for literally nothing. Where the quantity of sugar is not very large, and the copper test is used for its detection, its presence may be completely masked by the presence also of nitrogenised or albuminous matter. I have before now found this even in the examination of urine. The urine has contained both albumen and sugar; but the latter has not been susceptible of recognition by the copper test until the former has been coagulated and separated by heat and filtration.

In proof that the behaviour of the liver, where a solution of potash had been injected into its vessels instantly after death, did not depend upon a destruction of sugar having been effected by the alkali, I mentioned that if a little time were given for the formation of sugar to take place before the injection was practised sugar was afterwards discoverable in abundance. Upon this point Dr. Thudichum writes: "The hurry with which Dr. Pavy found himself obliged to operate to avoid finding any sugar has its ready explanation in the rapid decrease of the temperature which the liver does experience when the abdomen is opened. The higher the temperature at which sugar, potash, and oxygen meet the more rapid and complete is the destruction of sugar; if the liver is allowed to get a little cool before injecting the potash sugar is found, because it has not all been destroyed." Can it be possible, gentlemen, that such an argument has been seriously advanced? It is the purest assumption to consider that for sugar to be found a sensible cooling of the liver must take place, as Dr. Thudichum would have found if he had taken the trouble to experiment for himself. What appreciable reduction of temperature, I ask, can take place in the liver, to bring about so striking a difference in the result, from allowing a few minutes to elapse after death, before the abdomen is opened and the injection practised?—for this is all that is necessary for encountering an abundance of sugar. So much for the potash process, which Dr. Thudichum, upon the grounds I have exposed to you, characterises as "being now proved (!) to be fallacious;" and thence proceeds to declare that my "conclusions themselves, in so far as they are derived from the analysis with potash, are not any longer valid."

But there are other processes by which I have arrived at the conclusions I have advanced. These Dr. Thudichum summarily deals with, evidently considering a few strokes of the pen sufficient to despatch them. He remarks that the experiments in which freezing and citric acid are employed *he has not repeated!* He, however, expatiates upon the oxidising influence of alkaline citrates under exposure to the air upon the suboxide of copper—a phenomenon that I cannot see affords a tittle of direct evidence bearing on the point in question—and then confesses that he is unable to comprehend the meaning of the freezing experiment, but suggests that in my proceedings following the freezing there is much reason for distrusting this experiment also. The proceedings referred to are the use of potash and subsequent neutralisation with sulphuric acid, which I at first spoke of

as the *usual* process I adopted for procuring a liquid from the frozen liver for testing. In answer to Dr. Thudichum upon this point, I have simply to say that it was gratuitous on his part—nay, in direct opposition to evidence given—to assume that this particular mode of proceeding was indispensable for obtaining the result that I described.

There is, therefore, gentlemen, in Dr. Thudichum's "Experimental Epicrisis" nothing approaching a refutation of any of the facts or conclusions that I have advanced. The imputation of fallacy to me arises out of Dr. Thudichum having fallen into fallacy himself. But supposing a fallacy did exist with the use of the potash, it would really have no bearing upon the physiology of the question, because the employment of potash or any chemical agent, indeed, is not necessary for obtaining evidence of the condition that I describe. The argument against the experiment with freezing is only founded upon a groundless surmise. I therefore hope that subsequent writers upon this subject will pause before they bring forward what has issued from Dr. Thudichum's pen, as evidence against the validity of my results.

Next, gentlemen, let us examine the nature of the opposition that Dr. Harley has raised to the results of my researches, and see what he has done to advance our knowledge upon this matter. In 1858 I communicated to the Royal Society the new results I had obtained, in a paper bearing, as originally sent in, the open title, "Has the Liver a Sugar-forming Function?" I had made Dr. Sharpey, as a physiologist and Secretary to the Royal Society, acquainted with the nature of what I had discovered; and it was afterwards at his suggestion that I altered the title to "On the Alleged Sugar-forming Function of the Liver." I had also shown Dr. Sharpey, who visited my laboratory for the purpose, in company with Dr. Harley, my experiments; and I can only say both he and Dr. Harley seemed satisfied with the results, and left me with the impression that I had shown them something new. As pretty good evidence of this, I was given to understand by Dr. Sharpey that my paper was to be inserted in the *Philosophical Transactions;* indeed, it was sent to me to revise for that purpose. Some time afterwards I learnt that Dr. Harley, supported by Dr. Sharpey, had something new to bring forward, which was to refute what I had done. A profound secret seemed to be made of the nature of the refutation, for I could get no information about it until the paper was read at one of the meetings of the Royal Society in December, 1859. I was present at that meeting, and, much to my astonishment, not a single new fact was brought forward. The paper simply amounted to this,—that Dr. Harley had not succeeded in reproducing the results that I had described, and therefore, according to him, the facts remained as they stood before. Dr. Harley nowhere mentions a word in his paper about having witnessed the results that I had shown him. One would have thought, if there had been any erroneous description on my part, that it would have been very easy, without the performance of an elaborate series of experiments, to have said that I had failed in producing before him the results I had described. As I said that evening, gentlemen, I repeat again, I cannot hold myself responsible for Dr. Harley's experimental performances. I then challenged any gentlemen present, if they wished to see a verification of my statements, to come down to Guy's and witness my experiments. As the result, Messrs. Busk and Huxley did me the honour to come, and, without offering an opinion as to whether or not this had anything to do with it, my paper, which I was told had been, or would be, condemned to be deposited amongst the archives of the Society, was sent to me once more to reproduce in a condensed form; and this appeared in the *Transactions*.

Dr. Harley has recently reiterated his opinions on this subject in the *Medical Times and Gazette* for January 14, 1864, without, however, adducing a single fresh experiment in support—in fact, gentlemen, the only originality that I am aware has emanated from Dr. Harley upon this matter is the discovery that his own urine was rendered saccharine by freely partaking of asparagus salad, and that the injection of certain agents into the portal system produces a saccharine state of the urine.

If Dr. Harley has not succeeded in re-producing my results, I may mention to you that Dr. McDonnell, of Dublin, has. I have just received a *brochure*, entitled "Observations on the Functions of the Liver," which shows that Dr. McDonnell has gone most laboriously into the subject; and he fully confirms what I have done. He ingeniously suggests a mode of experimenting for coming down upon the condition of the liver belonging to life, which had not occurred to me. Thus, he says, if a healthy, well-fed hedgehog—an animal, you know, belonging to the hybernating group—be gradually reduced in temperature, by having ice placed near it until it becomes torpid, and the temperature then be further reduced until, by degrees, the entire animal is slowly frozen into a solid mass; its liver does not give the slightest evidence of the existence of sugar. By this device, Dr. McDonnell adds, it is possible, as it were, to steal so gently upon life that at the moment of its departure the amount of cold is sufficiently great to prevent any of the amyloid substance being converted into sugar.

Dr. Marcet, also, who is well known as a working physiologist, has repeated my experiments, and, I have his authority for saying, with a corroboration of my results.

As some collateral support to the justice of my conclusions, it is right that you should know the nature of the opposition that has been recently raised to the glycogenic theory in Paris. M. Longet, the Professor of Physiology to the Faculty of Medicine, writes, in his "Treatise on Physiology," Paris, 1861, that the glycogenic function of the liver, which was formerly thought to be incontestably established, seems now to be refuted by recent observations. The observations which Longet refers to are those of Rouget, which oppose the glycogenic theory upon very different grounds to those advanced by me. It has been ascertained that the amyloid substance is to be found in the muscles and lung-tissue under certain conditions in the adult, besides in the liver; and in a great variety of situations in the fœtus. Now, it is argued, that if it is intended for transformation into sugar in one locality, why should it not be also in another, and that we should then have to give to a variety of structures a glycogenic function. Longet concludes that the production of sugar is not the purpose, but only the consequence of the presence of amyloid substance in certain tissues.

I now come to Dr. Beale's remarks in the second edition of his work on "Urine, Urinary Deposits, etc.," 1864.

Dr. Beale, after mentioning Dr. Harley's and Dr. Thudichum's objections to my results, says that he has himself many times been surprised at the very distinct reaction which is obtained by testing cat's liver the instant death has occurred. The cat, gentlemen, is not an animal that my experience has induced me to show a partiality towards for physiological experiment. Nevertheless, I was going to offer Dr. Beale, if he would undertake to hold the animal, that I would undertake to manipulate, and should be quite content to risk the result. I find, however, on reading Dr. McDonnell's *brochure* I have before referred to, that he has experimented by preference upon cats, and what he has to say renders it unnecessary for me to do more than refer to his results. Dr. M'Donnell gives the details of two experiments out of several that he says he has performed with, as nearly as possible, similar results. Nothing I think can be possibly wanted of a more conclusive nature than the one I will place before you precisely as he gives it.

"A large healthy female cat, for some days before fed exclusively on flesh meat, was pithed," Dr. McDonnell says, "three and a-half hours after her last meal. At once a portion of the liver was cut off and thrown into a quart of boiling distilled water. After being boiled for fifteen minutes, it was taken out and weighed, and returned again to the same water. An equal weight (exactly 500 grains) of that portion of the liver which had remained in the animal was then (*i.e.*, after the lapse of twenty minutes) likewise placed in a quart of cold distilled water and boiled. Each was boiled down to one-half. The portions of liver in each were bruised to a pulp, and the boiling of each was then renewed, and finally each was evaporated to dryness on a water-bath. Each was treated with four ounces of proof spirit, which was filtered off, and the residue washed with additional spirit. The spirit was evaporated on a water-bath, and the dry residues treated with equal quantities of distilled water, and filtered so as to give a solution sufficiently clear for the application of the cupro-potassic test.

Result.

500 grains of liver, boiled immediately after death, gave an indication of sugar so slight as to be almost inappreciable, and incapable of being estimated.	500 grains of liver allowed to remain in the body of the animal for twenty minutes after death contained 12·5 grains of glucose."

Dr. Beale remarks: "I cannot think that the life of the animal can make all the difference which is supposed in the action of

the liver. Surely if a considerable quantity of sugar can be demonstrated to exist in the liver immediately after death we are not justified in considering this a mere post-mortem change. A piece of cat's liver, the instant death has taken place, exhibits the presence of sugar in precisely the same manner as a piece of the same liver removed during life." Dr. McDonnell's experiment I advance as a sufficient rejoinder to this remark. We cannot argue against fact. Dr. Beale's experimenting, I submit, has been at fault, and he has allowed it to influence his judgment. It is not, I contend, a question for discussing what difference the life of the animal can make, but a question of fact; and we must I urge, consider the considerable quantity of sugar which has embarrassed Dr. Beale to be the result of post-mortem change, because it is open to proof that it is so. Dr. Beale, if I mistake not, has seen at one of my Gulstonian Lectures at the College of Physicians the result of an experiment performed by me upon a rabbit; and I will ask him if the same train of reasoning could be applied to that, as he has applied to his own experimenting upon the cat.

Next, Dr. Beale argues from analogy, and I beg him to accept my thanks for his temperate reasoning and the careful thought he has bestowed upon the matter. Because many cells retain their vitality for a considerable time after death, and the liver cells are more likely to agree in character with these than with nerve cells which cease to manifest their activity immediately, Dr. Beale concludes that "it is impossible to resist the inference, except in the case of positive demonstration to the contrary, that the same substances are formed by these cells a few seconds after death, as were produced by them a few seconds before death. . . . Moreover," Dr. Beale continues further on, "it is most probable that the changes taking place in the amyloid matter of the liver cell are not *vital changes* at all, but due rather to chemical and physical actions only." With this latter proposition I am fully prepared to acquiesce. I do not assume that the amyloid substance is in a vitalised condition. I submit that it is simply an organic substance influenced by the conditions around. It happens to possess as one of its chemical properties great susceptibility of transformation into sugar. Under natural circumstances the conditions are such that this susceptibility is allowed to manifest itself only to quite an insignificant extent, whilst after death it is allowed to come into active play. But it is not necessary to assume that death of the cell is required for this. The conditions can be suddenly altered during life so as to bring about a sudden alteration of result. For example, injuring the superior cervical ganglia of the sympathetic immediately determines a saturation of the system with sugar—an artificial diabetic condition. Supplying another condition, which consists in previously introducing a certain quantity of carbonate of soda into the circulation, entirely prevents such a result.

(To be concluded.)

ORIGINAL COMMUNICATIONS.

ON THE

MECHANISM OF PARTURITION IN CASES OF PRESENTATION OF THE CRANIUM.

By CHAS. G. RITCHIE, M.D.,

Late Resident Physician to the Royal Hospital for Sick Children, Edinburgh.

The mechanism observed in the spontaneous evolution of a cross-birth is strikingly similar to that of natural parturition. Nature seems to have a general plan by which she expels the fœtus, no matter what be its primary position. The modifications of this general plan are, however, endless; and even in confining attention to the mechanism of a single presentation it is impossible to do more than sketch a general outline and bear in remembrance that every case has its own mechanism depending upon its individual circumstances.

Before labour the cranium may lie over the brim of the pelvis in one of four positions.

B. (*Occiput in Front.*) In the first position of the cranium the long diameter (occipito-frontal) of the head corresponds to the right oblique of the brim, and the occiput is in front; the forehead is close to the right sacro-iliac synchondrosis, and the occiput is just above the left cotyloid cavity. The position is "left occipito-cotyloid." If the direction of the child's head correspond with the plane of the brim of the pelvis—in other words, if its biparietal diameter coincide with or be parallel to the left oblique diameter of the inlet—then the head is necessarily oblique relatively to the plane of the horizon. Some writers assert that the obliquity goes farther than this; that the head is oblique not only relatively to the horizon but relatively to the brim. Perhaps the importance of this point has been over-estimated. The exact position at the brim varies slightly in every case; and if there be any obliquity of the head relatively to the plane of the inlet, that obliquity must be so slight that it is possible to overlook it, even when the whole hand has been introduced into the vagina for the express purpose of determining the question.

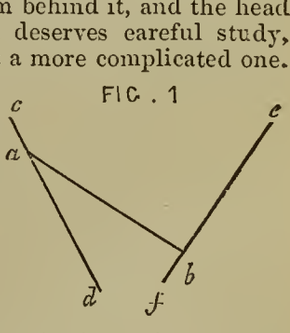
For the sake of convenience, the mechanism of the first cranial position may be divided into six steps; it being quite understood that these steps are not essentially distinct, but that, on the contrary, they run into each other, and sometimes occur simultaneously. They are—I. Flexion; II. First movement of descent; III. Levelling or adjusting movement; IV. Rotation; V. Second movement of descent and extension; VI. External rotation.

I. Almost every one allows that the first movement of the fœtal head in its course from the brim of the pelvis to the outer world is flexion (rotation on a transverse axis). The chin is pressed against the sternum, and consequently the sub-occipito bregmatic (a line running from beneath the occipital protuberance to the anterior fontanelle) diameter (3½ inches) is substituted for the occipito-frontal (4 inches) in the right oblique of the brim. The cause of this flexion is similarly described almost everywhere. We are told that the expulsive force of the uterus is communicated to the head of the child through its vertebral column, and that since the occipito-vertebral articulation is nearer the posterior than the anterior part of the cranium, the former is more forcibly pushed downwards than the latter, and flexion results.

A little reflection will show that this cannot be the correct explanation. As long as the membranes remain unruptured the ovum is to all intents and purposes an incompressible bag filled with water, and when the uterus contracts upon it it compresses it equably, and in so compressing it forces it downwards through the os uteri, the only point at which pressure is not exerted. When the membranes burst, the head acts as a plug to prevent the escape of the liquor amnii, the fluid remains in the uterus and continues to equalise the pressure on the fœtus. It is obvious, then, that the uterine force is not transmitted by the vertebral column of the fœtus, but that it may be looked upon as exerted directly in the axis of the womb.

The cause of the flexion is simple; it depends upon the head being articulated nearer the occiput than the face. Every part of the head is equally pressed upon from below by the resisting structures, but the sum of pressure in front of the spinal column is greater than the sum behind it, and the head rotates. Hubert, whose monograph deserves careful study, does not give this explanation, but a more complicated one. He says, if we engage a rod, *a b*, obliquely between two converging planes, *c d*, *e f*, and allow these planes to approach each other, the rod, *a b*, must rotate. He avers that the antero-posterior diameter of the head when in the funnel-shaped cervix is exactly in the position of the rod, *a b*, and that the cervix contracts and forces it to rotate. He does not, however, explain how the original obliquity occurs.

FIG. 1



The degree in which the head bends itself differs much, according to the relative dimensions of the pelvis. The movement is well marked where the pelvis is small, and, on the contrary, is very slight where the size of the head is well adapted to that of the canal through which it has to pass. In many of these cases, indeed, it is so slight as to be altogether overlooked.

II. The expulsive powers, *i.e.*, the contractions of the uterus, and the contractions of the abdominal muscles and diaphragm, are exerted in a direction downwards and backwards; the axis of the brim and of the upper part of the cavity is also downwards and backwards, so that the head has no difficulty in following that axis. The head then descends till the occiput reaches the lower part of the foramen ovale, and the bregma (or frontal protuberance, or some point between the two, according to the degree of flexion) is on a level with

the second bone of the sacrum. This is a movement of simple translation, and may be called the first movement of descent.

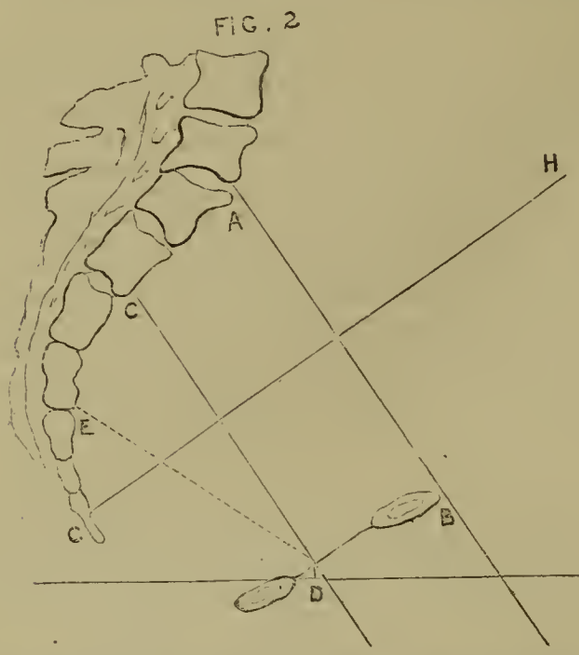


FIG. 2.—The anterior pelvic wall is supposed to be cut across opposite the extremity of the right oblique diameters. A B represents the position of the antero-posterior diameter of the head at the brim; C D, its position after the first movement of descent; and the dotted line, E D, its course after extension. G H is the axis of the brim and upper part of the cavity.

III. Most writers on Midwifery draw attention to the fact that the head generally unbends when it reaches the cavity of the pelvis. The forehead has a longer course to travel than the occiput has, and it, therefore, must move more quickly. The movement is not one, however, of simple extension. The position of the head is oblique, and while it is true that the sinciput has further to travel than the occiput, it is equally true that the left side of the head has further to travel than the right side. The movement is, then, oblique; it is a rotation on an axis somewhere between the transverse and the antero-posterior. It is partly an extension of the head, partly a flexion of it on the right shoulder. When this motion has been completed, the occipito-frontal diameter corresponds more or less perfectly to the right oblique diameter of the lower part of the cavity, and the biparietal nearly to the left oblique diameter of the same. The occiput remains behind the obturator foramen. As to the cause of this rotation. The occiput has begun to experience resistance greater than has as yet been offered to the sinciput, and whenever this difference of resistance is sufficient to outweigh the advantage gained by pressure on the sincipital or long end of the lever, then the head must begin to extend. The lateral flexion is produced in a similar manner, the anterior pelvic wall offers more resistance to the right side of the head than the left side encounters from the concave sacrum.

IV. The rotation *par excellence* is a rotation of the head upon its perpendicular axis. When it is completed, the antero-posterior diameter of the head corresponds no longer to the oblique, but more nearly to the antero-posterior diameter of the pelvis. The occiput at every pain seems to make an effort to pass behind the ascending branch of the ischium. At the same time it descends, so that the head becomes more flexed and the anterior fontanelle is no longer to be felt. During several, perhaps many pains, the occiput *feels its way*, advancing as the uterine contraction increases, and slipping back nearly to its former position when the pain comes to an end. At last the point is gained. The occipital protuberance has slipped fairly over the ascending branch of the ischium, and has no tendency to return. The cause of the rotation is evident. The occiput is being forced down upon a branch of bone running outwards and downwards, and whose inner and inferior edge is bevelled off, seemingly for the express purpose of throwing the head inwards. Rotation backwards is impossible, for the ischial spine rises up into a sharp point and forbids it, but there is no opposition to the turning of the hind head forward and inward. The sinciput again is just opposite the hollow of the sacrum, which seems to invite it, while its forward course is checked by the lesser sacro-sciatic ligament. The sub-occipito bregmatic diameter is thus acted on by two forces contrary, but not directly, opposed—its bregmatic extremity is being pressed inwards and to the left, its occipital inwards and to the right. Rotation is the necessary result.

Perhaps the obturator internus may have some little power of tilting the occiput forward and inward.

It occasionally happens that the head escapes the pivot movement when in the pelvis. It comes down obliquely on the perineum and suddenly wheels round, perhaps when it is on the point of passing through the vulva. The cause of the rotation in such a case lies in the perineum, which being attached on each side, is most distensible in its centre, so that when pressed upon it forms a groove from behind forwards. Now an oblong body pressed against a groove has always a tendency to accommodate itself to the direction of the groove, and therefore the antero-posterior diameter of the head has always a tendency to leave the oblique, and to get into the antero-posterior diameter of the maternal passage.

The fœtal head emerges from the pelvis somewhat obliquely. If (as Dr. Leishman has shown) a cord be held stretched between the coccyx of the mother and her pubic symphisis, the head in protruding from the vulva will necessarily impinge against the cord, and it will then be easy to draw a line which will show the exact part of the cranial vault which occupied the antero-posterior diameter of the pelvis when the head first became visible. This line when produced in each direction runs from the middle of the right limb of the lambdoidal suture over the cranial vault to the left frontal protuberance.

The obliquity is twofold—(1) The head has not pivoted an entire quarter of a circle, and consequently the antero-posterior diameter of the head scarcely corresponds to the conjugation of the pelvis; and (2) in spite of the adjusting or levelling movement, the left parietal protuberance is still rather higher in the pelvis than in the right one.

V. The head having rotated, the occiput is placed just behind the arch of the pubes, under which it passes. In so doing it is, of course, moving downwards and forwards. This motion is soon checked by the fœtal neck, which comes to press against the posterior surface of the symphisis, and thus fixes the occiput. The head now begins to extend, the forehead sweeps over the perineum, stretching it and depressing it, and at length reaches its anterior margin. The sub-occipito bregmatic, sub-occipito frontal, and sub-occipito mental diameters are successively presented, and the child's head is born. As to the mechanical cause of this movement. When the occiput is no longer pressed backward by the anterior wall of the pelvis, that has become free by lying behind the arch of the pubes, the head is acted upon by two forces, A B, the uterine force, and C D, the pressure of the posterior wall of the pelvis. A B is exerted downwards and backwards, C D is exerted almost directly forwards, and the head necessarily advances, as if it were pushed by a force C E, which bisects the angle of junction of A B, C D, and which is exerted downwards and a little forwards—*i.e.*, in the axis of the lower part of the pelvic cavity. Of course, the direction of the force

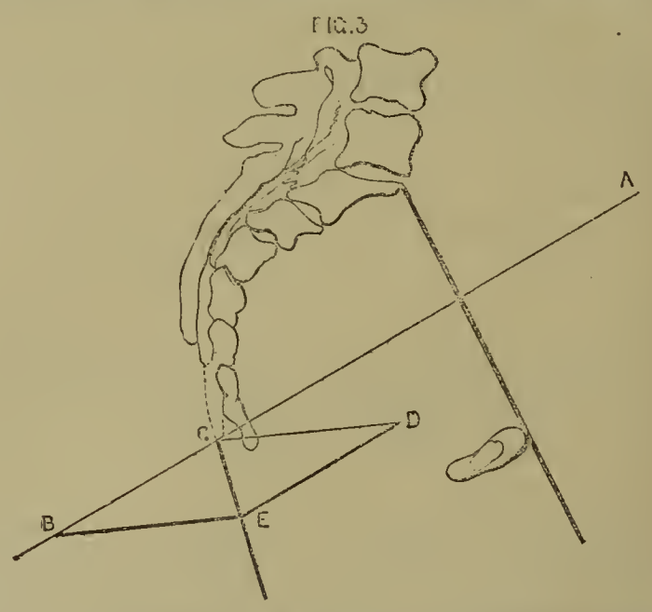

FIG. 3.—A B is the direction of the uterine force; C D is the resistance of the pelvic floor; C E the diagonal of a parallelogram formed by the two forces, being the direction in which the head is propelled.

C E is always varying as the head descends, because the direction of one of its constituents, C D, is constantly changing.

When the neck applies itself behind the symphisis pubes a new force comes into play. The force C E continues to push the sinciput downwards and forwards, but the occiput is resisted directly backwards. There are thus acting on the antero-posterior diameter of the head two forces contrary, but not directly opposed, and rotation—*i.e.*, extension—results.

The extension movement is only a continuation of the adjusting movement. From the moment that the head has accomplished its first movement of descent until it is altogether free of the maternal passages, this complicated movement is going on. After the pivot movement it somewhat changes its character. It is more of extension and less of lateral flexion, but still it continues; and even at the very moment that the face is sweeping over the perineum the head is not simply being extended, it is being also flexed on the right shoulder.

(To be continued.)

PAPERS ON

THE THERAPEUTIC AND PHYSIOLOGICAL ACTION OF REMEDIES.

By WM. MURRAY, M.D., M.R.C.P. Lond.

Physician to the Dispensary, and Lecturer on Physiology in the College of Medicine, Newcastle-on-Tyne.

No. 3.—On the Treatment and Cure of Abdominal Aneurism.

When M. W., was brought to London last May and shown to the Medico-Chirurgical Society, several gentlemen desired me to give an account of the case as soon as all risk of a return of the disease had passed away. To those interested in the subject I need not give much of the past history of this case. That the man had suffered for some months from aneurism of the abdominal aorta was acknowledged by all who examined him privately, and by the meeting of the Northumberland and Durham Medical Society as expressed in very decided terms by the President of the meeting. That the aneurism was consolidated and that the aorta and its terminal branches had ceased to beat was acknowledged by all who examined the patient at the meeting of the Medico-Chirurgical Society. Since June the patient has enjoyed a very considerable share of health. He has gained flesh and strength so rapidly, indeed, that he has been regularly engaged as a fitter in Messrs. Hawthorn's engine works, has worked generally twelve and sometimes fourteen hours a day, and has thereby been enabled to maintain his wife and his parents. His symptoms have been occasional loss of power in the legs and severe pain in the ham; and during the winter he has felt the cold very keenly, especially in his legs and feet. Once or twice he has had severe pain in the back, which has readily yielded to treatment. He has been subject to severe colds and headache, and his digestive organs have been sluggish with a tendency to constipation. Once, and once only (in October) he has had an epileptic fit, which was severe, and left him very prostrate. Notwithstanding these ailments, sometimes three or four weeks elapse during which he feels quite well.

The Aorta.—To this day I have not been able to discover the slightest pulsation in the aorta *below the tumour*, so that its occlusion may be considered an established fact. The femorals also are pulseless, and as far as I can make out there is no *large vessel* below the seat of the aneurism by which blood is circulating. The tumour has completely disappeared, and a dense resistance is all that can be felt over the seat of the aneurism; *above* this the aorta beats with a sharp forcible stroke.

So far, I think, it is clear, 1st, that this case of aneurism of the abdominal aorta has been cured by pressure; 2nd, that the aorta has been occluded without either temporary or permanent serious disorder; 3rd, that there must be a collateral system of vessels so complete as to carry on the circulation when the aorta is blocked. Since this case was brought forward others have been encouraged to adopt the treatment here employed. I had the pleasure of assisting Dr. Heath, of this town, in the treatment of a case of iliac aneurism by compressing the aorta, and the treatment has proved most successful. Since then, Dr. Mapother of Dublin, encouraged by the Newcastle cases, has achieved a brilliant success in a case of iliac aneurism treated in St. Vincent's Hospital. Each of these gentlemen will doubtless bring the particulars of his case fully before the Profession. Meantime, I add their experience to mine in making the following remarks:—

First Proposition.—The introduction of chloroform in the treatment by compression in no way interferes with the coagulation of blood or the deposition of fibrin; by *it* this treatment is applicable to arteries in the most sensitive and delicate situations, and it may be used for several hours continuously without danger to the patient. Its use will add greatly to the ease with which the treatment can be carried out, and therefore to its efficacy. It ought to be used in treating aneurism in *other* parts, as well as those in the abdomen.

Second Proposition.—From these three cases it is evident that consolidation of fibrin alone does not cure the aneurism; *this is due mainly to coagulation of blood.* This is proved, 1st, by the clear indications in Dr. Heath's case and my own that the tumour ceases to beat and becomes solid within the space of *one hour* (see report of case) when once the conditions of coagulation are established; 2nd, by the rapid disappearance of the tumour after it becomes solid. In the Newcastle cases the diminution in the size of the tumours was a surprise to us all. The rapid formation and removal of the clot argues powerfully *for* its sanguineous and *against* its fibrinous nature.

Third Proposition.—It is now established that the cure of an aneurism by pressure need not be a tedious process lasting many hours and extending over many days. The question may be stated thus:—Are we to have cure by coagulation of blood in *five hours* by completely arresting the current through the aneurism, or cure by lamination of fibrin in *twenty-five days* by frequently and imperfectly arresting the circulation? The answer of course depends upon the safety and efficacy of the *former* process. That it is as *safe* as the other I have no doubt, for in none of these cases has suppuration of the sac after treatment, or injury to the patient while being compressed, resulted. All that we can say with regard to the permanent efficacy of the treatment is, *that it has not failed in any one instance.*

Fourth Proposition.—The experience derived from the treatment of the two cases of iliac confirms an opinion I had formed, that in all cases of aneurism of the larger arteries springing from the abdominal aorta it is best and perfectly safe to press on the aorta itself. (To command the channel of the aorta and to arrest its pulsation seems to me after numerous trials to be a most feasible operation.)

I need scarcely apologise for introducing this somewhat mechanical remedy, for I consider it acts according to known physiological laws, and operating through them it is a therapeutic agent. I will not here enter on the question as to whether a stationary mass or a feeble current of blood is most likely to coagulate; on its settlement hangs the adoption of distal as well as proximal pressure. I would say, however, that I have a case where an aneurism seems to be developing very high in the epigastric region: and in this case when once the existence of the aneurism is certain, I shall apply a Signorini's tourniquet to the artery below the tumour, and by this *distal* pressure I hope to obtain a cure.

P.S.—I would compare the process of *coagulation* in an aneurism to those instances of crystallisation which occur when the slightest disturbance of the conditions of solution determines the immediate solidification of dissolved matter, where a sudden movement, a rough surface, etc., are enough to induce the formation of crystals—*vice versa*, the completely arrested current seems to assume the solid form *at once and decidedly* as soon as the conditions of the solution of fibrin are disturbed; we are still uncertain as to the exact nature of those conditions, but we can disturb them in an aneurism by the compression treatment.

Fabricated Port Wine.—A somewhat new article of commerce, Rhatany from Peru, is coming into considerable use for the fabrication of so-called port wine. This root of a bush grown in the environs of Arequipa, distinguished with difficulty in solution, even although the senses of the observer may be more acute than the guests of a worthy clergyman who, on leaving his table, affirmed that they had been served with port wine three times in different forms: first, smoking hot from a tureen, and then called hare soup; secondly, cold from a decanter; and, thirdly, hot with sugar and cream, the red-armed Hebe having the effrontery to declare that it was coffee. Rhatany, as an astringent, is used in medicine, but its high price, 2s. 9d. per lb. the first quality, and 1s. 6d. for ordinary, is evidently attributable to its service in the mode we have referred to.—*Wine Trade Review.*

Medical Times and Gazette.

SATURDAY, APRIL 15.

THE PROCEEDINGS OF THE MEDICAL COUNCIL.

The sittings of the Medical Council have been continued during the week, and will, it is said, be continued until Saturday. The proceedings, though leading as yet to no very definite results, have, on the whole, been interesting. We can recognise a more business character about them. There is still, however, a great deal too much talking,—too great a tendency to criticise and to enter upon minute details. Some of the more silent members, however, are more active than formerly, and, on the other hand, there is less of oratorical display. The amendments of the Medical Act, and the recommendation of the Council with regard to the registration of students, and with reference to Professional education, have chiefly occupied the attention of the Council. With reference to the amendments of the Medical Act, it has been determined to put in force, if required, the powers which the Council possess, under Section xx. of the Medical Act, before seeking for new or greater powers over the educational bodies. The amendment of Clause xxxi. has not yet been agreed on, its consideration being postponed with reference to the Pharmacy Bills now before Parliament. The fortieth clause of the Act—the registration clause—is that which has specially occupied attention. The clause as proposed by the English Branch Council has been adopted, with a most important alteration. As we explained a few weeks ago, the English Branch Council proposed that no one should be allowed to use any Medical title whatsoever, except he was registered, or in *possession of a qualification which entitled him to be registered.* This latter paragraph has been struck out, and thus the clause has been made to correspond with the views of the Scotch and Irish Branch Councils. In a word, registration is to be made compulsory on all qualified Practitioners. If the various licensing bodies do not object to this arrangement, which virtually deprives them of their licensing powers, and if the Profession submits to a regulation which trenches somewhat on means already not over abundant, there is no doubt that the proposed clause simplifies matters greatly, and may be, in many respects, beneficial in its operation. The consideration of other amendments of the Act has been referred to a Committee, the report of which has not as yet been brought forward. The registration of Medical students has also been under the consideration of the Council, and the result has been to place it in the hands of the Branch Registrars, in whose offices students will henceforth register. The only other proceedings of the Council to which we need now direct attention are a report from the Pharmacopœia Committee, which says that Messrs. Redwood and Warrington are engaged in the preparation of a new edition under the direction of a committee of the Council. We are not told when we may expect this new edition to be published. We see that interesting reports have been presented from the Director-General of the Army and Navy Medical Department. These valuable returns give the number that passed and were rejected by each of these Boards of legally qualified candidates who submitted themselves for examination, and the names of the institutions from which they obtained their qualifications. The Army Board rejected thirty-one out of one hundred and twenty candidates; the Navy Board rejected twenty-one out of forty-nine candidates. The inference to be drawn from these returns is this—that nearly one-third of those gentlemen who are declared by Examining Bodies having a pecuniary interest in the statement, to be fully qualified to practise the healing art amongst all Her Majesty's subjects, are found by independent Boards to be more or less ignorant and unqualified to treat Her Majesty's soldiers and sailors. These returns fix a great responsibility on the licensing bodies and on the Medical Council appointed to look after them. This duty it is proposed should be undertaken by the Branch Councils in the supervision of examination. The sooner this is done the better. Having said that nearly a whole sitting was unprofitably devoted by the Council to an attack on, and a defence of, the Irish Apothecaries' Hall, we believe we have stated nearly all that has been done by the Council up to the close of Tuesday's meeting. We shall next week follow up our review of the proceedings of the Council.

QUARANTINE.

In a country such as ours, whose commercial relations are so vast, whose very existence depends upon the free interchange with other nations of the products of industry and the gifts of the earth, whose merchant ships visit every port in the civilised world, and whose own seaboard is familiar with the flag of every maritime community, the bare mention of quarantine at once raises universal attention. Up to the present time our information as to the nature of the disease which is said to be prevailing in countries which border upon the Baltic, is so imperfect that we can form no calculation of the chances of its extension to ourselves, and hence it would be obviously premature to discuss the propriety of enforcing quarantine laws in this particular instance. But since the subject has been mentioned in Parliament, in connexion with the rumours that have reached this country, it may not be out of place to consider very briefly whether under any circumstances it is proper or needful to enforce these restrictions upon trade and inter-communication between nations; and if so, what method can be devised to render them less irksome, and to reduce to a minimum the inconveniences that naturally result from their adoption.

The doctrine of *contagia* is generally supposed to be the basis on which the imposition of quarantine regulations is supported. Hence it is the customary battle-field on which those contend who, on the one side, maintain that they are deserving of being preserved, and who, on the other side, hold that all such impediments to free intercourse should be swept away, as antiquated relics of a bygone and unenlightened age. Since it is with a view to provide against the introduction from abroad of diseases which are apt to spread among a people as epidemics that quarantine laws are enacted, it has become almost a necessity on the part of those who subscribe to the latter view to draw as broad a line as possible between epidemic and contagious disease. No one has ever done this more boldly than Dr. Maclean some forty years ago; and on this account we quote him as the mouthpiece of the party of which at the time he wrote he was the most uncompromising adherent:—"The causes, the laws, and the phenomena of epidemic and contagious diseases being so dissimilar, or opposite, those diseases themselves are necessarily incompatible and inconvertible. That a disease capable of being propagated by a specific *virus* can never be produced by any other cause, and that a disease produced by other causes can never be propagated by a specific virus, are, indeed, self-evident proposi-

tions."(a) Nothing can be clearer than this as an expression of doctrine; yet can any argument based upon such a foundation be anything else than a mere playing with words? The fact is, that at the present time we are familiar with many maladies which are contagious in every sense of the word, some even capable of communication by inoculation, and others by close approach of the healthy to the sick, by the medium of clothing or of other articles which have lain within the influence of emanations from the sick man's body, and yet diseases which become at times widely diffused amongst the population of a country, defying the detective who would track their march, attacking all ranks of society, and slaying, albeit with discrimination, rich and poor, high and low, noble and peasant. Epidemic at such times and such seasons we cannot well avoid designating them, if by that term we mean that they appear widely scattered among the people and breaking out, if not simultaneously yet nearly so, in different and distant parts of the same country. Contagious no less unquestionably they are, inasmuch as those are most liable to suffer who come most closely into relation with the sick; and those are most free from attack who separate themselves most thoroughly both from them and their belongings. If modern investigation tends to anything, it is to this: rather to merge the epidemic diffusion of disease into the operation of a contagion than to do away with the theory of contagion, in order to erect upon its ruins a doctrine which shall explain the phenomena in question by the hypothesis of an incomprehensible atmospheric influence. Let us not forget the instructive lesson read to the Profession by Dr. Budd a year or two ago upon the text afforded by the history of ovine small-pox as it lately appeared among the flocks in this country. Neither let us forget Dr. McWilliam's demonstration of the origin of the Bōa Vista outbreak of yellow fever through the crew of the *Eclair* in 1845.

Another line of argument adopted by the non-contagionists is based upon the fact that epidemic diseases, whatever form they assume, invariably select for their outbreak and for their chief foci localities abounding in elements of unwholesomeness, dirt, crowding, and misery. That such is the truth no one will be dispesed to deny; but they go further than this, and if they do not assert it in so many words, they leave us to infer the doctrine that these epidemic diseases are all modifications of one primary ideal type, whether the modification appear as typhus, plague, yellow fever, or cholera. "Epidemic diseases were formerly universally considered to be essentially different in their nature, each being thought to depend on its own specific contagion; and the correctness of this view seemed to be confirmed by the great apparent difference between typhus, scarlatina, influenza, plague, yellow fever, and cholera; but whether each of these diseases depends on a peculiar and specific cause, or whether they all derive their origin from one common agent essentially the same in nature, but modified by peculiarities of climate and other circumstances, and which, under varying conditions, give rise to various forms and types of disease, each having definite characters and running a particular course—whichever of these views be adopted, it is agreed by the most eminent investigators that there is a general resemblance between the various forms of disease, and that they have the following characters in common:—They are all fevers; they are all dependent on certain atmospheric conditions; they all obey similar laws of diffusion; they all infest the same sort of localities; they all attack chiefly the same classes, and, for the most part, persons of the like ages; and their intensity is increased or diminished by the same sanitary and social conditions." Thus, in 1849, did the non-contagionist author of a Board of Health report, paraphrase and envelope in verbosity the more simple and out-spoken declaration of creed by Dr. Maclean in 1824. "Whilst all epidemic diseases are in reality nothing else than modifications of the *causus* or *febris ardens* of the ancients, an almost endless variety of names has been given to them in modern systems, to the great detriment of science."(b) The practical conclusion is, that in place of annoying and vexatious quarantine regulations, it is enough that the State should provide, on any threatened invasion of disease, for the sanitary improvement of the surroundings of the people.

We have no hesitation as to the side on which to place ourselves in this old and constantly recurring controversy. It is one which has raged on various occasions, and which will inevitably rage again with its ancient ferocity should Government, at any future time, propose to erect a barrier against the importation of any foreign epidemic by the imposition of quarantine. Just upon the same principle that we should close our door against the introduction into our house, however wholesomely it may be kept, of a person suffering from plague, yellow fever, or small-pox, and so place every obstacle in our power in the way of intercourse with its inmates, so we hold that the State is doing no more than its duty to the people of this country when it holds at arm's length individuals similarly affected, until they show that there is no reasonable chance of mischief accruing from their free admixture with a healthy population.

There is another side, however, to this question, and from an empirical point of view we are bound to inquire what experience has to tell us about the value of quarantine as a national protective measure. That quarantine precautions have failed to prevent the advance of cholera—that they have equally failed on various occasions to prevent the introduction of yellow fever into a port—is quite true; but in admitting this we by no means debar ourselves from advocating the value of the practice. The objections which might be raised on this score lose much of their force when it is considered how little we even now know for certain as to the nature of the morbid poison which engenders the former disease, and how probable it is that other media than the atmosphere and fomites are engaged in its propagation. The objection also is lessened in force when the difficulties in enforcing a rigid quarantine are kept in mind, and the incessant endeavours which are made at its evasion when attempted to be enforced—endeavours which nothing but the greatest vigilance of quarantine officers will suffice to neutralise. That imperfect quarantine should fail to arrest the progress of disease, is nothing to be surprised at; but still this is no valid argument against the efficacy of the practice when thoroughly and completely carried out. We cannot here enumerate all the elements which go to make up such thorough completeness; but experience has attested its efficiency when complete in accomplishing the object in view. Witness, for example, the remarkable comparative freedom from plague which has attended its establishment in various places on the Mediterranean sea-board. Witness, also, the experience of the State of New York, where in 1845 the House of Assembly, after a most rigid inquiry into the operation of these quarantine laws against yellow fever, reimposed them on all vessels arriving from infected ports, on the ground that from some such rigid enforcement that State had for a quarter of a century been maintained free from any outbreak of the disease.

One thing, however, we are prepared to concede, and it is this: that the evidence of communication of disease through the medium of merchandise is so defective that, could any means be devised by which cargoes might be liberated while personal quarantine was carried out, we should be little disposed to interpose a dissentient voice. Again, while we are of opinion that the practice of quarantine is one which is commendable under certain contingencies, we are of opinion that it would be sufficient to enforce it only on such vessels

(b) *Op. cit.*, p. 203.

as have come directly or indirectly from some port actually infected. We would also limit the duration of personal quarantine as much as possible consistently with what is known of the incubative period of the disease that may be in question, that each case should be judged of upon its own merits, and that a discretion should be placed in the hands of a qualified Medical quarantine officer to allow free pratique, or to shorten the duration of quarantine in those instances where the voyage from the infected port has extended beyond the extreme period of incubation, on the necessary evidence being forthcoming of freedom from disease during the passage. Neither would we in the least degree relax, but rather push forward, all those proceedings which are calculated to render habitations wholesome, and especially those in the low neighbourhoods of our sea-port towns. The one should be done, and yet the other not left undone.

But, after all, what do all the arguments *pro* and *con.* upon this question of contagion practically amount to? Whether we are engaged in combating disease actually present or in guarding against its spread, little indeed should we effect did we fold our arms in complacent expectancy until we had obtained demonstrative proof of the absolute correctness of the data upon which we habitually ground very much of the practice of our art. Upon this subject we cannot do better than quote, in conclusion, some excellent remarks of Dr. Gooch at a time when (in 1825) he strenuously and successfully opposed a suggested alteration in the quarantine laws:—

"In Medicine, and all but the demonstrative sciences, there is often light enough to guide our conduct where there is not enough to gratify our curiosity; hence practical men are often compelled to act on evidence which would sound unsatisfactory in the statement. There is no paradox in saying that he who can give a striking reason for every measure he adopts is, for that very reason, a bad Medical adviser, because he must neglect many which are necessary and useful, but the reasons for which at the outset are extremely obscure."

WORKHOUSE IMPROVEMENTS.

It is said that the Government intend to bring in a Bill after Easter to enlarge the National Gallery in Trafalgar-square. At present the rooms are over-crowded with pictures; there is not nearly a sufficient amount of wall space, and our national collection, which contains many very valuable works of art, labours under great disadvantages. To remedy this evil, it is proposed to erect new galleries at the back of the present building, on the site now occupied by St. Martin's Workhouse and over a portion of the adjacent barrack-yard. The workhouse would of course be swept away, but the barrack-yard would not be curtailed, because the galleries would here be supported on pillars, so as to form a covered ground for the training and recreation of the soldiers in wet weather.

If this plan is carried out it will become necessary to rebuild St. Martin's Workhouse on a new site. In doing so we trust that the parish authorities will adopt some of the suggestions which have been made of late for a better classification of inmates and for ameliorating the condition of the sick poor. Not that St. Martin's Workhouse is inferior to others in these respects, but because an opportunity of improving it is likely to arise. Thanks to the operations of the Workhouse Committee of the Social Science Association, a great deal of light has recently been thrown on workhouse management and a great deal of interest excited in the subject. Within the last few days, also, the same theme has been ably and sensibly discussed in a pamphlet by Dr. Stallard.(a) The cases at the Holborn Union and the St. Giles's Workhouse, which have raised so much indignation, are but the natural results of the existing system; and the public have to thank themselves—at least, their legislators—for them. The whole system of the new Poor-law is well described by Dr. Stallard as one of *negative* philanthropy. The diet and relief supplied are sufficient to keep men and women from actual starvation, but they are not sufficient to maintain them at the normal point of health and strength. Take as an instance the diet at the St. Giles's Workhouse, where a full-grown man is kept for twenty-four hours on $1\frac{3}{4}$ lbs. of bread, $2\frac{1}{2}$ oz. of cheese, 2 pints of oatmeal porridge, and some onions. On three days in the week the $2\frac{1}{2}$ oz. of cheese are replaced by $\frac{1}{2}$ lb. of uncooked meat, on one day by $\frac{1}{4}$ lb. of bacon, and on the other days by a pint of broth or pea soup. In the same way, whilst in Hospitals supported by voluntary contributions the cure of the sick is aimed at, all that Union Hospitals (*i.e.*, in parsimonious parishes) are intended to provide is a supply of Medical attendance at the lowest possible price, and of necessaries of the coarsest possible kind—just sufficient to satisfy the public conscience that the pauper has not been "*neglected.*" The faulty construction of Union Hospitals, and the nursing by pauper nurses are only parts of the same system of Poor-law "relief." We believe that the best remedy to dispel the horrors that gather round the dying pauper left to the tender mercies of a drunken nurse who sells his rations for gin, would come from the active, voluntary, but combined benevolence of Christian women, and we commend to the various Sisterhoods which are springing up around us the Union Hospitals of London as a most fitting field for their exertions. But such efforts we know do not meet with favour in all quarters, and it is perhaps more relevant to take advantage of the present aroused state of public opinion, and to appeal to the Government for some measure of active reform. That there is a growing feeling that a reform is necessary is shown by the verdict which was returned a few days ago by the jury impanelled to inquire into the death of Richard Gibson, an inmate of the St. Giles's Workhouse. They "desire to call the attention of the Poor-law Board to Ward 47 of St. Giles's Workhouse, in which the said Richard Gibson was confined during his illness. They think the said ward deficient in lighting, ventilation, and proper accommodation for the patients, as well as its very bad position, and ought to be closed. They also think that the dietary of the sick poor in the said workhouse is deficient, and that patients ought not to go from 4 o'clock p.m. to 8 o'clock a.m. without food. They also think that more paid nurses should be appointed to attend upon the sick, and they are of opinion that the neglect of the nurses to change the linen in the case of Gibson is severely reprehensible." We consider this verdict one of great importance, and we regard it with no small satisfaction. It comes from the class of men who are most interested in keeping down the rates—a class from whom the guardians in our metropolitan districts are in part selected; and it shows that they are becoming alive to their responsibilities, and anxious that the sick poor should be properly cared for, even though it should entail a slight additional expense. To parish Medical officers the advantages of a more liberal dietary and of skilled nurses are obvious. We sincerely trust that the St. Giles's Board of Guardians, stimulated by the inquiry instituted by the Poor-law Board, will lose no time in carrying out the recommendations of the jury, and that the example here set will be extensively followed.

Should it become necessary to rebuild St. Martin's Workhouse, we hope that great improvements will be made in the arrangements for the sick and infirm; that both in construction and management the wards will be placed more on a footing with those in Hospitals; and that accommodation will be afforded for a more thorough classification of cases than is at present possible. Probably the best way of carrying out these objects would be to separate the wards for the sick and incurable from the workhouse, so that they might be conducted on different principles without encouraging pauperism.

THE WEEK.

UNIVERSITY OF LONDON.

We hear with great satisfaction that the Senate of this University have resolved on instituting the degree of Bachelor of Surgery (B.S.). This degree will, it is understood, be conferred simultaneously with that of Bachelor of Medicine, and on the same examination, with such modification as may be found necessary in relation to a practical examination in Surgery. This is certainly an advance in the right direction, and it is one which has been distinctly due to the graduates of the University. The regulations of the University have been such as to require from all graduates very high attainments in Surgery. Yet, however eminent those attainments may have been, there has been hitherto no public recognition of them, except that of Master of Surgery—a recent institution. Now a Bachelor of Medicine will also be recognised as a Bachelor of Surgery. The double qualification will be conferred by a single examination. There cannot be a doubt that all those who aim at a double qualification of a high order, and who having confidence in their own powers are ready to use them, will look to this degree. From this starting point those who wish to practise as Physicians will go on to take the M.D. degree, and the possession by them of a Surgical degree (B.S.) will be no valueless evidence of the extent of their Professional acquirements; whilst those who wish to practise as Surgeons can go on to the Master of Surgery degree, and to them the possession of a Medical degree, the M.B., will be even more valuable evidence of the extent of their Professional knowledge. The usefulness of the new degree will be further enhanced when it takes a place in Schedule (A) of the Medical Act. We see that notice has been given in the Medical Council that the like degree be recognised when conferred by any University. To such a proposal we cannot conceive that any objection can be made, for it is certainly in accordance with the expressed wishes of the Council that students should be rescued from multiplied examinations by a multiplicity of examining boards.

PARLIAMENTARY.—THE EPIDEMIC IN RUSSIA—THE EXPULSION OF THE METROPOLITAN POOR FROM THEIR DWELLINGS—MEDICINES FOR THE NAVY.

On Thursday, April 6,

Sir J. Pakington asked the Secretary of State for the Home Department whether the attention of Her Majesty's Government had been directed to the disease now prevailing in Russia and some parts of Prussia; and whether the Government proposed to take any steps to ascertain the true nature of the disease, and to avert its introduction into this country.

Sir G. Grey said the attention of the Government was directed to this subject by a statement which appeared in one of the daily papers of March 29. Instructions were immediately sent by telegraph to Sir A. Buchanan, at St. Petersburg, to make without delay the fullest inquiries into the subject, and to send from time to time all the information he can obtain as to the origin, nature, and progress of the disease, and as to the treatment of it. Instructions were also sent to Her Majesty's representatives at Berlin, Vienna, Copenhagen, and Stockholm, and to the consuls at the Baltic ports, to send full information as to the disease, should it appear in any of those parts of Europe. A Medical officer has also been directed to proceed at once to St. Petersburg to investigate and report upon the disease, and the officers of Customs have been directed to exercise the utmost vigilance in the examination of vessels coming from the Baltic. The information we have as yet received has been by telegraph, but Sir A. Buchanan says that he has forwarded by post a printed Medical report on the disease, which is stated to be a fever new in Russia, but not unknown in other parts of Europe, and it was said to be diminishing at St. Petersburg. Lord Napier says that the Minister of the Interior had told him that an unknown disorder had appeared along the valley of the Vistula, but that he was not aware that it came from Russia. The Consul at Dantsic, in a telegram dated to-day, says that a disorder prevalent in that district is a complaint of the brain, chiefly affecting children. The Consul at Warsaw, in a telegram also received to-day, says that some cases of typhus have occurred there, but no disease having the proportions of an epidemic disorder has up to the present time appeared in Poland. The Consul at Königsberg reports that no particular epidemic disorder exists there, and the Consul at Memel says that no symptoms of the disease have appeared in that district nor in the adjacent Russian provinces; and a telegram just received from the Consul at Stettin reports that no epidemic disorder prevails there.

In the House of Lords on Friday, the Lord Chancellor, in the absence of Lord Shaftesbury, moved the amendment to Standing Order No. 191, of which notice had been given. The object of the motion is to obtain for the House full information of the number of dwellings demolished and of the inmates displaced by proposed railway works in the metropolis, and to secure due notice to those persons who have to quit their residences.

Some discussion took place on the manner in which the amendment should be worded, the Bishop of London pointing out that the greatest difficulty would still remain unless houses were provided to which the people could remove. He suggested that the wealthy London companies might render some assistance in this difficulty.

The amendment was finally agreed to.

In answer to a question by the Bishop of Oxford in reference to the St. Petersburg epidemic, Earl Granville said it was quite true that a telegram had come that day from Berlin which gave a worse account of the epidemic than had been previously received from St. Petersburg. A Medical officer of great experience had been sent to St. Petersburg, and another gentleman of equal Professional attainments had since been sent to the Valley of the Vistula, to ascertain the real character of the disease. He was not aware that any further steps could be taken in the matter.

In the House of Commons, the consideration of the amended Metropolis Sewage and Essex Reclamation Bill was adjourned until the 25th inst.

In answer to a question by Mr. Onslow, Sir G. Grey said that the information received from the Continent was not such as to induce the Government to think of establishing a quarantine at present.

In a Committee of Supply on the Navy Estimates, £64,800 were voted for Medicines and Medical stores.

The House adjourned until Monday, the 24th.

FROM ABROAD.—A NEW PLESSIMETER—IDENTITY OF GRAVEL, DIABETES, AND ALBUMINURIA—DIMINISHED RATE OF MORTALITY IN PARIS—ELECTRICAL ANÆSTHESIA.

M. Moulin, an old pupil of Laennec's, describes, in the last number of the *Gazette des Hôpitaux*, a very simple plessimeter, which for many years past he has been in the habit of advantageously employing for the performance of percussion. It consists merely in a disc of caoutchouc, from two to four millimetres in thickness, and for ordinary purposes need not be larger than a five-shilling piece. It is pierced with a hole in the centre to facilitate the transmission of sound, and is easily carried about in the pocket-book, so as to be always at hand, which is not always the case with more elaborate instruments. Of course, it may be made of any form most convenient for use. The varieties of sound are transmitted with great exactitude and distinctness through this thin portion of an insonorous material.

M. Roubaud, a Medical Inspector of Mineral Waters at Pougues, has communicated to the Academy of Sciences a memoir having for its objects to prove that three affections, apparently so dissimilar as gravel, diabetes, and albuminuria are yet in their nature identical. He sums up his views as follows:—1. These three affections are not diseases of the urinary apparatus. 2. The anatomical lesions which during their course are met with in the organs of this apparatus, are either foreign to, or consecutive to, the affection in the immense majority of cases. 3. Their etiology is found in a more general circumstance—viz., an altered condition of the blood. 4. This alteration is constituted by the excess of an excrementitial product—uric acid—which, according to special conditions that lead it to remain insoluble, or to

react on the glucose or on the albumen of the blood, gives rise to either gravel or gout, to diabetes, or to albuminuria. 5. A future memoir will furnish an exposition of the circumstances which induce this varied mode of action of the uric acid. 6. The excessive formation of uric acid—*i.e.*, the evolution of the uric acid diathesis, is referable to disturbances in digestion or nutrition which render albuminoid products incapable of complete combustion. 7. It has been while pursuing the scientific investigation of Medical hydrology that I have arrived at the preceding considerations, which are amply justified by numerous cases that have come under my care at Pougues.

An interesting statistical document in relation to the more tality of Paris has just been published in the shape of a Report presented to the Prefect of the Seine by M. Deville, based upon the returns made by the Medical Inspectors for the Verification of Deaths during the years 1840—63. This system of inspection was instituted in 1840; this report, therefore, gives an account of its entire operations during twenty-four years. In 1836, which was the year in which the first quinquennial census was taken, the population of Paris was 868,438, and the number of deaths during the same year was 24,047—*i.e.*, about 1 death in 36 inhabitants. In 1846 there occurred 1 death in 37; and in 1851, 1 death in 38. In 1860 the limits of Paris were greatly extended, so as to form 20 in place of 12 arrondissements, and in that year the population being 1,696,114, there were 43,516 deaths—*i.e.*, 1 in 39, or 2·56 per cent. In the year 1863 the proportion of deaths is calculated at 1 in 40. Among the causes of this important amelioration, the reporter places—1. The extension of the superficies of the capital in relation to its population. This was in 1841 but 3402 hectares, with a population of 935,261; while since 1860 this has been 7802 hectares, or more than double, with a population of 1,696,141. An examination into the details of the mortality, and especially during the visitation of epidemics, shows that this is not merely proportionate to the extent of the arrondissement or its relative population, but to the amount of agglomeration and the bad hygienic conditions which result. 2. The next favourable condition which the report brings prominently into notice is the purification of the air by means of plantations, the number of which have been so much increased within the last ten years; for while in 1853 there were only 215 hectares of planted ground in Paris, in 1863 this amounted to 328 hectares. 3. Next comes the better supply of water, both for domestic use and for the effectual cleansing of the streets and houses. In 1840 the Administration was enabled to distribute for general and private use only 65,000 cubic metres of water in the twenty-four hours; but by 1861 this had reached 100,000; in 1862, 133,258; and in 1863, 136,634 cubic metres in the twenty-four hours. 4. Conjointly with this more abundant supply of water, a vast system of subterraneous sewerage has been carried out. 5. The operations of the *Commission des logement insalubres*, instituted in 1850, have also contributed to the amelioration of the sanitary condition of the habitations of Paris. 6. Lastly, the reporter attributes a portion of the improvements which have been attained to the progress of Medical science, and points out that the illegal practice of Medicine and charlatanism stand in the way of still greater progress.

Dr. Rodolfi has just held the second of what he terms his "electro-therapeutical sittings," in the Brescia Hospital, at which the anæsthetic power of the electrical current was again demonstrated before a numerous assembly, together with other phenomena. Among the latter was the production of a peculiar sound by the passage of the electrical current through the muscles. Four women suffering from nervous affections were experimented upon, it being first ascertained that as regards the intellect, sensibility, and motility, they were in a normal condition. 1. A woman, æt. 24, who had suffered from epileptic attacks for some years, submitted to De La Rive's electrical current for two minutes, manifested complete anæsthesia with slight "sub-delirium." The application having been continued for five minutes, the usual phenomena of epilepsy were induced. 2. On the other hand, another woman, who was seized with an epileptic attack in the presence of the assemblage, was at once submitted to the current. After this had been in operation during five minutes, the attack was completely suspended, the anæsthesia of the hands and forearm being obvious to all present. 3. In this woman, the subject of "a hysterical form of bronchitis," Dr. Rodolfi called the attention of his visitors to the special sound produced by the passage of the current through the muscles, and observed that, after long searching for a galvanometer suitable for measuring the intensity of the anæsthesia, and the force necessary for its production, he had found that patients themselves constituted the most exact of all galvanometers. The machine must be so regulated that the sound is produced, this diminishing or disappearing also in proportion as the anæsthesia is induced. It having been previously ascertained that no noise was audible in the arm of the patient prior to the introduction of the current, such noise was after this plainly heard in the flexors and extensors by those present. It was a continuous sound, resembling a distant approaching railway train or a roaring, and it diminished progressively with the appearance of the anæsthesia; so that after the current had continued for five minutes, and anæsthesia had become complete in the hands, the sound could only be heard in an intermittent manner along the arm, having completely ceased in the parts which had become anæsthetic. In the course of a quarter of an hour the anæsthesia had extended to the elbow. 4. In another woman suffering from cephalagia dependent on amennorrhœa, the sound heard immediately after the establishment of the current disappeared in one arm, and diminished in the other after the production of anæsthesia. The assembled *savants* determined that this sound should be termed the "electrical muscular sound."

GENERAL MEDICAL COUNCIL.

THURSDAY, APRIL 6.

(THIRD DAY.)

The Council met at 2 o'clock.

The minutes of the last meeting having been read and confirmed,

The President said that the first business of the meeting was the reading of the communications from the Directors-General of the Army and Navy Medical Departments.

The Registrar accordingly proceeded to read the communications.

Mr. Arnott, during the reading, moved that the documents be printed and marked "confidential," for the use of the Council.

Dr. Acland seconded the motion.

Dr. Corrigan rose to order. He said that in the face of the resolution of yesterday that the communications should be read, the Council could not entertain the motion just brought forward.

After a short discussion the remainder of the documents was read. They contained returns of the results of the examinations of candidates for appointments on the Medical staff of the Army and Navy. In the case of the candidates for appointments in the Navy, a large number were ignorant of the Latin language.

Dr. Andrew Wood moved "That the communications just read be received and printed on the minutes." He considered that there was not an examining board in the kingdom which would not be benefited by their publication. The thanks of the Council were due to Dr. Apjohn, who moved for the returns.

Dr. Parkes seconded the motion, and suggested that in future the Director-General of the Medical Department of the Army should also forward returns of the examinations of the candidates for appointments on the Medical staff of the Indian Army.

The motion was carried.

Dr. Apjohn moved, and Dr. Paget seconded, a vote of thanks to the Directors-General of the Army and Navy Medical boards for the returns, and a request to the Director-General of the Army Medical Board that the returns may henceforth include the examinations of candidates for Indian service.

The report of the committee of communications relative to the amendment of the Medical Acts was read.

Dr. Embleton moved "That the report be received and entered on the minutes."

Dr. Fleming seconded the motion.

The resolution was carried unanimously.

Mr. Arnott moved "That certain communications referred to by the Committee be read and printed on the minutes."

Dr. Paget said that some of the letters were personal, and it would be unadvisable to print them.

Dr. Aquilla Smith expressed the same view.

Mr. Arnott said the report stated that some of the letters were worthy of consideration. They could not consider them unless they had their contents before them.

Dr. Embleton said the letters should be printed.

Dr. Paget said that if they were printed names should be omitted.

Mr. Arnott agreed to append a clause to that effect to his motion.

The motion was seconded and carried.

Dr. Andrew Wood moved "That a committee be appointed to draw up a memorial to the Home Secretary in reference to the amendment of the Medical Act, and to report to the Council."

After a short delay,

Dr. Andrew Wood said he had ascertained that it would be better to defer that motion, in consequence of some reports having been brought forward by which circumstances were altered. He then moved "That the Council resolve itself into a General Committee on Education, and that the President take the chair."

The motion was seconded by Mr. Hargrave, and carried unanimously.

The Chairman asked whether the reporters should remain. He believed that when the Council were in committee the rule was that the proceedings should not be reported.

Dr. Andrew Wood said that he thought the presence of the press was a very wholesome check. The only object in going into committee was to get rid of the usual formalities of debate.

Dr. Corrigan said that it was most desirable that the press should be present on this occasion, and he should therefore move "That the reporters be allowed to remain."

Dr. Andrew Wood said there was no bye-law that reporters should be excluded from committees of the whole Council. The exclusion was intended to apply only to committees of part of the Council. It was his impression that those who wished to exclude the press must make a substantive motion to that effect.

Dr. Parkes moved, "That a Committee of three be appointed, one member from each division of the kingdom, to be called the Committee on Education. That the powers and duties of this Committee be—1. To prepare a definite statement of the systems of examination of the different licensing bodies, as stated in the documents already sent in to the Council, so that the agreements and differences of the several systems may be brought into one view. For this purpose the Committee shall be enabled to seek further information, if necessary, from the different licensing bodies, through the Registrar of the Council. 2. To arrange a plan by means of which, without actual visitation, the different examinations may be continually supervised, and to submit this to the several Branch Councils, after which the Committee be empowered to act upon it. 3. To arrange a plan for the visitation of examinations, when that is necessary, either by the agency of members of the Council or of other members of the Profession selected especially for this duty, and to submit this plan to the Branch Council, and subsequently, when it has been approved of, to act upon it." He said he considered the appointment of a Committee important. It would be their business to take into consideration the documents which were sent in from the different examining boards and frame some comprehensive scheme which might show the precise mode of examination, and to give particulars of the qualification required by the different licensing bodies. That plan should be submitted to the different Branch Councils in order that a general plan for the continual supervision of examinations might be adopted. The Committee should require from each licensing body a full statement of the questions which were put at each examination, and the amount of time occupied in each examination as to general, elementary, and practical subjects. They should also require a statement as to the mode in which the examination of the different candidates was considered and determined by the examiners and obtain samples of the written examinations. There should be constant supervision of the examinations, in order that a uniform system might be insured.

Dr. Paget seconded the motion.

Mr. Hargrave opposed it.

Dr. Corrigan said he did not think Dr. Parkes had estimated the frightful labour his motion would put on the Committee of three. In the first place, they would have all the papers to read.

Dr. Parkes: Not all; only some of them.

Dr. Corrigan said if they were to have only some of the papers the supervision would be totally valueless. The examining bodies would, perhaps, send only the most favourable. On the other hand, if all the papers were laid before them the labour would be enormous. There were about 4000 candidates, and they were examined in ten different subjects; that would give 40,000 papers, and he had estimated that they would take one hundred and seventy-five days and nights to read, without a wink of sleep. He should certainly himself refuse to be on the Committee. (Laughter.) The best safeguard for proper examinations, and the one most calculated to induce examiners to do their duty, was that advocated last year by Dr. Stokes—namely, the admission of the public at the examinations. In France the public were admitted to all Medical examinations, from the lowest to the highest degree.

Mr. Syme said that it appeared to him that if the supervision of examinations were to be carried on effectually it must be done by all the members of the Council taking part in it.

Dr. Quain said that the motion as it stood was impracticable. It must either be rejected as a whole or taken up clause by clause. He should suggest that the course pursued last year should be adopted, which would be better than a desultory discussion on several points at once.

Dr. Christison said he did not agree with Dr. Quain as to the value of a desultory discussion. The questions under consideration had been before the Council year after year, and it was time that some decisive step should be taken. He sincerely trusted that the Council would not separate this year without instituting a new system as to examinations, or declaring themselves satisfied with the present state of things. He would suggest that whatever motion was passed it would not contain any expression implying the assumption by the Council of any function which they did not possess. The motion spoke of supervision of the examination papers. The Act did not empower them to call upon examining bodies for the examination papers or to supervise those papers. He should be glad to see a committee appointed at the present session of the Council to take into consideration Clause 18 of the Act.

Dr. Aquilla Smith, in the course of some observations, called attention to the importance of efficient preliminary examinations. The fact, revealed by the army and navy returns, of a large number of the candidates being ignorant of the Latin language, showed the necessity of reform in the way of conducting preliminary examinations. He believed the classical attainments of students entering the Profession were every year becoming lower. Not only were some of them ignorant of the Latin language, but many of them were ignorant of the English language also. He did not expect any improvement as long as the present slovenly mode of preliminary examination was allowed to be followed.

Mr. Syme moved:—"That each of the Branch Councils, in compliance with Clause 18 of the Medical Act, shall visit the examinations in their respective districts, preliminary as well as Professional, for obtaining the qualifications mentioned in Schedule (A), and report to the General Council the result of those examinations."

Dr. Andrew Wood seconded the amendment.

Dr. Parkes said he was willing to consent to the amendment, and would simplify matters by withdrawing his motion.

Dr. Andrew Wood said that he considered that a system of visitation of examining boards should be established. It would be a most beneficial practice, and he believed there was no disposition on the part of the examining boards to object to visitation; and if any of them thought it would hurt their dignity the Act of Parliament would override their dignity.

*

He did not agree with publicity in examinations. In the first place, did those boards where publicity was allowed turn out the best men? ("Yes.") He would leave it to those gentlemen who made that assertion to prove it. He did not know whether Irish students were subject to "funk;" but at all events, publicity would not do in Scotland. (Laughter.) There were some of the most competent and best-qualified students in Scotland who would not be able to pass such examinations, because they would experience the feeling called "funk" in the presence of the public. Those who attended public examinations would not be the class of men calculated to raise the standard of such tests. Those professional men whose opinions were worth anything would be far too busy to attend. The class of persons attending would be students who were anxious to know the sort of questions which would be asked of them, and "grinders" who wished to find out what points to give prominence to next time they had a student to put on the grindstone. He objected to *viva voce* examinations. There were many who, from nervousness or inability to express themselves, would egregiously fail at a *viva voce* examination, but who would pass a written examination in the most creditable manner.

Dr. Corrigan opposed the motion. He believed the admission of the public tended to generate a sound public opinion as to the efficiency of an examination. With regard to "grinders," he did not agree with the terms of reprobation in which Dr. Wood had alluded to them. He believed they were a most useful class of men, and if any evils had arisen from their existence the crime lay on the examiners for not making the examinations practical.

Dr. Paget said he did not think it practicable for the Branch Councils to visit the examining boards according to Mr. Syme's motion.

Mr. Syme said he meant that a portion only of the Branch Councils should perform the visitation.

Dr. Andrew Wood: A committee of them.

Dr. Acland said he did not consider that the deputing to the three Branch Councils the visitation of the examining boards in their respective countries would promote the uniformity which was desired. A small committee composed of members from each of the Branch Councils, whose business it should be to draw up a uniform scheme of examination for adoption throughout the kingdom, would be a superior organisation.

The Chairman said that Mr. Syme had amended the wording of his resolution as follows:—"That each of the Branch Councils, or such of their members as may be deputed by such Council, shall, from time to time, visit the examinations conducted by the qualifying bodies in their respective kingdoms, preliminary as well as Professional, and report the results of their observations to the General Council."

Dr. Paget advocated a more general measure; but he gathered from what had occurred in the Council that they were not prepared to grant it, and therefore he would be content with a limited measure this session. He begged to move, as an amendment to Mr. Syme's motion—"That the Branch Councils be instructed severally to organise a set of trial visitations on a scale which may enable them to report upon the success of such visitations, the conditions of efficiency, and the requisite means for rendering them adequately extensive."

Dr. Sharpey said he was of opinion that gentlemen not belonging to the Council should be appointed to visit the examinations which took place in the United Kingdom from time to time. The duty of visitation would be a most invidious one, and it would be unadvisable for members of the Council to undertake it personally.

Dr. Storrar said he had always been an advocate for visitation; but he did not approve of conducting examinations in public. They were so conducted on the Continent, and he was never so dissatisfied with Continental examinations as he was at the present time.

Dr. Corrigan said there were difficulties in the way of visiting preliminary examinations as well as Professional, as proposed in the motion. The Council would have to visit every examining board from which they received certificates of preliminary examination. Those boards were very numerous and very distant from each other. One of them was situated in Barbadoes. (Laughter.)

The amendment and motion were then put from the chair. The number in favour of the amendment was 4, and for the motion 10.

The amendment being lost, the motion was put separately, and carried without opposition.

Dr. Andrew Wood moved, and Dr. Stokes seconded—"That the Council resume."

The motion was carried unanimously.

Dr. Quain submitted the report of the Pharmacopœia Committee. He observed that it was proposed as an alteration this year that instead of the book consisting of two divisions and an appendix, the materia medica and preparations should be arranged alphabetically and continuously.

It was resolved—"That the report be received and entered on the minutes."

The Council then adjourned.

FRIDAY, APRIL 7.

(FOURTH DAY.)

The Council met to-day at the usual hour.

The first business on the programme was the consideration of the report of the Committee on Communications relative to the Amendment of the Medical Act.

The first of the four communications particularised in that report was read by the Registrar. It was a letter from J. F. Milner, Esq., of Hereford, dated December 2, 1864, praying for protection of registered Medical Practitioners against the practice of Medicine by chemists and druggists, and against the holding of club appointments by the same.

Dr. Acland said that he had long thought that it was necessary for the subject raised in Mr. Milner's letter to be brought before the Council. It was acknowledged that the position of chemists and druggists was very unsatisfactory as far as regarded pharmacy. It was clear that the present Act of the Council had no power over chemists and druggists who practised as Medical men. He was not sure whether they ought to have that power, but, at all events, when they were about to go to Parliament for an amendment of the Act it was certainly desirable to consider whether any power should be sought. He did not propose to discuss the question, but to propose a motion merely to refer it to a Committee to consider the case. The matter had become a very complicated one, and he was not sure that it was the duty of the Council to seek any alteration. There was a large number of chemists and druggists who had had no Medical education, but who practised Medicine both in and out of their houses. There were skilled pharmaceutists who would not on any account practise Medicine, and there were duly qualified Medical men who found it most to their worldly advantage to keep a chemist and druggist's shop and practise in that way. It should be considered whether the Council had any duty to the public with regard to such cases. He then moved—"That with reference to the letter of Mr. Milner, of Hereford, a Committee be appointed to consider and report whether the Medical Council is charged under the Medical Act with any duty in relation to Medical and Surgical practice by chemists and druggists, and whether any, and if so what, changes in the Medical Act are desirable with regard to it, and to consider and report on the two Bills relating to pharmacy now before Parliament."

Dr. Parkes seconded the motion. He said that it should be requested of the promoters of the Pharmacy Bills now before Parliament that no persons belonging to their societies should be allowed to take charge of any case requiring Medical knowledge. The letter of Mr. Milner represented a great and widely-spread grievance.

Dr. Christison supported the motion.

Dr. Wood called attention to Clause 55 of the Medical Act. He said that he was not certain that the Council should support any bill which did not clearly define what were the proper functions of chemists and druggists. If they supported a bill in which those points were not clearly defined, they would be raising up another Apothecaries' Society.

Mr. Cooper said the subject was a very important one, and he was happy to find that it was going to be considered.

Dr. Acland said that, having long thought over the subject, he was doubtful whether it would not be well both for the public and for the Profession that the regulation of pharmacy should be entrusted to the Council, and that the Pharmaceutical Society should be represented at the Council.

The motion was carried unanimously.

The following gentlemen were appointed to serve on the Committee:—Dr. Acland (chairman), Dr. Christison, Dr. Parkes, Dr. Alderson, Mr. Rumsey, Dr. Paget, Dr. Thomson Dr. Apjohn, Dr. Storrar.

A letter from E. E. Tucker, Esq., of Abersychan, dated February 3, 1865, complaining of the practice of Surgery by a gentleman in his neighbourhood, whose only qualification is that of the Society of Apothecaries of London, was then read.

Dr. Wood said that the letter seemed to raise a very important question under Clause 31 of the Medical Act. The whole tenor of the working of the Act had tended to satisfy him of its deficiency. By Clause 31 a person who had obtained a qualification in Medicine might be registered and might practise that branch; and a person who had passed in Surgery might be registered and practise that branch; and those who had passed in both branches might practise both. The practical effect was that persons qualified only in Medicine practised Surgery, and *vice versa*. In the case mentioned in the letter, the gentleman had obtained a qualification from the Society of Apothecaries, and was therefore entitled to practise Medicine; but he had been found practising Surgery. That was a natural result, and he (Dr. Wood) was strongly convinced that no person should be registered who had not passed in all branches of the Profession. It was the duty of the Council to contribute as far as possible to securing that those sent out to treat the public should be qualified in every branch.

Mr. Syme moved "That Clauses 19 and 31 of the Medical Act be referred to the committee appointed to take into consideration the amendment of that Act."

Dr. Wood seconded the motion.

Dr. Acland said it was important for the examiners of the College of Surgeons to know how much Medicine a Surgeon should know, and for the examiners of the College of Physicians to know how much Surgery a Physician should know, and last year he moved a resolution to that effect. The collective wisdom of the Council ought to decide the question, for the protection of students and others.

Mr. Rumsey said he believed the Register had conferred the right of practising on persons who would not otherwise have been thought qualified, and it had thus tended to the degradation of the Profession. Recently, at a lunatic asylum in the West, a gentleman was proposed for appointment as the Medical officer who was merely a member of the College of Surgeons, and who had never been examined in Medicine. A member of the Board felt the difficulty, and applied to the Lunacy Commissioners in London to know what was to be done. The answer received was that the Register allowed them to appoint any one mentioned in Schedule (A) of the Medical Act. Before the publication of the Register he would have been regarded merely as a Surgeon. The question was a most important one, and touched the whole question of public appointments throughout the kingdom.

Mr. Arnott said that the evident answer to the letter under consideration was that the Council could not interfere. The branches of Surgery and Medicine were so blended that there were many cases in which it was impossible to define whether they were Surgical or Medical. In both branches there were, of course, some broad cases in which there could be no doubt as to which class they belonged; but in many great doubt existed, and it would be impossible for a jury to decide the point. He therefore contended that no person should be registered who did not possess the double qualification.

Mr. Cooper advocated the possession of the double qualification as the title to registration.

The motion of Mr. Syme was unanimously agreed to.

Mr. Arnott moved—"That a letter be written to Mr. E. E. Tucker, to the following effect:—The Council has learned with great regret the particulars of the case stated in Mr. Tucker's letter. The Council has not, under the present Act, the power to interfere for the protection of the public against ignorance of Surgery on the part of Practitioners who have no Surgical qualifications; but the subject now engages the serious consideration of the Council."

The motion was seconded and carried.

The Registrar read a letter from Dr. Styrap, of Shrewsbury, dated March 3, 1864, asking that increased powers be given to magistrates with respect to offences against the Medical Act, and that the penalty on second conviction be increased.

Dr. Embleton moved—"That an answer be returned to Dr. Styrap to the effect that the subjects of his letter are at present under the consideration of the General Medical Council."

Dr. Fleming seconded the motion, which, on being put to the meeting, was carried unanimously.

Dr. Embleton moved—"That the following sections of the Medical Act, viz., 38, 39, 40, and 41, be referred to the Committee on the amendment of the Medical Act."

The following memorial, dated April 3, 1865, from twenty-eight Licentiates in Dental Surgery of the Royal College of Surgeons of England, was read by the Registrar:—

"*To the General Council of Medical Education and Registration of the United Kingdom.*

"We, the undersigned, Licentiates in Dental Surgery of the Royal College of Surgeons in England,—(a Degree founded by the College on Section xlviii. of the present Medical Act)—although entitled to register under that Act, in virtue of our other Professional qualifications, considering it to be desirable, and believing it to be only just, that those persons who have taken this degree should be allowed the privilege of registering as 'Licentiates in Dental Surgery,' under the proposed amended Medical Act, beg respectfully to bring this, our view of the subject, under the consideration of your honourable Board.

"We are aware that the following objections have been raised to this privilege being allowed to the possessors of this degree:—

"First.—That, if the privilege were granted to persons who have taken this degree only, they would, under Clause xxxiv. of the present Medical Act, be considered in law as 'duly qualified Medical Practitioners,' and might, if so disposed, practise legally any or all branches of the Medical Profession without having received a full Medical education, and thereby interfere with the interests of the fully qualified Medical man.

"Second.—That to grant this privilege to them would be to infringe upon and injure the existing rights of those persons at present practising Dental Surgery who do not possess this degree, by giving to the new Act a retrospective character; and

"Third.—That it is open to those persons practising Dental Surgery who desire to possess the privilege of registering under any Medical Act to take the degree of 'Member' of the College of Surgeons, as well as that of 'Licentiate in Dental Surgery,' and to register under the former title.

"To the first of these objections we respectfully submit that the very slight additions we have suggested to the wording of Clauses xxxi. and xxxiv. of the present Medical Act would, if adopted, make it clear, beyond the possibility of a doubt, that the possessors of this degree only, if registered as 'Licentiates in Dental Surgery,' could not legally practise any other branch of Medicine or Surgery, and therefore that the incorporation of these, or similar words, into any amended Medical Act, would fully meet and do away with this objection.

"To the second objection we also respectfully submit that the few words proposed to be added to Clause lv. of the present Medical Act would, if adopted and incorporated with such amended Medical Act, completely protect all the existing rights of those persons at present practising Dental Surgery who do not possess this degree, as also the prospective rights of those at present preparing to practise Dental Surgery who may not have it in their power to take this degree, and so meet and do away with this objection.

"And to the third objection we respectfully submit:

"First.—That the argument on which it rests is founded upon an imperfect knowledge of the amount of 'special study' required to form the duly qualified Dental Surgeon, as we think will be apparent to your Honourable Board by a reference to the accompanying curriculum of education required by the College of Surgeons for the degree of licentiate in Dental Surgery;—

"Next.—That to expect the full course of education required for the 'membership' of the College to be added by the Dental Surgeon to the curriculum required for his special diploma, in order to give him the power of registering under such Act, would be to exact a more extensive and more expensive Professional education, both in respect to time and money, from the dental than from the general Surgeon—a requirement which we most respectfully submit would be both unnecessary and unjust; and

"Lastly.—That to be registered as a 'fellow' or 'member' of the College only does not *in itself* afford any proof that persons so registered are duly qualified to practise the speciality of Dental Surgery, as we think will also be apparent to your Honourable Board after referring to the curriculum above named.

"Entertaining these views, we think it right to bring them under the attention of your Honourable Board, and we pray that you will take them into your favourable consideration.

"Thomas Bell, F.R.C.S., L.D.S., F.R.S.,
"John Tomes, F.R.S., L.D.S., M.R.C.S.,
"Samuel Cartwright, F.R.C.S., L.D.S.,

Members of the Board of Examiners in Dental Surgery of the Royal College of Surgeons of England.

"Arnold Rogers, F.R.C.S., L.D.S., late Member of the above Board.
"W. A. Harrison, F.R.C.S., L.D.S.
"G. A. Ibbetson, F.R.C.S., L.D.S.
"Wm. A. Cattlin, F.R.C.S., L.D.S.
"A. G. Canton, M.R C.S., L.D.S.
"Thomas Rogers, M.R.C.S., L.D.S., President of the Odontological Society of Great Britain.
"H. J. Barrett, M.R.C.S., L.D.S.
"S. J. A. Salter, M.B., M.R.C.S., L.D.S., F.R.S.
"Henry Rogers, M.R.C.S., L.D.S.
"Alf. Barrow Jones, M.R.C.S., L.D.S.
"Edwin Sercombe, M.R.C.S., L.D.S.
"John W. Elliott, M.R.C.S, L.D.S.
"Nathaniel Stevenson, M.R.C.S., L.D.S.
"H. Howard Hayward, M.R.C.S., L.D.S.
"Joseph Rogers, M.R.C.S., L.D.S.
"William Cattlin, M.R.C.S., L.D.S.
"Alfred Coleman, M.R.C.S., L.D.S.
"Joseph Walker, M.R.C.S., L.D.S.
"J. H. Allingham, M.R.C.S., L.D.S.
"Charles Vasey, L.F.P.S., L.D.S.
"John Thomas Henry West, M.R.C.S., L.D.S.
"Geo. Gregson, M.R.C.S.E., L.D.S.
"E. H. G. King, M.R.C.S., L.D.S.
"Thomas C. White, M.R.C.S., L.D.S.
"Charles James Fox, M.R.C.S., L.D.S."

Dr. Storrar said that whatever the merits of the case now brought forward, it was utterly impossible to discuss the details. It would, however, be unjust to the memorialists to refuse to give their representation thorough consideration. The degree of Licentiate in Dental Surgery was founded by the Royal College of Surgeons in 1858 at the instance of a large number of its most respectable members, who wished to rescue dental science from the wholesale quackery in which it was involved. The movement of the Surgeon-dentists had been a decided success, and students attended their schools for the purpose of acquiring information on the subject of dental Surgery. He did not wish to propose that the memorial be acceded to, but he would move that it be referred to the Committee on the amendment of the Medical Act.

Mr. Hargrave seconded the motion.

Mr. Rumsey said he fully concurred with the remarks of Dr. Storrar, but he was sorry that he did not carry his motion farther. They might give a qualified approval to the application of the memorialists that licentiates in dental Surgery should be registered as such. That was no new principle. The privilege of registration was conferred on licentiates in midwifery, and it would be only placing licentiates in dental Surgery on the same footing to accord them the privilege of registration.

Dr. Christison said that the proposal of Mr. Rumsey would have the effect of extending the number of registered persons not qualified in all branches. (Hear, hear.)

Mr. Rumsey explained that it was only because the Council had the power of registering those qualified in some special branches that he suggested that they should be empowered to register another special branch.

Mr. Arnott opposed the motion.

The President said that, with all respect to the memorialists, he thought that the Council would be entering upon a very dangerous course if they consented to admit on their register gentlemen who simply had the qualification of Practitioners in dental Surgery from the Royal College of Surgeons. It would be very difficult for the public to distinguish those who were merely dentists from those who held the full Surgical qualification.

The motion was put and carried.

Dr. Sharpey moved, "1. That it is expedient to amend Clause 18 of the Medical Act by adding to it the following words, or words to the same effect, viz.: 'and may also inspect the written answers of the candidates, and report concerning the examinations and answers to the General Council; and to the persons deputed by the General Council as aforesaid, in such number as may be determined by the General Council, with the approval of one of Her Majesty's principal Secretaries of State, there shall be paid such fees for services and such reasonable travelling expenses as shall from time to time be allowed by the General Council and approved by the Commissioners of Her Majesty's Treasury; and the said payments shall be made out of the residue of the monies annually received for carrying this Act into execution, after defraying the expenses of the General Council and the Branch Councils, and, if necessary, out of further monies to be provided for the said purpose by vote of Parliament.' 2. That the proposed amendment be referred to the Committee on the Amendment of the Medical Acts." He said the objects of the motion proposed in the amendment was, first, to remove ambiguity as to the extent to which persons deputed by the Council may attend the examinations of candidates and ascertain and report on the result of such examinations; secondly, to remove ambiguity as to the extent to which the Council was empowered to allow expenses to the visitors at examinations; and thirdly, to provide that, in case the funds annually received should be insufficient to defray such expenses, the deficiency might be provided for by a vote of Parliament.

Dr. Storrar seconded the motion.

Dr. Christison said he quite agreed with the general principle of Dr. Sharpey's motion.

Dr. Corrigan objected to the motion. He said that it proposed what was impossible, and on the working of it it must fall to the ground. In addition to that, the necessity of supervision had been discussed, and its propriety had been questioned. There was a resolution passed on the previous day that a trial should be made as to the practicability of visitations, and he could not but regard Dr. Sharpey's motion otherwise than as an attempt by a side-wind to get the Council to appoint visitors. The supervision would be worthless unless first-rate men were employed, and first-rate men who had made a position in the Profession would not leave their work to enter on such visitations. To send inferior men would be an insult to examiners, and the Profession would regard the plan proposed as an attempt to divert their money to provide a salary for a new officer. He proposed as an amendment "That the Professional examinations conducted by the several licensing bodies should be public so far as admitting the graduates, members, or licentiates of the licensing body conducting such examination, and that such publicity will be sufficient to secure the maintenance of efficient examinations without inspection."

Dr. Wood said that the question was fully discussed yesterday: it could not be re-opened during this session. A system of trial visitations had been agreed on. He asked the President to rule as to whether the motion was in order.

The President said that it was quite competent for Dr. Sharpey to bring forward the motion; but he was rather surprised at his doing so after the resolution of yesterday, with which it seemed inconsistent.

Dr. Storrar said that, in order to rid himself from the suspicion of inconsistency with what took place yesterday, he wished to explain that Mr. Syme's motion of yesterday was one which could be put in effect at once, while the motion proposed by Dr. Sharpey had reference to the future, and was intended to provide for the possibility of the Council deciding at some future time to institute inspection of examinations.

Dr. Fleming said that the motion was quite distinct from that of Mr. Syme.

Dr. Aquilla Smith said that it was not reasonable to ask further sums from Parliament when they had about £25,000 in the Consolidated Funds. He seconded Dr. Corrigan's amendment.

Dr. Fleming remarked that the motion asked for the money only conditionally.

Dr. Sharpey, in reply, explained the reason why he brought forward the motion at the present time. They were now considering amendments in the Medical Act, and as this referred to that subject, the present was the proper opportunity to bring it forward.

The President took the vote of the Council as to the amendment. There were—in favour of it 5; and against it, 9. The amendment was therefore lost.

Dr. Wood then moved the following amendment on the original motion:—"That it be remitted to the Committee on the Amendments of the Medical Acts to consider the expediency of amending Clause 18 by adding to it the following words, or words to the same effect—viz., 'and may also inspect the written answers of the candidates, and report concerning the examinations and answers to the General Council; and to the persons deputed by the General Council as aforesaid, in such number as may be determined by the General Council, with the approval of one of Her Majesty's principal Secretaries of State, there shall be paid such fees for services and such reasonable travelling expenses as shall from time to time be allowed by the General Council and approved by the Commissioners of Her Majesty's Treasury; and the said pay-

ments shall be made out of the residue of the monies annually received for carrying this Act into execution, after defraying the expenses of the General Council and the Branch Councils, and, if necessary, out of further monies to be provided for the said purpose by vote of Parliament.' "

Dr. THOMSON seconded the amendment.

On a vote being taken, there were,—For the amendment, 10; and against it, 8.

It was then put as a substantive motion. There were,—For it, 11; and against it, 7.

The amendment was therefore carried.

Dr. CORRIGAN asked that names might be taken down. The division was as follows:—

For the amendment:—Dr. Alderson, Dr. Paget, Dr. Embleton, Dr. Storrar, Dr. Andrew Wood, Dr. Fleming, Mr. Syme, Dr. Thomson, Dr. Sharpey, Dr. Quain, and Dr. Christison.

Against the amendment:—Mr. Arnott, Mr. Cooper, Dr. A. Smith, Mr. Hargrave, Dr. Leet, Dr. Apjohn, Dr. Corrigan, and Dr. Stokes.

Dr. QUAIN moved "That a committee of the Council be appointed with the following duties:—1. To report on any further amendments which may seem to be required in the Medical Act. 2. To communicate with the Solicitor on the amendments already adopted, or that may be adopted by the Council. 3. To prepare a memorial to the Home Secretary on the amendment of the Medical Act."

Mr. HARGRAVE seconded the motion.

Dr. CORRIGAN said that it was thought desirable last year to interfere as little as possible with the Medical Act, and the members of the Council were then requested to confine their attention during the year to three clauses only—Nos. 20, 31, and 40. On the first day of the present session he moved that the clauses of the Bill should be taken up and discussed *seriatim*. That proposal was negatived; but now Dr. Quain had brought forward a motion which practically amounted to a proposal to do what on the first day they decided not to do. ("Vote.")

The motion was put. There were in favour of it, 15; against it, 4.

The following were appointed as the committee:—Dr. Wood (chairman), Mr. Syme, Dr. Sharpey, Dr. Smith, Dr. Embleton, Mr. Arnott, Dr. Stokes, Dr. Quain, and Dr. Paget.

The REGISTRAR read a communication from the Registrar of the Branch Council for Ireland enclosing a certificate of the conviction, at Castlebar, County Mayo, of John Carter Barrett, for felony. The certificate was read. The offence committed was that of making a false entry of a birth in the register, when no such birth took place.

Dr. AQUILLA SMITH said that under Clause 29 of the Medical Act the name of any registered Practitioner convicted of felony or misdemeanour might be erased from the register. He should, in accordance, move that the case of John Carter Barrett be referred to the Solicitor to the Council.

Dr. APJOHN seconded the motion, and it was carried unanimously.

The Council then adjourned.

SATURDAY, APRIL 8.

(FIFTH DAY.)

The Council re-assembled at two o'clock.

The REGISTRAR read particulars of a case submitted to Counsel as to the 9th section of the Medical Act on the subject of voting in the Council, and the opinion of Counsel thereon, were as follows:—

CASE.

"Counsel will please see the Medical Act, 1858, 21 and 22 Vic., cap. 90.

"By the 9th section, which regulates the meetings of the General Medical Council, it is enacted that 'all acts of the General Council shall be decided by the votes of the majority of the members present at any meeting, the whole number not being less than eight; and at all such meetings the President for the time being shall, in addition to his vote as a member of the Council, have a casting vote, in case of an equality of votes."

"At a recent meeting of the Council, fourteen members, including the Chairman, were present.

"On a motion being put to the meeting, six hands were held up for it and six against it, the President and one other member of the Council not voting.

"The President thereupon declared that the motion was not carried.

"A member of the Council required the President to give his casting vote, which the President refused to do, adhering to his decision that the motion was not carried.

"The Council desires to be advised as to the effect of the Act of Parliament in respect to voting. Are all the members present bound to vote? If any member declines to vote, must he be counted, in ascertaining whether any question is carried by the votes of a majority of the members present, or may he, by declining to vote, be considered and treated as if he were not present? Is the President, if the votes shall be equal (however that equality is to be ascertained), bound to give a casting vote? May he give such casting vote although he has not given his original vote as a member of Council; or may he simply, in the event of an equality, declare the motion not carried, without giving his casting vote?

"If the Act is to be read strictly, every motion must be carried by the votes of a majority of the persons present, and it is presumed that the term 'equality of votes' used in the clause must be construed with reference to the prior part of the clause. In the case which actually occurred, construing the Act strictly, there was no such majority. Six voted for the motion, six against it, and two did not vote. If the latter are to be counted, the motion was clearly negatived, and no case arose which would give the Chairman the right to a casting vote.

"If the Act may be read as meaning 'by the votes of a majority of the members present' (and voting), then there was an 'equality of votes,' and the question arises whether the President was bound to give a casting vote.

"COUNSEL is requested to advise on the con-
"struction of the Act with reference to
"the above observations."

OPINION.

"The question whether all the members present are bound to vote seems to be one of little practical importance. It is clear that any member could retire during the time of voting, if he did not desire to record his vote, and this perhaps would be the more strictly regular method of declining to vote; but if the question were to be decided in a court of law, whether everybody remaining in the room was compelled to vote, I think the decision would be in the negative, and that it would be considered that any member declining to vote might, for that purpose, be considered as having retired from the meeting.

"My answer to the first question involves the answer to the second. If it is true that a member may remain in the room and yet decline to vote, of course he cannot be counted in ascertaining on which side the majority is.

"The question with respect to the President's votes seems to me also to pertain more to form than to substance, for it is clear that a President, content by his inaction to leave a motion to be lost, might, if compelled to act, vote against it; and as it would be impossible ever to hold that a motion was carried on which the numbers were equally divided, and which the President, therefore, declared to be lost, I hardly see how the question ever could be raised. Still, in point of form, it seems to me to be proper that every one present at the voting and taking an active part in the business, which is necessarily the case with the President, ought to vote; for it is impossible to consider such a one as retiring from the meeting. If this is so, it follows that the President ought not to give his casting vote without first having given his private vote.

"ARTHUR HOBHOUSE.

"11, New-square, Lincoln's-inn, June 14, 1864."

ADDITIONAL STATEMENT.

"With reference to the second branch of the Opinion, as to the votes of the President in the chair, the Medical Council would desire to ask for further explanation.

"In many cases questions may arise on which the President might desire to reserve his opinion, either on public or private grounds.

"The Act says that the President, in addition to his vote as a member, is to have a casting vote. The Act does not, however, say that he shall be bound to exercise the privilege; and the Council do not clearly collect from your opinion whether the President is legally justified (in the case of an equality of votes of the other members voting) in declaring the motion not carried without giving either an original or a casting vote."

OPINION.

"I can only repeat my former opinion in slightly amplified

language. If the President wishes a motion not to be carried, the more regular course is that he should vote against it. This he may do without expressing any opinion except that which is necessarily involved in his vote—viz., an opinion that, for some reason or other, it is not expedient to carry the motion.

"The same opinion seems to me to be as much involved in the alternative course; for if the President is content to declare a motion lost, which by his vote he might carry, he obviously thinks that, for some reason or other, it is not expedient to carry the motion, otherwise he would vote for it.

"At the same time, if the President chooses to take the second course rather than the first, I do not think that he commits any illegality. It is, in my view, a mere irregularity, productive of no practical consequences at all; and I do not see how the question could be raised in any court of justice.

"ARTHUR HOBHOUSE.

"11, New-square, Lincoln's-inn, June 25, 1864."

Dr. AQUILLA SMITH said that the statement in the second paragraph of the opinion was clearly a contradiction of the standing order. The opinion was "that it was clear that any member declining to vote might retire during the time of voting." The order was that no member, after having taken his seat, might retire without the permission of the Chairman. He agreed with the remark that any member present at the voting and taking part in the business ought to vote. Gentlemen taking on themselves the responsibilities of the Council ought to express their views when there was a division on a question.

Mr. HARGRAVE supported the opinion that if any person took part in the business he ought to vote. Neutrality was contrary to the spirit of Englishmen.

Dr. AQUILLA SMITH moved—"That every member of the Council who is present at any debate shall be required to vote, or be permitted to declare his intention of not voting before the votes are taken."

Dr. STOKES seconded the motion.

Mr. HARGRAVE moved as an amendment—"That every member of the Council who has taken part in a discussion be required to vote, and, if necessary, that the Chairman be required to give his double vote."

Mr. ARNOTT did not agree with the motion or the amendment. He said there were many questions on which persons ought to be able to express their opinion without being bound to vote. In the House of Commons the Speaker was bound to give his casting vote on an equal division, and he invariably did so against the measure. In the House of Lords the Lord Chancellor had no casting vote. There was no judge in the land who, on an equal division of opinion, would undertake to give a casting vote. To compel the President of the Council to give a casting vote was an absurdity. It would virtually be compelling the President to vote on every question. Mr. Hargrave's amendment not being seconded, he would move as an amendment—"That the President, or presiding member shall not give his casting vote unless he has first given his private vote."

The PRESIDENT said the opinion expressed by Mr. Hobhouse only took up one side of the question; it did not give the legal interpretation of the Act of Parliament. He was left as much in the dark as he was before as to whether he was legally bound to give a casting vote. If so, he should not invariably bind himself to vote against every question on which there was an equal division; but still he should decline to carry any great public measure by a casting vote, and would rather sacrifice his own private opinion than undertake to carry an important motion on which opinion was so equally divided.

Dr. WOOD said the difficulty was a legal one, which the Medical Council were not competent to decide. The opinion of Mr. Hobhouse did not commend itself to his common-sense, and he should suggest that an opinion be obtained from another lawyer. ("Oh, oh!")

Dr. CORRIGAN said that of all Acts of Parliament which he ever read Section 9 seemed the most distinct and positive. It said, first, that all questions "*must* be decided" by the votes of the Council; and secondly, that the President "*shall* have a casting vote" besides his vote as a member.

After a little further discussion, the question was withdrawn.

Dr. STOKES moved the following resolution, which was left from the last session of the Council:—"That with reference to the resolution of this Council, on the motion by Dr. Leet, June 2nd, 1863—viz., 'That this Council is of opinion that registered licentiates of the Apothecaries' Company of Dublin are, as Apothecaries, entitled to practise Medicine in Great Britain and Ireland'—the Council resolve that it did not desire to convey that the licence of the Apothecaries' Company of Ireland carried any other qualification than that specified in the Act of Incorporation of the Company." He said the resolution referred to was unworthy of the Council. Misapprehension existed in the minds of some of the members of the Council as to the comparative requirements of the Apothecaries' Company of England and the Apothecaries' Company of Ireland. The Apothecaries' Company of England were required to examine all persons who applied to them, for the purpose of ascertaining the skill and ability of such persons in the science and practice of Medicine, and as to their fitness to practise in Medicine. In the Apothecaries' Society of Ireland there was no such power. The only certificate given by them was, that the directors authorised the person who had passed the examination to open a shop and practise the art and mystery of an Apothecary. That was the whole power comprehended in the certificate.

Dr. WOOD seconded the motion.

Dr. LEET said that, as the framer of the resolution, he felt bound to object to the motion. The whole matter had been before the Council over and over again, and in drawing up the resolution he had the assistance of the late President and of several members of the Council. He maintained that the Apothecaries' Society of Ireland were fully competent, as a qualifying body, for granting licenses to practise Medicine, and quoted authorities in support of that view, among which was an opinion expressed by the Attorney-General for England. His resolution of June 2, 1863, did not express any opinion on the rights conferred by the Apothecaries' Company, but only the peculiar privileges of the registered Licentiates of that body. Why did not those who supported the views expressed in Dr. Stokes's motion proceed against the Apothecaries' Society by *mandamus*, and bring them into a court of law, instead of continually bringing the subject before the Council for the purpose of satisfying a feeling of jealousy? ("Hear, hear," and "No.") He referred to a case which had recently occurred in Ireland before Mr. Justice Fitzgerald, in which his lordship decided that Apothecaries attending coroners' inquests were entitled to fees as duly-qualified Medical men. He was prepared to move an amendment if the motion were not withdrawn.

Mr. SYME said he saw no reason for making any alteration in the resolution of 1863. He moved as an amendment—"That the Council do not see any reason for entering into an explanation of their resolution of June 2, 1863, respecting the licences of the Apothecaries' Company of Dublin."

Dr. WOOD said that this was a wider question than the question whether the Apothecaries of Ireland were qualified to practise Medicine. It was a question whether the Council was entitled to grant charters in Medicine. He believed the decision of the Council had been wholly illegal. The Dublin Apothecaries' Company had no right to come to the Council and ask them to grant them a charter in Medicine; and the effect of the decision of the Council was, that they had now assumed the right to give licences in Medicine. The Council should have treated the application of the Apothecaries' Company as a legal matter on which they could not decide, as they had done in another case. It was no part of the business of the Council to give an opinion as to whether a particular body could qualify to practise. A body was qualified to practise just what its charter granted. He was not jealous of the Apothecaries' Company of Dublin, but he was jealous of the Council going out of its way to express opinions on the charters of any company.

Dr. STORRAR seconded the amendment.

Dr. CORRIGAN said he should cordially second the amendment, if it were not for the fact that the Poor-law Commissioners of Ireland had, in consequence of the resolution of June, 1863, accepted the licence of the Apothecaries' Company of Dublin as a sufficient qualification for the Medical officer discharging the duties of Physician of a Hospital or Dispensary, thus placing the licence of that body on a level with that of the highest University or of the College of Physicians itself. He could not believe that that was the intention of the Council; and if it was not, their resolution had been misunderstood, and therefore required explanation. The Poor-law Commissioners had been misled by the resolution, and it was desirable that the Council should give a clearer expression of what they intended. He believed the position of the Irish apothecary was a very important one. It was, in fact, equivalent to that of the *officier de santé* of France. He (Dr. Corrigan) was the last man in the world who would

interfere with the Irish apothecary. He was a most useful man, and was one much trusted by the poor. When the cases under his care became serious, he applied to the Physician or the Surgeon; but did the Council intend by their resolution to convey to the authorities in Ireland that they put the apothecary on a level with the Physician or the Surgeon? If they did not mean to imply that, an explanation was necessary, in order that the mistake into which the Poor-law Commissioners had fallen might be corrected. It had been asked why those who wished the resolution altered did not apply for a *mandamus* against the Apothecaries' Company, and that question was cheered by those gentlemen who did not understand the question. (Laughter.) The fact was that a *mandamus* would not affect the case, for the Poor-law Commissioners in Ireland had extraordinary powers. They had full powers by Act of Parliament to determine what they required, and they were entitled to receive what qualification they liked. He reviewed various Acts of Parliament bearing on the question for the purpose of showing that they contained no authority to the Apothecaries' Company of Dublin to examine in Medicine. Since the passing of the resolution of June, 1863, however, they had included in their certificate the qualification to practise Medicine.

Dr. Leet said that was not correct. The qualification in Medicine was included in the certificate before the passing of the resolution.

Dr. Corrigan: I will ask Dr. Leet this question—When did the Apothecaries' Company first issue that certificate referred to by Dr. Stokes?

Dr. Leet: This certificate, which is the one accepted by the Poor-law Commissioners, was issued before that resolution.

Dr. Corrigan: When was the certificate spoken of by Dr. Stokes issued for the first time?

Dr. Leet: They are exactly the same. It was before the resolution.

Dr. Corrigan disputed the statement.

The President said that Dr. Corrigan must see that Dr. Leet, who represented the Apothecaries' Company, must possess more definite knowledge on the subject than Dr. Corrigan himself, who had only general knowledge. The statement, therefore, was not open to dispute.

Dr. Corrigan referred to various certificates of the Dublin Apothecaries' Company to show that up to 1859 the qualification as to Medicine was not included. The assumption, therefore, in giving diplomas in Medicine had taken place since that year. It was for the Council, as their resolution had been misunderstood, to determine whether they would correct the misapprehension which had taken place, and whether they were content to endorse the examination in Medicine of the Apothecaries' Company, and thus make it equivalent to examinations of the most learned Medical bodies in the kingdom, under the most eminent Medical examiners. The examinations of the Apothecaries' Company were conducted by the shareholders of the Company, and they could not place the duty in the hands of any deputy. There were originally sixty shareholders in that Company, but now the shares had come into the hands of forty-seven persons. Some of those shareholders were barristers, and some were abroad, and there were only about twenty-eight apothecaries in the neighbourhood of Dublin among them. If the Council recognised their examinations, the most ignorant man among them who ever dissolved an ounce of salts could give a certificate of qualification which would be as valid as that of any examiner in the kingdom.

Dr. Embleton recommended that the question should be referred to the Committee on the Amendment of the Medical Act.

Dr. Storrar said that it was never meant that the "full qualification" of the Apothecaries' Company went to the same extent as the "full qualification" of the College of Physicians. It was only "full" as far as regarded the qualication to practise Medicine. Dr. Corrigan had said something about the shares in the Dublin Apothecaries' Company. He (Dr. Storrar) believed that those shares were very valuable—so valuable, in fact, that it had been worth the while of some of the members of the College of Physicians of Ireland to obtain some of those shares. ("No.")

Dr. Aquilla Smith denied the assertion.

Dr. Storrar: Is it not so?

Dr. Leet: Fellows and Licentiates.

Dr. Corrigan stated in explanation that two gentlemen of the College of Physicians held shares in the Apothecaries' Company. One of them had married the daughter of a very respectable apothecary, who was a shareholder, and he now held those shares in trust for his children. ("Oh," and laughter.) The other was Sir Robert Kane, who commenced his career as an apothecary, but who had given up his shares. The Society, however, had persisted on keeping his name on their list to give them an appearance of respectability. (Loud laughter and "Oh! oh!")

Dr. Storrar said that he would give Dr. Corrigan a remedy against the fear of the examinations of the Apothecaries' Company not being efficiently conducted. Let him vote for the inspection of examinations. Dr. Leet himself, the representative of that body, had supported such inspection.

Dr. Thomson said that the resolution of June, 1863, merely declared that the Licentiates of the Dublin Apothecaries' Company were entitled to practise Medicine. It did not, in itself, confer that authority upon them.

Dr. Stokes, in replying to the observations which had been made, remarked that the certificate of the Apothecaries' Company of Ireland giving license to practise Medicine was illegal. He most strongly repudiated the imputation of jealousy of the Apothecaries' Company.

The amendment was put to the meeting. There were in favour of it 10, and against it 6.

The amendment being, therefore, carried was put as a substantive motion, and carried by 10 against 6.

Dr. Wood moved for the names to be taken.

The division was as follows:—

For the motion:—Dr. Alderson, Dr. Embleton, Dr. Storrar, Dr. Fleming, Mr. Syme, Dr. Thomson, Mr. Hargrave, Dr. Leet, Dr. Sharpey, and Dr. Christison.

Against the motion:—Mr. Arnott, Dr. Wood, Dr. A. Smith, Dr. Apjohn, Dr. Corrigan, and Dr. Stokes.

Declined to vote:—The President, Mr. Cooper, and Dr. Quain.

Absent:—Dr. Acland, Dr. Paget, Dr. Parkes, and Mr. Rumsey.

Dr. Stokes, according to notice, moved "That a committee be appointed to consider and report as to what should be the subjects of general education in which all students should be examined prior to the commencement of their Professional studies."

Mr. Arnott seconded the motion.

Dr. Storrar said the subject was a wide one, but if there was a motion for placing the preliminary education in the hands of literary men instead of Professional, he would hold up both hands in its favour.

The motion was agreed to.

The committee appointed were as follows:—Dr. Stokes (Chairman), Mr. Arnott, Dr. Storrar, Dr. Quain, Dr. Paget, Dr. Thomson, Dr. Apjohn, and Dr. Acland.

The Council adjourned at 6 o'clock.

MONDAY, APRIL 10.

(SIXTH DAY.)

The Council reassembled at two o'clock. The business commenced as usual with the calling of the roll and the reading of the minutes of the last meeting.

In reference to the conviction, at Castlebar, County Mayo, of Carter Barrett, of making a false entry of a birth,

Mr. Ouvry, Solicitor to the Council, stated that the crime of which Mr. Barrett was convicted was, according to Act of Parliament, felony.

It was asked whether the certificate was a proper one.

The Solicitor said he did not know that that question had been raised. He had assumed that the certificate was a proper one.

The President said that it was also desirable to know whether what took place amounted to a conviction.

The question was referred back to the Solicitor for farther inquiry.

Dr. Wood moved—"That the Council resolve itself into a General Committee on Education, and that the President take the chair."

Mr. Hargrave seconded the motion, and it was carried unanimously.

Dr. Acland moved—"That the returns from the various licensing bodies mentioned in Schedule (A) be printed and laid on the table for the use of the Council."

The paper referred to consisted of Observations and Suggestions on the Report of the Select Committee on Education, appointed by the General Medical Council in 1864, received from—The Royal College of Physicians, London, Royal

College of Surgeons, England, University of Cambridge, Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, Faculty of Physicians and Surgeons, Glasgow, University of St. Andrews, King and Queen's College of Physicians in Ireland, Royal College of Surgeons in Ireland, Apothecaries' Hall of Ireland, University of Dublin, University of Edinburgh, University of Oxford, Queen's University in Ireland, University of Glasgow.

Dr. PAGET seconded the motion.

Dr. CORRIGAN said that the documents should be printed, so that they might be put into the hands of each member of the Council.

The PRESIDENT suggested that it might be better to print them separately, instead of encumbering the minutes with them.

Dr. WOOD said that, when the observations were extracted, they would not be so bulky as they appeared. The surest way of preserving them would be to place them on the minutes.

Dr. CORRIGAN said the Council could not deal with the documents until they were before them. They could not be before the Council unless they were printed *in extenso*.

Mr. ARNOTT supported the proposition that they should be put on the minutes. In order that that might be done, they might be taken as read.

Mr. RUMSEY said it would facilitate business if the President's proposition to print them as a separate pamphlet were acted on.

The REGISTRAR said that all the documents, with the exception of three letters, had been printed, and been in circulation among the members for some weeks.

Dr. CORRIGAN moved, in amendment, "That the communications be accepted as read and printed on the minutes."

Dr. WOOD seconded the amendment.

Dr. ACLAND withdrew his motion.

The amendment of Dr. Corrigan was put, and carried.

Dr. WOOD moved, "That a Committee be appointed to consider and report on what should be the minimum course of Professional study through which all candidates should be required to pass before receiving any qualification entitling them to register." He said that the Council had for some time been asked to state what they considered the minimum amount of study, and the minimum number of subjects which a course of Professional study should embrace. It would be a very appropriate subject for the Council to express an opinion upon.

Dr. EMBLETON seconded the motion.

Dr. CORRIGAN said he should support the resolution if he thought it likely to lead to any practical benefit. He thought, however, that it would lead to the mischief of meddling improperly. There would not be one point on which there would not be a great variety of opinion and dissent; and the very prospect of that ought to deter the Council from taking any step in the direction indicated by the resolution. A student who had gone through the minimum, and was not proficient for practice, might turn round and say, "Why do you demand of me any more? The General Council has said that the course I have gone through is sufficient as a minimum." He believed the resolution would lead to mischievous results.

Mr. SYME opposed the motion. He did not consider that they could enforce the minimum if they fixed it.

Mr. ARNOTT said that at this late period of the Session there was not time to consider the numerous points which would be raised by such a resolution as that proposed. He said that the Council might express an opinion as to the general course which should be followed, but it was now impracticable to take up the consideration of the many details involved. A general expression would answer the purpose at present.

Dr. WOOD regretted that it had not been possible to bring on the resolution sooner, but he was satisfied that if the members were in earnest in the matter there would be plenty of time to enter into the subject. It was not creditable that the Council had been sitting so long year after year without endeavouring to guide the educating bodies as to the subject and mode of study which should be pursued. Mr. Syme's objection to the motion involved an abnegation of those very powers which the Legislature had entrusted to them, and it amounted to saying that neither by moral suasion nor force of law would they make any attempt to fix the course of Professional study.

The question was then put to the meeting. There were—for it, 6; against it, 15.

It was required that the names should be taken. The division was as follows:—

For the motion—Dr. Alderson, Dr. Acland, Dr. Embleton, Dr. Andrew Wood, Dr. Fleming, and Dr. Parkes.

Against the motion—Mr. Arnott, Mr. Cooper, Dr. Storrar, Mr. Syme, Dr. Thomson, Dr. A. Smith, Mr. Hargrave, Dr. Apjohn, Dr. Corrigan, Dr. Sharpey, Dr. Quain, Mr. Rumsey, Dr. Christison, and Dr. Stokes.

Not voting—The President and Dr. Leet.

Dr. CORRIGAN moved:—"That it seems impossible to lay down any scheme of education and examination comprising details which would be applicable to, or could be uniformly carried out by, all the licensing bodies enumerated in the Medical Act; and that this Council is of opinion that the Committee of Education, leaving all details to be carried out in such manner as may appear fit to them by the several licensing bodies, confine itself, in considering the question of education, to the following points—viz., that there be, 1, registration and adequate preliminary examination in arts; 2, the time to be interposed between the passing of the preliminary examination and the final examination; 3, the mode of subdivision of the Professional examination, and the period of study at which each part of the examination should be gone through, and the subjects to be comprised in each part." He said that with regard to lectures, terms, and several other points connected with study, there were no two Medical Schools which followed the same course. Sufficient instances would occur to all present to show that it would be impossible to confine all schools to the same course. The resolution pointed to the registration of students. It was painful to have always to tell the truth; but it was a monstrous fact that in some cases students received certificates for past years during which they had never attended the Medical School. That state of things would never be abolished while there were schools competing with each other and deriving profits from the sale of certificates unless a system of registration were adopted. Under such a system no such abuse would be possible. No certificate of preliminary education should be received unless it was known what subjects were included in that preliminary course; but when it was ascertained that the proper subjects had been studied the student should not be required to go through them again.

Dr. SHARPEY seconded the motion.

Dr. PARKES suggested that a smaller committee than one of the whole Council should be appointed.

Dr. QUAIN asked whether the Council was not going back to the resolutions passed on the last day of last session. It was then resolved "That all students pass an examination in general education before they commence their Professional studies." It was also decided that after a certain time Medical students should be required to be registered. The Council were beginning the same things *de novo*. There was a Committee on education appointed last year. He should therefore move that the Report of the Select Committee on Education be now proceeded with.

Dr. WOOD said that the registration clause did not lay down clearly that students were to be registered before commencing their Professional education. The Council were probably beginning *de novo*, but they were beginning at the right end.

Dr. CORRIGAN said that the resolution he proposed did not prevent registration, and did not interfere with Professional education; but it merely expressed an opinion that the Committee on Education should confine its attention to the questions of registration, preliminary education, and Professional education.

The amendment was seconded and put to the meeting. There were—for it 10, against it 9. It was then put as a substantive motion, when the numbers were—for it 15, against it 3.

Dr. AQUILLA SMITH moved, with reference to the proposed registration of Medical students—"1. That the registration of Medical students be placed under the charge of the Branch Registrars. 2. That every student be registered at the commencement of Professional study, the date of such registration to be considered as the date of commencement of Professional studies. 3. That each of the Branch Registrars shall open a register of Medical students from the 1st of April to the 15th

of May, and from the 1st of October to the 1st of December, in each year, according to the subjoined form :—

Date of Registration.	Name.	Age last birthday.	Preliminary Examination in Arts, and Date.

4. That every person desirous of being registered as a Medical student shall apply in writing to any one of the Branch Registrars, according to a form to be had on application, and shall produce or forward to him a certificate of his having passed a preliminary examination in arts recognised by the General Medical Council, and furnish satisfactory proof of his age, whereupon the said Branch Registrar shall enter his name and other particulars in the Students' Register, and the Registrar shall give him a certificate of such registration accordingly. 5. That each of the Branch Registrars shall supply to the several qualifying bodies, Medical schools, and Hospitals in that part of the United Kingdom of which he is Registrar a sufficient number of blank forms of application for the registration of Medical students. 6. That a copy of the Register of Medical Students so prepared by the Branch Registrars be transmitted to the Registrar of the Medical Council, who shall, under the direction of the Executive Committee, prepare and print an alphabetical list of all registered students, and supply a copy of such authorised list to each of the bodies enumerated in Schedule (A) to the Medical Act. 7. That the several licensing bodies be requested, after October, 1868, to abstain from examining any candidate for licence or degree whose name does not appear on the authorised list of Medical students or whose name is not already on the *Medical Register;* and that they be also requested to recognise the date of each student's registration as the commencement of Professional study. 8. That the several Branch Councils shall have power to admit special exceptions to the foregoing regulations as to registration, for reasons which shall appear to them satisfactory." He said that the system of registration adopted by the schools themselves was unsatisfactory and the returns were confused. It was desirable that the registration of students should be placed in the hands of the Branch Registrars, and that the returns should be transmitted by them to the Registrar of the General Council.

Dr. Fleming suggested that it would facilitate the business if Dr. Smith would move the different parts of the resolution *seriatim*.

Dr. Aquilla Smith accordingly moved "That the registration of Medical students be placed under the charge of the Branch Registrars."

The motion was seconded by Dr. Fleming, and carried unanimously.

Dr. Aquilla Smith then moved "That every student be registered at the commencement of Professional study, the date of such registration to be considered as the date of commencement of Professional studies."

Dr. Corrigan moved "That every student be registered at or before the commencement of Professional study."

Dr. Fleming moved "That each student shall be only once registered—namely, at the time he enrolls himself as a Medical student."

Mr. Syme advocated the registration of students, and said he thought that that most painful, most demoralising, and most useless system of certificates should be abandoned.

Dr. Paget said that the resolution of last year as it was finally settled could not be misunderstood. He proposed that the motion of last year should be adhered to. It accomplished all that was necessary. It was that students should be registered at the commencement of Professional study.

Mr. Syme seconded the motion.

The President entreated the Council to consider whether a change was really necessary. It was undesirable to alter so recent a decision as that of last year unless there was some valid reason for it. It would make it appear that the Council had no settled purpose.

Dr. Wood said he was not in favour of alterations, but the resolution of last year left it in the power of any Medical school to slip through the noose.

Dr. Paget observed that if the registration were to be "at or *before*" the commencement of Professional study, a student might be registered before he commenced his studies, and so have only two years instead of four.

Mr. Arnott said the chief object of the registration was to determine when the Professional study really began.

Dr. Thomson said the only real difficulty which suggested itself to anybody with reference to Medical education was to determine what time should elapse between the preliminary examination and the commencement of Professional education. Registration was necessary only at the commencement of the Medical education, but it should be provided that no registration should take place until a preliminary examination should be passed.

Dr. Aquilla Smith said that all that was wanted in the first instance was proof of preliminary examination.

Dr. Paget said that the determination of the preliminary education took place at the last session of the Council, and stood on the rules.

Dr. Wood said that that stood on the minutes; but it did not go forth to the different licensing bodies as a requirement of the Council.

Mr. Syme proposed the following motion in substitution for that of Dr. Smith :—"That all Medical students shall be registered at the commencement of Professional study, and not until they have passed a preliminary examination."

Dr. Sharpey seconded and Dr. Wood supported the amendment.

Dr. Corrigan said that before the Council could pass such a resolution they must define what was the commencement of Professional study. It was a point on which a diversity of opinion might arise; and the words "at or before the commencement of Professional study" would meet the difficulty.

The motion of Dr. Smith was not seconded.

The motion of Mr. Syme was put and carried by a large majority.

Dr. Aquilla Smith moved :—"That each of the Branch Registrars shall open a Register of Medical students from the 1st of April to the 15th of May, and from the 1st of October to the 1st of December in each year, according to the subjoined form."

Date of Registration.	Name.	Age last birthday.	Preliminary Examination in Arts, and Date.

Dr. Alderson seconded the motion.

Dr. Fleming said that the provision would give a latitude of two months to some of the schools, which was a very serious matter.

Mr. Arnott said that that latitude would be a very great evil. Two months in the winter session were of the highest importance.

Dr. Aquilla Smith said that he was willing to alter the resolution so that the registration should take place within fifteen days of the commencement of the session.

Dr. Corrigan asked how the resolution was to be carried out. There was no authority for anything of the sort in the Act of Parliament, and he wished to know how the Branch Registrar was to be paid for the duty? The Treasury would not sanction a payment for any purpose not included in the Act.

Dr. Wood said the case might be met simply by increasing the salary of the Branch Registrar.

Dr. Paget said the place of study should be mentioned in the register to avoid confusion in the case of two names being alike. He moved "That a column for the 'place of study' should be added."

Dr. Fleming seconded the amendment.

Dr. Apjohn said that fifteen days was too short to allow for registration. It should be twenty-five days.

Dr. Parkes raised the question whether there was any clause in the Act which would entitle the Council to require the registration.

Dr. Paget said that that question might be taken up by the Committee on the amendment of the Act.

Dr. Wood said that the opinion of Mr. Ouvry, the solicitor to the Council, was that the registration was only part of the machinery by which the Council could get information as to the course and manner of study pursued by Medical schools, and, therefore, it was allowable.

The amendment of Dr. Paget for the addition of a column for "place of study" was carried, and was then put as a substantive resolution and carried.

A question was raised as to whether the passing of the amendment precluded a further alteration of the original resolution.

The PRESIDENT said he considered that it did. He appealed to Dr. Paget as to whether he meant his amendment to carry the time allowed for registration, and the rest of the resolution entire.

Dr. PAGET answered in the affirmative.

The sudden closing of the question having taken the Council generally by surprise, it was resolved that the consideration of Dr. Smith's motion be re-considered, and that the decision on Dr. Paget's amendment be set aside.

Mr. RUMSEY said that, in order to make the time for registration shorter and more definite, he would move as an amendment—"That after the words 'Medical students,' the following words should be added, 'and that every student be required to register within twenty-five days after the commencement of each session or term;' and that a column be added for 'place of study.'"

Mr. HARGRAVE seconded the amendment.

Dr. CHRISTISON thought that twenty-five days were too long. Fifteen days would be long enough.

Dr. THOMSON said he was in favour of requiring the registration to take place as soon as possible, but he considered fifteen days too short a time. He would suggest that twenty-one days should be allowed. He was aware that the attendance was much improved by shortening the time for registration.

Dr. WOOD said that the Council would be going backwards in its requirements if it allowed twenty-five days.

The amendment of Mr. Rumsey was modified as follows:—"That after the words 'Medical students,' there should be added, 'and that application be made by every such student for registration within fifteen days after the commencement of Professional study,' and that a column be added for the place of study to be entered."

The amendment as modified was then put and carried.

It was afterwards put as a substantive motion, and carried unanimously.

Dr. AQUILLA SMITH then moved—"That every person desirous of being registered as a Medical student shall apply in writing to any one of the Branch Registrars, according to a form to be had on application, and shall produce or forward to him a certificate of his having passed a preliminary Examination in Arts recognised by the General Medical Council, and furnish satisfactory proof of his age; whereupon the said Branch Registrar shall enter his name and other particulars in the Students' Register, and the Registrar shall give him a certificate of such registration accordingly."

Mr. ARNOTT said that proof of age and preliminary examination were not sufficient to constitute a person a Medical student, and the Branch Registrar ought to have fuller proof of his being a student than that before registering him as one.

Dr. SHARPEY said that a certificate of his being entered as a student at a Medical school should also be required.

Mr. RUMSEY said the difficulty might be met by the production of a certificate of entering a Medical school.

Dr. AQUILLA SMITH agreed to add to his resolution, after the word "age," the words "and place of study."

Dr. CHRISTISON said he did not think that a certificate of age should be required of a student on commencing his Professional study. A declaration would be sufficient in that case. He should not, however, be allowed to receive a diploma to practise until he produced evidence of his being twenty-one years of age.

The PRESIDENT said he did not see any reason to make any requirement as to proof of age at the commencement of Professional education. Previous acts of the Council provided that he should not be allowed to practise until he was twenty-one years of age.

Dr. CORRIGAN advocated the omission of all allusion to age in the resolution.

Dr. FLEMING moved that, in the original resolution, after the words "General Medical Council," there should be added the words "and of his having entered on Medical study."

Mr. RUMSEY seconded the amendment.

After a few further suggestions,

Dr. AQUILLA SMITH agreed to alter his resolution as follows:—"That every person desirous of being registered as a Medical student shall apply in writing to the Branch Registrar of the kingdom in which he resides, according to a form to be had on application, and shall produce or forward to him a certificate of his having passed a preliminary examination in Arts recognised by the General Medical Council, and place of study; whereupon the said Branch Registrar shall enter his name and other particulars in the Students' Register; and the Registrar shall give him a certificate of such registration accordingly."

Mr. RUMSEY said that, after having heard the resolution as altered by Dr. Smith, he should prefer it to the amendment which he had seconded; and, if Dr. Fleming would allow him, he would withdraw his name from the amendment.

Dr. FLEMING said he considered the alteration he had raised a very important one, and he could not allow Mr. Rumsey to withdraw his name.

The amendment was then put and lost.

The original motion as altered, on being submitted, was carried by a large majority.

Dr. AQUILLA SMITH moved, "That each of the Branch Registrars shall supply to the several qualifying bodies, Medical schools, and Hospitals in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of Medical students."

Dr. CORRIGAN seconded the motion, and it was unanimously agreed to.

Dr. AQUILLA SMITH moved, "That a copy of the Register of Medical Students so prepared by the Branch Registrars be transmitted to the Registrar of the General Council, who shall, under direction of the Executive Committee, prepare and print an alphabetical list of all registered students, and supply a copy of such authorised list to each of the bodies enumerated in Schedule (A) to the Medical Act."

The motion was seconded by Dr. Corrigan, and carried.

Dr. AQUILLA SMITH moved, "That the several licensing bodies be requested not to admit to examination, after October, 1869, any candidate for licence or degree whose name does not appear in the authorised list of Medical students, or whose name is not already on the Medical Register."

Dr. CORRIGAN seconded the motion.

The motion, on being submitted, was carried unanimously.

Dr. AQUILLA SMITH moved—"That the several Branch Councils shall have power to admit special exceptions to the foregoing regulations as to registration, for reasons which shall appear to them satisfactory."

Dr. CORRIGAN seconded the motion, which was carried unanimously.

Dr. ANDREW WOOD moved, as an addition to the regulations as to registration, "That the Branch Councils be desired to take means to make these resolutions known to the Medical students of the various Medical schools."

Dr. FLEMING seconded the motion, and it was unanimously agreed to.

Moved by Mr. HARGRAVE, seconded by Mr. COOPER, and resolved, "That the Council resume."

Dr. EMBLETON, moved, according to notice, "That the returns from the licensing bodies, in compliance with recommendation 23 of the Committee on Education, and the Registers of the Medical Students in England and Ireland, be referred to a Committee."

Dr. WOOD seconded the motion, and it was carried unanimously.

The following were appointed as the Committee for the purpose:—Dr. Embleton (Chairman), Mr. Cooper, Dr. Thomson, Dr. Leet, Dr. Apjohn, and Dr. Stokes.

The Council then adjourned.

TUESDAY, APRIL 11.

(SEVENTH DAY.)

The proceedings were resumed at the usual hour.

After the reading of the minutes,

Dr. WOOD moved—"That the Council resolve itself into a General Committee on Education, and that the President be requested to take the chair."

The motion was seconded, and carried unanimously.

The consideration of the Report of the Select Committee on Education was resumed.

Dr. WOOD said there were one or two points in the resolutions of yesterday which might be amended. For instance, it was resolved that students intending to enrol themselves should apply according to a certain form. Where was the form to be got?

Dr. Corrigan rose to order. He said it would be better not to alter the resolution of yesterday until the whole Report was before the Council.

Dr. Wood moved—"That the age of 21 shall be the earliest age at which any licence shall be obtained, and that in all instances the age shall be duly certified." This was the recommendation of the Select Committee on the subject. In the University of Edinburgh no final examination took place until a student was 21 years of age.

Dr. Aquilla Smith said that at some places a diploma was granted before that age.

Dr. Wood said that was a very great evil, and means should be taken to prevent it. A man should not be allowed to engage in practice till he was of age.

Mr. Syme moved—"That the age of 21 be the earliest age at which the candidate for any Professional license shall pass his final examination, and that the age in all instances shall be duly certified; and that a return, with the exceptions to this recommendation allowed by the licensing bodies, together with the reasons for such exceptions, be transmitted to the Branch Council of that part of the United Kingdom in which they have been granted."

Dr. Paget seconded the motion.

Dr. Arjohn thought the motion unnecessary. It was a very rare occurrence for students to be examined before they were 21. The authorities in Dublin opposed the restriction.

Dr. Stokes said that the Council should reflect on the disadvantage at which they might place a young man by refusing to examine him before the age of 21 years. There were many who improved themselves after their final examination, and if they were not examined till they were 21, they would be deprived of a large amount of that quiet study which often intervened between the final examination and the age of 21.

Dr. Thomson said that young men were often better fit to be examined at 20 than at 21. After their final examination they often went through a very valuable preparation for practice up to the age of 21, which they could not undergo if the prospect of the final examination were kept hanging over their heads during that time. They would in that case be only repeating the exercises of the grinder. To decide that no diploma should be granted till a candidate was 21 was another matter, but the test for that diploma might be applied at the end of the prescribed course of Professional education. Twenty-one years of age was early enough to come into contact with the public, but he believed that the resolution would be a bar to a very great amount of useful preparation.

Mr. Arnott said he entirely coincided with the motion. The duty of the Council was to decide what would be the best thing for the public, and he contended that candidates should be tested at the latest possible time as to their fitness to go amongst the public to practise.

Dr. Paget supported the motion.

Dr. Corrigan moved, as an amendment—"That the age of 21 be the earliest date at which any Professional license be obtained, and that the age shall, in all instances, be duly certified." The resolution would inflict a great hardship in many cases. A young man might come of age in October, and yet he would not be eligible for the examination in June or July previously. He might be going out to the colonies as soon as he had passed, but in consequence of such a resolution as that proposed by Mr. Syme, he would be kept in England for nearly twelve months after his majority. A case had occurred in his own experience in which a young man would be of age about four weeks after the examination, and it was absolutely impossible for him, from the circumstances in which he was placed, to remain in the country till the next examination. The authorities allowed him to be examined, but withheld his licence until he was of age. A candidate would not come before the public one hour sooner in consequence of the amendment than he would if the resolution were passed.

Mr. Cooper said he quite agreed with the resolution. The age of twenty-one should be the earliest at which the final examination should take place.

Dr. Corrigan called attention to the fact that the amendment which he had moved had been embodied in the recommendations which were circulated last year; and it would be breaking faith with the licensing bodies if the Council were to go from that recommendation after those bodies had agreed to support the proposal. It would not be a fair way of treating them, as they had assented to the amendment, and had had no opportunity of expressing an opinion on the motion of Mr. Syme.

Dr. Wood said that Dr. Corrigan had argued, by inference, that the Council were not to pass a recommendation because all the Medical bodies would not agree to it. That was a position which ought not to be enforced on the Council. The Council ought not to be told that they were not to reconsider a recommendation which they promulgated last year. Dr. Corrigan had himself, during the sittings of the Council, helped to set aside a recommendation as to registration which the Council had made last year; and, therefore, the argument he had used was not a fair one. The case cited by Dr. Corrigan would certainly be a hard one, and probably some modification of the resolution might be required.

Dr. Sharpey said that a provision might be introduced into the resolution, leaving exceptional cases, such as had been instanced by Dr. Corrigan, to the discretion of the Branch Council.

Dr. Stokes asked the Council to pause before they took such a step as that proposed in the resolution.

Dr. Thomson said that an exceptional clause, such as had been suggested, would meet the necessities of the case.

Dr. Acland said that the recommendation embraced in the amendment was one which the Council decided on long ago, after much discussion; and, until some abuse arose in connection with it, there was surely no reason for altering it. The spirit of the Council was that twenty-one years of age was the earliest date at which a medical man should be allowed to practise, and he believed that that opinion would be respected. Each of the members of the Council might do the best they could with their own bodies to get the recommendations of the Council observed.

Dr. Quain said that the final examination and the license for practice were practically one and the same thing. He had learned for the first time during this discussion that they were two things. (A Voice: "So they are.")

Dr. Corrigan said that there was no analogy between the alteration which he had proposed with regard to registration, and which was referred to by Dr. Wood, and the present case.

The President said that he had had the honour of being a lecturer and examiner at Cambridge for a long period, and also of being a lecturer in a metropolitan school of Medicine. His experience of students, extended over a long period, was that there were many cases in which young men of precocious talents and immense industry were ready for examination before the age of 21 years, but the Council were not to legislate for exceptional cases. They should lay down a general rule, which, though it might operate with some inconvenience on some candidates, would be applicable to the great majority of students and advantageous to the public. If a young man were ready for final examination before the age of 21, it could be no hardship to him to spend a few months extra in the wards of a Hospital, and in the pathological theatre attached to it.

The amendment was then put and lost.

The original motion was carried.

The next section of the Report referred to the duration of Professional study.

Dr. Wood moved—"That no licence be obtained at an earlier period than after the close of the last winter session of the fourth year of study after the registration of the candidate as a Medical student."

Mr. Arnott said that the real question raised was whether the time of study should be four years, or three years and a half. The motion seemed to be a limitation of the period by a side wind.

Dr. Fleming seconded the motion.

The President said that this was comparatively a new topic for discussion. The Council came to no decision on the subject last year.

Dr. Paget moved, as an amendment—"That no licence be obtained at an earlier period than after forty-eight months of study subsequent to the date of registration of the candidate as a Medical student."

Mr. Arnott seconded the motion.

Dr. Corrigan suggested the omission of the words "of study," as every young man had some vacation.

Dr. Paget agreed to omit the words.

Dr. Thomson asked whether Dr. Paget meant that if a student were registered in October or November he could not obtain a licence until that time four years. That was not the present practice, and he believed that Dr. Wood's motion was based on what was known to be the *bonâ fide* practice.

The President said that the motion and amendment involved two different principles. Some thought that Medical

education commenced only with attendance at a Medical school, while some thought that it might commence otherwise.

Dr. Storrar said that the motion might secure the commencement of study by a summer course, in which such subjects as botany and chemistry might be taken in hand before the October session. Four years might be taken up profitably in that way.

On the amendment being submitted, the numbers were—for it, 12; against it, 7.

On being put as a substantive motion it was carried by 12 against 8.

The next recommendation of the report was Clause 2, under the head of Professional study. It was: "That the course of study required for a licence shall comprehend attendance during not less than four winter sessions, or three winter and two summer sessions, at a recognised Medical school; and that evidence shall be produced that the remaining period of the four years has been passed in the acquisition of Professional knowledge."

Mr. Hargrave moved the adoption of the recommendation.

Dr. Paget seconded the motion.

Dr. Corrigan said that the proposition would destroy several of the schools in Ireland. There were few of the schools which had resident Medical teachers, and therefore could not be strictly a Medical school. He would recommend the Council to decide what was a "recognised Medical school."

Dr. Parkes said that the case might be met by the insertion of the words "a Medical school recognised by the body granting the licence."

Dr. Wood said that the Council should decide what a recognised Medical school was. It was a very important question, and should not be left to the licensing body. The body to which he belonged had rather a high standard on the subject. Dr. Corrigan was quite right in raising the question, and the definition given must determine how the members were to vote.

Dr. Embleton moved, as an amendment, "That the Council, before proceeding further, determine what are the requisites for constituting a Medical school under their recommendations." He said that that was a question which it was absolutely necessary to settle.

Dr. Wood seconded the motion.

Mr. Hargrave said the importance of the question was exaggerated. It was a point on which there could not be any great mistake.

Dr. Aquilla Smith said that the Council ought to accept as a Medical school any school recognised as such by the licensing body.

Dr. Parkes said that there would be a difficulty if the Council decided that a Medical school must have a Hospital attached to it.

The President observed that King's College, London, and University College were a long time without Hospitals.

Dr. Acland said he attached very great importance to the proper definition of what should be regarded as a Medical School. In many institutions scientific instruction was in a very peculiar position, and a resolution should not be passed which would exclude the scientific instruction given at those institutions from the Medical Profession. Oxford, which he represented, was a case in which valuable scientific instruction was given. If the Council passed a resolution cutting Oxford off from the recognised Medical Schools, it would not matter the least to Oxford, but it would matter to the Medical Profession. He should, when the opportunity occurred, propose, as he did last year, the insertion after the words "Medical School" of the words "or other institution recognised by the several licensing bodies and approved by the Council."

Dr. Aquilla Smith said that there was a sufficient definition already existing.

The President said that the Council should bear in mind that, in addition to Medical Schools, there were many institutions in England which gave scientific instruction on subjects ancillary to Medicine. Certainly no objection could be raised to a person taking his instruction on those subjects at those places. The recognition must not be too limited. What was wanted was, to secure that a proper amount of study should be given to those subjects.

Dr. Christison said that the definition should not be too limited. The recognition of Medical Schools should be left with the licensing bodies.

Dr. Aquilla Smith agreed with Dr. Christison.

The amendment of Dr. Embleton was put and lost.

Dr. Acland moved that after the words "Medical school," in the original motion, should be added "or other institution recognised by the several licensing bodies, and approved by the Council."

Dr. Parkes seconded the amendment.

After some conversation,

Dr. Acland agreed to substitute for his amendment one suggested by Dr. Christison.

Dr. Christison accordingly moved, "That the course of Professional study required for licence shall comprehend attendance during not less than four winter sessions, or three winter and two summer sessions, at a school recognised by any of the licensing bodies mentioned in Schedule (A) of the Medical Act."

Dr. Parkes seconded the amendment.

Dr. Corrigan said that the amendment would limit the period of study to two years and a half.

Dr. Paget said that the amendment provided that the course should "comprehend" certain sessions, but it did not say that it should be restricted to them. That was an answer to Dr. Corrigan's objection.

Dr. Christison said that the Council might give some instructions as to how the remainder of the four years might be filled up; but he recommended the Council not to legislate in that direction. It was often desirable to relieve students from study for a time, in order to give them some relaxation. It would be a great hardship to require that the whole of the forty-eight months should be devoted to unintermitting study.

Dr. Fleming said that the amendment laid down the minimum of the time which must be spent during the four years in attendance at a Medical school.

The amendment was then put. There were in favour of it 15, and against it 1. It was then put, and carried as a substantive motion.

Dr. Parkes proposed that Clause 3 of the Report be omitted.

Dr. Storrar seconded the motion.

The motion was unanimously agreed to.

The next recommendation was Clause 4, and was as follows:—"That it be recommended to the several licensing bodies that the courses of instruction required by them should be framed in such a manner as to secure a due share of attention, both to preparatory branches and to those more strictly connected with the practice of Medicine and Surgery; and that it be suggested accordingly to these bodies that their regulations should be such as to prevent attendance upon lectures from interfering with Hospital and clinical study."

Mr. Syme moved that the paragraph be adopted as a recommendation of the Council.

Dr. Storrar seconded the proposition.

Mr. Hargrave objected to the motion, but said he had not an amendment on the subject.

The motion was put and carried.

The Council then considered the 5th Clause, which was—"That, while avoiding for the present all other details by which this object may be attained, it be recommended that no subject of lectures be enforced by regulation to be attended oftener than once."

Dr. Thomson moved that Clause 5 be omitted. The resolution already passed provided all that was necessary.

Dr. Embleton seconded the motion.

Mr. Syme moved as an amendment—"That Clause 5 stand part of the recommendations of the Council on the subject of Professional study."

Dr. Aquilla Smith seconded the amendment. He said that compulsory attendance at more than one course of lectures on the same subject was a great grievance to Medical students. The recommendation as it stood would be a great boon to students, and would prevent the crowding together of several subjects at once.

Dr. Corrigan supported the motion. The Council had no right to interfere with any educating body if it thought that more than one course of lectures on the same subject were necessary.

Dr. Apjohn thought that the regulation might be injurious, as in the case of anatomy, in which it could not be said that one course was sufficient.

Mr. Hargrave said he was surprised to find the clause proposed. All that a student would learn in his first course was the A B C of his Profession; and, if such a clause were adopted, the students would confine themselves to the miserably insufficient and inadequate amount of study comprised

in one course of lectures on each subject. If the clause were carried, the body he represented were prepared to go before the Privy Council; and they had plenty of funds to enable them to do so. (Laughter.)

Mr. Arnott said the recommendation would go far to interfere with the proper amount of lectures which ought to be attended. There were many subjects in which the details were so numerous that they could not be learned from books. They required the help of a teacher to bring them fully before the student. A discretion should be left to the educating body.

The amendment was lost, and the original motion, for the omission of the clause, was carried.

Clause 6 was—"That the Council intimate that they will view with approbation any encouragement held out by the licensing bodies to students to prosecute the study of the natural sciences before they engage in studies of a strictly Professional character."

Dr. Storrar moved that Clause No. 6 should be adopted.

Dr. Embleton seconded the motion.

Dr. Apjohn said he thought the young men would be much better employed by pursuing general education than Professional, previous to the Professional course. He moved that it be omitted.

Mr. Arnott said he saw no objection to the clause. There were many subjects on which the minds of young men of 17 or 18 years of age might be very usefully employed, and which might be taken up with advantage to their observing and reasoning faculties.

Dr. Corrigan seconded Dr. Apjohn's amendment.

Dr. Wood said that such subjects as zoology, botany, and natural history were good training subjects. In the College of Surgeons in Edinburgh they were included in the preliminary examination, but they were made optional. In addition to the advantage of them as training subjects, the knowledge of them acquired before the Professional course tended to relieve that course of the pressure of subjects.

Dr. Aquilla Smith supported the motion.

Dr. Corrigan said that he thought that the Council in making the recommendation would be going beyond their functions. He should like to know what the nature of the encouragement held out was to be. If that were explained, he might vote for it.

Dr. Christison said that there had been more discussion on the subject than he anticipated. He had not supposed that there would have been a division of opinion on it. He considered the requirement that young men should include some of the natural sciences in their preliminary education was a very wise one. He himself had taken some of the natural science courses before he knew that he should be a Medical man. The same was the case with Professor Syme. If a young man were required to take his chemistry before his Professional course commenced, it would do him a great amount of good.

Dr. Storrar requested that the Council would allow him to strike out from the beginning of his motion the words "intimate that they."

The alteration was allowed.

The amendment for the omission of Clause 6 was put to the meeting and negatived.

Dr. Acland moved as an amendment to the original motion,—"That the Council recommend that the licensing bodies take into their consideration what portion of natural science shall be comprised in the course of general education prior to the commencement of strictly Professional study."

Mr. Rumsey seconded the amendment.

It was then put to the meeting and lost.

The original motion was then put in the following altered form:—"That the Council will view with approbation any encouragement held out to the licensing bodies to students to prosecute the study of the natural sciences before they engage in studies of a strictly Professional character."

Clause 7 was then read by the President. It was, "That the several licensing bodies be requested to furnish a short statement of the mode in which their examinations are now conducted, whether by written, oral, or practical examination, and of the length of time a candidate is under examination in each or all of these ways."

Dr. Aquilla Smith proposed its adoption.

Dr. Apjohn seconded the motion.

Dr. Parkes moved an amendment, but as the time for rising was drawing near, it was deferred, Dr. Wood, Chairman of the Business Committee, promising to put it in the programme for to-morrow.

Dr. Aquilla Smith said he would withdraw his motion, that the amendment of Dr. Parkes might become the substantive motion.

The Council then resumed, on the motion of Dr. Wood.

The President informed the Council that the Solicitor had reported that the certificate of the conviction of John Carter Barrett, at Castlebar, for felony, was a proper document.

On the motion of Dr. Smith, seconded by Dr. Stokes, it was resolved that the name of John Carter Barrett be removed from the Register.

The Council then adjourned.

FOREIGN CORRESPONDENCE.

GERMANY.

Berlin, April 2.

Two different epidemics have of late attracted much attention in Eastern and Central Europe,—viz., the recurrent or relapsing fever of St. Petersburg, and the cerebro-spinal meningitis which has appeared in several parts of Germany. About the first of these the most exaggerated accounts have appeared in the newspapers, describing it as one of the most horrible plagues ever seen in Europe, and calling upon all governments to close their frontiers and ports against Russia, etc. The fact is that within the six months from September, 1864, when the epidemic first appeared, until the end of February, only 1722 more persons have died in St. Petersburg than in the corresponding months of the previous year, from which it is evident that this recurrent fever is not nearly so bad as cholera has been. The Government has done a great deal towards mitigating the sufferings of those affected by transforming barracks into Hospitals, and other measures. At present the epidemic has rather increased than diminished, and it will most probably continue until summer has fairly set in. Not much is known about its origin, although there can be no doubt that the severe cold, the dram-drinking, which is now carried to an unheard-of extent, the vile quality of the spirituous compound which is sold to the people, the bad black bread, the stinking canal water which is used for drinking, and the miserable lodging accommodation that is afforded to the poor population, have much contributed towards rendering the epidemic severe. Scurvy has also appeared, as it generally does about this season. The recurrent fever has been almost entirely limited to the working classes.

The general symptoms of the recurrent fever have been the following:—The disease commenced with a severe rigor, and on the second day the temperature rose to 104°. The fever then continued for about ten or twelve days, during which time there were such considerable variations in the temperature as have not yet been observed in any other form of fever. There was, moreover, not the slightest regularity in these variations; sometimes it fell on the second or third day of the illness from 104° to 86°, and that during twelve hours. A few days after it again rose to 104° or 105°, at which it continued for some days, and then fell again considerably. This latter fall was evidently a "critical" one, being accompanied with profuse perspiration and "critical" urine, bleeding from the nose, and the appearance of herpes labialis. The rapid fall of the temperature was occasionally accompanied with chills. The patients now appeared to be in a fair way of recovery, when three or four days afterwards they were again attacked, the temperature rising once more to 104°. This fresh attack usually lasted from two to four days, but sometimes longer; there being the same irregular variations of temperature during that time. The second attack ended as the first. Some patients, in the interval between the two attacks, appeared to be so well that they left the Hospital, others only complained of weakness and loss of appetite. In some patients then a third attack supervened, being similar to the two former ones. In all these cases the liver and spleen were considerably enlarged, and extremely sensitive to pressure, while the attacks lasted; as soon as the temperature fell, the size and sensitiveness of these organs were as suddenly diminished.

In some cases a petechial eruption was observed on the skin of the nape of the neck, and of the upper and lower extremities. Sometimes pneumonia supervened, which occasionally proved fatal; in other cases there was parotitis, and abscesses in the cellular tissue; icterus was sometimes severe. There was also albuminuria in a few cases. The patients generally complained of weakness, headaches, ringing in the ears,

thirst, loss of appetite, pain in the liver and spleen, and in the extremities. There was generally sleeplessness, but no delirium. The post-mortem examination showed acute parenchymatous inflammation of the liver and kidneys; the spleen was greatly enlarged in consequence of hyperæmia. The acini of the liver were enlarged, and their contents turbid; some cells contained an emulsion of fat. The treatment was at first expectant and symptomatic; after the true nature of the disease was understood, quinine was administered in two-grain doses every two hours, with evident benefit in most cases.

The other epidemic which I mentioned in the beginning of this letter is of a far more severe character, and would certainly prove a terrible calamity were it to assume considerable dimensions, being fully as dangerous as the worst forms of typhus, yellow fever, and cholera. Epidemic cerebro-spinal meningitis first appeared in Geneva in 1805. A somewhat more extended endemic occurred from 1837 to 1842 in the south of France, and another also in France from 1846 to 1849. It then appeared in certain places in southern Italy and Sicily, where it was called "tifo apoplettico;" in Algiers, in the United States, in Gibraltar, in Denmark, and Sweden, and in some workhouses in Dublin, Belfast, and Edinburgh (1846). In 1859 it again broke out in Norway, and in 1860 amongst the Dutch troops stationed at Arnhem. At present we have rather alarming accounts of it from the eastern provinces of Prussia, and also from Hesse, Brunswick, and Hanover. The average mortality is from 50 to 60 per cent., and death is preceded by terrible sufferings.

The disease consists of purulent inflammation of the pia mater of the brain and spinal cord. In some cases there are premonitory symptoms, such as vertigo, headache, weakness, stiffness in the muscles of the neck, and occasional chills; but in others the disease begins quite suddenly with delirium and convulsions, and death ensues within twenty-four hours. In the majority of cases, however, the symptoms are as follows:—A severe rigor sets in towards night, followed by intense heat; the patients complain of severe headache and vomit freely. Then there is a feeling of tension in the nape of the neck, great restlessness, tremor, especially of the extremities, and considerable hyperæsthesia of the skin, so that the merest touch makes the patients scream. They have the appearance of drunken men, with glazed eyes, reddened conjunctiva, contracted pupils; the pulse is sometimes accelerated, sometimes normal. After this condition has lasted for a few hours tetanic spasms of the trapezius and other muscles of the nape of the neck set in, the head being sometimes placed in a right angle to the trunk. Tetanic convulsions of the extremities occasionally follow, accompanied with delirium, which is succeeded by sopor and coma. The vomiting continues, and in the intervals of consciousness the patients complain of violent pain in the head and the stomach.

This stage of the distemper generally lasts from 24 to 36 hours, and is succeeded by one of depression and prostration. The patients do not answer questions, are lying on the back in a state of torpor, the extremities tremble, the pulse is very much retarded, the skin cool, the face pale, the pupils dilated; tetanus in the muscles of the neck and back continues, and eruptions of various kinds take place on the skin. Sometimes these resemble measles, at other times the scarlet rash, or erysipelas, and herpes, the latter being chiefly observed in the face. The coma increases, there is ptosis, strabismus, paraplegia, intermittent pulse, and death closes the scene.

In other cases there seems to be rapid absorption of the effusion, and the patients quickly recover. Again, in others, all the symptoms gradually vanish, and convalescence sets in, which is, however, very protracted. Secondary diseases are not unfrequently observed during the course of the distemper—viz., catarrh of the intestinal mucous membrane, pleurisy, pericarditis, parotitis, and inflammations of the eye. During the time of the epidemic many people suffer from symptoms resembling those of the first stage of the disorder; but if carefully treated they fall into a profuse perspiration and recover. This mild form has the same relation to the more severe one as English cholera to Asiatic cholera.

The post-mortem appearances are as follows:—The sinuses of the dura mater contain a very large quantity of blood, and sometimes coagula of fibrine; the arachnoid is dry and turbid; the pia mater covered with a purulent effusion, which is occasionally tinged with blood. The quantity of this effusion is sometimes so considerable that the arachnoid and pia are altogether disconnected; in the cerebrum it is chiefly found on the base, about the pons, the optic nerves, and the medulla oblongata; in the spinal cord chiefly about the dorsal and lumbar swelling. The brain is generally swollen or dry; sometimes there are small foci of softening. The changes in the other organs are not constant. There may be appearances of pleurisy and pericarditis, swelling of all the intestinal glands, hyperæmia of the liver and spleen. In the cavities of the large joints, accumulations of purulent matter have not unfrequently been discovered.

The disease seems to be quite independent of soil and climate, but is certainly most severe where there is dirt, over-crowding, bad air, and water. There can be no doubt about the existence of an actual contagion, for in those epidemics which occurred in France, the distemper generally stuck to certain regiments, which, when dislocated, carried it with them to other places. Evacuation of ill-ventilated barracks has occasionally checked the spreading of the complaint amongst the military. In some former epidemics the military have suffered most, and, amongst them, privates were more frequently affected than officers. Last year there were fourteen cases amongst the privates of the Alexander regiment and the 2nd regiment of Guards in this city. In the epidemic which is at present observed in Hanover, Brunswick, and Hesse, it seems chiefly children and young people who suffer. In Einbeck, a small place in Hanover, not less than eighty children and only five adults have been affected since January last. The mortality was there 33 per cent. Remedies seemed to be utterly powerless to check the disease; sometimes trismus prevents the internal administration of medicines, and in such cases the subcutaneous injection of morphia might, perhaps, be useful in diminishing the pain and spasms, and soothing the patients.

GENERAL CORRESPONDENCE.

OVARIOTOMY—CLAY'S ADHESION CLAM.

Letter from Professor John Clay.

[To the Editor of the Medical Times and Gazette.]

Sir,—In the abstract of Mr. Baker Brown's admirable paper "On a New Method of Securing the Pedicle in Ovariotomy," read before the Fellows of the Obstetric Society in February last, Mr. Brown is reported to have said—"Having repeatedly used the actual cautery of late, employing Dr. Clay's instruments," etc. In the same paper the name of Dr. Clay, of Manchester, is more than once mentioned in reference to the procedures of the operation, and the inference to be drawn from the above quotation is, that the instruments used by Mr. Brown were some devised by Dr. Clay, of Manchester. As I was not aware at the time of reading the report that Dr. Clay had devised any instruments to be used as an actual cautery, or that he agreed with that mode of securing the pedicle, or dividing the adhesions in the operation of ovariotomy, I addressed a note to Mr. Baker Brown requesting to be informed whose the instruments were which he employed, and he kindly sent me a reply, of which the following is a copy. I regret to learn that my note was not answered earlier in consequence of Mr. Brown's indisposition:—

"17, Connaught-square, Hyde-park, W.

"My dear Sir,—I have been prevented by illness from replying to your note before this. I certainly spoke of your clam as Mr. Clay's—the word "Dr." was a typical error entirely. Ever since you first introduced your clam to the Profession I have used it, and now seldom or ever use any ligatures, and as you see I even use the clam, or rather an improvement on yours, to secure the pedicle. As you are fairly entitled to all the credit due to the clam, you are perfectly at liberty to make any use of this note you choose.

"Ever yours sincerely,

"To John Clay, Esq., Birmingham." "J. B. Brown.

I may be allowed to add that I am the more anxious that this explanation should be publicly made, as the instruments have been considered by an eminent ovariotomist unfitted for the purpose for which they were invented. I may state, however that the gentleman referred to heated the cauterising iron in boiling water, which was a perversion of the application of the instruments which I never contemplated. The instrument heated by the flame of a spirit lamp has never failed in my hands in severing the adhesions and effectually preventing any hæmorrhage. From experiments which I have recently made, I found that the cauterising iron requires to be heated to about 800° Fahr. To attain this uniform tem-

perature with easy and accuracy, I found that this may be accomplished by immersing the iron in a metal bath composed of one part each of lead and zinc, melted in a suitable iron ladle. The iron when immersed in the metal is apt to become coated with it, which is of little importance in the operation, having no injurious effects on the structures to be divided. This coating of metal, if desired, can be removed by subjecting the iron to a greater heat than that of the metal bath.

Mr. Brown merits every acknowledgment for the skill and courage he has evinced in employing the actual cautery for securing the pedicle in ovariotomy, a mode of procedure which has opened a new era in the performance of this important operation. I am, &c.

John Clay, Professor of Midwifery,
Queen's College, Birmingham.

CASE OF ARREST OF DEVELOPMENT.

Letter from Mr. John Gould.

[To the Editor of the Medical Times and Gazette.]

Sir,—I send you a most extraordinary case of an arrest of development, should you think it worthy a place in your valuable journal.

I was recently called to attend a woman in her fourth labour. I was informed on my arrival she did not expect her confinement for a month; delivery, however, was very quickly terminated.

The first birth—for it was a case of twins—was one of the most extraordinary monsters I ever beheld. It had no head, arms, nor legs, there were only body and thighs; at the termination of each of the latter was a very small flat protuberance, evidently rudimentary feet, as the edges had little prominences representing undeveloped toes. The umbilical cord at its junction with the body was preternaturally dilated, and destitute of its external investing membrane. Two inches above the umbilicus was an irregular opening about half an inch in diameter, through which protruded a membranous-looking substance. Immediately above, and a little to the left of this orifice, was a small patch of hair about the size of a shilling. In place of the mammæ and nipples were two small transverse depressions, the left somewhat higher than the right. The sexual organs were those of a female, but the vagina and anus were included in one common orifice.

I enclose a rough sketch, of which the above is a brief description, and have also preserved the specimen in spirits.

I have heard it said that monstrosity never occurs except in cases of twins. I should be exceedingly glad to know the opinion of members of the Profession who may have had much experience in similar cases.

I am, &c. John Gould.

Hatherleigh, April 3.

OBITUARY.

We are sorry to have to announce the deaths of two active members of the Obstetrical Society—viz., Dr. F. W. Mackenzie, of 11, Chester-place, Hyde-park-gardens, and Dr. Edwin E. Day, of 48, Hertford-street, Mayfair. The crowded state of our columns forbids more than this announcement at present; next week we shall give a fuller account of each. Dr. Mackenzie had already obtained a wide-spread reputation, and Dr. E. Day was steadily working his way to it; both were suddenly removed after a few days' illness, which came upon them whilst in the midst of Professional work.

Testimonial to Dr. Cookworthy.—Dr. Cookworthy, of Plymouth, has lately been presented with a handsome library chair by some of the patients of the Plymouth Dispensary, an institution which he has served as Physician for more than half a century.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, February 1.

Dr. Barnes, President, in the Chair.

A paper, by Dr. T. Snow Beck, was read

ON PUERPERAL FEVER.

The author related minutely the case of a young lady, aged 24 years, who was confined of her first child, presented symptoms of puerperal fever on the second day, and sank three days afterwards, or on the fifth day after her confinement. He pointed out that the leading feature in the case was the absence of that contractile power of the uterus necessary to the expulsion of the child and provide for the safety of the mother after its birth, this being apparent at each stage of the labour—the languid contractions of the uterus, the inability to increase the force of these contractions by the usual agents, the requirement for the use of the forceps, the necessity for the removal of the placenta, the hæmorrhage which followed, the existence of a large flabby open uterus when the hand was introduced, the great difficulty to induce sufficient contraction of the organ to prevent further hæmorrhage, and the impossibility to procure a firm persistent contraction after the cessation of the hæmorrhage. This lax condition of the uterus permitted the uterine sinuses to remain pervious, and arose from the absence of that due contraction of the muscular tissue which is essential to prevent any fluids circulating along their canals. Another case of puerperal fever was given, which also occurred in a healthy young woman, after apparently a perfectly natural labour, and which proved fatal on the ninth day. The body was examined thirty-six hours after death, and copious effusion of fluid into the abdomen, with shreds of soft friable recent lymph, and some injection of the peritoneum, were found. The uterus was large, pear-shaped, even on the surface, soft, and rather flabby; its interior was everywhere covered by a soft membrane, which presented the usual microscopic characters of the mucous membrane, and was covered by a red mucous secretion. All the tissues of the uterus were examined, and found to be perfectly healthy; no appearance of inflammatory product presented itself in any part of the organ. But the uterine sinuses were open, and water thrown into the larger veins of the abdomen readily traversed these canals, and escaped at the open orifices on the surface of the uterus. From the careful examination of these cases, the following deductions were drawn:—1. The phenomena of puerperal fever may be produced by the introduction of poisonous fluids into the general system. 2. The uterine sinuses remaining pervious to the flow of fluids would afford a means by which the poisonous fluid or fluids would enter the system. 3. The pervious condition of the sinuses remained in consequence of the absence of that firm and persistent contraction of the uterus after childbirth which appears necessary to effectually close these canals, and prevent all circulation of fluid along them. 4. The secretion from the interior of the uterus was probably sufficient, when mixed with the blood, to induce the effects observed. And it would further follow that—5—the various phenomena observed in puerperal fever may arise from this cause, modified infinitely by many incidental states; and the various inflammatory actions and products observed in the course of the disease would not be the essential parts of the disease, but morbid phenomena which occurred during the course of it. 6. The primary, though not the only, object in the prevention of these attacks of puerperal fever will then be to procure a firm, complete, and persistent contraction of the uterus after the birth of the child, and thus effectually to shut off all circulation within the vessels of this organ. The author considered that these cases gave a decided negative to the opinions that puerperal fever was caused by uterine phlebitis, lymphangitis, endometritis, metritis, or any similar inflammatory condition of the uterine organs, as no product of inflammation was anywhere discovered after a careful and even microscopic examination. The results were also opposed to the opinion of Cruvelhier, who compared the internal surface to a vast solution of continuity, and the gaping orifices of the sinuses to the open-mouthed vessels of an amputated limb. For here the internal surface of the organ was everywhere covered by a soft membrane containing all the elements of the

mucous membrane, and covered by a red mucous secretion; whilst the gaping sinuses could only be compared to the open-mouthed vessels of an amputated limb when the uterine sinuses were pervious and admitted fluids to circulate within them: the real point of comparison not being the open orifices, but the open canals leading from these into the veins of the general system. The comparison between puerperal fever and surgical fever was also founded on an erroneous basis; for again a natural condition of the vessels of an amputated limb was compared with an unnatural state of the vessels of the uterus, which ought not to be, and might in the majority of cases be prevented. The propositions given by Dr. R. Ferguson in his valuable essay on Puerperal Fever were examined. The author differed essentially from Dr. Ferguson on the causes of the vitiation of the blood and on the varieties of puerperal fever. The effect of this noxious impregnation of the general system was next considered, and it was shown that the quantity modified the result in a most singular way—a small quantity being eliminated by intestinal or urinary secretion, whilst a larger dose killed. When the uterus was very lax, and admitted of a ready flow of noxious fluid through the sinuses, the woman was stricken down as if by some fell pestilence, and sank in a few hours—"where the secretions are all suspended, and the patient sinks with rapidity." Where the deleterious fluid is introduced in smaller quantity, the system, after a vain struggle with the poisonous infection, sinks in a few days, the chief morbid appearance after death being extensive peritonitis of a peculiar character, copious exudation of soft friable lymph, and much serosity. To a yet smaller amount of deleterious impregnation were attributed uterine phlebitis, metroperitonitis, distension of the lymphatics with purulent fluid; the effects being more local, and the inflammations being the consequences of the first changes induced. Whilst a still smaller amount of infection would produce low febrile conditions, extending over an indefinite period, and sometimes inducing purulent infiltration in various organs of the body. Each of these states being influenced by a variety of concomitant circumstances—as the original condition, state of health, the character of the fluids secreted, the existence of any diathetic disease, epidemic influences, etc. On the question of contagion and the occurrence of epidemics, the author showed that the most experienced in this disease varied so much that no decided conclusion could be drawn. The prevention of the disease, it was urged, could be most effectually accomplished by procuring a complete and persistent contraction of the uterus after the completion of the labour; and that the means usually recommended were not sufficient for this object, it being generally considered sufficient to procure such an amount of contraction as to prevent any hæmorrhage, though it was necessary to go beyond this point of contraction before the safety of the woman could be secured. A nourishing and supporting diet was also necessary to remove the physical fatigue and mental anxiety of the labour, to restore the health from the waste occasioned by the previous months of pregnancy, and to enable the woman to pass through the subsequent changes which had yet to take place: much, however, depending upon the previous habits, state of health, and other incidental circumstances. On the subject of treatment, when the disease was once developed, the principles were considered to be—(1) to prevent the further injurious impregnation of the system, either by obstructing the further flow along the uterine sinuses, or by removing the noxious fluids from the interior of the uterus; (2) by supporting the system during the struggle in which it is engaged, and by meeting any incidental complication which might present itself; and (3) perhaps a further source of treatment was now afforded, which might enable us to counteract, to some extent at least, the deleterious impregnation which has already taken place. The first would be attained by procuring, if possible, the further contraction of the uterus, or by inducing the coagulation of the blood in the uterine sinuses. But the principal curative means appeared to rest upon the removal of all noxious fluids from the interior of the uterus, by cleansing it with a tepid solution of any sulphite or hyposulphite of soda each day or oftener; and should any fluid gain entrance into the uterine sinuses, it would probably be more beneficial than otherwise. The means to support the system were too well known to require further notice; whilst deleterious impregnation, which had already taken place, might be met by the internal administration of sulphite of magnesia or lime, in doses of one scruple to half a drachm every two or three hours.

Dr. Graily Hewitt stated that, having had considerable opportunities of witnessing the disease now under discussion, he would give some of the results of his own observations, although it was impossible in a few words to include a consideration of all parts of the subject. He had long entertained the idea that a very close connexion subsisted between a loose relaxed condition of the uterus after delivery, and the supervention of puerperal fever. He had followed a plan of treatment based on this idea, and had frequently insisted upon it in teaching. He considered that the author of the paper had offered anatomical proof of what had been a matter of surmise among many obstetric authorities of late years—namely, that puerperal fever and allied disorders are not necessarily and inseparably connected with the existence of inflammatory changes in the tissues of the uterus and neighbouring parts. He believed, with the author, that the disease arose from the introduction of putrescent or decomposing material into the uterine sinuses, and thence into the general circulation. This was the case in by far the majority of instances, but he believed that the poison was sometimes introduced by other channels. He could not regard puerperal fever as a disease *per se*, and he considered it would be difficult to distinguish anatomically and pathologically between ordinary puerperal fever and that condition produced by the contagion of scarlet fever or other fevers in the lying-in woman; for though the cause might be different, the effect was or might be the same. The essential part of puerperal fever is poisoning of the blood, and this may be effected in various ways. He had, as he had already stated, observed a very close connexion to subsist between the relaxed uterus and puerperal fever: he had always found the uterus larger than it should be at the outset of the attack, this increase of size being accompanied with tenderness and other signs. In this respect, therefore, he quite agreed with the author of the paper. It would afford confirmation of the truth of this view of the subject to describe the treatment which he (Dr. Graily Hewitt) had for some time adopted in cases of puerperal fever and its results. Disregarding entirely and completely the old ideas as to inflammatory changes in the uterus, he was in the habit of applying the bandage very tightly over the uterus the moment the first symptoms appeared, and of administering internally a stimulant diet, including large doses of alcohol. Other remedies were used, but they were quite subordinate. Depleting and lowering medicines were wholly omitted. The quantity of alcohol given was sometimes at the rate of as much as two ounces of brandy every two hours. This treatment he had seen cut the disease short in the course of twelve hours. He had the greatest confidence in the efficacy of such treatment in bad cases of puerperal fever, having seen not a few apparently hopeless cases recover under it. In reference to the prophylaxis of the disease, these observations were interesting. The binder served a very important purpose, and he was in the habit of paying the greatest attention to its careful application; believing that in a well-contracted uterus we have the best safeguard against puerperal fever. The facts related by the author of the paper bearing on this latter subject were very important.

The President said the subject was one of such paramount importance that it deserved a special discussion every year. He believed if attention were thus continually brought to it, that much would be done in the way of preventing this the most destructive of all causes to puerperal women. It was impossible to advert now to more than one or two points. He agreed with Dr. Beck that puerperal fever was a distinct thing from typoid or scarlatina, which often attacked puerperæ, but preserved their essential characters. On the leading idea of the paper — the necessity of contraction of the uterus as a preventive of puerperal fever,—he would say, that contraction was eminently desirable to accomplish, but he had seen repeatedly puerperal fever occur in women after perfect contraction, and, on the other hand, no puerperal fever, although the uterus remained relaxed. After the great discussion at the Académie de Médécine, Dr. Martineng published a memoir setting forth this view, and advocating the use of ergot and all means to ensure contraction as preservative against fever. Dr. Barnes, having under observation 2000 or more cases yearly of poor women attended by the Royal Maternity Charity, thought he was able to negative the proposition that puerperal fever was more frequent amongst the poor and badly fed. The cases in the Charity were very rare. For one case amongst these women, he saw ten amongst the easier classes. As a means of preventing the loss of blood—as hæmorrhage undoubtedly predisposed to puerperal fever,—he had found nothing of equal efficacy to the injection of a solution of perchloride of iron into the uterus after clearing out the cavity of placental remains

and clots. He had used this plan for several years, and in a large number of cases after labour and abortion, and had always had reason to congratulate himself upon the result. The perchloride of iron had the further advantage of being antiseptic. He had certainly saved several women from death from flooding, and believed these and others had been rendered less liable to puerperal fever. In reply to a question from Dr. Timothy Pollock, the President stated that the plan he adopted was to carry in his "obstetric bag" a saturated solution of the salt. Of this solution he used one part to eight of water. But he thought that even a weaker solution was sufficient. It instantly coagulated the blood in the mouths of the uterine vessels.

Dr. Snow Beck briefly replied, and stated that he considered puerperal fever essentially distinct and different from typhus fever, typhoid fever, scarlet fever, or any of the acute specific diseases; each of the latter being caused by a distinct and definite poison, which might be communicated from individual to individual in the same ward; whilst the former was produced by the introduction of putrid or similar fluids into the general system through the sinuses of the uterus, when they remained pervious after a confinement, and was not communicated from individual to individual in the same ward. Perhaps the term "puerperal fever" was not the most appropriate, but it had been concentrated by long usage, and it was not desirable to change it without good cause. There was a great distinction between puerperal fever and febrile states occurring during the puerperal period, the former being incurable up to the present time, the latter readily admitting of cure. This distinction had been clearly drawn by Professor P. Dubois. He had used the soluble sulphites as injections for cleansing the interior of the uterus, from the opinion that they were the most effectual agents in correcting the condition of the fluids secreted. But he had no doubt other agents would be found equally and perhaps more efficacious, and amongst them possibly the preparation of iron mentioned. But if it were even admitted that this plan of treatment was advisable, and devoid of the great danger sometimes attributed to it, then an important step had been attained. He, however, would strongly urge the necessity of procuring complete and persistent contraction of the uterus, and of carrying this contraction further than was usually considered sufficient, as being one of the most effectual means of preventing this most serious disease. He thought that by separating the many diseases occurring during the puerperal period, and included under the one designation "puerperal fever," though differing essentially in their nature, course, and treatment, great good would result.

MEDICAL NEWS.

Royal College of Physicians of London.—At a general meeting of the Fellows, held on Monday, April 10, 1865, Thomas Watson, M.D. Cantab., D.C.L. Oxon., was unanimously re-elected President of the College for the ensuing year. At the same meeting, the following gentlemen, having undergone the necessary Examination, were duly admitted Members of the College:—

Samuel Jones Gee, M.B. Lond., 46, Queen Anne-street; John Southey Warter, M.D. Edin., 23, Frederick-street, Gray's-inn-road; Benjamin Bingay Thurgar, M.D. Edin., 35, York-street, Portman-square; George Bernard Brodie, M.D. St. Andrews, 10, Bolton-row; and Offley Bohun Shore, M.D. Edin., Stamford.

At the same meeting, the following gentlemen were reported by the Examiners to have passed the first part of the Professional Examination for the Licence of the College:—

Nathaniel E. Davies, St. Bartholomew's Hospital; Alfred Harwood, Guy's Hospital; Lyttleton Hallett, St. Bartholomew's Hospital; Mowbray Jackson, St. Bartholomew's Hospital; Osmer King, Guy's Hospital; Edwd. James Leverton, St. Bartholomew's Hospital; Philip Henry Mules, St. George's Hospital; Edward Nettleship, King's College; Campbell Orme, St. Bartholomew's Hospital; Lestock Holland Reid, St. Bartholomew's Hospital; William Alsept Richards, King's College; Wm. James Tattersall, St. Bartholomew's Hospital; Herbert Tibbits, St. Bartholomew's Hospital; Wentworth Raynes Tindale, St. George's Hospital; Samuel John Truman, Guy's Hospital; Herbert Chrippes Upton, St. Bartholomew's Hospital; and Matthew Hall Wright, Birmingham.

Royal College of Surgeons of England.—The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on April 11, and when eligible will be admitted to the Pass Examination:—

E. M. Owens, Henry Maynard, W. J. Richards, E. L. Crowther, Arthur Matthews, George Spearman, R. C. Lucas, T. B. Dyer, William Johns, and H. W. Fagge, Students of Guy's Hospital; J. R. Walker, H. F. Parsons, J. R. Hill, J. G. Randall, and E. B. Owen, of St. Mary's Hospital; Waren Tay, W. E. Ditchett, F. M. Mackenzie, and F. S. Colquhoun, of the London Hospital; H. C. Buckley, E. W. Parkinson, G. W. Barroll, and F. W. Jackson, of St. George's Hospital; J. A. J. Timmins, B. W. Lamb, J. B. Hughes, and F. D. Power, of St. Bartholomew's Hospital; T. F. Hopgood and T. B. Hay, of University College; C. S. Blythman and J. R. Perkins, of King's College; J. R. James, of the Middlesex Hospital; and Kenneth Reid, of Montreal.

The following passed on April 12:—

R. B. Moore, John Quick, H. B. Pattinson, F. H. Haynes, W. G. Kemp, Bernard Renshaw, D. F. Boulton, H. G Wilson, W. B. Burn, E. H. McClean, and J. E. M. Finch, students of St. Bartholomew's Hospital; R. T. Wright, F. W. Parsons, G. A. Canton, Edward Ireland, O. T. Molecey, and J. H. Bell, of King's College; W. E. Cant and W. R. Tindal, of St. George's Hospital; S. E. Solly and J. J. Ridge, of St. Thomas' Hospital; A. G. Evans and T. E. Stainthorpe, of the Middlesex Hospital; A. B. Elliott and B. N. Dalton, of Guy's Hospital; F. A. Holmes, of St. Mary's Hospital; J. K. Hyde, of Charing-cross Hospital; Thomas Loane, of the London Hospital; F. W. Strange, of Liverpool; J. D. Bush, of Newcastle; D. E. Bernard, of Bristol; George Fisher, of Leeds; and James Sawyer, of Birmingham.

Apothecaries' Hall. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, April 6, 1865:—

Edward Charles Evans, Cardiff, South Wales; Charles James Harris, King William-street, Charing-cross; Ralph Alexander Busby, Royal Free Hospital; Lewis Wayne Morgan, The Hafod, Pontypridd; George Cox Grantham; Frederic Ruffe, Tamworth; Charles James Wright, East Parade, Leeds; Henry Edward Herbert, Charing-cross Hospital; John Stuckey, Langport, Somerset.

The following gentlemen, also on the same day, passed their first Examination:—

Thomas Bell Hay, University College; Thomas Cuddeford, St. Bartholomew's Hospital; W. I. Tattersall, St. Bartholomew's Hospital; Isaac Coalbank, St. Bartholomew's Hospital; Herbert Chrippes Upton, St. Bartholomew's Hospital; John E. M. Finch, St. Bartholomew's Hospital; Frederic Richard Fisher, St. George's Hospital; John Sherwin, King's College; Matthew Hall Wright, Sydenham College, Birmingham.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

Charlton, Egbert, M.D. St. And., has been appointed Medical Officer for the Dartford Union Workhouse.

Hobley, Mr. S. H., has been appointed Resident Dispenser to the Hitchin Infirmary.

Harmer, W. Milsted, M.R.C.P. Edin., has been appointed Physician to the North Grove House Private Lunatic Asylum, Hawkhurst.

Jeaffreson, George E., M.R.C.S. Eng., has been appointed Medical Officer to the Suffolk Albert Memorial College at Framlingham.

Milburn, F. Le Fevre, M.R.C.S. Eng., has been appointed Assistant-House-Surgeon to the Sheffield Public Hospital and Dispensary.

Shears, Arthur, M.D., Edin., has been appointed Assistant-Surgeon to the Nottingham Dispensary.

Summerhayes, Henry, M.R.C.S. Eng., has been elected Surgeon to the Islington Dispensary.

DEATHS.

Affleck, Robert, M.D. St. And., at St. George's, Grenada, on March 1.

Blair, William H., L.R.C.P. Edin., House-Surgeon to the Royal Infirmary, Windsor, at Peterborough, on March 20, aged 25.

Chalk, Frederick M., M.R.C.S. Eng., Assistant-Surgeon 2nd Batt. 2nd Regt., at Bermuda, on February 9, aged 29.

Day, Edwin E., M.B., M.R.C.P. Lond., at 48, Hertford-street, Mayfair, W., on April 7, aged 29.

Denton, Samuel, B.A., M.R.C.S. Eng., off Java Head, on board the ship *Montrose*, on December 7.

James, George W., M.D., at Woburn, Bucks, on March 24.

Lovell, William Cecil, M.R.C.S. Eng., late of Chepstow-place, Bayswater, on April 6, aged 38.

Mackenzie, Frederick W., M.D. Lond, at 11, Chester-place, Hyde-park-square, W., on April 3, aged 49.

Ratton, Surgeon-Major James, 3rd Light Cavalry, on his way from Kamptee to Bombay, on March 5, aged 51.

Reed, William H., M.D., D.L., of Underdown, Pembrokeshire, at Haverfordwest, on March 26.

Renaudin, M., Medical Director of the Asylum at Mareville, near Nancy, and for more than twenty years one of the editors of the *Annales Médico-Psychologiques*, died early in the present month.

Seccombe, John Collier, M.R.C.S. Eng., at Greenhithe, Kent, on April 5, aged 59.

Tearne, Edward M., M.R.C.S., Eng., at Presteign, Radnorshire, on April 8, aged 42.

Walmesley, Thomas, M.R.C.S. Eng., at Wem, Salop, on March 21, aged 65.

The Devon and Exeter Hospital.—An election to the office of Surgeon to this Hospital, vacant by the death of Mr. W. H. James, has just taken place. The candidates were Messrs. Roper and Cumming. The following was the result

of the poll:—Mr. Roper, 118; Mr. Cumming, 105; majority for Mr. Roper, 13.

THE RUSSIAN EPIDEMIC.—The Medical Department of the Council have already despatched Dr. Whitley, late Medical Registrar of Guy's Hospital, to St. Petersburg, and Dr. J. Burdon Sanderson to Dantsic and Elbing, to report upon the alarming epidemic. Next week Dr. Thudichum will proceed to another chief seat of the disease.

THE FRENCH ACADEMIES.—At the *Académie de Médecine* M. Bergeron has been elected into the section of Hygiene by the votes of 52 of the 80 academicians present. At the *Académie des Sciences* Wilhelm Weber, of Göttingen, was elected a corresponding member in place of De la Rive, declared foreign associate. The other candidates were Dove, Berlin; Groves, London; Jacoby, St. Petersburgh; Kirchoff, Heidelberg; Kupffer, St. Petersburgh; Plucker, Bonn; Rich, Berlin; and Stokes, Cambridge.

SURGICAL OPERATION.—A most successful Surgical operation was performed last week in the Military Hospital. Dr. Holmes, assisted by Dr. Stratford, extracted a stone from the bladder of a boy about eight years of age. He is now doing well and in a fair way for recovery. This is only the second operation of the kind which has been performed in this colony, Dr. Stratford having successfully operated some years ago upon a boy about four years of age, who is now living and in good health.—*New Zealand Herald.*

THE JAMAICA INQUEST.—The *Colonial Standard* of March 10 states that "the coroner's jury on the case of Richard Bailey, a patient in the Public Hospital, who died after an operation performed on him by Dr. Anderson, the Medical officer of that institution, terminated their labours on the 27th ult., after a sitting of seven days, and returned the following verdict:—'The jurors find that Richard Bailey died at the Public Hospital on February 11, 1865; that he laboured under chronic disease, and that his death was hastened by improper Surgical treatment whilst in that institution.'" Our readers will not feel much surprise at this verdict, recollecting the character of the Medical evidence given at the inquest, to which we called attention in the *Medical Times and Gazette* of March 25.

ROYAL COLLEGE OF SURGEONS.—At the last meeting of the Council, one of the Jacksonian prizes was awarded to Mr. William Adams, F.R.C.S, of Henrietta-street, Cavendish-square, Surgeon to the Royal Orthopædic Hospital, as the author of the best essay "On Club Foot: its Causes, Pathology, and Treatment;" and a special honorarium was awarded to Mr. John Crown Agnis, F.R.C.S., Surgeon to the Royal Horse Guards, his essay being next in merit to that by the former gentleman, and in consideration of the original research displayed in it by the author. The remaining prize was awarded to Mr. Thomas Annandale, M.R.C.S., formerly of Newcastle-on-Tyne, but now of Edinburgh, for his essay "On the Malformations, Diseases, and Injuries of the Fingers and Toes, with their Surgical Treatment." For the Collegiate triennial prize, "On the Structural Anatomy and Physiology of the Lymphatic Vessels and Glands," no one had competed. At the same meeting of the Council, Messrs. William Griffith, of Oswestry, and Richard Forth Snape, of Bolton-le-Moors, who had been elected Fellows at a previous meeting of the Council, were admitted as such, their diplomas bearing date respectively, March 16, 1838, and June 13, 1842. Professor Ferguson, F.R.S., will commence his course of lectures "On the Progress of Surgery during the Present Century" early in June next. The examinations on Anatomy and Physiology commenced on Saturday, when 107 candidates presented themselves.

ODONTOLOGICAL SOCIETY.—A meeting was held on April 3; the President, Thos. A. Rogers, Esq., in the chair. After the ordinary business, Mr. Merryweather exhibited a case of casts, showing the conditions of the same mouth from 4 years of age till 21, at intervals of six months. Mr. Vasey exhibited models referred to at last meeting. Mr. Walker related the history of several cases which had occurred in Hospital practice of abscesses formed in the jaws. Mr. Harrington explained the nature of a self-acting drill which he exhibited adapted to lessen the difficulty of cutting away the carious parts of teeth. He has successfully used the drill since June, 1863. Mr. Hulme read a paper on "Rhizodontripy;" or the operation of drilling into the pulp cavity. After referring to the history of this operation, the author related the circumstances attending its performance on a patient of his own, whose tooth he had a subsequent opportunity of dissecting. The tooth showed a secondary deposit of dentine. From this and other cases the author deduced conclusions favourable to the theory of Dr. Hullihen, and observed that in any case the subject was worthy of investigation. He recommended that a careful collection of statistics should be made. An interesting and lengthened discussion followed, in which Messrs. Rogers, Harrison, Vasey, Walker, and Coleman took part. The Society then adjourned.

CURIOUS ACCIDENT CAUSED BY A PIPE.—A schoolmaster was playing at snow-balling with his scholars, having a long pipe in his mouth, when he fell forwards, hurting his mouth with the end of the pipe. He wiped away the little blood that flowed; but when he wished to resume his pipe he found that the mouth-piece was missing, and search for it in the snow was made in vain. A few days after he applied to Dr. Fingerhoth on account of some difficulty in swallowing and a stiffness in the region of the right sterno-cleido-mastoideus. On that side of the palate there was some redness and swelling, but no trace whatever of a wound, while under the mastoid process there was also a small soft swelling, only tender upon great pressure. Leeches were applied to the angle of the jaw and gargles were ordered, and the redness of the throat and difficulty of swallowing were relieved, but kept recurring again at intervals until August, the external swelling having during the whole period remained unaltered. By September the swelling in the neck had attained a diameter of three inches, while the tonsil and palate again were swollen, and a large quantity of blood was discharged from the mouth. The author found him in an exhausted state, and another attack of hæmorrhage carried him off. At the post mortem, a ragged opening was found in the fold of the velum palati communicating with the mouth, and a female catheter passed through this penetrated into the tumour formed in the vicinity of the mastoid process. This swelling contained about 2 lbs. of blood and putrid pus, and when this was removed the end of the pipe, $1\frac{3}{4}$ inch long, was found, roughened and deprived of its polish. In the course which it took it had irritated the carotid artery, which had become narrowed and fragile, and a small aperture beneath the narrowed part had given rise to the fatal hæmorrhage.—*Preuss. Med. Zeit.*, No. 23.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

We are obliged to postpone our notice of Dr. Lankester's paper on the *Inquests in Central Middlesex*, as likewise the article on *Modern Dermatology.*

Student.—Buy Ellis and Ford's "Dissections." They appear alternate months, price 3s. 6d., and will be completed in twenty-five parts, of which thirteen have appeared already. Nothing can equal their naturalness and precision.

Erratum.—In Mr. M. Jennett's letter in our last week's impression, *for* "2.15 p.m.," *read* "2.15 a.m."

COMMUNICATIONS have been received from—

Mr. M. JENNETT; Mr. JOHN DIXON; Dr. QUINLAN; Mr. W. COPNEY; Dr. D. B. WHITE; Dr. R. F. SNAPE; Mr. JAMES BLAIR; Dr. C. HANDFIELD-JONES; APOTHECARIES' HALL; ODONTOLOGICAL SOCIETY; Dr. FOTHERBY; MEDICAL SOCIETY OF LONDON; Mr. FAIRLIE CLARKE.

APPOINTMENTS FOR THE WEEK.

April 15. *Saturday* (*this day*).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.; Royal Free Hospital, 1½ p.m.

17. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

MEDICAL SOCIETY OF LONDON. Postponed until the 24th.

18. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ANTHROPOLOGICAL SOCIETY OF LONDON, 8 p.m. Meeting.

PATHOLOGICAL SOCIETY, 8 p.m. Meeting.

19. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

HUNTERIAN SOCIETY, 8 p.m. Mr. Hutchinson, "The Medical Aspects of Constitutional Syphilis."

20. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

HARVEIAN SOCIETY OF LONDON, 8 p.m. Meeting.

21. *Friday.*

Operations, Westminster Ophthalmic 1½ p.m.

ORIGINAL LECTURES.

LECTURES ON CHEMICAL AND MECHANICAL DISEASES AND THEIR RELATIONSHIP.

By H. BENCE JONES, A.M., M.D., F.R.S.

Lecture V.

DISEASES OF SUBOXIDATION.—ON GOUT.

The gouty diathesis consists in an excess of urate of soda not only in the serum of the blood, but in the fluid that diffuses from it into all the vascular and non-vascular textures of the body. An attack of gout is a chemical process of oxidation set up in the parts where the urates are most able or liable to accumulate. By the oxidising action the urates are wholly or partly changed into urea and carbonates, which can more readily pass from the textures into the blood, and be excreted by the kidneys, skin, and lungs. The oxidation even in the bloodless textures causes increased flow of blood and mechanical pressure in the vessels nearest to the inflamed part, and hence pain and redness, and then swelling and œdema, proceed. Though the gouty diathesis is a disease of the textures as well as of the blood, yet in its origin and situation an attack of gout is even more a disease of the tissues than a disease of the blood.

The urate of soda bears the same relation to gout that sugar does to diabetes; and as the want of oxidation of sugar is the cause of the diabetic diathesis, so the want of oxidation of the urates, and their consequent accumulation in the textures and blood, is the cause of the gouty diathesis. Errors excepted, as almost every grain of starch passes through the stage of sugar, so almost every grain of albuminous substance that enters the blood sooner or later, in its way out, passes through the stage of uric acid, and, if thoroughly oxidised, escapes as urea, carbonic acid, and water. The number of substances that are formed between albumen and urea are vastly more than between starch and carbonic acid; but, whatever their number, uric acid is the penultimate, and urea the ultimate, product of oxidation. Hence there are at least two ways in which an excess of uric acid may occur in the blood and textures: 1st, from an excess of animal or vegetable albuminous food entering the system,—*i.e.*, from excessive production; and 2nd, from an arrest of oxidation,—*i.e.*, from want of destruction. Of course, the greatest accumulation of uric acid will occur when the albuminous food is excessive, and when at the same time the oxidation is least. Even if no excess of albuminous food is taken, yet if the oxidising action is deficient, uric acid may accumulate in the serum, and it will immediately diffuse even into the bloodless textures. On the other hand, an excess of albuminous food may be taken, and, provided the oxidising action is also in excess, no accumulation of uric acid in the blood or textures may occur. It is therefore evident that there are two modes of preventing the gouty diathesis: 1st, by diminishing the amount of vegetable and animal albuminous food; and 2nd, by promoting oxidation. In other words, the smallest amount of food and the greatest amount of air are the antidotes for the gouty diathesis. If an excess of fresh air is taken whilst a large quantity of food is eaten, these cause no gouty diathesis as long as the antidote (oxygen) destroys the *materies morbi* (urates); but if from any cause the oxidation becomes less, the urates accumulate in the liquor sanguinis, and pass by diffusion into and around the cells of all the vascular and non-vascular structures of the body, and remain unoxidised where there is least oxidation, and even form crystals of urate of soda in consequence of the slow deposition of the urates on the surface and within the structure of the non-vascular cartilages. Where urate of soda accumulates it acts like a foreign body, increasing friction, setting up irritation and inflammation, by which the uric acid is more or less oxidised, and thus being made soluble, it is more or less removed, and when the inflammation subsides, effused fibrin almost alone may remain to mark the situation of the attack.

If no inflammation comes on, the liquor sanguinis may free itself of urates by the kidneys, and then the deposited crystals may more or less entirely re-dissolve, and diffuse back into the blood; or, if the serum continues full of urates, the chalk stones may gradually increase in the direction of least resistance, making the joints more and more rigid, and the skin more and more thin, until the pressure breaks the surface, and the chalk stones escape as myriads of microscopic crystals. Thus, the fingers and toes may become supplementary kidneys, to the great relief of the blood and textures, and the gouty diathesis may almost be considered as microscopic gravel in the textures, and an attack of gout as a chemical operation for the removal of the gravel from the part in which it had accumulated.

That the urates diffuse into the synovial fluid and on to the surface of the cartilages, the following case shows:—W. W., aged 48, was admitted into St. George's Hospital on November 23, 1855. He was a painter and glazier in good circumstances, and had suffered more or less from gout for eighteen years; otherwise he enjoyed good health, and never had colic. The urine contained a small quantity of albumen; the heart's action was feeble; the right hand was red and swollen; his feet were slightly œdematous; chalk stones existed in his ears. The acute attack of gout in a fortnight gradually subsided, and he was about to leave the house when a fresh inflammation of the hands, feet, and knees came on, with great prostration of strength. In a few days he was seized with epileptic fits; the slightest motion immediately brought on an attack; the pupils were contracted, there was excessive tremor of the limbs, and he sank four weeks after his admission.

Both knee-joints were carefully opened. They contained two or three drachms of thick synovia, and in each cavity there was a flake of fibrin about an inch and a-half long, shreddy, with whitish specks visible to the naked eye. On examination under the microscope, small acicular crystals were seen mixed with fibrinous matter, and when a drop of dilute hydrochloric or acetic acid was added, the whole surface of the fibrin in a few minutes became covered with microscopic uric acid crystals. The moist fibrin from both joints showed these crystals of uric acid, and when the fibrin was treated with nitric acid and evaporated, there was distinct evidence of uric acid. On the surface of the cartilage there was only a very small spot free from the deposit of urate of soda. Both great toes at their tasso metatarsal articulations contained the same deposit on the surface.

The spleen was large and soft; the kidneys granular, and the cortex much wasted. There were some small deposits of red sand visible to the naked eye in the mammary processes.

A man, aged 41, was admitted into St. George's Hospital with continued fever, and died on August 20, 1849. On examination by Dr. Handfield Jones, gouty deposit was found in both knee-joints: 1st, under the synovial membrane at the margin of the cartilage; 2nd, in the superficial structure, or on the surface of the cartilage, from whence it could not be removed by gentle washing or scraping; 3rd, in the substance of the cartilage at some depth; 4th, in the cancelli of the subjacent bone (the patella).

The gouty matter appeared for the most part as aggregations of amorphous masses, varying in size, and encrusted over frequently with minute crystalline spiculæ.

The cartilage was remarkably thickened, being at least three times its ordinary dimensions. Near its middle it was much more elevated than towards its margin, and very soft and yielding. When a vertical section was made of it, the surface exhibited a marked fibrous structure, quite visible to the naked eye, the fibres being arranged vertically to the surface, and being much more marked in the deeper than in the superficial layers.

The microscope showed that the basis substance was considerably increased, the cells being in much scantier proportion than natural, but not essentially altered. The fibres were not isolated from each other. The fibres or bands were of some considerable width, separated by narrow intervals of healthy structure.—*Proceedings of Pathological Society*, vol. ii., p. 103.

On the Means of Detecting Gout.

The chemical test for the gouty diathesis—that is, for excess of urates in the blood and textures—is based on an analysis of the urine and of the serum of the blood.

Even long before the gouty diathesis is formed, the urine will give warning of the future disease. An excess of urea in the urine may be caused either by an excess of exercise or by an excess of vegetable or animal albuminous food. The amount of urea bears a certain, though not direct, proportion to the amount of daily exercise; when the exercise is moderate, an excess of urea in the urine indicates that albuminous food in excess is passing through the system; when the oxidation of the albumen is perfect, urea and carbonic acid are formed; but with less perfect oxidation, urea and oxalic acid

result. Hence, oxalate of lime, with excess of urea, constitute the earliest evidence of imperfect oxidation of an excess of albuminous food. When the oxidation is still less, then oxalic acid and urea are not formed from the uric acid, but the urine shows an increase in the quantity of urates.

Simple inspection of the urine is quite worthless as a means of determining the amount of urates in the urine, for the clearest urine may have the greatest amount of urates dissolved in it, and urine that thickens on cooling may contain less uric acid than perfectly clear water. You will see in a paper I published in the *Philosophical Transactions*, Part ii., 1849, p. 249, that urine passed at 5.10 p.m. became thick on standing, and contained 0·52 grain uric acid per 1000 grs. urine; urine passed at 11 p.m. remained clear on standing, and contained 0·87 grain uric acid per 1000 grs. urine. Again (p. 251), urine passed at 7.35 p.m. became thickish on standing, and contained 0·29 grain uric acid per 1000 grs. urine; urine passed at 10·5 p.m. remained clear on standing, and contained 0·33 grain uric acid per 1000 grs. urine. Again, urine passed at 7·55 p.m. became thickish on standing from urates, and contained 0·31 grain uric acid per 1000 grs. urine; urine passed at 10.45 p.m. remained clear on standing, and contained 0·90 grain uric acid per 1000 grs. urine.

When analysis shows that an excess of uric acid is thrown out of the body, this is a proof that the gouty diathesis is ready to form whenever the kidneys cease to remove the excess from the system. The presence of any urates at all in the urine is a sign that oxidation is not so perfect as it might be, and the more urates in the urine the more imperfect the oxidation in the system must be considered; but as long as the products of the imperfect oxidation are thrown out by the kidneys or skin no gouty diathesis is produced.

Thus, then, first, excess of urea when little exercise is taken; secondly, oxalate of lime with excess of urea; and thirdly, urates in excess, by analysis, constitute the three tests of the different degrees of suboxidation which precede the establishment of the gouty diathesis.

When uric acid in excess is in the system, analysis of the urine may not indicate any excess there—indeed, the uric acid may be absent from the urine and be retained in the blood—as, for example, in Bright's disease. Then the chemical examination of the serum may give positive proof of the existence of this imperfect oxidation, and lead to the certainty of the textures containing the same urates ready to set up inflammation of a gouty nature at any moment; usually symptoms of gout begin to make themselves felt by pain, followed by heat and redness, and then the chemical methods for detecting gout are usually quite unnecessary.

(To be continued.)

ORIGINAL COMMUNICATIONS.

ON THE

MECHANISM OF PARTURITION IN CASES OF PRESENTATION OF THE CRANIUM.

By CHAS. G. RITCHIE, M.D.,
Late Resident Physician to the Royal Hospital for Sick Children, Edinburgh.

(Continued from page 383.)

VI. When the head is born the occiput turns slightly towards the left thigh of the mother; there is a short pause, and then the occiput again, and this time more distinctly, turns to the left. The reason of this double movement of external rotation is this:—While the head is clearing the outlet the shoulders are entering the pelvis in the left oblique diameter, so that the neck is slightly twisted, and the first very partial rotation is its untwisting. Often the movement is altogether absent, in which case no doubt the shoulders descend more in the transverse diameter. The second rotation is produced by the shoulders turning into the antero-posterior diameter in the same way and to the same degree as the head has just done. The rotation of the shoulders is like that of the head, imperfect; the right shoulder is the lower one, and when it rotates it places itself a little to the right of the symphisis. It is thus in position analogous to the occiput, and it is, therefore, not surprising that the left shoulder, like the forehead, disengages first. It sweeps over the perineum, and emerges at the posterior comissure. In primiparæ, where the perineum is very strong and resistant, it not unfrequently happens that the right shoulder descends steadily and is the first born. The explanation of the movements executed by the shoulders is the same as that just given for those of the head, their more uncertain course being due to the less resistance which they offer to the pelvic canal.

Occasionally the head, instead of turning with the occiput to the left thigh of the mother, rotates in the contrary direction; the bisacromial diameter, probably transverse at first, having turned into the right oblique instead of the left oblique diameter of the pelvis.

B. (*Occiput in Front.*) In the second position of the cranium the long diameter (occipito-frontal) of the head corresponds to the left oblique of the brim, and the occiput is in front. The position is "right occipito-cotyloid," and its mechanism is identical with that of the first position, the word right being substituted for the word left, and *vice versa*.

C. (*Occiput Behind.*) In the third position the occipito-frontal diameter lies in the right oblique of the pelvis, and the occiput is posterior. The position is "right occipito-sacro-sciatic. In occipito-anterior positions parturition is comparatively easy, because the body of the fœtus does not enter the pelvis until the head has left it. The neck of the child is long enough to allow the occiput to disengage itself from under the pubic arch before the shoulders enter the brim. The length of the fœtal neck is $3\frac{1}{2}$ inches, the length of the anterior wall of the pelvis is only $1\frac{1}{2}$ inches. In occipito-posterior positions the neck is not long enough to allow of the disengagement of the head before the entry of the body. The posterior wall of the pelvis is $4\frac{4}{5}$ inches in depth, and to this must be added the whole length of the extended perineum, which may be computed at from 8 to 10 inches. The lateral wall is $3\frac{1}{2}$ inches in depth on the dried specimen, and its depth is increased in the living subject by the psoas muscle. Again, in occipito-anterior cases, after the head has been flexed, the flat neck is applied against the flat anterior wall of the pelvis, and the convex sinciput fits into the concave posterior and postero-lateral walls. In occipito-posterior cases these advantages are lost.

The first movement of the head in the third cranial position is flexion; the second descent. The occiput descends until it reaches the floor of the pelvis. Already difficulty is experienced because the occiput does not fit into the concavity of the postero-lateral walls, and so space is lost. The hind head is now pushed forwards by the pelvic floor, just as the sinciput is in the first position. The forehead can evidently not participate in this forward movement, and the consequence is flexion still more forced, provided that be possible. This resource soon fails, and then the only possibility of an advance of the occiput lies in the body of the fœtus becoming simultaneously engaged in the pelvis. The dorso-frontal diameter of four and a-half inches is offered to the right oblique of the inlet. The occiput, unable to advance in the axis of the outlet, still descends, and presses against the perineum with extreme force. If that structure does not give way the presenting part may at length reach the posterior comissure; it emerges half obliquely, and then the head is born by extension. The cause of the extension is easily understood. When the occiput has once disengaged itself, rotation of the head on its transverse axis becomes comparatively easy; the occiput can advance no further, and therefore the expelling force acts on the forehead and causes extension. In cases where the fœtus is premature and macerated, the extension movement may be altogether absent. The dorso-frontal diameter even of a seventh month fœtus may pass through a normal pelvic outlet, provided the fœtus be macerated.

With the mechanism just described, a normally-sized child in a normally-sized pelvis would have very little chance of being born alive, if at all. Fortunately there is another mechanism. In the great majority of occipito-posterior cases the head rotates three-eighths of a circle and emerges—"occiput to the pubis." The descending occiput, after the head has been well flexed, reaches the floor of the pelvis, and is resisted by the right sacro-sciatic ligament, the lower part of the sacrum, and the coccyx, this resistance being exerted in a direction inwards and forwards. Obviously the occiput cannot move forwards, downwards, and inwards without forcing the sinciput against the antero-lateral wall of the pelvis, the consequence of which is pressure on the forehead directed backwards and inwards. Thus, then, there are two forces contrary, but not opposed, and rotation must follow. Unfortunately, the forces are both very oblique, very much directed inwards, and it may happen occasionally that they are directly opposed, in which case rotation is impossible.

What occurs under such circumstances? The uterus contracts strongly, and the occiput is firmly resisted; the forehead begins to descend, the anterior fontanelle is pushed backwards, and the superciliary ridge is to be felt behind the pubis. The relations of the head to the pelvis are thus altered, and it may be that the oblique forces are no longer directly opposed. If that be so, the rotation begins, and the forehead re-ascends.

It is puzzling, at first, that the anterior planes of the pelvis should cause the occiput to rotate under the pubes, and instead of having the same effect on the forehead should send it backwards to the sacro-iliac synchonchosis; while, on the other hand, the posterior planes, instead of allowing the occiput to rotate into the hollow of the sacrum, should force it forwards. The grand reason is that the occiput is always lower than the sinciput, and experiences the first and greatest resistance from the floor of the pelvis. When that resistance begins to make itself felt in first positions, the occiput is on a level with the pubic arch, and the forehead with the cavity of the sacrum. In third positions the resistance begins when the occiput is past the sacral cavity and the forehead far too high for the arch of the pubes.

The question of the exact period of labour at which the rotation is effected is extremely interesting. There is no doubt that it may occur at various periods, according to the degree of resistance, and we have seen that if the resistance be slight it does not occur at all. It may be laid down as an axiom that in occipito-posterior cases, as long as they remain so, difficulties increase in proportion as the labour advances. If, then, the child be not very large, its head will not rotate until it is almost in the vulva; while, on the contrary, if it be of considerable size, the pivot movement will take place much earlier. There is one part of the cavity of the pelvis in which I conceive rotation to be nearly impossible: it is on a level with the ischial spines. These spines are much more prominent in some pelves than in others; but in the great majority of cases they project enough to oppose the occiput very efficiently in its course forwards.

Perhaps in those tedious cases where the forehead begins to come down this is really the cause of difficulty. The occiput is on a level with the ischial spine. It can descend no further because it is resisted from below, and it cannot rotate. The forehead descends, the occiput slips up above the obstruction, and the pivot movement begins.

There is still a third way in which occipito-posterior cases may terminate. It has just been shown that when the occiput reaches the floor of the pelvis and begins to be violently resisted, there is a tendency to extension of the head. This extension may proceed a certain length, the superciliary ridges may even become visible, and still the head rotate at last. If, however, the head be very small, extension may go on. The forehead then descends behind the pubis to the floor of the pelvis; the eyes, nose, and mouth show themselve successively; and the head is disengaged, as in the first position, by the face. During this extension there must be a moment at which the occipito mental diameter of the child, which is 5 inches in length, corresponds to a pelvic diameter of $4\frac{1}{2}$ inches. Such a mechanism is evidently impossible where the head and pelvis are normally proportioned.

D. (*Occiput Behind.*)—In the fourth or left occipito-sacro-sciatic position, the mechanism is exactly analogous to that of the third position. The occiput rotates three-eighths of a circle, and emerges from under the pubes.

In the rapid sketch just given, much has been omitted. The mechanism of parturition includes the mechanism of the opening of the os uteri, the protrusion and rupture of the membranes, the preparation of the soft parts, and the compression of the fœtal head. To none of these has allusion been made; all that has been attempted has been to show the skeleton of the process, and from the charge of presumption we may defend ourselves by Naegele's quotation from Seneca:—"Multum restat adhuc operis multumque restabit. Nec ulli nato postmille sæcula præcluditur occasio aliquid adhuc adjiciendi."

Wounded Soldiers in the Field.—The terms of the Convention agreed to in August last at Geneva, by the representatives of most of the European Sovereigns, for "ameliorating the condition of the wounded in armies in the field," were accepted, on behalf of Her Majesty's Government, by Earl Russell, on February 18. The instrument is now published as a Parliamentary paper.

CASE OF ALLEGED POISONING.

By W. PROCTER, M.D., F.C.S.

M. N., aged 32, had been for twelve or thirteen years in the habit of taking morphia in the form of either the acetate or hydrochlorate. According to the statement of her husband, it was first prescribed for her in America to allay palpitation of the heart. The use of it had thus become habitual, and she gradually increased the dose until she took five, ten, or fifteen grains, according to the quantity which she could afford to purchase. On November 19 last she sent her daughter, an intelligent little girl, to the shop of the druggist who usually supplied her for five grains of morphia. The druggist himself was absent, and the girl was served by a porter (who, in the absence of his master, occasionally waited upon customers) from a drawer which contained strychnia, other alkaloids, and poisonous substances besides the acetate and hydrochlorate of morphia. The mother having received the powder, said, after putting it into a glass of water, that the morphia was not like that she usually had obtained, being different in colour and not sinking so readily in the water, but reconciled this apparent difference by saying that it was probably owing to a new bottle being opened. She then swallowed the contents of the glass, and without further remark went upstairs with her daughter. This occurred about three o'clock in the afternoon, and she had taken no food that day except a single cup of coffee. On going upstairs she sat down to read, and shortly afterwards complained of feeling unwell, had slight tremors, looked wild, seemed to have pain in the chest, felt faint, and "clutched her clothes." She was then laid on the floor and "seemed to swoon." Dr. Ure was sent for, but on his arrival she was dead, so that the only account of the symptoms which could be obtained was from the women about her at the time, and all tending to show that she died in a state of syncope. Not more than twenty-five minutes, or at the utmost half an hour, could have elapsed from taking the morphia to the time of her death.

I was requested by the Coroner to make a post-mortem examination of the body and conduct the necessary analysis. The body was that of a well-formed, tolerably healthy-looking woman. There was no spasm or rigidity of any of the muscles, the right arm was laid over the chest, and the left arm without contraction by the side. The body was laid flat on the back, the legs being extended without any retraction of the feet; there were no external marks of violence; the pupils were dilated, and the mouth was closed with the tongue behind the teeth. In examining the several cavities of the body: 1. The Head.—The membranes of the brain were slightly congested, and a small amount of serous effusion existed in the ventricles. 2. The Thorax.—The lungs were congested in a small degree; the cavities of the heart were empty, not contracted, and there was no appearance of disease of either the valves or of the valvular apparatus; the heart itself was flabby and softened, with thinning of the ventricular walls. Microscopic examination showed it to have undergone fatty degeneration to a great extent, with well-marked characters; in some portions the whole fibre seemed to be made of granular matter, in other portions the transverse muscular stria were absent, and their place supplied by minute fatty or oily globules. 3. The Abdomen.—After the removal of the stomach, all the other organs were observed to be healthy; the bladder was empty. The blood was fluid throughout the body.

Examination of the Stomach and its Contents.—Both internally and externally this organ was natural and healthy; it contained about two ounces of a darkish, inodorous, semi-fluid matter, having an acid reaction, and several small pieces of fatty substance floating in it, which the microscope showed to have the characters of bacon, and some minute portions of coffee berry were also detected. The stomach and its contents were then submitted to analysis; they were in the first place tested for hydrocyanic acid and the cyanides without any result; an examination for the alkaloids was then made by a modification of the process of Staas; no evidence could, however, be obtained of any of them except morphia, which gave well-marked and distinct reaction. No mineral poison was found.

Such were the results of the examination made for the purpose of answering the question—What was the cause of death? It is proper to state that great local interest was excited in the case, on account of an impression having gained

ground that the porter had made a mistake and given the girl strychnia instead of morphia; but the history of the case, coupled with the post-mortem appearances, independent of the analysis, at once remove any conclusion of this kind.

Did, then, the morphia cause the death of this woman? It is true that the post-mortem appearances are reconcilable with the effects of this alkaloid, but absence of all coma, etc., and the mode of death, does not coincide with the symptoms usually displayed where an over-dose of morphia has been taken. Then, again, the period intervening between taking the powder and the time of death would render the case one of unusually short duration for morphia poisoning, even admitting that the empty state of the stomach and the extreme dilution of the drug were conditions highly favourable to both rapid action and rapid absorption. But in this particular case there are other special circumstances to be borne in mind. This woman had for a series of years been in the habit of taking daily large quantities of this substance; it seems, therefore, scarcely probable that in such a person, accustomed to take fifteen grains, a single dose of five grains should prove so rapidly fatal. The post-mortem examination revealed extensive disease of the heart, to the insidious and fatal character of which numerous writers have drawn especial attention, and one from which death arising has frequently been ascribed to another cause. Taking, then, all the circumstances of the case into consideration, it seems a reasonable and probable conclusion that the death was due rather to the disease of the heart than to the morphia which was taken. If this is correct, the case is of interest from affording an illustration of a circumstance frequently met with in practice, and of the greatest value in Medico-legal investigations, that the apparent is not always the real cause of death.

SATURDAY, APRIL 22.

THE PROCEEDINGS OF THE MEDICAL COUNCIL.

The Session of the Medical Council, which commenced on Tuesday, the 4th inst., came to a termination on Monday evening last, the 17th inst. As the result of proceedings thus protracted, we discover, in the midst of a vast deal of *chaff*, very little substance. When we have said that more efficient arrangements have been decided on for the registration of Medical students; that a fixed period of forty-eight months from the date of registration to the final examination has been agreed on as the duration of Medical study, we believe we have recorded all the actual results arrived at.

The subject of supervising examinations has been referred to the Branch Councils, and the proposed amendments of the Medical Act have been submitted to the Home Secretary. For the results of these proceedings we must, however, wait, and may now resume our sketch of each day's operations. On Wednesday, the 12th, the discussion on the Report of the Committee on Education was continued, and the Report of the Committee on the Medical Act Amendments was brought up and ordered to be printed. On the following day this Report was the subject of consideration, which was commenced by an unsuccessful effort on the part of Dr. Corrigan to postpone all attempts at legislation to a future year. The only important point in the report is that which refers to the 40th clause of the Act, and which recommends compulsory registration. It was agreed to submit the proposed amendments to the Home Secretary by a deputation, which was accordingly appointed, and which attended at the Home Office on Saturday last.

It is most important that all parties concerned should have clear notions as to what this compulsory registration means, and as to the results to which it may lead. No one, however qualified, can, if the proposed clause become law, practise Medicine or Surgery, using his title or designation, however acquired, except he be registered. No one can be registered except he possess one of the qualifications granted by one of the bodies named in Schedule (A) of the Medical Act. All the power of an Act of Parliament will hereafter be required to make the slightest change in this schedule. The difficulty of obtaining such an act has already been happily well illustrated by the proceedings immediately following the return of the deputation from the Home Office, which may possibly be a warning to the bodies named in Schedule (A), still more to the Government, whose duty it is to protect the public, as to what may be expected in any attempts that may be made to amend this Schedule. We last week mentioned the important movement of the University of London in establishing the degree of Bachelor of Surgery, and briefly pointed out the advantages likely to result from it. The representative of the University at the Council proposed on Saturday that in the amended Act the degree of B.S. conferred by this or any other University authorised by charter to confer the same should be rendered registerable. The proposal was rejected. The motive for this rejection was so slightly disguised that one of the opponents honestly admitted that "the whole matter was simply a question of shop." Nothing, therefore, can be more clear than if this council of corporations succeed in obtaining the object proposed we shall be saddled with a monopoly more intolerable than anything which existed in the days of old "corporate rights and privileges." The Licensing Bodies may be content with the monopoly thus secured to them, and may be indifferent as to the future; but this cannot be the case with those who have to watch over the interests of the public, the future requirements of a rapidly increasing population, and of a still more rapid extension of scientific knowledge, as well as of Professional acquirements. And we believe that there will be no difficulty found in suppressing the false assumption of titles by quacks without establishing a monopoly of the character proposed.

The other points which have occupied the attention of the Council, and which require mention, are the request of the Licentiates in Dental Surgery to be placed on the Register, and the Pharmacy Acts. In our report of the proceedings on another page will be found very reasonable grounds for refusing to accede to the request of the Dental Surgeons, and on the same pages will be found the report on the Pharmacy Bills. The impression we derive from reading this report is, that if the Council was not prepared to do more than is here set forth, it would have been wise to have done less—to have done nothing at all. "The Committee see great danger to the interests of the public and of the Medical Profession, from the body which will be constituted by the Bill;" and "the Committee have considered whether the danger here indicated might not be averted by extending the jurisdiction of the General Medical Council, so as to include control over pharmaceutic chemists as well as over Practitioners in Medicine. But they believe such a plan to be, for the present at least, inadvisable and even impracticable." Nothing daunted, however, "the Committee

have further considered whether the danger they have pointed out might be averted by some simple provision in the Pharmacy Bill. By Section xvii. of the bill of the Pharmaceutical Society, it is declared that—

'Nothing in this Act contained shall extend, or be construed to extend, to lessen or prejudice, or in anywise to interfere with, any of the rights, privileges, and immunities heretofore vested in, and exercised, and enjoyed by any duly qualified Medical Practitioner.'

"This clause sufficiently protects Medical Practitioners in such right of practising pharmacy as they have hitherto enjoyed, but it does not attempt to prevent pharmaceutic chemists from practising Medicine. Considering their peculiar temptations to practise it, however, some check seems desirable. The Committee suggest that this object may be attained, in some measure, were the following clause to be added to Section xvii., viz. :—

'Or, to entitle any person registered under this Act to practise Medicine or Surgery, or any branch of Medicine or Surgery.'

"The members of the pharmaceutic body would thus have constantly before them the sentiments of the Legislature as to the principles on which the Pharmacy Act was founded." And that is all. Surely if the Medical Council cannot, at this moment of vigorous legislation in pharmaceutical matters, do something towards suppressing the clear and circumscribed form of illegitimate "counter practice," it is vain to hope that it can reach that viler form which is altogether beyond the pale of law.

Some few other points worth notice may still be found amongst the proceedings of the Council, to which we shall probably again refer.

MODERN DERMATOLOGY.—No. III.(a)

It would be a very profitless and thankless task to compare in detail all the modern classifications of diseases of the skin, or to attempt to thoroughly "ventilate" the question, What is the best basis of classification? We have said enough to show that, notwithstanding the courage and industry of dermatologists, little real, solid advance has been made in this matter since the time of Willan and Bateman. We shall be safe, probably, in saying that all dermatologists admit that the acute specific eruptions or eruptive fevers, and the syphilitic eruptions, may be formed into distinct, well-defined classes; and that the great majority recognise also parasitic diseases as forming a third definite class; but the authorities are not agreed as to the members of the three classes respectively, and outside of them nearly all is doubt and uncertainty if we depart from the Willanean principle of classification. Add to those three classes one to contain the "hæmorrhagiæ," and re-distribute somewhat the members of Willan's orders, and you have pretty well all the clear advance made. Nor can we be much surprised that but slight success has attended the attempts made to classify skin diseases on strictly anatomical, pathological, or etiological grounds, if we consider what a complex structure the skin is, how great its supply of blood, how delicate, rich, and manifold its nervous endowments, and how innumerable, varied, and complicated are the causes of disease to which it is ever obnoxious; in common with the other tissues of the body, it is exposed to all general and constitutional causes of disorder—to every alteration of the powers of nutrition, all disturbances of the general circulation, or of nervous force, and all blood diseases; and it is peculiarly exposed to the effect of external and local factors of diseased action, to the effects of excesses of heat and cold, of moisture and dryness, and to irritants of all kinds. The examination of any one of the works we have mentioned will satisfy the reader as to the difficulties arising out of these considerations. For a full and complete account of the anatomy and physiology of the skin—the foundation-stone of a knowledge of its diseases—we especially recommend Mr. Wilson's book; Dr. Hillier also gives a short chapter on the same subject. Both these gentlemen, and Dr. Fox, give very useful and clear definitions of the terms usually employed in descriptions of skin diseases to designate the elementary and secondary lesions of the skin.

When we come to inquire into "causation," it must be confessed that we get very little clear and definite information. As Dr. Fox remarks, "The causation of skin diseases is a subject of much dispute; almost every conceivable thing has at one time or another been supposed to produce this or that local eruption." In some, the cause is clear enough: they arise from well-known, if not well-understood, internal general causes, as the acute specific fevers, syphilis, and the scrofulous diathesis. Some appear to be due to diseases of individual internal organs; as urticaria, eczema, acne, and some pigmentary affections, to disease of the liver, the sexual organs, the kidneys, and the supra-renal capsules; while "menstruation, pregnancy, and dentition are each liable to be attended with symptomatic skin affections;" but, as Dr. Hillier remarks, "the precise manner in which the internal disease is connected with the cutaneous malady, unfortunately, we are not in a position to explain." Dr. Hillier and Dr. Fox both give some general remarks on causation—*i.e.*, remarks on what may be termed the general etiology of skin diseases. Among the "influences regarded as most efficient in producing eruptions" are enumerated:—

Specific poisons—the zymotic and syphilitic affections.

Dietetic poisons—as shell-fish,—urticaria, and erythema fugax.

Peculiarities of diet—as deficiency of some nutritive elements, or too great richness; ecthyma and scurvy being caused by the former, psoriasis and eczema by the latter.

Hereditary diathesis—as in psoriasis, icthyosis, leprosy of the East, and syphilides.

The tuberculous, scrofulous, and lymphatic habits—giving rise to non-specific eruptions.

Special states of malnutrition—as in keloid, cancer, etc.

The gouty and rheumatic diathesis—as in lichen agrius.

Altered nutrition from various causes—as exhausted nervous power, bad living, poverty, misery.

The accumulation of excreta in the blood from non-excretion, suppression of natural discharges, etc.

Convalescence from severe and lowering diseases.

With regard to most of these "influences," we may repeat Dr. Hillier's remark, that as to how the "causes" and the cutaneous eruptions are connected, "unfortunately, we are not in a position to explain."

The effect of external influences is much more simple and comprehensible, such as mal-hygiene and want of cleanliness, effects of climate and season, special occupations causing exposure to special local irritants, as in grocers, bakers, washerwomen, masons and bricklayers, paperhangers and artificial flower makers (arsenite of copper), cooks, firemen, etc., and ordinary local irritants, as animal and vegetable parasites. Here the connexion of cause and effect seems uniform and clear; but concerning the action of internal causes we know so very little that it is, perhaps, safest to say with Mr. Wilson, in a lately delivered address, "the primary causes of cutaneous disease are only two in number—namely, *debility* and *specific poison*." Dr. Fox also remarks, "The why and wherefore, however, we cannot at present determine; but of one thing we are certain, that the basis of most skin eruptions is *debility*." Mr. Wilson further recognises four forms of debility: "*nutritive debility*, in which the symptoms are chiefly those of deficient nutritive power, with waste of the tissues of the body, a state which gradually passes on to exhaustion and atrophy; *assimilative debility*, in which the symptoms are such as accompany disorder of the digestive and assimilative functions, and the secretions dependent on those functions; *nervous debility*, in which the symptoms take their origin in a weakened, irritable, and exhausted nervous system"; and *local debility*, a debility of

(a) *Erratum.*—In the last article on Modern Dermatology, at page 338, col. 1, line 10, instead of *eczema*, read *a vesicle*.

parts or tissues. We must confess to not quite comprehending the difference between nutritive debility and assimilative debility, nor can we appreciate the separation of these from nervous debility; as "all the functions of the animal body are so completely bound up together that none can be suspended without cessation of the rest" (Carpenter's "Physiology"), so can no one function be weakened without the rest suffering also; and as the properties of the tissues and organs depend upon their healthy nutrition, and this on a due supply of healthy blood, we do not see how there can be nervous debility or nutritive debility without disorder or debility of assimilation. Would it not be simpler and more correct to say that debility is a predisposing cause; but that in some diseases the symptoms of disorder of assimilation are especially prominent, in others those of nervous derangement, and so on? And when Mr. Wilson gives the "remote predisposing causes" and the "exciting causes" of his four forms of debility, we find that he includes, in fact, every cause of debility or disorder of the human system. Thus, in speaking of eczema, he says:—"The nature of the remote predisposing causes may be gathered from the following list—viz., hereditary diathesis, strumous diathesis, weakly parentage, vaccination, dentition, eruptive and malarious fevers; errors of diet; errors of air, exercise, and clothing; vicissitudes of cold, heat, and moisture; ungenial climate; transition of seasons; excessive or rapid growth; sexual excess; deranged digestion; deranged menstruation; uterine, reproductive, and puerperal derangements; overstrained mental and physical labour; anxiety, fatigue, and affliction; nervous shock and fright; gouty and rheumatic diathesis; constitutional and organic diseases; general cachexia; and hæmorrhage. The *exciting causes* may be judged of by the consideration of those which give rise to the local affection, and are as follows:—Cold, heat, moisture with cold, moisture with heat, errors of clothing and bedding, friction, mechanical and chemical irritants, and varicose veins"! The "list" somewhat forcibly reminds one of the remark we quoted from Dr. Fox, that "almost every conceivable thing has at one time or another been supposed to produce this or that local eruption."

It will be remarked that Mr. Wilson includes vaccination among the "remote predisposing causes" of eczema; the "remote predisposing causes" being "the distant beginnings of a state that is eventually to resolve itself into debility and disease," that is, they are the causes of that state of debility which is the "predisposing cause" of the skin disease. He also enumerates vaccination as in the same way a cause of lichen and lichen strophulosus, and adult vaccination as a cause of gutta rosacea; but he is content thus simply to support the popular charge against vaccination without any explanation or remark.

Dr. Hillier has some sensible observations on the subject; after noting that vaccination is "frequently regarded by mothers and the public generally as the cause of numerous cutaneous diseases," he says, "No doubt many children become eczematous very shortly after vaccination; but then it must be remembered that vaccination is usually performed at an age when eczema is very liable to occur without vaccination. In many families nearly every child is liable to eczema during the whole period of primary dentition, whether it is vaccinated or not. The slight febrile disturbance attending dentition brings out eczema, and the slight disturbance of health caused by vaccination is also sometimes sufficient to determine the occurrence of an attack of eczema in children naturally predisposed to it. Strophulus in the same manner may be thus determined; and I have several times met with cases of pruriginous strophulus which appeared to have been excited by vaccination. . . There is nothing improbable in the notion that the introduction of a virus like that of vaccine into the blood of an unhealthy person may so unsettle the health as to lead to subsequent cutaneous eruptions; just as an attack of measles, of variola, or even of varicella may have this effect. The cases in which this occurs are, however, so few as to form no argument against the general adoption of vaccination, but probably supply sufficient reasons for carefully attending to the health of the subjects submitted to vaccination." No one will dispute the justice and good sense of these observations; and we will add that it would be well to sometimes warn parents of the possibility or likelihood of an eczematous eruption following vaccination, and to explain its occurrence and the connection between the two, when such an event does happen, instead of pooh-poohing the charge that "vaccination caused this eruption, Sir," as is, we fear, too generally the mode of meeting, or rather of not meeting, it.

Dr. Hillier speaks of "children naturally predisposed" to eczema, and Mr. Wilson, among "remote predisposing causes," mentions "the eczematous diathesis," so that these authors recognise in some degree the existence of a diathesis especially predisposing the subjects of it to certain skin diseases—the "eczematous affections" of Mr. Wilson; this can only be the "dartrous diathesis" of some of the French dermatologists, and it will be well to consider the arguments in favour of its existence, for could it be clearly established a great step would be made in the simplification of etiology.

THE WEEK.

RE-ELECTION OF MR. SOLLY AT ST. THOMAS'S HOSPITAL.

We are glad to find that Mr. Solly was re-elected to the office of Senior Surgeon to St. Thomas's Hospital, at the Court of Governors on April 18, by a majority of 45 to 18.

So little is known to the public of the earlier history of our most successful Surgeons—of the struggles and sacrifices undergone in early life, of the numbers who succumb, who lose their lives, or health, or reason, or who retire disgusted of the race,—that we do not hesitate to give publicity to the following extract from Mr. Solly's appeal to the Governors of St. Thomas's, in which he shows the equitable grounds on which he asks to be re-elected. The income of a great Surgeon may be equal to that of a rich merchant; but the merchant has not to encounter all the toil and unpaid drudgery of the Surgeon. But the results are before us. Eminent English Surgeons are what they are, because they have been tempted to undergo the preliminary drudgery by the love of science, with the hope of future reward, in the shape of Hospital appointments and consultation practice. Is it better for us to have such a set of scientific men, working on and teaching during the best part of their lives—making anatomical investigations (on the brain, for example), or doing some other work *quod alteri sæculo prosit?* or shall we have a race of young Surgeons grasping at early practice, and each advertising a book on the rectum?

"Statement of Mr. Solly to the Governors of St. Thomas's Hospital.

"As I shall attain the age of 60 years in May next, and as the rule of your Hospital, passed in April, 1858, which limits the period of service of each Physician and Surgeon, applies in terms to me, I beg your kind consideration of the hardship and injustice of the application of that rule to myself. . . .

"That my position as full Surgeon has fallen considerably short of twenty years' duration has arisen from accidental circumstances for which I am not responsible, while they led to my giving thirty years of almost gratuitous service to the Hospital.

"The facts connected with my position at the Hospital are as follow. I was apprenticed to Mr. Travers in 1822, to whom my father paid a fee of 500 guineas. I worked for four years in the dissecting-rooms, preparing all dissections for the illustration of the lectures. As the result and proof of this labour I was appointed Demonstrator and Lecturer on Practical Anatomy one year before I was out of my apprenticeship, or old enough to obtain the diploma of the College. On receiving this appointment I demonstrated anatomy in the dissecting-rooms for three hours daily, and lectured on the same subject gratuitously for six years. During one of these years I lectured, from October 14 to the end of April, five days in

each week without intermission, except the Christmas week. These appointments now have salaries attached to them. I then held the office of Assistant-Surgeon for five years without any salary at all; then, for five years at £50 per annum (the salary is now £100 per annum). In the case of Mr. South and Mr. Mackmurdo it was decided that the law limiting the period of service should not come into operation till five years had elapsed from the time at which it passed: this enabled Mr. Mackmurdo to serve the Hospital for twenty years, and Mr. South for a much longer period, and attain the age of 67 before he resigned.

"In every other Hospital (with one single exception) where a limit to service has been made, the age fixed is 65, not 60; and the rule has in no instance been made retrospective—*i.e.*, applicable to the then existing staff.

"I, therefore, respectfully submit to the Governors of the Hospital that in making the rule of age to apply to me an injustice is done me, because the great prize for which I struggled so earnestly is taken from me under circumstances never dreamed of when my father placed me with Mr. Travers, and when I made the large sacrifices of time, labour, and thought which I have endeavoured to point out. May I venture, therefore, further to submit that, having served the Hospital faithfully, and I believe I may say usefully, for so many years, and being as equal to my duties in every respect as I have ever been, I may now claim at your hands that indulgence which has been accorded to others—namely, to serve the Hospital as full Surgeon for the full period of twenty years?"

THE OFFICIAL ACCOUNT OF THE RUSSIAN EPIDEMIC.

Until they are modified or contradicted by more trustworthy evidence, we must accept the answers made on the part of the Russian Government to the inquiries of the English Ambassador as the best account that has reached us of the nature, extent, and causes of the St. Petersburg epidemic. Our readers well know that it is the common policy of a Government to put the best face on an official account of the condition of its population, and that some allowance must be made for a praiseworthy desire to reassure the minds both of subjects and of foreigners. But if we receive even with some reserve the Russian Minister's account, it is quite clear that the present epidemic in St. Petersburg does not amount either in extent or mortality to what is popularly understood by "a plague." The *Times*, with its usual ignorance of the signification of Medical terms, falls into an amusing mistake when it remarks, in reference to the catalogue of symptoms given by the Minister, that "the 'bubocs' characteristic, but not distinctive, of plague, are not mentioned." Jupiter ought to get the aid of Esculapius before he writes articles on mortal ailments. The passage in the official document which tells of extensive phlegmons on the trunk and extremities, and of suppuration of the inguinal glands, often terminating in death, evidently failed to convey to the mind of the writer in the *Times* the faintest idea that such manifestations are identical with what our ancestors called "pestilential buboes." Of course, Medical men know that bubo is occasionally seen in typhus fever all over the world, and that this fact is one of the main arguments in support of the theory that plague is only an exaggerated form of typhus, but whenever the symptom does occur in fever it may always be accepted as evidencing a high degree of malignancy. In fact, the whole account given by the Russian Government fully warrants some measures of precaution in the case of sickly crews arriving from Russia, and we are very glad to see that the British Government have taken the initiative in the matter. Jupiter's satellite "S.G.O." sneers at such old-fashioned measures of precaution, and recommends that we should begin at once exterminating typhus by demolishing its nests. We yield to none in our appreciation of the value of sanitary improvements, but it is quite clear that it will take some time to pull down all the rookeries of London, and provide fresh homes for their inhabitants, even supposing that a grant for the purpose were obtained from Parliament; and meanwhile a few cases of malignant bubo-fever from St. Petersburg dropped here and there amongst the river-side population, or straggling up into St. Giles's or Drury-lane, would soon make a sensible difference in the Registrar-General's returns. By all means get rid of our typhus nests directly, if you can, but do not allow fresh foci of contagion to be planted whilst you are doing it. We subjoin an abridgment of the Russian Ambassador's statement, which was published on April 12. The questions to which it is an answer refer to the following heads:—

"1. *Nomenclature.*—The epidemic does not offer any new features of note, nothing unknown to science, no special form but the typhoid class with various known modifications; thus typhoid fever, petechial fever, bilious typhus fever (biliœses typhoïd of the Germans) *fièvre récurrente* (febris recurrens), *reeurrirendes fieber*, of the Germans; relapsing fever of the English. Typhus and typhoid fever prevail at St. Petersburg nearly every year in the autumn, and diminish towards the month of November—a period at which a great number of workmen leave the capital; towards the following months of March and April—the period of the return of the vagrant workmen to the capital—those fevers reappear, and always without offering any particularities unknown to Medical science. The typhus which is now committing ravages does not differ from the fevers of which we have just spoken, except by a greater extension and a greater intensity of the symptoms which characterise it; yet other maladies, appertaining to the same species of typhoid maladies, have shown themselves for the first time at St. Petersburg, and the number of cases returned has exceeded that of the typhoid fevers during the months of November and December, 1864, and January, February, and March of this year. They are bilious typhoid fever, and especially relapsing fever (*fièvre typhoide bilieuse*, and especially *fièvre réeurrente*).

"2. *History of the Epidemic.*—Although the relapsing fever (*fièvre réeurrente*) had never been observed at St. Petersburg, it has been previously observed in other localities. In 1840 that malady committed great ravages in Moscow, especially under a bilious form, and in 1857-58 at Novo-Archangelsk (Russian America), where it was studied by Dr. Govorlivoy, and last year it made its appearance at Odessa. At the present moment, while it prevails in the capital, it has also shown itself in various districts of the St. Petersburg radius (Novaïa-Ladoga, Gdow, Peterhof, and Tsarskoé-Selo), and on some points of the district of Novogorod, especially on the railway line, whither it seems to have been brought from the capital. But it is especially the petechial typhus which has committed ravages in this latter district, as also in the districts of Penza, Tauris, and Kharkow; in some other districts (Astrakhan, Vitebsk, Minsk, Volhynia, Vladimir, Kalouga, Kieu, Koursk, and Toula) the typhoid fever has attained but a slight development, and the returns do not show a high rate of mortality. With the exception of the epidemic of 1840 at Moscow, which was followed by the simple typhoid fever, in no part of Russia has the epidemic of the relapsing and bilious fever acquired any considerable development.

"3. *Contagion.*—The relapsing fever, simple and bilious (*la fièvre réeurrente, simple et bilieuse*), has shown itself to be contagious, like the general typhus. Some Doctors, Surgeons, attendants, and nurses have caught the malady in the Hospital wards; as yet but two cases of death are reported among the Doctors, and a few cases among the attendants and nurses. It is especially, as is the case with all epidemics, in the dwellings of the working men of the indigent classes that the contagion spreads, on account of the bad ventilation and the immediate contact with the clothing.

"4. *Causation, Symptomatology, and Treatment.*—The origin of this epidemic may be attributed to bad hygienic arrangements; to the consumption of vegetables which have been grown under unfavourable climatical conditions; to the immoderate use of spirits made from grain by the working and lower classes; to an unusual agglomeration of workmen in the capital towards last autumn, which occasioned a considerable crowding in their dwellings—a crowding very baneful to health, especially in the Russian climate. To these accidental causes there must still be added (and this is applicable to all epidemics) the frequent atmospheric variations, especially so common on the shores of the Gulf of Finland. The relapsing fever (*fièvre récurrente*), which made its first appearance towards the end of last August at the rate of five to six cases daily, progressed rapidly. In November there were already no less than 500 cases of disease in the town Hospitals;

towards the end of January and at the commencement of February the epidemic had reached its height, as many as 150 persons being taken to the Hospital in one day, and if we include the cases of ordinary typhus and other severe diseases the number arose to 250 and even 300 per diem. We must, however, observe that this last number does not give the exact number of the sick, as for many days during the time requisite for preparing temporary Hospitals numbers of sick had to remain in their own domiciles. During the last week the number of cases of relapsing fever (*fièvre récurrente*) has considerably diminished, and the petechial typhus, the typhoid fever—to which the relapsing fever often turns in its second paroxysm—takes the place of the relapsing fever. At the present moment the average total admission into the town Hospitals is from 100 to 150 per diem, including the petechial typhus, or typhoid fever, and other severe maladies. As regards the symptoms, the relapsing fever (*fièvre récurrente*) has shown itself under two forms—a simple form and a bilious form. Premonitory symptoms are always observed; the persons attacked have a shivering fit, sometimes two attacks at a short interval, sometimes a continuous attack. When the attack is over the patient is much prostrated; he complains of headache, thirst, sickness (*mal au cœur*), and want of appetite; vomiting occurs at times; the patient is generally constipated; the prostration then increases, and he suffers extreme pain in the extremities; however, these latter symptoms might not appear or might diminish in a short time; they are neither permanent nor constant. Generally speaking this period of incubation is not of long duration; often after twenty-four hours only the disease displays itself in most distinct characters. The face has an altered appearance, the lines are depressed, the colour of the face red with some and of a gray yellow with others; is sometimes icterical; the skin is hot and dry, the head heavy and burning. If a thermometer is placed under the armpit of the patient it marks 30 deg., 40 deg., and 41 deg. C., and this temperature is nearly the same all over the body. The tongue is generally moist, never quite dry; red at the edges and point, it is furred at its base. In the greater number of cases respiration is perfectly free, while in others the patient has a slight cough without much expectoration. The abdomen is not much swollen, yet it is sensitive to touch, especially under pressure of the left hypochondrium. The liver is much larger than in a natural state, as it often extends as far as the navel, and completely occupies the left hypochondrial region. The spleen is constantly enlarged. The invalid does not eat, and even shows disgust for every species of food, but he has intense thirst; the bowels are loose, and the motions do not show anything extraordinary,—they are rather liquid than solid; the urine, passed without difficulty, is slightly acid, at times albuminous. The patient, much prostrated, is taken with giddiness, and cannot stand upright. The pulse is weak and slow; from 100 pulsations it reaches 130, at the rate of 140 pulsations per minute. Delirium very seldom occurs. The state which we have just described lasts four, seven, and even ten days; the patient then begins to perspire copiously, and that perspiration, accompanied by a most marked diminution of all the symptoms, continues sometimes from twelve to thirty-six hours; but the prostration remains the same, and the twitches of the muscles continue unabated. This state continues for many days, when suddenly cold ensues, followed by shivering fits, and they are followed by all the symptoms above mentioned, and torment the patient for many days more. Yet, generally, this second attack is not so violent or so long as the first, and the patient enters into a state of convalescence. The convalescence is very slow. Very often the patient has one or two relapses, apparently less violent, but leaving him in a most prostrate condition. In some rare cases death occurs in the first paroxysm—that is to say, before the second attack of shivering, consequent upon a cerebral or pulmonary hæmorrhage, or from acute meningitis, or from paralysis of the heart (Dr. Hermann, Aboukhoff Hospital). Later, the patient dies either from inflammation of the lungs, or rather from a stasis in the lungs, or from an abscess in the spleen or loins, flux from the bowels, or hydropsy. At the workmen's Hospital extensive phlegmons of the trunk and extremities have been observed, with suppuration of the inguinal glands, often resulting in death. Recently (as already previously observed) the relapsing fever at its second paroxysm has turned into typhus or typhoid fever. The second form of the malady —bilious relapsing fever—*La fièvre récurrente bilieuse*, may arise from the first just described; however, it shows itself at once. From the first day the patient is in an icterical state, he vomits bile, and has fearful headache. He becomes delirious, and remains in a prostrate state. This very dangerous condition does not always end in death, but convalescence is always slow. The autopsy has always shown that the seat of the malady is in the organs of the abdomen, especially in the spleen and liver, which are always greatly enlarged and completely changed; sometimes the kidneys are also affected by this inflammation; a catarrhal affection of the mucous membrane of the stomach and bowels is also observable, which sometimes reaches the mucous membrane of the biliary channels, and which occasion icterical phenomena during life. Moreover, in complicated cases the results are found of inflammation of the lungs, of suppurative pericarditis and of hæmorrhage into the tissue of the spleen, even with the rupture of that organ. Men are more subject to the malady than women. The workmen who are addicted to drink have been chiefly victims to it. As yet no treatment suitable to every case has been discovered; the Physician who turns his attention to the fever and to the state of the abdominal organs succeeds best. Mineral acids (acid elixir of Haller) and chlorinated preparations are mostly preferred. Symptomatic and palliative treatment suited to local complications always find their indication; also laxatives, resin oil, calomel, warm applications, opium, etc., according to circumstances. Sulphate of quinine, recommended by some, has not always been attended with good results. But its usefulness was chiefly admitted as a palliative to relieve pain and as a strengthening remedy during the period of convalescence, where it has at times been used with preparations of iron, and a nutritious diet, especially when anæmia had to be met with in the convalescence.'

"5. *Spread.*—If we take 500,000 as the approximate number of inhabitants, we have as a maximum during some weeks only of February 300 cases daily of relapsing fever, typhus and other maladies included. We add:—The number of admissions to the Hospitals in the last months of 1864 showed upon the admissions of the corresponding months of 1864 an increase of 30 to 40 per cent.; in January, 1865, it was 50 per cent. above those of 1864, and the number of admissions of February, 1865, exceeded that of 1864 by 100 per cent.

"6. *Mortality.*—It is not to relapsing fever that the greatest number of cases of death must be attributed, but to petechial typhus and typhoid fever. Thus, at the commencement of the epidemic, the relapsing fever showed the proportion of (1·20) one death on 20 sick in the Hospitals; in its greatest development it gave (1·12 and 10) one death on 12, or 10 sick and even less in some Hospitals. The petechial typhus always showed much more unfavourable proportions (1·5 and 1·4), one death out of five, or even four sick in some Hospitals. Generally, the number of deaths during the last six months of 1864 and January, 1865, exceeded that of the corresponding month of 1863 by *circa* 2,000. The relative mortality in the Hospitals had also greatly increased, especially during the first months of 1865. If, therefore, we compare the month of January, 1864, with the month of January, 1865, we find:—For the first (1·17) one death on 17 sick, and for the second (1·11) one death on 11 sick, comprising all violent and chronic diseases. It is evident, then, that if we only include the relapsing fever and typhus the proportion would be still more unfavourable.

"7. *Daily Mortality.*—The daily mortality from epidemic maladies in the Hospitals from typhus and relapsing fever has not reached the maximum of more than 60 per diem, and the average has been 25 to 30 per diem."

The Pritchard Case.—A few days ago we were enabled to state that the report of the Medical men on the chemical analysis on the remains of Mrs. Taylor, conducted here, would be received in Glasgow at the end of the week, and would be of a tenour to show that the deceased lady did not die a natural death. The report was sent to Glasgow on Thursday, and we understand that it ascribes the death of Mrs. Taylor, in common with that of Mrs. Pritchard, to the effects of antimony.—*Scotsman.*

Pharmaceutical Society of Great Britain.—Names of candidates who passed the examination, April 12, as pharmaceutical chemists:—Alfred Berridge, Leicester; Edwin Bing, Cambridge; Thomas Farnsworth, Codnor; William Hogarth, Preston; William Jarvis, New Brighton; Richard Morgan, Newton; John Yeoman, Stockport.

GENERAL MEDICAL COUNCIL.

WEDNESDAY, APRIL 12.

(EIGHTH DAY.)

THE Council met at 2 o'clock.

With reference to the decision of the Council yesterday to erase from the Register the name of John Carter Barrett, in consequence of his conviction for felony at Castlebar, County Mayo,

Dr. ALDERSON said that, although Barrett had been convicted, he was not sentenced, but was merely required to appear for judgment when called upon. It seemed hard to strike his name off the Register, and thus take a more penal step than the magistrates who convicted him.

Dr. WOOD rose to order. He said the question could not be reopened. The Council had exercised a judicial function under the advice of their Solicitor. If they now took the matter up again it would appear to the public, and very naturally, that the Council acted without due consideration.

Mr. ARNOTT said he had before expressed his regret that there was no opportunity allowed to the Council to reconsider their decisions. This was a case in which the disadvantage of the absence of that opportunity was apparent.

Dr. CORRIGAN said that if Dr. Alderson thought the Council had taken a wrong step he could give notice of a motion to rescind the resolution of yesterday.

The Council then resolved itself into a General Committee on Education, the President in the chair. The consideration of the report of the Select Committee on Education was resumed.

Clause 7, section 3 (Professional study), was considered. It was "That the several licensing bodies be requested to furnish a short statement of the mode in which their examinations are now conducted, whether by written, oral, or practical examination, and of the length of time a candidate is under examination in each or all of these ways."

Dr. STOKES moved that the clause be omitted.

Mr. SYME seconded the motion.

Dr. PARKES said that, much as he respected the opinions of Dr. Stokes and Mr. Syme, he must differ from them in this instance. The clause had been submitted to the licensing bodies, and several of them had said that they should have no objection to furnish the information when called on. The power to get the information was conferred on the Council by Clause 18 of the Medical Act. They were authorised to supervise the examinations, but seven sessions had passed without any step being taken. The examinations could not be supervised unless the Council knew how they were conducted. If they did not obtain the knowledge in the manner proposed by the clause they would have to obtain it by personal visitation. He could conceive of no opposition being offered to the motion unless it was on the part of those who disagreed with the supervision altogether. He therefore moved, "That Clause 7 be adopted." By adopting it, the Branch Councils would be able to question the examiners as to the system they pursued.

Dr. WOOD seconded the amendment of Dr. Parkes. He said that no man agreed with the supervision of examinations more fully than Mr. Syme, and he (Dr. Wood) believed that Mr. Syme, on further consideration, would not persist in the motion which he had seconded. If there was one function of the Council more clearly marked than another, it was that of the supervision of examinations. There were disputes about some of the powers of the Council, but there could be none about this. It was desirable to obtain uniformity not merely in the curricula of the various educating bodies, but also in the system of examination, and he believed the Legislature intended that they should secure that uniformity, and be furnished with the powers necessary for the purpose.

Mr. SYME said that his only objection to the clause was that it appeared to him unnecessary.

Dr. APJOHN supported the amendment.

Dr. CORRIGAN said that he did not agree with the suggestion of Dr. Parkes that the Branch Councils should supervise the examinations. The task would be an invidious one, and the system would be impracticable. The proper and most efficient way of supervising examinations was to make them public. There would not then be a question and answer which any one present might not send to the public journals.

Dr. EMBLETON said the Council were not only authorised by the Medical Act to obtain information on the points mentioned in the clause, but they would be very much in fault if they did not obtain it. None of the bodies in Schedule (A) would refuse to give it. The necessity for it was shown by the result of some of the examinations last year.

Dr. STOKES said that Dr. Parkes' remarks seemed to convey that those who did not approve of the clause withheld their approval because they were opposed to supervision. He (Dr. Stokes) disavowed on behalf of himself and fellow-examiners any such objection to supervision. As to uniformity in examinations, he believed it would be impossible to obtain it.

Dr. PARKES said that the object of the clause was not necessarily to obtain uniformity in examinations, but to ascertain whether the examinations were efficient. Uniformity might come afterwards.

The amendment was carried.

The Council then proceeded to Section 4 of the report—(Examinations).

Mr. SYME moved—"That Clause 1 be adopted." It was —"That the licensing boards be advised to encourage the periodical examination of students at their several classes."

Dr. WOOD seconded the motion.

Dr. PAGET thought that it dealt with a matter of detail, on which it was unadvisable for the Council to legislate.

Dr. WOOD said that this was not a matter of mere trivial detail, but an important and fundamental point. When he was a student at college, the only means of information with which he was privileged was the listening to lectures for about five days in the week. There were no measures taken to test whether the students understood the lectures. The consequence was that students neglected their studies until almost the end of their course, when they had to go through a tremendous course of cramming. The resolution would inflict no hardship upon the student, but, on the contrary, it would be a great boon. It would ensure his proper attention to his course, and thus save the tremendous effort which had to be made by negligent students as the examination approached.

Dr. AQUILLA SMITH said that the system of class examinations was adopted with benefit in some instances, but he believed that if the resolution were passed, the teachers would regard it as an undue interference with their system of instruction.

Dr. SHARPEY said he did not think there was much difference of opinion in the Council on the subject of the resolution. It did not propose to make the class examinations compulsory, but he believed that the sanction of the Council would have the effect of encouraging the teachers in pursuing the practice of periodical examinations in their classes.

Mr. COOPER said that the question was one for the teachers, and not for the licensing bodies.

Dr. PAGET said that he believed the competition among the many eminent teachers would be a sufficient guarantee that they would teach in the best possible way.

Dr. CORRIGAN opposed the motion. He said the licensing bodies were not teaching bodies, and they had no machinery for encouraging class examinations. There was only one efficient test by which a man could be properly admitted into the Profession, and that was a practical examination at the end of four years.

The PRESIDENT said that he considered the question one of detail, although it was a very important one. The Council had fixed on certain cardinal principles with reference to registration and education, and he entreated them not to occupy themselves with details which would delay more important business. Let them be true to the principles on which they had agreed, and they would then accomplish a large amount of good.

Dr. PAGET moved as an amendment, "That, while acknowledging the great educational value of the periodical class examination of students, the Council decline to issue advice or instruction on the subject."

Dr. THOMSON seconded the amendment. He thought that the Council, although they might approve strongly of class examinations, should decline to issue any regulation with reference to them.

Mr. SYME said he thought possibly that the amendment might have the effect of discouraging the class examinations.

The amendment was submitted to the meeting and negatived.

The original motion for the adoption of the clause was also negatived.

Dr. WOOD requested that the names should be taken.

The division was,—

For—Dr. Embleton, Dr. Andrew Wood, Dr. Fleming, Mr. Syme, Dr. Sharpey, Dr. Parkes, and Dr. Christison.

*

Against—Dr. Alderson, Mr. Arnott, Mr. Cooper, Dr. Acland, Dr. Paget, Dr. Thomson, Dr. A. Smith, Mr. Hargrave, Dr. Leet, Dr. Apjohn, Dr. Corrigan, and Dr. Stokes.

Did not vote—The President, Dr. Storrar, and Dr. Quain.

Absent—Mr. Rumsey.

Clause 2 was then considered. It was:—"That the final examinations of the Licensing Boards be so carried on as to be an efficient test of the practical acquaintance of candidates with the several branches of Medical knowledge, and especially with the practice of Medicine and Surgery."

Dr. Hargrave moved that the second clause be omitted.

Dr. Storrar seconded the motion. He said he considered the clause quite unnecessary, and that it would have no effect on the examiners.

Mr. Syme said he thought it an absurdity to expect that young men just entering on Professional practice would be sufficiently advanced to undergo a practical examination.

Dr. Wood said that he did not agree with Mr. Syme's opinion. It ought to be the object of an examination to test the candidate's practical skill. If the tests applied were to be worth anything, they ought to be directed to ascertaining that the young man was fit to go into practice. The necessity for a practical examination was shown by Dr. Parkes last year, when he stated that there was a great degree of laxity on the subject. He moved as an amendment that the clause be retained.

Dr. Parkes seconded the amendment.

On being put, the amendment was negatived.

The original motion was then carried.

Dr. Wood moved for the names of the division on the omission of the clause.

For—Dr. Acland, Dr. Embleton, Dr. Storrar, Mr. Syme, Dr. Thomson, Dr. A. Smith, Mr. Hargrave, Dr. Leet, Dr. Apjohn, Dr. Corrigan, Dr. Sharpey, and Dr. Stokes.

Against—Dr. Alderson, Mr. Arnott, Mr. Cooper, Dr. Paget, Dr. Andrew Wood, Dr. Fleming, and Dr. Parkes.

Not voting—The President, Dr. Quain, and Dr. Christison.

Absent—Mr. Rumsey.

Clause 3 was then read. It was as follows:—"That the Professional examination for any license be divided into two parts; the first embracing the primary or fundamental branches of Medicine; and the second the branches directly connected with the practice of Medicine and Surgery; that the former be not undergone till after the close of the Winter Session of the second year of Professional study, and the latter, or final examination, not till after the close of the Winter Session of the fourth year of such study."

Mr. Hargrave moved—"That as the Council has decided the important questions of registration, age for licence to practise and Professional study, the remaining recommendations on education be postponed to the next session."

This motion was not seconded.

Dr. Storrar proposed "That Clause No. 3 be adopted down to the word 'Surgery.'"

Dr. Aquilla Smith said he would second the motion with much pleasure, as he knew it to be consistent with what was practised in the schools of Ireland.

Dr. Fleming moved, as an amendment, "That the Professional examination for any licence be divided into two parts; the first embracing the primary or fundamental branches of Medicine; and the second the branches directly connected with the practice of Medicine and Surgery; that the former be not undergone till after the close of the Winter Session of the second year of Professional study, and the latter, or final examination, not till after the close of the prescribed period of Professional study."

Dr. Paget seconded the amendment. He said that the clause as altered by Dr. Storrar would allow the two examinations to take place in immediate succession. That was an evil which should be avoided.

Dr. Storrar, by permission of the Council, withdrew his motion.

Dr. Fleming's amendment then became the substantive motion.

Dr. Corrigan moved, as an amendment, "That Clause 3 stand with the addition of the words 'That, with the view of promoting the adequacy of Professional examinations, the final *vivâ voce* examination be public so far as admitting graduates or licentiates of the examining body.'" He said that they could not expect by the present mode of examining to ensure young men being proficient Practitioners. It was, however, the duty of the Council to attain that end if possible, and it should be their care to ensure that those to whom the lives of the community were to be entrusted should possess the requisite amount of knowledge to warrant them in being safely trusted. It was a fact that in Scotland the examinations were private, for some reason best known to the Scotch licensing bodies themselves. It had been urged that the diffidence of Scotchmen about appearing before the public was a reason why the examinations should be private. A large number of Irish students, however, for some reason went to Scotland to be examined. Therefore the objection would not apply as far as they were concerned. [A voice: "Only two went last year."] Then if that were so, he (Dr. Corrigan) never felt more proud of his country than when he heard that only two Irish candidates went to Scotland for examination last year. (Laughter.)

Clause 4 was "That the examination in Chemistry, Botany, and Natural History may be undergone at an earlier period."

Dr. Storrar proposed the adoption of the clause with the addition of the words "than the Professional examination."

Dr. Sharpey seconded the motion.

Dr. Acland said that he should like to see physics introduced.

Dr. Storrar explained that it was proposed to include physics in the preliminary examination. He should prefer it being included in the preliminary examination.

Dr. Apjohn moved, as an amendment, the examination in chemistry should be omitted. It was a subject which required a lengthened period of study.

The amendment was not seconded.

Dr. Acland moved, "That in the clause, as altered by Dr. Storrar, the word 'physics' should be added."

Dr. Storrar agreed to allow his resolution to be altered to meet the proposal of Dr. Acland, and

Dr. Acland withdrew his amendment.

Dr. Wood moved that chemistry should be omitted. It would be a very serious disadvantage to a student if he were to be encouraged in the notion that chemistry was a preliminary subject which might be omitted. It was not a preliminary, but a complemental subject to Medicine, and the student's acquaintance with it should be tested at the latest period. The amendment would read, "That the examination in Physics, Botany, and Natural History may be undergone at an earlier period than the first Professional examination."

Dr. Apjohn seconded the amendment. He did not think a student could pass a respectable examination in those important branches of chemistry which were connected with Medical science until after the second year of his Professional course.

Dr. Paget remarked that if students did not commence the study of chemistry until they became Medical students Dr. Wood's amendment would be important, but the fact was that chemistry was becoming a subject of general study, and youths were often fit for examination in it at an early age.

Dr. Thomson said that there was a large branch of chemistry which did not affect the science of Medicine, and teachers had often found a great difficulty in embracing the whole subject in the period allowed for its study. He believed that it would be an advantage if the examination in elementary chemistry took place at the earlier period. He saw no objection to the examination on applied chemistry taking place afterwards. Physiology was a subject in which two examinations took place.

Dr. Acland said that there were many youths who, before the commencement of their Professional course, obtained a larger amount of chemical knowledge than the average of Medical Practitioners possessed; and it would be a positive hardship to debar them from choosing the time at which they should be examined in that science. The clause was a permissive one, which should not be omitted.

Dr. Wood said that there might be a considerable amount of chemical knowledge possessed by a youth, although when he came to study the science in the applied form in which it should be studied by Medical men there would be many difficulties to be mastered.

The amendment for the omission of chemistry was then put and carried. It then became a substantive motion, in the following form:—"That the examination in Physics, Botany, and Natural History may be undergone at an earlier period than the first Professional examination."

Dr. Thomson moved as an amendment that the words "elementary chemistry" be added.

Dr. Paget seconded the amendment. He said he believed that if the Council imposed on the student the necessity of waiting till the end of the second year for his examination in

elementary chemistry it would be one of the greatest discouragements to the study of the science which could be imagined.

The amendment was negatived.

The substantive motion was then put and carried *nem. con.*

Dr. Wood, at this stage, moved that the Council resume. He said there were some very important reports which it was imperative to consider.

The motion was seconded by Dr. Embleton, and carried unanimously.

The Report of the Committee on General Education was read by the Registrar.

The report was received and ordered for entry on the Minutes.

The Report of the Committee on the Amendment of the Medical Act of 1858 was submitted by Dr. Wood, together with the draft of a proposed bill to be introduced into Parliament for the amendment of the Act. The Report also embraced a memorial to the Home Secretary, calling his attention to the provisions of the Amendment Bill, and requesting him to introduce it into Parliament.

Dr. Wood moved the adoption of the Report, and its entry on the minutes.

The motion was seconded and agreed to.

Dr. Wood stated that Mr. Waddington, of the Home Office, had intimated that the deputation could be received on Saturday, at one o'clock.

The Council re-resolved itself into a General Committee on Education.

Dr. Storrar moved the adoption of Clause 5, Section 4, of the Report of the Select Committee. It was—"That the Professional examinations be conducted both in writing and orally; and that they be practical in all branches in which they admit of being so."

Dr. Sharpey seconded the motion.

Dr. Corrigan moved the omission of the words "conducted both in writing and orally." His experience was not in favour of written examinations. He also proposed to add some words to the clause, making it read as follows:—"That the Professional examinations be practical in all branches in which they admit of being so; and that with the view of promoting the adequacy of Professional examinations the final *vivâ voce* examination be public so far as admitting graduates or Licentiates of the examining body."

Dr. Parkes said he believed that the nervousness to which some candidates were subject was very disadvantageous to oral examinations. He was aware that many important bodies conducted their examinations in that way; but he believed the students were placed at a disadvantage, while they would be able to undergo a written examination with great credit.

Mr. Arnott said he believed that oral examinations were the most efficient.

Dr. Corrigan withdrew that part of his amendment which proposed the omission of the words "conducted both in writing and orally."

Dr. Christison quoted statistics to show that the results of examinations in private and examinations in public by the Army Board were very nearly the same. There was a very small difference between the percentages of rejected candidates in both cases.

Dr. Corrigan said that there was a fallacy at the bottom of the army return. It might be that the lowest examining body might return the largest number of successful candidates, because their examination might cost less than that of higher bodies. The body which supplied most successful candidates to the Army Board rejected only 8 per cent. of its candidates. Young men who wanted admission to the army office would be likely to get their diploma where they could have it cheapest.

Dr. Paget said that the candidates who presented themselves to the Army Board did not present a fair average of Medical men, because the army was an unpopular sphere of service.

Dr. Wood said that the price of a diploma was not the test of the value of an examination. The proper test was the amount of previous education required by the body granting it.

The amendment was negatived, and the original motion was carried.

Clause 6 was then read. It was—"That the Professional examinations be held by the several licensing bodies, except in special cases, at stated periods, to be publicly notified."

Dr. Storrar moved its adoption.

Dr. Parkes seconded the motion, and it was unanimously agreed to.

Clause 7 was then read. It was as follows:—"That returns from the licensing bodies in Schedule (A) be made annually, on the 1st of January, and in the subjoined form, to the General Medical Council, stating the number and names of the candidates who have passed their first as well as their second examinations, and the number of those who have been rejected at the first and second examinations respectively; and that the Registrar forward a sufficient number of forms with a notice for their being returned in due time."

Form of Return of Examinations, and their Results.

Passed.				Rejected.	
1st Examination.		2nd Examination.		1st Examination.	2nd Examination.
No.	Name.	No.	Name.	No.	No.

Dr. Storrar moved that Clause 7 be adopted.

The motion was seconded by Dr. Sharpey, and carried unanimously.

It was resolved that the Council resume.

The proceedings then terminated.

THURSDAY, APRIL 13.

(NINTH DAY.)

The minutes of the last meeting were read and confirmed.

Dr. Andrew Wood moved that the Report of the Committee on the Amendment Acts be adopted. He said that though the Report appeared a long one, the Council had really decided on the gist of it. The Committee considered with the greatest care the subjects which were remitted to them for consideration. As to the qualifications which should be possessed by Medical men to entitle them to registration, the Report of the Committee stated:—"In reference to the amending of Sections xv. and xxxi., with the view of securing that all persons to be placed on the Register should have been duly educated, tested, and qualified in all branches of the Profession, whether Medical or Surgical, the Committee are of opinion that it is highly desirable that every Medical Practitioner should have a complete or double qualification. They see difficulties, however, in the way, for the present, of framing compulsory clauses which would secure that important object. They would, however, point out that by Section xix. of the Medical Act, which is a permissory section, powers have been provided by which any two or more of the licensing bodies may unite and co-operate in conducting examinations required for qualifications to be registered under the Act. Were this course carried out in London and in Dublin, as it has already been successfully carried out in Scotland, the Committee believe that in this way, without the necessity of compulsory legislation, the great object would be effected of combining and concentrating the licensing bodies, to the relief of the student, and the advantage of the Profession and the public." He was of opinion that all licensed Practitioners should be educated, tested, and qualified in all branches of the Profession, but there were many obstacles in the way of introducing any compulsory legislation on the subject. The object, however, could be attained by the co-operation between the different licensing bodies referred to in Clause 19 of the Act. With regard to the visitation of examinations, the Committee did not consider any change necessary. Section 18 of the Act provided that—"The several colleges and bodies in United Kingdom, mentioned in Schedule (A) to this Act, shall, from time to time, when required by the General Council, furnish such Council with such information as they may require, as to the courses of study and examinations to be gone through in order to obtain the respective qualifications mentioned in Schedule (A) to this Act, and the ages at which such courses of study and examination are required to be gone through, and such qualifications are conferred, and, generally, as to the requisites for obtaining such qualifications; and any member or members of the General Council, or any person or persons deputed for this purpose by such Council, or by any Branch Council, may attend and be present at such examinations." It had been proposed to amend the section

by adding to it a clause to the following effect:—"And may also inspect the written answers of the candidates, and report concerning the examinations and answers to the General Council; and to the persons deputed by the General Council as aforesaid, in such number as may be determined by the General Council, with the approval of one of Her Majesty's principal secretaries of state, there shall be paid such fees for services and such reasonable travelling expenses as shall from time to time be allowed by the General Council and approved by the Commissioners of Her Majesty's treasury; and the said payments shall be made out of the residue of the monies annually received for carrying this Act into execution, after defraying the expenses of the General Council and the Branch Councils, and, if necessary, out of further monies to be provided for the said purpose by vote of Parliament." On this subject the Report stated that the Committee did not consider this amendment either necessary or expedient. The Branch Councils had the power under the Act as at present to visit the examinations of the licensing bodies, or to depute any person or persons to do so; they had also the power, as the Committee were advised by Mr. Ouvry, to remunerate the visitors of the examinations from the funds contributed under the Act. The Committee considered that it would be inexpedient to go to Parliament to ask a supplementary money grant for the purpose. They trusted that ere long the expense of the meetings of the Council would be diminished, and that there would be sufficient funds to meet the expenses of visitation in any form that might be deemed necessary. With reference to increasing the penalties under the Act, the Committee believed that if the clause proposed in lieu of Section 40 proved effective, the present power and penalties would be found adequate. They did not approve of the registration of Licentiates in Dental Surgery, the consideration of which had been referred to them in consequence of the memorial addressed to the Council by the Dental-Surgeons. The Committee were of opinion that such registration would place another difficulty in the way of the public distinguishing Practitioners in specialties from fully qualified Practitioners. He (Dr. Wood) did not approve of the registration of special Practitioners, and he should like to see the Licentiates in Midwifery expunged from the Register. It had been said that Licentiates in Dental-Surgery might be put in a separate list in the Register. That suggestion seemed possible, but he would suggest to the Dental-Surgeons that they might obtain an Act of Parliament for themselves, and keep a distinct register. Perhaps that plan might be worthy of their adoption. The alteration in Clause 40 was a very important one. That part of the Act had altogether failed. It had been ruled in the courts of law that no person was liable to the penalty of that Section who did not falsely pretend to be registered under the Act when, in fact, he was not so registered. At present unqualified persons might adopt any Medical title with impunity, and the Section was inoperative. The alteration proposed in the draft bill would make it penal for unqualified persons to assume any Medical title whatever.

Dr. Embleton seconded the motion.

Dr. Corrigan moved "That the consideration of the Report on the proposed amendment of the Medical Act be postponed to the next meeting of this Council, inasmuch as a resolution of this Council of May 4, 1864, directed the attention of the Branch Councils only to clauses 20, 31, and 40, while in the amended bill now proposed for adoption amendments are introduced which have never previously come under the consideration of this Council, and no opportunity is afforded to the several licensing bodies to take those amendments into consideration. ("Oh, oh.") He said his resolution had been met with cries of "oh, oh," which, he supposed, arose from a belief that it would be possible to carry the bill during this sitting of Parliament. He believed that it would be quite impossible to carry it, because it contained amendments which the licensing bodies had never had submitted to them. The consequence would be that, as soon as the bill was introduced, the objecting licensing bodies would send representations to Sir George Grey, any one of which representations would be sufficient to stop the bill from passing during this session. He moved a resolution last year to the effect that it was inexpedient at so late a period of the session to go into the consideration of the amendment of the Act.

Dr. Wood moved, as an amendment, that the Council should fix an early day for the consideration of the subject during its next session.

That amendment was carried, and there was an understanding that the Council should meet this year previous to the commencement of the session of Parliament, in order that there might be an opportunity to submit the proposed alterations to the different licensing bodies before a bill was introduced.

The President said that there was no understanding that the Council should meet before the Parliamentary session commenced. He, as President, was responsible for the time of meeting, and he wished such an impression to be corrected. If such an understanding had taken place he should certainly have acted on it.

Dr. Corrigan said that some of the new clauses proposed in the draft bill drawn up by the Amendment Committee had never come before the Profession or the Council until the present time. He had always been an advocate for the amendment of the whole Act, but the Branch Councils were requested by the General Council last year to confine their attention to the amendment of sections 20, 31, and 40 of the Act. He was satisfied that many of the licensing bodies would strongly object to some of the amendments proposed by the Committee, and of which they had had no notice.

Dr. Aquilla Smith seconded the amendment.

The amendment was put to the vote. There were for it 3, and against it 13.

Dr. Quain moved "That the report of the Committee on the Amendment of the Medical Acts be considered clause by clause, except such clauses as have been already decided on by the Council."

Dr. Apjohn seconded the amendment.

The amendment was carried unanimously.

Dr. Wood moved the adoption of the preamble of the Amendment Bill, which was as follows:—"Whereas the Medical Act, 1858, has been found ineffectual to enable persons requiring Medical aid to ascertain who are qualified Practitioners, and it is desirable to amend the said Act in several respects, be it therefore enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords spiritual and temporal and Commons in the present Parliament assembled, and by the authority of the same, as follows."

The motion was seconded and carried.

Dr. Wood moved that Clauses 1 and 2 of the Bill be adopted as follows:—"1. This Act may for all purposes be cited as 'The Medical Act Amendment Act, 1865.' 2. This Act shall take effect from the passing thereof."

Mr. Hargrave seconded the motion, and it was carried.

Dr. Wood moved the adoption of Clause No. 3:—"The following sections of the Medical Act, 1858, shall be and the same are hereby repealed—viz., Section 14 and Section 40; but without prejudice to any proceedings which may be pending under such section or any of them."

Dr. Parkes seconded the motion.

The motion was carried unanimously.

Dr. Wood moved the adoption of Clause 4, which was:—"It shall be the duty of the Registrars to keep their respective registers correct, in accordance with the provisions of this Act, and the orders and regulations of the General Council, and to erase the names of all registered persons who shall have died, or who, having ceased to practise, shall desire to have their names removed from the register, and from time to time to register all alterations in the addresses or qualifications of the persons registered under the Medical Act, 1858. The Registrars, in these respects, may act upon such evidence as may appear to them sufficient, subject to any rules or regulations which the General Council may make thereon. And for the purposes aforesaid, the Registrar may write a letter to any registered Medical Practitioner, addressed to him according to his registered address, to inquire whether he has ceased to practise or has changed his residence; and if the answer to such letter be that the person has ceased to practise and desires his name to be removed from the register, or if no answer be returned to such letter within the period of six months from the sending of the letter, it shall be lawful to erase the name of such person from the register. Provided always that any name which may be erased by the Registrars may be restored by the direction of the General Council. No person whose name has been erased from the register by order of the General Council or any Branch Council shall be re-registered, either on the original or any new qualification, except by the direction of the General Council or Branch Council, as the case may be."

Dr. Embleton seconded the resolution.

The President said that he thought the proposal to remove a name from the Register in case of no answer being returned

to the inquiry letter within six months a very arbitrary regulation. There were many circumstances which might lead to the loss of a letter, and it was desirable to make provision for that risk.

It was resolved to adopt the clause, with an alteration to secure the sending of two letters in the six months.

Clause 5, which had been previously adopted by the Council, was as follows:—"Any person practising Medicine or Surgery, or being engaged in the treatment of diseases or injuries, not being registered under this Act, who shall take or make use of any of the titles or designations enumerated in Schedule (A) to this Act, or that of Physician, Surgeon, Doctor, Professor of Medicine, Professor of Surgery, or any other title, name, or designation used by, or used to distinguish, duly qualified Practitioners in Medicine or Surgery, shall, upon a summary conviction, be liable to a penalty not exceeding £20 for each offence."

Dr. Wood moved the adoption of Clause 6, which was,—"That the words 'qualified to be' in the seventh section of the Medical Act, 1858, shall be, and the same are hereby repealed."

Dr. Wood said he would agree to withdraw Clause 7, which was,—"It shall, notwithstanding anything in the Medical Act, 1858, contained, be lawful for Her Majesty, by Charter, to grant to the Royal College of Surgeons of Edinburgh, the Royal College of Surgeons in Ireland, and the Faculty of Physicians and Surgeons of Glasgow, or any or either of them power to institute and hold examinations for the purpose of testing the fitness of persons to practise as Dentists who may be desirous of being so examined, and to grant certificates of such fitness."

Dr. Parkes seconded the omission of the clause.

The resolution was carried unanimously.

Dr. Wood moved, and Dr. Parkes seconded, the adoption of the first portion of the report down to, and inclusive of, the remarks with reference to section 40 of the Act.

The motion was agreed to.

On the motion of Dr. Wood, seconded by Dr. Apjohn, it was resolved that that portion of the report relating to section 48 be not adopted.

Dr. Wood moved that the remaining portion of the report be adopted.

Dr. Parkes seconded the motion.

Mr. Arnott moved as an amendment that that portion of the report relating to the registration of Dental Surgeons should be altered so as to provide for their enrolment in a separate list in the Medical Register. He thought that preferable to letting them go to Parliament for a distinct Act and a Register of their own. They ought to be under the regulations of the General Council.

Dr. Wood said he must oppose the amendment. The proposition to register Licentiates in Dental Surgery would complicate the Medical Act with a subject with which it was undesirable to encumber it.

Mr. Arnott's motion was not seconded.

Dr. Apjohn moved the omission of the paragraph relating to sections 15, 19, and 31.

Dr. Leet seconded the amendment, and on being submitted to the meeting it was negatived.

Dr. Quain moved, and Dr. Alderson seconded, the omission from the paragraph of the reference to Clause 19.

The amendment was put, and passed.

On its becoming a substantive motion,

Dr. Wood moved, as an amendment, "That the paragraph be adopted down to the words 'under the Act,'—namely:—'In reference to the amending of sections 15 and 31, with the view of securing that all persons to be placed on the register should have been duly educated, tested, and qualified in all branches of the Profession, whether Medical or Surgical, the committee are of opinion that it is highly desirable that every Medical Practitioner should have a complete or double qualification. They see difficulties, however, in the way, for the present, of framing compulsory clauses which would secure that important object. They would, however, point out that by section 19 of the Medical Act, which is a permissory section, powers have been provided by which any two or more of the Licensing Bodies may unite and co-operate in conducting examinations required for qualifications to be registered under the Act.'"

The motion was seconded and carried.

Dr. Quain moved that the following words of the paragraph be not adopted:—"Were this course carried out in London and in Dublin, as it has already been successfully carried out in Scotland, the Committee believe that in this way, without the necessity of compulsary legislation, the great object would be effected of combining and concentrating the Licensing Bodies, to the relief of the student, and the advantage of the Profession and the public."

Dr. Christison seconded the motion, and it was carried unanimously.

Dr. Wood moved the adoption of those portions of the report relating to Sections 18 and 40.

Dr. Embleton seconded the motion, and it was carried unanimously.

Mr. Arnott moved that the clause of the Report relating to the registration of Dental Surgeons be adopted in the following amended form:—"4. In regard to the question of the registration of Licentiates in Dental Surgery, the Committee having given that consideration to the memorial of the Dental-Surgeons to which it is justly entitled, are of opinion that it is inexpedient to place upon the *Medical Register* Dental Practitioners not otherwise qualified, holding as they do that that would constitute a further obstacle, in addition to those at present existing, to the securing that all persons whose names shall be inserted in the *Medical Register* shall be fully qualified to practise all branches of their Profession."

The motion was seconded and carried.

Dr. Corrigan, according to notice, moved—"That it would be advisable to have a clause inserted in the amended Bill, or in any Pharmacy Bill introduced by the Legislature, rendering it imperative on the apothecaries and compounding chemists of the United Kingdom to follow, in compounding prescriptions, the formularies of the British Pharmacopœia, unless otherwise specially directed by the prescriber, inasmuch as compounding indifferently from the formularies of four different Pharmacopœias is dangerous to the lives of the community." He said his reason for moving the resolution was, that before the publication of the British Pharmacopœia there were an English and an Irish Pharmacopœia both under the sanction of Acts of Parliament, and a Scotch Pharmacopœia not under Act of Parliament. When the British Pharmacopœia was published, the College of Physicians of Ireland decided that they would no longer take the supervision of chemists' shops. There were now four different Pharmacopœias from which medicines were compounded, and the question of compounding was in a very unsettled state. He had himself, as a prescriber, been the subject of some terror lest injury might result from the medicines being compounded from the wrong formula. In some instances, what was a minimum dose according to one Pharmacopœia was poison according to another. That was the case with tincture of aconite, five drops of which were a minimum dose under the British Pharmacopœia, while that quantity was a poison, or very nearly so, under the Irish formula. If death resulted through an error arising from such discrepancy, the fault would be traced up to its source, and the Council ought to be able to lay their hands on such a resolution as he had proposed to show that the crime did not rest with them.

Dr. Apjohn seconded the motion.

Dr. Leet said he agreed with the proposal.

Dr. Sharpey supported the proposal. He said that from inquiries he had made he had found that there had not been 1000 copies of the British Pharmacopœia sold in Ireland.

Dr. Christison said that he did not consider that the motion was necessary as far as Scotland was concerned. The practice there was to use the British Pharmacopœia. That was gradually displacing the others, and young men were now trained to its use.

Dr. Quain said that one effect of such an enactment as that proposed might be to poison persons by Act of Parliament, and a chemist might be compelled to put up what he knew to be a poisonous dose.

Mr. Cooper said that as far as his observation went the British Pharmacopœia was working its way, and that prescriptions were now dispensed from it unless there was a note to the effect that one of the other Pharmacopœias was to be used.

Dr. Corrigan said that his own personal experience was that the British Pharmacopœia was seldom used. He merely wished to call the attention of the Secretary of State to the subject in order that some legislation might take place on the subject.

The resolution was carried unanimously.

On the motion of Dr. Corrigan, it was resolved—"That a copy of the clause be forwarded to the Home Secretary."

Dr. Wood moved—"That the memorial contained in the Report of the Medical Acts Amendment Committee be

addressed to the Home Secretary by the President without delay."

Dr. Acland seconded the motion, and it was unanimously agreed to.

The following is a copy of the memorial :—

"General Medical Council, 13th April, 1865.

"Sir,—I am requested by the General Medical Council respectfully to solicit your attention to certain points on which it has been found, by experience, that the working of the Medical Act, 1858, has not been satisfactory, and to ask you to introduce a Bill in the present Session for the amendment of that Act.

"In order to place the matter before you in a practical form, the Council has caused the draft of a Bill to amend the Medical Act to be prepared, and such draft is transmitted herewith.

"The only amendment to which I need direct your special attention as involving an important change is that which affects the 40th section of the Act of 1858. It has been found, in practice, almost impossible to establish the false pretence, which is the offence punishable under that section, and accordingly ignorant pretenders, possessing no legal qualification to practise, and, assuming falsely Medical and Surgical titles, with impunity deceive the public, prey upon their credulity, and endanger their lives.

"The most effectual remedy for this state of things would be the absolute prohibition of practice by persons not possessing the qualifications mentioned in the Act of 1858; but as the Council considers that there might be difficulty in inducing Parliament to adopt so stringent a rule, the Council has framed a clause which it is hoped may meet the evil which the present existing Act has been found inadequate to suppress.

"The other suggested amendments do not require separate remark, but I am to ask that you will be good enough to receive a deputation from the Council, when the reasons on which the proposed amendments rest will be fully stated to you.

"As it is earnestly wished that the proposed Act should pass this Session, I am to urge that you will be pleased to appoint a time for receiving the proposed deputation at your earliest convenience.

"I have the honour to be, Sir,

"Your most obedient servant,

"George Burrows, M.D., President.

"The Right Hon. Sir Geo. Grey, Bart., G.C.B., M.P.,
Secretary of State for the Home Department."

Dr. Stokes moved, "That the report of the Committee on the Medical and Surgical Practice of Chemists and Druggists and the Pharmacy Bills be taken as read and entered on the minutes."

Dr. Wood moved, "That the report of the Medical Acts Amendment Committee, as now adjusted by the Council, be printed and inserted on the minutes."

Dr. Fleming seconded the motion.

Dr. Storrar said he had a notice of motion on the paper relative to allowing persons holding the degree of Bachelor of Surgery from any University of Great Britain to be registered for practice. He was anxious that the draft bill should not be forwarded until that matter was settled.

After some discussion, Dr. Storrar gave notice that he would bring on his motion at 2 o'clock on Saturday.

The resolution was carried unanimously.

It was moved by Dr. Sharpey, seconded by Dr. Aquilla Smith, and resolved, "That the report of the Finance Committee be received."

Dr. Embleton moved, "That a Committee be appointed to arrange and digest the recommendations as to education and examination agreed to during the past and present sessions by the Committee on Education."

The motion was seconded, and carried unanimously.

Dr. Quain moved, "That the following form a deputation to wait on the Secretary of State on Saturday to call his attention to the Bill for the Amendment of the Medical Act :—The President, Dr. Wood, Dr. Stokes, and Mr. Arnott."

Mr. Hargrave seconded the motion, and it was agreed to.

The Council then adjourned to Saturday.

SATURDAY, APRIL 15.

(tenth day.)

The Council re-assembled at the usual time.

The minutes of Thursday's meeting were read and confirmed.

The President said he thought the Council would be glad to know what took place with regard to the deputation in the morning. The deputation appointed, accompanied by the Registrar and the Solicitor, waited upon Mr. Waddington, the Under-Secretary of State for the Home Department, and had an interview with him. They had the satisfaction of finding that Mr. Waddington had given his close attention to the report of the Committee on the Amendment of the Medical Act, and was prepared to enter into the subject. They had the opportunity of explaining to him each particular change contemplated, and the result of the interview was most satisfactory. Mr. Waddington assured them that he would take the earliest opportunity of sending to Sir George Grey, who was out of town, a report of the deputation and the letter addressed to him by the President at the instance of the Council. On the whole, the deputation were very much satisfied and gratified with their interview with Mr. Waddington.

Dr. Storrar moved—"That Section 10 of Schedule (A) of the Medical Act be amended by the introduction of the words 'or Bachelor,' after the word 'Master,' in the first line." He said that the University of London had been desirous of putting Surgery on the same footing as Medicine, and had therefore established the degree of "Bachelor of Surgery" to correspond with "Bachelor of Medicine." He now asked the Council to give their sanction to the degree of Bachelor of Surgery. He believed the science of Surgery would have cause to regret the absence of such an academic distinction in Surgery. He could not conceive what reason could be urged against the sanction being given to this degree in Surgery, to give it an equivalency with the corresponding degree in Medicine.

Mr. Syme seconded the motion.

Mr. Arnott objected to the proposal. He said that the University of London was a great and very valuable machine for granting degrees, but it did not teach. The examinations were conducted by quite an independent body of examiners, who had had nothing to do with the teaching; but in Edinburgh, for instance, the examinations were conducted by the teachers themselves, and therefore the proposal would act unfairly to the great institutions of the metropolis, and of Oxford and Cambridge, where the examinations were not conducted by the teachers. The teachers in the Scotch schools would be able to confer the double qualification on their own pupils, and the clause would thus act detrimentally to such institutions as the University of London.

Mr. Hargrave said that the education at the University of London was a superficial one. He should therefore move as an amendment—"That the education of Bachelor of Surgery appears to this Council not sufficient to constitute a good Practitioner of Surgery, and consequently that degree should not be placed in the Register as a legal qualification to practise Surgery."

This amendment was not seconded.

Dr. Quain said that the University of London gave as rigid an examination as any institution in the Kingdom. That University had a perfect right by its Charter to grant the degree of Bachelor of Surgery, and all that was now asked was that they might be able to register it as a qualification to practise.

Dr. Wood said that the motion would apply to any University in the Kingdom which had the power of making a Bachelor of Surgery.

Dr. Quain said that the intention was that the Bachelor of Medicine might take the degree of Bachelor of Surgery. He believed the legalising the degree as a qualification to practise was a step which would produce general Practitioners of the highest class. If the amendment proposed were not made in the Medical Act, the University of London would be compelled to go to Parliament to legalise the degree of Bachelor of Surgery as a qualification to practise, for at present it was penal to practise under that degree.

Dr. Aquilla Smith recommended that the University of London should go to Parliament.

Dr. Christison said that the motion would not give to any University which was not empowered by charter to grant the degree of Bachelor of Surgery power to grant that degree.

Mr. Cooper, in reference to a remark made by Dr. Quain, wished to be informed whether the Apothecaries' Society of London had been deficient in its duty as regards testing the fitness of the present Practitioners. If a better class of Practitioners were to be obtained, it should be done by making the existing examinations more stringent. He should oppose any motion which would imply a degradation to the present class of general Practitioners.

Dr. Paget said that the legalising the Bachelorship of Surgery as a qualification to practise would create a competi-

tion between those licensing bodies granting the degree of Bachelor of Surgery and those which did not grant so low a degree in Surgery. Competition in general was a good thing for the public. That was the case with competition between teaching bodies, but competition between licensing bodies had quite an opposite effect. The proposal might operate in such a way as to lower the Surgical requirements of Practitioners.

Dr. Corrigan said that the charters of the Colleges of Surgeons were granted because Surgery was a branch very much neglected by Universities. And it was now found by the Universities that the sale of diplomas was profitable, and it was sought to extend the business by securing for the degree of Bachelor of Surgery a recognition as a qualification to practise.

Dr. Acland protested against such an assertion. Speaking for the University of Oxford, he could say that there was no such object sought.

Dr. Apjohn opposed the motion.

Dr. Quain moved, as an amendment, "That if the University of London possess the right by charter to confer the degree of Bachelor of Surgery, and seeks to register the same under the amended Medical Act, this Council can see no reason why such degree should not be registered."

The amendment was not seconded.

Dr. Storrar said that the fact of the registration of the degree of Bachelor of Surgery would not tend to lower the qualifications of Practitioners, if the University which granted the degree of Bachelor also granted the higher degree of Master of Surgery. If the qualification for the degree of Bachelor of Surgery was not high enough in some Universities others should not suffer on that account.

The motion was submitted to the meeting, and negatived.

At the request of Dr. Quain the names were taken down.

For the motion—Dr. Storrar, Mr. Syme, Dr. Sharpey, Dr. Quain, Dr. Christison, and Dr. Stokes.

Against the motion—Mr. Arnott, Mr. Cooper, Dr. Paget, Dr. Wood, Dr. Fleming, Dr. A. Smith, Mr. Hargrave, Dr. Apjohn, and Dr. Corrigan.

Did not vote—The President, Dr. Alderson, Dr. Acland, Dr. Embleton, and Dr. Leet.

The Report of the Pharmacopœia Committee was read by the Registrar. It was as follows:—"The Pharmacopœia Committee beg to report that, after much careful consideration, they requested Mr. Warrington, of the Apothecaries' Hall, and Dr. Redwood, of the Pharmaceutical Society, to undertake the preparation of the next edition of the Pharmacopœia, under the supervision of the Committee. The gentlemen named accepted the duty, and they are engaged actively in its performance. The Committee, in the first instance, prepared an outline of the subjects which seemed to them to require revision; and these subjects are made the basis of careful inquiries by Messrs. Warrington and Redwood, who have submitted, and will continue to submit, their reports thereon, together with such suggestions as they think proper to make for the consideration and decision of the Committee. The Committee have also received valuable assistance from Dr. Farre, appointed by the English Branch Council, and from Dr. Moore, appointed by the Irish Branch Council, to report on the improvement in the progress of Pharmacy; and they hope that the services of these gentlemen, as well as of Dr. Christison, may be continued. Taking the first edition of the Pharmacopœia as a basis, compiled, as it has been, with great labour and expense, the Committee hope that, without making any very extensive or fundamental changes, the next edition will be found acceptable to the Profession.—George Burrows, M.D., Chairman. April 3rd, 1865."

Dr. Quain moved its adoption. He said that there would be no longer two sizes of the work. It would be published of one uniform size.

Dr. Apjohn seconded the motion.

Dr. Wood asked when the next edition of the Pharmacopœia would be published. He also wished to know whether there would be a toxicological table in it, and whether the attention of Practitioners would be called definitively to the changes made.

Dr. Quain, in reply, said that the next edition would be published after the next ordinary meeting of the Council. It was proposed that there should not be any toxicological table, but that the doses of all remedies would be mentioned with each article. Every alteration to be made in the work would be mentioned.

Mr. Cooper said it was very important that the doses should be stated.

Dr. Corrigan said a proof of the Pharmacopœia should be placed in the hands of the Council a month before the work was to be published, in order that practical men might be able to examine it.

Mr. Syme said that great inconvenience and delay would be occasioned by allowing the Pharmacopœia to be castigated by the Council for a month before its publication.

Dr. Christison said that if the Committee were not to be trusted he for one should decline to act on it. The proper time for the members of the Council to make suggestions was not after the work was printed, but before.

Dr. Wood said it was very necessary that proofs of the work should be placed in the hands of the Council, as they were responsible for it. It was their wish not to pick holes in it, but to make it as complete as possible.

Dr. Corrigan moved, "That it is desirable to have a proof copy of the new Pharmacopœia in the hands of the General Medical Council at least one month before the meeting at which the opinion of the General Medical Council is to be given relative to its publication." The members of the Council could then immediately communicate with the Committee as to any alteration they thought desirable.

Dr. Christison said he had no objection to that course, provided the right were reserved to the Committee to adopt or reject the alterations as they thought fit.

Dr. Wood seconded the amendment.

Dr. Corrigan agreed to add to his amendment the words, "In order to afford to the members of the Council the opportunity of making such suggestions to the Committee as they may think desirable."

The motion and amendment were, by leave of the Council, put successively as independent motions, and were both carried.

On the motion of Dr. Quain, it was resolved that the Committee be authorised to enter into a contract for the printing of the work.

Dr. Quain moved, "That the sum ordered to be placed at the disposal of the Pharmacopœia Committee in May, 1864, be extended from £100 to £300."

The motion was seconded by Mr. Cooper, and unanimously agreed to.

The following report of the Committee on the subjects of General Education was read to the meeting by the Registrar:—"The Committee on the subjects of General Education having duly considered the subject remitted to them, resolve to recommend to the Council—That after the year 1867 the examinations in subjects of General Education be left entirely to the National Educational Bodies recognised by the Medical Council—the Council confining its regulations on General Education to publishing a list of the examinations which may from time to time be approved of by them, it being understood that no certificate which does not affirm the proficiency of the candidate in Latin, and also his knowledge of the elements of Geometry, and of the elements of Mechanics and Hydrostatics, be accepted."

Dr. Stokes said that the Council must be aware that the practice for teachers in Arts being themselves the examiners and the judges of what was required was a very objectionable one. In making that statement, he did not in any way impugn the abilities and talents of the different licensing bodies; but it was best that examinations should be conducted by those who confined themselves to examination. Great abuses had arisen under the system of examinations being conducted by the teachers, although of late years that a better state of things had prevailed. All honour was due to the Royal College of Surgeons of England for establishing an examination in Arts outside their own body. In the College of Surgeons of Ireland the examination in Arts was entirely suspended; and they granted licenses to men without ascertaining whether they could spell, or whether they were acquainted with the English grammar. The candidates who had passed their examination could then go down to the Apothecaries' Company of Ireland, who assisted to give a double qualification to persons who might not be able to spell.

Dr. Leet said that an examination in Arts was required by the Apothecaries' Company of Ireland.

Dr. Stokes said that the present standard of general education was too low. The Council should fix those subjects which it was desirable to include in the course of general education. He moved the adoption of the Report of the Committee.

Dr. Paget seconded the adoption of the Report. He believed the requirements in the Report were a considerable

advance upon the general education now required by the Council.

Dr. Wood said that the regulation of the general education of the Practitioner was one of the most important subjects which could come before the Council; but he was not prepared at so late a period of the Session to adopt so meagre a Report as that submitted. A very unnecessary slur had been cast on the general education examinations of the licensing bodies. The body which he represented established such an examination before there was one established by the University of Edinburgh. He asked whether there was any educational body which was content with such a standard of general education as that mentioned in the report.

Dr. Paget said there was.

Dr. Wood: A licensing body?

Dr. Paget: Yes.

Dr. Wood: Which is it?

Dr. Paget: I would rather not name it; but I can. It is an educational body.

Dr. Wood said that was an argument against taking the general education examination out of the hands of the licensing bodies who required a higher standard, and intrusting it to educational bodies who were content with so low a standard. He moved—"That, as at this late period of the Session it is impossible duly to consider the important question brought forward in the Report of the Committee on General Education, the consideration of that Report be delayed till the next Session."

Dr. Fleming seconded the amendment.

Dr. Corrigan said the Council were now in a difficulty with regard to general education, which he foresaw when they decided on the first day of the session that Clause 20 of the Act should have no alteration made in it. He believed that the matriculation examination of the Universities was not sufficient, and the licensing bodies ought themselves to conduct the examination in general education, as was done in the case of solicitors and barristers.

Mr. Hargrave said the College of Surgeons in Ireland had appointed a special mode for examinations in Arts, and that mode was always pursued. He considered that some important branches of knowledge were omitted from the subjects included in the report brought up from the General Education Committee.

Dr. Storrar said that he did not consider that at any University there should be a special Arts education leading up to any particular branch of science. Dr. Corrigan had said that in Ireland a special general examination was instituted for solicitors, and that the examining body did not rely on the general examinations of general educating bodies. In England quite a different course was adopted, and every encouragement was held out for raising the standard of general education before Professional study was entered on. He did not think the Committee had wished to cast a slur on the general examination of the licensing bodies, but they were only anxious that "Cæsar's wife should be beyond suspicion." Dr. Wood had said that the requirements laid down by the Committee were meagre; but it must be borne in mind that the Committee demanded all the other subjects included in the general examinations of the education bodies, and had mentioned those special subjects in the report, to make it clear that they must be on no account omitted.

Mr. Cooper stated that the Apothecaries' Society of London required that all applicants for examination should hold a degree in Arts or undergo an examination equal to that degree. He knew that that requirement was conscientiously carried out. He underwent his studies sixty years ago, and he believed that if he now had to undergo the examination required by the Society at the present time he should be rejected. (Laughter, and "Vote.")

Dr. Stokes, in reply, explained, as had been stated by Dr. Storrar, that it was meant by the Committee that the subjects mentioned in the report should be *plus* the subjects included in the Arts examinations of the general educational bodies.

The amendment was carried.

Dr. Embleton moved, and Dr. Wood seconded, "That the standing order be suspended, and that the Council sit till seven o'clock." The business of the session might probably be concluded by that hour.

The President expressed an opinion that there was more business remaining than could be done in an hour.

Dr. Acland thought that one hour extra would be valuable, even if the Council had to sit again on Monday.

The motion was lost.

The Executive Committee was then balloted for, four members being required in addition to the President. The four members elected were Mr. Arnott, Dr. Acland, Dr. Paget, and Dr. Sharpey.

The Council then adjourned.

MONDAY, APRIL 17.

(ELEVENTH DAY.)

The Council met at two o'clock.

Dr. Acland submitted the following Report of the Committee on the Pharmacy Bills:—

"*Report.*

"1. The Committee appointed on April 7, 1865, to report whether the Medical Council is charged under the Medical Act with any duty in relation to Medical and Surgical practice by chemists and druggists, and also to consider and report on the two Bills relating to pharmacy now before Parliament, report as follows:—

"'2. In 1864 the General Medical Council represented to Her Majesty's Government the necessity of regulating by statute the practice of pharmacy by chemists and druggists throughout the kingdom. The Committee are of opinion that this necessity continues as cogent as ever; and that the Council ought to encourage and support any approved measure for effecting such legislation.

"'3. Two Bills for the purpose have been introduced into the House of Commons during the present Session—one promoted by the Pharmaceutical Society, the other by chemists and druggists not belonging to that body. The Bill of the latter is confined to England and Wales; that of the former to Great Britain.

"'4. After carefully considering both Bills, the Committee are of opinion that the preferable mode of legislation is that which adopts the Pharmaceutical Society as a basis. They think the Bill promoted by the Society well fitted to attain various important objects, reasonable in its demands for powers and privileges, and liberal—perhaps even too much so—in its provisions for admitting into the Society other chemists and druggists now practising pharmacy.

"'5. The main objects of the Bill are to form a register of legally qualified pharmaceutic chemists; to prohibit the use of certain pharmaceutic titles by persons not on the register; to confine to those registered the privilege of executing the prescriptions of Medical Practitioners; but not to restrict the sale of medicines asked for in any other manner.

"'6. The Committee desire to bring before the Council certain defects which it appears to them necessary to correct before the Bill becomes law.

"'7. The Bill should be altered so as to apply to Ireland, as well as to England and Scotland. They are not aware that any state of things exists in Ireland to render the regulation of pharmacy by the State less necessary there than in Britain.

"'8. The Committee are of opinion that a clause should be inserted in any Pharmacy Bill, rendering it imperative on chemists and druggists to follow, in compounding prescriptions, the formularies of the British Pharmacopœia, unless otherwise directed by the prescriber.

"'9. The Committee consider that the promoters of the Bill, probably from a desire to disarm opposition, propose to admit, on too easy terms, into their Society, pharmaceutical chemists and druggists not now belonging to it. The proposal is to admit all who offer themselves for examination, or who produce a certificate from a qualified Medical Practitioner that they have been in the practice of dispensing medicines from the prescriptions of Medical men before January 1, 1866. The latter alternative implies a facility of entrance which will be apt to lead to abuse. The Committee recommend that no one should be admitted who was not in business prior to the passing of the Act, nor unless the certificate be signed on personal knowledge by two qualified Medical Practitioners.

"'10. The last important defect in the Bill which the Committee have to notice is that no adequate provision has been made towards preventing registered pharmaceutic chemists from converting themselves into unqualified Medical Practitioners.

"'11. Looking to the history of Medical practice in this country, the Committee see great danger to the interests of the public and of the Medical Profession from the body which will be constituted by the Bill, should it become an Act in its present shape. The General Medical Council, in carrying out the objects of the Medical Act, have raised, and, it is hoped, may further raise, the qualifications of legally-qualified Medical Practitioners. It is well known that many existing

chemists and druggists, both members of the Pharmaceutical Society and others, practise Medicine, although not qualified by law nor competent by education. To a limited extent this practice cannot be prevented. But the existence of it gives peculiar facilities and temptations to the pharmaceutic chemist to embark largely in irregular Medical practice as an unqualified Practitioner.

"'12. The Committee have considered whether the danger here indicated might not be averted by extending the jurisdiction of the General Medical Council, so as to include control over pharmaceutic chemists as well as over Practitioners in Medicine. But they believe such a plan to be, for the present at least, unadvisable and even impracticable.

"'13. By Clause 55 of the Medical Act, chemists and druggists are expressly exempted from the provisions of the Act, so far as the "selling, compounding, and dispensing medicines" is concerned. Nor is there any provision in the Act which gives the Medical Council any greater power to prevent chemists and druggists from practising Medicine than the Act enables the Council to exercise over all other unqualified persons. It is plain, therefore, that the Act did not contemplate the exercise by the Medical Council of any control over chemists and druggists; and the Committee consider that it would be unwise to seek to alter, in this respect, in any way the relations subsisting between the Medical Council and chemists and druggists.

"'14. The Committee have further considered whether the danger they have pointed out might be averted by some simple provision in the Pharmacy Bill. By Section 17 of the Bill of the Pharmaceutical Society, it is declared that—"Nothing in this Act contained shall extend, or be construed to extend, to lessen or prejudice, or in anywise to interfere with, any of the rights, privileges, and immunities heretofore vested in, and enjoyed by any duly-qualified Medical Practitioner." This clause sufficiently protects Medical Practitioners in such right of practising pharmacy as they have hitherto enjoyed, but it does not attempt to prevent pharmaceutic chemists from practising Medicine. Considering their peculiar temptations to practise it, however, some check seems desirable. The Committee suggest that this object may be attained, in some measure, were the following clause to be added to Section 17, viz., "or, to entitle any person registered under this Act to practise Medicine or Surgery, or any branch of Medicine or Surgery." The members of the pharmaceutic body would thus have constantly before them the sentiments of the Legislature as to the principles on which the Pharmacy Act was founded. The Committee have reason to believe that the Council of the present Pharmaceutical Society have every desire to discourage the practice of Medicine by its members. They, therefore, apprehend that no opposition would be made to the addition of such a clause.

"'15. The Committee recommend that the promoters of both Bills should be conferred with on behalf of the Medical Council, and that the above observations should be laid before the Secretary of State for the Home Department, the Chairman of the Select Committee, and the promoters of the two Bills.

"'Signed on behalf of the Committee,

"'HENRY W. ACLAND, *Chairman*.'"

Dr. WOOD said that the College of Surgeons of Edinburgh had the power to practise Anatomy, Surgery, and Pharmacy. He wished to know whether the Pharmacy Bill would override that power.

Dr. CHRISTISON said it certainly did not.

Dr. ACLAND moved that the Report be adopted.

The motion was seconded by Dr. PAGET.

Mr. RUMSEY said that he thought that the Committee had not been stringent enough as to the proposal in the bill for admitting into the Pharmaceutical Society chemists and druggists now practising pharmacy. The effect would be that a large number of ignorant persons would be admitted to the right to practise pharmacy. He considered such a measure would be a very dangerous one to the lives of the public. He believed that in neither of the bills relating to chemists and druggists, now before Parliament, there was any provision for admitting Government control over them.

Dr. ACLAND said that that was not the case.

Mr. RUMSEY read a series of resolutions which he intended to propose as emendations on the Report of the Committee on the Pharmacy Bills, but it being decided that the most convenient course of proceeding would be to deal with the Report clause by clause, Mr. Rumsey agreed to reserve his resolutions until the Council arrived at those portions of the Report to which the emendations referred. He said he could not help expressing his strong conviction that it would be almost impossible to get Government to pass a stringent measure for the purpose of restraining chemists and druggists from practising Medicine, unless Medical Practitioners were discouraged from practising pharmacy.

Dr. ACLAND moved, and Dr. PAGET seconded, the adoption of the first clause of the Report.

The motion was carried. Clauses 2 and 3 were also agreed to.

Dr. ACLAND then moved the adoption of the fourth clause.

Dr. PAGET seconded the motion.

Mr. RUMSEY moved as an amendment that the words after the word "privileges" be omitted.

Dr. CHRISTISON said he did not think there could be any material objection to the words.

Mr. SYME said that the words seemed to imply a general approval of the provision in question.

Dr. CORRIGAN suggested the insertion of the words "with the Pharmacy Act of 1852" after the words "Pharmaceutical Society."

After some discussion,

Dr. ACLAND agreed to embody the suggestions in his motion.

The clause was then passed in the following amended form:—"After carefully considering both Bills, the Committee are of opinion that the preferable mode of legislation is that which adopts the Pharmaceutical Society with the Pharmacy Act of 1852 as a basis. They think the Bill promoted by the Society well fitted to attain various important objects, and reasonable in its demands for powers and privileges."

The adoption of Clause 5 was moved by Dr. ACLAND, and seconded by Dr. PAGET.

Dr. WOOD objected to the clause. He said that in many parts of Scotland the only dispensers of medicines were the duly qualified Medical Practitioners.

The PRESIDENT said that the clause was merely a statement of the main objects of the Bill.

Dr. WOOD said that it was not the fact that one of the main objects of the Bill was to restrain the dispensing of medicines by qualified Medical men.

Dr. CORRIGAN proposed the insertion of the words "subject to the provision hereinafter named," after the words "Medical Practitioners."

Dr. AQUILLA SMITH seconded the amendment.

The amendment was put, and carried, and then became a substantive motion.

Dr. WOOD moved, that after the words "Medical Practitioners," the words "subject to the provision hereinafter contained, which preserves the rights and privileges of incorporations duly entitled to qualify for the practice of pharmacy, and of duly qualified Medical Practitioners generally."

Dr. LEET seconded the alteration.

The amendment was lost.

The substantive motion was then carried.

Dr. ACLAND moved the adoption of Clause 6.

The motion was seconded by Dr. PAGET, and carried.

Dr. ACLAND moved the adoption of Clause 7.

Dr. PAGET seconded the motion.

Dr. LEET said he was taken by surprise by the statement. He flattered himself that the state of things in Ireland with regard to Pharmacy was perfect. (Laughter.) Every provision contained in the Bill was carried out in Ireland. Those who practised Pharmacy were qualified Apothecaries, and, therefore, there could be no injury arising from their practising it. The control of Pharmacy lay with the Apothecaries' Company. They would oppose the provision for the Bill to apply to Ireland. He moved as an amendment "That the Bill should be so altered that the provision should not apply to Ireland."

Mr. SYME seconded the amendment.

Dr. CORRIGAN opposed the amendment. He said that one of his reasons for doing so was that the Apothecaries' Society of Ireland had abdicated its functions, and in their last prospectus they had stated that their license was a full qualification to practise Medicine. They required that no one should practise Medicine who had not passed their examination. That examination included subjects which it was unreasonable to expect an acquaintance with on the part of the dispensers of prescriptions.

Dr. HARGRAVE expressed surprise that Dr. Leet should have moved an amendment. The Act was very much required in Ireland.

The amendment was withdrawn.

Dr. CHRISTISON said that in order for a pharmaceutical

business to be properly carried on the principal should be in it as much as possible. That could not be if he were allowed to practise Medicine.

The motion was carried.

Dr. Acland moved the adoption of Clause 8 of the Report.

Dr. Paget seconded the motion, and it was carried unanimously.

Dr. Acland moved the adoption of Clause 9.

Dr. Paget seconded the motion.

Mr. Rumsey objected to the clause. He said that it would tend to authorise complicity between the inferior class of Medical Practitioners and certain chemists and druggists. He moved as an amendment that the following words should be substituted for the last sentence of the clause:—"The Committee are of opinion that more satisfactory evidence of qualification should be required."

Dr. Christison said that the Council ought to express to the promoters of the Bill what sort of evidence would be satisfactory to them.

Mr. Rumsey said that it was the place of the promoters of the Bill to suggest the kind of evidence which should be given.

Mr. Arnott said that, in his opinion, chemists and druggists should be admitted only under a proper examination.

Dr. Corrigan suggested that the clause should end at the words "passing of the Act."

Dr. Storrar said that unless there was something more than the mere title of "pharmaceutical chemist" to distinguish the first members of the Society from other chemists and druggists, there would not be a sufficient inducement to chemists now in business to pay a sum of money to undergo an examination for admission into the Society.

The amendment proposed by Mr. Rumsey was seconded by Mr. Hargrave, and carried.

Dr. Acland moved that Clause 10 of the Report be adopted.

Dr. Paget seconded the motion.

The motion was carried *nem. con.*

Dr. Acland moved the adoption of Clause 11. He called attention to the fact that by the Bill a qualified Medical Practitioner could not keep a chemist's shop. He did not see the reason for that restriction.

Dr. Paget seconded the motion.

Dr. Christison moved, "That after the words 'Medical Practitioner,' there should be inserted the words, 'but their labours will be in vain should the creation of a new race of unqualified Medical Practitioners be inadvertently encouraged by an Act of Parliament."

Dr. Wood seconded the amendment.

The clause as amended was passed.

Dr. Acland moved the adoption of Clause 12 of the Report.

Dr. Paget seconded the motion.

Mr. Rumsey moved, as an amendment, "That the last part of paragraph 12, from the words 'Medical Council,' be as follows: 'so as to include some control over chemists and druggists, with proper representation in the Council, securing thereby the consent of the Council to all educational measures suggested for persons who are to be publicly licensed as dispensers of medicine and of the prescriptions of Medical Practitioners. But after deliberation they believe their plans to be at present impracticable.'"

Mr. Hargrave seconded the amendment.

Dr. Aquilla Smith asked whether Mr. Rumsey implied that the Pharmaceutical Society should be represented at the Council.

Mr. Rumsey said he did not propose anything of the sort.

Dr. Aquilla Smith said the amendment seemed to contemplate it. As that was the case he should object to it.

Mr. Syme said he did not agree with the amendment.

Mr. Rumsey said he must adhere to the proposal he had made.

Mr. Arnott said he thought the amendment would do harm rather than good.

Dr. Acland said that when the Council was constituted seven years ago there seemed to be a disposition on the part of the Government to refer to the Council on all questions connected with Medical subjects. It was remarkable, however, that no question had been referred to them.

The amendment was then put to the meeting, and negatived.

Dr. Corrigan moved a further amendment. He said it was not desirable to tell the Government that any further control which they might feel disposed to commit to them was "unadvisable and impracticable." He, therefore, proposed that the last sentence of the clause should be, "But they are of opinion that such a plan is at present attended with difficulties."

Dr. Christison said that that was a very mild form of expression. They had never asked any good thing of the Legislature which was not attended with difficulties.

Dr. Apjohn seconded the amendment.

The amendment was carried, and then became a substantive motion.

Dr. Wood moved, as an amendment, that the whole clause be left out.

Mr. Cooper seconded the omission of the clause.

The amendment was lost.

The substantive motion was then carried *nem. con.*

Dr. Acland moved that Clause 13 of the report be adopted.

Dr. Paget seconded the motion.

Mr. Rumsey objected to the last sentence of the clause, on the ground that it referred to "relations subsisting between the Medical Council and chemists and druggists," while, in fact, no such relations existed. He therefore moved that the concluding sentence be as follows, instead of as at present standing, namely:—"And the Committee recommend that the Medical Council, and the Pharmaceutical Society, respectively, should use all reasonable means in their power to ensure competent skill in their own departments on the part of all persons included on their registers, and, as far as is consistent with the necessities of the public, to restrict each to that sphere for which they are qualified, and for which they have been licensed."

Dr. Leet seconded the amendment.

It was then submitted to the meeting and lost.

Dr. Aquilla Smith proposed the insertion of the words "on this occasion" after the word "otherwise" in the last sentence.

Mr. Cooper denied that there were relations subsisting between the Council and chemists and druggists.

Dr. Christison maintained that there were relations existing between them.

After some discussion the clause was placed in the following altered form:—"By Clause 55 of the Medical Act, chemists and druggists are expressly exempted from the provisions of the Act, so far as 'selling, compounding, and dispensing medicines' is concerned. Nor is there any provision in the Act which gives the Medical Council any greater power to prevent chemists and druggists from practising Medicine than the Act enables the Council to exercise over all other unqualified persons. It is plain, therefore, that the Act did not contemplate the exercise by the Medical Council of any control over chemists and druggists; and the Committee consider that it would be unwise to seek to alter the existing relations between the Medical Council and chemists and druggists."

Dr. Acland proposed that Clause 14 should be adopted.

Dr. Paget seconded the motion.

Mr. Rumsey said he agreed with the whole of the clause.

The clause was unanimously agreed to.

Mr. Rumsey then moved that the following addition be made to the report, after Clause 14:—"The Committee call attention to the fact that the Bill proposes to confer on the whole body of chemists and druggists the right of dispensing and selling medicines without any control on the part of the Government. The Medical Profession has not been so dealt with in the Medical Act. The Medical Council is properly restricted in its action by the Medical Corporations and Universities, and is also controlled by the Privy Council. They submit that the whole profession of pharmacy ought to be subjected to some control."

Mr. Hargrave seconded the motion.

Dr. Christison asked whether the clause proposed by Mr. Rumsey was to apply to pharmaceutical chemists only, or over the whole body of chemists and druggists?

Mr. Rumsey said he meant it to apply to all. He would insert the words "except such as is exercised by the Pharmacy Act over registered pharmaceutical chemists," after the word "Government," if that would secure Dr. Christison's support.

Dr. Christison said he should be most willing to accede to the clause with that alteration.

The additional clause, as altered, was agreed to unanimously.

The last clause of the Report was then adopted with the omission of the words "and the promoters of the two Bills" at the end of the clause.

It was agreed that the Report as amended be entered on the minutes.

Dr. Embleton moved the adoption of the following Report of the Committee on returns received from the bodies in Schedule (A) and the registers of Medical students.

"*Report.*

"The Committee on the Returns from the Bodies in Schedule (A), according to the Recommendation 7, Section iv. of the Report of the Select Committee on Education, May 5, 1864 (previously Recommendation 23, 1862), and on the Register of Medical Students, present the following tables, carefully deduced from the Returns placed before them.

"It will be observed in the table of the Register of Students that no Return has been received from the Registrar of the Branch Council for Scotland.

"The number of students admitted to Professional study before having passed a Preliminary Examination in Arts is now considerably less than in previous years, being 105 out of a total of 1315 students registered in England and Ireland.

"D. EMBLETON, Chairman."

Form of Return according to the Recommendation 7, Sect. 4, of the Report of the Select Committee on Education, May 5, 1864 (previously Recommendation No. 23) of the General Medical Council, 1862.

Mr. HARGRAVE seconded the motion, and it was agreed to.

Dr. SHARPEY moved the adoption of the following Report of the Finance Committee:—

"*Report.*

"The Finance Committee beg leave to present, in the table subjoined, a statement of the estimated and actual income and expenditure of the year 1864; also an estimate of the income from ordinary sources and the ordinary expenditure, as far as the Committee are able to judge, for the year 1865.

"A statement of the receipts and disbursements on account of the British Pharmacopœia since the date of the account presented last year is given up to January 5, 1865.

"With reference to the audit of the accounts of the General Council, it appears that the Executive Committee has from its first appointment been charged with the duty of examining these accounts, and that the appointment of auditors, ordered by the General Council by resolution passed on May 7, 1864, on the recommendation of the Finance Committee, is unnecessary. Accordingly the Finance Committee now recommend that the said resolution be rescinded; but the Committee are of opinion that it should be recommended to the Branch Council of England to appoint auditors of their annual accounts, in conformity with the practice followed by the Branch Councils of Scotland and Ireland.

William Sharpey, Chairman.

He remarked that there was a deficiency of £59 11s. 6½d. in the income of last year; but that need not be regarded with any alarm, because there was an outlay of about £600 last year which might be regarded as extra expenses which would not be likely to occur again, and the actual income of last year was considerably in advance of the estimate for the year.

Dr. Storrar seconded the adoption of the report.

Dr. Wood said that he believed the actual expenditure of next year would be very much in excess of the estimated expenditure, because a system of trial visitations has been agreed on.

Dr. Sharpey moved, "That the resolution adopted on the 7th of May, 1864, directing that two members of the Executive Committee be annually appointed to audit the accounts of the Council, be rescinded, and that the standing order, Sect. vi., No. 14, founded thereon, be repealed."

Dr. Storrar seconded the motion, and it was carried unanimously.

Dr. Paget moved, "That it be delegated to the Executive Committee, in case of the death or incapacity from illness of the Registrar, when the General Council is not in session, to appoint a person to perform temporarily the duties of Registrar." He said the sole object of the motion was to save the expense of a meeting of the General Council in case of the event referred to—one which, he was sure, they would very much deplore.

The motion was seconded by Mr. Arnott, and carried unanimously.

Dr. Corrigan, according to notice, brought before the Council the correspondence between the War Office and King and Queen's College of Physicians, relating to insertion of Medical titles in the *Army List*, with resolution referring thereto of General Medical Council of May 6th, 1864. He said he had caused copies of the correspondence to be sent to all the members of the Council. It had come to the knowledge of the King and Queen's College of Physicians, Ireland, that the Surgeons and Assistant-Surgeons of the army who had obtained degrees in Medicine from any University had M.D. appended to their names in the *Army List*, while those who had obtained diplomas from a College of Physicians had no Medical affix to their names. Some correspondence had taken place between the College of Physicians, Ireland, and the Director-General of the Army Medical Department. On May 6, 1864, he (Dr. Corrigan) brought the subject before the Medical Council, and the following resolution was passed:—"That it is the opinion of the General Medical Council that it would not be advisable to insert the letters 'Phys.;' but that it is the opinion of the General Medical Council that the several Medical qualification which Army Surgeons possess, as in the Medical Register, might be entered after their names in the *Army List*." On July 29, 1864, the following letter was received by the Registrar of the College of Physicians:—

"29th July, 1864.

"Sir,—I am directed by the Secretary of State for War to acknowledge the receipt of your letter of the 14th March last, in which, on behalf of the President and Fellows of King and Queen's College of Physicians in Ireland, you renew the recommendation that the word 'Physician' should be inserted in the 'Army List' after the names of such army Surgeons as may possess the qualification of that College.

"In reply, I am to acquaint you that Earl de Grey, having consulted the General Medical Council, finds that the opinion of that body is not favourable to the proposal; and his Lordship, after fully considering the subject, does not think it desirable to make any change in the existing practice.

"I have the honour to be, Sir, your obedient servant,

"L. Atthill, Esq., M.D." "Douglas Galton."

He (Dr. Corrigan) should therefore now move—"That the correspondence, as now submitted, between the Director-General of the Army Medical Department, the Secretary of State for War, the General Medical Council, and the King and Queen's College of Physicians in Ireland, be inserted in the Minutes, and that the Registrar be requested to write to the Secretary of State for War, enclosing a printed copy of the above, and explaining to his Lordship that the General Medical Council are of opinion, for the reasons stated in the correspondence mentioned above, that initials, indicating the several Medical qualifications which Army Surgeons possess, should be inserted after their names without distinction or preference to one degree or license over another, each Surgeon, when he possesses more than one Medical qualification, having, however, only one Medical qualification appended to his name."

Dr. Apjohn seconded the motion.

On being submitted to the meeting the motion was carried unanimously.

It was resolved that the standing order be suspended, and that the Council sit till seven o'clock.

Dr. Corrigan then moved—"That a letter be addressed to the Director-General of the Army Medical Department, requesting that he would direct the future returns from the Army Service to have columns attached similar to those in the Navy return, specifying in similar detail the number of candidates, and the heads under which the candidate failed to answer."

The motion was seconded by Dr. Apjohn, and carried unanimously.

Dr. Acland moved—"That a Committee of not more than five, and the President, be appointed to consider and report to the Council what are the means best calculated to expedite the business of the General Council; and what are the several objects on which the funds of the Council may, consistently with the spirit of the Medical Act, be expended."

Dr. Stokes seconded the motion.

After a short discussion, the motion was negatived.

Dr. Embleton moved—"That the Report of the Committee appointed to arrange and digest the recommendations as to education and examination agreed to during the present Session by the General Committee on Education to be con-

sidered be adopted, and that the recommendations therein embodied be printed, under the direction of the Executive Committee, in a separate form, circulated among the members of the Council, and sent to each of the licensing bodies."

The motion was seconded by Dr. LEET, and carried.

Dr. CORRIGAN moved, "That this Council in recommending in their resolution of April 6, 1865, the visitation of examinations by the Branch Councils, or members of such Councils deputed by them, did not contemplate payment for such duties."

Dr. APJOHN seconded the motion.

The Council divided, and the motion was carried by 7 against 4.

Dr. ANDREW WOOD moved, "That the powers and duties delegated to the Executive Committee in accordance with Sect. ix. of the Medical Act (see Standing Orders, Sect. vi.), shall be vested in the Committee until the next meeting of the General Medical Council; and that, in addition, it be delegated to them to communicate with the Government in order to carry out the views of the Council in regard to the bill for amending the Medical Acts."

Dr. EMBLETON seconded the motion.

The following amendment was moved by Dr. APJOHN, and seconded by Dr. CORRIGAN:—"That the words 'in order to carry out the views of the Council,' be omitted, and the following sentence added to the foregoing resolution: 'it being understood, however, that no concession shall be made by the Committee inconsistent with the amended Bill proposed by the amended Council.'"

The amendment was carried, and having been put as a substantive motion, was also carried.

Dr. CORRIGAN moved—"That a third volume be published, without delay, of the proceedings of the past and present meetings of the General Medical Council, with full index attached."

The motion was seconded by Dr. APJOHN, and agreed to.

Votes of thanks were cordially passed to Dr. Sharpey and Dr. Quain, Treasurers, to the Royal College of Physicians for the use of their premises, to Dr. Andrew Wood for his valuable services as Chairman of the Business Committee, and to the President for his courteous and efficient services.

The Session then terminated.

The following were the communications received from the Directors-General of the Army and Navy Medical Departments, relative to the examinations of candidates for Medical commissions:—

"Army Medical Department, 20th June, 1864.

"Sir,—In acknowledging the receipt of your letter, dated 27th ultimo, conveying the request of the General Council of Medical Registration to be furnished annually with information on the following points, viz.:—

"'(*a*) The total number of candidates for Medical commissions who have presented themselves for examination;'

"'(*b*) The number of those who passed and of those who did not pass the examinations of the Board, distinguishing the number of successful and unsuccessful candidates under the respective heads of the several licensing bodies mentioned in Schedule (A) to the Medical Act, and specifying their qualifications, Medical and Surgical, and whether they had failed in Medicine or Surgery;'

"'(*c*) The general nature and scope of the examination conducted by the Board, together with a list of the questions proposed by the examiners;'

"I have the honour to inform you, in reply, that Lord de Grey has been pleased to accede to the wish of the General Council, and I shall be obliged by your signifying from what date the information is required.

"I have the honour to be, Sir,

"Your most obedient humble Servant,

"(Signed) "J. B. GIBSON, Director-General.

"F. Hawkins, Esq., Registrar,

"General Council of Medical Education,

"32, Soho-square, W."

"Army Medical Department, 23rd February, 1865.

"Sir,—With reference to your letters dated 27th May and 24th June last, the former communicating a resolution passed at a late Session of the General Council of Medical Education, that certain information should be furnished by this Department annually, in regard to the number of candidates who have presented themselves for examination, and specifying certain points on which the Council request to be informed, I have the honour to forward a statement on the subject, with a list of the questions proposed by the Examiners, and to observe, in regard to the general nature and scope of the examination, that the enclosed copy of the regulations for the admission of candidates into the Medical Department of Her Majesty's army (section 5, page 8), (b) will probably supply the information which the Council are desirous to obtain.

"I have the honour to be, Sir,

"Your most obedient humble Servant,

"(Signed) J. B. GIBSON, Director-General.

"Fras. Hawkins, Registrar,

"General Council of Medical Education.

"32, Soho-square."

Statement of the Degrees, Diplomas, and Licences of the Candidates for Commissions in the Medical Department of the Army, who during the year 1864 have presented themselves for Examination, showing the number that passed and did not pass, also distinguishing the Qualifications, both Medical and Surgical, under the heads of the several Licensing Bodies, and specifying whether the Candidates failed in Medicine or Surgery.

(b) *Subjects of Examination.*—On producing the foregoing qualifications the candidate will be examined by the Examining Board in the following subjects:—Anatomy and Physiology; Surgery; Medicine, including Therapeutics; the Diseases of Women and Children; Chemistry and Pharmacy; and a practical knowledge of drugs. (The examination in Medicine and Surgery will be in part practical, and will include operations on the dead body, the application of Surgical apparatus, and the examination of Medical and Surgical patients at the bedside.) The eligibility of each candidate for the Army Medical Service will be determined by the result of the examinations in these subjects only. Candidates who desire it will be examined in Comparative Anatomy, Zoology, and Botany, with special reference to Materia Medica; and the number of marks gained in these subjects will be added to the total number of marks obtained in the obligatory part of the examination by candidates who shall have been found qualified for admission, and whose position on the list of successful competitors will thus be improved in proportion to

Table showing the Qualifications, according to Schedule (A), of the Different Candidates who were Examined for Medical Commissions in the Royal Navy in 1864, *with the Results of the Examinations.*

28	..	..	..	1	..	..	..	1	..	..	..	..	..	..	..	..	Rejected	Anatomy bad; Surgery and Practice of Medicine indifferent.
29	..	1	..	..	..	..	1	..	..	..	..	..	..	..	..	..	Passed	Anatomy good; Surgery and Practice of Medicine fair; other branches fair.
30	..	1	..	..	1	..	..	..	..	..	..	..	..	..	..	..	Rejected	Anatomy indifferent; Surgery bad.
31	..	1	..	..	..	1	..	..	..	..	..	..	..	..	..	..	Do.	Utterly ignorant of the Latin language.
32	..	..	..	..	1	..	..	..	..	..	..	..	..	..	..	1	Passed	Anatomy indifferent; Surgery, Practice of Medicine, and other branches only fair.
33	..	1	..	..	1	..	..	..	1	..	..	..	..	..	..	..	Rejected	Anatomy only fair; Surgery bad; Practice of Medicine indifferent.
34	..	1	..	..	1	..	..	..	..	..	..	..	..	..	..	..	Passed	Anatomy and Practice of Medicine good; Surgery only fair; other branches fair.
35	..	..	..	..	..	1	..	..	..	..	..	..	..	..	..	..	Do.	Anatomy good; Surgery fair; Practice of Medicine indifferent; other branches fair.
36	..	..	..	1	..	..	..	1	..	..	..	..	..	..	..	..	Rejected / Passed	1st Examination. Anatomy and Surgery bad. 1865, 2nd Examination. Passed a good examination in all branches.
37	..	..	..	..	..	..	..	..	..	..	..	1	..	1	..	..	Passed	Anatomy Surgery, and Practice of Medicine good; other branches fair.
38	..	..	..	1	..	..	..	..	..	..	..	..	..	..	..	..	Rejected	Latin and Anatomy bad.
39	..	..	..	1	..	..	..	1	..	..	..	..	..	..	..	..	Do.	Anatomy indifferent; Surgery only fair; other branches and Latin bad.
40	..	..	..	..	1	..	..	..	..	..	1	..	..	..	..	..	Do.	Anatomy indifferent; Surgery bad; and other branches bad.
41	..	..	..	1	..	..	..	..	..	..	..	..	..	..	1	..	Passed	2nd Examination. Anatomy, Surgery, Materia Medica, and Botany good; other branches fair.
42	..	..	..	1	..	..	..	1	..	..	..	..	..	..	..	..	Rejected	Latin, Anatomy, and Surgery bad.
43	..	..	..	1	..	..	..	..	..	..	1	..	..	..	..	..	Passed	A good examination in all branches.
44	..	..	..	..	..	..	..	..	..	..	..	1	..	1	..	..	Do.	Anatomy and Practice of Medicine good; Surgery only fair; other branches fair.
45	..	..	..	..	1	..	..	..	..	..	..	..	..	..	..	..	Rejected	Latin and Anatomy and Surgery indifferent; Materia Medica bad.
46	..	..	..	1	..	..	..	1	..	..	..	..	..	..	..	..	Passed	A good examination in all branches.
47	..	..	..	1	..	..	..	1	..	..	..	..	..	..	..	..	Do.	A good examination in all branches, excepting Practice of Medicine, which was only fair; Latin indifferent.
48	..	..	..	..	..	..	1	..	1	..	..	..	..	..	..	..	Rejected	Utterly ignorant of the Latin language.

Note.—Several of the Candidates possessed qualifications which are not included in Schedule (A).

"Admiralty, W.C., 13th March, 1865.

"Sir,—With reference to your letter of the 27th of May last, I have the honour to forward, for the information of the General Council of Medical Education and Registration of the United Kingdom, a Report from the Board of Examiners on the examinations of candidates for Medical commissions in the Royal Navy during the year 1864.

"I have the honour to be, Sir,

"Your very humble Servant,

"(Signed) A. Bryson, Director-General.

"Dr. F. Hawkins, Registrar of the General Council
"Medical Education and Registration of the
"United Kingdom, 32, Soho-square."

their knowledge of these branches of science. The subjects for this part of the examination will be taken from the following books:—(1) "Animal Kingdom," by W. S. Dallas, F.L.S; (2) "Outlines of the Structure and Functions of the Animal Kingdom," by Rymer Jones; or "Cours Elémentaire d'Histoire Naturelle," par Milne Edwards; (3) Lindley's "School Botany;" Lindley's "Medical and Economic Botany;" Henfrey's "Elementary Course of Botany." Candidates who desire it may also be examined in the Elements of Physics and in Physical Geography. The following books are recommended for this purpose:—(1) "Elements of Natural Philosophy," by Golding Bird and C. Brooks; (2) "Physical Geography," by Mrs. Sommerville.

"Admiralty, Somerset House, 6th March, 1865.

"Sir,—We have the honour to submit, for the information of the General Council of Medical Education and Registration of the United Kingdom, the following Report on the examinations of candidates for Medical commissions in the Royal Navy during the year 1864:—

"1. The total number of candidates who presented themselves for examination during the year was forty-nine; of these twenty-one were rejected, having failed to satisfy us as to their Professional knowledge, and one was found to be physically unfit for the service.

"2. The accompanying table supplies the information required by the Medical Council with reference to the qualifications of the candidates, and the points on which they were chiefly deficient.

"3. The examination is *vivâ voce*, but each candidate is furnished with a paper containing a question or questions upon subjects of a Professional nature, to which he is expected to reply in writing; and previous to the oral examination, he is required to translate a paragraph from a Latin author.

"4. In its scope the examination embraces all the ordinary subjects of Professional study—viz., Anatomy, Surgery, Practice of Medicine, Midwifery, Materia Medica, Chemistry, and Botany.

"5. Being a *vivâ voce* examination, and the questions being left to the judgment of each individual examiner, it is not possible to furnish a return of those actually proposed, but appended hereto is a list of the subjects on which the candidates have at different times been examined, and which, put in the interrogative form, gives a fair idea of the general character of the questions. The Council is, doubtless, fully aware that in such examinations the same question requires to be put in a variety of forms, to meet the various comprehensions to which they are addressed.

"6. We regret to have to report that in a very large number of cases indeed the candidates displayed a lamentable ignorance of Latin; some were scarcely able to translate the Pharmacopœia, and but few possessed a useful knowledge of the language. From the nature of the excuse most frequently made by them, it appears to us that very many had acquired only a sufficient acquaintance with the language to enable them to pass the preliminary examination of other Boards, and that they had then thrown it aside as altogether useless.

"7. We have also to regret that so important a branch of Professional education as Operative Surgery on the dead body should so rarely enter into the curriculum of study of those who come before us; and we desire to express a strong opinion that no Surgical diploma should be attainable, without satisfactory evidence being produced that the principal operations in Surgery had been performed on the dead body under a qualified teacher.

"We have the honour to be, Sir,

"Your very humble Servants,

"E. Hilditch, M.D., Inspector-General,

"J. W. Salmon, Deputy Inspector-General,

"Alex. E. Mackay, M.D., Deputy Inspector-General.

"Dr. Bryson, F.R.S., &c., &c., &c., Director-General."

The Brighton Review.—The only serious casualty that occurred during the day was one which happened to Joseph Lambert, of Poplar, gunner in the Tower Hamlets Artillery. He was acting with the men of the 1st Middlesex Artillery, when, in trying to clear the wheel of an ordinary carriage which was passing close to the cannon, he fell and one of the wheels of the gun passed over his thigh, not breaking, but bruising it very badly. The poor fellow was at once conveyed in one of the Netley ambulances from the field to the temporary hospital fitted up in case of accidents at the review, where he was attended to by Brigade-Surgeon Burrows, of the 1st Sussex Artillery, assisted by the Doctor of the Civil Service Corps. This little Hospital is very neat and airy. It contains four beds, an operating table, and all the appliances necessary in Surgical cases of emergency. In addition there were four accident beds provided at Bevendean Farm, and a ward to accommodate thirty or forty cases was secured in the Industrial Schools. Brigade-Surgeon Burrows had charge of these arrangements, which were altogether exclusive of those in the general Hospital of the town. Two of the men of the Carbineers had falls from their horses. One soon recovered from the shock he received in falling, and was able to mount again. The horse trampled on the knee of the other soldier and hurt it, but even in this case the injury is believed not to be a serious one.

FOREIGN CORRESPONDENCE.

GERMANY.

Berlin, April 9.

As epidemic cerebro-spinal meningitis continues to be one of the most prominent subjects of the day, I begin with mentioning the symptoms and post-mortem appearances of one of the cases observed by Dr. Frentzel in the barracks of the Alexander Regiment, and which will be sufficient to prove that this disease is totally different from typhus, with which it has by some recent writers been confounded. J. M., aged 20, previously in good health, had rigors one night, and complained of headache. He vomited a mucous liquid once. In the morning he was almost unconscious, and did not answer questions. The head was drawn backwards, the muscles of the neck very rigid, and slight pressure on the nape of the neck, especially near the vertebræ, made him scream. The abdominal muscles were also rigid, and pressure on the parietes was painful. The patient lay on the side or on the stomach, but not on the back. Mouth firmly closed, considerable force being necessary to open it in order to see the tongue. Roseola over the whole surface of the body; but this disappeared the next day. Chest healthy; no tumour of the spleen; pulse 75 in the morning—100 in the evening; temperature 103·6; number of inspirations, 30; pulse next morning, 132—in the evening, 92. On the third day, the pupils appeared very much contracted, and did not act against light. The patient, who had been delirious during part of the previous day and night, became now very quiet and comatose. There was opisthotonus, and great sensitiveness of the back. On the fourth day, there appeared inflammation of the orbit, prominence of the eyeball, and œdema of the conjunctiva. The next day there was a bloody motion and bleeding from the nose. On the morning of the sixth day death ensued. The autopsy was made thirty-three hours after death, the temperature being then 55°. Livid spots along the back and the extremities; muscles of the back very dark. The dura mater of the spinal cord generally pale; the veins considerably filled on its posterior surface. It had a yellowish colour in the lower parts of the lumbar portion; and the pia here contained a considerable quantity of fluid, pale, yellow pus. The quantity of pus in the pia diminished towards the upper part of the spine. In the cervical region there was no pus at all. About the seventh cervical vertebra the veins were more filled than usual. Purulent infiltration extended below on both sides, from the cord to the posterior roots of nerves, which in their course in the vertebral canal were completely enveloped by pus. On the *anterior* surface of the spinal cord the internal aspect of the dura was normal. In the lumbar portion of the pia there was considerable purulent infiltration; in the dorsal portion this was only seen in a few places; the cervical portion was normal. Cervical portion of the cord normal; in dorsal portion the white matter was rather moist; at the posterior horns pretty extensive injection of blood-vessels; the grey matter of lumbar portion was extensively reddened. *Skull* large; top rather thin; diploe full of blood; dura hyperæmic; numerous soft coagula in sinus longitudinalis; inner surface of dura dry; pia rather dry on the gyri, while the large veins in the sulci are filled with a great deal of dark blood; pia there being œdematous, and infiltrated with pus. Pus most considerable on the left side close to the median line, but also on the right side, especially in the anterior portions. Pacchionian granulations likewise filled with pus. Extensive purulent infiltration on the basis cerebri, more especially at the infundibulum and the anterior portion of the pons. Both optic tracts thickly covered with pus; posteriorly the pus follows the course of the basilar artery; is very thick on the vermis inferior of cerebellum. Lateral ventricles rather wide, contain a yellowish turbid liquid. Velum choroides thickened, contains a yellow mass which cannot be separated, but is in the tissue itself. Brain matter very flabby; vessels of white matter congested. Grey matter dark and extensively reddened. Near the left corpus striatum, at the nucleus lentiformis, numerous extravasations of blood. Fourth ventricle wide. Between the lower surface of the pons and the aqueduct of Sylvius a fissure filled with fresh blood. Extensive purulent infiltration of left orbita, but no changes in periosteum, muscles, or retina. Sinuses at the base of the brain contain much dark and nearly coagulated blood. The appearances in the other organs did not show anything worth mentioning.

Latest advices from St. Petersburg mention that the epidemic of recurrent or relapsing fever continues, and that three different forms of it may now be distinguished. The worst form is "the cyanotic," which speedily ends in death like asphyctic cholera, but has only been observed in about a dozen cases. The "simple form" has been described in my last letter; the third form is the "bilious" one. In this there is icterus from the commencement, vomiting of bile, delirium, and great prostration. Pulse and temperature fall below the standard, the tongue gets dry, there is a collapsus faciei, and other ominous symptoms; yet the patients often recover, although convalescence is very protracted. Large doses of quinine, which were given at first, have now been abandoned, as it seems that the patients get on better without such medication.

(To be continued.)

OBITUARY.

DR. EDWIN E. DAY.

Last week we announced the death of this amiable young Physician, in his 30th year, after a short, but painful illness. He was the only son of Mr. Day, who for many years enjoyed an extensive practice at Acton, in Middlesex, and was educated first in the School of King's College, and afterwards, at the proper age, in the Medical School of that Institution, where he gained the gold medal for general proficiency in Professional knowledge, as well as the special prizes given at King's College for correct conduct and religious knowledge. After passing the Hall and College, he succeeded his father as general Practitioner at Acton; but soon found that this place afforded no sufficient scope for his ambition or his activity. So he removed to London, determined to try his fortune as a Physician-Accoucheur, and obtained first an obstetric appointment at King's College Hospital, and then one or more of those dreary hopeless opportunities of drudgery, unpaid and unthanked, in the shape of the Physicianship to the Farringdon, and to the St. George's and St. James's Dispensaries. Thus his time and strength were expended in the study of disease amongst the destitute or dissolute poor, and in acquiring the experience and popularity which might have been hoped to bear fruit hereafter. He also worked hard at obstetric investigations, contributed several papers to the *Transactions* of the Obstetrical Society, and was engaged to read a paper at the Medical Society of London, almost on the day of his death. But his constitution was little adapted for such toil in the murky atmosphere of out-patient rooms. Stout and muscularly strong though he were, there was often a languor and air of relaxation and debility about him, and, as he said on his death-bed, he never fancied that he possessed the same energy as other men of his age, and always had a presentiment that he should not live to be thirty. At last, on March 23, after assisting at the post-mortem examination of some puerperal cases in King's College Hospital, he took to his bed with erysipelas of the head and face. This disappeared in a very few days, and was succeeded by acute rheumatism; and this induced pericarditis, to which he succumbed on April 7, after many days of obstinate, but hopeless struggle for breath. Throughout his illness there was the most marked depression of mind and body, and utter absence of all relish for nourishment; but the intellect was marvellously acute; the sufferer noticed every minute circumstance in his own case, and well knew its bearing on his chances of recovery; and he exhibited the most manly fortitude, and met the great change impending over him with the resignation and devotion of a true Christian. He was buried in the family vault at Acton, amidst the tears of the whole poor population, to whom he had endeared himself by his patient and considerate kindness whilst he was in practice there. Dr. Day, if he had been content with the hard work and narrow income of a country Practitioner in a not very wealthy neighbourhood, might have lived to a good age in pure air. As it is, he is one of a class of little-heeded martyrs to foul air and gratuitous attendance on the poor. The officious philanthropists who get up Dispensaries give their annual guinea; the Medical officers too often give their lives.

Dr. William Frederick Mackenzie, whose early death we announced last week, was born in New South Wales. He received his Professional education at University College School and Hospital, where he distinguished himself greatly as a student, and finally received the honour of being elected Fellow and Member of Council of the College. He was a member of the University of London, and took honours at the M.D. examination, 1841, obtaining the gold medal for Medicine, and a certificate of special proficiency in Medicine. In 1855 he joined the Royal College of Physicians, London. He was fellow of the Royal Medical and Chirurgical Society, and succeeded the late Dr. Babington as Physician to the Queen Charlotte's Hospital; he also held several other, but minor, obstetrical appointments. His literary labours, though not numerous, were full of value and practical importance. In his Lettsomian lectures at the Medical Society of London he contributed largely to the "pathology and treatment of phlegmasia dolens," a subject which he continued to work and take great interest in. To the Obstetrical Society he sent several important papers, and to the Medical and Chirurgical Society one of much interest, "On the Action of Galvanism upon the Gravid Uterus, and its Remedial Powers in Obstetric Practice." Dr. Mackenzie began in general practice at Bayswater. Continuing a practice already there established, he rapidly obtained a larger and larger influential connection, and became as much liked by his patients as by his friends. He had the great misfortune to lose his wife about two years since, and it may be said with truth never recovered the affliction. His illness was of short duration, lasting only a week or ten days, and the proximate cause of death seems to have been disease of the kidneys. Dr. Mackenzie was in his 49th year, and has left, besides a large circle of friends to mourn his loss, an only surviving son, who is now at the Wellington College.

MEDICAL NEWS.

Royal College of Surgeons of England.—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Court of Examiners on April 13, and when eligible will be admitted to the pass examination:—

George Lucas, W. W. Inglis, F. Rainbow, F. W. Smith, and A. C. Maybury, students of St. Thomas's Hospital; James Rawlings, W. P. Boyle, J. W. Morris, J. P. Cheetham, and S. K. Watson, of Guy's Hospital; Joseph Oakman, Walter Moore, W. C. Watson, and R. C. Brookes, of the Westminster Hospital; J. W. Melson, George Chapman, Frederick Hopkins, and M. H. Wright, of Birmingham; Edward Nettleship, R. H. Robinson, and E. H. Seccombe, of King's College; W. J. Tattersall, H. C. Upton, and E. C. Maxwell, of St. Bartholomew's Hospital; J. W. Pinder and Charles Wills, of the Middlesex Hospital; George Hails and S. K. Powell, of Newcastle; and Timothy Lewis, of University College.

Out of the 107 candidates who offered themselves only twelve were rejected.

The following gentlemen passed on the 18th inst., viz.:—

George Roots, C. J. W. Meadows, G. S. Elliston, J. R. Stocker, H. K. King, Charles Sangster, J. W. Cooke, and Henry Moon, students of Guy's Hospital; W. H. Ellis, E. J. Leverton, Isaac Coulbank, M. L. Heelas, and C. D. Batt, of St. Bartholomew's Hospital; William Bonney, J. C. Bailey, J. H. Casson, and Hugh Ferguson, of the Middlesex Hospital: George Mannings, Walter Smith, and A. A. Napper, of King's College; John Sykes, T. E. Scatchard and Edmund Robinson, of Leeds; R. E. Ash and C. E. Howard, of St. Mary's Hospital; T. R. Loy and Edgcumbe Cornish, of University College; Arthur Hill, Westminster Hospital; J. W. Booth, St. Thomas's Hospital; and M. S. McDonnell, of Hull.

The following gentlemen passed on the 19th inst., viz.:—

Arthur Humphry, P. D. Hopgood, John Tremearne, R. H. Coombs Frank Ewbank, and J. M. Dixon, Students of St. Bartholomew's Hospital; S. J. Truman, W. G. Palmer, T. A. Buck, F. A. Thomas, and Douglas Wills, of Guy's Hospital; G. H. R. Dabbs, Denis Daly, R. L. Wilcox, W. H. Mills, and G. H. Snape, of King's College; S. S. White, J. A. Hayden, and George Aircy, of Charing-cross Hospital; W. P. Pindor and R. M. Pryce, of University College; Thomas Horder and R. F. Hay, of the London Hospital; F. B. Farley and J. E. Schön, of the Middlesex Hospital; T. J. Quicke and M. W. Chambers, of the Westminster Hospital; John Ockenden, of St. Mary's Hospital; William Makinson, of Manchester; Moses Taylor, of Birmingham; and Edward Malins, of Edinburgh.

The following gentlemen passed on the 20th inst., viz.:—

Arthur Goodwin, G. F. Trotter, W. F. Thurston, and W. H. Rawlings, students of Guy's Hospital; C. M. Heim, Herbert Tibbits, W. J. Garrett, and Edmund Exell, of St. Bartholomew's Hospital; E. C. Ring, P. H. Mules, and Robert Anderson, of St. George's Hospital; G. M. Lowe, Robert Thorburn, and Alexander Steven, of Edinburgh; Joseph Ludlam and J. W. Langmore, of University College; W. W. Smith, of the Middlesex Hospital; J. W. Booth, of St. Thomas's Hospital; J. W. Allin, of Charing-cross Hospital; T. E. Bowkett, of the London Hospital; J. L. Cooke, of Birmingham; H. M. Fothergill, of Newcastle; R. A. Mowell, of Liverpool; Alexander Paterson, of Aberdeen; and A. J. Farr, of Bristol.

It appears that out of the 105 candidates who offered themselves for examination no less than 20 were referred back to their studies.

APOTHECARIES' HALL. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, April 13, 1865 :—

Henry Hargreaves Birtwell, Blackburn; Archibald Megget, Scarborough; Henry Nelson Edwards, 1, Finsbury-square.

As Assistants :—

Charles Henry Barrett, Bristol; Christopher Emmott, Gray's-inn-road.

The following gentlemen, also on the same day, passed their first Examination :—

Edward James Leverton, St. Bartholomew's Hospital; Henry Cecil Smith, Guy's Hospital; Philip Henry Mule, St. George's Hospital.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ARMSTRONG, JOHN CHRISTOPHER, M.R.C.S., has been elected Surgeon to the Gravesend and Milton Infirmary and Dispensary.

BENNETT, GEORGE J., M.R.C.S. Eng., has been appointed Surgeon to the 1st Newcastle-upon-Tyne Artillery Volunteers, and Honorary Surgeon to the Gateshead Dispensary.

CLEMENTS, GEORGE, M.R.C.S. Eng., has been appointed Physicians' Assistant to the Royal Manchester Infirmary.

HOWES, FRANK, M.R.C.S. Eng., has been elected Resident Medical Officer to the Eastern Dispensary, Bath.

DEATHS.

HARVEY, HENRY OFFLEY, M.R.C.S. Eng., Assistant-Surgeon 1st battalion 21st Fusiliers, at Anglesea Barracks, Portsmouth, recently, aged 29.

KEBBELL, MARK, M.R.C.S. Eng., at Wellington, New Zealand, on February 3, aged 38.

MARRIOTT, WILLIAM M., M.R.C.S. Eng., at Kibworth House, Leicester, on April 12, aged 67.

SHARPE, GEORGE G., M.D., at Epsom, Surrey, on April 18, aged 86, formerly of Peckham and Stamford.

ODONTOGRAPHIC SOCIETY OF PENNSYLVANIA. — On February 7 Professor Thomas H. Huxley, F.R.S., F.L.S., was elected an honorary member, and Charles James Fox, M.R.C.S., L.D.S., a corresponding member of this Society.

THE BRITON MEDICAL AND GENERAL LIFE ASSOCIATION. —The eleventh annual Report of this Association states that the proposals for new assurances have been 3280 in number, amount proposed £818,888. Of these 212 for £49,540 have been absolutely declined, 390 for £91,188 have not been carried into effect, and 224 for £56,275 were in course of progress at the close of the year. The remaining 2454 have been completed, and that number of policies issued, assuring £621,885, and producing in new annual premiums the sum of £20,060 14s. 3d. Four annuities have been granted, and £650 received as the purchase-money for the same. The directors further report that the gross income of the Association has increased to the sum of £124,091 7s. 4d., and that after the payment of all outgoings the balance of income over expenditure for the year is £30,560 10s. 10d. The assets of the Association now amount to £247,593 8s. 3d., or within a trifle of a quarter of a million of money. Dr. Sieveking's name is now added to the list of directors.

THE RUSSIAN PESTILENCE.—The annexed general order regarding the Russian pestilence has been transmitted to the Customs' collectors of the various ports of the United Kingdom :—

"Custom House, London, April 5.

"Sir,—I am desired by the Board to transmit for your Government the accompanying copy of a letter from Mr. Helps, Clerk of the Council, dated the 4th inst., relative to the pestilence which is alleged to prevail in certain parts of Russia, and I am to direct you to instruct the proper officers at your port, in the event of the arrival from any port in the Baltic of a vessel in which there is any case of cholera, small-pox, typhus or typhoid fever, or in which any disease whatever is extensively prevalent, forthwith to report the circumstance to you, and you are immediately to communicate the same to the local authorities, in order that they may take such measures as they see fit for the protection of the public health within their jurisdiction, observing, however, the greatest discretion in the mode of conveying the information, in order that no avoidable alarm may be created, and reporting your proceedings to the Board.

"With regard to vessels arriving with plague or yellow fever on board, you are to be guided by the orders already issued in respect to placing such vessels under the restraint of quarantine.

"I am, Sir, your obedient servant,

"The Collector, ——." "GEO. DICKINS.

"Counell Office, Whitehall, April 4.

"Sir,—I am directed by the Lords of the Counell to transmit to you, for the information of the Commissioners of Customs, the enclosed copy of the correspondence which has taken place between the Foreign Office and this department relative to the pestilence which is said to prevail in certain parts of Russia, and I am directed by their Lordships to request that you will move the Commissioners to give such instructions to their officers at the various ports in the United Kingdom as will insure the exercise of the utmost possible vigilance in the examination of all vessels arriving from any of the ports in the Baltic.

"I am, Sir, your obedient servant,

"The Secretary, Customs." "ARTHUR HELPS.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

In consequence of the large amount of space occupied by the proceedings of the Medical Council, we are obliged to postpone our Hospital Reports, Reports of Societies, Reviews of Books, and several Original Communications and Letters, until next week.

We regret that we are again compelled to defer our notice of the Second Annual Report of the Coroner of the Central Division of Middlesex.

Mr. R. Griffin.—The circular has not been received.

M.D., R.N., Plymouth.—As a member of the College, you will not be required to pay an additional fee on undergoing the examination for full Surgeon. You could attend next week.

GRIFFIN TESTIMONIAL FUND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The following subscriptions have been further received on behalf of the above fund :—Richard Grimbly, Esq., Banbury, £1; Richd. Mallam, Esq., Banbury, 5s.; Jeremiah McGreal, Esq., Banbury, 5s.; and Thos. Elkington, Esq., Southam, 10s., per Richard Grimbly, Esq., Banbury. Richard Wilding, Esq., Church Stretton, 5s. 3d. Amount previously announced, £123 6s. Received at *Lancet* Office, £9 9s.

I am, &c.

ROBERT FOWLER, M.D., Treasurer and Hon. Sec.

145, Bishopsgate-street Without, April 20.

COMMUNICATIONS have been received from—

DR. SAMUEL WILKS; BRITON LIFE ASSOCIATION; APOTHECARIES' HALL; MR. RICHARD GRIFFIN; MEDICUS; M. A. B.; M.R.C.S. Eng.; PHARMACEUTICAL SOCIETY; HARVEIAN SOCIETY OF LONDON; DR. FOTHERBY; ADVICE GRATIS; DR. ROBERT FOWLER; MR. CHARLES J. FOX; MR. THOMAS P. SKINNER; MR. B. B. ORRIDGE; ETHNOLOGICAL SOCIETY OF LONDON; MR. S. WHITFORD; DR. T. MASSIE HARDING; MR. GEORGE CLEMENTS; MR. J. S. BRAZIER; ROYAL INSTITUTION; DR. C. KIDD; DR. JOSEPH BULLAR; MR. FURNEAUX JORDAN; J. E.; ONENESS; MEDICAL SOCIETY OF LONDON; MR. JOHN NUNN.

BOOKS RECEIVED.

De la Guérison des Fièvres intermittentes et Larvées. Par N. Brault et E. Peneau. Bourges. 1864.

*** This tract has been written to celebrate the virtues of powdered cuttle-fish bones and oyster shells in the cure of intermittent fevers. The learned authors tell us that already the list of substances to which similar properties have been assigned would almost fill a volume, but that practically it may be compressed into two—quinine and arsenic. Now, of these, the first is too dear, the second too dangerous; but sepia bones and oyster shells may be substituted, with certain success, for both. We congratulate the authors on their discovery, and recommend them to continue their investigations into the virtues of animal remains. The human skull had formerly medicinal virtues assigned to it when it was obtained from a churchyard under certain conditions, and here is an epitome of the curative powers of bones from Adams's "Paulus Ægnieta," which we commend as suggestive to Messrs. Brault and Peneau :—"The ankle-bone of a sow when burnt is said to cure flatulence and tormina. And some cure epilepsy and arthritis by giving burnt bones to drink. And burnt ankle-bone of an ox is said to fasten loose teeth; but if drunk with honey, it removes round worms, and with oxymel it reduces the spleen, and when rubbed in relieves leuce. It is also an aphrodisiac," etc., etc.

Statistical Tables of the Patients under Treatment in the Wards of St. Bartholomew's Hospital during 1864. By G. Edwards, M.D., and A. Willett, F.R.C.S. Lond. Adlard. 1865.

*** Of the 6096 patients admitted, 169 contracted other diseases in the Hospital,—viz., 7 measles, 7 scarlatina, 19 typhus, 1 typhoid, 40 erysipelas, 44 cellular inflammation or pyæmia, 1 diphtheria, 9 rheumatism, 19 phagædena, 6 gangrene, 1 tetanus, 15 delirium tremens. Of the typhus, 7 patients and 2 *nurses* recovered; 5 patients and 3 nurses died. These tables contain every particular to be expected or desired in such a work.

Lectures on Nursing. By Dr. J. C. Lory Marsh, M.D. Second Edition. London: W. Kent and Co.

*** A cheap shilling's-worth to any woman beginning the practice of nursing.

Heat Considered as a Means of Motion. By John Tyndall, F.R.S. London: Longman and Co.

*** A second edition of the well-known "Lectures," more formally written and divided into chapters. The author's latest researches on Radiant Heat are added, and that part which relates to vital phenomena is newly written.

A Manual of Physiology, including Physiological Anatomy. By W. B. Carpenter, M.D. Fourth Edition. London: John Churchill and Sons. 1865.

*** The number of pages and of woodcuts is largely increased in this edition. The author gives in his adhesion to Professor Beale's views of nutrition, as lately published in these columns, except in so far as regards the denial of vitality to the "formed material."

Edinburgh Medical Journal. No. 118. April. Edinburgh: Oliver and Boyd.

*** Several interesting articles,—*e.g.*, by Dr. Rutherford Haldane on Uræmic Convulsions, Dr. Arthur Mitchell on Consanguineous Marriages, and Mr. Thomson, of Perth, on the Dietary of Scottish Agricultural Labourers. He takes a coarse mechanical version of the views of Dr. E. Smith, and believes that the Scottish labourer's oatmeal diet is better than that of the English labourer. It may be so on paper, but, if it be so, it is odd that the Scotsman should be so ready to change it when he gets the chance.

Annual Report of the Manchester and Salford Association for the Year 1864.

Report of the Health of Liverpool during the Year 1864. By W. S. Trench, M.D.

*** These reports on Manchester and Liverpool are admirable documents, and shall be noticed in another page.

The Watch-Tower. No. 1. London: 158, Fleet-street.

*** The first number of a monthly religious shilling magazine. It contains some sensible things,—*e.g.*, we have marked with approbation what one writer says about the necessity of manly exercise for clergymen, and on the odiousness of eccentricity in women; upon the whole, the thing seems flat, and has a strong smack of the Lock Hospital about it. The first article is by Mr. Capel Molyneux, Chaplain to that institution.

The Day of Rest. No. 1.

*** A weekly penny magazine. Why it should be called the "Day of Rest" we know not: but, at any rate, it contains a jolly tale called "My First Patient," and if people read such things on Sundays, under parsonable authority, things must have taken a jolly turn with the parsons, and we hope they will put a little fun into their sermons.

Observations on Medical Education. By R. Quain. London: Walton and Maberly.

*** Is too purely in the interest of the Royal College of Surgeons; otherwise gives a very able account of past and present state of Medical education, and shall be noticed more at length.

Autobiography of the late Sir Benjamin C. Brodie, Bart. London: Longman and Co. Pp. 187.

*** No better present can be imagined for any boy entering any profession.

The Westminster Review. April. London: Trübner and Co.

*** Contains a very useful exposition of M. Auguste Comte's Philosophy.

A Dictionary of Chemistry. By H. Watts, B.A., F.C.S. Part XXV. London: Longman and Co.

*** Completes letter M, with index to vol. iii.

The Journal of Mental Science. April. London: John Churchill and Sons.

*** Contains many able and unusually vigorous articles,—*e.g.*, one on G. Victor Townley and one on Dr. Barclay's "Medical Errors."

The Glasgow Medical Journal. April. Glasgow: W. Mackenzie.

*** Dr. C. G. Ritchie, of London, has some valuable Obstetric Reports, and Dr. Buchanan some good observations on Vaccinal Syphilis, and on Complication of Syphilis with Scabies.

Suggestions for an Institution for Trained Nurses in Connection with the Infirmary at Salisbury. By John Roberts, M.D. Salisbury: Brown and Co.

*** Valuable and incontrovertible as these suggestions are, why do not the Salisbury people carry them out?

On a New Mode of Treating Cases of Vesico-Vaginal Fistula. By A. Meadows, M.D., etc.

*** From the Obstetrical *Transactions*. The author does not believe in the necessity of absolute rest after the operation; but the title leads one to expect more than one finds in the paper.

The Personal Responsibility of the Insane. By James T. Duncan, M.D. Dublin: Fannin and Co.

The Quarterly Journal of Science. No. 6. April, 1865. London: John Churchill and Sons.

*** A good article on Microscopic Spectrum Analysis Applied to Blood Stains, and another on Prehistoric Records, which is very interesting.

The Veterinary Review. April, 1865. Edinburgh: W. P. Nimmo.

*** Contains a good deal that is interesting to Medical men,—as the questions of diseases of cows, and of *goitre* in foals as a sign of constitutional debility.

The Geological Magazine. April, 1865. London: Longman and Co.

*** An interesting number, in which we are glad to see the names of a rising race of Lankesters and Carpenters as contributors.

The British Journal of Dental Science. March, 1865. London: John Churchill and Sons.

Stammering and Stuttering, their Nature and Treatment. By James Hunt. Sixth Edition. London: Longman and Co.

The British and Foreign Medico-Chirurgical Review. No. 70. April. London: John Churchill and Sons.

On the Method of the Study of the Mind. By H. Maudsley, M.D. London: John Churchill and Sons.

Annual Report of the Cumberland and Westmoreland Lunatic Asylum for the Year 1864.

Homes without Hands. Part 16. By the Rev. Hy. Wood, M.A. London: Longman and Co.

Revelations of Quacks and Quackery. By "Detector." Reprinted from the *Medical Circular*.

A Brief Sketch of the Past and Present Condition of the Bengal Medical Service. By a Surgeon of the Bengal Army. Calcutta: *Englishman* Press. 1865. Pamphlet.

On Primary Cancer of the Brain. By G. Mackenzie Bacon, M.D. London: John Churchill and Sons. Pamphlet.

A Critical Inquiry regarding Superfœtation, with Cases. By George Lindsay Bonnar, M.D. London: John Churchill and Sons. Pamphlet.

Report of the Wilts County Asylum, Devizes, 1864.

Report of the Norfolk Lunatic Asylum, 1864.

Report of the Northampton Lunatic Asylum, 1864.

VITAL STATISTICS OF LONDON.

Week ending Saturday, April 15, 1865.

BIRTHS.

Births of Boys, 1036; Girls, 937; Total, 1973.
Average of 10 corresponding weeks, 1855-64, 1885·2.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29·963 in.
Mean temperature	52·4
Highest point of thermometer	72
Lowest point of thermometer	37·4
Mean dew-point temperature	43·5
General direction of wind	Variable.
Whole amount of rain in the week	0·15 in.

APPOINTMENTS FOR THE WEEK.

April 22. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m. Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m. Royal Free Hospital, 1½ p.m.

24. *Monday.*

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.

Medical Society of London, 8½ p.m. Morell Mackenzie, M.D., "Dysphagia: its Varieties and Treatment." Arthur Leared, M.D., "On Disguised Disease of the Heart."

25. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

Ethnological Society of London, 8 p.m. Rev. Jas. Brodie, "Observations on the Peculiarities of National Pronunciation as a Means of Tracing the Origin and History of Nations."

Royal Medical and Chirurgical Society, 8½ p.m. Dr. T. Laycock, "On the Influence of Nerve-centres on Dropsies and Dropsical Effusions."

Royal Institution, 4 p.m. Professor Frankland, F.R.S., "On Organic Chemistry."

26. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.

27. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; West London Hospital, 2 p.m.

Royal Institution, 8 p.m. Professor Frankland, F.R.S., "On Organic Chemistry."

28. *Friday.*

Operations, Westminster Ophthalmic 1½ p.m.

Royal Institution, 3 p.m. Professor Lyon Playfair, F.R.S., "On the Diet of Man, etc."

ORIGINAL LECTURES.

LECTURES ON CHEMICAL AND MECHANICAL DISEASES AND THEIR RELATIONSHIP.

By H. BENCE JONES, A.M., M.D., F.R.S.

Lecture V.

DISEASES OF SUBOXIDATION.—ON GOUT.

(Continued from page 408.)

On the Symptoms of Gout.

The blood when loaded with urates varies every moment in the quantity of these crystals which it contains, and in its power of keeping them in solution; moreover, every moment by diffusion some of the urates pass with the nutriment and oxygen into the textures. The oxidation in the blood and textures may balance the supply or fresh formation, and no accumulations or congestions may occur until some Medical or Surgical accident—that is, some sprain or injury, some cold or other accident, as, for example, even an apoplectic attack—happens to determine the flow of blood or nutriment to any one part more than the rest; then and there gouty deposit and inflammation will be set up.

When no accident is the immediate cause, some ordinary occurrence may be sufficient to give rise to the gouty inflammation—thus a long walk, a tight shoe, a full meal, a strong dose of medicine, a fright, will determine the commencement of the local action, which may be of any degree of mildness or intensity. Thus it may be limited to a continuous feeling of burning and tenderness in the feet, or even to a few passing twinges in the great toe or heel, that may last only a few minutes; or it may fall upon one joint after another and produce an amount of suffering and general fever with a degree of redness and heat, and ultimately of swelling of the surface, that may surpass the products of any ordinary inflammation.

When the effusion which constitutes most of the swelling takes place from the vessels the tension in the capillaries is relieved, and the violent action becomes less.

Usually, the gout, like an abscess, fixes on one spot, and there remains until the whole attack is over; but as in pyæmia abscesses may occur in any number outside the bloodvessels as in the joints, so also when urates in excess are in the blood and textures they may set up congestion and combustion in any part, either successively or simultaneously, according to the amount of urates that diffuses into any part.

The pain arises from increased sensibility of the nerves, produced by the increased flow of blood from the oxidising action which is going on in and around the painful nerve; and this increased action is fed by the increased flow of blood in every part where complete obstruction does not occur; so that the pain is the best measure of the local symptoms. The general symptoms will vary with the age, sex, constitution, temperature, idiosyncrasies, and unsoundness of the patient. The same amount of urate poison in the blood and textures will in different persons produce totally different effects, and these will vary in the same person according as the combustion is slow or rapid; in other words, according as the attack is chronic or acute.

There is nothing in the general or local symptoms that can enable the eye to tell that any inflammation is certainly gouty; any other inflammation in the same parts will at first have precisely the same local and general symptoms, though the history of the attack will generally, though not always, lead to the truth. Thus secondary inflammations from traumatic or idiopathic pyæmia may be easily mistaken for gout.

Rheumatic inflammation so closely resembles gouty inflammation in all its local and general phenomena that no positive differentiation between the two diseases can be made, except in the *materies morborum*. The rheumatic poison has not yet been insulated; that it differs from uric acid in its solubility, and probably in its volatility, is shown by its not forming calculi, not depositing itself visibly on the joints, escaping by the skin and giving rise to local symptoms when the secretion of the skin is checked by cold and wet. In the analysis of sweat, as yet only one acid that at all approaches to uric acid in composition is known—sudoric or hydrotic acid ($C_{10}H_8NO_{13}HO$?). It may be that this is the rheumatic poison, and that an excess of it in the blood causes the rheumatic diathesis, and its local oxidation a rheumatic attack. But whatever the acid, there is no reason why the rheumatic and gouty acids should not coexist in the same blood, causing a rheumatic-gouty diathesis; nor why a local oxidation of both acids should not take place at the same time in the same part, constituting an attack of rheumatic gout. Certainly there is no positive proof as yet that this happens, but animal chemistry is still very young, and will speak much plainer on this and many other subjects when grown up. Meanwhile, the rheumatic poison exists as surely as the scarlet fever poison, and a skilful chemist may at any moment insulate both.

The local symptoms and the general symptoms of gout, rheumatism, and rheumatic gout closely resemble those of an ordinary inflammation, but there is a very important difference in that these specific inflammations are set up and modified in their course by the presence of specific substances in the textures that take part in the peroxidation. Hence, as soon as these substances are destroyed by oxidation in any part, or generally, the symptoms disappear from that part or from the body, and are transferred to another place or entirely subside. Thus the rate of transference is a measure of the intensity of the local action and of the amount of poison in the textures. In the severest attacks a few hours finds the seat of the inflammation changed, whilst in a very slight attack one joint may be slightly affected for months continuously.

There is another great difference between ordinary inflammation and rheumatic or gouty inflammations in these specific inflammations; pus comparatively rarely forms, while an excess of fibrin in rheumatism, perhaps even more than in gout, exudes wherever local action is taking place. How far this deposition of fibrin is connected with the peculiar oxidation of rheumatic and gouty inflammation, animal chemistry has to determine; certain it is that only in the weakest and most debilitated constitutions, in those in whom the actions of nutrition and oxidation are most imperfectly carried on, does pus in any quantity form either in the gouty or in the rheumatic inflammation.

The history and the causes of the attack usually furnish the means of determining the nature of the inflammation, but ultimately animal chemistry will tell with perfect certainty whether gout, rheumatism, rheumatic gout, or some other modified combustion is going on in the blood and textures. Even now Dr. Garrod has shown how from a few drops of serum obtained from a blister, uric acid, by its insolubility in dilute acid, may be proved to be present or absent; and who can foresee what new methods of quantitative or qualitative analysis of urates or sudorates may be discovered?

Professor Stokes by spectrum analysis can trace the oxidation or deoxidation of the blood globules, and we are beginning to recognise differences in the chemical composition of the sun and the fixed stars, and to determine the chemical and physical constitution of the nebulæ; whilst, by the same means, even the twelve-millionth of a grain of lithium can be detected in distilled water, and the sixth-millionth part of a grain in the urine.

On the Complications and Consequences of Gout.

As the gouty diathesis arises from urate of soda in the serum and serous fluid which passes out of the blood into every cell, so in every vascular as well as non-vascular texture urates may accumulate and set up an exaggerated process of oxidation so as to cause more or less severe inflammation. In the vascular textures the accumulation of urates is very unlikely to occur, and when it does happen, rapid circulation quickly causes an oxidation which removes the urates and restores the part to a healthy state.

An excess of urates while passing through the capillaries of the kidney is liable, like silver or other metallic poison, to be caught in the texture of the kidney, and to set up parenchymatous nephritis, which causes permanent organic disease.

Many of the complications of gout arise from some functional or structural disease to which the patient is liable, independently of the imperfect combustion of the urates in the tissues and blood. If any function or structure be wrong, the disturbance produced in the system by the local oxidation of the urates will, in some cases, increase the previous wrong action, and thus complicate the attack of gout.

Still, in other cases the counter-irritation, derivation, and purification of the blood and textures from urates by oxidation do remedy previous disorders, but there is a reverse truth which frequently makes itself evident in the increased suffering and weakness produced by an attack of gout accompanying or following some other disease. So that an attack of gout instead of being always a cure, is sometimes an aggravation of other ailments.

A gentleman about 70 years of age was entirely deprived by an apopletic attack of the use of his right side. Two days after the stroke the most violent gout came on in his right foot. The violent pain in the foot caused constant involuntary motion of the limb, over which he had no control. The paralytic state of the limb had no influence over the progress of the attack of gout, but the involuntary motion increased the suffering from the gout fearfully, but did not hinder his ultimate recovery.

A gentleman, 73 years of age, was under treatment for irritable bladder, dependent on chronic inflammation of the prostate; he had been confined to the house for some days by frequency and pain in voiding water, when violent gout came first in one foot, and when this subsided quite as severe an attack came in the other foot, disabling him for three weeks. Throughout the attack the irritability was even worse than before the gouty attack, and after the gout ceased there was no immediate improvement in the state of the bladder.

A gouty gentleman had for some months complained of pain in his head when he coughed, or sneezed, or shook his head, and without any cause he had become deaf. This lasted for two months, and was attributed to latent gout. He caught a very severe cold, which confined him to his bedroom, and the third or fourth evening he suddenly became comatose. He could not be roused to take his medicine or his food, and he passed his water under him. Active counter-irritation was used to the neck and extremities, and in the morning violent gout came in one foot, and he lost his head symptoms entirely. The gout was most intense in every joint of the body, and it was more than a month before he could move. When he began to drive out, he again began to complain of his headache when the road was rough; this increased, and in three or four days he again became very heavy, and before a week was over he died perfectly comatose, the attempt to bring out the gout again entirely failing.

The great mechanical consequence of gout is the loss of voluntary motion from the joints becoming fixed. The progress is from the toes and fingers through every joint to the jaws. I have seen a patient unable to stand for sixteen years —unable to move either hand or arm except to the slight degree that enabled him to sign his name somehow; unable to open his mouth except for very small morsels of food; unable to turn his head in any direction—a recumbent statue, with moving eyes, and heart, and diaphragm, sloughing from the constant pressure which he was unable to remove, while never-ending pain wore down the system until it was unable to resist a complication of disease.

(To be continued.)

ORIGINAL COMMUNICATIONS.

A DEFENCE OF "HUNTER ON THE VENEREAL DISEASE."

By SAMUEL WILKS, M.D.

I HAVE perused with considerable interest your valuable articles on syphilography, and agree with nearly all you say on that important subject, but I confess to some feeling of regret to see the name of Hunter so little venerated by you. You show, indeed, good reason why many of his doctrines cannot be received at the present day; and being so well acquainted with the subject, you are in a good position to refute them, but I think that an opinion expressed dictatorially by yourself is very apt to carry more weight with it than you intend, and thus the memory of one of the greatest men who ever adorned our Profession suffers unintentionally in your hands. You say that "John Hunter's celebrated treatise on the venereal disease, published in 1786, was the most mischievous book that ever was written; that no book ever printed contains such unwarranted deductions, and further that you cannot define modern syphilography better than by saying that it signifies the total refutation of Hunter's doctrines." In these conclusions I must humbly beg to disagree, for I consider that more will be found, both in doctrine and practice, in Hunter's treatise in accordance with the most advanced modern views than in any other work which has been written before or since his time, excepting those of a very recent period. I consider, indeed, that the very errors into which he is supposed to have fallen, and the extraordinary doctrines which he is said to have advanced, are indications of his having regarded the subject in a much more comprehensive and scientific spirit than all other writers of subsequent times. I candidly own to a reverence for the name of Hunter which would compel me to weigh more carefully his utterances than those of any other man, and I confess also to a prejudice in his favour on the subject of venereal disease, before I had studied his writings, from the fact of my old master, Mr. Aston Key, having always been ready to defend Hunter against charges of erroneous doctrine, which were constantly being made by those who were really strangers to his writings. Thus, in a short paper on syphilis written in the Guy's Hospital Reports by Mr. Key in 1840, this Surgeon says that much was laid to his charge of which he is wholly innocent. The excessive and indiscriminate use of mercury in all sores thought to be syphilitic as recorded and practised by Surgeons in the school of Hunter has no authority in the precepts of that great master of our art. His doctrine was considered as antiquated and his treatment mischievous; the erroneous views prevail because Hunter is not studied, the crude notions held by Hunter's contemporaries, and adopted by their immediate successors, unfortunately led to a practice prejudicial to Mr. Hunter's character as a pathologist. I believe Mr. Key was earnestly protesting against the excessive mercurial treatment which was erroneously charged on Hunter, rather than advocating his doctrines of venereal disease, which were not so well understood five-and-twenty years ago as at the present time.

Although, therefore, I may differ from you in respect to Hunter's merits, I trust you will allow me to occupy a space in your journal, in order to state some of the reasons which I have for concluding that this eminent man was in possession of the great truth which more recent writers are now upholding—the specific nature of the venereal disease and its resemblance to other constitutional maladies. I shall do little more than quote from his writings, and trust that younger members will read the original for themselves, as at the present day I am sorry to say our students almost ignore Hunter and his works.

For a proper understanding of his doctrines, however, I may just remark, in a few words, that the subject of venereal disease seems to have been for many centuries in an utter state of confusion, owing to the associating together all sexual diseases, including local sores, locally contaminating affections and sores containing within them a virus which was capable of infecting the whole system, or, as Carmichael says, "the syphilitic disorder which was imported at the end of the 15th century was confounded with all kinds of venereal diseases, and to the disgrace of our Profession (with two or three splendid exceptions) have continued from that day to the present, more than three centuries, to be confounded with it by the general body of Practitioners." It has remained for men still living to show, that a disease which affected the whole constitution, and had its analogies in the exanthemata, was a malady *sui generis*, not necessarily originating in the sexual organs, and, therefore, one to be absolutely separated from other diseases having their seat in those parts. Modern observations show that the virus may be introduced into any part of the system, but more usually on the genital organs, from these being the parts which are brought closest in contact, and that the virus is apt to locate itself in the most convenient lurking places; that the poison begins after some days to work in the system, and then the spot of introduction puts on peculiar characters; that afterwards febrile symptoms arise with cutaneous rashes, and subsequently all parts of the body are liable to be affected in a peculiar way from the deposition of a syphilitic lymph.

Now, I may ask, what writer has ever regarded the subject in a manner so near the truth as John Hunter? Indeed, I venture to think that his opening chapters would adorn any of the works on syphilis which have been written since his day. "Every infectious disease has its peculiar manner of being caught, and among mankind there is generally something peculiar in the way of life, or some attending circumstance, which exposes them at one time or other to contract such diseases, and which, if avoided, would prevent their propagation. The itch, for instance, is generally caught by a species of civility—the shaking of hands; therefore, the hand is the part most commonly first affected, and as the venereal infection is generally caught by the connexion between the sexes, the parts of generation commonly suffer first. From this circumstance people do not suspect the disease when the symptoms are anywhere else, whilst they always suspect it in every complaint of those parts. In the lower class of people one as naturally thinks of the itch when there is an eruption

between the fingers as in young men of the venereal disease whose genitals are affected; but as every secreting surface, whether cuticle or not cuticle, is liable to be infected by the venereal poison when it is applied to it, it is possible for many other parts besides the genitals to receive this disease. Therefore, it appears in the anus, mouth, nose, eyes, ears, and, it has been said in the nipples of women who suckle children affected by it in their mouths, which children have been affected in their birth from the diseased parts of the mother. The venereal poison is capable of affecting the human body in two different ways; locally, that is, in those parts only to which it is first applied; and constitutionally, that is, in consequence of the absorption of the venereal pus which affects parts while diffused in the circulation. When the matter has got into the constitution and is circulating with the blood, it there irritates to action. There are produced from that irritation many local diseases, as blotches on the skin, ulcers on the tonsils, thickening of the periosteum and bones."

Hunter, in the passage just quoted, takes a correct view of syphilis as a specific constitutional disease. The same is seen in numerous other parts of his treatise, and is obvious, from the fact of his separating his chapters on chancre and on lues venerea. "The venereal disease arising from a poison which as it is produced by disease, and is again capable of producing a similar disease, I call a morbid poison, to distinguish it from other poisons, as animal, vegetable, and mineral. Those which are capable of affecting the body locally and constitutionally, I call compound. The venereal poison, when applied to the human body, possesses a power of propagating or multiplying itself, and as it acts both locally and constitutionally, it is a compound morbid poison." The following also shows that Hunter looked upon the disease as a constitutional one, and only accidentally produced through the introduction of a poison by the genital organs:—"If the disease had taken place in any other part of the body than the organs of generation, it might never have probably gone further than the first person in whom it arose; but being seated in the parts of generation, where the only natural connexion takes place between one human body and another (except between mother and child), it was a most favourable situation for being propagated." If all the readers of Hunter had duly weighed the following quotations and understood his propositions, much error would have been avoided; and if all subsequent writers had been content to copy him, it would have been better, both for doctrine and practice:—"I have been speaking of the effect of the poison when applied to a secreting surface and without a cuticle. I now explain its effects when covered with a cuticle. I may be here allowed to remark that the penis, the common seat of chancre, is, like every other part of the body, liable to diseases of the ulcerative kind, and if attention is not paid to cleanliness, we have often excoriations or superficial ulcers; from that cause, also, these parts, when once they have suffered from the venereal disease, are very liable to ulcerate anew. Since, then, this part is not exempted from the common diseases of the body, and as every disease in this part is suspected to be venereal, great attention is to be paid in forming our judgment of ulcers here." "The poison much more readily contaminates if it is applied to a fresh wound than to an ulcer, in this resembling the inoculation of the small-pox. Whether there are any other parts of the skin or any other parts of the body more susceptible of this irritation than others, in consequence of local irritation, is not yet ascertained. It is generally caught on the parts of generation in consequence of a connexion between the sexes, but any part of the body may be affected by the application of venereal matter, especially if the cuticle is thin." So far from syphilis being a necessarily *venereal* disease, Hunter saw that this character was accidental, as also was the part most likely to be affected. "It is more liable to affect the penis from the configuration of the parts, and thus a favourite seat is between the angle and glans near the frænum, not from any peculiar tendency in those parts to catch the disease, but from allowing venereal matter to lie undisturbed in the chinks, by which it has time to irritate and inflame the parts; but as venereal matter is more easily rubbed off from prominent parts by everything that touches it, it is a reason why they so often escape." Can any passage proclaim in a clearer light the immeasurable superiority of Hunter over those who were treating the local sore as the main disease, and which he clearly shows is a mere accidental part of the complaint?

I will quote another passage in order to show how well Hunter understood the nature of the complaint, and yet how very strangely his successors have misunderstood him. "The lues venerea, I have already observed, arises in consequence of the poisonous matter being absorbed and carried into the common circulation. This form, which I have called the *constitutional*, would appear to be much more complicated both in the different ways in which it may be caught, etc. It generally arises from local complaints before taken notice of, the matter being absorbed and carried into the constitution. It may be taken in by simple application, by being applied to common ulcers, also by wounds." He goes on to say that the poison may get into the system, although exceptionally, without any evidence of local disease, or by a mere discharge, which he styles gonorrhœa.

It is true that Hunter did not believe in the contagious nature of venereal disease, but in this nearly every subsequent author of any eminence has agreed with him, and it has remained for quite a recent period to see the doctrines of contagion advocated. There is, however, a vast difference between those who simply ignore the doctrine of contagion or never think of it at all, and men like Hunter, who discard it only after much thought and many experiments. The vastly comprehensive mind of Hunter could not fail to see that if syphilis was a constitutional disease, and had its analogies in small-pox (to which he refers), that the fluids and secretions of the body affected would also be contaminated. He pursued the subject to its natural consequences, and according to the more advanced opinions of the few he fell into error. His experiments were founded on right reason, and yet for this he has been called speculative, and said to have wandered from his usual practical teachings. Then, again, Hunter in regarding the disease as a constitutional one, was necessarily alive to the fact that all the tissues of the body might be affected. It is true that others had previously come to the same conclusion; but in comparing Hunter with most of those writers who have followed him, a wide difference is seen between the man who brought the matter under consideration, and those who either ignored the occurrence of internal syphilitic affections, or had never thought of the possibility of such conditions. Hunter certainly was not aware of the extent to which the syphilitic virus might contaminate the tissues, but he said, with modesty, that, as far as he knew, the internal organs were not affected. "It would appear that some parts of the body are much less susceptible of the *lues venerea* than others and not only so, but many parts, so far as we know, are not susceptible of it at all. For we have not yet had every part of the body affected; we have not seen the brain affected, the heart, stomach, liver, kidneys, nor other viscera, although such cases are described by authors. The lungs have been believed to have been affected with the venereal disease, both from circumstances preceding the complaint, and from the complaint itself being cured by mercury." Hunter, therefore, being alive to the fact that the whole system might be affected (though he was ignorant of the diseases produced thereby), clearly shows his right appreciation of the nature of the affection. He also saw that various ill-consequences might arise. "The venereal disease often becomes the immediate cause of other disorders, by calling forth latent tendencies to action. If the venereal disease attack the lungs, although that disposition may be corrected, consumption may ensue."

Another reason for concluding that Hunter entertained a correct view of the nature of syphilis is the fact that he spoke of it in connexion with small-pox and other exanthemata, and argued the question of the possibility of syphilis occurring twice in the same person. As is well known, he inoculated his patient with fresh matter, and drew his conclusions. At the present day most conflicting opinions are held with respect to the subject; but Hunter's mind had already penetrated it.

With reference to the so-called Hunterian chancre, I find many Medical men holding the opinion that Hunter described all chancres as of the indurated kind, but I think this is not correct. The fact, however, of his dwelling upon the induration is another evidence of his appreciation of the true character of syphilis, and illustrates his wonderful powers of observation:—"If the glans be affected, generally a small pimple appears full of matter, without much hardness or seeming inflammation, and with very little tumefaction; but if on the prepuce, a more considerable inflammation than the former soon follows." In speaking of the frænum and prepuce, he says:—"Thickening comes on, which at first, and while of the true venereal kind, is very circumscribed, not diffusing itself gradually and imperceptibly with the surrounding parts, but terminating rather abruptly. Its base is hard, and the edges a little prominent;" and in another place he says:—"A chancre has commonly a thickened base, and although the

common inflammation spreads further, yet the specific inflammation is confined to this base." Let me ask whether the most advanced syphilographer uses other terms than the thickening of common inflammation, and that due to a specific cause?

I will now say a few words with reference to the subject for which, more than any other, Hunter has been condemned, and on account of which his treatise has been by many laid aside as worthless: I mean his association of gonorrhœa and syphilis. I believe all now admit that these two diseases should be regarded as distinct, but it is scarcely remembered that difficulties often exist of which casual observers are not aware, and that at the present day almost every Surgeon of eminence must admit that he witnesses cases of the kind which led Hunter into error; and even more than this, there are some who hold Hunter's doctrine as the true one; that the syphilitic sore as applied to different surfaces will produce a local sore or a discharge. Hunter's doctrine was as follows:—"The gonorrhœa always proceeds from a secreting surface, and the chancre is formed on a non-secreting surface. By secreting surface, I mean all passages for extraneous matters, including ducts of glands, and by non-secreting, the skin, to which I may add a third kind of surface, leading from one to the other, as the glans penis, inside of lips, pudendum, which surfaces may be affected in both ways. To produce the chancre the venereal matter may be applied in three different ways: the first and most certain is by a wound into which it may be introduced; the second by applying the matter to a surface with a cuticle, and the thinner that is, it allows the matter to come more readily to the cutis; and the third is by applying the matter to a common sore already formed. A specific inflammation is produced, and the matter produced is of the same nature as the matter applied."

I will not argue as to the correctness of these doctrines; but why should they be regarded of so extraordinary a nature when any Surgeon can inform you that he had seen constitutional syphilis without any trace of sore, and that when there has been a history of gonorrhœa he assumes that a chancre has existed in the urethra? I say every Surgeon of experience sees such cases, and, ridiculing Hunter's theory, assumes another. Some Surgeons also might be asked what they mean by such terms as gonorrhœal iritis, etc. It is very remarkable that one of the latest writers, Dr. Hammond, of New York, has laid down certain laws respecting the infection of syphilis, and which, it will be seen, is a revival of Hunter's exploded doctrines. He says, "that the virus of an infecting chancre deposited on a secreting mucous membrane may give rise to an inflammation of that surface attended with a muco-purulent discharge without a chancre being necessarily formed unless an abrasion exists; that the affection is a syphilitic gonorrhœa; that it is followed by constitutional symptoms, and is contagious; that the virus of a soft, non-infecting chancre, when deposited on a secreting mucous surface upon which there is no abrasion, generally gives rise to a muco-purulent discharge without the necessary production of a chancre; that the discharge is contagious, but is not followed by specific constitutional symptoms; that the matter of each of these forms of gonorrhœa gives rise to its own peculiar form of chancre, but longer contact is necessary than when direct from a chancre. Muco-purulent discharges arising from other causes are not contagious and not possessed of specific characteristics." It may be remembered, also, that Wallace spoke of catarrhal syphilis, an inflammation of the mucous membranes of the genital organs arising from the application of venereal poison, but he would not attribute all urethral discharges to this poison.

Hunter believed that the virus might be introduced through the skin, through a mucous secreting surface, or through a wound, or through a sore. Should there be a simple sore on the genital organs, as the soft sore of the present day, and this should be inoculated with a syphilitic virus, we have the *chancre mixte* of Rollet. Thus are Hunter's doctrines revived.

In referring to the treatment, Hunter's great idea of the introduction of a poison into the system through the chancre is still manifest, for, he says, "the simplest plan is to destroy or to extirpate it, whereby it is reduced to the state of the common sore or wound, and heals up as such." Again, "if the chancre be destroyed almost immediately upon its appearance we may reasonably suppose there has not been time for absorption." If Hunter did not here discriminate between hard and soft, or infecting and non-infecting chancres, it may be asked who can do so at the present day at a very early period of their occurrence; but it is clear that he had two ends in view, to alter the character of the sore and to prevent the virus entering the system—a subject not now much further advanced than in Hunter's day.

Now, with reference to the treatment by mercury and Hunter's theories regarding the operation of this medicine. Herein will be found, according to my opinion, the most powerful argument of all in favour of the correctness of the views of this great man, and yet perhaps no part of his treatise has been so much condemned as that bearing upon treatment, both because it has been assumed that Hunter was an advocate for the indiscriminate use of mercury, and also because here will be found some remarkable theories which his commentators have denounced as speculative or unintelligible. I apprehend, however, that these very doctrines show his deep insight into the nature of the disease, and which most of his successors had failed to perceive. Let me for a moment allude to the prevailing opinion at the present day with reference to the influence of mercury in venereal disease. It seems to be this, that the disease is dependent upon a poison on the system, and that therefore time is necessary for it to wear itself out; that its progress is assisted by eliminative medicines, but that mercury itself will not cure; whether it shortens the whole duration of the disease is a question *sub judice*. Most writers at the present day seem of the opinion that it will cure or modify certain existing symptoms or effects of the disease; but since these return it has not got rid of the cause itself. The drug will not arrest or cure the disease, but it will for a time cure its effects. To use the words of Welbank, "Mercury antagonises the influence excited by the syphilitic virus, but is no specific antidote to the virus itself, which must be gradually modified or eliminated by the system at large;" or, according to Ricord, "Le mercure fait disparaitre les manifestations actuelles; il ne neutralize pas la diathèse." Hunter clearly saw the difference between destroying the cause, or the virus, and the effects, although in his time, and for a long period since, his expressions "disposition" and "action" seemed to be misunderstood. His theory, so far from being speculative, was founded on correct and close observation. "I have asserted that what will cure an action will not cure a disposition; if so, we should push our medicine no further than the cure of the visible effects of the poison, and allow whatever parts may be contaminated to come into action afterwards." The mercurialists have condemned Hunter for thus recommending the advent of symptoms before treatment, and yet at the present time some of the most eminent in our Profession are advocating similar principles. Hunter did not fail to perceive the beneficial effects of mercury in removing many of the symptoms of the disease, and thus he called it a specific, a term which has been in constant use when an unknown but decided action has been witnessed. "Mercury in lues venerea is the great specific, and hardly anything else is to be depended on. It is necessary that we should always consider well the effects of this medicine, etc." This is not stronger language than is used by some of the most eminent and judicious men of the present day. He approved, probably erroneously, of the early exhibition of the remedy, in order to prevent the manifestation of the disease, clearly showing, as before said, Hunter's true notion of its character. "The remedy should be given for some time after the chancre has healed, in order to hinder the venereal disposition from forming. The quantity should be given in such a way as to affect the mouth slightly." The last sentence is sufficient evidence to show that those who believe Hunter's practice was to produce pints of saliva in order to eliminate the disease, can never have read his book. Hunter was quite alive to its indiscriminate use and to the vulgar prejudice against it, as well as knowing there were those amongst his brethren who would join in the outcry against the remedy for the sake of pandering to popular opinion. Hunter was too high-minded and independent for this. "Nothing can show more the ungrateful or unsettled mind of man than his treatment of this medicine. If there is such a thing as a specific, mercury is one for the venereal disease in two of its forms (indurated chancre and constitutional syphilis), yet mankind are in pursuit of other specifics. The prejudices against it are supported by the public, who have in their mind a dread of this medicine, arising from the want of knowledge of our predecessors in administering it, and many of the present age who also are equally ignorant, take advantage of this weakness."

He goes on to say that mercury is a much more efficacious, manageable, and safe medicine than it was formerly thought to be, and he mentions how inunction is preferable where the intestines are irritable, and remarks how "mercury acts on all

parts of the machine, cures those which are diseased, affecting little those which are sound." Now, I look upon this as a capital piece of therapeutical observation, and applies also to the action of iodide of potassium and other remedies; for it seems to be the fact that a medicine like mercury requires to be given for a considerable length of time in order to produce a degeneration of the tissues, but that previous to this event it acts merely on the new and low formed material, and causes its disintegration and removal. Hunter says in another place "mercury in general seldom or never does any injury to the constitution; it should seem only to act for the time, and to leave the constitution in a healthy state."

Hunter allowed his patients to live well while taking a mercurial course. It may be here remarked that some years ago, as in the early days of Sir A. Cooper, all venereal diseases were treated by mercurials; and thus I have heard it stated that it was Hunter's practice to give these remedies in gonorrhœa. But here again his treatise cannot have been read, for he says, "I have observed that mercury has no more effect in curing the gonorrhœa than any other medicine."

Although Hunter uses the term specific for the peculiar action of mercury on the syphilitic disease, yet, as before said, he certainly does not mean that it is antidotal to the poison, as some have regarded his opinion, but rather that it removes the effects only, or, as he puts it, the medicine does not destroy the disposition, but only the action. If there were any doubt about his meaning, the cases which he gives in illustration would decide the question, as, for instance, a man in the year 1781 had a chancre, and being treated by mercury he soon got well. Three months afterwards he had febrile symptoms, with copper-coloured eruption, pains in bones, etc. He rubbed in mercury, and again got well. After some months he had affections of the eyes, with sore throat. He gave mercury, and was again cured. "Let us consider," says Hunter, "how far this case corresponds with the opinion of the action being easier of cure than the disposition. The first action—that is, the chancres—were perfectly cured by the quantity of mercury he took at first, for they never recurred; but the venereal matter had produced the disposition in the constitution which was not cured by the same quantity of mercury, for blotches appeared three months after; but all the parts that had taken on the disposition at that time and had not then come into action were cured by the second course of mercury; and the other parts which had not yet taken on the action went on with the disposition till the influenza (which happened eleven months after) brought them into action. The first class of pocky appearances were perfectly cured by the second course of mercury as the local had been cured by the first; for they never re-appeared, not even with the second. The second set of pocky symptoms, we have showed, appeared to be perfectly cured by the third course of mercury. How far there may be a third set of pocky symptoms to come forth time can only tell." Although, therefore, Hunter said that mercury was a specific for the venereal disease, he intended merely that the symptoms disappeared under its use; but it did not eradicate the poison from the system, for in another place he says "It is probable that mercury can cure the action only, and not the disposition."

Once more, as showing how Hunter's idea corresponded with that now held by many:—"In the cure of chancre we have two points in view, the cure of the chancre and the prevention of the contamination of the habit. The first by mercury applied either locally or internally through the circulation. The second object, to prevent the constitution from contamination, is obtained by shortening the duration of the chancre, which shortens the time of absorption." This doctrine, which was once considered illogical, is now held by some of the most practical Surgeons, as well as by the leading pathologists; the one will endeavour to show that the secondary symptoms are more severe in proportion to the duration of the hard chancre, and Virchow and his school maintain that a poison is being generated at the spot, and is thus being continually diffused through the system. In reference to these views Hunter says,—"This is not speculative, but the result of experience, and the destruction of chancres confirm it." Instead of ignoring Hunter, it would have been as well if his practice had been followed, and, if found correct, a blessing to mankind would have resulted.

I must not occupy your space further, having, I believe, sufficiently justified Hunter against the imputations of those who have never read his treatise. To those who know his works well and choose to differ I have nothing to say; indeed, my object in sending you these remarks is not to prove Hunter right or to advance any opinion of my own, but merely to show that this great Surgeon was in accord with many of the most advanced opinions of the present day. At this I am not surprised, for the subject of venereal disease is one which requires very careful observation, coupled with great judgment and prolonged study, and therefore admirably suited for the mind of Hunter, and, on the other hand, a subject which would never be understood by many of his successors, who, although admirable Surgeons, had devoted all their energies to a practical skill in their art.

11, St. Thomas's-street, Southwark.

HOLIDAY NOTES ON SOME CONTINENTAL SPAS.

(Second Series.)

BAGNERES-DE-LUCHON.

By HERMANN WEBER, M.D., F.R.C.P.,
Physician to the German Hospital.

(Continued from page 249.)

The *physiological action* of the sulphuretted springs of Luchon is that of the waters characterised by the predominance of sulphuret of sodium (a) Their *curative action* is, according to the authors, based on their especial power of promoting the renewal,—the building up of the tissue. Bordeu has expressed this by the term "remontement général de l'organisme;" and this "remontement,' or "building up," is effected by the excitation of the oxygenation of the blood, of the capillary circulation, and of the interstitial nutrition. Although this assumption cannot be called proved, yet it deserves to be mentioned and to be weighed.

The *morbid conditions* which are favourably influenced have all in common the character of being *chronic*, which in itself implies a lowered state of nutrition; the revival of the morbid process, and the re-establishment of a more acute action, seem to be the usual effect of the waters and the way to the cure; thus, chronic cutaneous eruptions are frequently observed at first to spread, neuralgic pains become often more violent, chronic catarrh of the bronchi is said to become acute.

Although all the sulphuretted sources of Luchon resemble each other in their action, yet some are found to be much more efficacious in the removal of certain pathological conditions than others seemingly of a similar composition. The fact above mentioned, that the different sources show great differences with regard to their stability and to their products of decomposition, may, in part, explain this apparent discrepancy. The sources "Ferras," "Blanche," and "la Reine" are, according to Lambron, especially adapted to the treatment of herpetic eruptions, while the sources "Richard" and "d'Etigny" possess greater power in rheumatic affections. The water of some "buvettes," or drinking fountains, as "Ferras," is more easily digested, and is, therefore, particularly suitable in the beginning of the course, and in cases of gastralgia; while that of others, as of the buvette "Prè, No. 1," is most frequently prescribed in scrofulous cases and in affections of the respiratory organs.

The morbid conditions for which Bagnères-de-Luchon is most frequently resorted to are,—*diseases of the skin*, *scrofulous affections*, *rheumatism and its allied diseases*, *affections of the fauces and respiratory organs*, and *secondary syphilis and mercurialism*.

Diseases of the skin furnish a considerable contingent to the list of patients at Luchon; and it cannot be denied that many of them are cured there with more certainty than at most of the non-sulphuretted Spas; but not all kinds of skin diseases are influenced in the same manner. The *dry affections* are in general less modified by the waters than those attended with a moist eruption; *psoriasis* and *lepra*, excepting the recent cases, are rarely cured by the waters alone; *ichthyosis* (non-congenita) is said to be improved; some cases of *lupus* are likewise enumerated among the cures. Fontan and Lambron have seen also improvement in recent cases of *tubercular leprosy*. *Pityriasis versicolor* yields but slowly to the baths. *Acne* is, in general, cured. *Prurigo* and *lichen* are mentioned by Lambron as easily conquered, "nos eaux triomphent de prurigo et du lichen," (l.c. p. 561); but I am afraid that this triumph is in some cases not a permanent one: such is, at all events, my own experience in several obstinate cases of this affection, while in others I have seen a ready and permanent cure

(a) Conf. this journal, p. 170. 1865.

effected at various sulphuretted baths. In some instances I have witnessed a more permanent result from the baths of Leuk (Loeche) and Sehinznach, in Switzerland, where the patients remain several hours in the water, and through this contract the *poussée*, leading to a thorough modification of the nutrition of the skin. Among the *moist* cutaneous affections, *eezema* is the one most frequently observed at Luchon. Lambron says: "l'eczema ne resiste pas à nos eaux, quelque invéterée qu'elle soit" (l.e. p. 561); he demands, however, in inveterate eases a long-continued use of the waters, and a renewal of the visit during several successive summers. For the greater number of eczematous patients I can confirm this assertion, but I have also met with some, fortunately rare exeeptions, cases of general chronic eezema, in which various sulphuretted waters, Luchon amongst them, and also some other baths were tried in vain; the visit to Luchon was, it is true, not repeated in these cases, but only for this reason, that the patients did not think themselves sufficiently benefited by their first trial. All of us know the troublesome character of general ehronie eczema in children, who often scratch themselves with a peevish violenee, as if tearing their flesh with their nails were the greatest of luxuries to them; but in the aged this affeetion is sometimes even more tedious, and, if I may judge from my limited experience, more obstinate. The cases alluded to as having resisted the influence of the sulphuretted Spas relate to old people. The *pustular* (impetiginous) eruptions yield in general more easily.

Some dermatologists have divided the cutaneous diseases, aecording to the constitutional conditions on which they are based, into scrofulides, arthritides, herpetides, syphilides, etc. It would obviously lead me too far if I were to enter into this subject, but I cannot omit saying a few words regarding the term "*herpetism*," which is constantly used by the Physicians of the Pyrenean spas. Fontan ("Recherches sur les eaux minérales," etc., 1853,) and others signify by this term a peculiar condition, the existenee of a virus in the blood, or of a eonstitutional transmissible vice, which manifests itself by various morbid phenomena, especially cutaneous eruptions, but also by bronchial catarrh, gastralgia, neuralgia, piles, ete. Noël Gueneau de Mussy ("Traité de l'angine glanduleuse," 1857) brings the "angine glandulense" in intimate connexion with this "herpetism." All the morbid conditions based on herpetism, however different their manifestations may be, are considered as especially suitable for the treatment at Luchon.

The *serofulous* and *lymphatie* affections furnish almost as large a number of patients as the skin diseases, and the Pyrenean Physicians regard them as one of their principal specialities. Scrofulous eruptions, glandular enlargements, cutaneous ulcers, chronic inflammation and thickening of the eyelids, rhachitis, caries of bones, and many allied affections, are often sent to Luchon. Many of the patients thus affected are greatly benefited; but I do not consider this as a sufficient proof of the *speeial influenee of sulphur on serofula*. I am rather inclined to think that the united influence of the hygienie conditions (especially the mountain air) and of the hydro-thermal treatment on the nutrition forms the principal eause of the improvement. The torpid and lymphatic constitutions derive the greatest benefit, and scrofulous complaints, when occurring in such constitutions, are likewise most favourably modified. Most of the characteristic scrofulous affections, however, as glandular enlargements and white swellings, gain, as far as my experience goes, more advantage from the mineral waters rich in chlorides, and especially where these are combined with bromides and iodides, as the *Adelheidoquelle*, near Tölz, in Bavaria; *Creuznaeh* and *Oeynhausen*, in Prussia; *Nauheim*, in Hesse-Cassel; *Hall*, in Austria; *Aehselmannstein*, near Reichenhall, in Bavaria, and many others.

Rheumatism, in all its forms and localisations, is often treated at Luchon, and with much success; but I am inclined to ascribe this beneficial influence less to the *sulphurous* than to the *hydro-thermal* elements of the treatment. At all events, the same success may be witnessed at Aix-les-Bains, where the sulphurous elements are only slightly represented, while those of the hydrotherapia thermalis are remarkably well developed.(b) They are principally the more atonic forms of rheumatism which are to be recommended to the Pyrenean spas, while the more irritable constitutions may be sent with greater safety to the so-called "*indifferent thermal springs*" as *Gastein*, near Salzburg; *Wildbad*, in Wurtemberg; *Teplitz*, in Bohemia; *Ragatz*, in Switzerland, and similar spas. The chronic rheumatic affections of the joints attended with enlargement and solid deposits derive more benefit from the thermal springs rich in chlorides as *Aix-la-Chapelle* or *Wiesbaden*, the latter especially, if there is some serofulous taint in the constitution.

Gout, in its genuine form, is not claimed by the Doctors at Luchon as curable by their sources.

Affections of the Respiratory Organs.—Persons affected with *ehronie eatarrh of the bronehi* derive, mostly, great benefit from the use of the Luchon waters, and from sulphuretted waters in general; the latter seem, indeed, *especially* applicable to such cases, and more so by the aetion of the sulphur than by an aecessory agent. Some patients, however, derive much greater advantages than others, and amongst the former are partieularly those with hæmorrhoidal tendency. I have mentioned already before the "*angine glanduleuse*," the chronic eatarrh of the mucous follicles of the pharynx and larynx (clergyman's sore-throat, follicular disease of the pharyngo-laryngeal membrane) as a class of complaints especially amenable to the treatment at the sulphurous spas. It is in these cases where the local douches with the pulverised water are employed, while in the affections of the bronchial mucous membrane, and the pulmonary tissue itself, the aspiration of the gases emanating from the warm springs ("humage") is preferred. The relation of the sulphuretted waters to *pulmonary tubereles* I will consider under "Eaux Bonnes," which is, at present, the place of predilection for consumptive people, although Cauterets and Luchon, too, have many adherers.

The subject of *Surgieal affeetions*, as old gunshot wounds, stiffness, and contraction from luxation or fracture, sequestred bones, etc., I will defer to the account of Barèges, which enjoys an unsurpassed reputation for its healing powers in these eonditions.

Cases of *paralysis* are often sent to Luchon, but I cannot find that it has any particular claim in this respect by virtue of its sulphurous elements. In cerebral paralysis, where there is the slightest tendency to congestion, it may do harm, and the same must be said of paraplegia from myelitis; in rheumatic paralysis, in paraplegia of traumatic origin, if caused either by concussion alone or by an affection of the spinal periosteum or of the membranes, great benefit may be derived from Luchon, from Barèges, and other Pyrenean spas; but this benefit is owing, not to the sulphurous, but to the thermal elements, and is obtained to the same degree at Aix-les-Bains and other merely thermal spas. The same remark is applicable to those rarer cases of paralysis from exhaustion.

Anæmia, ehlorosis, and *gastralgia in anæmie subjeets* figure likewise in the list of diseases treated at Luchon; but it is quite certain that most of the patients thus affected would derive more benefit from chalybeate springs. There are, however, exceptional cases in which iron is not borne under any shape or in any combination whatever. In such cases great benefit is derived from sulphuretted spas, especially those of an elevated situation, as Luchon.

Much has been written on the use of the sulphuretted waters in *syphilitie affeetions*, by Bordeu, Anglada, Fontan, Vidal, Astrié, James, Wetzlar, Reumont, Pigot, Lambron, and others. These waters cannot be called anti-syphilitie but yet they are often of great use in the treatment of syphilitic affections. Thus it frequently happens that patients cannot take the specific remedies administered in the usual manner; they soon lose their appetite, are inclined to diarrhœa, become the subjects of mental depression, ete.; while the same patients, when under the influence of the sulphuretted thermal treatment, bear the energetic administration of mercury as well internally as externally, and at the same time improve rapidly in health; it is exceedingly rare that the gums become affected, and if so it is but in a slight degree; the only symptom which has been occasionally mentioned to me is the appearance of superficial sores on the tongue and gums, which, by touching with caustic, easily disappeared. Patients with the *eombined mereurial and syphilitie* cachexia improve likewise rapidly at the sulphuretted spas. Experience seems in this respect to strengthen Astrié's view ("De la Médication Thermale Sulfureuse Appliquée," Thèse, de Paris), that the sulphites and hyposulphites of soda formed in the body from the sulphurets prevent the formation of the insoluble combination of mercury and albumen, and dissolve it where it has been formed; and that they, in addition, accelerate the removal of the mercurial combinations by stimulating the organs of secretion. Great advantage is, besides, derived in those most tedious cases of *syphilis eombined with serofula*. Thus, the thermal sulphuretted waters,

(b) Conf., *Med. Times and Gazette*, 1861, vol. ii., pp. 550 and 576.

although not strictly anti-syphilitic, are yet of great service in many cases of secondary syphilis and its complications. Finally, they are used as means of diagnosis in doubtful cases. It often happens that it is impossible to say with certainty whether a person formerly affected with syphilis is perfectly cured; in such cases a course of the sulphuretted waters will, if there be any latent syphilis, bring to light the most indubitable symptoms, while the non-appearance of such symptoms forms almost a certificate of cure. Observations of this kind have been made, however, not only by Medical men practising at sulphurous and sulphuretted spas,—as Luchon, Barège, Aix-la-Chapelle, and Aix-les-Bains—but also by those of non-sulphurous spas, as by Dr. Loretan, at Loëche (Leukerbad).

With regard to the manner in which the waters of Luchon are used, it may be said that the external application is of more importance than the internal use, although the latter, too, is prescribed in many cases. The principal apparatus in use have been mentioned above; the separate bath, the douche, and the piscine are the most frequently used. The temperature of the separate baths is, in general, about 95° F., but it is, according to the effect desired, occasionally lowered or increased; the usual duration of the bath is between twenty minutes and an hour. The temperature of the grand douche varies from 106° F. to 113° F.; the duration is between ten and twenty minutes. The temperature of the small piscines is about 95° F., that of the large piscine, or swimming basin, varies from 89° F. to 92° F. The piscines are especially valuable where the movement of the whole body, or of certain portions of the body, is to be encouraged, as in rheumatism, stiffness of joints, muscular atrophy, paraplegia, general debility, etc. There are patients who object to the baths in the piscines, but the principal objection, that contagious diseases may be contracted in them, is perfectly unfounded, as such an occurrence never has been observed. Another objection, that the water of the piscines is less clean than that of separate baths, is likewise much exaggerated, as the water is several times every day renewed, and as persons affected with diseases of the skin attended with discharge are not admitted. A third objection, on account of delicacy, is not very reasonable, as at Luchon the sexes are separated, and as, in addition, every bather has a kind of bathing dress.

The quantity of water taken internally varies from half-a-glass to four glasses, containing rather less than nine ounces (250 grms.). If the quantity does not exceed one glass it may be taken either before, or during, or after the bath; if it amounts to two glasses, the first is usually taken before, the second after the bath; if more than two are taken, the remainder is, in general, distributed over the other part of the day. In many instances the mineral water is mixed with milk, or various syrups, or occasionally also with other remedies.

The duration of the course of treatment varies from three to six weeks, and this period is sometimes advantageously divided into two parts with a shorter or longer interval between them.

No visitor at Luchon ought to use the waters without the advice of a Medical man of the place, otherwise he may not derive the benefit which he expects. Drs. Lambron, Barrié, Fontan, and Pégot are well known by their scientific researches, but there are, besides, several other Medical men of good reputation.

The hotels and lodging-houses at Luchon offer very fair accommodation—better, perhaps, than those of any other place in the Pyrenees. The hotel which is nearest to the thermal establishment, and which enjoys the finest view, is the Hotel Bonnemaison (M. Vidal); other good houses are the Hotel d'Angleterre (M. Seveilhac), the Hotel des Bains (Madame Merans), the Hotels du Parc, des Princes, and Sacarron. The prices are moderate—*i.e.*, for rooms, from 2 to 6 francs per day; for board—*i.e.*, two full meals at table d'hôte, at 10 a.m. and 5 or 6 p.m., 5 francs per day. There is a large number of good guides, who let small horses well adapted for mountain excursions. The season is from June until October, but the best time is in July, August, and the first half of September.

(To be continued.)

Dr. Barnes has resigned his appointment of Obstetric Physician to the London Hospital. Dr. Barnes has been for some time Obstetric Physician and Lecturer on Midwifery at St. Thomas's Hospital. There is therefore a vacancy for an Obstetric Physician at the London Hospital.

OBSERVATIONS ON THE VALUE OF THE METHOD OF SLINGING FOR WOUNDS OF THE LOWER LIMBS, ESPECIALLY FOR STUMPS AFTER AMPUTATION.

By BOWATER J. VERNON, F.R.C.S.

Assistant-Demonstrator, late House-Surgeon to St. Bartholomew's Hospital

The plan of treating fractures of the bones of the lower extremity by swinging or slinging them has been carried out in the accident wards of St. Bartholomew's and other Hospitals for many years; and in all the ordinary forms of such injury greater comfort with security could hardly be desired than are so obtained. So satisfactory have been the results of the practice, that it is remarkable that its employment should not have been long since extended to the management of many other varieties of wounds or injuries. From personal observations I can affirm that it may be most advantageously employed in many such cases, and with great gain in cases of ulcers of all kinds which are to be found represented in our Surgical wards. Its use is not limited to these, however, and I wish to show how it has rendered most valuable services in the dressing of stumps after amputation.

So far as I can ascertain, Mr. Edlin, a former House-Surgeon of Mr. Paget, was the first to sling a stump; his first case was one of amputation immediately above the ankle-joint of a man. The apparatus he employed was simply a back splint made of iron slung beneath a cradle by leathern straps; in short, the swing apparatus (called Salter's) in daily use for fractures; the upstanding footpiece was, however, removed from the back splint, being no longer required. The ease and comfort which the patient derived from this would have of themselves been amply sufficient to justify further trials, and a repetition of the plan in one or two similar cases only served to strengthen Mr. Edlin's opinion of its advantages.

On succeeding to the care of Mr. Paget's wards, and with that gentleman's approval, I worked out and extended Mr. Edlin's method; so that, with hardly an exception, nearly every case of amputation through the lower extremity, and they were not a few, was treated with some modification of this plan of slinging.

A more correct appreciation of the changes which occur in a wound undergoing repair, and especially those in stumps, has led to greater care being taken to ensure that exact adaptation of parts by moderate pressure, and to the avoidance of the excessive and unnecessary pressure so generally applied to them by older Surgeons. In addition to careful and accurate bandaging, some kind of splint has been often employed, and in Mr. Paget's wards is almost invariably used, for a well-adjusted splint not only serves as a great protection to the stump, but very materially diminishes its tendency to jump and twitch, as well as serving as a foundation for any necessary bandages or compresses.

A stump after amputations through the leg can generally be very well slung upon the apparatus first employed by Mr. Edlin, and for cases of Syme's or Pirogoff's amputation through the ankle, a modification of his plan has in my hands succeeded admirably.

If it be necessary to maintain steady support when union of soft parts is desired, very much more advisable would be its maintenance when we wished to unite two bony surfaces, as in the case of Pirogoff's amputation through the os calcis.

In order, then, to apply support to the apex of such a stump, the end of the ordinary back iron splint may be turned up like the point of an oriental shoe, and this being carefully padded, the most exact and uniform pressure may be brought to bear upon the opposed bony surfaces; in several cases this has been so satisfactory that one could not but suppose that the surfaces of bone had united by first intention, or at all events with the least possible amount of effusion having taken place between them, and in stumps such as this the advantages of neutralising the irregular twitchings of important muscles must be sufficiently obvious.

Experience showed, however, that there were several objections to be urged against the universal use of such a splint and cradle. They were very well suited to the well-formed limb of a labourer, who had lost his foot from accident, but were not so well adapted to an emaciated limb, or to the much smaller limb of a young girl, where the foot had been destroyed by disease; for the cradle is a large one, and in winter interferes much with a patient's warmth and general comfort. After various attempts to remedy these defects, I substituted a light wooden splint for the heavy iron one, and

a simple linen sling for the cradle and straps, slinging the limb to the smallest cradle I could find.

The sling consisted of a piece of stout linen—an old sheet is always at hand—which, if simply passed under the limb below the knee, and then tied over the cradle, would suspend the limb well enough; but it requires care, to prevent the limb being fretted and made uneasy by wrinkles and uneven pressure, and besides would be soon worse than useless from soaking up discharges, or inducing them to run up the limb. To avoid this latter trouble, the sling must be covered with gutta percha tissue; and by a very simple contrivance it can be made to hang perfectly smoothly and without wrinkles. The two ends may be tacked down so as to form a broad hem; through each of these is passed a small piece of wood, corresponding to the breadth of the sling; and the whole is completed by a piece of india-rubber cord, which is fastened to the centre of each of these pieces of wood, and is then passed over the centre bar of a small cradle. The stump is lightly and carefully fastened to a smoothly-padded splint, and may then be slung in a position most comfortable to the patient and most suitable for drainage and free escape of discharges; a height of a few inches from the bed will generally be the most comfortable position; a greater elevation would interfere with the escape of discharges. By an arrangement of this sort very much handling when the stump is dressed is entirely dispensed with, the stump can be washed and looked at without disturbance, and the limited motion is just enough to allow the patient to shift his own position without fear and trouble; moreover, it serves as a great safeguard if the stump should twitch or jump during sleep. In two cases of delirium tremens after amputation a simple sling of this kind was a perfect protection to the stump when tossed about, thus obviating the troubles likely to be induced by the application of tight straps to the limb above.

The splint had better be rather broader than the stump, so that its edges entirely prevent any undue pressure from the sling itself when tightened by the weight of the limb. Stumps made immediately below the knee cannot be fixed to a straight splint; the knee is always in such cases more or less flexed, and consequently an iron splint with a hinge joint is the best for such a case; but such stumps always seem to support themselves so well over the edge of a pillow that I am not sure whether a sling would entail a greater degree of comfort, while in one such case I certainly found its application less simple than in other cases.

To stumps made from the thigh it is not possible, nor would it be desirable, to allow so much motion; but still this linen sling may be used with great comfort and advantage in their management. In Mr. Paget's wards such stumps are always fixed upon a thin, flexible wooden splint, and then they can as readily and easily rest in the sling as on the pillow usually employed. The sling here is rather to support and bear the weight of the stump than to permit its movement. Its use here is in the increased facilities for dressing; and a more important gain than this, the assistance it affords to nurses when changing soiled linen, etc. In several cases where, from the rotation of the stump outwards, the direction of the wound has become vertical, the sling has maintained most valuable lateral pressure.

I very speedily found out that there were some stumps which you cannot make comfortable in a sling. However, this is the case in many fractures of the leg. Often patients cannot bear the swinging of the broken limb, though they could give no better reason for it than that it was not comfortable; but on the other hand, patients have very generally expressed the relief which such a position has afforded them.

Very many cases of chronic ulceration of the lower extremities which so often occupy our Surgical beds require little else for their cure or relief than a well-chosen and carefully-maintained position. In the majority of cases there can be no question that the constant elevation of the foot is the position required. Now, simple as it may seem, this is not always such an easy matter to attain, and, when attained, is not always the most comfortable for the patient.

A linen sling such as I have described, if made considerably larger, so as to support the heel thoroughly, will be found a most simple and yet effectual remedy for some of these cases.

As all will allow that during the repair of injuries the most perfect rest of body and mind are to be secured if possible, I need offer no apology for occupying your space with what seems a small matter, as I am convinced that by such a plan of dressing wounds, patients have derived very much comfort and relief of pain.

REPORTS OF HOSPITAL PRACTICE
IN
MEDICINE AND SURGERY.

ST. BARTHOLOMEW'S HOSPITAL.

DRY GANGRENE OF THE FEET AND LOWER THIRD OF BOTH LEGS FOLLOWING TYPHUS.

(Under the care of Mr. PAGET.)

Mary R., aged 6, was transferred from the London Fever Hospital to one of Mr. Paget's wards on October 31, of last year. She was the child of very poor parents, and had just had a very severe attack of typhus. In the state of extreme prostration to which she had been reduced during the acute period of the fever, dry gangrene of the feet and the lower third of both legs had taken place; the tip of the nose also was dry and withered, and some bed sores had formed over the sacrum. No extension of the gangrene occurred after her admission; spontaneous separation soon commenced, and proceeded with such rapidity that it was complete, excepting the bones, at the end of five weeks from the first appearance of the gangrene. The healthy soft parts became retracted from the mortified tissues, leaving the bones quite bare, and of a dead white colour for about an inch. The simple operation of sawing through the bones on a level with the granulating surface above was now performed by Mr. Paget.

After the removal of the feet the patient progressed favourably for a few days, but she ultimately died of exhaustion depending chiefly on the rapid extension of the bed sores before referred to. No post-mortem examination of the body was allowed.

The activity of the vital processes in early life is so great that gangrenous affections are seldom met with in children as the result of a simple failure of nutrition. In instances in which sloughing does occur, the parts destroyed are usually those that are involved in the morbid local action which accompanies some specific disease; for example, it is under such circumstances that sloughing of the cheek occurs in cancrum oris, or of Peyer's glands in typhoid fever. Here tissues lose their vitality through the operation of a single cause acting directly as a local poison. In the case just related the gangrene which ensued was not produced in this way; it was more allied in its causes to that which is met with in older people. The tissues perished because the conditions necessary for their support were not fulfilled. When attacked with typhus the patient was enfeebled by having lived in very poor circumstances for some time previously, so that the nutrition of the body must have been reduced below its healthy standard. In consequence of the diminished force of the circulation which took place as the fever advanced, the parts at a distance from the heart were left without their ordinary supply of blood, and that which they did receive was rendered inappropriate for their maintenance by the presence of the fever poison.

Mortification under similar circumstances is not infrequently observed during the extreme depression and exhaustion into which patients fall towards the end of severe attacks of fever. Dr. Murchison (a) records cases of a parallel kind; and Dr. Daniell (b) states that it is not all uncommon in negroes who are in the last stage of the adynamic fevers of the African coast for death and decomposition to extend gradually upwards from the extremities to the trunk, so that the former may be in a state of absolute putrescence before the circulation and respiration have been brought to a stand.

In a clinical lecture on the above case Mr. Paget made a passing allusion to instances occasionally met with in which, in consequence of impaired nutrition, the vitality of some parts of the body is habitually so low that they can scarcely be said to be living tissues, although they do not absolutely mortify; and in illustration of this class of cases he mentioned that he had recently had a man under his care, suffering from emphysema and heart disease, in whom the forefinger of one hand had remained dusky, half-livid, insensible, and cold at the end for some weeks, and, what was remarkable, for the whole period during which the finger had remained in this state no growth of the nail had occurred. Mr. Paget was unable to state the subsequent course of the case, as the man had passed from under his observation.

(a) Treatise on Continued Fevers.
(b) Lectures on Life and Death. W. S. Savory.

At a recent meeting of the Pathological Society, Mr. Partridge related a case of gangrene of the penis following fever. In reference to this subject, Dr. Murchison said that gangrene of the penis had been not an uncommon sequela of the present epidemic of typhus. In some of the cases there had been gangrene of the nose as well.

KING'S COLLEGE HOSPITAL.

CASE OF GLANDERS—DEATH—AUTOPSY—CLINICAL REMARKS.

(Under the care of Dr. JOHNSON.)

For the notes of this case we are indebted to Mr. Kelly.

In reference to the following case, Dr. Johnson remarked that from the first the nature of the disease was unquestionable. There was a distinct history of exposure to the poison of glanders, and the symptoms were very characteristic of that form of disease which is called "farcy," there having been no discharge from the nose except for a brief period at the commencement of the illness. There was no evidence as to the channel by which the poison entered the system, but it was remarkable that symptoms of constitutional disturbance preceded the occurrence of the local swellings and suppuration. It would appear, therefore, that the poison entered the blood, possibly with the inspired air, and that the successive abscesses were a result of this blood poisoning.

Dr. Johnson remarked that the odour of the matter discharged from the abscesses was quite *sui generis*, and would alone suffice for the diagnosis of the disease. It was as peculiar and characteristic as the odour of typhus, or small-pox, or gangrene of the lung, or the odour of the breath in cases of extreme uræmia.

John H., aged 47, a groom, admitted, under the care of Dr. Johnson, in No. 5 Ward, November 27, 1864. No serious illness before the present attack. Of moderately temperate habits. States that before admission he had been working in some stables where the horses had been affected with glanders, and two of these had been under his own care. About a fortnight before admission he felt rheumatic pains in his joints; he also had shiverings, was feverish, low, and nervous. A week after the appearance of these symptoms he noticed a swelling on the outer and upper part of the right forearm, which at first was accompanied by a little pain. At the same time there was a thin, watery, very fœtid discharge from his nose. Condy's fluid was injected up the nostrils, by which means the discharge ceased, and there was no recurrence of it.

On admission, his state was as follows:—A thin, pale man, with an anxious expression of countenance. A swelling was noticed on the right forearm, as before mentioned. There was no wound on the arm, nor any cracks in the skin, nor were there any inflamed lymphatics leading to the swelling.

An incision was made into the abscess, when a considerable quantity of thin, greenish-yellow pus escaped, No discharge was noticed coming from the nose. Skin cool; temperature in axilla 98·5°; pulse 64; tongue coated, brown, and dry.

On November 28 another swelling was noticed in the centre of the left anterior tibial region, which, being opened, a good deal of pus escaped. Face more anxious-looking. Tongue coated; thirsty; appetite bad. Although he could answer questions rationally, he seemed to care but little for what was going on around him. Urine pale, clear, abundant, no albumen. Ordered—℞. Tinct. ferri. mur., ♏xx.; quinæ sulph., gr.ij.; spir. chloroform., ♏x.; aquæ ad, ℥j., ter die. sum. Beef-tea and two chops; brandy 9 oz.

29th.—A third abscess was opened in the centre of the anterior tibial region of right leg, symmetrical with the last one; some pus escaped; all the abscesses were poulticed, and discharge freely. Pulse 60, feeble; tongue furred, brown, dry; bowels open.

December 3.—A peculiar smell was noticed about the patient; a fourth abscess was opened about the upper and outer part of right leg. There seemed to be more prostration; he could take his food pretty well, and felt no pain anywhere. Pulse 54, weak. To omit the iron. Addi haustui, pot. chlorat gr. x.; acid hydroch. dil. ♏x.

6th.—A fifth abscess was opened on the outer part of the left forearm in a position exactly similar to the one which first appeared on the right arm. Pulse 60, small; tongue browner, dry; bowels open.

9th.—A firm swelling was noticed on the outer and middle part of left upper arm, but no fluctuation could be detected.

12th.—There seemed some improvement; no more abscesses had formed; tongue cleaner and moister; expression of face more natural; appetite pretty good; pulse 72, stronger. The formation of the abscesses has at no time been attended with pain; they discharge freely.

23rd.—Tongue was brown again and dry. The abscesses had nearly healed and no fresh ones had formed; the swelling on the left upper arm had subsided.

28th.—Face wears an oppressed look; is haggard, rather sallow, and has a vacant stare; has become deaf; takes but little notice of anything; at times he mutters to himself incoherently; sleeps badly. Pulse 114, feeble; tongue red and glazed. The right knee is swollen, red, and painful, and fluctuation may be felt; the right ankle is also inflamed and swollen; an opening being made on the outer side a thin bloody fluid came away; the dorsum of right foot is œdematous; the left ankle was likewise swollen, and on an opening being made on the outer side some pus escaped. Brandy 12 oz.

January 2.—His aspect is dull and stupid; he can no longer feed himself; passes everything under him; has a general trembling in all his limbs; is delirious at times; quite deaf; has no discharge from his ears or nose; does not seem to suffer any pain. On the dorsal surface of both wrists is a red blush rapidly extending. The left knee is red and inflamed. On the left side of the face just outside and below the orbit may be noticed a small pustule—the first and only one that appeared during the illness. He is much emaciated, and the smell is more characteristic. Pulse 120, irregular.

January 4.—No alteration in the symptoms, but he is weaker. He sank gradually and died at 1 p.m.

January 8.—Autopsy Ninety-Eight Hours After Death.—Body much emaciated; sallow. On the left side of the face was a pustule, but no more were noticed. Right knee joint full of pus, but the cartilages were quite healthy. Left knee joint, no pus; no affection of the cartilages; right ankle, diffused abscess over, but not within the joint. Left ankle joint not affected. Lungs much congested at their bases, engorged with serum; several tubercular masses were found scattered about, not softened, varying in size from a pea to a small nut. Some old adhesions were found on the walls of the thorax. Heart healthy; right side full. Kidneys, 13½ ozs. the two; slightly fatty, otherwise healthy. Liver, 5 lbs.; fatty. Spleen 11 ozs.; apparently healthy.

WINDSOR ROYAL INFIRMARY.

TETANUS FOLLOWING AMPUTATION OF THE MIDDLE FINGER OF THE RIGHT HAND FOR GUNSHOT WOUND.

(Under the care of Mr. E. PEARL.)

[Reported by Mr. BRICKWELL, House-Surgeon.]

Cases of recovery from tetanus have always a great interest. They are so few, however, and the treatment adopted has been so various, that it is difficult to arrive at any conclusions as to which is the best plan of medication. In the following case the drug most continuously given was aconite; but chloroform was frequently given also.

P. F., a chimney-sweep, aged 18. This man came to the Infirmary on June 26, 1864, having a few hours previously sustained a gunshot wound of the right hand, which had smashed the middle finger, the charge of small shot having apparently passed completely through the finger near the metacarpal end of the first phalanx. The limb was amputated by Mr. Pearl, and all seemed to be going on comfortably till July 14, when the patient complained of great stiffness of his lower jaw, with inability to open it; stated that he felt this stiffness on July 12, two days previously, but thinking it only a slight cold, he did not think it worth while to mention it.

July 14.—With difficulty opens the jaw to the extent of half an inch. There is a slight stiffness about the articulation. No rigidity of the muscles of the neck or of the abdomen; no pain in the legs. Ordered calomel, gr. iv.; pulv. jalapiæ, gr. xv., statim; sp. æth. sulph. co., ♏x.; tct. cannabis indicæ, ♏v.; mist. camph., ℥i., 4tis horis. Broth diet.

15th.—Passed a restless night. Powder has not acted. Stiffness of the jaw continues. No rigidity of muscles of neck or abdomen. Has had no tetanic spasms. Repeat the powder and mixture.

16th.—Much the same. Some rigidity of the muscles of the abdomen. Slight tetanic convulsions of the muscles of the abdomen. Complains of his belly feeling so very hard, and refers to the umbilical region as the seat of pain. Enema terebinthinæ, statim.

17th.—Lying on his back; countenance anxious; thin sweating profusely. Pulse 86, small, compressible. 9 p.m.—The vapour of forty minims of chloroform inhaled, followed by twenty more, relieve the pain and spasms, and he falls into a quiet sleep.

18th.—Had several severe spasms early this morning, causing opisthotonos. 9 p.m.—Spasms very violent; has just been thrown out of bed, and is standing upright by the bedside in great agony. The vapour of one drachm of chloroform to be inhaled; to take at once two ounces of brandy in some warm water; one grain of opium every four hours. Urine drawn off by a catheter, as he passed none during the day.

19th.—Had some dozes during the intervals of severe spasms. Facies Hippocratica well marked. Tongue covered with a thick creamy fur, moist. Pulse 100, small and thready. Pulv. opii, gr. ij. every hour; brandy one ounce every hour. 3 p.m.—Applied ice in a flannel bag to the whole length of the spine for two hours. He complained greatly of the cold, and of a pricking sensation in the skin, and stated that he felt comfort from the application. Drew off three-quarters of a pint of turbid urine. 9 p.m.—Chloroform vapour one drachm; enemata terebinthinæ, statim; brandy, one ounce every hour; opium, two grains every hour.

20th, 8 a.m.—Symptoms much the same; passed the catheter, and drew off half a pint of turbid urine having the characteristic odour consequent on taking turpentine. Chloroform vapour one drachm; brandy one ounce every hour. 12 Noon.—Tr. aconite (Fleming's), ♏iij., every four hours. 3 p.m.—Tr. aconite, ♏iij., every hour.

21st, 3 a.m.—Has taken the tr. of aconite every hour, making in all thirty-nine minims in sixteen hours. He now complains of burning pain in his chest and throat, tingling in his fingers and hands, but no numbness of the tongue. He is very thirsty, and sweats profusely. Intermit the tr. aconite. Says he still has the spasms, but that "they are of no consequence now to what they have been." No action of the bowels; no urine has passed. 8 a.m.—Recommence the tr. aconite, ♏iij., omni horâ. 5 p.m.—Chloroform vapour two drachms, sent him to sleep. 7 p.m.—Tingling and numbness of fingers has returned.—Discontinue the aconite. 9·30.—Numbness and tingling of fingers has gone off. Recommence the aconite, ♏iij., every hour. No action of the bowels; says he feels better; spasms very short, though frequent; has passed water freely. 12 midnight.—Spasms have returned violently. Chloroform vapour, one drachm, sent him to sleep.

22nd.—Says he feels better; breathes easier; spasms much less severe; has had four hours' good sleep; has passed urine naturally; but the bowels have not acted. Ate two eggs for breakfast. Says his tongue is all in blisters. Continued the aconite till twelve o'clock, when it was discontinued on account of the numbness and tingling of the fingers. 12 noon.—Chloroform vapour, two drachms. 2 p.m.—Has had some comfortable sleep. The spasms have left the right side of the abdomen, which is lax and soft, the left muscles being still rigid. Recommence tr. aconite, ♏iij., every hour. 7 p.m.—Omit the aconite. 8 p.m.—Spasms very severe again. Chloroform vapour, one drachm and a-half, relieved him. 9 p.m.—Chloroform vapour, two drachms; croton oil, gtt.ij., statim; half a pint of beer. 11 p.m.—A simple enema caused violent spasms; brought away a former injection, a little feculent matter, and much flatus. Chloroform vapour, two drachms, sent him into a quiet doze.

23rd.—Two drachms of chloroform inhaled every two hours from 12 midnight till 6 a.m., when he had a copious watery stool, and passed urine freely. 6.30.—Two drops of croton oil in pil. 9 a.m.—To recommence the aconite every hour. 10.—Has severe spasms; put him freely under chloroform, and dressed his hand. The wound looks well and healthy. Slept from this time till 5 p.m. Asks to be allowed to suck a raw egg, which was granted. Olei crotonis, gtt. ij., statim. Says he cannot take the aconite, as it makes him so sick. From 9 p.m. to 10 a.m. July 24 administered chloroform vapour in quantities of two drachms every two hours, as the spasms were severe and continuous, and chloroform appears to be the only immediate relief to his sufferings.

24th.—The spasms have much abated in severity; he has had some good sleep, and expresses himself as tolerably comfortable; at 1 o'clock he is able to sit up and eat some custard pudding, which he says he enjoys. Has drank freely of ginger beer, which he asks for, and has taken beef tea. 9·30 p.m.—Has passed a quiet day; has been tolerably free from spasms till the present time, when he states that he has some rather severe attacks. Chloroform vapour two drachms.

25th, 3 a.m.—Pain returned very intensely. Chloroform vapour. 8.30 a.m.—Has been in great pain at times since 3 o'clock; sitting up propped up by pillows; face pale, expressive of suffering; skin cool and moist; thirst great; appetite bad; no further treatment at present. 1 p.m.—Has felt very severe pain through his stomach to his back; has not had many spasms, and they have been of slight duration; tried the recumbent posture for him, but found the spasms return with such intensity as to necessitate his being propped up again. 10 p.m.—Says he feels very comfortable; has taken some sheeps'-feet broth which he asked for. Morphia gr. ij., divide into three pills, and give him one every four hours.

26th, 8 a.m.—Sleeping comfortably; had a very comfortable night; had no spasms sufficiently severe to cause him to move; bowels have not acted. 10 p.m.—Has taken food well to-day; countenance cheerful; skin cool and soft; pulse, good volume, soft and compressible, 84; abdomen, soft, tolerant. To repeat the morphia.

27th.—Sitting up in bed, propped up by pillows; has passed a comfortable night, and has had some good sleeps; countenance cheerful and free from expression of suffering; skin cool and moist; appetite good; no great thirst; has no spasms beyond a slight hiccough; can move his legs and open his jaw to the extent of an inch and a half. Croton oil one minim in pil.

28th.—Passed a comfortable night without taking morphia; had a natural and abundant stool last night; can open his jaws and protrude his tongue better; is obliged to be propped up in bed, as the spasms come on if he lies down.

29th.—Did not sleep well last night, though he took two doses of the morphia containing two-thirds of a grain in each; Skin cool and soft; countenance cheerful; appetite very good; no great thirst; has had no action of his bowels. Haust sennæ co. ℥jss., statim; middle diet.

30th.—Going on well; slight spasmodic action of muscles of abdomen occasionally.

Was discharged cured on August 25.

SATURDAY, APRIL 29.

THE LONDON COLLEGE OF PHYSICIANS AND THE PUBLIC SERVICES.

The desire for combination and centralisation, so common in our day, has not been without its effect upon the London College of Physicians. The College has been aiming of late years at occupying a position in the Medical world more in accordance with its dignity, reputation, and authority as the principal Medical corporation. It has aspired to occupy the first, the leading position, as the federal head and representative of all branches of Medical science. The history of the College during the last few years has been marked by a more ambitious, as well as a wiser spirit of progress, and this policy has tended to increase the reputation of the College, and to elevate the character of the Medical Profession. Quite recently, however, a retrograde movement has taken place. Some of the Fellows of the College seem to have acted, on the evening of the 21st inst., as if they had been determined to stultify themselves by one of the most illogical and short-

sighted proceedings imaginable—a proceeding which, in our opinion, will do grievous injury to the reputation of the College—will tend to bring it into ridicule as a corporate body—as it must inevitably exercise a disastrous influence upon the Army and Naval Medical Services. The unfortunate members of those services will have cause to exclaim "Save us from our friends!"

Our readers can only be too well aware of the grievous and universal discontent reigning in the Medical services. Journals, Professional and lay, have teemed with complaints. Medical Universities, colleges, and associations have represented to the authorities the lamentable state of our Profession in the public services. The army has been studiously avoided of late years by all good men, and the Medical Profession in 1865 holds exactly the same very low estimate of the army which the Royal Commission in 1857 declared to be universal among the men forming the councils of the most eminent Medical and Surgical bodies in this country. When the notoriety of the evils had rendered the matter a scandal, the London College of Physicians could scarcely remain mute and inactive without belying the spirit and character of its modern course of conduct and without being false to its reputation and position. It was naturally jealous of this position as the principal and central Professional body, and it was desirous of being in the van of those who were advocating an honourable cause instead of appearing far off in the rear as the victory was being gained by others. The London College aspired to this, no doubt; but it has grounded itself and made total shipwreck of the cause it desired to serve by a want of heart and moral courage to follow the road of its own conclusions or to push these to their legitimate extent. Before the unfortunate appearance of the numerous third-class candidates, it was well known that the authorities were on the eve of accepting the necessities of their position and of yielding to the public pressure put upon them. The accession of candidates, however, securely fixed the time-honoured and unvarying policy of the Horse Guards towards our Profession. When it was known that the Royal College of Physicians had appointed a committee of able and disinterested men to inquire into the condition of the Army and Navy Medical officers, the Profession was gratified at the spirit of the step which the College had taken, and it anxiously awaited the results. The committee was composed of six of the Fellows—viz., the Senior Censor, Dr. Gavin Milroy, Dr. Sibson, Dr. A. P. Stewart, Dr. Armstrong, and Dr. Markham.

The Committee spent several months in the investigation. After a considerable amount of work, of the most onerous and laborious kind—after a very patient, conscientious, and searching inquiry—that Committee had collected such an array of *facts*, and obtained such full and authentic information on the subject as fully to have convinced themselves of the solid foundation on which the grievances rested.

The Committee prepared its Report, casting aside all considerations about the small pecuniary advantages, the insufficiently progressive nature of the pay, the length and nature of the Medical officers' services, and the fifty other minor grievances which, in the aggregate, make the Army so intolerable to the highly educated and independent Medical man. The Committee mainly confined itself to the question of the status of the Medical officer and the treatment accorded to him by the Horse Guards. The tortuous and vacillating policy of the Horse Guards was traced—the breaches of faith and the abrogation of Royal Warrants were clearly and exactly indicated; the inferior, unsettled, and ambiguous, and, therefore, unfair and difficult, position of the Army Medical officer, both in his relations to his brother officers and in the special performance of his duties, was pointed out, and it was declared that the Medical officer had to beg or fight for that which ought naturally to fall to him as a right, and which does naturally fall to every other soldier as a right. Of course, if the truth had to be told, the Report could hardly abound in fulsome flattery of H.R.H. the Duke of Cambridge, and we dare say it did not.

This report was to have been discussed on the 21st. We say was to have been, for no semblance of discussion in reality took place. A glance at the Fellows then present made it perfectly plain that many came *to vote only*. Horse Guards and Court influence had penetrated Pall Mall. The *old* College, not the *young* College, was represented. Again and again the Committee challenged the Fellows to indicate any inaccuracy in their Report. Without any real reason being assigned, the College decided upon rejecting the Report of their own Committee. The Fellows, who had not already thoroughly made up their minds how to vote, were swayed by the voices of those who were utterly and entirely ignorant of the subject, prejudiced, or, what was worse, by the voices of those who were interested only in protecting the tender sensibilities of the Horse Guards from being wounded. Of course it was open to the London College of Physicians to have shut its eyes to the injuries under which the Medical Departments were labouring, and never to have entered upon this inquiry at all. The College might have acted upon the selfish precept expressed by one Fellow, that the condition of the Army Doctors was nothing to the College of Physicians. It might have shirked the thing altogether; but it was bound by every consideration for its own reputation, if not by a feeling of common courtesy towards its own Committee, to have pursued the matter to the end. We have no patience to record the nonsense which was talked by one Fellow, who could speak of the Medical services from his experience in them some forty years ago. Surely this was ignorance as enthusiastic as it was lamentable. A Fellow whose connection with the army must have led him to know of the universal discontent prevailing in the Medical Department, however ignorant he might be, from any personal experience, of the actual working of the Department, could not venture to contradict a single statement in the Report. Sympathy was certainly expressed by the Fellows as to the condition of the Army and Navy Medical officers, and much fear was entertained lest the acts of the College should injure their cause; but the Director-General himself could not have guarded the sensibilities of the Duke more jealously than did many Fellows of the London College of Physicians.

It could not be said that the *form or wording* of the Report was the cause of its rejection. The Committee voluntcered any amount of alteration so long as the bare statement of facts remained.

If the matter be allowed to rest here it will be a disgrace to the College. It only remains for us as journalists to say that the Committee did its duty most fearlessly, most conscientiously. Each member of it spoke out his opinion with a sincerity and frankness deserving of all praise, particularly as, in some instances, this was done at considerable personal risk. They pressed on the College facts which could not be gainsaid; but prejudice, fear, or listlessness would appear to have been all powerful.

THE CORONER'S COURT AND DR. LANKESTER'S SECOND REPORT.

Dr. Lankester, the "Medical" Coroner for Central Middlesex, is making the most of his office. It is no sinecure, and he clearly doesn't mean that it shall be; in fact, by having undertaken to give an annual account of his proceedings, he has taken the step of all others best calculated to keep himself alert, and at the same time to adapt his Court to the necessities and circumstances of the day in which we live. We have heard a great deal from the Registrar-General about "avoidable deaths;" but it is only a small section of the scientific world, for the most part, that trouble themselves with what the Registrar-General says or thinks. Dr. Lankester, however, can compel the masses to attend to this

*

subject. Every inquest he holds is a practical lecture, and because practical more likely to be heeded by the class of persons who for the most part constitute coroners' juries. The doctrine taught, whether sanitary or ethical, comes home to the intelligence of the uneducated, and the repetition of the lesson must in time succeed in fixing it in the mind. From the inquest-room it goes to the public-house parlour, and there it is talked over, and into the shops, and there it is gossiped about, and into the family, and there the wife learns it. Can it be believed that such a work carried on earnestly and conscientiously, as Dr. Lankester carries it on, shall fail in producing some impression upon those ranks in society which it is most important to reach, and which it is otherwise so difficult to reach? If other coroners would take the same advanced views of their office and of their public rights, and take as much advantage of their *independence*, we should soon see some improvement in various matters affecting the public well-being.

We have used the word "independence;" for after all it is this thorough freedom of the coroner to hold an inquest when and where he will, on whomsoever he pleases, and of the jury to append to their verdict any expression of opinion they think proper, and all this without the liability to have their proceedings overhauled or controlled by any superior court, that constitutes the great value of this ancient institution. "Independence!" yes; and Dr. Lankester shows that he means to be independent. He has had a little tiff with the St. Pancras Vestry, because he thought proper to appoint his own summoning officer in that parish; but Mr. Lush and Mr. Welsby, whose opinion was sought by the Vestry, gave it against these gentlemen. The coroner may employ the most active officer he can find to do his bidding and gather information, and neither Vestry nor any other body of men can quote precedent against him. The coroner can innovate if he pleases, and where he thinks he may do so to the public advantage he does it. And it would be in the worst taste if any opposition should meet him from the Profession of which he is so distinguished a member. And yet a remark in the report (a) before us indicates a leaning towards innovation in regard to the relation of the Profession towards himself. We can quite understand the delicacy of Dr. Lankester's position. Raised to his present post on the shoulders of his Medical brethren, it would appear a most ungracious and ungrateful proceeding in him to turn round upon them after two years' time and tell them to their faces that they are, as a body, unfit to assist in the investigations carried on by his court. Nor, in fact, does he say so. What he does say is this, and we believe he says all he means:—

"A certain number of cases come before the coroner's court in which it is impossible to arrive at any conclusion as to what may be the cause of death. This sometimes arises from the inability of the Medical man, even after an accurate post-mortem examination, to say what may have caused death. There is, however, a great difference in Medical men in this respect, some hesitating between a variety of causes and placing the jury in a position of doubt, while others very readily adopt prevailing opinions as to the causes of death. . . . . I should be glad if it could be arranged that all post-mortem examinations (the incomplete and unsatisfactory method of performing which Dr. Lankester chiefly complains of) could be made by some one or more gentlemen who had made this subject an especial study, and who, by devoting their whole time to it, would be able to draw up reports which would form not only a valuable contribution to pathology, but would render more satisfactory the conclusions of the coroner's court with regard to the cause of death."

We quite agree with him. We wish that some such arrangement could be come to. We think it might be come to if Dr. Lankester expressed his views more fully upon the subject. We think some such arrangement would tend to the public benefit, and that it would tend to reduce very much those miserable exhibitions in our higher courts of law which bring our Profession into disrepute and show us to the public in a light neither amiable nor dignified. Depend upon it, also, the mass of the Practitioners of Medicine in Dr. Lankester's district need be no losers pecuniarily by the adoption of some plan such as is hinted at. It is to be recollected that, although Medical evidence cannot usually be dispensed with at inquests, the coroner is not bound to order a post-mortem examination at all unless he thinks proper, and has reasonable ground for believing that it will throw light upon his inquiry. Let this thing be thought over, and neither hastily taken up nor hastily rejected.

The subjects which provoked most discussion at the meeting of the Public Health Department of the Social Science Association when this second report was read were the questions of inquests on persons dying in workhouses, the mortality amongst infants where mothers have gone out as wet-nurses, and infanticide. As to the first of these, we quite agree with Dr. Lankester in the following remarks:—"As the coroner's inquiry is no doubt a great protection to those who die in prisons and lunatic asylums, it is, I think, a question well worthy of consideration, in view of the helpless condition of the great majority of the inhabitants of workhouses, as to whether the coroner's inquest should not be held in all cases on persons dying in workhouses; or, at least, that all certificates of death be submitted to the coroner before interment is allowed." Some recent events will give force to this remark. Where there is workhouse neglect, it is not usually the Medical man who is in fault, and an inquiry in suspicious cases will be for the benefit of the Profession in every way. It will have the effect of showing poor-law guardians that they are not following the course of popular feeling by grinding down the poor to save sixpences out of the rates. On the second of the subjects referred to, we again quote Dr. Lankester. "On looking at the ages of persons in which these inquests have been held (inquests in which the verdict has been death from "natural causes"), it will be seen that nearly half the cases were persons above forty years of age, while nearly half the remainder are cases of children under one year of age. From the facts elicited in these inquiries there is too much reason to fear that old persons and children, especially illegitimate children, are neglected; and the circumstance that a coroner's jury is summoned to inquire into the cause of death indicates either suspicion of ill-treatment, or the entire absence of Medical attendance at the time of death. In a large number of these cases the jury feel it necessary to add that the death had been accelerated by want of proper food, nursing, or Medical attendance. In the cases of children under one year, such a verdict implies blame, but not of such a nature as to warrant committing persons for manslaughter. Thus, a frequent cause of death amongst illegitimate children is the want of proper food. The mother leaves her offspring in the charge of a nurse, and sells the food destined for her own child to that of another. There is here no crime, but there is undoubtedly immorality somewhere in this kind of destruction of infant life. The law may not interfere with the right of persons to sell or buy human milk, but where a human being suffers as the result, the moral right may be fairly open to question." Every one knows that prosecutor, judge, and jury all try to avoid a verdict of wilful murder in cases of infanticide, and how the law assists them by calling for proof of actual birth and entire separation from the mother. Dr. Lankester does not suggest any method of meeting this practical difficulty in the administration of the law and in checking a practice as immoral as criminal. But there is one fact to which he directs attention, namely, "that, in inquiries into the cause of the death of illegitimate children, the putative father of the child very seldom contributes to its support." Is this worth following up as a basis for legislation?

(a) "The Second Annual Report of the Coroner for the Central District of Middlesex," by Edwin Lankester, M.D. 1858.

THE WEEK.

CONSTANCE EMILIE KENT.

The case of this unhappy young woman will raise all those questions of the difference between voluntary and involuntary crime, between wilful wickedness and irresistible impulse, which have furnished such battle-fields in the case of Townley and others. "Was it this woman's fault, or her parents' that she was born"—not blind,—but endowed with strange moral perversity? Such is the first question that arises. For, as some persons without merit of their own may be born with the grace of a placid amiable temper, so others with various degrees of malignant propensity, which are no original demerit of theirs. What we conceive human beings to be responsible for is, the degree to which they resist, aided by the lights of reason, conscience, and religion, those evil propensities which exist in greater or less degree in us all; and the danger at present is, that the doctrine of human responsibility, without which society would not be safe for a moment, shall give way to the doctrine of "irresistible impulses." There is, we believe, no doubt that the earliest family surroundings of this unhappy girl were most unfortunate, and that her early childhood was marked by strange propensity to acts of malice, for the mere pleasure of annoying other persons gratuitously. It is said that when a child, on a visit at a friend's house, she has been known to hide a dressing-case, for the mere purpose of giving annoyance; and that other evidence of inherent maliciousness exist abundantly. We earnestly hope that no more women will be hanged in England; but for all that, the doctrine that children of any age must not give way to naughty tempers must be vindicated.

THE SIBERIAN PLAGUE.

In the report of the proceedings of the Swedish Society of Physicians for the 2nd of August last, published in the "Supplement" to the *Hygiea* for 1864, the following discussion appears with reference to the above disease:—

"Hr. Huss gave, from communications received through the Foreign Department of the Royal College of Health, some information respecting the so-called Siberian plague. This disease, resembling the pustula maligna, or *milz-brand*, (a) which, under the name of tara-plague, has long been endemic on the banks of the Irtish, attacks both animals and men. In several governments the disease has, during the course of this summer, as well as in many previous summers, occurred with a decidedly epidemic character, which has this year (1864) been particularly violent. Dr. S. Ssposobin, District Physician to the Government of Novgorod, who has himself had the care of a great number of persons attacked with the disease, describes the following diagnostic signs of the various forms of the affection:—

"1. The first sign of the disease is a pustule, which causes violent itching, and, when scratched, breaks, leaving in its place a discoloured ulcer with swollen edges; the ulcer extends and the swelling increases for from two to ten days, accompanied with general indisposition, headache, and præcordial pains.

"2. Without being preceded by any pustule or spot, a swelling appears, usually on the neck, face, or eyelids. Together with general indisposition this gradually increases, and, unless Medical aid be obtained, death occurs from the first to the third day.

"3. Without any external sign, general debility, violent pain in the epigastrium, anxiety, and difficulty of breathing come on. With these symptoms, death ensues, after extreme suffering and incessant vomiting, lasting for from twelve to twenty-four hours.

"The treatment adopted by the above-named Physician consists in the external use of caustic potash, fuming muriatic acid, or the actual cautery, the sore being diligently fomented with compresses soaked in camphorated oil. Two grains of calomel are at the same time administered every hour. If eight powders be taken without effect, the dose should be doubled. This simple mode of treatment is most highly recommended by the proposer.

"Hr. Fr. Lundberg considered that the epidemic—at least, its first two forms, the ulcerative and the œdematous or erysipelatous — were completely identical with milz-brand. But as to the third form, its symptoms differed somewhat from those usually occurring in cases of anthrax, which latter might nevertheless probably be placed to the account of the now prevailing epidemic. That severe epidemics of milz-brand have long prevailed in Russia and Finland is most clearly seen from the essays published on the subject by Haartman, between the years 1754 and 1783, in which that writer states that a number of men were attacked by the cattle distemper. Virchow speaks of milz-brand fever without external pustules occurring in consequence of the internal deposition of the matter of anthrax. For many years the disease has in summer been quite common in Northern Russia, both in horses and cattle, and for the last three years it has appeared epidemically around St. Petersburg, among both animals and men. In the latter it almost always occurs on uncovered parts of the body, as on the face and hands, first with a red spot, afterwards with a pimple, which passes into a pustule, with hardened surroundings. The pustule becomes an actual anthrax, and at the same time the internal symptoms make their appearance. That a volatile miasm diffused through the atmosphere causes the disease to attack not only persons occupied about cattle, but also others, cannot be denied; nevertheless, immediate contact must be looked upon as its most general source, and hence is easily explained the rapid spread of the disease among those who live under the same roof with cattle. Hr. Lundberg also briefly recapitulated the various form of the disease and the pathologico-anatomical changes it exhibits in domestic animals."

(a) A fatal distemper of cattle, accompanied with gangrenous destruction of the spleen.

NURSES WANTED.

Under this title the *Cornhill Magazine* for the present month contains a very interesting article, drawing attention to the opening there is just now for properly qualified nurses. It appears that the various institutions in the metropolis which undertake to train nurses for the sick cannot meet the demands that are made upon them. We have heard the sad tale of the dressmakers and needlewomen till we are heartsick and almost in despair. We have tried to find employment for women in printing and lithography, and other occupations which have hitherto been reserved for men, but with very doubtful success. Here, however, is a branch of industry for which women are pre-eminently suited—where they are not brought into competition with the opposite sex—where work is abundant and well-paid—offering the advantages of an active and varied life, not without interest and excitement; and yet, strange to say, the supply falls far short of the demand. In fact, the demand for trained nurses both at home and in the colonies is almost unlimited, and will afford an outlet for women for many years to come. Surely this state of things only requires to be made known, and the demand will soon be supplied. What are wanted are young women of good character, who will put themselves, either wholly or for a time, under the direction of one of the institutions to which we have referred, in order that they may be instructed in the art of nursing at one of our large Hospitals. We commend the paper on this subject in the *Cornhill Magazine* to the attention of our readers. It is an admirable effort to make known to the public the importance of skilful nursing, and the excellent opening that is here offered for the employment of women. As Medical men, we are especially interested in seeing that the country is supplied with properly qualified nurses.

FROM ABROAD. — PROFESSOR VIRCHOW AND THE VIENNA UNIVERSITY—LAW IN RELATION TO MEDICAL ASSISTANTS IN FRANCE — PREPARATION AND PROPERTIES OF ESÉRINE—IMPROVEMENTS AT THE PARIS MATERNITÉ.

The celebration of the 500th anniversary of the foundation of the Vienna University is to be one of the grand events of the present summer in Germany. Unfortunately, discord has arisen between the Government, the students, and some of

the Professors, with respect to the day on which the celebration is to take place, it being feared that the one originally intended would give rise to political reminiscences of an unpleasant character to the reigning powers; and the probability is that the completeness of the event will be much marred by the numerous abstensions which will take place on the day determined upon by the authorities. Another curious *contretemps* has occurred, which shows that a considerable amount of wrongheadedness prevails at the head-quarters of the University. It having been determined to confer the honorary Doctor's diploma upon various celebrated Professors, a committee of the Medical Faculty has presented to the Consistorium of the University a list of no less than twenty-two names as candidates for the honour. Among these are the names of Dubois-Reymond, Helmholtz, v. Graefe, Frerichs, Langenbeck, Middledorpf, Donders, Scanzoni, Pettenkofer, Purkinje, Weber, and others of lesser note. Whoever peruses the list must be at once struck with the absence of a name which most will think ought to have headed it—that of Virchow, and would be puzzled to account for the omission. Incredible as this may seem, the omission has been intentional, and for the most trivial reason. It seems that at the Scientific Congress at Stettin, in 1863, when the subject of trichiniasis, then exciting much attention, was under discussion, in answer to an observation that the trichina had never been detected in Austria, Virchow was reported to have replied that this arose from their not knowing how to look for it there. This seemingly harmless criticism—the fact of having made which even Virchow publicly denied—gave mortal offence, and, coupled with the recollection that the Berlin Professor had more than once previously expressed himself disrespectfully of the pragmatic Vienna school, his liberal tendencies being also, we suspect, distasteful to some of its magnates, led to this petty insult being offered to him on an occasion when the claims of his scientific reputation ought to have been paramount. It is supposed that the Consistorium will interfere, and save the University from stultifying itself in the eyes of the whole scientific world.

It has been recently decided in one of our county courts that a Medical Practitioner cannot recover for services rendered by his unregistered Medical Assistant. It seems that the law bears very much harder upon him in France, where he is liable to a fine, if informed against, if he employs a pupil or an assistant unfurnished with a diploma to visit his patients. A Dr. X., of Voulx, had permitted a Medical student to visit his patients on several occasions. M. Hoste, an *Officier de Santé*, practising in the same locality, conceiving his interests to be thus interfered with, summoned the Medical student before the tribunal of Fontainebleau for practising illegally. He was condemned in a fine of 36 francs, his employer, Dr. X., being declared civilly responsible. On appeal, this judgment has just been confirmed by the *Cour Impériale*. This was a particularly hard case, for the student in question had passed all his examinations, and was preparing his thesis for the diploma, and had been nominated *interne* by *concours*. His qualifications, in fact, were far superior to those of an *Officier de Santé*, who, by a strange inconsistency of the law, may, if he choose, usurp the title of Doctor with impunity.

M. Vée brought under the notice of the Paris Medico-Chirurgical Society the new alkaloid *esérine* extracted from the Calabar bean, the properties of which he has been investigating with M. Leven. *Esérine* is a solid, crystallised substance, possessing a very slight bitter taste, slightly soluble in water, but very soluble in alcohol, chloroform, and the acids. To obtain it, the alcoholic extract of the bean is heated with water acidulated by tartaric acid. This solution is supersaturated with bicarbonate of soda, and agitated with ether, which is allowed to evaporate. It may not crystallise at first, in which case it must be re-dissolved in acidulated water, precipitated by acetate of lead and filtered. An excess of soda is to be added, and agitation with ether repeated. When this alkaloid is dissolved in exactly the necessary quantity of a diluted acid and introduced under the skin, it produces all the symptoms of poisoning by the Calabar bean. The absorption of one or two milligrammes by the guinea-pig, and three to five milligrammes by the rabbit, suffices to cause death. At the autopsy, the nervous centres are found in a normal condition, the lungs being exsanguineous and the heart flaccid. In about half the animals killed by it, an absence of contraction of the pupils has been noted. This was especially observed in a guinea-pig rapidly poisoned by placing a concentrated solution on the globe of the eye. Yet, whenever a diluted solution (*e.g.*, $\frac{1}{1000}$) of *esérine* is dropped between the eyelids, whether in man or animals, contraction of the pupils is observed. This substance has been administered in certain nervous affections, such as contraction of the limbs, etc.; but the trials have as yet been too few to report upon.

The discussions on Hospital hygiene which have of late been carried on so actively in Paris have borne some good fruit in a reform of the condition of that terrible pest-house the Paris *Maternité*. According to the *Moniteur*, this has undergone a thorough reorganisation, the number of beds being considerably diminished and the amount of space per bed correspondingly increased. The lying-in wards have been subdivided, so that each shall contain but six beds, effectual ventilation and warmth being secured by means of windows and open chimneys in place of stoves. The subdivisions of the wards are alternately evacuated, and kept for a time under constant and active ventilation, while all foul linen is immediately removed, and water-closets on the English plan have been constructed. The wards of the infirmary have undergone corresponding improvement, only from two to four patients being placed in each. All direct communication between the lying-in wards and the infirmary has been cut off, the pupils and Medical attendants not being allowed to re-enter the lying-in wards after having visited the Infirmary or being present at an autopsy. Eventually, it is intended to construct a detached Infirmary in the garden. In consequence of the suppression of several beds by the above arrangements, a lying-in Hospital, constructed upon entirely new principles, has just been erected in the garden of the Cochin Hospital. That great benefit will result from these judicious reforms, tardy though their adoption has been, we doubt not.

"LICENSED ASSISTANTS, OR A LOWER GRADE OF MEDICAL MEN?"

(*From a Correspondent.*)

We have opposed, and shall continue to do so, the counter practice of chemists and druggists. Still there is no doubt that this supplies a public want; it does for the public what the old apothecaries, with their open shops, used to do. But the old apothecary is improved, literally, off the face of the earth. He deserves a better name and higher rank, and has got both. The question is moving in many minds as to how the prevalent want shall be supplied; how shall we get a race of men, able to treat petty illnesses—walking illnesses, as they may be called—and content with the profit they may get on the few pence or shillings they may charge for their medicine? Shall they be *pharmaceutists* or a new grade of *apotheeary*, analogous to *the class of licensed Assistants* which the Apothecaries' Act created? If the public acted with common sense they would no more go to such men than they would go to a law stationer or discarded attorney's clerk for legal advice, for it is too much, with human nature as it is, to expect such men to give up a case frankly when it becomes too deep for them. Still if the public *will* have such a class of Practitioners, it is well to look out ahead, and see who or what they should be. On this topic the following remarks from an intelligent and acute observer of Medical men and things deserve attention. If the truth must be said, it is not the pharmaceutist who apes the Practitioner so much as it is the unqualified Practitioner who apes the pharmaceutist:—

"Persons who have passed the examinations of the Pharma-

ceutical Society (as a rule) wish only for the legitimate exercise of their calling; almost without an exception the 'prescribing' druggist turns out to have been an unqualified assistant to a general Practitioner.

"But as regards the employment of unqualified men by general Practitioners, what is to be done? It is no use to blink the question, for, in reality, it is becoming a very serious one. Year by year the difficulty of procuring legally qualified men becomes greater. Opportunities offer in the public services, in the colonies, in the great ship companies, and wherever our language is spoken, for energetic young Medical men. Salaries have been doubled in twenty years, yet men get scarcer. Education for the Profession is longer and more expensive, and Practitioners are in a manner forced to get dispensers, whom they teach to attend midwifery, and visit on emergency. These men either ultimately become legally qualified to practice, or enter into business as chemists, and import into their shops what they learned in Surgeries. And this is by no means an easy matter to see a remedy for. If qualified assistants are scarce, what is the Practitioner to do? yet if he educates an unqualified person he begets a prescribing druggist.

"Would a more extensively authorised assistants' examination by Apothecaries' Hall mitigate the difficulty?"

"Of one thing I am perfectly sure, that the more you investigate the matter the more assured you will be that the educated pharmaceutist hates prescribing, and recommends the Doctor—those who have been in some measure trained in Surgeries engender the difficulty.

"The person alluded to in the memorial of Mr. Milner, of Hereford, to the Medical Council is rather an unqualified Medical man than a chemist, and the latter name is merely assumed for convenience."

REVIEWS.

De l'Ataxie Locomotrice et en particulier de la Maladie Appelée Ataxie Locomotrice Progressine. Par le Docteur Paul Topinard, Interne des Hôpitaux. Ouvrage Couronné par l'Académie Impériale de Médecine. (Prix Civrieux, 1864.) Paris: Baillière et Fil. 1864. Pp. 575.

This work obtained last year the Civrieux prize awarded by the Académie de Médecine. It is based upon 252 observations, of which 43 are original. They are thus divided:—136 relate to progressive locomotive ataxia, 70 to a variety of morbid conditions accompanied by locomotive ataxia, and 46 are cases where indeed there was no ataxia, but which are directly connected with the subject of the essay. The essay is divided into two parts. In the first the condition of locomotive ataxia is regarded as belonging to the domain of general pathology, or a symptom to be traced out among the principal groups of diseases. The second part treats of a particular kind of locomotive ataxia, and is the direct reply to the question proposed by the Academy—namely, "to give the history of progressive locomotive ataxia." Two extracts, which sum up the first and second parts of the essay respectively, will give our readers a better idea of the contents and scope of the work than any summary of it that we could draw up.

"Locomotive ataxia, in the sense that attaches to the term at the present time—that is to say, synonymously with disorder of locomotion and equilibrium, compatible with perfect integrity of the muscular force and different from trembling, from chorea, and from convulsions—is a symptom, like paralysis or anæsthesia, common to a host of diseases. We have met with it in order of frequency thus: In affections reputed chronic myelitis, about 150 times; in diseases of the cerebellum, 24 times; in hysteria, 7 times; in alcoholism, 6 or 7 times; in syphilis, 4 times; in worms, 3 times; in general paralysis, twice; in old cerebral apoplexy, old medullary apoplexy, cerebral softening, tumours of the peduncles of the brain, lead poisoning, mercurial poisoning and consecutively to scarlatinous angina, each once; and finally in rheumatism generally; in the total, 53 times at least in diseases other than chronic myelitis, against three times the number in the latter disease. It appears under three forms; one evidently of cephalic origin, consisting in unusual impulsions; another, also of encephalic origin, or perhaps arising in the medulla oblongata, and characterised by a simple disturbance of the sense of equilibrium; the third, or common form, of special origin, consisting in a defect of co-ordination, the anatomical cause of which is an alteration of the posterior columns of the cord."—P. 122.

The following are the general conclusions which M. Topinard arrives at with respect to "progressive locomotive ataxia:"—

"3. Progressive locomotive ataxia has been included in Germany among the numerous species of *tabes dorsalis*, and even described with sufficient accuracy by Hufeland, Steinthal, Wunderlich, and Romberg. In England, Todd has marked out one of its forms with precision. M. Duchenne, in France, has given the most complete clinical description of it up to that period (1858). 4. Progressive locomotive ataxia is a morbid variety detached from the group of affections known as chronic myelitis. The precise information we possess upon it, its frequency in practice, the importance of its anatomical lesion, the combination of its two fundamental clinical characters,—namely, primary functional disturbance of the cranial nerves, and ulterior locomotive ataxia—authorise its being named and described separately. 5. The anatomical lesions occupy—1st, the periphery of the cranial nerves; 2nd, the posterior columns of the spinal cord through a great part of their length; 3rd, the posterior roots of the spinal nerves; 4th, exceptionally, the nerves of the limbs; it is an atrophy of the nervous tubules, with hypertrophy of the intermediate elements; it represents the advanced stage of a morbid phase which up to now has escaped our recognition and our formulæ. 6. Progressive locomotive ataxia has its origin often with the other affections passing under the name of chronic myelitis. Sometimes it touches upon general paralysis. Two of its modes of termination are insanity and paralysis. In close relation with it is a malady the history of which is yet to be written, in which grey degeneration attacks the brain, the cranial nerves, the anterior columns more than, or as well as, the posterior columns, without locomotive ataxia forming any part of its symptoms. The word 'entity' is thus inapplicable to progressive locomotive ataxia. 7. The primary cause which engenders progressive locomotive ataxia operates upon the whole of the nervous system, with a preference for the medulla, just as calcareous degeneration affects the whole of the vascular system, with a preference for the valves of the heart. In making progressive ataxia a disease of the cord, we imitate those Physicians who, in the latter instance, recognise mainly an affection of the heart. 8. Progressive locomotive ataxia presents itself under three forms: the first, complete or general, in which the disturbances of the cranial nerves show themselves some years before those of the limbs, or at the same time with them; the second, damaging, or paraplegic, in which there is merely deficiency. (Sometimes the ophthalmoscope or the autopsy unsuspectedly demonstrate their existence); the third, cerebral, characterised by superadded cerebral symptoms. 9. The progress of the disease is not fatally progressive; it exhibits stationary conditions of long duration, and even some spontaneous retrogressions. The spinal symptoms are generally severe at the outset, and more or less apparent in the four limbs. The third or advanced period has for its principal symptom an alteration in muscular power. Up to the present time there exists no instance of a recovery from an unquestionable progressive locomotive ataxia. Death succeeds by an intercurrent disease. 10. The Physician can give relief, can suspend the progress of the malady or ameliorate it. He will have thus an active part to play; in the first place he will judge from the indications, and will rest, according to the individual upon hygienic treatment, upon tonics, hydrotherapeia, sulphurous baths, mineral waters, revulsions to the spine, etc., each one of which appropriately used will give him some success. In the last place, he will seek assistance from empirical agents,—that is, in fault of anything better, from nitrate of silver. Progressive locomotive ataxia rejects an uniform treatment, and up to the present time possesses no one specific remedy. 11. The locomotive ataxia in this form of disease does not coincide necessarily with an integrity of the motive power. It is dependent neither upon muscular debility, nor upon cutaneous anæsthesia, nor upon muscular anæsthesia, nor upon mixed anæsthesia. 12. The muscles are endowed with two kinds of sensibility; the one general, appreciable by means of electricity, pinching, or the bistoury when they are the seat of inflammation, etc.; the other, special (or sensorial)—the sense of muscular activity. The perception of passive movement, the knowledge of position as well as sensibility to pressure, depend upon a complex sensibility, in which all the tissues of the limb concur. 13. Walking, in the physiological condition, is subordinate, like respiration, to two influences; the one, which commands—periodical; the other, which executes and co-ordinates. The former is the will, the latter is the reflex power of the spinal

cord. Locomotive ataxia is produced whenever the reflex power is altered or diminished. 14. Locomotive ataxia, properly speaking, is marked by a truly characteristic physiognomy only in the lower limbs. Its effects in the upper limbs approach those which determine in them trembling, incomplete paralysis, and cutaneous anæsthesia. The reason is, that the reflex or co-ordinating power, of which locomotive ataxia is the functional disturbance, is physiologically less developed in the brachial than in the lumbar portion of the spinal marrow."—P. 536.

Preservation of Dead Animals from Putrefaction.

(1) *Alla R. Accedemia delle Scienze de Torino Relazione.* Di Paolo Gorini, sui lavori da lui eseguiti per la Conservazione delle Sostanze Animali. Milano. 1864. Pp. 33.

Report to the Royal Academy of Sciences of Turin on the Works of Paul Gorini on the Preparation of Animal Substances. Milan. 1864. Pp. 33.

(2) *Sui Preparati Cadaverici.* Di Paolo Gorini. Rapporto Approvato della R. Accademia delle Scienze de Torino. Pp. 16. 8c. 1864.

Paul Gorini's Preparation of Dead Bodies. Report approved by the Royal Academy of Sciences of Turin. Pp. 16. 1864.

The author of the above work (1) is a professor of natural philosophy in Lodi, near Turin, who for the last twenty-two years "has patiently laboured at the preparation of animal substances." His object was to find a method (1) of hardening animal substances; (2) of indefinitely preserving dead animals for cabinets of natural history, or embalming the bodies of the human race; (3) preservation of subjects used for dissection indefinitely; (4) preservation of anatomical preparations; (5) preservation of butchers' meat without change. The author informs us that he can preserve meat in a state fit for food for several months; and with regard to the embalming of the human body, it appears that M. Dubois, of Amiens, said, in 1847, "I must say that I first of all consulted M. Gannal concerning the process of embalming of M. Gorini. M. Gannal had informed me that the preparations made by M. Gorini were of a marvellous beauty! I admit that I had been astonished to hear M. Gannal praise thus a method not his own;.but M. Gannal made no difficulty in confessing with sincerity that M. Gorini not being able to compete with him because of time and expense he was not at all afraid to praise his preparations;" and M. Poiseulle, who reported on M. Gorini's preparation to the Academy in 1847, said: "Amongst the preparations which he (M. Gorini) has shown us, some imitate the most beautiful works in wax, although they are really parts of the human body. According to the author, volume of the part is preserved by his process, and even the expression appears scarcely altered. The skin does not peel off. The eyelids are so well preserved that they can completely cover the aperture of the eyes; the lips remain tinged and completely cover the mouth; the nose is not pinched, and in general the expression remains unaltered, like life in death.

As to the preservation of subjects for dissection, it is important in warm climates, such as Italy, and in warm weather in this country, when we often see many subjects rendered unfit for dissection in a short time. In 1864, in the month of July, it appears that a report was made to the Academy of Physical Sciences of Turin on the subject of Professor Gorini's method of keeping dead bodies from putrefaction. He had stated,—

1. That by his method there could be preserved for the space of about six months bodies in such a state of softness and freshness as to be able to serve as subjects for dissection; and that dissections which were undertaken even two or three months after the process might easily be carried on for two months, no putrefaction being to be apprehended, and all cadaveric odour and danger of dissection wounds being at the same time removed.

2. That these same subjects, when this time has gone by (six months), commence to become hard and turn into mummies, and at the end of another couple of months they finish by drying up and becoming exceedingly hard; and from that time, for an indeterminate number of years, by means of prolonged immersions for some weeks in water, the softness and roundness of forms may be restored, so as to resemble fresh subjects, and to serve again for dissection.

3. That this process has the power of hardening the bodies with so slight an alteration of form as that the personal identity can readily be maintained.

The following is a part of the conclusions come to by the Commissioners of the Academy, held in December, 1864, in Turin:—

"After having verified that in M. Gorini's method no incision of the vessels takes place, nor any cutting into the bodies, it was also found that no injections into the intestines were used, as had been supposed. Your Commissioners have to declare that by means of the process of Signore Gorini may be obtained the preservation of bodies intact for a time which may be called indefinite. These bodies remain for some months in a state of natural softness, more or less inodorous, according to the condition in which they were when prepared. As long as this state lasts they are always fit for dissection; at the end of this time, in place of passing into putrid fermentation, they dry up, or, as others would say, turn into mummies; but they are able always, even after long and complete dessication, to resume again their primitive softness by prolonged immersion in a bath of water. Thus softened, they are of use again, as before, for dissection, excluding always the brain, the eyes, and the fine microscopic tissues. The viscera of the two cavities, thoracic and abdominal, are preserved in a marvellous manner. The nerves, the muscles, and the vessels can be perfectly dissected out, even to their finest ramifications. The odour which is given forth from the bodies thus softened, when prepared at fit seasons, is a mixture of that of rancid fat and of macerated epidermis—disagreeable, it is true, but not strong. The subjects which have been dissected for some time may again be plunged into water, whence they may again be taken after a long time, even in summer. . . . Knives and other instruments are not injured by these subjects more than by unprepared subjects. The process of M. Gorini will also be useful for the preservation of bodies in Medico-legal inquiries."

"The effective summing up of all the advantages of this process which we have just enumerated depends strictly on the material conditions of execution of the process. These are not known. Signor Gorini keeps them a secret, and our delicacy hinders us from insisting that this should be revealed. We thus have limited ourselves to some questions which it was our duty to make, and here we note down the answers obtained, not without adding that the well-known character of Signor Gorini dissipates all doubts relative to their credibility. Signor Gorini has assured us (1) that for the simple preservation of subjects for dissection only one day is required; (2) that the cost of this operation is small, and for each subject would not exceed five francs (= four shillings); (3) that different substances may be used for the purpose, the novelty being in the operative procedure; (4) that, for the reduction to the state of mummies, preserving the colour and forms of the body, the substances used for the operation are particular ones, and that the operation is simple, but long, requiring daily supervision of the dissective process.

"Your Commissioners conclude by expressing the wish that Professor Gorini may be induced to render public his discovery, certain, as they are, that this will render great advantage to science, and the more so when it is remembered that no discovery is perfect at its birth, and that the discovery of Professor Gorini given forth to the public will not be long in becoming perfected.

"S. Berruti. A. Sobrero.
"G. Moleshott. F. De Filippi."

A Ward Manual; or, Index of Surgical Diseases and Injuries. By T. W. Nunn. London: Hardwicke. Pp. 79.

This appears to be intended as a catalogue of diseases to be filled up by the student as he sees specimens of the various diseases indicated, so that he may know which of the multiform varieties of diseases he has had opportunities of seeing, and which he has not. There is at the end a short account of inflammation and other constitutional diseases, compiled with care from standard authors, although we must except the account of syphilis, which is meagre and confused. The author gives as the character of *tertiary* syphilis, what is truly the essence of all syphilis, and misses a good opportunity of conveying the germs of a good modern syphilography to his readers.

The Benefits of Sanitary Reform, as shown at Salisbury in Nine Years' Experience thereof. By A. B. Middleton. London: Simpkin, Marshall, and Co. One shilling.

A thoroughly scholarly, well-written, interesting, and most unbiassed account of one of the best sanitary experiments of

the century. We have read few pamphlets which more show the author's power of looking at all sides of a question, and of exercising a sound judgment. The facts he gives as to the effects of the sewage on the trout in the Avon bear out Mr. Chadwick's doctrine; and his opinions on the relative claims of filth, poverty, and those unknown quantities which we call "epidemic" as factors of pestilence, meet with our heartiest commendation.

London Meteorological Diagram, showing the Daily Elements throughout the Year 1864. By C. O. F. Cator, M.A. London: Edward Stanford, 6, Charing-cross.

This very elaborate sheet shows as clearly as possible, by means of a coloured diagram, every element of the meteorology of London during every day of 1864. The maximum and minimum and daily mean of barometer, thermometer, wind, rain, weekly mortality, moon's phases, etc. All these, too, are *London* elements, not *Greenwich*, for the Greenwich mean of temperature is nearly 1·5 degree below the London. This diagram is so well done, so clear, and gives all epidemiologists and sanitarians such a mass of information of the most desirable sort that we hope it will be largely bought and imitated; and for this latter purpose we see that blank sheets are prepared by Messrs. Stanford at half-a-crown a piece.

The Applications of Geology to the Arts and Manufactures. By Professor D. T. Ansted, M.A. London: Hardwicke, 192, Piccadilly. 1865. Pp. 300.

This is an expanded edition of the Cantor Lectures delivered by Professor Ansted at the Society of Arts in 1864-5. These lectures commemorate a benefaction from the late Dr. Cantor, of the East India Medical Service, and are intended to illustrate various applications of science to the arts. In the volume before us, Professor Ansted shows who may be benefited by a scientific knowledge of geology, and how. Agriculture, water supply, sands, clays, cements, concrete, stone, Fuller's earth, salt, bitumen, iron stone, coal, and metallic veins, are all considered in turn, and thus a book is formed, every page of which shows some useful or interesting fact.

A Dictionary of Science, Literature, and Art. Part I. Edited by W. T. Brande, D.C.L., and the Rev. G. W. Cox. London: Longman and Co. 1864.

This is the first number of what promises to be a most useful addition to our libraries. It is to comprise the "definitions and derivations of the scientific terms in general use; to enter into the history and descriptions of the scientific principles of nearly every branch of human knowledge;" and is proposed to be completed in twelve monthly parts at 5s. Amongst the contributors to those articles which will more especially interest our readers are—Professor R. Owen and C. Carter Blake, on Biology; Lindley and Moore, on Botany; Brande, Frankland, and Attfield, on Chemistry; Ansted and Bristow, on Geology and Mineralogy.

The Pritchard Case.—Dr. Pritchard was on Friday examined by Sheriff Sir Archibald Alison at the North Prison, Glasgow, with reference to the death of his mother-in-law, Mrs. Taylor. The prisoner declared that he was neither directly nor indirectly accessory to the death of Mrs. Taylor, but declined to make any further statement on the subject. He was subsequently committed for trial on the additional charge of poisoning Mrs. Taylor. We believe that it is considered not impossible that the trial of Dr. Pritchard may begin on Monday, May 8, before the High Court of Justiciary here.—*Scotsman.*—It is only common justice to the accused to refrain from all assumption as to his innocence or guilt until the evidence in the case has been placed before a jury. We think that the tone of many of the paragraphs which have appeared in the Scottish newspapers in reference to the case has been most objectionable. Nearly everything which has appeared has been written under the supposition of the prisoner's guilt. It must be remembered that the possession of antimony is really worth nothing as evidence when the accused person is a Medical Practitioner, and even the discovery of antimony in the tissues of the deceased may lose much of its significance when the full history of the cases are known.

FOREIGN AND PROVINCIAL CORRESPONDENCE.

GERMANY.

(Continued from page 430.)

Berlin, April 9.

One of the most successful clinical teachers of this University is Professor Traube, who is also well known by his original researches on fever, animal temperature, and diseases of the chest. He has been connected with this University for nearly twenty years, and had lately the gratification of receiving the honorary title of "Privy Councillor of Medicine"—an incident which is worth recording, in so far as it is, to my knowledge, the first similar distinction ever bestowed by Government upon a Jew. Professor Traube is at present in Italy recruiting his health, which has severely suffered in consequence of the very great assiduity with which he has devoted himself to his work, both in Hospital and private practice, and in the physiological laboratory. A few notes from his lectures on the diagnosis of chest diseases may be of interest to your readers, and I will to-day only allude to "what the inspection of the thorax tells us," and the diagnostic value of certain sputa.

As regards the abnormal shape of the thorax observed in certain affections of the chest, Professor Traube distinguishes the increased and diminished volume of the thorax. Where there is increased volume we may have (a) the *emphysematous* thorax; in this the sternum is curved like an arch, and the anterior sides of both halves of the thorax have a similar shape. The bulging commences generally in the second or third intercostal space. The lower parts of the thorax are only altered where emphysema is exceedingly severe. The upper ends of the ribs are elevated, and the angle which they form with the cartilages approaches a straight line. In such persons certain muscles of the neck, such as the sterno-cleido-mastoids, the scaleni and trapezii are generally hypertrophied. The dorsal part of the vertebral column is strongly curved. This form of thorax, with hypertrophy of the muscles mentioned, is observed in persons who have suffered from dyspnœa, and who have been forced to make frequent inspirations. In young people we occasionally notice a variety of this form of thorax; its upper part is abnormally prominent, while from that point where the sixth and seventh rib join with their cartilages there is considerable flattening. The cause of this form is generally bronchitis during infant life.

Another form of thorax, with increased volume, is (b) the *ectatic* thorax, which is produced by pressure from within outwards, either by gas or by liquid within the chest. In this form the anterior wall of the thorax is strongly prominent, although not so strongly as in the emphysematous form; a second prominence is seen from the sixth to the twelfth rib. The intercostal spaces are filled up and enlarged, and if the pressure is severe they may even bulge outwards. Simultaneous with this form is bulging of the diaphragm into the abdomen, and displacement of the heart. If the right half of the thorax is ectatic, the heart is displaced towards the left side, and *vice versâ*.

A third form of thorax with increased volume is the conical form, which is caused by tumours or liquid in the cavity of the abdomen. In this form the periphery of the lower margin of the ribs is increased.

There are also different forms of thorax with diminished volume of the same. The most common form of this kind is the *paralytic* thorax, which is just the reverse of the emphysematous one. The anterior surface forms a straight plane; the sternum may also form a straight line, and there is a peculiar position of the shoulders and collar-bones. A line drawn from the neck to the shoulders is very much inclined towards the horizon, while in the normal thorax it is straight; and the same is the case with the collar-bones. The shoulders are therefore lower than usual, so that the neck appears longer. The angle which the ribs form with their cartilages is somewhat considerable. The upper intercostal spaces are considerably dilated; the lower ones are much narrowed. This is probably owing to the muscles which elevate the thorax having lost their tone. This so-called "phthisic habitus" is not always produced by tubercular disease of the lungs, but persons with such a thorax are predisposed to tuberculisation of the lungs. Another form of thorax is that which is due to pleuritic effusions; that half of

the thorax which is affected is smaller in every respect. In consequence of the shortening of the longitudinal diameter, the corresponding shoulder is lower. The lateral wall of the chest is concave, the shoulder-blade of the same side is further apart from the back, and the spine is curved, its convexity looking towards the healthy side.

The normal type of inspiration is the costo-abdominal one. The movements of the ribs are much less considerable than those of the abdomen, the latter being only caused by contraction of the diaphragm. In observing the movements of the thorax it is of importance to notice which muscles participate in the motion. The muscles of respiration are, according to Professor Traube, of a threefold kind—viz., (a) one constant muscle of respiration—viz., the diaphragm; (b) accessory muscles of respiration, which take part in the act of breathing, but are not essential; these are the scaleni, the levatores costarum, the internal and external intercostals, and the cartilaginei; and finally (c) accidental muscles of respiration, which only come into play where there is a considerable impediment to breathing. These are the sterno-cleido-mastoids, the trapezii, the pectorales minores and the levatores alæ narium. Under ordinary circumstances the ribs are only slightly moved in males, while in females there is a very distinct elevation of the upper ribs. True abdominal breathing is observed where the spinal cord below the exit of the phrenic nerves is diseased. True costal type is seen, on the other hand, where there is pain in deep breathing, most frequently in pleurisy, and also where the lower portion of the lungs has been consolidated. For expiration no muscular force is necessary, as the lungs, in consequence of their inherent elasticity, continually tend to contract as soon as they have been expanded by extraneous forces.

Sputa of a greenish colour are, although not very frequent, yet not rare, and have always attracted much attention in consequence of their striking appearance. Hitherto their origin and significance have been believed to be always of the same kind, but from some curious cases lately observed by Prof. Traube it appears that we must distinguish at least two varieties which, as regards their causes and their import, are entirely different. Greenish sputa are found where there is a complication of icterus with an affection of the respiratory organs. They have been chiefly noticed in what is called bilious pneumonia. It is generally believed that the sputum owes its colour in this instance to an admixture of bile-pigment, and there can be no doubt that cholepyrrhine is, under the influence of atmospheric oxygen, changed into biliverdine. Prof. Traube has, however, observed that not only in bilious pneumonia, but also in ordinary bronchitis with mucous expectoration, the sputa may be of a green colour, if there is a complication with icterus. On the other hand, greenish sputa may be observed where there is no trace of icterus; and they are, then, the product of pneumonia with a stealthy and protracted course. In the latter class of cases we must distinguish three different conditions: (a) the ordinary croupous pneumonia, where the affection does not terminate by a crisis, but where, while the fever slowly disappears, resolution is still possible; (b) in cases of croupous pneumonia, with termination in abscess; (c) in the commencement of "cheesy pneumonia," with a sub-acute course, whether complicated with tuberculosis or not. In these last-mentioned cases the green colour of the sputa does not depend upon bile-pigment, but upon a green colouring matter which must proceed from a peculiar alteration of hæmatine. M. Andral has asserted that the peculiar varieties in the colour of sputa observed in pneumonia are due to the quantity of hæmatine contained in them, so that the lighter shades, such as the rusty, or the lemon-coloured sputum, would be produced by a very small quantity of blood mixed with the sputum. Professor Traube has, however, shown by a series of experiments that if a solution of gum or albumen is mixed with blood, the deepness of the colour varies according to the quantity of blood added, but remains always blood-red, and never assumes a different tint. From this it seems obvious that the peculiar shades in the colour of sputa in pneumonia must have a different cause. There is no doubt that they have a certain connection with the number of blood-corpuscles contained in them, for we may, by the aid of the microscope, always discover blood-corpuscles in such sputa, and they are the more numerous the richer the colour of the sputum. Now, it seems reasonable to suppose that, in the mass of the sputum, the hæmatine will gradually leave the blood-corpuscles, and become dissolved in the liquid, where, under the influence of atmospheric oxygen, it gradually passes through the same changes of colour which we observe where blood has been effused into the cutis (for instance, in a "bad black eye"). The blood-red spots which appear at first in consequence of contusions are, as everybody is aware, gradually changed into a rusty, lemon, and greenish colour before they finally disappear. Having regard to these facts, we are justified in explaining the grass-green colour of sputa in pneumonia with a stealthy course, by assuming the presence of a colouring-matter, which is the last oxidation product of hæmatine. With this view of the matter, it is easy to answer the question why, in acute croupous pneumonia without icterus, there is never a green sputum. It is because the sputum containing hæmatine is, in this instance, expectorated before the latter could pass through all the metamorphoses of the pigment. Green sputa are, therefore, of considerable importance both for diagnosis and prognosis, being mostly of ominous import.

IRELAND.

Dublin, April 11.

At the last meeting of the Surgical Society of Ireland, Dr. Fleming brought under consideration the subject of the endoscopic examination of the urethra and bladder, and took the opportunity of exhibiting the endoscope. He wished it to be understood that he confined his investigation to the clinical objects of the instrument, and had used the form of the latter recommended by its advocate, M. Desormeaux. Dr. Cruise, who was the first to bring forward the instrument in Dublin, made and contemplated improvements which, no doubt, would, in his hands, be found most useful. The fluid used for the lamp on this occasion by Dr. Fleming was gazogene, as recommended by M. Desormeaux, the light flame of it being, as stated by the French writer, best suited for the special illumination required. Dr. Fleming showed the usual endoscopic instruments and described the mode of their application, particularly noticing the endoscopic speculum for the examination of the urethra in its several portions, and the endoscopic catheter for the exploration of the interior of the bladder, which he suggested might be termed the "fenestrated catheter." He did not enter more fully into the subject on this occasion, as his experience was necessarily too limited to justify the expression of any decided opinion respecting the value of the instrument. He had, however, learned sufficient to convince him of the necessity for its study as an additional aid in the diagnosis of the most intricate and painful diseases to which man is liable. In the living subject he could satisfy himself as to the appearances of the lining membrane of the urethra and of the bladder, and in the dead he was enabled to recognise the outlines and the colour of foreign substances introduced into the latter.

Dr. Cruise, whose improvements of the endoscope are alluded to in the foregoing communication by Dr. Fleming, and whose demonstration of the instrument before the Medical Society of the King and Queen's College of Physicians was noticed in the number of your journal for March 25 (p. 323), has been good enough to afford me an opportunity of inspecting his endoscope, and of comparing it with that of Desormeaux. As to the superiority of the former, there can be no second opinion; the illumination in Dr. Cruise's instrument excels that in Desormeaux's as much as daylight does twilight. The illuminating power which Dr. Cruise uses is the light evolved from the *thin edge* of the flat flame of a petroleum lamp. In order to obtain the utmost steadiness and intensity of light, Dr. Cruise employs a tall draught chimney and dissolves a large proportion of camphor in the petroleum. The disadvantages of this light are its great heat and small size, rendering peculiar ventilating and adjusting arrangements necessary. The heat is avoided by encasing the lantern of the instrument in thin mahogany, and by having a constant draught of cold air traversing it. The adjusting arrangements are as follow:—The lens which condenses the light upon the inclined mirror placed at the top of the exploring tube, is mounted on a doubly-shifting stage, having an up and down and a right and left movement. By this arrangement the proper position can be obtained in a moment.

The light is magnificent; in fact, so bright that the observer cannot look *directly* at it for even one minute without the eye being dazzled and unfitted for use for some time. By its aid the endoscope is rendered a perfect success.

I have thought it well to take the opportunity afforded me in noticing Dr. Fleming's communication, to bring more distinctly before your readers than has heretofore been done, the details of the most important of Dr. Cruise's improvements.

GENERAL CORRESPONDENCE.

CERTIFICATES IN LUNACY.—FORM OF GUARANTEE.

LETTER FROM DR. JOSEPH BULLAR.

[To the Editor of the Medical Times and Gazette.]

SIR,—May I request you to give publicity to the inclosed? It is a form of guarantee drawn by an experienced barrister against the possible consequences of signing a lunacy certificate. It should be signed by as many of the relatives who can be induced to do it—(in a recent case where I used it there was no difficulty in obtaining the signatures of the wife and two brothers and two sisters),—and it should be witnessed by two witnesses, and sent within a fortnight to Somerset House to be stamped. The stamp is sixpence.

Some of your readers may agree with me that where the risk is so considerable it is wise to take every precaution, and may like to keep a copy of this by them for these emergencies.

I am, &c. JOSEPH BULLAR, M.D.,
Physician to the Royal South
Southampton, April 18. Hants Infirmary.

"*To Dr. ——, and Dr. ——.*

"Gentlemen,—We, the undersigned, having requested you to sign a certificate for the admission into a lunatic asylum of Mr. ——, of ——, whom we believe to be a person of unsound mind who ought to be confined in an asylum for lunatics, do hereby in consideration of your so signing the same, and permitting the same to be used at our request, agree and undertake as follows:—

"First, to guarantee and save harmless you and each of you against all costs, damages, and expenses of you or either of you, and all claims and demands against you or either of you by reason of or touching your signing the same certificate or permitting the same to be used; and

"Secondly, that you and each of you shall be completely indemnified by us against all the consequences of you and each of you so signing the same and permitting the same to be used.

Thirdly, we undertake to defend at our own cost any action, suit, or other proceeding against you or either of you touching or relating to that certificate, or to the use thereof, or to the confinement and treatment of the said lunatic by reason thereof. As witness our hands, this day of , 186 ."

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 11.

Dr. ALDERSON, President.

A PAPER, by HERMANN WEBER, M.D., F.R.C.P., was read

ON SOME FORMS OF DELIRIUM OR ACUTE INSANITY DURING THE DECLINE OF ACUTE DISEASES, ESPECIALLY THE DELIRIUM OF COLLAPSE.

Dr. Hermann Weber prefaced his paper by the remark that he did not intend to treat on the usual delirium arising during the increase and acme of acute diseases, but on a form which occurred occasionally after the crisis, or towards the termination of such diseases, and which was attended with the phenomena of collapse, a form which he was inclined to designate as the "delirium of collapse," and which resembled much more the mental derangement usually termed insanity than the common delirium. After having alluded to the literature of the subject, he described seven cases, which in reality were equal to nine, as in two of them there were two separate attacks of disease; and he remarkedthat the delirium occurred when the pyrexia and the other active symptoms had already much abated; that in all there was a feeble, mostly frequent, and sometimes irregular pulse; that in the majority the face and extremities were more or less cold, and the skin in profuse perspiration. The delirium was characterised by the suddenness of the outbreak, which almost always occurred on waking, and more frequently in the early morning. The delusions were in the majority of cases of fixed nature, and the subjects of a gloomy kind, repeatedly traceable to the occupation of the mind just before the commencement of the illness. There were hallucinations of the senses, especially of hearing, but occasionally also of sight. The duration of the mental derangement varied from eight to forty-eight hours. The condition of the brain and nervous system appeared to be allied to anæmia; and to be connected with that peculiar shock not rarely experienced by the whole system during the decline, but sometimes also at the time of the crisis of acute diseases, and significantly termed "collapse." The writer alluded also to the occasional but more rare occurrence of transitory mental derangement, different from the common febrile delirium, during the increase of acute diseases, which might be similar to the derangement in the cases before the Society, and farther to the mental aberrations occurring during the advanced convalescence. He maintained, however, that not all the mental disturbances observable during the decline of acute diseases were of one and the same nature; and considered also the peculiar delirium or insanity arising during, and at the decline of, rheumatic fever as different from the delirium here described as the delirium of collapse. Regarding the treatment, Dr. H. Weber thought that rest and the use of stimulants externally and internally, according to the degree of the collapse and the concomitant circumstances, would probably in the majority of cases suffice, but that opiates, which in this condition seemed to be well borne, even in large doses, appeared to accelerate the recovery.

The PRESIDENT observed that the paper of Dr. Weber presented many points of interest and embraced a large range of diseases, as measles, scarlet fever, typhoid fever, and rheumatism, in which the Author described the peculiar delirium as coming on after protracted illness. They had all seen this form of delirium in protracted cases of typhoid fever in young persons, especially after a continued use of stimulants, sometimes excited or set up apparently by most trivial circumstances. In his own experience he had generally seen the best effects from slight counter-irritants, to relieve what may be reasonably attributed to temporary congestion of the brain or its membranes; for it is well known that after delirium in typhoid fever, in fatal cases, no appreciable lesion is ever found. He had seen the symptoms described by the Author of the paper in long-continued cases of rheumatism complicated with pericarditis, when there was found after death extensive effusion in the pericardium; but he confessed that in those cases he always looked upon the maniacal symptoms as of fatal character.

Dr. SANKEY said that, having been connected with the Fever Hospital for nine years, and having afterwards for nine years studied insanity, he would offer a few remarks on the paper. He had seen cases exactly like those described by the author. The delirium occurred after waking, and was more of the character of acute melancholia, and was attended by apprehensions. He had known both illusions and delusions, and related a case in point. He agreed with the author that collapse was the chief element in causing the delirium. The cases were, he believed, rare, as, after having had under observation 8000 cases of fever, he believed he had only seen twenty or thirty cases. Without referring to his notes, he could not say whether it occurred more frequently after typhus or typhoid. He had treated his cases by stimulants, and the delirium had generally passed off; but in one case it did not, and the patient was sent to a lunatic asylum. His subsequent experience had not been so clear. Although many cases of insanity had been attributed to fever, yet the ignorance of the patient's friends prevented certainty on that point. He could not say, therefore, in his experience that any case had become a permanent one. The patient whose case he had just alluded to was well again in a month.

Dr. FULLER thought that such cases were not unfrequently met with, and said that he had seen four or five during the last few years. A girl one day, when convalescent, became "raving mad," but soon recovered under the influence of stimulants. In another, the symptoms continued for some time, and the patient was sent to Hanwell, but recovered in six weeks. He thought that he saw at least one or two cases a-year. He objected to the term delirium of collapse. It is true the delirium occurs in a state when the patient is most exhausted, but he had not found that it occurred in those specially exhausted, but, on the contrary, in those who had gone through the disease pretty well.

Dr. WEBSTER had listened to the paper with great pleasure.

He asked if there had been any history of previous insanity, or of any hereditary tendency. He believed that such cases occurred from collapse after fever, and similar cases followed want of food and exposure. One of the commonest symptoms in illness after shipwreck was delirium or temporary insanity. He agreed with the Author, that the delirium was due to physical exhaustion, and also that it was to be best treated by opiates. Dr. Webster then remarked on the delirium attending convalescence from bronchitis and pneumonia.

Dr. Goodfellow considered that the delirium in the cases related by the Author was allied to delirium tremens. He had seen after typhoid fever a transitory delirium, like that of delirium tremens; after typhus a more permanent delirium. Many other circumstances might give rise to similar delirium —want of rest, extreme anxiety, etc. In all the delirium was due to debility, and resembled the delirium of delirium e potu.

Dr. Wood was disposed to agree with Dr. Fuller, that the cases were not so very rare. No doubt the cause was physical exhaustion, the form of delirium being given by the patient's peculiar idiosyncrasy. His experience as regards treatment coincided with the Author's—viz., that by opium. Stimulants were obviously important, too; but opium was to be chiefly relied on.

Dr. A. P. Stewart said such cases were rarely found after typhoid; more frequently after typhus. He had not seen a case in which the delirium became permanent; but such cases occurred. He would have liked to have heard from the Author details as to the sleep of the patients during the earlier part of the disease. As the opium treatment had been so successful, he was led to think that there must have been wakefulness before. He agreed with Dr. Goodfellow that the delirium was allied to delirium tremens, and that it might occur from many circumstances preventing sleep. Dr. Stewart then instanced the case of Hugh Miller as one of insanity due to long-continued mental labour. He wished also to know the temperature of the external air, as it had a remarkable effect on mental health. The many cases of insanity which occurred during the retreat from Moscow showed the great influence of alteration of temperature in producing insanity.

Dr. Horace Dobell asked if difference in treatment of fevers, which were followed by delirium oftener in the experience of some than others, might not account for the difference in frequency in the practice of different speakers.

Dr. Goodfellow said that his remarks applied to various diseases, and not to cases of fever only.

Dr. Wynn Williams said that he had seen a similar kind of delirium in women who had nursed their children too long. He had also seen several cases occurring after the subsidence of typhoid fever. He had treated them successfully, not by opiates, but by blisters to the nape of the neck.

Mr. Gant remarked as follows:—"I would ask the able Physicians present whether the delirium in the cases described can be regarded as the effect of either 'collapse' or 'anæmia?' This question is essentially important, it having reference to the pathological condition, of which the delirium was the most prominent symptom, and to which it was immediately due—a question, in fact, as to the pathology of the cases themselves, and determining their affinity to other cases in which delirium is present. That the delirium was not due to the collapse in these cases, would appear from the well-known fact that no delirium is ever present in the collapsed stage of cholera, which might be said to be the very type of collapse. Nor, again, was it due to the anæmia; for, in cases of extreme hæmorrhage, delirium is, generally, if not invariably absent. Surveying the history of the cases observed, the pathological condition which would appear to have been the *immediate* cause of the delirium was 'cardiac syncope,' or simply failure of the heart's action, more or less prolonged."

Dr. Weber, in replying to Dr. Webster's remarks, stated that he had not discovered any hereditary predisposition to insanity in his patients; he did, however, not think that this point could decide whether their mental aberration ought to be regarded as acute insanity or delirium, but agreed with Dr. Wood that there was no real difference between delirium and insanity; he thought that neither the duration of the mental aberration, nor the presence or absence of fever, nor the nature of the delusions, warranted our drawing a line of demarcation. He was unable to give exact answers to Dr. Stewart, but, as far as he could remember, the patients had not been altogether deprived of sleep before the outbreak of the delirium; they had, however, manifested that degree of sleeplessness peculiar to most febrile diseases, especially the febrile exanthemata. He was also not aware that any remarkable change of the external temperature had been concomitant with the outbreak of the delirium. In reference to Dr. Goodfellow's observations, he acknowledged that there were points of resemblance between the delirium described and the delirium tremens, although alcoholic beverages had been taken by none of his patients to an immoderate degree; but as in delirium tremens the removal of the accustomed stimulus (by accident, or by nausea, and dislike to it) caused, or, at all events, preceded the commencement of the delirium, so in these cases the sudden diminution of the stimulus of the blood, though the diminished power of the heart, appeared to him a most important cause. The feeble and often irregular pulse, the cold, pale face and extremities, and the profuse perspiration pointed in that direction, as also the facts that the delirium almost always broke out immediately after waking, and in the early morning—viz., at the time when in the decline of acute diseases the remissions were strongest, the temperature of the blood and the action of the heart at the lowest: when, therefore, the difference between the previously much increased and then much diminished power of the heart were greatest. Mr. Gant's objection to the view that collapse had given rise to delirium, the author thought, might be due to the double sense in which the word collapse was used; while Mr. Gant seemed to apply it to that state of loss or depression of power which might be caused by the action of a poison on the system, or of excessive secretions, as in cholera, he (Dr. Weber), in his paper, understood by it that peculiar shock frequently observed during and after the crisis of acute diseases, which often was very slight and almost imperceptible, like a transitory chilliness, or a rigor, or a feeling of faintness and anxiety, with more than usual perspiration, which was, however, in some cases, accompanied by all the phenomena of serious prostration, causing the greatest alarm to the patient himself, as well as to those around him. It would be desirable to find different terms for these different conditions.

THE PATHOLOGICAL SOCIETY.

Tuesday, April 2.

Dr. Peacock, President.

Dr. Crisp exhibited several morbid specimens, casts in wax, and drawings to illustrate the various forms of

TUBERCLE, ITS SEAT AND ORIGIN IN THE LOWER ANIMALS.

Dr. Crisp said that he had never found tubercle in an invertebrate animal; but in fishes he had seen tumours that had some resemblance to tuberculous deposit in the higher vertebrata. One great peculiarity in the lung tubercle in birds and mammals was the general absence of cavities, and the large amount of earthy matter in many orders, especially in the ruminants. Another important fact which he had before mentioned was the comparative infrequency of tubercle in the purely animal feeders. The lungs, spleen, kidneys, and a portion of the peritoneum of a gruet monkey were shown, all of them studded with tubercles; those on the peritoneum were very vascular, about the size of a millet seed, and connected with a small branch of an artery. A portion of the lung of a Bactrian camel which Dr. Crisp had recently dissected was also exhibited. It consisted chiefly of nodules, varying in size from a pea to that of a nut, and both lungs were throughout affected with these tubercles, which contained a large amount of earthy matter. The bronchial glands were much enlarged, and they contained so much earthy material that, on drying, they were seen to be hard and stone-like. It was well known that the blood of the camelidæ was of an eliptical form, unlike that of all other mammals; but the blood of this animal, although the spleen and liver were sound, contained a very large number of white corpuscles, which were round and about three times the short diameter of the red discs. Some glands of a peculiar character in the colon, cæcum, and ileum of this animal not before described were also exhibited. In both the animals above named, the liver was sound, and hence the prolongation of life under such an amount of lesion of pulmonary structure, the liver evidently taking on a part of the office of the lungs. When both liver and lungs were extensively diseased, life was soon extinguished. The camel and the monkey had been in a travelling menagerie, where limited space, unnatural food, and a vitiated atmosphere would all tend to occasion the lesions enumerated. Tubercle in wild animals (excepting rabbits in unhealthy localities) was rarely or never met with.

Dr. Wale Hicks showed a specimen of

OPEN FORAMEN OVALE.

A boy, 2½ years old, died of croup after a few days' illness. The foramen was widely open, and the pulmonary valves were thickened. The boy had never been ill before the croup, and the only noticeable symptom he had had was blueness of the hands occasionally when he was cold. The dimensions of the orifice at the pulmonary artery were below the average at the patient's age, according to the observations given in the President's book.

The President said the case was interesting as regards the absence of cyanosis. Under ordinary circumstances there must at all times have been admixture of venous and arterial blood, and yet the cyanosis was only occasionally noticed. This was doubtless to be explained by the circumstances that, though the pulmonary valves were thickened, the orifice was large and the ventricle powerful, and therefore probably there had been but little actual obstruction to the circulation.

Mr. Norton exhibited a specimen of

MALIGNANT DISEASE OF LARYNX.

The subject of this disease was an out-patient of St. Mary's Hospital, under the care of Dr. Sieveking. For five months he suffered from severe cough, constant secretion of sputa, hoarse whistling, prolonged inspiration, frequent paroxysms of urgent dyspnœa; pulmonary sounds perfectly normal. By the aid of the laryngoscope a tumour was seen on the left side of the epiglottis, but the cords were not visible owing to the glottis being filled with muco-purulent sputa. The post-mortem verified the laryngoscopic examination. Malignant disease occupied the left side of the larynx, extending from the epiglottis downwards between the left cord and the left ala of the thyroid cartilage. The diseased mass under the microscope presented a comparatively small amount of fibrous stroma, the chief part consisting of cells of the most variable form, some containing several nuclei.

Mr. Holmes asked if the possibility of relief by tracheotomy had been entertained?

Mr. Norton said that the patient had not been seen either by himself or by Dr. Sieveking in a paroxysm of dyspnœa. He seemed to be sinking from cancer.

In reply to the President, Mr. Norton said that no cancer had been found in other parts of the body.

Dr. Gibb remarked that Mr. Pemberton had stated to him that no well authenticated case of cancer of the larynx was recorded in which there was no cancer in other parts of the body. He (Dr. Gibb) however had recorded several cases in which cancer appeared to have begun in the larynx, and to have then affected other parts of the body secondarily. It was well, he considered, to disabuse the Professional mind of the belief that cancer of the larynx was always secondary, or tracheotomy might be usefully performed in some cases.

The President suggested that drawings of the specimens should be made, as, although primary cancer of the larynx did occur, it was undoubtedly rare.

Dr. Murchison showed a specimen of

HYDATID CYST OPENING INTO THE BILE DUCT.

The patient had jaundice and colic, and then a discharge of hydatids from the bowels. He continued to pass them for from ten to fourteen days. He gradually recovered, and got to business again. He felt well, except that he had pain in his abdomen. One night pain and vomiting came on suddenly, and he died of peritonitis.

Dr. Murchison then showed

A SPLEEN FROM A PATIENT WHO HAD DIED OF TYPHOID FEVER.

There had been, he remarked, much discussion as to the so-called typhoid matter in enteric fever. It was said to have been found in the larynx and in the spleen. No doubt ulceration of the larynx occurred in typhoid fever, but he had never found any deposit in it. It was also quite exceptional to find any deposit in the spleen, and it appeared to him that it was more of the nature of embolism. In the specimen exhibited were two wedge-shaped masses, the result, Dr. Murchison believed, of embolism.

Dr. Thomas Ballard showed a specimen of

DISEASED KIDNEY.

The patient had had pus in his urine, and had suffered from incontinence of urine. There had been an abscess in the left loin, which, at the autopsy, was found to communicate with the kidney. There was also a communication with the rectum. The kidney was much disorganised.

The President supposed the specimen was one of strumous pyelitis.

In reply to Dr. Hillier, Dr. Ballard said that he had not been able to make a complete examination, but no tubercle was found in other parts of the body, so far as he had been able to investigate.

Mr. Spencer Wells exhibited a

SEMI-SOLID OVARIAN TUMOUR,

which weighed thirty-seven pounds after four pounds of fluid had drained out of it, and which he had removed entire the day before from a woman, 30 years of age, in the Samaritan Hospital. It was non-adherent, but as it contained no large cysts, a long incision was required—the longest, Mr. Wells said, he had ever made. It extended twenty inches in the distended integument; but when united and the skin had contracted it only measured thirteen inches. The patient rallied well at first, but sank exhausted twenty-seven hours after the operation. The tumour consisted of an immense number of very small cysts, many of them being filled with fibrine in different stages of fatty change. The operation would have been done some months earlier, but the patient then suffered from effusion into the left pleura and also into the peritoneal cavity. The ascitic fluid was twice removed by tapping, the pleural fluid was absorbed, the general health improved, and then the operation was done, though with very little hope of success, on account of the still weakly state of the patient and the large size of the solid tumour.

Mr. Spencer Wells also showed a

FATTY TUMOUR FROM THE RECTO-VAGINAL SEPTUM,

or from the recti-ischiatic fossa, which had completely closed the vagina in a young lady. It was lobulated, and weighed two pounds when removed. There was no difficulty in the operation. The specimen was shown to make known a very cheap and efficient mode of preserving morbid preparations. It was simply placed on a sheet of glass, a little ammonia placed beside it on blotting-paper, and then a glass shade was put on and sealed round the edges with a little lard. This specimen had been so preserved nearly two years, and it retained its original appearance almost as well as a wax model. Mr. Wells said that chloroform was said to be as good a preservative as ammonia, and if so it might answer better, as it would not saponify fat.

NEW INVENTIONS, INSTITUTIONS, ETC.

GENERAL NURSING INSTITUTE.

We can mention with thorough approbation the General Nursing Institute, whose head-quarters are at 5, Henrietta-street, Covent-garden. The management appears to be in able and respectable hands, and we believe that Medical Practitioners can on emergencies obtain nurses promptly, who will do their duty well.

SALT'S NEW UMBILICAL TRUSS.

We must give the description of this instrument in the words of its inventor:—

"The umbilical truss consists of two main parts—the pad and the encircling belt.

"The belt is made of soft and flexible rubber web, which exerts its compressing power on the pad.

"In this pad lies the chief novelty of the invention. It consists of a circular disc, or plate, into which is fastened, by machine work, a facing of soft leather (as are the pads of the patent orthonemic trusses exhibited to the Royal Medico-Chirurgical Society, November 5, 1864), backed up, for solidity, by thick paper. To give softness and flexibility to the pad, a rubber cup is inserted, having a spiral spring coiled within it, which causes the pad to follow the bowel in its return, and to retain it securely within the abdomen.

"The belt is attached to the pad by means of a pair of clasps, which, by a novel application, are made to clip the web by compression, without stitching, thus reducing the cost and complication of the apparatus. The ends of these clasps fit into a series of holes in the pads, which are cut in a semi-circular form on the outer side, to admit of the belt moving without displacing the pad.

"The chief advantages of these belts are :—

"1. Their greater simplicity, lightness, and facility of application.

"2. The perfect immoveability of the pads when once placed in position over the hernial opening.

"3. The exquisite roundness and smoothness of the edges of the pad, which renders them perfectly incapable of rubbing or abrasing the skin."

Certainly nothing can exceed the finish of the truss which has been sent us as a specimen, and we commend it to the attention of our Surgical brethren. Mr. Salt is already favourably known for his well-devised and comfortable abdominal belts.

DOMESTIC HOT AIR BATHS.

Any one who is passing by North Audley-street would do well to call at No. 20, and examine the various ingenious baths for the application of heated air to the whole body, or to any part of it. They consist of a double layer of sheet metal, with water between, which can be raised to any given temperature by means of a lamp; and are adapted for the whole body, or for face, arm, leg, etc. The bath for the entire body is, in fact, a portable Turkish bath, which takes up the room of an old-fashioned easy-chair, and may be used in any dressing-room. We suspect that these baths are less liable to abuse or mischief than the well-known popular lamp bath, and that they are good remedies in gouty and rheumatic cases, etc.

We understand that they can be obtained on hire as well as on purchase, and that they are patented by Dr. Robertson, a retired member of our Profession.

MEDICAL NEWS.

University of Aberdeen.—At the late Medical Graduation term, the following candidates, after the usual Examinations, received Degrees in Medicine and Surgery :—

THE DEGREE OF M.D.

Edward Batt, M.R.C.S.E. and L.S.A., Oxfordshire
John Tasker Evans, M.R.C.S., Hertford
James Farquharson, Edinburgh
George Findlay, A.M., Keith
James E. Fowler, A.M., Aberdeenshire
Jas. Thos. Gage, Aberdeen
Alfred O. Jones, M.R.C.S. and L.M., London
William C. Lucey, M.R.C.S., L.S.A., and L.M., Surrey
Edwin B. Muskett, Norfolk
Thomas Seccombe, F.R.C.S.E., Plymouth
Joseph B. Siddall, M.R.C.S.E. and L.S.A., Derbyshire
Edward Sutcliff, M.R.C.S. and L.R.C.P.L., Surrey
James Taylor, Banffshire
Martindale C. Ward, M.R.C.S.E., M. and L.S.A., and L.M., London.

THE DEGREE OF M.B.

William S. Birnie, New Pitsligo
William Center, A.M., Aberdeen
Anthony C. Colborne, L.R.C.P., L.S.A., London
John Dawson, M.R.C.S. and L.S.A., Norfolk
William Duncan, Aberdeen
Alex. Gibb Grant, Aberdeen
George Garvin, Colombo, Ceylon
David A. Kerr, Aberdeen
George King, Aberdeen
John Macpherson, Huntly
Robert M. Milne, Dunnottar
Thomas Milne, Aberdeenshire
Alexander G. Mitchell, A.M., Rayne
John Murray, M.R.C.S. Eng., Aberdeen
Alexander Ogston, Aberdeen
Samuel Rowe, M.R.C.S.E., London
Charles E. Saunders, M.R.C.S., London
John Simpson, Kintore
Francis Snaith, M.R.C.S. and L.S.A., Lincolnshire.

THE DEGREE OF M.C.

William Center	John Macpherson
Anthony C. Colborne	Robert M. Milne
John Dawson	Thomas Milne
William Duncan	Alexander G. Mitchell
John Tasker Evans	John Murray
George Findlay	Edwin B. Muskett
James Fowler	Alexander Ogston
James Thomas Gage	Joseph B. Siddall
George Garvin	John Simpson
Alex. Gibb Grant	Francis Snaith
Alfred O. Jones	Charles E. Saunders
David A. Kerr	Edward Sutcliff
George King	Martindale C. Ward.
William C. Lucey	

Of the before-mentioned candidates,

William Center	George King
Anthony C. Colborne	Alex. Ogston
John Tasker Evans	Joseph B. Siddall
James Thos. Gage	Edward Sutcliff

and Martindale C. Ward

received their Degrees in Medicine and Surgery, with highest Academical honours.

James Elsmie Fowler | Edwin B. Muskett
and Charles E. Saunders

received their Degrees in Medicine, with Academical honours, and

William Duncan

his Degree in Surgery, with Academical honours.

At the same time,

Alfred Swaine Lethbridge and
Frederick John Wadd

were certified as having passed all the Examinations, and are entitled to receive Degrees on their attaining the necessary age.

And the following were declared to have passed part of their Examinations :—

William S. Aitken	Alex. R. Gray
George H. Anderson	John Thos. Hughes
Alexr. Cameron	Charles Maclean
John M. Campbell	William Macrae
John Carless	Alexr. C. Reid
Jas. C. G. Carmichael	James Rodger
Jas. Allan Coutts	John Shives
William W. Galloway	Alexr. B. Strahan
Benjamin Graham	Hercules S. Traill
Wm. R. Gordon	David Young
Charles D. Grant	

The next Professional Examination for Degrees in Medicine commences on Monday, July 24, 1865.

Royal College of Physicians of London.—At a General Meeting of the Fellows, held on Friday, April 21, 1865, the following gentlemen, having undergone the necessary Examination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practise Physic as Licentiates of the College :—

James Byers Thomas, Palamcotta, India; James Jones, 88, St. John-street, Clerkenwell; Franklin Gould, 26, Charlotte-street, Bedford-square; Ernest Rudolph Gotthard Groth, M.D. Berlin, 12, Sutherland-terrace, Brixton; Edwin Burrell, Westley, Bury St. Edmunds; John Spencer Ferris, 62, Great Russell-street; Henry Cripps Lawrence, 4, Palace-road, Kingston-on-Thames; Edward Septimus Earle, 22, Queen Anne-street; Joseph Frederick Eyeley, Llanymynech; Thomas Sheldon Foster, Carnarvon; Newton Greenwood, Penryn, Cornwall; Robert Lamb, 162, Caledonian-road.

Royal College of Surgeons of England.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners on the 25th inst. :—

Alfred Courtnay Baillie Melhado, Bayswater; Alexander M'Ivor Tindall, Falsegrave, near Scarborough; Paul Quick Karkeek, Pentreve, Truro; George Jones, L.S.A., Loughborough-road, Brixton; and Francis Bateman, Canterbury, students of St. Bartholomew's Hospital. John Gill, Weston-under-Redcastle, Salop; Howard David Reynolds, Haverfordwest; Jabez Thomas, Swansea; and Henry Whiting, Southend, Essex, of Guy's Hospital. George Arthur Brown, L.S.A., Welshpool, Montgomery; John Oakley, Shrewshury; Franklin Gould, B.A. and L.R.C.P. Lond., Charlotte-street, Bedford-square; and Richard Murhall Hickman, Leaton, near Shrewshury, of King's College. Richard Ley, South Molton, Devon; Rees Llewellyn, Maesgwyn, Breconshire; and Edward Seymour Wright, March, Cambridgeshire, of the London Hospital. Charles George Firman, L.F.P. and S. and L.M. Glasgow, Wivenhoe; John Swindale, L.S.A., Appledore, Devon; and Alfred Jones, Chepstow, of the Middlesex Hospital. John Stuckey, L.S.A., Langport, Somerset, and George Washington Evans, Streatley, near Reading, of University College. Henry John Foulds, Derby, and Thomas Stretch Dowse, Bradford-on-Avon, of the Charing-cross Hospital; and James Algernon Temple, M.D. M'Gill Univ., Quebec, Lower Canada.

Admitted on the 26th :—

Henry Rundle, Plymouth; Josiah Oake Adams, Plymouth; John Thomas Laugley, Monmouth; Richard Avery Rix, Beccles, Suffolk; Henry Cripps Rogers, Newport Pagnell; Frederick Robertson Hayward, Halesworth and Chas. Arthur Brigstocke, Carmarthen, students of St. Bartholomew's Hospital. John Henry Gray, Poplar; Wm. Wiles, Wootton-under-Edge and Edward Monro Spooner, L.S.A., Blandford, of the London Hospital. Francis John Grose, Bengal; George Outhwaite Spencer, Notting-hill; and Henry Clothier, Haselmere, of University College. Thomas Edward Gaggs Bywater, Knottingley; James Bailey Peacock, Leeds; and Joseph Westmorland, Leeds, of the Leeds School. Edward England Phillips, Bath, and James Wells, Nailsworth, of the Bristol School; Jonas Richard Leake, Upper Norwood, Guy's Hospital; Richard Morgan Williams Merthyr Tydvil, Middlesex Hospital; John Harrington Wright, Woolwich King's College; and James Kieran Hyland, Dublin.

At the same meeting of the Court,

Edward Brereton Broster, of H.M. Dockyard, Woolwich, and Thomas Leaman Bickford, of H.M.S. *Fisgard*, Woolwich,

passed their Examinations for Naval Surgeons. These gentlemen had previously been admitted members of the College, their diplomas bearing date respectively June 15, 1855, and March 19, 1858.

APOTHECARIES' HALL. — Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, April 20, 1865 :—

David Leslie, 69, Warwick-street, Pimlico; John Wickham Legg, Alverstoke, Hampshire; Joseph Hainsworth, Leeds; George Covey, Basingstoke; John Thomas Jaeques, Birstall, near Leicester.

The following gentlemen, also on the same day, passed their first Examination :—

Samuel John Truman, Guy's Hospital; George Longbotham, Newcastle-on-Tyne.

APPOINTMENTS.

*** The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

PUZEY, CHAUNCY, L.R.C.P. Lond., has been appointed Junior House-Surgeon to the Liverpool Royal Infirmary.

SOPER, WILLIAM, M.R.C.S. Eng., has been appointed Surgeon to the Jews' Hospital, Lower Norwood.

DEATHS.

ALLEYNE, JAMES H., M.D. Edin., at 27, Gloucester-place, Hyde-park, on April 21, aged 67, late Colonial Surgeon of British Guiana.

BOOTH, SAMUEL, jun., M.D. St. And., M.R.C.S. Eng., at No. 11, The Crescent, Salford, Manchester, on April 15, aged 27, Surgeon to the 56th Lancashire Rifle Volunteers.

DAVIES, JOHN EDWARD, M.R.C.S. Eng., of Manor-street, Clapham, at Hastings, on April 13, aged 37.

OVEREND, WILSON, F.R.C.S. Eng., J.P., D.L., at Sharrow Head, Sheffield, on April 22, aged 58.

WELCHMAN, EDWARD, M.R.C.S. Eng., at Southam, Warwickshire, on April 17, aged 51.

THE KING OF THE BELGIANS.—Dr. Jenner has been in attendance on the King of the Belgians, at Brussels, in conjunction with Drs. Koepel and Wimmer.

CHARING-CROSS HOSPITAL.—The friends of this institution will be glad to hear that the late Major-General Sir Charles Hopkinson, of King-street, St. James's, has bequeathed £500 to the funds of the charity, and has also made the novel bequest of £50 to his Surgeon, on condition that before his body is placed in the coffin it be opened by his Medical friend.

JOSELAND *v.* THE GREAT WESTERN COMPANY. — In this case, which obtained an unenviable notoriety from the number of eminent Medical men who appeared as witnesses on each side, and gave strongly opposed testimony, the Railway Company moved in the Court of Queen's Bench on April 22 for a rule to diminish the damages (£6000) as excessive, and as not supported by the evidence. The Court, however, were of opinion that there were no sufficient grounds on which they could disturb the verdict, it being eminently, they deemed, a case for determination by the jury upon the whole of the evidence. Rule refused.

DEATH FROM HAMBURGH SPIRIT.— On Monday, April 24, Mr. W. J. Payne, the Deputy-Coroner of the City and Southwark, held an inquest at the Vestry-room in Horsleydown on the body of John West, late a labourer at Fenning's Wharf, who came by his death in the following manner :— Daniel Crummings stated that he was employed at Fenning's Wharf, and that on Friday last deceased came to him and asked if a "drop" could be got out of some casks which they both supposed contained brandy or wine. They both had a "suck at the monkey," as it was called, and while the witness was somewhat burnt in the inside by what he took, the other man died in a few hours. Mr. Arkless, the Custom House gauger, said the spirit in the cask sucked by deceased was pure Hamburgh spirit 66·8 over proof, and was, in fact, "liquid fire." It was shown by the evidence of Mr. Lacey, a Surgeon, that death was caused by the collapse arising after taking an acrid poison, and a verdict to this effect was returned.

CAUSES OF MORTALITY IN WAR.—Dr. Chenu, Physician of the French army, has just published and presented to the Imperial Academy of Medicine a large 4to volume, containing a report of the Medical service of the army during the war in the Crimea, from 1854 to 1856. It appears from this work that the number of men killed in battle was 10,240; and of wounded, 34,606. Of this last number about 100 died in the Hospitals in Turkey. But that was not the whole of the losses; we must take into account those who died of cold, cholera, typhus, scurvy, &c., and Dr. Chenu gives the following table of the losses experienced by the French army in the East from the 1st of April, 1854, to the 31st of December, 1857, for many soldiers died after their return to France in consequence of wounds received or diseases contracted in the Crimea :—Killed on the field of battle or missing, 10,240; lost in the Sémillante, 702; died of various diseases and cholera before the battle of Alma, 8084; died of cold, apoplexy, &c., before Sebastopol, 4342; died in field and general Hospitals to the 31st December, 1857, 72,247; total, 95,615. The effective force sent by France to the East was only 309,264 men; consequently about one-third of them perished. It is to be remarked that as the number actually killed in battle or dead from wounds does not exceed 20,000, according to Dr. Chenu, disease alone carried off about 74,000 men, or one-fourth of the army. Dr. Chenu attributes these enormous losses by disease to the feeble constitutions of a portion of the contingent. He says that many conscripts, totally unable to bear the fatigues of a campaign, are declared fit for service; but they no sooner join the army than they have to be sent to the Hospitals.

THE WATER SUPPLY OF CARLISLE.—In the course of a very able and eloquent lecture on water, delivered by Dr. Wheatley, at the Mechanics' Institute of Carlisle, he gave the following account of the water supply of that town, the cause of its impurities, and the effect which he believed it exerted in the production of endemic disease :—So far as our country was concerned, Carlisle stood well. As a general rule, speaking of the present supply of water to the town, the lecturer considered the wells not fit to be drawn from in consequence of the hardness of the water, and the impurities which must necessarily have percolated into them from the increasing population and sewerage, and the increasing pollution of the soil by gas and other offensive things. As to the supply from the water works, he had it on the authority of Mr. Gordon, the city surveyor (to whom he was indebted for much information), that the average supply was thirty-three gallons per head per day. The next consideration was as to quality; and another question as to the continuousness of that supply. Being drawn from a large river, there was no fear of its not being continuous, but only so far as a single reservoir could make it so. The present elevation of that reservoir did not allow the water to be available either in the case of fire or for machinery operations. The average level to which the water rose in Carlisle was about the first floor of the Bush Hotel, and as considerable pressure was required for the purpose of moving machinery, it was not available for that. As to its quality, the water of the river Eden, taken at the place at which it entered the pipes at the engine-house, and in the ordinary state of the stream, was of fair average quality. Water taken from the reservoir contained considerable organic impurity, and the water from the supply pipes in the town delivered to the inhabitants, contained about one-third more of organic impurity. At least, this was the state of the water when examined a fortnight or three weeks ago. A short time before that, and since, the water had been slightly better than it was when he examined it. What was the cause of this anomaly? It was easily explained. Having no sedimentary reservoirs, the Eden water during a flood, being charged with all sorts of impurities which were held in suspension, was pumped into the reservoir, there to settle down, so that it was no wonder that after two or three floods a considerable deposit of mud in the reservoir was the result. The consequence was that all subsequent supplies of clean water to the reservoir became contaminated by the decomposition of the slime and filth which had been allowed to accumulate at the bottom of the basin; passing thence into the mains, with very imperfect filtration (if any), it received its next charge of impurity from the faulty system of distribution. The chief cause of that was the use of what were called "blind pipes"—pipes closed at the end, and not allowing the water to circulate. The water consequently stagnated at the end of those pipes, and deposited its impurities, which in the course of time accumulated, the result being extra contamination of the water supplied to houses through the doubtful medium—a blind pipe. It would be fresh in the recollection of all what an awful and fatal endemic of typhus there was last year in Annetwell-street and the neighbourhood; he (Dr. Wheatley) was of opinion—and he appealed to the axioms of Dr. Parkes—that that visitation was solely caused by the bad supply of water. Indeed, the general spread of disease in Carlisle of late years, arising from blood poisons, had been too palpable to require any further comment.

Mercurialised Collodion in Herpes Zona.—M. Devergie, although by no means recommending abortive means in zona in general, thinks that in certain cases, as where it attacks the scalp, face, or neck in the young, giving rise to symptoms much resembling those of a severe cerebral affection, and in the zona of aged persons, when deep and very painful ulcers are apt to follow the bullæ, giving rise to great nervous irritation, such means are desirable, and recommends an application formed of elastic collodion, 30 grammes, bichloride of mercury, half a gramme. By this a brilliant pellicle is formed over each group of bullæ, and in less than twenty-four hours all the unpleasant symptoms disappear, and the local inflammation is completely subdued. If the affection has already lasted some time, the application will have to be repeated daily for a few days. It is to be remarked that the pains which are usually consecutive to zona are by this means either entirely prevented or much alleviated. In place, too, of ulcers following the bullæ, there are dry eschars, which on becoming detached leave a clean cicatrix.—*Bull. de Therapeutique*, July 15.

Absinthe Drinkers.—Drinking *absinthe* seems to have acquired amongst certain classes in France and Switzerland almost as extensive a prevalence as gin-drinking among ourselves, while its effects are still more deleterious. M. Decaisne, as the result of an investigation into these, comes to the following conclusions:—1. Absinthe in equal doses, and at the same degree of concentration as brandy, exerts more marked and more mischievous effects upon the economy; 2. It induces intoxication much more rapidly, and the conditions known as chronic and acute *alcoholism* are much more easily developed. It must, however, be remembered that the alcohol in absinthe is generally very concentrated; 3. The effects of absinthe upon the nervous system are generally more marked than those produced by brandy, and they resemble those of a narcotico-acid poison; 4. One of the great dangers of absinthe arises from the adulterations it is the subject of; 5. Absinthe of good quality and in moderate quantity (as a glass or two a day) is not exempt from danger, and always produces, in a longer or shorter period, and according to individual aptitudes, more or less sensible disorders in the economy, and especially in the digestive organs.—*Comptes Rendus*, August 1.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Next week we hope to publish Dr. Lyon Playfair's lecture on the food of man in its relation to his useful work, delivered at the Royal Institution on the 28th inst.

Portsea.—Apply to Dr. Lane, Sudbrook-park, Petersham, Surrey.

Charon shall be answered in our next.

ustitia.—We think that the person receiving the honorarium should offer half of it to his partner.

Park Hall, Notts.—Our obituary notices are strictly confined to members of the Medical Profession.

Mr. Chadwick on Defence against Epidemic Visitations.—Mr. Edwin Chadwick has been delivering an admirable address at Salisbury on this subject. We shall give some account of it next week.

M.D., R.N., Portsmouth.—The examination at the R.C.S. on promotion is thoroughly practical, but requires some preparation; for at a meeting of the Court of Examiners on the 26th inst., two Members of the College were sent back for three months. The Secretary will let you know when there will be another meeting.

A Subscriber.—1. Yes. 2. We believe so, provided the Practitioner is registered and dispenses his own medicines, but on this point you had better write to the Secretary of the Court of Examiners, Apothecaries' Hall. 3. Yes, because a pupil cannot register until he has passed his preliminary examination. The Medical Council require four years' Medical education, dating from the first registration.

Chemists and Druggists Bill.—Amendments proposed to be inserted in the No. 1 Bill by the Metropolitan Counties Branch of the British Medical Association. To Clause 17, which saves the rights of Medical Practitioners, it is proposed to add:—

"And it shall not be lawful for any person registered under this Act to prescribe for any patient, or undertake the treatment of disease, or in any way assume to act as a Medical Practitioner, and every chemist and druggist so offending shall, upon a summary conviction, forfeit or pay a sum not exceeding £10."

As Clause 19 insert the following:—

"No patent, quack, or other medicine shall be sold, unless a sworn certificate of its composition be lodged with the Registrar appointed under this Act, and a copy thereof be open for inspection in the shop or place in which such medicine is sold, and any person or proprietor of a shop selling any secret remedy shall, on summary conviction for each such offence, be liable to a penalty not exceeding £20."

Importance of India-rubber to Medical Men.—There is scarcely one department of practical Medicine or Surgery, or chemistry, that has not derived benefit by the improvements in the manufacture of india-rubber which have taken place of late years. The ovariotomist twists an india-rubber letter band across the needles with which he has transfixed the edges of the wound, and thus has material for an easy twisted suture. Instead of the old seton, a fine india-rubber tape is inserted that is almost indestructible by putrefaction. M. Chassaignaic's Drainage Tube provides an exit for discharges from carious bone, and saves abscess and, possibly, need of excision of joints. India-rubber syringes of small price supply apparatus most desirable in every case of disease of internal cavity; for eye douches, ear syringes, urethral, vaginal, and rectal injections. Weak or displaced parts are kept up by india-rubber pessaries, springs to trusses, and elastic belts and stockings. India-rubber air and water pads are available for Surgical pressure in the modern cure of aneurism; and hot or cold water or ice in india-rubber bags serve for modifying the temperature of any part of the body in rheumatism, gout, inflammation, etc. Simple india-rubber tubes take the place of troublesome *lutes* for the air-tight junction of chemical apparatus: and the estimate of the alcoholic strengths of wine at the Custom-house in glass stills with india-rubber caps made the Chancellor of the Exchequer's wine duties possible. Consciences are elastic enough already, and most stomachs need no vulcanisation to enlarge their powers of distension; but many a Medical man wishes he could give a little india-rubber quality to the heart and lungs of the asthmatic, and certainly to the purse-strings of most patients after recovery. We therefore say a devout R.I.P. to the late Thomas Hancock, of Stoke Newington, the father of the india-rubber manufacture, who has enabled so many a fellow-creature to die at ease on a soft india-rubber mattrass. When 73 he published a work entitled "The Origin and Progress of the India-rubber Manufactures." The late Mr. Brockedon always spoke of him as having done service to science and art, especially in the matter of elastic moulds for bas-reliefs; and he himself always recurred with pleasure to his having had the honour to produce a raised type in rubber for blind readers. Between the years 1820 and 1847 he took out fourteen patents, one of which, "Vulcanisation," underwent the severest trial by writ of *scire facias*, but resulted in a verdict for Mr. Hancock. They were all worked by his firm, and led to a considerable accession of wealth to the patentee. Mr. Hancock was never married, but had adopted the seven daughters and two sons of his late brother John Hancock. He was a great admirer of rose-trees, and in his grounds were several hundred, which he pruned, grafted, and cultivated, and in which he took especial delight. May he now enjoy the gardens of Paradise!

The Russian Epidemic.—The following letter has appeared in the *Vienna Medical News*. It is dated St. Petersburg, April 9:—

"The conduct of Government in this emergency is really unpardonable. Instead of allowing the inhabitants of this city to learn anything about the nature and progress of the prevailing epidemic, they are systematically cut off from the sick as well as from all news relating to the sickness. Exactly the same way the Physicians are treated. Unless a Doctor happens to be employed by the police or the military, he is, in the eyes of this Government, a mere ignoramus. He has no admission to the Hospitals, nor, in fact, any opportunity for studying the disease. No sooner is a case reported to the authorities, than the poor are carried off to the Hospitals, and the wealthy forced to employ a Doctor provided by Government. You will not wonder, then, at my being unable to give you anything but a very general and rather indefinite account. From the provinces we get no news whatever, the papers being strictly forbidden to mention as much as the name of the Siberian plague. Government won't hear of a plague, and so there is none. Foreign papers, we hear, are full of Russian news; but though all of them are freely admitted, and may be seen easily enough in this capital, we are none the wiser for reading them, at least on this particular head. Whole columns are effaced with printer's ink, and nothing but a few lines left in a readable state, provided they contain a *dementi*. As to ascertaining anything about the plague through the medium of the many foreign Physicians sent here, this is a hope which, if it was ever entertained, will be soon enough exploded in your part of the world. These gentlemen have been received with open arms, and in course of time will return home decorated with orders, and perhaps also be requited with a remuneration for the time they have been here;—but that is all. They are shown over the Hospitals at a double quick pace. They are mostly admitted to one wing only, where a few slight cases have been collected expressly for the inspection of the foreign gentlemen; and when a vast number of compliments have been paid them by Doctors and attendants, luncheon is announced, and a good deal is consumed at the expense of the Hospital, though not without its monetary advantages to the Doctor *du jour*. His metropolitan studies being thus at an end, the foreign Doctor is then, officially of course, sent on to the provinces. Of course all these gentlemen have written long letters home. Anybody may write letters in Russia, but the worst is they so seldom reach their destination."

Medical and Surgical.

To the Editor of the Medical Times and Gazette.

Sir,—In the proceedings of the Medical Council it is reported that Mr. Arnott said, "It should be borne in mind that it was impossible to define what was a Medical case and what a Surgical. There were some broad cases, no doubt, that could be easily distinguished, but there were others of a mixed character in which the distinction could not be drawn; and if it was impossible for Medical men to draw the distinction, how could it be expected that a lawyer or a jury should do so? Any man might practice Surgery and Medicine, whether with a diploma or not; he was simply prohibited from taking certain names and designations, and had no power to recover his charges at law."

In case of a prosecution under the Apothecaries' Act, how is one to prove a Medical case? If any of your readers will be kind enough to define a Medical case I shall esteem it a favour. I am, &c.

Rugby, April 25. An Old Subscriber.

Midwifery Hieroglyphics.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—If any of your correspondents would favour me with an answer to the following question, I shall be much obliged:—Some midwifery Practitioners in entering cases of childbirth in their ledger, after the name of the patient, etc., put the letters B.D., D.B., or D.D. What do these letters usually mean? I am, &c. Jas. M.

Palpitation in Pregnancy.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Can any of your readers inform me of an effective remedy for excessive palpitation of the heart, accompanied with occasional fainting fits, during pregnancy? I have tried opium and belladonna plasters to the part, and administered valerian, musk, ether, etc., with only partial relief, the pain and palpitation recurring again and again upon the slightest emotion. I am, &c.

April 14. Medicus.

Dr. Davies' Treatment of Rheumatic Fever.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Will you be good enough to inform me, through your "Answers to Correspondents," what sized blisters Dr. Davies uses in his treatment of acute rheumatism? Does he envelope the whole of the affected joint in a blister, or is a small one only applied to the part? What length of time are the blisters kept on? Does it never happen that the patient's strength is greatly exhausted by the profuse discharge and irritation which must be occasioned by such a multitude of blisters?

Middlesborough, April 17. I am, &c. J. E.

*** The blisters are applied around the limbs, above, and not upon, but in close proximity to, the inflamed joints. Their width varies, of course, with the joints affected, being usually two or three inches wide when placed above the knees. They are applied until vesicles are well formed and the elimination of the serum (with, as Dr. Davies thinks, the contained rheumatic virus) is fully established. Linseed meal poultices are kept on the discharging surfaces for some hours, for the promotion of the same object. Dr. Davies tells us, that with the experience derived from the treatment of nearly sixty cases on his plan, he has no reason to fear the production of any untoward symptom beyond occasional strangury—a condition which readily yields to henbane—that exhaustion never follows the establishment of these large discharging surfaces, but that, on the contrary, the elimination of the *materies morbi* by the blister treatment rapidly reduces the abnormal heat of the body, quiets the pulse, produces an almost immediate abatement of all the febrile symptoms, and that in the majority of cases where the plan has been fully, decisively, and early adopted, it leads to a speedy convalescence of the patient. In the last instance recorded in this journal the patient was utterly disabled from acute rheumatism on the (Friday) night of his admission. The blisters were at once applied, and the man was perfectly free from pain on Sunday, and was able to walk down the ward on Monday. A chop and Bass's ale were given on Tuesday, and he was discharged sound in every respect within fourteen days from the day of his entering the London Hospital.

We shall be happy to publish a brief report of cases treated by J. E. on this plan.

Poor-law Medical Relief.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—At a meeting of a majority of the Poor-law Medical officers of the Weymouth Union, held at my house this day, the following letter it was agreed should be sent to the guardians of this Union, for which you will oblige me by finding space, as it may act as a guide for the great body of Poor-law Medical officers. I am, &c.

12, Royal-terrace, Weymouth, April 24. Richard Griffin.

"To the Board of Guardians of the Weymouth Union.

"Gentlemen,—In consequence of the Poor-law Board having issued a circular letter to you and all other Boards of Guardians throughout England and Wales, relative to the supply of cod-liver oil, quinine, and other expensive medicines for the poor, we have felt it our duty to you, as your Medical officers, to hold a meeting on the subject, in order that we may, if possible, assist you in arriving at a right decision on the questions involved, as they are purely Medical, and are with difficulty understood, excepting by Medical men.

"We think it right to premise our remarks by stating that the recommendation of the Select Committee on Poor-law Relief was made for the benefit of the poor, as it was felt that, owing to the expensive nature of many drugs, the Poor-law Medical officers could not afford to purchase them out of the very low salaries now paid to them, and, as a consequence, the poor have been but inadequately supplied with them; if, therefore, the guardians should carry out the recommendation of the Select Committee, the present Medical officers must not be expected to contribute from their salaries towards the extra expense, but they will most readily assist you towards obtaining them in the most economical manner.

"With regard to cod-liver oil, we have no suggestion to offer on the recommendation of the Poor-law Board further than to inform you that it may be purchased at prices varying from 8s. to 30s. per gallon, according to quality, some of the cheaper kinds being very nauseous to the taste; at about 20s. per gallon a very good quality ought to be obtained. We would advise your purchasing it done up in 4-ounce and 6-ounce bottles; in that state it may be given out to the sick poor, either at the workhouse, as named by the Poor-law Board, or direct from a druggist, if purchased in Weymouth, or a certain number of bottles may be given to those Medical officers residing in the county for their delivery to the poor.

"With regard to quinine and other expensive medicines, we feel a difficulty in advising you as to the best course to be pursued, as several drugs frequently enter into the composition of one bottle of medicine, some very expensive and others of but slight cost; for instance, quinine is rarely given alone, although it may form the most important ingredient in the mixture. Opium in its various forms, sarsaparilla, iodide of potassium, and the ethers are all expensive medicines, but are seldom given by themselves. Under these circumstances, you must either place confidence in your Medical officers, and allow them to charge extra for these medicines, or else you will allow your officers to order them from the druggists. We beg further to recommend that leeches should also be found by the guardians, as they are frequently of great importance in the treatment of diseases, but from their expensive nature they cannot be found by the Medical officers to any very great extent.

"We have the honour to be, Gentlemen,

"Your most obedient servants,

"Weymouth, April 24, 1865." "———.

The "Glasgow Morning Journal" on Dr. Pritchard's Awful Position.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Had it not been for the *Medical Times and Gazette* giving publicity, April 8, to an article which appeared in the *Glasgow Morning Journal*, the Profession would have been in almost entire ignorance of the following statements:—

"There can be no doubt, however, after what we have learnt, that for several weeks past Dr. Pritchard was really in possession of tartarised antimony, and this, moreover, in *unusually large* quantities, purchased by himself at the establishment of a respectable wholesale druggist in town. We believe we are within the mark in stating *that not less than two ounces* of this medicine was thus procured by him within the space of two months. Another somewhat striking circumstance is that a few days before the death of Mrs. Taylor he was supplied from the same warehouse with a goodly quantity of Fleming's tincture of aconite, a medicine possessed of virulently poisonous qualities when administered incautiously. It is quite true that both of the drugs mentioned are largely used in the healing art, but it is not easy to *guess at first sight what need any Surgeon in private practice should have for great quantities of them, more especially of tartar emetic.* A very free use of antimony as an outward application might, perhaps, partially explain the necessity of purchases so *unusually large, but we are led to understand that any such practice has been of late years almost completely laid aside by Medical Practitioners who keep pace with the Pharmaceutical improvements* of the day, as we may reasonably assume Dr. Pritchard to have done. A grave question, then, must now arise as to what has become of the powerful poisons which the accused is known to have bought."

Now, sir, it would be impossible for me to find words to express my feelings on reading the above quotation, but I would ask any unprejudiced member of the Profession whether two ounces of tartarised antimony is not an unusually small quantity for a general Practitioner to order of his wholesale druggist. I would also draw attention to the words, "goodly quantity of Fleming's tincture of aconite" How much does a "goodly quantity" mean? Then, again, we are informed that "the ointment of tartarised antimony has been of late years almost completely laid aside by Medical Practitioners." I can only state that I am one of the new school of Medicine, and frequently prescribe the ointment of tartarised antimony for sciatica, rheumatism, etc. Moreover, the ointment still occupies a place in the new Pharmacopœia. And lastly, tartarised antimony is not so powerful a poison as above stated, and every Medical man knows how readily it may be detected after death.

If false statements or undue prejudices are permitted to go forth to the world when life and death are suspended in the balance, one can only tremble for the consequences. I could say more, but will not trespass upon your valuable pages: trusting, however, that the article which appeared in the *Glasgow Morning Journal* will not operate against the accused. Suspicion, however strong, should be left in the hands of judge and jury, and not be magnified by the pen of a non-Medical writer.

The italics in the above quotation have been introduced by myself.

I am, &c. A Lover of Justice.

Army Medical Appointments.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Much has latterly been said and written on the subject of gazetting Medical officers to corps. On both sides many arguments have been advanced; but the "abolitionists," if I may be allowed the term, are most unquestionably increasing their ranks, at the expense of those who advocate the regimental system. I don't think that out of India it is generally known that the second Assistant-Surgeon can be removed from his regiment and detained for further service in India at the will and pleasure of the Inspector-General of Hospitals. There are instances enough on record now of this iniquitous system to have established it as a principle. It was done in Bombay with an Assistant-Surgeon of the 64th, in Bengal with an Assistant-Surgeon of the 8th Hussars, and in Madras with Assistant-Surgeons of the 74th and 66th Regiments. These are instances of especial hardship, and furnish a very strong argument in favour of a Medical Staff Corps. I don't think it at all hard that officers of the Medical Department should have to pay mess and band donations and subscriptions. On the contrary, I would have them do so; but the donation should be given to their own mess and band fund, and their subscription to the mess and band funds of the corps with which they may be doing duty.

A Horse Guards' order of August 27, 1864, provides in part for the expense consequent upon the transfer of Assistant-Surgeons, "should it not be at their own request;" but they do not consider the expense attendant upon the change of uniform, the sacrifice of the old, the expense of providing the new kit. In one of the removals it must have been a fearful expense, that from the Highland regiment to the artillery; and I believe that officer was appointed to the Horse Artillery. I have as yet said nothing of the disappointment it must have been to those officers who at the very last moment were informed that they would not be allowed to accompany their respective regiments home, the "exigencies of the service" requiring them to remain in India. How many of them at the time of appointment to their corps imagined that they would be thus treated on the departure of their corps from India? Surely no Medical officer with these facts before him would now ask for a regiment. I like my regiment very much; but I would rather be a staff Assistant-Surgeon doing duty with it. Regimental Medical officers are quite as directly under the control of the Medical authorities, and so we ought to be. In time of war, indeed, it is necessary that the Medical officers of the expedition should be under the absolute control or orders of the senior Medical officers of the force; and in time of peace I cannot conceive what advantage is gained by being made regimental. It cannot be denied that it is a pecuniary loss to the Department, and I don't think any advocate for the present system has yet shown that it is an advantage to the service. I know that these sentiments are entertained by my colleagues in the regiment, and by nine out of ten of the officers of the Department with whom I have talked on the subject. If you deem this letter worthy of communication, I trust you will devote a portion of your valuable space to its publication. I am, &c.

India, March, 1865. Oneness.

THE DIRTY QUACKS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I enclose an advertisement cut out from a paper which came into my hands after having already circulated through several respectable families; and I imagine that my eyes were not the only ones which fell accidentally upon the unusually filthy and abominable advertisement of the so-called Dr. Hammond.

Is he possessed of the qualifications mentioned by him? if so, why should not the Colleges erase his name? and if not, could not the Medical Council or Registration Society do something more than they appear to be doing for the sake of public decency? I am, &c.

April 12, 1865. M.R.C.S. Eng.

(From the *Suffolk Mercury*, April 1, 1865.)

"MEDICAL AID (BY LETTER OR PERSONALLY) BY

"DR. HAMMOND (of the Lock Hospital; Member of the College of Physicians and Surgeons) on all those Diseases which embitter and shorten the duration of human life. He offers Hints whereby Manly Vigour and all the attributes of Perfect Manhood can be secured. The Married Life Rendered Happy, and the cause of all domestic discord removed. Those who desire to Marry restored to Health, Beauty, Grace, and Elegance. Also on 'The Arrest, Cure, and Isolation of Nervous, Physical, and Sexual Debility, Spermatorrhœa, Nocturnal and Diurnal Losses, Painful Dreams, Wasting of the Organs of Generation, Impotence, Sterility, and all Diseases of Indiscretion.' The Author's chief aim is to mitigate human suffering, and in proof of the efficacy of the Author's theory, he will advise Invalids how to Cure themselves, by calling on him; and that others who cannot attend personally are advised to enclose 6 stamps for The Self-Curative Manual, which will enable sufferers to effect a speedy and Private Cure without Dangerous and Abortive so-called Remedies.—All Letters to be prepaid and addressed DR. HAMMOND, No. 11, Charlotte-street, Bedford-square, London.
